2 About TiDB

2.1 TiDB Introduction

TiDB (/'ta di bi:/, "Ti" stands for Titanium) is an open-source NewSQL database that supports Hybrid Transactional and Analytical Processing (HTAP) workloads. It is MySQL compatible and features horizontal scalability, strong consistency, and high availability. The goal of TiDB is to provide users with a one-stop database solution that covers OLTP (Online Transactional Processing), OLAP (Online Analytical Processing), and HTAP services. TiDB is suitable for various use cases that require high availability and strong consistency with large-scale data.

The following video introduces key features of TiDB.

2.1.1 Key features

- **Horizontally scaling out or scaling in easily**

  The TiDB architecture design of separating computing from storage enables you to separately scale out or scale in the computing or storage capacity online as needed. The scaling process is transparent to application operations and maintenance staff.

- **Financial-grade high availability**

  The data is stored in multiple replicas. Data replicas obtain the transaction log using the Multi-Raft protocol. A transaction can be committed only when data has been successfully written into the majority of replicas. This can guarantee strong consistency, and availability when a minority of replicas go down. To meet the requirements of different disaster tolerance levels, you can configure the geographic location and number of replicas as needed.

- **Real-time HTAP**

  TiDB provides two storage engines: TiKV, a row-based storage engine, and TiFlash, a columnar storage engine. TiFlash uses the Multi-Raft Learner protocol to replicate data from TiKV in real time, ensuring that the data between the TiKV row-based storage engine and the TiFlash columnar storage engine are consistent. TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.

- **Cloud-native distributed database**

  TiDB is a distributed database designed for the cloud, providing flexible scalability, reliability and security on the cloud platform. Users can elastically scale TiDB to meet the requirements of their changing workloads. In TiDB, each piece of data has 3 replicas at least, which can be scheduled in different cloud availability zones to tolerate

the outage of a whole data center. TiDB Operator helps manage TiDB on Kubernetes and automates tasks related to operating the TiDB cluster, which makes TiDB easier to deploy on any cloud that provides managed Kubernetes. TiDB Cloud, the fully-managed TiDB service, is the easiest, most economical, and most resilient way to unlock the full power of TiDB in the cloud, allowing you to deploy and run TiDB clusters with just a few clicks.

- **Compatible with the MySQL 5.7 protocol and MySQL ecosystem**

  TiDB is compatible with the MySQL 5.7 protocol, common features of MySQL, and the MySQL ecosystem. To migrate your applications to TiDB, you do not need to change a single line of code in many cases or only need to modify a small amount of code. In addition, TiDB provides a series of data migration tools to help easily migrate application data into TiDB.

2.1.2 Use cases

- **Financial industry scenarios with high requirements for data consistency, reliability, availability, scalability, and disaster tolerance**

  As we all know, the financial industry has high requirements for data consistency, reliability, availability, scalability, and disaster tolerance. The traditional solution is to provide services in two data centers in the same city, and provide data disaster recovery but no services in a third data center located in another city. This solution has the disadvantages of low resource utilization, high maintenance cost, and the fact that RTO (Recovery Time Objective) and RPO (Recovery Point Objective) cannot meet expectations. TiDB uses multiple replicas and the Multi-Raft protocol to schedule data to different data centers, racks, and machines. When some machines fail, the system can automatically switch to ensure that the system RTO 30 seconds and RPO = 0.

- **Massive data and high concurrency scenarios with high requirements for storage capacity, scalability, and concurrency**

  As applications grow rapidly, the data surges. Traditional standalone databases cannot meet the data capacity requirements. The solution is to use sharding middleware or a NewSQL database (like TiDB), and the latter is more cost-effective. TiDB adopts a separate computing and storage architecture, which enables you to scale out or scale in the computing or storage capacity separately. The computing layer supports a maximum of 512 nodes, each node supports a maximum of 1,000 concurrencies, and the maximum cluster capacity is at the PB (petabytes) level.

- **Real-time HTAP scenarios**

  With the fast growth of 5G, Internet of Things, and artificial intelligence, the data generated by a company keeps increasing tremendously, reaching a scale of hundreds of TB (terabytes) or even the PB level. The traditional solution is to process online transactional applications using an OLTP database and use an ETL (Extract, Transform, Load) tool to replicate the data into an OLAP database for data analysis. This solution

has multiple disadvantages such as high storage costs and poor real-time performance. TiDB introduces the TiFlash columnar storage engine in v4.0, which combines with the TiKV row-based storage engine to build TiDB as a true HTAP database. With a small amount of extra storage cost, you can handle both online transactional processing and real-time data analysis in the same system, which greatly saves the cost.

- **Data aggregation and secondary processing scenarios**

  The application data of most companies are scattered in different systems. As the application grows, the decision-making leaders need to understand the business status of the entire company to make decisions in time. In this case, the company needs to aggregate the scattered data into the same system and execute secondary processing to generate a T+0 or T+1 report. The traditional solution is to use ETL and Hadoop, but the Hadoop system is complicated, with high operations and maintenance cost and storage cost. Compared with Hadoop, TiDB is much simpler. You can replicate data into TiDB using ETL tools or data migration tools provided by TiDB. Reports can be directly generated using SQL statements.

2.2 TiDB 6.4.0 Release Notes

Release date: November 17, 2022

TiDB version: 6.4.0-DMR

Quick access: Quick start | Installation packages

In v6.4.0-DMR, the key new features and improvements are as follows:

- Support restoring a cluster to a specific point in time by using `FLASHBACK CLUSTER TO TIMESTAMP` (experimental).
- Support tracking the global memory usage of TiDB instances (experimental).
- Be compatible with the Linear Hash partitioning syntax.
- Support a high-performance and globally monotonic `AUTO_INCREMENT` (experimental).
- Support range selection of array data in the JSON type.
- Accelerate fault recovery in extreme situations such as disk failures and stuck I/O.
- Add the dynamic planning algorithm to determine table join order.
- Introduce a new optimizer hint `NO_DECORRELATE` to control whether to perform decorrelation for correlated subqueries.
- The cluster diagnostics feature becomes GA.
- TiFlash supports the SM4 algorithm for encryption at rest.

- Support using a SQL statement to compact TiFlash replicas of specified partitions in a table immediately.
- Support backing up a TiDB cluster using EBS volume snapshots.
- DM supports writing upstream data source information to the extended columns of the downstream merged table.

2.2.1 New features

2.2.1.1 SQL

- Support using a SQL statement to compact TiFlash replicas of specified partitions in a table immediately #5315 @hehechen

  Since v6.2.0, TiDB has supported the feature of compacting physical data immediately on a full-table replica of TiFlash. You can choose the right time to manually execute SQL statements to immediately compact the physical data in TiFlash, which helps to reduce storage space and improve query performance. In v6.4.0, we refine the granularity of TiFlash replica data to be compacted and support compacting TiFlash replicas of specified partitions in a table immediately.

  By executing the SQL statement `ALTER TABLE table_name COMPACT [PARTITION PartitionNameList] [engine_type REPLICA]`, you can immediately compact TiFlash replicas of specified partitions in a table.

  For more information, see User document.

- Support restoring a cluster to a specific point in time by using `FLASHBACK CLUSTER TO TIMESTAMP` (experimental) #37197 #13303 @Defined2014 @bb7133 @JmPotato @Connor1996 @HuSharp @CalvinNeo

  You can use the `FLASHBACK CLUSTER TO TIMESTAMP` syntax to restore a cluster to a specific point in time quickly within the Garbage Collection (GC) lifetime. This feature helps you to easily and quickly undo DML misoperations. For example, you can use this syntax to restore the original cluster in minutes after mistakenly executing `DELETE` without a `WHERE` clause. This feature does not rely on database backups and supports rolling back data at different time points to determine the exact time when data changes. Note that `FLASHBACK CLUSTER TO TIMESTAMP` cannot replace database backups.

  Before executing `FLASHBACK CLUSTER TO TIMESTAMP`, you need to pause PITR and replication tasks running on such tools as TiCDC and restart them after the `FLASHBACK` is completed. Otherwise, replication tasks might fail.

  For more information, see User document.

- Support restoring a deleted database by using `FLASHBACK DATABASE` #20463 @erwadba

  By using `FLASHBACK DATABASE`, you can restore a database and its data deleted by `DROP` within the garbage collection (GC) life time. This feature does not depend on any external tools. You can quickly restore data and metadata using SQL statements.

For more information, see User document.

2.2.1.2 Security

- TiFlash supports the SM4 algorithm for encryption at rest #5953 @lidezhu

  Add the SM4 algorithm for TiFlash encryption at rest. When you configure encryption at rest, you can enable the SM4 encryption capacity by setting the value of the `data-encryption-method` configuration to `sm4-ctr` in the `tiflash-learner.toml` configuration file.

  For more information, see User document.

2.2.1.3 Observability

- Cluster diagnostics becomes GA #1438 @Hawkson-jee

  The cluster diagnostics feature in TiDB Dashboard diagnoses the problems that might exist in a cluster within a specified time range, and summarizes the diagnostic results and the cluster-related load monitoring information into a diagnostic report. This diagnostic report is in the form of a web page. You can browse the page offline and circulate this page link after saving the page from a browser.

  With the diagnostic reports, you can quickly understand the basic health information of the cluster, including the load, component status, time consumption, and configurations. If the cluster has some common problems, you can locate the causes in the result of the built-in automatic diagnosis in the diagnostic information section.

2.2.1.4 Performance

- Introduce the concurrency adaptive mechanism for coprocessor tasks #37724 @you06

  As the number of coprocessor tasks increases, based on TiKV's processing speed, TiDB automatically increases concurrency (adjust the value of `tidb_distsql_scan_concurrency` ↪) to reduce the coprocessor task queue and thus reduce latency.

- Add the dynamic planning algorithm to determine table join order #37825 @winoros

  In earlier versions, TiDB uses the greedy algorithm to determine the join order of tables. In v6.4.0, the TiDB optimizer introduces the dynamic planning algorithm. The dynamic planning algorithm can enumerate more possible join orders than the greedy algorithm, so it increases the possibility to find a better execution plan and improves SQL execution efficiency in some scenarios.

  Because the dynamic programming algorithm consumes more time, the selection of the TiDB Join Reorder algorithms is controlled by the `tidb_opt_join_reorder_threshold` ↪ variable. If the number of nodes participating in Join Reorder is greater than

this threshold, TiDB uses the greedy algorithm. Otherwise, TiDB uses the dynamic programming algorithm.

For more information, see User document.

- The prefix index supports filtering null values. #21145 @xuyifangreeneyes

  This feature is an optimization for the prefix index. When a column in a table has a prefix index, the `IS NULL` or `IS NOT NULL` condition of the column in the SQL statement can be directly filtered by the prefix, which avoids table lookup in this case and improves the performance of the SQL execution.

  For more information, see User document.

- Enhance the TiDB chunk reuse mechanism #38606 @keeplearning20221

  In earlier versions, TiDB only reuses chunks in the `writechunk` function. TiDB v6.4.0 extends the chunk reuse mechanism to operators in Executor. By reusing chunks, TiDB does not need to frequently request memory release and SQL queries are executed more efficiently in some scenarios. You can use the system variable `tidb_enable_reuse_chunk` to control whether to reuse chunk objects, which is enabled by default.

  For more information, see User document.

- Introduce a new optimizer hint `NO_DECORRELATE` to control whether to perform decorrelation for correlated subqueries #37789 @time-and-fate

  By default, TiDB always tries to rewrite correlated subqueries to perform decorrelation, which usually improves execution efficiency. However, in some scenarios, decorrelation reduces the execution efficiency. In v6.4.0, TiDB introduces the optimizer hint `NO_DECORRELATE` to tell the optimizer not to perform decorrelation for specified query blocks to improve query performance in some scenarios.

  For more information, see User document.

- Improve the performance of statistics collection on partitioned tables #37977 @Yisaer

  In v6.4.0, TiDB optimizes the strategy of collecting statistics on partitioned tables. You can use the system variable `tidb_auto_analyze_partition_batch_size` to set the concurrency of collecting statistics on partitioned tables in parallel to speed up the collection and shorten the analysis time.

2.2.1.5 Stability

- Accelerate fault recovery in extreme situations such as disk failures and stuck I/O #13648 @LykxSassinator

  For enterprise users, database availability is one of the most important metrics. While in complex hardware environments, how to quickly detect and recover from failures has always been one of the challenges of database availability. In v6.4.0, TiDB fully

optimizes the state detection mechanism of TiKV nodes. Even in extreme situations such as disk failures and stuck I/O, TiDB can still report node state quickly and use the active wake-up mechanism to launch Leader election in advance, which accelerates cluster self-healing. Through this optimization, TiDB can shorten the cluster recovery time by about 50% in the case of disk failures.

- Global control on TiDB memory usage #37816 @wshwsh12

  In v6.4.0, TiDB introduces global control of memory usage as an experimental feature that tracks the global memory usage of TiDB instances. You can use the system variable `tidb_server_memory_limit` to set the upper limit for the global memory usage. When the memory usage reaches the threshold, TiDB tries to reclaim and release more free memory. When the memory usage exceeds the threshold, TiDB identifies and cancels the SQL operation that has the highest memory usage to avoid system issues caused by excessive memory usage.

  When the memory consumption of TiDB instances has potential risks, TiDB will collect diagnostic information in advance and write it to the specified directory to facilitate the issue diagnosis. At the same time, TiDB provides system table views `INFORMATION_SCHEMA.MEMORY_USAGE` and `INFORMATION_SCHEMA.MEMORY_USAGE_OPS_HISTORY` that show the memory usage and operation history to help you better understand the memory usage.

  Global memory control is a milestone in TiDB memory management. It introduces a global view for instances and adopts systematic management for memory, which can greatly enhance database stability and service availability in more key scenarios.

  For more information, see User document.

- Control the memory usage of the range-building optimizer #37176 @xuyifangreeneyes

  In v6.4.0, the system variable `tidb_opt_range_max_size` is introduced to limit the maximum memory usage of the optimizer that builds ranges. When the memory usage exceeds the limit, the optimizer will build more coarse-grained ranges instead of more exact ranges to reduce memory consumption. If a SQL statement has many `IN` conditions, this optimization can significantly reduce the memory usage of compiling and ensure system stability.

  For more information, see User document.

- Support synchronously loading statistics (GA) #37434 @chrysan

  TiDB v6.4.0 enables the synchronously loading statistics feature by default. This feature allows TiDB to synchronously load large-sized statistics (such as histograms, TopN, and Count-Min Sketch statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

  For more information, see User document.

- Reduce the impact of batch write requests on the response time of lightweight transactional writes #13313 @glorv

The business logic of some systems requires periodic batch DML tasks, but processing these batch write tasks increases the latency of online transactions. In v6.3.0, TiKV optimizes the scheduling of read requests in hybrid workload scenarios, so you can enable the `readpool.unified.auto-adjust-pool-size` configuration item to have TiKV automatically adjust the size of the UnifyReadPool thread pool for all read requests. In v6.4.0, TiKV can dynamically identify and prioritize write requests as well, and control the maximum bytes that the Apply thread can write for one FSM (Finite-state Machine) in one round of poll, thus reducing the impact of batch write requests on the response time of transactional writes.

2.2.1.6 Ease of use

- TiKV API V2 becomes generally available (GA) #11745 @pingyu

  Before v6.1.0, TiKV only provides basic Key Value read and write capability because it only stores the raw data passed in by the client. In addition, due to different coding methods and unscoped data ranges, TiDB, Transactional KV, and RawKV cannot be used at the same time in the same TiKV cluster; instead, multiple clusters are needed in this case, thus increasing machine and deployment costs.

  TiKV API V2 provides a new RawKV storage format and access interface, which delivers the following benefits:

  - Store data in MVCC with the change timestamp of the data recorded, based on which Change Data Capture (CDC) is implemented. This feature is experimental and is detailed in TiKV-CDC.
  - Data is scoped according to different usage and API V2 supports co-existence of TiDB, Transactional KV, and RawKV applications in a single cluster.
  - Reserve the Key Space field to support features such as multi-tenancy.

To enable TiKV API V2, set `api-version = 2` in the `[storage]` section of the TiKV configuration file.

For more information, see User document.

- Improve the accuracy of TiFlash data replication progress #4902 @hehechen

  In TiDB, the `PROGRESS` field of the `INFORMATION_SCHEMA.TIFLASH_REPLICA` table is used to indicate the progress of data replication from the corresponding tables in TiKV to the TiFlash replicas. In earlier TiDB versions, the `PROCESS` field only provides the progress of data replication during the creation of the TiFlash replicas. After a TiFlash replica is created, if new data is imported to a corresponding table in TiKV, this field will not be updated to show the replication progress from TiKV to TiFlash for the new data.

  In v6.4.0, TiDB improves the update mechanism of data replication progress for TiFlash replicas. After a TiFlash replica is created, if new data is imported to

a corresponding table in TiKV, the `PROGRESS` value in the `INFORMATION_SCHEMA.TIFLASH_REPLICA` table will be updated to show the actual replication progress from TiKV to TiFlash for the new data. With this improvement, you can easily view the actual progress of TiFlash data replication.

For more information, see User document.

2.2.1.7 MySQL compatibility

- Be compatible with the Linear Hash partitioning syntax #38450 @mjonss

  In the earlier version, TiDB has supported the Hash, Range, and List partitioning. Starting from v6.4.0, TiDB can also be compatible with the syntaxt of MySQL Linear Hash partitioning.

  In TiDB, you can execute the existing DDL statements of your MySQL Linear Hash partitions directly, and TiDB will create the corresponding Hash partition tables (note that there is no Linear Hash partition inside TiDB). You can also execute the existing DML statements of your MySQL Linear Hash partitions directly, and TiDB will return the query result of the corresponding TiDB Hash partitions normally. This feature ensures the TiDB syntax compatibility with MySQL Linear Hash partitions and facilitates seamless migration from MySQL-based applications to TiDB.

  If the number of partitions is a power of 2, the rows in a TiDB Hash partitioned table are distributed the same as that in the MySQL Linear Hash partitioned table. Otherwise, the distribution of these rows in TiDB is different from MySQL.

  For more information, see User document.

- Support a high-performance and globally monotonic `AUTO_INCREMENT` (experimental) #38442 @tiancaiamao

  TiDB v6.4.0 introduces the `AUTO_INCREMENT` MySQL compatibility mode. This mode introduces a centralized auto-increment ID allocating service that ensures IDs monotonically increase on all TiDB instances. This feature makes it easier to sort query results by auto-increment IDs. To use the MySQL compatibility mode, you need to set `AUTO_ID_CACHE` to `1` when creating a table. The following is an example:

  ```
  CREATE TABLE t (a INT AUTO_INCREMENT PRIMARY KEY) AUTO_ID_CACHE = 1;
  ```

  For more information, see User document.

- Support range selection of array data in the JSON type #13644 @YangKeao

  Starting from v6.4.0, you can use the MySQL-compatible range selection syntax in TiDB.

  - With the keyword `to`, you can specify the start and end positions of array elements and select elements of a continuous range in an array. With `0`, you can specify the position of the first element in an array. For example, using `$[0 to 2]`, you can select the first three elements of an array.

  - With the keyword `last`, you can specify the position of the last element in an array, which allows you to set the position from right to left. For example, using `$[last-2 to last]`, you can select the last three elements of an array.

This feature simplifies the process of writing SQL statements, further improves the JSON type compatibility, and reduces the difficulty of migrating MySQL applications to TiDB.

- Support adding additional descriptions for database users #38172 @CbcWestwolf

  In TiDB v6.4, you can use the `CREATE USER` or `ALTER USER` to add additional descriptions for database users. TiDB provides two description formats. You can add a text comment using `COMMENT` and add a set of structured attributes in JSON format using `ATTRIBUTE`.

  In addition, TiDB v6.4.0 adds the `USER_ATTRIBUTES` table, where you can view the information of user comments and user attributes.

```
CREATE USER 'newuser1'@'%' COMMENT 'This user is created only for test'
    ↪ ;
CREATE USER 'newuser2'@'%' ATTRIBUTE '{"email": "user@pingcap.com"}';
SELECT * FROM INFORMATION_SCHEMA.USER_ATTRIBUTES;
```

```
+--
    ↪ ---------+------+-----------------------------------------------------+
    ↪
| USER     | HOST | ATTRIBUTE                                           |
+--
    ↪ ---------+------+-----------------------------------------------------+
    ↪
| newuser1 | %    | {"comment": "This user is created only for test"} |
| newuser1 | %    | {"email": "user@pingcap.com"}                     |
+--
    ↪ ---------+------+-----------------------------------------------------+
    ↪
2 rows in set (0.00 sec)
```

  This feature improves TiDB compatibility with MySQL syntax and makes it easier to integrate TiDB into tools or platforms in the MySQL ecosystem.

2.2.1.8 Backup and restore

- Support backing up a TiDB cluster using EBS volume snapshots #33849 @fengou1

  If your TiDB cluster is deployed on EKS and uses AWS EBS volumes, and you have the following requirements when backing up TiDB cluster data, you can use TiDB Operator to back up the data by volume snapshots and metadata to AWS S3:

- Minimize the impact of backup, for example, to keep the impact on QPS and transaction latency less than 5%, and to occupy no cluster CPU and memory.
- Back up and restore data in a short time. For example, finish backup within 1 hour and restore data in 2 hours.

For more information, see User document.

2.2.1.9 Data migration

- DM supports writing upstream data source information to the extended columns of the downstream merged table #37797 @lichunzhu

  When merging sharded schemas and tables from upstream to TiDB, you can manually add several fields (extended columns) in the target table and specify their values when configuring the DM task. For example, if you specify the names of the upstream sharded schema and table for the extended columns, the data written to the downstream by DM will include the schema name and table name. When the downstream data looks unusual, you can use this feature to quickly locate the data source information in the target table, such as the schema name and table name.

  For more information, see Extract table, schema, and source information and write into the merged table.

- DM optimizes the pre-check mechanism by changing some mandatory check items to optional ones #7333 @lichunzhu

  To run a data migration task smoothly, DM triggers a precheck automatically at the start of the task and returns the check results. DM starts the migration only after the precheck is passed.

  In v6.4.0, DM changes the following three check items from mandatory to optional, which improves the pass rate of the pre-check:

  - Check whether the upstream tables use character sets that are incompatible with TiDB.
  - Check whether the upstream tables have primary key constraints or unique key constraints
  - Check whether the database ID `server_id` for the upstream database has been specified in the primary-secondary configuration.

- DM supports configuring binlog position and GTID as optional parameters for incremental migration tasks #7393 @GMHDBJD

  Since v6.4.0, you can perform incremental migration directly without specifying the binlog position or GTID. DM automatically obtains the binlog files generated after the task starts from upstream and migrates these incremental data to the downstream. This relieves users from laborious understanding and complicated configuration.

  For more information, see DM Advanced Task Configuration File.

- DM adds more status indicators for migration tasks #7343 @okJiang

  In v6.4.0, DM adds more performance and progress indicators for migration tasks, which helps you understand the migration performance and progress more intuitively and provides you with a reference for troubleshooting.

  - Add status indicators (in bytes/s) showing data importing and exporting performance.
  - Rename the performance indicator for writing data to the downstream database from TPS to RPS (in rows/s).
  - Add progress indicators showing the data export progress of DM full migration tasks.

  For more information about these indicators, see Query Task Status in TiDB Data Migration.

2.2.1.10 TiDB data share subscription

- TiCDC supports replicating data to Kafka of the `3.2.0` version #7191 @3AceShowHand

  From v6.4.0, TiCDC supports replicating data to Kafka of the `3.2.0` version and earlier.

2.2.2 Compatibility changes

2.2.2.1 System variables

Variable name	Change type	Description

Variable name	Change type	Description

tidb_constraint_check_in_place_pessimistic ↪	Modified	Removes the GLOBAL scope and allows you to modify the default value using the pessimistic ↪ - ↪ txn ↪ . ↪ constraint ↪ - ↪ check ↪ -in ↪ - ↪ place ↪ - ↪ pessimistic ↪ configuration item. This variable controls when TiDB checks the unique constraints in pessimistic trans- ac-

Variable name	Change type	Description
tidb_ddl_flashback_concurrency ↪	Modified	Takes effect starting from v6.4.0 and controls the concurrency of FLASHBACK ↪ ↪ CLUSTER ↪ TO ↪ ↪ TIMESTAMP ↪ . The default value is 64.

Variable name	Change type	Description
`tidb_enable_clustered_index` ↪	Modified	Changes the default value from `INT_ONLY` ↪ to `ON`, meaning that primary keys are created as clustered indexes by default.

Variable name	Change type	Description
tidb_enable_paging	Modified	Changes the default value from OFF to ON, meaning that the method of paging to send coprocessor requests is used by default.
tidb_enable_prepared_plan_cache	Modified	Adds the SESSION scope. This variable controls whether to enable Prepared Plan Cache.

Variable name	Change type	Description
tidb_memory_usage_alarm_ratio	Modified	Changes the default value from 0.8 to 0.7. This variable controls the memory usage ratio that triggers the tidb-server memory alarm.

Variable name	Change type	Description
tidb_opt_agg_push_down	Modified	Adds the GLOBAL scope. This variable controls whether the optimizer executes the optimization operation of pushing down the aggregate function to the position before Join, Projection, and UnionAll.

Variable name	Change type	Description
`tidb_prepared_plan_cache_size` ↪	Modified	Adds the SESSION scope. This variable controls the maximum number of plans that can be cached in a session.

Variable name	Change type	Description
`tidb_stats_load_sync_wait` ↪	Modified	Changes the default value from `0` to `100`, meaning that the SQL execution can wait for at most 100 milliseconds by default to synchronously load complete column statistics.

Variable name	Change type	Description
tidb_stats_load_pseudo_timeout ↪	Modified	Changes the default value from OFF to ON, meaning that the SQL optimization gets back to using pseudo statistics after reaching the timeout of synchronously loading complete column statistics.

Variable name	Change type	Description
`last_sql_use_plan_cache` ↪	Newly added	Shows whether the previous statement uses a cached chunk object (chunk allocation). This variable is read-only and the default value is `OFF`.

Variable name	Change type	Description
tidb_auto_analyze_partition_batch_size ↪	Newly added	Specifies the number of partitions that TiDB can automatically analyzes at a time when analyzing a partitioned table (which means automatically collecting statistics on a partitioned table). The default value is 1.

Variable name	Change type	Description
tidb_enable_external_ts_read	Newly added	Controls whether TiDB reads data with the timestamp specified by tidb_external_ts. The default value is OFF.
tidb_enable_gogc_tuner	Newly added	Controls whether to enable GOGC Tuner. The default value is ON.

Variable name	Change type	Description
`tidb_enable_reuse_chunk` ↪	Newly added	Controls whether TiDB enables chunk objects cache. The default value is `ON`, meaning that TiDB prefers to use the cached chunk object and only requests from the system if the requested object is not in the cache. If the value is `OFF`, TiDB requests chunk objects from the system directly.

Variable name	Change type	Description
`tidb_enable_prepared_plan_cache_memory_monitor` ↪	Newly added	Controls whether to count the memory consumed by the execution plans cached in the Prepared Plan Cache. The default value is `ON`.

Variable name	Change type	Description
tidb_external_ts ↪	Newly added	The default value is 0. If tidb_enable_external_ts_read ↪ is set to ON, TiDB reads data with the timestamp specified by this variable.

Variable name	Change type	Description
`tidb_gogc_memory_threshold` ↪	Newly added	Specifies the maximum memory threshold for tuning GOGC. When the memory exceeds this threshold, GOGC Tuner stops working. The default value is `0.6`.

Variable name	Change type	Description
`tidb_memory_usage_alarm_keep_record_num` ↪	Newly added	When the tidb-server memory usage exceeds the memory alarm threshold and triggers an alarm, TiDB only retains the status files generated during the recent 5 alarms by default. You can adjust this number with this variable.

Variable name	Change type	Description
`tidb_opt_prefix_index_single_scan` ↪	Newly added	Controls whether the TiDB optimizer pushes down some filter conditions to the prefix index to avoid unnecessary table lookup and to improve query performance. The default value is `ON`.

Variable name	Change type	Description
tidb_opt_range_max_size ↪	Newly added	Specifies the upper limit of memory usage for the optimizer to construct a scan range. The default value is 67108864 ↪ (64 MiB).

Variable name	Change type	Description
`tidb_server_memory_limit` ↪	Newly added	Controls the upper limit of memory usage for the optimizer to build scan ranges (experimental). The default value is `0`, meaning that there is no memory limit.

Variable name	Change type	Description
tidb_server_memory_limit_gc_trigger ↪	Newly added	Controls the threshold at which TiDB tries to trigger GC (experimental). The default value is 70%.

Variable name	Change type	Description
tidb_server_memory_limit_sess_min_size ↪	Newly added	After you enable the memory limit, TiDB will terminate the SQL statement with the highest memory usage on the current instance. This variable specifies the minimum memory usage of the SQL statement to be terminated. The default value is 134217728 ↪

Variable name	Change type	Description

2.2.2.2 Configuration file parameters

Configuration file	Configuration parameter	Change type	Description
TiDB	`tidb_memory_usage_alarm_ratio`	Deleted	This configuration item is no longer effective.
TiDB	`memory-usage-alarm-ratio`	Deleted	Replaced by the system variable `tidb_memory_usage_alarm_ratio`. If this configuration item has been configured in a TiDB version earlier than v6.4.0, it will not take effect after the upgrade.

Configuration file	Configuration parameter	Change type	Description
TiDB	pessimistic-txn.constraint-check-in-pessimistic	Newly added	Controls the default value of the system variable tidb_constraint_check_in_place_pessimistic. The default value is true.
TiDB	tidb-max-reuse-chunk	Newly added	Controls the maximum cached chunk objects of chunk allocation. The default value is 64.
TiDB	tidb-max-reuse-column	Newly added	Controls the maximum cached column objects of chunk allocation. The default value is 256.

Configuration file	Configuration parameter	Change type	Description
TiKV	`cdc.raw-min-ts-outlier-threshold`	Deprecated	This configuration item is no longer effective.
TiKV	`causal-ts.alloc-ahead-buffer`	Newly added	The pre-allocated TSO cache size (in duration). The default value is `3s`.
TiKV	`causal-ts.renew-batch-max-size`	Newly added	Controls the maximum number of TSOs in a timestamp request. The default value is `8192`.

Configuration file	Configuration parameter	Change type	Description
TiKV	`raftstore` ↪ `.` ↪ `apply` ↪ `-` ↪ `yield` ↪ `-` ↪ `write` ↪ `-` ↪ `size`	Newly added	Controls the maximum number of bytes that the Apply thread can write for one FSM (Finite-state Machine) in one round of poll. The default value is `32KiB`. This is a soft limit.

Configuration file	Configuration parameter	Change type	Description
PD	`tso-update-physical-interval`	Newly added	Takes effect starting from v6.4.0 and controls the interval at which PD updates the physical time of TSO. The default value is `50ms`.
TiFlash	`data-encryption-method`	Modified	Introduces a new value option `sm4-ctr`. When this configuration item is set to `sm4-ctr`, data is encrypted using SM4 before being stored.

Configuration file	Configuration parameter	Change type	Description
DM	routes. ↪ route ↪ - ↪ rule ↪ -1. ↪ extract ↪ - ↪ table ↪	Newly added	Optional. Used in the sharding scenario for extracting the source information of sharded tables. The extracted information will be written to the merged table in the downstream to identify the data source. If this parameter is configured, you need to manually create a merged table in the downstream in advance.

Configuration file	Configuration parameter	Change type	Description
DM	routes. ↪ route ↪ - ↪ rule ↪ -1. ↪ extract ↪ - ↪ schema ↪	Newly added	Optional. Used in the sharding scenario for extracting the source information of sharded schemas. The extracted information will be written to the merged table in the downstream to identify the data source. If this parameter is configured, you need to manually create a merged table in the downstream in advance.

Configuration file	Configuration parameter	Change type	Description
DM	routes. ↪ route ↪ - ↪ rule ↪ -1. ↪ extract ↪ - ↪ source ↪	Newly added	Optional. Used in the sharding scenario for extracting the source instance information. The extracted information will be written to the merged table in the downstream to identify the data source. If this parameter is configured, you need to manually create a merged table in the downstream in advance.

Configuration file	Configuration parameter	Change type	Description
TiCDC	`transaction-atomicity`	Modified	Changes the default value from `table` to `none`. This change helps reduce replication latency and OOM risks. In addition, TiCDC now only splits a few transactions (the size of a single transaction exceeds 1024 rows), instead of all transactions.

2.2.2.3 Others

- Starting from v6.4.0, the `mysql.user` table adds two new columns: `User_attributes` and `Token_issuer`. If you restore system tables in the `mysql` schema from backup data

of earlier TiDB versions to TiDB v6.4.0, BR will report the `column count mismatch` ↪ error for the `mysql.user` table. If you do not restore system tables in the `mysql` schema, this error will not be reported.

- For files whose names match the format of Dumpling exported files but end with uncompressed formats (such as `test-schema-create.sql.origin` and `test.table` ↪ `-schema.sql.origin`), the way how TiDB Lightning handles them is changed. Before v6.4.0, if the files to be imported include such files, TiDB Lightning skips importing such files. Starting from v6.4.0, TiDB Lightning assumes that such files use unsupported compression formats, so the import task will fail.
- Starting with v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.

2.2.3 Improvements

- TiDB
  - Allow modifying the noop variable `lc_messages` #38231 @djshow832
  - Support the `AUTO_RANDOM` column as the first column of the clustered composite index #38572 @tangenta
  - Use pessimistic transactions in internal transaction retry to avoid retry failure and reduce time consumption #38136 @jackysp
- TiKV
  - Add a new configuration item `apply-yield-write-size` to control the maximum number of bytes that the Apply thread can write for one Finite-state Machine in one round of poll, and relieve Raftstore congestion when the Apply thread writes a large volume of data #13313 @glorv
  - Warm up the entry cache before migrating the leader of Region to avoid QPS jitter during the leader transfer process #13060 @cosven
  - Support pushing down the `json_constains` operator to Coprocessor #13592 @lizhenhuan
  - Add the asynchronous function for `CausalTsProvider` to improve the flush performance in some scenarios #13428 @zeminzhou
- PD
  - The v2 algorithm of the hot Region scheduler becomes GA. In some scenarios, the v2 algorithm can achieve better balancing in both configured dimensions and reduce invalid scheduling #5021 @HundunDM
  - Optimize the timeout mechanism of operator step to avoid premature timeout #5596 @bufferflies
  - Improve the performance of the scheduler in large clusters #5473 @bufferflies
  - Support using external timestamp which is not provided by PD #5637 @lhy1024
- TiFlash

  - Refactor the TiFlash MPP error handling logic to further improve the stability of MPP #5095 @windtalker
  - Optimize the sorting of the TiFlash computation process, and optimize the key handling for Join and Aggregation #5294 @solotzg
  - Optimize the memory usage for decoding and remove redundant transfer columns to improve Join performance #6157 @yibin87

- Tools

  - TiDB Dashboard

    * Support displaying TiFlash metrics on the Monitoring page and optimize the presentation of metrics on that page #1440 @YiniXu9506
    * Show the number of rows for results in the Slow Query list and SQL Statement list #1443 @baurine
    * Optimize the Dashboard to not report the Alertmanager errors when Alertmanager does not exist #1444 @baurine

  - Backup & Restore (BR)

    * Improve the mechanism for loading the metadata. The metadata is loaded into memory only when necessary, which significantly reduces the memory usage during PITR #38404 @YuJuncen

  - TiCDC

    * Support replicating the exchange partition DDL statements #639 @asddongmen
    * Improve non-batch sending performance for the MQ sink module #7353 @hi-rustin
    * Improve performance of TiCDC puller when a table has a large number of Regions #7078 #7281 @sdojjy
    * Support reading historical data in the downstream TiDB by using the `tidb_enable_external_ts_read` variable when Syncpoint is enabled #7419 @asddongmen
    * Enable transaction split and disable safeMode by default to improve the replication stability #7505 @asddongmen

  - TiDB Data Migration (DM)

    * Remove the useless `operate-source update` command from dmctl #7246 @buchuitoudegou
    * Fix the issue that DM full import fails if the upstream database uses DDL statements that are incompatible with TiDB. You can create the schema of target tables in TiDB manually in advance using DDL statements supported by TiDB to ensure successful import #37984 @lance6716

  - TiDB Lightning

    * Optimize the file scanning logic to accelerate the scan of schema files #38598 @dsdashun

2.2.4 Bug fixes

- TiDB
  - Fix the potential issue of index inconsistency that occurs after you create a new index #38165 @tangenta
  - Fix a permission issue of the `INFORMATION_SCHEMA.TIKV_REGION_STATUS` table #38407 @CbcWestwolf
  - Fix the issue that the `grantor` field is missing in the `mysql.tables_priv` table #38293 @CbcWestwolf
  - Fix the issue that the join result of common table expressions might be wrong #38170 @wjhuang2016
  - Fix the issue that the union result of common table expressions might be wrong #37928 @YangKeao
  - Fix the issue that the information in the **transaction region num** monitoring panel is incorrect #38139 @jackysp
  - Fix the issue that the system variable `tidb_constraint_check_in_place_pessimistic` ↪ might affect internal transactions. The variable scope is modified to SESSION. #38766 @ekexium
  - Fix the issue that conditions in a query are mistakenly pushed down to projections #35623 @Reminiscent
  - Fix the issue that the wrong `isNullRejected` check results for `AND` and `OR` cause wrong query results #38304 @Yisaer
  - Fix the issue that `ORDER BY` in `GROUP_CONCAT` is not considered when the outer join is eliminated, which causes wrong query results #18216 @winoros
  - Fix the issue of the wrong query result that occurs when the mistakenly pushed-down conditions are discarded by Join Reorder #38736 @winoros
- TiKV
  - Fix the issue that TiDB fails to start on Gitpod when there are multiple `cgroup` and `mountinfo` records #13660 @tabokie
  - Fix the wrong expression of a TiKV metric `tikv_gc_compaction_filtered` #13537 @Defined2014
  - Fix the performance issue caused by the abnormal `delete_files_in_range` #13534 @tabokie
  - Fix abnormal Region competition caused by expired lease during snapshot acquisition #13553 @SpadeA-Tang
  - Fix errors occurred when `FLASHBACK` fails in the first batch #13672 #13704 #13723 @HuSharp
- PD
  - Fix inaccurate Stream timeout and accelerate leader switchover #5207 @CabinfeverB

- TiFlash
  - Fix the OOM issue due to oversized WAL files that occurs when PageStorage GC does not clear the Page deletion marker properly #6163 @JaySon-Huang
- Tools
  - TiDB Dashboard
    * Fix the TiDB OOM issue when querying execution plans of certain complex SQL statements #1386 @baurine
    * Fix the issue that the Top SQL switch might not take effect when NgMonitoring loses the connection to the PD nodes #164 @zhongzc
  - Backup & Restore (BR)
    * Fix the restoration failure issue caused by PD leader switch during the restoration process #36910 @MoCuishle28
    * Fix the issue that the log backup task cannot be paused #38250 @joccau
    * Fix the issue that when BR deletes log backup data, it mistakenly deletes data that should not be deleted #38939 @Leavrth
    * Fix the issue that BR fails to delete data when deleting the log backup data stored in Azure Blob Storage or Google Cloud Storage for the first time #38229 @Leavrth
  - TiCDC
    * Fix the issue that `sasl-password` in the `changefeed query` result is not masked #7182 @dveeden
    * Fix the issue that TiCDC might become unavailable when too many operations in an etcd transaction are committed #7131 @asddongmen
    * Fix the issue that redo logs might be deleted incorrectly #6413 @asddongmen
    * Fix performance regression when replicating wide tables in Kafka Sink V2 #7344 @hi-rustin
    * Fix the issue that checkpoint ts might be advanced incorrectly #7274 @hi-rustin
    * Fix the issue that too many logs are printed due to improper log level of the mounter module #7235 @hi-rustin
    * Fix the issue that a TiCDC cluster might have two owners #4051 @asddongmen
  - TiDB Data Migration (DM)
    * Fix the issue that DM WebUI generates the wrong `allow-list` parameter #7096 @zoubingwu
    * Fix the issue that a DM-worker has a certain probability of triggering data race when it starts or stops #6401 @liumengya94
    * Fix the issue that when DM replicates an `UPDATE` or `DELETE` statement but the corresponding row data does not exist, DM silently ignores the event #6383 @GMHDBJD

    * Fix the issue that the `secondsBehindMaster` field is not displayed after you run the `query-status` command #7189 @GMHDBJD
    * Fix the issue that updating the checkpoint may trigger a large transaction #5010 @lance6716
    * Fix the issue that in full task mode, when a task enters the sync stage and fails immediately, DM may lose upstream table schema information #7159 @lance6716
    * Fix the issue that deadlock may be triggered when the consistency check is enabled #7241 @buchuitoudegou
    * Fix the issue that task precheck requires the `SELECT` privilege for the `INFORMATION_SCHEMA` table #7317 @lance6716
    * Fix the issue that an empty TLS configuration causes an error #7384 @liumengya94
  - TiDB Lightning
    * Fix the import performance degradation when importing the Apache Parquet files to the target tables that contain the string type columns in the`binary` encoding format #38351 @dsdashun
  - TiDB Dumpling
    * Fix the issue that Dumpling might time out when exporting a lot of tables #36549 @lance6716
    * Fix lock errors reported when consistency lock is enabled but the upstream has no target table #38683 @lance6716

2.3 TiDB Features

This document lists the features supported in each TiDB version. Note that supports for experimental features might change before the final release.

2.3.1 Data types, functions, and operators

Data types, functions, and operators	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Numeric types	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Date and time types	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
String types	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
JSON type	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Control flow functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
String functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Numeric functions and operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Date and time functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Bit functions and operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Cast functions and operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Encryption and compression functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Information functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
JSON functions	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Aggregation functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Window functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Miscellaneous functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Character sets and collations [1]	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
User-level lock	Y	Y	Y	Y	N	N	N	N	N	N	N

2.3.2 Indexing and constraints

Indexing and constraints	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Expression indexes	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental

[1] TiDB incorrectly treats latin1 as a subset of utf8. See TiDB #18955 for more details.

Indexing and constraints	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Columnar storage (TiFlash)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
RocksDB engine	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Titan plugin	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Invisible indexes	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
Composite `PRIMARY KEY`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Unique indexes	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Clustered index on integer `PRIMARY KEY`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
Clustered index on composite or non-integer key	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N

2.3.3 SQL statements

SQL statements [2]	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Basic `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `REPLACE`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`INSERT ON DUPLICATE KEY UPDATE`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`LOAD DATA INFILE`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`SELECT INTO OUTFILE`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`INNER JOIN`, LEFT|RIGHT [OUTER] JOIN	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`UNION`, `UNION ALL`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`EXCEPT` and `INTERSECT` operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
`GROUP BY`, `ORDER BY`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Window Functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Common Table Expressions (CTE)	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
`START TRANSACTION`, `COMMIT`, `ROLLBACK`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`EXPLAIN`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`EXPLAIN ANALYZE`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
User-defined variables	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
`BATCH [ON COLUMN] LIMIT INTEGER DELETE`	Y	Y	Y	Y	N	N	N	N	N	N	N
`ALTER TABLE ... COMPACT`	Y	Y	Y	Experimental	N	N	N	N	N	N	N

2.3.4 Advanced SQL features

Advanced SQL features	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2
Prepared statement cache	Y	Y	Y	Y	Y	Y	Y	Experim
SQL plan management (SPM)	Y	Y	Y	Y	Y	Y	Y	Y
Coprocessor cache	Y	Y	Y	Y	Y	Y	Y	Y
Stale Read	Y	Y	Y	Y	Y	Y	Y	Y
Follower reads	Y	Y	Y	Y	Y	Y	Y	Y
Read historical data (tidb_snapshot)	Y	Y	Y	Y	Y	Y	Y	Y
Optimizer hints	Y	Y	Y	Y	Y	Y	Y	Y
MPP Execution Engine	Y	Y	Y	Y	Y	Y	Y	Y
Index Merge	Y	Y	Y	Y	Y	Y	Experimental	Experim
Placement Rules in SQL	Y	Y	Y	Y	Y	Experimental	Experimental	N

2.3.5 Data definition language (DDL)

Data definition language (DDL)	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Basic `CREATE`, `DROP`, `ALTER`, `RENAME`, `TRUNCATE`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Generated columns	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Views	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Sequences	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Auto increment	Y[3]	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Auto random	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
DDL algorithm assertions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Multi-schema change: add columns	Y	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Change column type	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
Temporary tables	Y	Y	Y	Y	Y	Y	Y	N	N	N	N
Concurrent DDL statements	Y	Y	Y	N	N	N	N	N	N	N	N
Acceleration of `ADD INDEX` and `CREATE INDEX`	Experimental	Experimental	Experimental	Experimental	N	N	N	N	N	N	N
Metadata lock	Experimental	Experimental	Experimental	Experimental	N	N	N	N	N	N	N
`FLASHBACK CLUSTER TO TIMESTAMP`	Experimental	Experimental	Experimental	N	N	N	N	N	N	N	N

[3] Starting from v6.4.0, TiDB supports high-performance and globally monotonic `AUTO_INCREMENT` columns

2.3.6 Transactions

Transactions	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Async commit	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
1PC	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N
Large transactions (10GB)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Pessimistic transactions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Optimistic transactions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Repeatable-read isolation (snapshot isolation)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Read-committed isolation	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

2.3.7 Partitioning

Partitioning	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Range partitioning	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Hash partitioning	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
List partitioning	Y	Y	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	N
List COLUMNS partitioning	Y	Y	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	N
`EXCHANGE PARTITION`	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	N
Dynamic pruning	Y	Y	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	N	N
Range COLUMNS partitioning	Y	Y	N	N	N	N	N	N	N	N	N
Range INTERVAL partitioning	Experimental	Experimental	N	N	N	N	N	N	N	N	N

2.3.8 Statistics

Statistics	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
CMSketch	Disabled by default	Disabled by default	Disabled by default	Disabled by default	Disabled by default	Disabled by default	Disabled by default	Y	Y	Y	Y
Histograms	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Extended statistics	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	N
Statistics feedback	N	N	N	Deprecated	Deprecated	Deprecated	Experimental	Experimental	Experimental	Experimental	Experimental
Automatically update statistics	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Fast Analyze	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Dynamic pruning	Y	Y	Y	Y	Experimental	Experimental	Experimental	Experimental	Experimental	N	N

2.3.9 Security

Security	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Transparent layer security (TLS)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Encryption at rest (TDE)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Role-based authentication (RBAC)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Certificate-based authentication	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`caching_sha2_password` authentication	Y	Y	Y	Y	Y	Y	Y	Y	N	N	N
`tidb_sm3_password` authentication	Y	Y	N	N	N	N	N	N	N	N	N
`tidb_auth_token` authentication	Y	N	N	N	N	N	N	N	N	N	N
MySQL compatible `GRANT` system	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Dynamic Privileges	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
Security Enhanced Mode	Y	Y	Y	Y	Y	Y	Y	Y	Y	N	N
Redacted Log Files	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N

2.3.10 Data import and export

Data import and export	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
Fast Importer (TiDB Lightning)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
mydumper logical dumper	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated
Dumpling logical dumper	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Transactional `LOAD DATA`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	N [4]
Database migration toolkit (DM)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
TiDB Binlog	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Change data capture (CDC)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

2.3.11 Management, observability, and tools

Management, observability, and tools	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0
TiDB Dashboard UI	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
TiDB Dashboard Continuous Profiling	Y	Y	Y	Y	Y	Experimental	Experimental	N	N	N	N
TiDB Dashboard Top SQL	Y	Y	Y	Y	Y	Experimental	N	N	N	N	N
TiDB Dashboard SQL Diagnostics	Y	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental

[4] For TiDB v4.0, the `LOAD DATA` transaction does not guarantee atomicity.

Management, observability, and tools	6.4	6.3	6.2	6.1	6.0	5.4	5.3	5.2	5.1	5.0	4.0

2.4 TiDB Experimental Features

This document introduces the experimental features of TiDB in different versions. It is **NOT** recommended to use these features in the production environment.

2.4.1 Performance

- Support collecting statistics for `PREDICATE COLUMNS` (Introduced in v5.4)
- Control the memory quota for collecting statistics. (Introduced in v6.1.0)
- Cost Model Version 2. (Introduced in v6.2.0)
- FastScan. (Introduced in v6.2.0)
- Extended statistics. (Introduced in v5.0.0)
- Randomly sample about 10000 rows of data to quickly build statistics (Introduced in v3.0)
- Globally control the memory usage of a tidb-server instance. (Introduced in v6.4.0)

2.4.2 Stability

- Improve the stability of the optimizer's choice of indexes: extend the statistics feature by collecting the multi-column order dependency information (Introduced in v5.0).
- Background Quota Limiter (Introduced in v6.2.0): You can use the background quota-related configuration items to limit the CPU resources to be used by the background. When a request triggers Quota Limiter, the request is forced to wait for a while for TiKV to free up CPU resources.

2.4.3 Scheduling

Elastic scheduling feature. It enables the TiDB cluster to dynamically scale out and in on Kubernetes based on real-time workloads, which effectively reduces the stress during your application's peak hours and saves overheads. See Enable TidbCluster Auto-scaling for details. (Introduced in v4.0)

2.4.4 SQL

- The expression index feature. The expression index is also called the function-based index. When you create an index, the index fields do not have to be a specific column but can be an expression calculated from one or more columns. This feature is useful for quickly accessing the calculation-based tables. See Expression index for details. (Introduced in v4.0)
- Generated Columns (Introduced in v2.1)
- User-Defined Variables (Introduced in v2.1)
- Cascades Planner: a cascades framework-based top-down query optimizer (Introduced in v3.0)
- Table Lock (Introduced in v4.0.0)
- Metadata Lock (Introduced in v6.3.0)
- Range INTERVAL partitioning (Introduced in v6.3.0)
- Add index acceleration (Introduced in v6.3.0)
- Restore a cluster to a specific point in time using the `FLASHBACK CLUSTER TO TIMESTAMP` syntax (Introduced in v6.4.0)
- `AUTO_INCREMENT` MySQL compatibility mode (Introduced in v6.4.0)

2.4.5 Storage

- Titan Level Merge (Introduced in v4.0)
- Divide Regions are divided into buckets. Buckets are used as the unit of concurrent query to improve the scan concurrency. (Introduced in v6.1.0)

2.4.6 Backup and restoration

- Back up and restore RawKV (Introduced in v3.1)

2.4.7 Data migration

- Use WebUI to manage migration tasks in DM. (Introduced in v6.0)
- Configure disk quota for TiDB Lightning. (Introduced in v6.2.0)
- Continuous Data Validation in DM (Introduced in v6.2.0)

2.4.8 Data share subscription

- Cross-cluster RawKV replication (Introduced in v6.2.0)

2.4.9 Garbage collection

- Green GC (Introduced in v5.0)

2.4.10 Diagnostics

- TiKV-FastTune dashboard (Introduced in v4.0)

2.5 MySQL Compatibility

TiDB is highly compatible with the MySQL 5.7 protocol and the common features and syntax of MySQL 5.7. The ecosystem tools for MySQL 5.7 (PHPMyAdmin, Navicat, MySQL Workbench, mysqldump, and Mydumper/myloader) and the MySQL client can be used for TiDB.

However, some features of MySQL are not supported. This could be because there is now a better way to solve the problem (such as XML functions superseded by JSON), or a lack of current demand versus effort required (such as stored procedures and functions). Some features might also be difficult to implement as a distributed system.

In addition, TiDB does not support the MySQL replication protocol, but provides specific tools to replicate data with MySQL:

- Replicate data from MySQL: TiDB Data Migration (DM) is a tool that supports the full data migration and the incremental data replication from MySQL/MariaDB into TiDB.
- Replicate data to MySQL: TiCDC is a tool for replicating the incremental data of TiDB by pulling TiKV change logs. TiCDC uses the MySQL sink to replicate the incremental data of TiDB to MySQL.

> **Note:**
>
> This page describes general differences between MySQL and TiDB. See the dedicated pages for Security and Pessimistic Transaction Mode compatibility.

2.5.1 Unsupported features

- Stored procedures and functions
- Triggers
- Events
- User-defined functions
- `FOREIGN KEY` constraints #18209
- `FULLTEXT` syntax and indexes #1793
- `SPATIAL` (also known as `GIS/GEOMETRY`) functions, data types and indexes #6347
- Character sets other than `ascii`, `latin1`, `binary`, `utf8`, `utf8mb4`, and `gbk`.
- SYS schema
- Optimizer trace
- XML Functions
- X-Protocol #1109
- Column-level privileges #9766
- `XA` syntax (TiDB uses a two-phase commit internally, but this is not exposed via an SQL interface)
- `CREATE TABLE tblName AS SELECT stmt` syntax #4754
- `CHECK TABLE` syntax #4673
- `CHECKSUM TABLE` syntax #1895
- `REPAIR TABLE` syntax
- `OPTIMIZE TABLE` syntax
- `HANDLER` statement
- `CREATE TABLESPACE` statement
- "Session Tracker: Add GTIDs context to the OK packet"

2.5.2 Features that are different from MySQL

2.5.2.1 Auto-increment ID

- In TiDB, the values (IDs) of an auto-incremental column are globally unique. They are incremental on a single TiDB server. If you want the IDs to be incremental among multiple TiDB servers, you can use the `AUTO_INCREMENT` MySQL compatibility mode. But the IDs are not necessarily allocated sequentially. It is recommended that you do not mix default values and custom values. Otherwise, you might encounter the `Duplicated Error` error message.

- You can use the `tidb_allow_remove_auto_inc` system variable to allow or forbid removing the `AUTO_INCREMENT` column attribute. The syntax of removing the column attribute is `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE`.

- TiDB does not support adding the `AUTO_INCREMENT` column attribute, and this attribute cannot be recovered once it is removed.

- See `AUTO_INCREMENT` for more details.

Note:

- If you have not specified the primary key when creating a table, TiDB uses `_tidb_rowid` to identify the row. The allocation of this value shares an allocator with the auto-increment column (if such a column exists). If you specify an auto-increment column as the primary key, TiDB uses this column to identify the row. In this situation, the following situation might happen:

```
mysql> CREATE TABLE t(id INT UNIQUE KEY AUTO_INCREMENT);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(),(),();
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT _tidb_rowid, id FROM t;
+-------------+------+
| _tidb_rowid | id |
+-------------+------+
|           4 |   1 |
|           5 |   2 |
|           6 |   3 |
+-------------+------+
3 rows in set (0.01 sec)
```

Note:

The `AUTO_INCREMENT` attribute might cause hotspot in production environments. See Troubleshoot HotSpot Issues for details. It is recommended to use `AUTO_RANDOM` instead.

2.5.2.2 Performance schema

TiDB uses a combination of Prometheus and Grafana to store and query the performance monitoring metrics. Performance schema tables return empty results in TiDB.

2.5.2.3 Query Execution Plan

The output format, output content, and the privilege setting of Query Execution Plan (`EXPLAIN`/`EXPLAIN FOR`) in TiDB is greatly different from those in MySQL.

The MySQL system variable `optimizer_switch` is read-only in TiDB and has no effect on query plans. You can also use optimizer hints in similar syntax to MySQL, but the available hints and implementation might differ.

See Understand the Query Execution Plan for more details.

2.5.2.4 Built-in functions

TiDB supports most of the MySQL built-in functions, but not all. The statement `SHOW BUILTINS` provides a list of functions that are available.

See also: TiDB SQL Grammar.

2.5.2.5 DDL

In TiDB, all supported DDL changes are performed online. Compared with DDL operations in MySQL, the DDL operations in TiDB have the following major restrictions:

- When you use a single `ALTER TABLE` statement to alter multiple schema objects (such as columns or indexes) of a table, specifying the same object in multiple changes is not supported. For example, if you execute the `ALTER TABLE t1 MODIFY COLUMN c1 INT, DROP COLUMN c1` command, the `Unsupported operate same column/index` error is output.
- It is not supported to modify multiple TiDB-specific schema objects using a single `ALTER TABLE` statement, such as `TIFLASH REPLICA`, `SHARD_ROW_ID_BITS`, and `AUTO_ID_CACHE`.
- `ALTER TABLE` in TiDB does not support the changes of some data types. For example, TiDB does not support the change from the `DECIMAL` type to the `DATE` type. If a data type change is unsupported, TiDB reports the `Unsupported modify column: type %d not match origin %d` error. Refer to `ALTER TABLE` for more details.
- The `ALGORITHM={INSTANT,INPLACE,COPY}` syntax functions only as an assertion in TiDB, and does not modify the `ALTER` algorithm. See `ALTER TABLE` for further details.
- Adding/Dropping the primary key of the `CLUSTERED` type is unsupported. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.
- Different types of indexes (`HASH|BTREE|RTREE|FULLTEXT`) are not supported, and will be parsed and ignored when specified.
- Table Partitioning supports `HASH`, `RANGE`, and `LIST` partitioning types. For the unsupported partition type, the `Warning: Unsupported partition type %s, treat as normal table` error might be output, where `%s` is a specific partition type.
- Table Partitioning also supports `ADD`, `DROP`, and `TRUNCATE` operations. Other partition operations are ignored. The following Table Partition syntaxes are not supported:
  - `PARTITION BY KEY`

- `PARTITION BY LINEAR KEY`
- `SUBPARTITION`
- `{CHECK|TRUNCATE|OPTIMIZE|REPAIR|IMPORT|DISCARD|REBUILD|REORGANIZE|COALESCE} PARTITION`

For more details, see Partitioning.

2.5.2.6 Analyze table

Statistics Collection works differently in TiDB than in MySQL, in that it is a relatively lightweight and short-lived operation in MySQL/InnoDB, while in TiDB it completely rebuilds the statistics for a table and can take much longer to complete.

These differences are documented further in `ANALYZE TABLE`.

2.5.2.7 Limitations of `SELECT` syntax

- The syntax `SELECT ... INTO @variable` is not supported.
- The syntax `SELECT ... GROUP BY ... WITH ROLLUP` is not supported.
- The syntax `SELECT .. GROUP BY expr` does not imply `GROUP BY expr ORDER BY expr` as it does in MySQL 5.7.

For details, see the `SELECT` statement reference.

2.5.2.8 `UPDATE` statement

See the `UPDATE` statement reference.

2.5.2.9 Views

Views in TiDB are not updatable. They do not support write operations such as `UPDATE`, `INSERT`, and `DELETE`.

2.5.2.10 Temporary tables

For details, see Compatibility between TiDB local temporary tables and MySQL temporary tables.

2.5.2.11 Character sets and collations

- To learn the details of the character sets and collations supported by TiDB, see Character Set and Collation Overview.
- To learn the MySQL compatibility of the GBK character set, see GBK compatibility .
- TiDB inherits the character set used in the table as the national character set.

2.5.2.12 Storage engines

For compatibility reasons, TiDB supports the syntax to create tables with alternative storage engines. In implementation, TiDB describes the metadata as the InnoDB storage engine.

TiDB supports storage engine abstraction similar to MySQL, but you need to specify the storage engine using the `--store` option when you start the TiDB server.

2.5.2.13 SQL modes

TiDB supports most SQL modes:

- The compatibility modes, such as `Oracle` and `PostgreSQL` are parsed but ignored. Compatibility modes are deprecated in MySQL 5.7 and removed in MySQL 8.0.
- The `ONLY_FULL_GROUP_BY` mode has minor semantic differences from MySQL 5.7.
- The `NO_DIR_IN_CREATE` and `NO_ENGINE_SUBSTITUTION` SQL modes in MySQL are accepted for compatibility, but are not applicable to TiDB.

2.5.2.14 Default differences

- Default character set:
  - The default value in TiDB is `utf8mb4`.
  - The default value in MySQL 5.7 is `latin1`.
  - The default value in MySQL 8.0 is `utf8mb4`.
- Default collation:
  - The default collation of `utf8mb4` in TiDB is `utf8mb4_bin`.
  - The default collation of `utf8mb4` in MySQL 5.7 is `utf8mb4_general_ci`.
  - The default collation of `utf8mb4` in MySQL 8.0 is `utf8mb4_0900_ai_ci`.
- Default value of `foreign_key_checks`:
  - The default value in TiDB is `OFF` and currently TiDB only supports `OFF`.
  - The default value in MySQL 5.7 is `ON`.
- Default SQL mode:
  - The default SQL mode in TiDB includes these modes: `ONLY_FULL_GROUP_BY,`
    ↪ `STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO`
    ↪ `,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`.
  - The default SQL mode in MySQL:
    * The default SQL mode in MySQL 5.7 is the same as TiDB.
    * The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY`
      ↪ `,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_`
      ↪ `,NO_ENGINE_SUBSTITUTION`.

- Default value of `lower_case_table_names`:
  - The default value in TiDB is `2` and currently TiDB only supports `2`.
  - The default value in MySQL:
    * On Linux: `0`
    * On Windows: `1`
    * On macOS: `2`
- Default value of `explicit_defaults_for_timestamp`:
  - The default value in TiDB is `ON` and currently TiDB only supports `ON`.
  - The default value in MySQL:
    * For MySQL 5.7: `OFF`.
    * For MySQL 8.0: `ON`.

2.5.2.15 Date and Time

2.5.2.15.1 Named timezone

- TiDB uses all time zone rules currently installed in the system for calculation (usually the `tzdata` package). You can use all time zone names without importing the time zone table data. You cannot modify the calculation rules by importing the time zone table data.
- MySQL uses the local time zone by default and relies on the current time zone rules built into the system (such as when to start daylight saving time) for calculation; and the time zone cannot be specified by the time zone name without importing the time zone table data.

2.5.2.16 Type system differences

The following column types are supported by MySQL, but **NOT** by TiDB:

- FLOAT4/FLOAT8
- `SQL_TSI_*` (including SQL_TSI_MONTH, SQL_TSI_WEEK, SQL_TSI_DAY, SQL_TSI_HOUR, SQL_TSI_MINUTE and SQL_TSI_SECOND, excluding SQL_TSI_YEAR)

2.5.2.17 Incompatibility caused by deprecated features

TiDB does not implement certain features that have been marked as deprecated in MySQL, including:

- Specifying precision for floating point types. MySQL 8.0 deprecates this feature, and it is recommended to use the `DECIMAL` type instead.
- The `ZEROFILL` attribute. MySQL 8.0 deprecates this feature, and it is recommended to instead pad numeric values in your application.

2.6 TiDB Limitations

This document describes the common usage limitations of TiDB, including the maximum identifier length and the maximum number of supported databases, tables, indexes, partitioned tables, and sequences.

2.6.1 Limitations on identifier length

Identifier type	Maximum length (number of characters allowed)
Database	64
Table	64
Column	64
Index	64
View	64
Sequence	64

2.6.2 Limitations on the total number of databases, tables, views, and connections

Identifier type	Maximum number
Databases	unlimited
Tables	unlimited
Views	unlimited
Connections	unlimited

2.6.3 Limitations on a single database

Type	Upper limit
Tables	unlimited

2.6.4 Limitations on a single table

Type	Upper limit (default value)
Columns	Defaults to 1017 and can be adjusted up to 4096
Indexes	Defaults to 64 and can be adjusted up to 512
Rows	unlimited
Size	unlimited
Partitions	8192

- The upper limit of `Columns` can be modified via `table-column-count-limit`.
- The upper limit of `Indexes` can be modified via `index-limit`.

2.6.5 Limitation on a single row

Type	Upper limit (default value)
Size	Defaults to 6 MiB and can be adjusted to 120 MiB

You can adjust the size limit via the `txn-entry-size-limit` configuration item.

2.6.6 Limitation on a single column

Type	Upper limit (default value)
Size	Defaults to 6 MiB and can be adjusted to 120 MiB

You can adjust the size limit via the `txn-entry-size-limit` configuration item.

2.6.7 Limitations on data types

Type	Upper limit
CHAR	256 characters
BINARY	256 characters
VARBINARY	65535 characters
VARCHAR	16383 characters
TEXT	Defaults to 6 MiB and can be adjusted to 120 MiB
BLOB	Defaults to 6 MiB and can be adjusted to 120 MiB

2.6.8 Limitations on SQL statements

Type	Upper limit
The maximum number of SQL statements in a single transaction	When the optimistic transaction is used and the transaction retry is enabled, the upper limit is 5000.

You can modify the limit via the `stmt-count-limit` configuration item.

2.6.9 Limitations on TiKV version

In your cluster, if the version of the TiDB component is v6.2.0 or later, the version of TiKV must be v6.2.0 or later.

2.7 Credits

Each contributor has played an important role in promoting the robust development of TiDB. We sincerely appreciate all contributors who have submitted code, written and translated documents for TiDB.

2.7.1 TiDB developers

TiDB developers contribute to new feature development, performance improvement, stability guarantee, and bug fixes. The following is the list of contributors in TiDB related repos:

- pingcap/tidb
- tikv/tikv
- pingcap/parser
- tikv/pd
- pingcap/tiflash
- pingcap/tidb-operator
- pingcap/tiup
- pingcap/br
- pingcap/dm
- pingcap/tidb-binlog
- pingcap/tidb-dashboard

- pingcap/tiflow
- pingcap/tidb-tools
- pingcap/tidb-lightning
- pingcap/tispark
- pingcap/dumpling
- tikv/client-java
- tidb-incubator/TiBigData
- ti-community-infra

For the full list of contributors, see SIG | TiDB DevGroup.

2.7.2 Writers and translators for TiDB documentation

Writers and translators write and translate documents for TiDB and the related projects. The following is the list of contributors in TiDB documentation related repos:

- pingcap/docs-cn
- pingcap/docs
- pingcap/docs-tidb-operator
- pingcap/docs-dm
- tikv/website

3 Quick Start

3.1 Quick Start Guide for the TiDB Database Platform

This guide walks you through the quickest way to get started with TiDB. For non-production environments, you can deploy your TiDB database by either of the following methods:

- Deploy a local test cluster (for macOS and Linux)
- Simulate production deployment on a single machine (for Linux only)

Note:

- TiDB, TiUP and TiDB Dashboard share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.
- The deployment method provided in this guide is **ONLY FOR** quick start, **NOT FOR** production.

- To deploy an on-premises production cluster, see production installation guide.
- To deploy TiDB on Kubernetes, see Get Started with TiDB on Kubernetes.
- To manage TiDB in the cloud, see TiDB Cloud Quick Start.

3.1.1 Deploy a local test cluster

- Scenario: Quickly deploy a local TiDB cluster for testing using a single macOS or Linux server. By deploying such a cluster, you can learn the basic architecture of TiDB and the operation of its components, such as TiDB, TiKV, PD, and the monitoring components.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly build the test cluster by taking the following steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

If the following message is displayed, you have installed TiUP successfully:

```
Successfully set mirror to https://tiup-mirrors.pingcap.com
Detected shell: zsh
Shell profile: /Users/user/.zshrc
/Users/user/.zshrc has been modified to add tiup to PATH
open a new terminal or source /Users/user/.zshrc to use it
Installed path: /Users/user/.tiup/bin/tiup
===============================================
Have a try:   tiup playground
===============================================
```

Note the Shell profile path in the output above. You need to use the path in the next step.

2. Declare the global environment variable:

Note:

After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in

the following `source` command according to the path. In this case, `$ ↪ {your_shell_profile}` is `/Users/user/.zshrc` from the output of Step 1.

```
source ${your_shell_profile}
```

3. Start the cluster in the current session:

    - If you want to start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

    ```
    tiup playground
    ```

    - If you want to specify the TiDB version and the number of the instances of each component, run a command like this:

    ```
    tiup playground v6.4.0 --db 2 --pd 3 --kv 3
    ```

    The command downloads a version cluster to the local machine and starts it, such as v6.4.0. To view the latest version, run `tiup list tidb`.

    This command returns the access methods of the cluster:

    ```
    CLUSTER START SUCCESSFULLY, Enjoy it ^-^
    To connect TiDB: mysql --comments --host 127.0.0.1 --port 4001 -u
       ↪ root -p (no password)
    To connect TiDB: mysql --comments --host 127.0.0.1 --port 4000 -u
       ↪ root -p (no password)
    To view the dashboard: http://127.0.0.1:2379/dashboard
    PD client endpoints: [127.0.0.1:2379 127.0.0.1:2382 127.0.0.1:2384]
    To view Prometheus: http://127.0.0.1:9090
    To view Grafana: http://127.0.0.1:3000
    ```

    Note:

    - Since v5.2.0, TiDB supports running `tiup playground` on the machine that uses the Apple M1 chip.
    - For the playground operated in this way, after the test deployment is finished, TiUP will clean up the original cluster data. You will get a new cluster after re-running the command.
    - If you want the data to be persisted on storage, run `tiup --tag ↪ <your-tag> playground ...`. For details, refer to TiUP Reference Guide.

4. Start a new session to access TiDB:

    - Use the TiUP client to connect to TiDB.

    ```
    tiup client
    ```

    - You can also use the MySQL client to connect to TiDB.

    ```
    mysql --host 127.0.0.1 --port 4000 -u root
    ```

5. Access the Prometheus dashboard of TiDB at http://127.0.0.1:9090.

6. Access the TiDB Dashboard at http://127.0.0.1:2379/dashboard. The default username is `root`, with an empty password.

7. Access the Grafana dashboard of TiDB through http://127.0.0.1:3000. Both the default username and password are `admin`.

8. (Optional) Load data to TiFlash for analysis.

9. Clean up the cluster after the test deployment:

    1. Stop the above TiDB service by pressing Control+C.
    2. Run the following command after the service is stopped:

    ```
    tiup clean --all
    ```

> **Note:**
>
> TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly build the test cluster by taking the following steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

If the following message is displayed, you have installed TiUP successfully:

```
Successfully set mirror to https://tiup-mirrors.pingcap.com
Detected shell: zsh
Shell profile: /Users/user/.zshrc
/Users/user/.zshrc has been modified to add tiup to PATH
open a new terminal or source /Users/user/.zshrc to use it
Installed path: /Users/user/.tiup/bin/tiup
===============================================
Have a try:   tiup playground
===============================================
```

Note the Shell profile path in the output above. You need to use the path in the next step.

2. Declare the global environment variable:

> **Note:**
> After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path.

```
source ${your_shell_profile}
```

3. Start the cluster in the current session:

   - If you want to start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

     ```
     tiup playground
     ```

   - If you want to specify the TiDB version and the number of the instances of each component, run a command like this:

     ```
     tiup playground v6.4.0 --db 2 --pd 3 --kv 3
     ```

     The command downloads a version cluster to the local machine and starts it, such as v6.4.0. To view the latest version, run `tiup list tidb`.

     This command returns the access methods of the cluster:

     ```
     CLUSTER START SUCCESSFULLY, Enjoy it ^-^
     To connect TiDB: mysql --host 127.0.0.1 --port 4000 -u root -p (no
         ↪ password) --comments
     To view the dashboard: http://127.0.0.1:2379/dashboard
     PD client endpoints: [127.0.0.1:2379]
     ```

```
To view the Prometheus: http://127.0.0.1:9090
To view the Grafana: http://127.0.0.1:3000
```

> **Note:**
> For the playground operated in this way, after the test deployment is finished, TiUP will clean up the original cluster data. You will get a new cluster after re-running the command. If you want the data to be persisted on storage, run `tiup --tag <your-tag> playground ...`. For details, refer to TiUP Reference Guide.

4. Start a new session to access TiDB:

    - Use the TiUP client to connect to TiDB.

    ```
    tiup client
    ```

    - You can also use the MySQL client to connect to TiDB.

    ```
    mysql --host 127.0.0.1 --port 4000 -u root
    ```

5. Access the Prometheus dashboard of TiDB at http://127.0.0.1:9090.
6. Access the TiDB Dashboard at http://127.0.0.1:2379/dashboard. The default username is `root`, with an empty password.
7. Access the Grafana dashboard of TiDB through http://127.0.0.1:3000. Both the default username and password are `admin`.
8. (Optional) Load data to TiFlash for analysis.
9. Clean up the cluster after the test deployment:

    1. Stop the process by pressing Control+C.
    2. Run the following command after the service is stopped:

    ```
    tiup clean --all
    ```

> **Note:**
>
> TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

3.1.2 Simulate production deployment on a single machine

- Scenario: Experience the smallest TiDB cluster with the complete topology and simulate the production deployment steps on a single Linux server.

This section describes how to deploy a TiDB cluster using a YAML file of the smallest topology in TiUP.

3.1.2.1 Prepare

Prepare a target machine that meets the following requirements:

- CentOS 7.3 or a later version is installed
- The Linux OS has access to the Internet, which is required to download TiDB and related software installation packages

The smallest TiDB cluster topology is as follows:

> **Note:**
>
> The IP address of the following instances only serves as an example IP. In your actual deployment, you need to replace the IP with your actual IP.

Instance	Count	IP	Configuration
TiKV	3	10.0.1.1 10.0.1.2 10.0.1.3	Avoid conflict between the port and the directory

Instance	Count	IP	Configuration
TiDB	1	10.0.1.1	The default port Global directory configuration
PD	1	10.0.1.1	The default port Global directory configuration
TiFlash	1	10.0.1.1	The default port Global directory configuration

Instance	Count	IP	Configuration
Monitor	1	10.0.1.1	The default port Global directory configuration

Other requirements for the target machine:

- The `root` user and its password is required
- Stop the firewall service of the target machine, or open the port needed by the TiDB cluster nodes
- Currently, the TiUP cluster supports deploying TiDB on the x86_64 (AMD64) and ARM architectures:
  - It is recommended to use CentOS 7.3 or later versions on AMD64
  - It is recommended to use CentOS 7.6 1810 on ARM

3.1.2.2 Deploy

> **Note:**
>
> You can log in to the target machine as a regular user or the `root` user. The following steps use the `root` user as an example.

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Declare the global environment variable.

> **Note:**
> After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path.

```
source ${your_shell_profile}
```

3. Install the cluster component of TiUP:

```
tiup cluster
```

4. If the TiUP cluster is already installed on the machine, update the software version:

```
tiup update --self && tiup update cluster
```

5. Use the root user privilege to increase the connection limit of the `sshd` service. This is because TiUP needs to simulate deployment on multiple machines.

    1. Modify `/etc/ssh/sshd_config`, and set `MaxSessions` to 20.
    2. Restart the `sshd` service:

    ```
    service sshd restart
    ```

6. Create and start the cluster:

    Edit the configuration file according to the following template, and name it as `topo.yaml`:

```
# # Global variables are applied to all deployments and used as the default value of
# # the deployments if a specific deployment value is missing.
global:
 user: "tidb"
 ssh_port: 22
 deploy_dir: "/tidb-deploy"
 data_dir: "/tidb-data"

# # Monitored variables are applied to all the machines.
monitored:
 node_exporter_port: 9100
 blackbox_exporter_port: 9115
```

```
server_configs:
 tidb:
   log.slow-threshold: 300
 tikv:
   readpool.storage.use-unified-pool: false
   readpool.coprocessor.use-unified-pool: true
 pd:
   replication.enable-placement-rules: true
   replication.location-labels: ["host"]
 tiflash:
   logger.level: "info"

pd_servers:
 - host: 10.0.1.1

tidb_servers:
 - host: 10.0.1.1

tikv_servers:
 - host: 10.0.1.1
   port: 20160
   status_port: 20180
   config:
     server.labels: { host: "logic-host-1" }

 - host: 10.0.1.1
   port: 20161
   status_port: 20181
   config:
     server.labels: { host: "logic-host-2" }

 - host: 10.0.1.1
   port: 20162
   status_port: 20182
   config:
     server.labels: { host: "logic-host-3" }

tiflash_servers:
 - host: 10.0.1.1

monitoring_servers:
 - host: 10.0.1.1

grafana_servers:
 - host: 10.0.1.1
```

- `user: "tidb"`: Use the `tidb` system user (automatically created during deployment) to perform the internal management of the cluster. By default, use port 22 to log in to the target machine via SSH.
- `replication.enable-placement-rules`: This PD parameter is set to ensure that TiFlash runs normally.
- `host`: The IP of the target machine.

7. Execute the cluster deployment command:

```
tiup cluster deploy <cluster-name> <tidb-version> ./topo.yaml --user
    ↪ root -p
```

- `<cluster-name>`: Set the cluster name
- `<tidb-version>`: Set the TiDB cluster version. You can see all the supported TiDB versions by running the `tiup list tidb` command
- `-p`: Specify the password used to connect to the target machine.

> **Note:**
> If you use secret keys, you can specify the path of the keys through `-i`. Do not use `-i` and `-p` at the same time.

Enter "y" and the `root` user's password to complete the deployment:

```
Do you want to continue? [y/N]: y
Input SSH password:
```

8. Start the cluster:

```
tiup cluster start <cluster-name>
```

9. Access the cluster:

- Install the MySQL client. If it is already installed, skip this step.

```
yum -y install mysql
```

- Access TiDB. The password is empty:

```
mysql -h 10.0.1.1 -P 4000 -u root
```

- Access the Grafana monitoring dashboard at http://%7Bgrafana-ip%7D:3000. The default username and password are both `admin`.

- Access the TiDB Dashboard at http://%7Bpd-ip%7D:2379/dashboard. The default username is `root`, and the password is empty.
- To view the currently deployed cluster list:

```
tiup cluster list
```

- To view the cluster topology and status:

```
tiup cluster display <cluster-name>
```

3.1.3 What's next

- If you have just deployed a TiDB cluster for the local test environment:
  - Learn Basic SQL operations in TiDB
  - Migrate data to TiDB
- If you are ready to deploy a TiDB cluster for the production environment:
  - Deploy TiDB using TiUP
  - Deploy TiDB on Cloud using TiDB Operator
- If you're looking for analytics solution with TiFlash:
  - Use TiFlash
  - TiFlash Overview

3.2 Quick Start Guide for TiDB HTAP

This guide walks you through the quickest way to get started with TiDB's one-stop solution of Hybrid Transactional and Analytical Processing (HTAP).

> **Note:**
>
> The steps provided in this guide is ONLY for quick start in the test environment. For production environments, explore HTAP is recommended.

3.2.1 Basic concepts

Before using TiDB HTAP, you need to have some basic knowledge about TiKV, a row-based storage engine for TiDB Online Transactional Processing (OLTP), and TiFlash, a columnar storage engine for TiDB Online Analytical Processing (OLAP).

- Storage engines of HTAP: The row-based storage engine and the columnar storage engine co-exist for HTAP. Both storage engines can replicate data automatically and keep strong consistency. The row-based storage engine optimizes OLTP performance, and the columnar storage engine optimizes OLAP performance.
- Data consistency of HTAP: As a distributed and transactional key-value database, TiKV provides transactional interfaces with ACID compliance, and guarantees data consistency between multiple replicas and high availability with the implementation of the Raft consensus algorithm. As a columnar storage extension of TiKV, TiFlash replicates data from TiKV in real time according to the Raft Learner consensus algorithm, which ensures that data is strongly consistent between TiKV and TiFlash.
- Data isolation of HTAP: TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.
- MPP computing engine: MPP is a distributed computing framework provided by the TiFlash engine since TiDB 5.0, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. In the MPP mode, the run time of the analytic queries can be significantly reduced.

3.2.2 Steps

In this document, you can experience the convenience and high performance of TiDB HTAP by querying an example table in a TPC-H dataset. TPC-H is a popular decision support benchmark that consists of a suite of business oriented ad-hoc queries with large volumes of data and a high degree of complexity. To experience 22 complete SQL queries using TPC-H, visit tidb-bench repo or TPC-H for instructions on how to generate query statements and data.

3.2.2.1 Step 1. Deploy a local test environment

Before using TiDB HTAP, follow the steps in the Quick Start Guide for the TiDB Database Platform to prepare a local test environment, and run the following command to deploy a TiDB cluster:

```
tiup playground
```

> **Note:**
>
> `tiup playground` command is ONLY for quick start, NOT for production.

3.2.2.2 Step 2. Prepare test data

In the following steps, you can create a TPC-H dataset as the test data to use TiDB HTAP. If you are interested in TPC-H, see General Implementation Guidelines.

> **Note:**
>
> If you want to use your existing data for analytic queries, you can migrate your data to TiDB. If you want to design and create your own test data, you can create it by executing SQL statements or using related tools.

1. Install the test data generation tool by running the following command:

```
tiup install bench
```

2. Generate the test data by running the following command:

```
tiup bench tpch --sf=1 prepare
```

   If the output of this command shows `Finished`, it indicates that the data is created.

3. Execute the following SQL statement to view the generated data:

```
SELECT
  CONCAT(table_schema,'.',table_name) AS 'Table Name',
  table_rows AS 'Number of Rows',
  FORMAT_BYTES(data_length) AS 'Data Size',
  FORMAT_BYTES(index_length) AS 'Index Size',
  FORMAT_BYTES(data_length+index_length) AS'Total'
FROM
  information_schema.TABLES
WHERE
  table_schema='test';
```

   As you can see from the output, eight tables are created in total, and the largest table has 6.5 million rows (the number of rows created by the tool depends on the actual SQL query result because the data is randomly generated).

```
sql +---------------+---------------+-----------+------------+-----------+
↪  | Table Name | Number of Rows | Data Size | Index Size | Total |
↪ +---------------+---------------+-----------+------------+-----------+
↪  | test.nation | 25 | 2.44 KiB | 0 bytes | 2.44 KiB | | test.region
↪  | 5 | 416 bytes | 0 bytes | 416 bytes | | test.part |        200000
↪  | 25.07 MiB | 0 bytes | 25.07 MiB | | test.supplier |    10000 |
↪  1.45 MiB | 0 bytes | 1.45 MiB | | test.partsupp |     800000 |
```

```
↪ 120.17 MiB| 12.21 MiB | 132.38 MiB| | test.customer | 150000 | 24.77
↪  MiB | 0 bytes | 24.77 MiB | | test.orders |    1527648 | 174.40
↪ MiB| 0 bytes | 174.40 MiB| | test.lineitem |  6491711 | 849.07 MiB|
↪ 99.06 MiB | 948.13 MiB| +---------------+---------------+----------+----------
↪  8 rows in set (0.06 sec)
```

This is a database of a commercial ordering system. In which, the `test.nation` table indicates the information about countries, the `test.region` table indicates the information about regions, the `test.part` table indicates the information about parts, the `test.supplier` table indicates the information about suppliers, the `test.partsupp` ↪ table indicates the information about parts of suppliers, the `test.customer` table indicates the information about customers, the `test.customer` table indicates the information about orders, and the `test.lineitem` table indicates the information about online items.

3.2.2.3 Step 3. Query data with the row-based storage engine

To know the performance of TiDB with only the row-based storage engine, execute the following SQL statements:

```
SELECT
    l_orderkey,
    SUM(
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    o_orderdate,
    o_shippriority
FROM
    customer,
    orders,
    lineitem
WHERE
    c_mktsegment = 'BUILDING'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < DATE '1996-01-01'
AND l_shipdate > DATE '1996-02-01'
GROUP BY
    l_orderkey,
    o_orderdate,
    o_shippriority
ORDER BY
    revenue DESC,
    o_orderdate
limit 10;
```

This is a shipping priority query, which provides the priority and potential revenue of the highest-revenue order that has not been shipped before a specified date. The potential revenue is defined as the sum of `l_extendedprice * (1-l_discount)`. The orders are listed in the descending order of revenue. In this example, this query lists the unshipped orders with potential query revenue in the top 10.

3.2.2.4 Step 4. Replicate the test data to the columnar storage engine

After TiFlash is deployed, TiKV does not replicate data to TiFlash immediately. You need to execute the following DDL statements in a MySQL client of TiDB to specify which tables need to be replicated. After that, TiDB will create the specified replicas in TiFlash accordingly.

```
ALTER TABLE test.customer SET TIFLASH REPLICA 1;
ALTER TABLE test.orders SET TIFLASH REPLICA 1;
ALTER TABLE test.lineitem SET TIFLASH REPLICA 1;
```

To check the replication status of the specific tables, execute the following statements:

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
    ↪ ' and TABLE_NAME = 'customer';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
    ↪ ' and TABLE_NAME = 'orders';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
    ↪ ' and TABLE_NAME = 'lineitem';
```

In the result of the above statements:

- `AVAILABLE` indicates whether the TiFlash replica of a specific table is available or not. `1` means available and `0` means unavailable. Once the `AVAILABLE` field becomes `1`, this status does not change anymore.
- `PROGRESS` means the progress of the replication. The value is between 0.0 and 1.0. 1 means that the replication progress of the TiFlash replica is complete.

3.2.2.5 Step 5. Analyze data faster using HTAP

Execute the SQL statements in Step 3 again, and you can see the performance of TiDB HTAP.

For tables with TiFlash replicas, the TiDB optimizer automatically determines whether to use TiFlash replicas based on the cost estimation. To check whether or not a TiFlash replica is selected, you can use the `desc` or `explain analyze` statement. For example:

```
explain analyze SELECT
    l_orderkey,
    SUM(
        l_extendedprice * (1 - l_discount)
```

```
    ) AS revenue,
    o_orderdate,
    o_shippriority
FROM
    customer,
    orders,
    lineitem
WHERE
    c_mktsegment = 'BUILDING'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < DATE '1996-01-01'
AND l_shipdate > DATE '1996-02-01'
GROUP BY
    l_orderkey,
    o_orderdate,
    o_shippriority
ORDER BY
    revenue DESC,
    o_orderdate
limit 10;
```

If the result of the `EXPLAIN` statement shows `ExchangeSender` and `ExchangeReceiver` operators, it indicates that the MPP mode has taken effect.

In addition, you can specify that each part of the entire query is computed using only the TiFlash engine. For detailed information, see Use TiDB to read TiFlash replicas.

You can compare query results and query performance of these two methods.

3.2.3 What's next

- Architecture of TiDB HTAP
- Explore HTAP
- Use TiFlash

3.3 Explore SQL with TiDB

TiDB is compatible with MySQL, you can use MySQL statements directly in most of the cases. For unsupported features, see Compatibility with MySQL.

To experiment with SQL and test out TiDB compatibility with MySQL queries, you can run TiDB directly in your web browser without installing it. You can also first deploy a TiDB cluster and then run SQL statements in it.

This page walks you through the basic TiDB SQL statements such as DDL, DML and CRUD operations. For a complete list of TiDB statements, see TiDB SQL Syntax Diagram.

3.3.1 Category

SQL is divided into the following 4 types according to their functions:

- DDL (Data Definition Language): It is used to define database objects, including databases, tables, views, and indexes.
- DML (Data Manipulation Language): It is used to manipulate application related records.
- DQL (Data Query Language): It is used to query the records after conditional filtering.
- DCL (Data Control Language): It is used to define access privileges and security levels.

Common DDL features are creating, modifying, and deleting objects (such as tables and indexes). The corresponding commands are `CREATE`, `ALTER`, and `DROP`.

3.3.2 Show, create and drop a database

A database in TiDB can be considered as a collection of objects such as tables and indexes.

To show the list of databases, use the `SHOW DATABASES` statement:

```
SHOW DATABASES;
```

To use the database named `mysql`, use the following statement:

```
USE mysql;
```

To show all the tables in a database, use the `SHOW TABLES` statement:

```
SHOW TABLES FROM mysql;
```

To create a database, use the `CREATE DATABASE` statement:

```
CREATE DATABASE db_name [options];
```

To create a database named `samp_db`, use the following statement:

```
CREATE DATABASE IF NOT EXISTS samp_db;
```

Add `IF NOT EXISTS` to prevent an error if the database exists.

To delete a database, use the `DROP DATABASE` statement:

```
DROP DATABASE samp_db;
```

3.3.3 Create, show, and drop a table

To create a table, use the `CREATE TABLE` statement:

```
CREATE TABLE table_name column_name data_type constraint;
```

For example, to create a table named `person` which includes fields such as number, name, and birthday, use the following statement:

```
CREATE TABLE person (
    id INT(11),
    name VARCHAR(255),
    birthday DATE
    );
```

To view the statement that creates the table (DDL), use the `SHOW CREATE` statement:

```
SHOW CREATE table person;
```

To delete a table, use the `DROP TABLE` statement:

```
DROP TABLE person;
```

3.3.4 Create, show, and drop an index

Indexes are used to speed up queries on indexed columns. To create an index for the column whose value is not unique, use the `CREATE INDEX` statement:

```
CREATE INDEX person_id ON person (id);
```

Or use the `ALTER TABLE` statement:

```
ALTER TABLE person ADD INDEX person_id (id);
```

To create a unique index for the column whose value is unique, use the `CREATE UNIQUE INDEX` statement:

```
CREATE UNIQUE INDEX person_unique_id ON person (id);
```

Or use the `ALTER TABLE` statement:

```
ALTER TABLE person ADD UNIQUE person_unique_id (id);
```

To show all the indexes in a table, use the `SHOW INDEX` statement:

```
SHOW INDEX FROM person;
```

To delete an index, use the `DROP INDEX` or `ALTER TABLE` statement. `DROP INDEX` can be nested in `ALTER TABLE`:

```
DROP INDEX person_id ON person;
```

```
ALTER TABLE person DROP INDEX person_unique_id;
```

> **Note:**
>
> DDL operations are not transactions. You don't need to run a `COMMIT` statement when executing DDL operations.

3.3.5 Insert, update, and delete data

Common DML features are adding, modifying, and deleting table records. The corresponding commands are `INSERT`, `UPDATE`, and `DELETE`.

To insert data into a table, use the `INSERT` statement:

```
INSERT INTO person VALUES(1,'tom','20170912');
```

To insert a record containing data of some fields into a table, use the `INSERT` statement:

```
INSERT INTO person(id,name) VALUES('2','bob');
```

To update some fields of a record in a table, use the `UPDATE` statement:

```
UPDATE person SET birthday='20180808' WHERE id=2;
```

To delete the data in a table, use the `DELETE` statement:

```
DELETE FROM person WHERE id=2;
```

> **Note:**
>
> The `UPDATE` and `DELETE` statements without the `WHERE` clause as a filter operate on the entire table.

3.3.6 Query data

DQL is used to retrieve the desired data rows from a table or multiple tables.

To view the data in a table, use the `SELECT` statement:

```
SELECT * FROM person;
```

To query a specific column, add the column name after the `SELECT` keyword:

```
SELECT name FROM person;
```

```
+------+
| name |
+------+
| tom |
+------+
1 rows in set (0.00 sec)
```

Use the `WHERE` clause to filter all records that match the conditions and then return the result:

```
SELECT * FROM person where id<5;
```

3.3.7 Create, authorize, and delete a user

DCL are usually used to create or delete users, and manage user privileges.

To create a user, use the `CREATE USER` statement. The following example creates a user named `tiuser` with the password `123456`:

```
CREATE USER 'tiuser'@'localhost' IDENTIFIED BY '123456';
```

To grant `tiuser` the privilege to retrieve the tables in the `samp_db` database:

```
GRANT SELECT ON samp_db.* TO 'tiuser'@'localhost';
```

To check the privileges of `tiuser`:

```
SHOW GRANTS for tiuser@localhost;
```

To delete `tiuser`:

```
DROP USER 'tiuser'@'localhost';
```

3.4 Explore HTAP

This guide describes how to explore and use the features of TiDB Hybrid Transactional and Analytical Processing (HTAP).

Note:

If you are new to TiDB HTAP and want to start using it quickly, see Quick start with HTAP.

3.4.1 Use cases

TiDB HTAP can handle the massive data that increases rapidly, reduce the cost of DevOps, and be deployed in either on-premises or cloud environments easily, which brings the value of data assets in real time.

The following are the typical use cases of HTAP:

- Hybrid workload

  When using TiDB for real-time Online Analytical Processing (OLAP) in hybrid load scenarios, you only need to provide an entry point of TiDB to your data. TiDB automatically selects different processing engines based on the specific business.

- Real-time stream processing

  When using TiDB in real-time stream processing scenarios, TiDB ensures that all the data flowed in constantly can be queried in real time. At the same time, TiDB also can handle highly concurrent data workloads and Business Intelligence (BI) queries.

- Data hub

  When using TiDB as a data hub, TiDB can meet specific business needs by seamlessly connecting the data for the application and the data warehouse.

For more information about use cases of TiDB HTAP, see blogs about HTAP on the PingCAP website.

3.4.2 Architecture

In TiDB, a row-based storage engine TiKV for Online Transactional Processing (OLTP) and a columnar storage engine TiFlash for Online Analytical Processing (OLAP) co-exist, replicate data automatically, and keep strong consistency.

For more information about the architecture, see architecture of TiDB HTAP.

3.4.3 Environment preparation

Before exploring the features of TiDB HTAP, you need to deploy TiDB and the corresponding storage engines according to the data volume. If the data volume is large (for example, 100 T), it is recommended to use TiFlash Massively Parallel Processing (MPP) as the primary solution and TiSpark as the supplementary solution.

- TiFlash
  - If you have deployed a TiDB cluster with no TiFlash node, add the TiFlash nodes in the current TiDB cluster. For detailed information, see Scale out a TiFlash cluster.
  - If you have not deployed a TiDB cluster, see Deploy a TiDB Cluster using TiUP. Based on the minimal TiDB topology, you also need to deploy the topology of TiFlash.
  - When deciding how to choose the number of TiFlash nodes, consider the following scenarios:
    * If your use case requires OLTP with small-scale analytical processing and Ad-Hoc queries, deploy one or several TiFlash nodes. They can dramatically increase the speed of analytic queries.
    * If the OLTP throughput does not cause significant pressure to I/O usage rate of the TiFlash nodes, each TiFlash node uses more resources for computation, and thus the TiFlash cluster can have near-linear scalability. The number of TiFlash nodes should be tuned based on expected performance and response time.
    * If the OLTP throughput is relatively high (for example, the write or update throughput is higher than 10 million lines/hours), due to the limited write capacity of network and physical disks, the I/O between TiKV and TiFlash becomes a bottleneck and is also prone to read and write hotspots. In this case, the number of TiFlash nodes has a complex non-linear relationship with the computation volume of analytical processing, so you need to tune the number of TiFlash nodes based on the actual status of the system.
- TiSpark
  - If your data needs to be analyzed with Spark, deploy TiSpark. For specific process, see TiSpark User Guide.

3.4.4 Data preparation

After TiFlash is deployed, TiKV does not replicate data to TiFlash automatically. You need to manually specify which tables need to be replicated to TiFlash. After that, TiDB creates the corresponding TiFlash replicas.

- If there is no data in the TiDB Cluster, migrate the data to TiDB first. For detailed information, see data migration.
- If the TiDB cluster already has the replicated data from upstream, after TiFlash is deployed, data replication does not automatically begin. You need to manually specify the tables to be replicated to TiFlash. For detailed information, see Use TiFlash.

3.4.5 Data processing

With TiDB, you can simply enter SQL statements for query or write requests. For the tables with TiFlash replicas, TiDB uses the front-end optimizer to automatically choose the optimal execution plan.

> **Note:**
>
> The MPP mode of TiFlash is enabled by default. When an SQL statement is executed, TiDB automatically determines whether to run in the MPP mode through the optimizer.
>
> - To disable the MPP mode of TiFlash, set the value of the tidb_allow_mpp system variable to `OFF`.
> - To forcibly enable MPP mode of TiFlash for query execution, set the values of tidb_allow_mpp and tidb_enforce_mpp to `ON`.
> - To check whether TiDB chooses the MPP mode to execute a specific query, see Explain Statements in the MPP Mode. If the output of `EXPLAIN` statement includes the `ExchangeSender` and `ExchangeReceiver` operators, the MPP mode is in use.

3.4.6 Performance monitoring

When using TiDB, you can monitor the TiDB cluster status and performance metrics in either of the following ways:

- TiDB Dashboard: you can see the overall running status of the TiDB cluster, analyse distribution and trends of read and write traffic, and learn the detailed execution information of slow queries.
- Monitoring system (Prometheus & Grafana): you can see the monitoring parameters of TiDB cluster-related componants including PD, TiDB, TiKV, TiFlash,TiCDC, and Node_exporter.

To see the alert rules of TiDB cluster and TiFlash cluster, see TiDB cluster alert rules and TiFlash alert rules.

3.4.7 Troubleshooting

If any issue occurs during using TiDB, refer to the following documents:

- Analyze slow queries
- Identify expensive queries
- Troubleshoot hotspot issues
- TiDB cluster troubleshooting guide
- Troubleshoot a TiFlash Cluster

You are also welcome to create Github Issues or submit your questions on AskTUG.

3.4.8 What's next

- To check the TiFlash version, critical logs, system tables, see Maintain a TiFlash cluster.
- To remove a specific TiFlash node, see Scale out a TiFlash cluster.

3.5 Import Example Database

Examples used in the TiDB manual use System Data from Capital Bikeshare, released under the Capital Bikeshare Data License Agreement.

3.5.1 Download all data files

The system data is available for download in .zip files organized per year. Downloading and extracting all files requires approximately 3GB of disk space. To download all files for years 2010-2017 using a bash script:

```
mkdir -p bikeshare-data && cd bikeshare-data

curl -L --remote-name-all https://s3.amazonaws.com/capitalbikeshare-data
    ↪ /{2010..2017}-capitalbikeshare-tripdata.zip
unzip \*-tripdata.zip
```

3.5.2 Load data into TiDB

The system data can be imported into TiDB using the following schema:

```
CREATE DATABASE bikeshare;
USE bikeshare;

CREATE TABLE trips (
 trip_id bigint NOT NULL PRIMARY KEY AUTO_INCREMENT,
```

```
 duration integer not null,
 start_date datetime,
 end_date datetime,
 start_station_number integer,
 start_station varchar(255),
 end_station_number integer,
 end_station varchar(255),
 bike_number varchar(255),
 member_type varchar(255)
);
```

You can import files individually using the example `LOAD DATA` command here, or import all files using the bash loop below:

```
SET tidb_dml_batch_size = 20000;
LOAD DATA LOCAL INFILE '2017Q1-capitalbikeshare-tripdata.csv' INTO TABLE
    ↪ trips
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES
(duration, start_date, end_date, start_station_number, start_station,
end_station_number, end_station, bike_number, member_type);
```

3.5.2.1 Import all files

> **Note:**
>
> When you start the MySQL client, use the `--local-infile=1` option.

To import all `*.csv` files into TiDB in a bash loop:

```
for FILE in *.csv; do
 echo "== $FILE =="
 mysql bikeshare --local-infile=1 -e "SET tidb_dml_batch_size = 20000; LOAD
    ↪ DATA LOCAL INFILE '${FILE}' INTO TABLE trips FIELDS TERMINATED BY
    ↪ ',' ENCLOSED BY '\"' LINES TERMINATED BY '\r\n' IGNORE 1 LINES (
    ↪ duration, start_date, end_date, start_station_number, start_station,
    ↪  end_station_number, end_station, bike_number, member_type);"
done;
```

4 Develop

4.1 Developer Guide Overview

This guide is written for application developers, but if you are interested in the inner workings of TiDB or want to get involved in TiDB development, read the TiDB Kernel Development Guide for more information about TiDB.

This tutorial shows how to quickly build an application using TiDB, the possible use cases of TiDB and how to handle common problems.

Before reading this page, it is recommended that you read the Quick Start Guide for the TiDB Database Platform.

4.1.1 TiDB basics

Before you start working with TiDB, you need to understand some important mechanisms of how TiDB works:

- Read the TiDB Transaction Overview to understand how transactions work in TiDB, or check out the Transaction Notes for Application Developers to learn about transaction knowledge required for application development.
- Understand the way applications interact with TiDB.
- To learn core components and concepts of building up the distributed database TiDB and TiDB Cloud, refer to the free online course Introduction to TiDB.

4.1.2 TiDB transaction mechanisms

TiDB supports distributed transactions and offers both optimistic transaction and pessimistic transaction modes. The current version of TiDB uses the **pessimistic transaction** mode by default, which allows you to transact with TiDB as you would with a traditional monolithic database (for example, MySQL).

You can start a transaction using `BEGIN`, explicitly specify a **pessimistic transaction** using `BEGIN PESSIMISTIC`, or explicitly specify an **optimistic transaction** using `BEGIN OPTIMISTIC`. After that, you can either commit (`COMMIT`) or roll back (`ROLLBACK`) the transaction.

TiDB guarantees atomicity for all statements between the start of `BEGIN` and the end of `COMMIT` or `ROLLBACK`, that is, all statements that are executed during this period either succeed or fail as a whole. This is used to ensure data consistency you need for application development.

If you are not sure what an **optimistic transaction** is, do ***NOT*** use it yet. Because **optimistic transactions** require that the application can correctly handle all errors returned by the `COMMIT` statement. If you are not sure how your application handles them, use a **pessimistic transaction** instead.

4.1.3 The way applications interact with TiDB

TiDB is highly compatible with the MySQL protocol and supports most MySQL syntax and features, so most MySQL connection libraries are compatible with TiDB. If your application framework or language does not have an official adaptation from PingCAP, it is recommended that you use MySQL's client libraries. More and more third-party libraries are actively supporting TiDB's different features.

Since TiDB is compatible with the MySQL protocol and MySQL syntax, most of the ORMs that support MySQL are also compatible with TiDB.

4.2 Quick Start

4.2.1 Build a TiDB Cluster in TiDB Cloud (Serverless Tier)

This document walks you through the quickest way to get started with TiDB. You will use TiDB Cloud to create a Serverless Tier cluster, connect to it, and run a sample application on it.

If you need to run TiDB on your local machine, see Starting TiDB Locally.

4.2.1.1 Step 1. Create a Serverless Tier cluster

1. If you do not have a TiDB Cloud account, click here to sign up for an account.
2. Log in to your TiDB Cloud account.
3. On the **Clusters** page, click **Create Cluster**.
4. On the **Create Cluster** page, **Serverless Tier** is selected by default. Update the default cluster name if necessary, and then select the region where you want to create your cluster.

   Your TiDB Cloud cluster will be created in approximately 30 seconds.

5. After your TiDB Cloud cluster is created, click **Security Settings**. In the **Security Settings** dialog box, set a root password to connect to your cluster, and then click **Submit**. If you do not set a root password, you cannot connect to the cluster.

6. Click **Connect**. A connection dialog box is displayed. Under **Connect with a SQL Client** in the dialog, click the tab of your preferred connection method, and then save the corresponding connection string. The following section uses MySQL client as an example.

> **Note:**
>
> For Serverless Tier clusters, when you connect to your cluster, you must include the prefix for your cluster in the user name and wrap the name with quotation marks. For more information, see User name prefix.

4.2.1.2 Step 2. Connect to a cluster

1. If the MySQL client is not installed, select your operating system and follow the steps below to install it.

For macOS, install Homebrew if you do not have it, and then run the following command to install the MySQL client:

```
brew install mysql-client
```

The output is as follows:

```
mysql-client is keg-only, which means it was not symlinked into /opt/
   ↪ homebrew,
because it conflicts with mysql (which contains client libraries).

If you need to have mysql-client first in your PATH, run:
  echo 'export PATH="/opt/homebrew/opt/mysql-client/bin:$PATH"' >> ~/.zshrc

For compilers to find mysql-client you may need to set:
  export LDFLAGS="-L/opt/homebrew/opt/mysql-client/lib"
  export CPPFLAGS="-I/opt/homebrew/opt/mysql-client/include"
```

To add the MySQL client to your PATH, locate the following command in the above output (if your output is inconsistent with the above output in the document, use the corresponding command in your output instead) and run it:

```
echo 'export PATH="/opt/homebrew/opt/mysql-client/bin:$PATH"' >> ~/.zshrc
```

Then, declare the global environment variable by the `source` command and verify that the MySQL client is installed successfully:

```
source ~/.zshrc
mysql --version
```

An example of the expected output:

```
mysql Ver 8.0.28 for macos12.0 on arm64 (Homebrew)
```

For Linux, the following takes CentOS 7 as an example:

```
yum install mysql
```

Then, verify that the MySQL client is installed successfully:

```
mysql --version
```

An example of the expected output:

```
mysql Ver 15.1 Distrib 5.5.68-MariaDB, for Linux (x86_64) using readline
    ↪ 5.1
```

2. Run the connection string obtained in Step 1.

```
mysql --connect-timeout 15 -u '<prefix>.root' -h <host> -P 4000 -D test
    ↪  --ssl-mode=VERIFY_IDENTITY --ssl-ca=/etc/ssl/cert.pem -p
```

Note:

- When you connect to a Serverless Tier cluster, you must use the TLS connection.
- If you encounter problems when connecting to a Serverless Tier cluster, you can read Secure Connections to Serverless Tier Clusters for more information.

3. Fill in the password to sign in.

4.2.1.3 Step 3. Execute a SQL statement

Let's try to execute your first SQL statement on TiDB Cloud.

```
SELECT 'Hello TiDB Cloud!';
```

Expected output:

```
+--------------------+
| Hello TiDB Cloud! |
+--------------------+
| Hello TiDB Cloud! |
+--------------------+
```

If your actual output is similar to the expected output, congratulations, you have successfully execute a SQL statement on TiDB Cloud.

4.2.2 CRUD SQL in TiDB

This document briefly introduces how to use TiDB's CURD SQL.

4.2.2.1 Before you start

Please make sure you are connected to a TiDB cluster. If not, refer to Build a TiDB Cluster in TiDB Cloud (Serverless Tier) to create a Serverless Tier cluster.

4.2.2.2 Explore SQL with TiDB

> **Note:**
>
> This document references and simplifies Explore SQL with TiDB. For more details, see Explore SQL with TiDB.

TiDB is compatible with MySQL, you can use MySQL statements directly in most cases. For unsupported features, see Compatibility with MySQL.

To experiment with SQL and test out TiDB compatibility with MySQL queries, you can run TiDB directly in your web browser without installing it. You can also first deploy a TiDB cluster and then run SQL statements in it.

This page walks you through the basic TiDB SQL statements such as DDL, DML, and CRUD operations. For a complete list of TiDB statements, see TiDB SQL Syntax Diagram.

4.2.2.3 Category

SQL is divided into the following 4 types according to their functions:

- **DDL (Data Definition Language)**: It is used to define database objects, including databases, tables, views, and indexes.

- **DML (Data Manipulation Language)**: It is used to manipulate application related records.
- **DQL (Data Query Language)**: It is used to query the records after conditional filtering.
- **DCL (Data Control Language)**: It is used to define access privileges and security levels.

The following mainly introduces DML and DQL. For more information about DDL and DCL, see Explore SQL with TiDB or TiDB SQL syntax detailed explanation.

4.2.2.4 Data Manipulation Language

Common DML features are adding, modifying, and deleting table records. The corresponding commands are `INSERT`, `UPDATE`, and `DELETE`.

To insert data into a table, use the `INSERT` statement:

```
INSERT INTO person VALUES(1,'tom','20170912');
```

To insert a record containing data of some fields into a table, use the `INSERT` statement:

```
INSERT INTO person(id,name) VALUES('2','bob');
```

To update some fields of a record in a table, use the `UPDATE` statement:

```
UPDATE person SET birthday='20180808' WHERE id=2;
```

To delete the data in a table, use the `DELETE` statement:

```
DELETE FROM person WHERE id=2;
```

> **Note:**
>
> The `UPDATE` and `DELETE` statements without the `WHERE` clause as a filter operate on the entire table.

4.2.2.5 Data Query Language

DQL is used to retrieve the desired data rows from a table or multiple tables.

To view the data in a table, use the `SELECT` statement:

```
SELECT * FROM person;
```

To query a specific column, add the column name after the `SELECT` keyword:

```
SELECT name FROM person;
```

The result is as follows:

```
+------+
| name |
+------+
| tom |
+------+
1 rows in set (0.00 sec)
```

Use the `WHERE` clause to filter all records that match the conditions and then return the result:

```
SELECT * FROM person WHERE id < 5;
```

4.3 Example Applications

4.3.1 Build a Simple CRUD App with TiDB and Golang

This document describes how to use TiDB and Golang to build a simple CRUD application.

> **Note:**
>
> It is recommended to use Golang 1.16 or a later version.

4.3.1.1 Step 1. Launch your TiDB cluster

The following introduces how to start a TiDB cluster.

Use a TiDB Cloud Serverless Tier cluster

For detailed steps, see Create a Serverless Tier cluster.

Use a local cluster

For detailed steps, see Deploy a local test cluster or Deploy a TiDB Cluster Using TiUP.

4.3.1.2 Step 2. Get the code

```
git clone https://github.com/pingcap-inc/tidb-example-golang.git
```

Compared with GORM, the go-sql-driver/mysql implementation might be not a best practice, because you need to write error handling logic, close `*sql.Rows` manually and cannot reuse code easily, which makes your code slightly redundant.

GORM is a popular open-source ORM library for Golang. The following instructions take `v1.23.5` as an example.

To adapt TiDB transactions, write a toolkit util according to the following code:

```
package util

import (
    "context"
    "database/sql"
)

type TiDBSqlTx struct {
    *sql.Tx
    conn       *sql.Conn
    pessimistic bool
}

func TiDBSqlBegin(db *sql.DB, pessimistic bool) (*TiDBSqlTx, error) {
    ctx := context.Background()
    conn, err := db.Conn(ctx)
    if err != nil {
        return nil, err
    }
    if pessimistic {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "pessimistic
            ↪ ")
    } else {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "optimistic")
    }
    if err != nil {
        return nil, err
    }
    tx, err := conn.BeginTx(ctx, nil)
    if err != nil {
        return nil, err
    }
    return &TiDBSqlTx{
        conn:       conn,
        Tx:         tx,
        pessimistic: pessimistic,
    }, nil
}
```

```
func (tx *TiDBSqlTx) Commit() error {
    defer tx.conn.Close()
    return tx.Tx.Commit()
}

func (tx *TiDBSqlTx) Rollback() error {
    defer tx.conn.Close()
    return tx.Tx.Rollback()
}
```

Change to the `gorm` directory:

```
cd gorm
```

The structure of this directory is as follows:

```
.
├── Makefile
├── go.mod
├── go.sum
└── gorm.go
```

`gorm.go` is the main body of the `gorm`. Compared with go-sql-driver/mysql, GORM avoids differences in database creation between different databases. It also implements a lot of operations, such as AutoMigrate and CRUD of objects, which greatly simplifies the code.

`Player` is a data entity struct that is a mapping for tables. Each property of a `Player` corresponds to a field in the `player` table. Compared with go-sql-driver/mysql, `Player` in GORM adds struct tags to indicate mapping relationships for more information, such as `gorm:"primaryKey;type:VARCHAR(36);column:id"`.

```
package main

import (
    "fmt"
    "math/rand"

    "github.com/google/uuid"
    "github.com/pingcap-inc/tidb-example-golang/util"

    "gorm.io/driver/mysql"
    "gorm.io/gorm"
    "gorm.io/gorm/clause"
    "gorm.io/gorm/logger"
)
```

```
type Player struct {
    ID    string `gorm:"primaryKey;type:VARCHAR(36);column:id"`
    Coins int    `gorm:"column:coins"`
    Goods int    `gorm:"column:goods"`
}

func (*Player) TableName() string {
    return "player"
}

func main() {
    // 1. Configure the example database connection.
    db := createDB()

    // AutoMigrate for player table
    db.AutoMigrate(&Player{})

    // 2. Run some simple examples.
    simpleExample(db)

    // 3. Explore more.
    tradeExample(db)
}

func tradeExample(db *gorm.DB) {
    // Player 1: id is "1", has only 100 coins.
    // Player 2: id is "2", has 114514 coins, and 20 goods.
    player1 := &Player{ID: "1", Coins: 100}
    player2 := &Player{ID: "2", Coins: 114514, Goods: 20}

    // Create two players "by hand", using the INSERT statement on the
       ↪ backend.
    db.Clauses(clause.OnConflict{UpdateAll: true}).Create(player1)
    db.Clauses(clause.OnConflict{UpdateAll: true}).Create(player2)

    // Player 1 wants to buy 10 goods from player 2.
    // It will cost 500 coins, but player 1 cannot afford it.
    fmt.Println("\nbuyGoods:\n => this trade will fail")
    if err := buyGoods(db, player2.ID, player1.ID, 10, 500); err == nil {
        panic("there shouldn't be success")
    }

    // So player 1 has to reduce the incoming quantity to two.
    fmt.Println("\nbuyGoods:\n => this trade will success")
```

```
    if err := buyGoods(db, player2.ID, player1.ID, 2, 100); err != nil {
        panic(err)
    }
}

func simpleExample(db *gorm.DB) {
    // Create a player, who has a coin and a goods.
    if err := db.Clauses(clause.OnConflict{UpdateAll: true}).
        Create(&Player{ID: "test", Coins: 1, Goods: 1}).Error; err != nil {
        panic(err)
    }

    // Get a player.
    var testPlayer Player
    db.Find(&testPlayer, "id = ?", "test")
    fmt.Printf("getPlayer: %+v\n", testPlayer)

    // Create players with bulk inserts. Insert 1919 players totally, with
    ↪ 114 players per batch.
    bulkInsertPlayers := make([]Player, 1919, 1919)
    total, batch := 1919, 114
    for i := 0; i < total; i++ {
        bulkInsertPlayers[i] = Player{
            ID:    uuid.New().String(),
            Coins: rand.Intn(10000),
            Goods: rand.Intn(10000),
        }
    }

    if err := db.Session(&gorm.Session{Logger: db.Logger.LogMode(logger.
    ↪ Error)}).
        CreateInBatches(bulkInsertPlayers, batch).Error; err != nil {
        panic(err)
    }

    // Count players amount.
    playersCount := int64(0)
    db.Model(&Player{}).Count(&playersCount)
    fmt.Printf("countPlayers: %d\n", playersCount)

    // Print 3 players.
    threePlayers := make([]Player, 3, 3)
    db.Limit(3).Find(&threePlayers)
    for index, player := range threePlayers {
        fmt.Printf("print %d player: %+v\n", index+1, player)
```

```
    }
}

func createDB() *gorm.DB {
    dsn := "root:@tcp(127.0.0.1:4000)/test?charset=utf8mb4"
    db, err := gorm.Open(mysql.Open(dsn), &gorm.Config{
        Logger: logger.Default.LogMode(logger.Info),
    })
    if err != nil {
        panic(err)
    }

    return db
}

func buyGoods(db *gorm.DB, sellID, buyID string, amount, price int) error {
    return util.TiDBGormBegin(db, true, func(tx *gorm.DB) error {
        var sellPlayer, buyPlayer Player
        if err := tx.Clauses(clause.Locking{Strength: "UPDATE"}).
            Find(&sellPlayer, "id = ?", sellID).Error; err != nil {
            return err
        }

        if sellPlayer.ID != sellID || sellPlayer.Goods < amount {
            return fmt.Errorf("sell player %s goods not enough", sellID)
        }

        if err := tx.Clauses(clause.Locking{Strength: "UPDATE"}).
            Find(&buyPlayer, "id = ?", buyID).Error; err != nil {
            return err
        }

        if buyPlayer.ID != buyID || buyPlayer.Coins < price {
            return fmt.Errorf("buy player %s coins not enough", buyID)
        }

        updateSQL := "UPDATE player set goods = goods + ?, coins = coins + ?
            ↪ WHERE id = ?"
        if err := tx.Exec(updateSQL, -amount, price, sellID).Error; err !=
            ↪ nil {
            return err
        }

        if err := tx.Exec(updateSQL, amount, -price, buyID).Error; err != nil
            ↪  {
```

```
            return err
        }

        fmt.Println("\n[buyGoods]:\n 'trade success'")
        return nil
    })
}
```

Change to the `sqldriver` directory:

```
cd sqldriver
```

The structure of this directory is as follows:

```
.
├── Makefile
├── dao.go
├── go.mod
├── go.sum
├── sql
│   └── dbinit.sql
├── sql.go
└── sqldriver.go
```

You can find initialization statements for the table creation in `dbinit.sql`:

```
USE test;
DROP TABLE IF EXISTS player;

CREATE TABLE player (
    `id` VARCHAR(36),
    `coins` INTEGER,
    `goods` INTEGER,
   PRIMARY KEY (`id`)
);
```

`sqldriver.go` is the main body of the `sqldriver`. TiDB is highly compatible with the MySQL protocol, so you need to initialize a MySQL source instance `db, err := sql.Open ("mysql", dsn)` to connect to TiDB. Then, you can use `dao.go` to read, edit, add, and delete data.

```
package main

import (
    "database/sql"
    "fmt"
```

```
    _ "github.com/go-sql-driver/mysql"
)

func main() {
    // 1. Configure the example database connection.
    dsn := "root:@tcp(127.0.0.1:4000)/test?charset=utf8mb4"
    openDB("mysql", dsn, func(db *sql.DB) {
        // 2. Run some simple examples.
        simpleExample(db)

        // 3. Explore more.
        tradeExample(db)
    })
}

func simpleExample(db *sql.DB) {
    // Create a player, who has a coin and a goods.
    err := createPlayer(db, Player{ID: "test", Coins: 1, Goods: 1})
    if err != nil {
        panic(err)
    }

    // Get a player.
    testPlayer, err := getPlayer(db, "test")
    if err != nil {
        panic(err)
    }
    fmt.Printf("getPlayer: %+v\n", testPlayer)

    // Create players with bulk inserts. Insert 1919 players totally, with
    ↪ 114 players per batch.

    err = bulkInsertPlayers(db, randomPlayers(1919), 114)
    if err != nil {
        panic(err)
    }

    // Count players amount.
    playersCount, err := getCount(db)
    if err != nil {
        panic(err)
    }
    fmt.Printf("countPlayers: %d\n", playersCount)

    // Print 3 players.
```

```
    threePlayers, err := getPlayerByLimit(db, 3)
    if err != nil {
        panic(err)
    }
    for index, player := range threePlayers {
        fmt.Printf("print %d player: %+v\n", index+1, player)
    }
}

func tradeExample(db *sql.DB) {
    // Player 1: id is "1", has only 100 coins.
    // Player 2: id is "2", has 114514 coins, and 20 goods.
    player1 := Player{ID: "1", Coins: 100}
    player2 := Player{ID: "2", Coins: 114514, Goods: 20}

    // Create two players "by hand", using the INSERT statement on the
        ↪ backend.
    if err := createPlayer(db, player1); err != nil {
        panic(err)
    }
    if err := createPlayer(db, player2); err != nil {
        panic(err)
    }

    // Player 1 wants to buy 10 goods from player 2.
    // It will cost 500 coins, but player 1 cannot afford it.
    fmt.Println("\nbuyGoods:\n => this trade will fail")
    if err := buyGoods(db, player2.ID, player1.ID, 10, 500); err == nil {
        panic("there shouldn't be success")
    }

    // So player 1 has to reduce the incoming quantity to two.
    fmt.Println("\nbuyGoods:\n => this trade will success")
    if err := buyGoods(db, player2.ID, player1.ID, 2, 100); err != nil {
        panic(err)
    }
}

func openDB(driverName, dataSourceName string, runnable func(db *sql.DB)) {
    db, err := sql.Open(driverName, dataSourceName)
    if err != nil {
        panic(err)
    }
    defer db.Close()
```

```
    runnable(db)
}
```

To adapt TiDB transactions, write a toolkit util according to the following code:

```
package util

import (
    "context"
    "database/sql"
)

type TiDBSqlTx struct {
    *sql.Tx
    conn       *sql.Conn
    pessimistic bool
}

func TiDBSqlBegin(db *sql.DB, pessimistic bool) (*TiDBSqlTx, error) {
    ctx := context.Background()
    conn, err := db.Conn(ctx)
    if err != nil {
        return nil, err
    }
    if pessimistic {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "pessimistic
            ↪ ")
    } else {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "optimistic")
    }
    if err != nil {
        return nil, err
    }
    tx, err := conn.BeginTx(ctx, nil)
    if err != nil {
        return nil, err
    }
    return &TiDBSqlTx{
        conn:       conn,
        Tx:         tx,
        pessimistic: pessimistic,
    }, nil
}

func (tx *TiDBSqlTx) Commit() error {
```

```
    defer tx.conn.Close()
    return tx.Tx.Commit()
}

func (tx *TiDBSqlTx) Rollback() error {
    defer tx.conn.Close()
    return tx.Tx.Rollback()
}
```

dao.go defines a set of data manipulation methods to provide the ability to write data. This is also the core part of this example.

```
package main

import (
    "database/sql"
    "fmt"
    "math/rand"
    "strings"

    "github.com/google/uuid"
    "github.com/pingcap-inc/tidb-example-golang/util"
)

type Player struct {
    ID    string
    Coins int
    Goods int
}

// createPlayer create a player
func createPlayer(db *sql.DB, player Player) error {
    _, err := db.Exec(CreatePlayerSQL, player.ID, player.Coins, player.Goods
        ↪ )
    return err
}

// getPlayer get a player
func getPlayer(db *sql.DB, id string) (Player, error) {
    var player Player

    rows, err := db.Query(GetPlayerSQL, id)
    if err != nil {
        return player, err
    }
```

```
    defer rows.Close()

    if rows.Next() {
        err = rows.Scan(&player.ID, &player.Coins, &player.Goods)
        if err == nil {
            return player, nil
        } else {
            return player, err
        }
    }

    return player, fmt.Errorf("can not found player")
}

        return count, err
    }

    defer rows.Close()

    if rows.Next() {
        if err := rows.Scan(&count); err != nil {
            return count, err
```

```
        }
    }

    return count, nil
}

func buyGoods(db *sql.DB, sellID, buyID string, amount, price int) error {
    var sellPlayer, buyPlayer Player

    tx, err := util.TiDBSqlBegin(db, true)
    if err != nil {
        return err
    }

    buyExec := func() error {
        stmt, err := tx.Prepare(GetPlayerWithLockSQL)
        if err != nil {
            return err
        }
        defer stmt.Close()

        sellRows, err := stmt.Query(sellID)
        if err != nil {
            return err
        }
        defer sellRows.Close()

        if sellRows.Next() {
            if err := sellRows.Scan(&sellPlayer.ID, &sellPlayer.Coins, &
                ↪ sellPlayer.Goods); err != nil {
                return err
            }
        }
        sellRows.Close()

        if sellPlayer.ID != sellID || sellPlayer.Goods < amount {
            return fmt.Errorf("sell player %s goods not enough", sellID)
        }

        buyRows, err := stmt.Query(buyID)
        if err != nil {
            return err
        }
        defer buyRows.Close()
```

```
        if buyRows.Next() {
            if err := buyRows.Scan(&buyPlayer.ID, &buyPlayer.Coins, &
                ↪ buyPlayer.Goods); err != nil {
                return err
            }
        }
        buyRows.Close()

        if buyPlayer.ID != buyID || buyPlayer.Coins < price {
            return fmt.Errorf("buy player %s coins not enough", buyID)
        }

        updateStmt, err := tx.Prepare(UpdatePlayerSQL)
        if err != nil {
            return err
        }
        defer updateStmt.Close()

        if _, err := updateStmt.Exec(-amount, price, sellID); err != nil {
            return err
        }

        if _, err := updateStmt.Exec(amount, -price, buyID); err != nil {
            return err
        }

        return nil
    }

    err = buyExec()
    if err == nil {
        fmt.Println("\n[buyGoods]:\n 'trade success'")
        tx.Commit()
    } else {
        tx.Rollback()
    }

    return err
}

func playerToArgs(players []Player) []interface{} {
    var args []interface{}
    for _, player := range players {
        args = append(args, player.ID, player.Coins, player.Goods)
    }
```

```
    return args
}

func buildBulkInsertSQL(amount int) string {
    return CreatePlayerSQL + strings.Repeat(",(?,?,?)", amount-1)
}

func randomPlayers(amount int) []Player {
    players := make([]Player, amount, amount)
    for i := 0; i < amount; i++ {
        players[i] = Player{
            ID:   uuid.New().String(),
            Coins: rand.Intn(10000),
            Goods: rand.Intn(10000),
        }
    }

    return players
}
```

`sql.go` defines SQL statements as constants:

```
package main

const (
    CreatePlayerSQL    = "INSERT INTO player (id, coins, goods) VALUES (?, ?,
        ↪  ?)"
    GetPlayerSQL       = "SELECT id, coins, goods FROM player WHERE id = ?"
    GetCountSQL        = "SELECT count(*) FROM player"
    GetPlayerWithLockSQL = GetPlayerSQL + " FOR UPDATE"
    UpdatePlayerSQL    = "UPDATE player set goods = goods + ?, coins = coins
        ↪ + ? WHERE id = ?"
    GetPlayerByLimitSQL = "SELECT id, coins, goods FROM player LIMIT ?"
)
```

4.3.1.3 Step 3. Run the code

The following content introduces how to run the code step by step.

4.3.1.3.1 Step 3.1 Table initialization

No need to initialize tables manually.

When using go-sql-driver/mysql, you need to initialize the database tables manually. If you are using a local cluster, and MySQL client has been installed locally, you can run it directly in the `sqldriver` directory:

```
make mysql
```

Or you can execute the following command:

```
mysql --host 127.0.0.1 --port 4000 -u root<sql/dbinit.sql
```

If you are using a non-local cluster or MySQL client has not been installed, connect to your cluster and run the statement in the `sql/dbinit.sql` file.

4.3.1.3.2 Step 3.2 Modify parameters for TiDB Cloud

If you are using a TiDB Cloud Serverless Tier cluster, modify the value of the `dsn` in `gorm.go`:

```
dsn := "root:@tcp(127.0.0.1:4000)/test?charset=utf8mb4"
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `mysql.RegisterTLSConfig` and `dsn` as follows:

```
mysql.RegisterTLSConfig("register-tidb-tls", &tls.Config {
    MinVersion: tls.VersionTLS12,
    ServerName: "xxx.tidbcloud.com",
})

dsn := "2aEp24QWEDLqRFs.root:123456@tcp(xxx.tidbcloud.com:4000)/test?charset
    ↪ =utf8mb4&tls=register-tidb-tls"
```

If you are using a TiDB Cloud Serverless Tier cluster, modify the value of the `dsn` in `sqldriver.go`:

```
dsn := "root:@tcp(127.0.0.1:4000)/test?charset=utf8mb4"
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `mysql.RegisterTLSConfig` and `dsn` as follows:

```
mysql.RegisterTLSConfig("register-tidb-tls", &tls.Config {
    MinVersion: tls.VersionTLS12,
    ServerName: "xxx.tidbcloud.com",
})

dsn := "2aEp24QWEDLqRFs.root:123456@tcp(xxx.tidbcloud.com:4000)/test?charset
    ↪ =utf8mb4&tls=register-tidb-tls"
```

4.3.1.3.3 Step 3.3 Run

To run the code, you can run `make build` and `make run` respectively:

```
make build # this command executes `go build -o bin/gorm-example`
make run # this command executes `./bin/gorm-example`
```

Or you can use the native commands:

```
go build -o bin/gorm-example
./bin/gorm-example
```

Or run the `make` command directly, which is a combination of `make build` and `make run`.

To run the code, you can run `make mysql`, `make build` and `make run` respectively:

```
make mysql # this command executes `mysql --host 127.0.0.1 --port 4000 -u
    ↪ root<sql/dbinit.sql`
make build # this command executes `go build -o bin/sql-driver-example`
make run # this command executes `./bin/sql-driver-example`
```

Or you can use the native commands:

```
mysql --host 127.0.0.1 --port 4000 -u root<sql/dbinit.sql
go build -o bin/sql-driver-example
./bin/sql-driver-example
```

Or run the `make all` command directly, which is a combination of `make mysql`, `make build` and `make run`.

4.3.1.4 Step 4. Expected output

GORM Expected Output

go-sql-driver/mysql Expected Output

4.3.2 Build a TiDB Application Using Spring Boot

This tutorial shows you how to build a Spring Boot web application using TiDB. The Spring Data JPA module is used as the framework for data access capabilities. You can download the code for this sample application from GitHub.

This is a sample application for building a RESTful API, which shows a generic **Spring Boot** backend service using **TiDB** as the database. The following process was designed to recreate a real-world scenario:

This is an example of a game where each player has two attributes: `coins` and `goods` ↪ . Each player is uniquely identified by an `id` field. Players can trade freely if they have sufficient coins and goods.

You can build your own application based on this example.

4.3.2.1 Step 1: Launch your TiDB cluster

The following introduces how to start a TiDB cluster.

Use a TiDB Cloud Serverless Tier cluster

For detailed steps, see Create a Serverless Tier cluster.

Use a local cluster

For detailed steps, see Deploy a local test cluster or Deploy a TiDB Cluster Using TiUP.

4.3.2.2 Step 2: Install JDK

Download and install the **Java Development Kit** (JDK) on your computer. It is a necessary tool for Java development. **Spring Boot** supports JDK for Java 8 and later versions. However, due to the **Hibernate** version, it is recommended that you use JDK for Java 11 and later versions.

Both **Oracle JDK** and **OpenJDK** are supported. You can choose at your own discretion. This tutorial uses JDK 17 from **OpenJDK**.

4.3.2.3 Step 3: Install Maven

This sample application uses **Apache Maven** to manage the application's dependencies. Spring supports Maven 3.3 and later versions. As dependency management software, the latest stable version of **Maven** is recommended.

To install **Maven** from the command line.

- macOS:

```
brew install maven
```

- Debian-based Linux distributions (such as Ubuntu):

```
apt-get install maven
```

- Red Hat-based Linux distributions (such as Fedora, CentOS):
  - dnf:

    ```
    dnf install maven
    ```

  - yum:

    ```
    yum install maven
    ```

For other installation methods, refer to the Maven official documentation.

4.3.2.4 Step 4: Get the application code

Download or clone the sample code repository and navigate to the `spring-jpa-hibernate` directory.

4.3.2.5 Step 5: Run the application

In this step, the application code is compiled and run, which produces a web application. Hibernate creates a `player_jpa` table within the `test` database. If you make requests using the application's RESTful API, these requests run database transactions on the TiDB cluster.

If you want to learn more about the code of this application, refer to Implementation details.

4.3.2.5.1 Step 5.1 Change parameters

If you are using a TiDB Cloud Serverless Tier cluster, change the `spring.datasource.url`, `spring.datasource.username`, `spring.datasource.password` parameters in the `application.yml` (located in `src/main/resources`).

```
spring:
  datasource:
    url: jdbc:mysql://localhost:4000/test
    username: root
    #    password: xxx
    driver-class-name: com.mysql.cj.jdbc.Driver
  jpa:
    show-sql: true
    database-platform: org.hibernate.dialect.TiDBDialect
    hibernate:
      ddl-auto: create-drop
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

Accordingly, the parameters must be set as folows:

```
spring:
  datasource:
    url: jdbc:mysql://xxx.tidbcloud.com:4000/test?sslMode=VERIFY_IDENTITY&
       ↪ enabledTLSProtocols=TLSv1.2,TLSv1.3
    username: 2aEp24QWEDLqRFs.root
    password: 123456
    driver-class-name: com.mysql.cj.jdbc.Driver
  jpa:
    show-sql: true
    database-platform: org.hibernate.dialect.TiDBDialect
    hibernate:
      ddl-auto: create-drop
```

4.3.2.5.2 Step 5.2 Run

Open a terminal session and make sure you are in the `spring-jpa-hibernate` directory. If you are not already in this directory, navigate to the directory with the following command:

```
cd <path>/tidb-example-java/spring-jpa-hibernate
```

Build and run with Make (recommended)

```
make
```

Build and run manually

If you prefer to build manually, follow these steps:

1. Clear cache and package:

   ```
   mvn clean package
   ```

2. Run applications with JAR files:

   ```
   java -jar target/spring-jpa-hibernate-0.0.1.jar
   ```

4.3.2.5.3 Step 5.3 Output

The final part of the output should look like the following:

```
  .   ____          _            __ _ _
 /\\ / ___'_ __ _ _(_)_ __  __ _ \ \ \ \
( ( )\___ | '_ | '_| | '_ \/ _` | \ \ \ \
 \\/  ___)| |_)| | | | | || (_| |  ) ) ) )
  '  |____| .__|_| |_|_| |_\__, | / / / /
 =========|_|==============|___/=/_/_/_/

   ↪ for 1.654)
```

The output log indicates the application behavior during startup. In this example, the application starts a **Servlet** using Tomcat, uses Hibernate as the ORM, uses HikariCP as the database connection pool implementation, and uses `org.hibernate.dialect.TiDBDialect` as the database dialect. After startup, Hibernate deletes and re-creates the `player_jpa` table and the `player_jpa_id_seq` sequence. At the end of startup, the application listens on port `8080` to provide HTTP services to the outside.

If you want to learn more about the code of this application, refer to implementation details.

4.3.2.6 Step 6: HTTP requests

After the service is up and running, you can send the HTTP requests to the backend application. http://localhost:8080 is the base URL that provides services. This tutorial uses a series of HTTP requests to show how to use the service.

4.3.2.6.1 Step 6.1 Use Postman requests (recommended)

You can download this configuration file locally and import it into Postman as shown here:

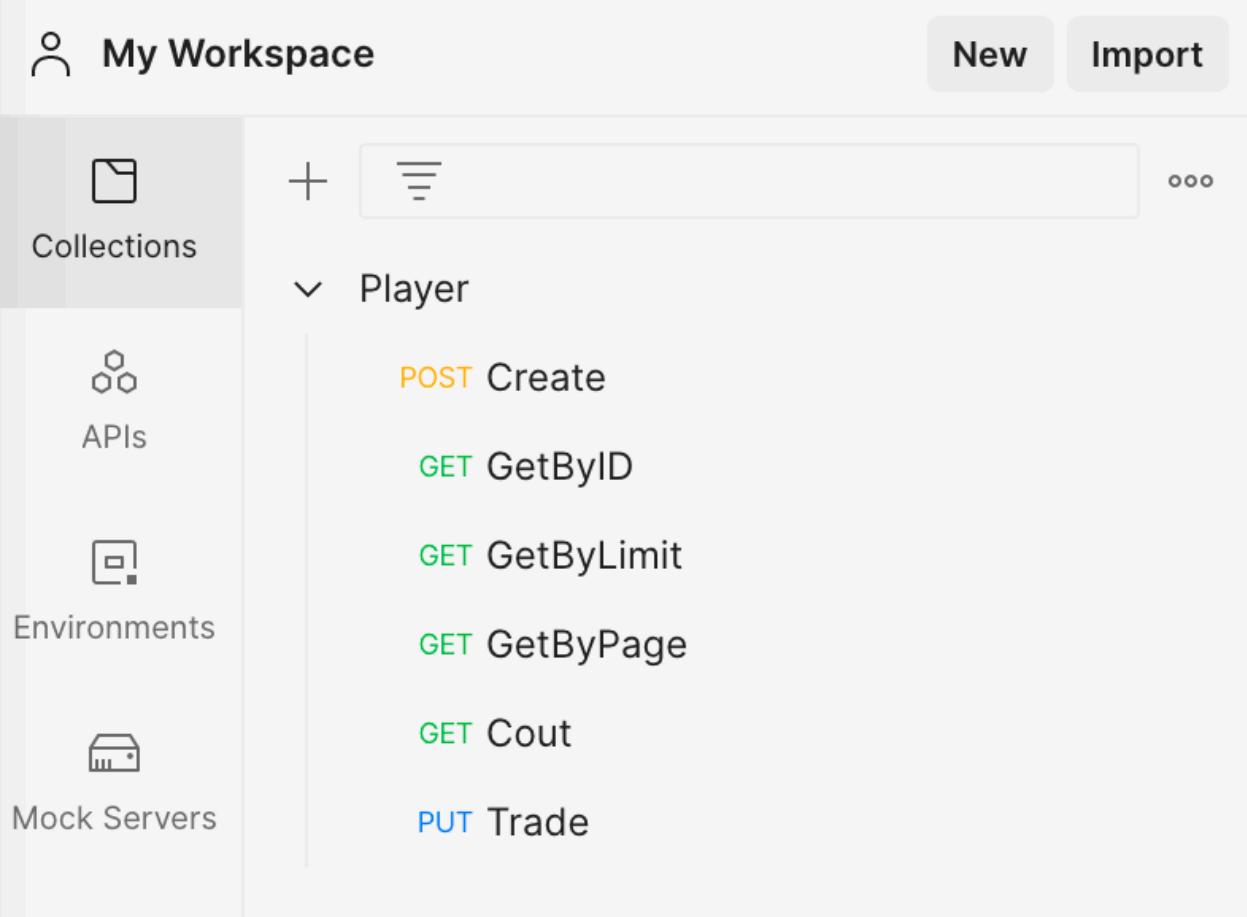

Figure 1: import the collection into Postman

Create players

Click on the **Create** tab and the **Send** button to send a POST request to `http://localhost:8080/player/`. The return value is the number of players added, which is expected to be 1.

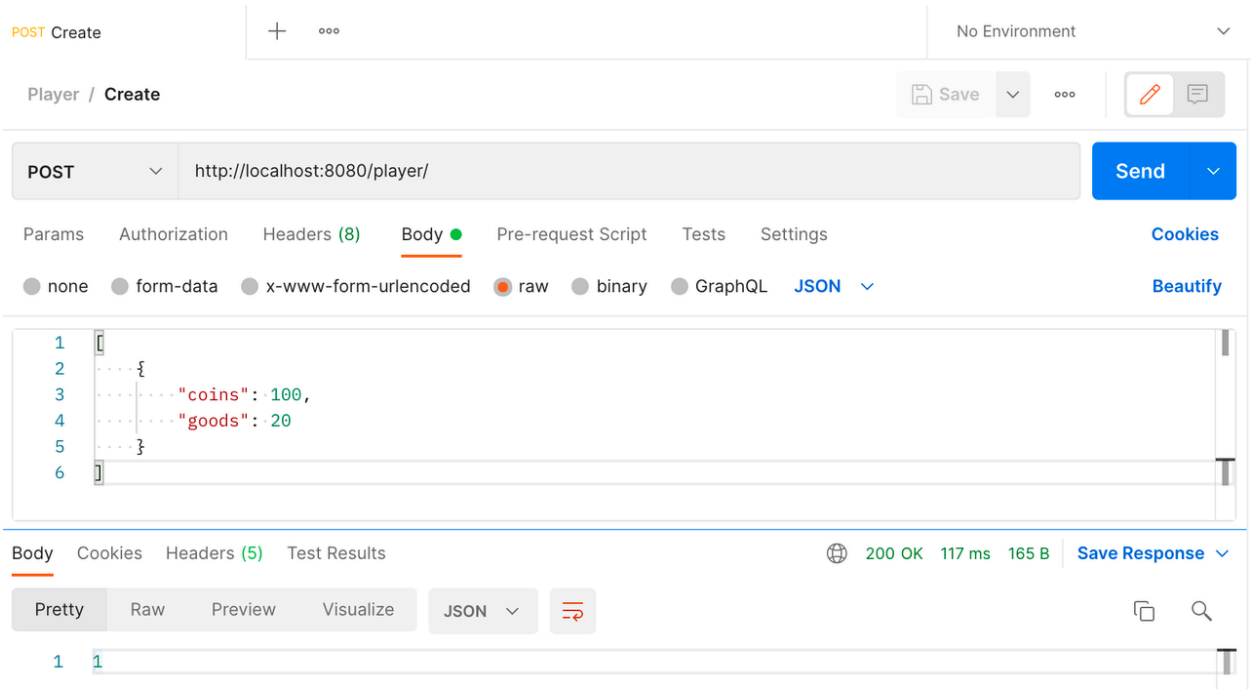

Figure 2: Postman-Create a player

Get player information by ID

Click on the **GetByID** tab and the **Send** button to send a GET request to `http://localhost:8080/player/1`. The return value is the information of the player with ID 1.

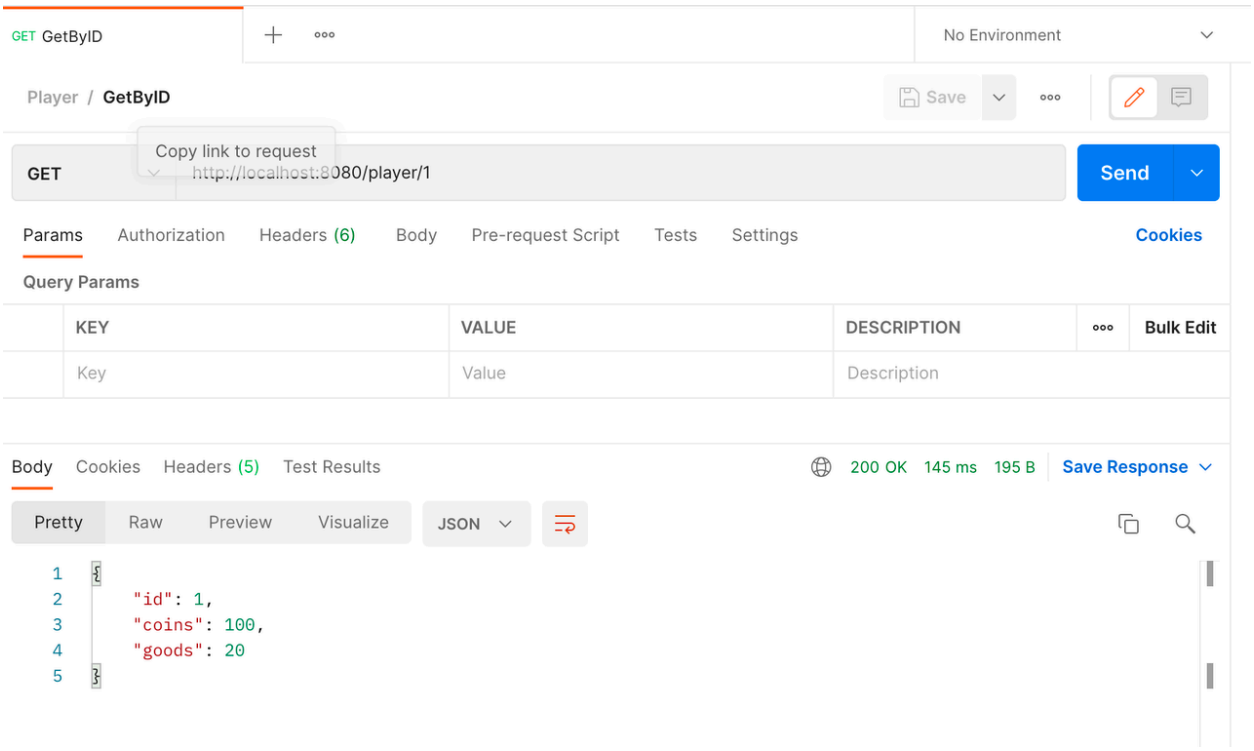

Figure 3: Postman-GetByID

Get player information in bulk by limit

Click on the **GetByLimit** tab and the **Send** button to send a GET request to `http://localhost:8080/player/limit/3`. The return value is a list of information for up to 3 players.

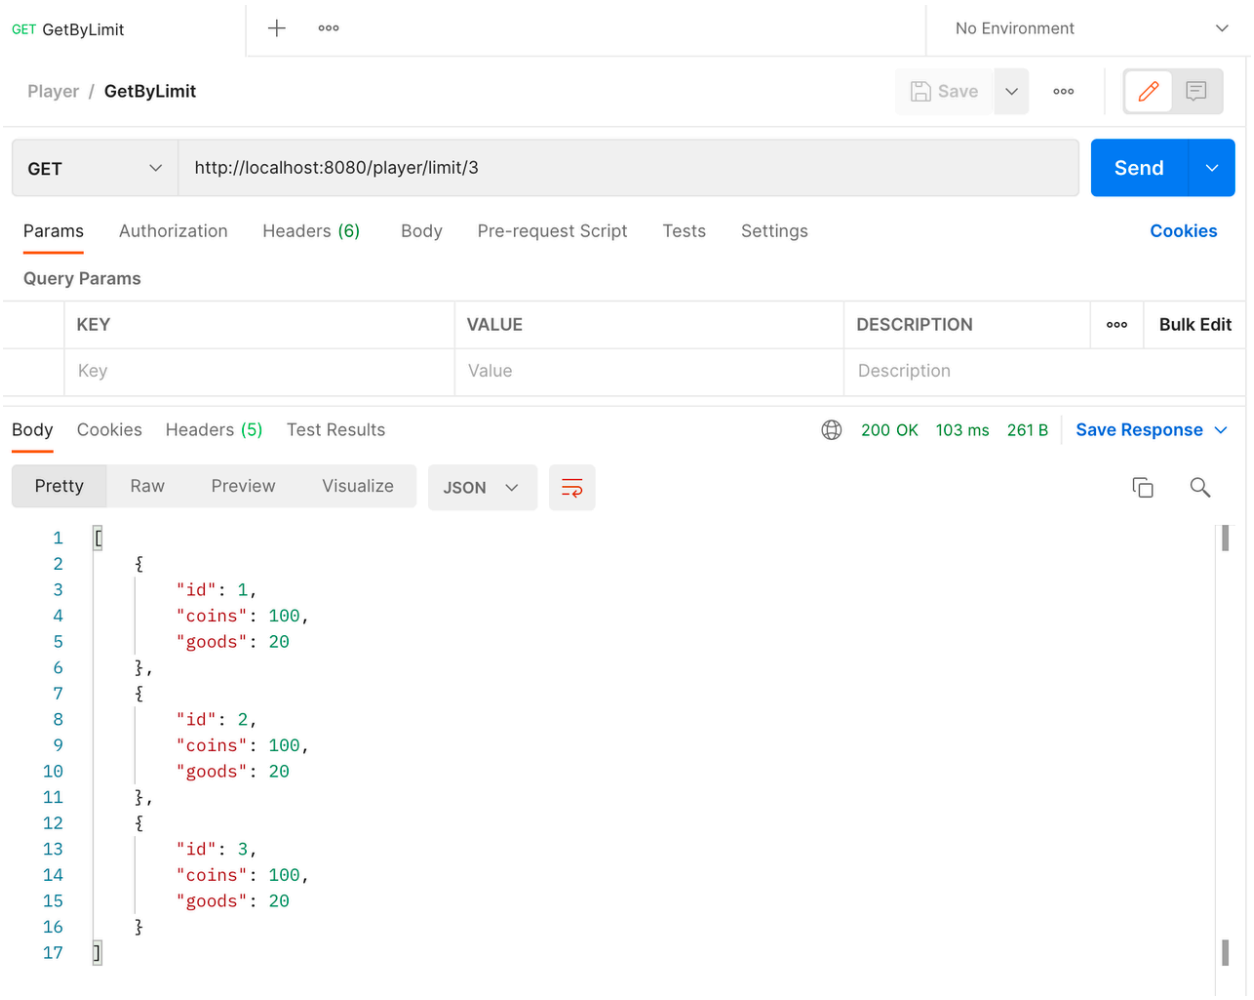

Figure 4: Postman-GetByLimit

Get player information by page

Click on the **GetByPage** tab and the **Send** button to send a GET request to `http ↪ ://localhost:8080/player/page?index=0&size=2`. The return value is the page with index `0`, with `2` players per page. The return value also contains the paging information such as offset, totalPages, and sort.

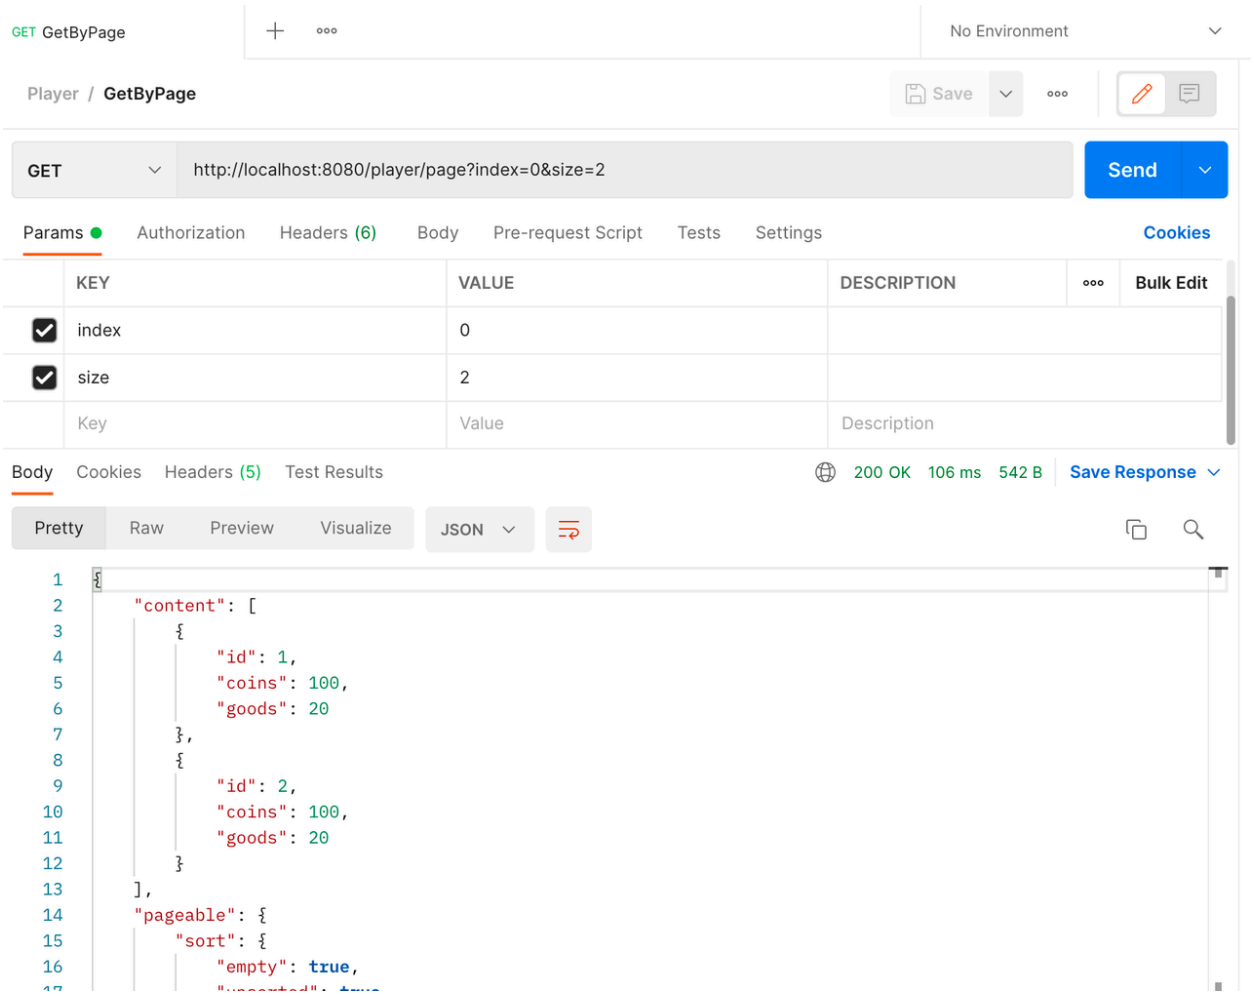

Figure 5: Postman-GetByPage

Count players

Click the **Count** tab and the **Send** button to send a GET request to `http://localhost:8080/player/count`. The return value is the number of players.

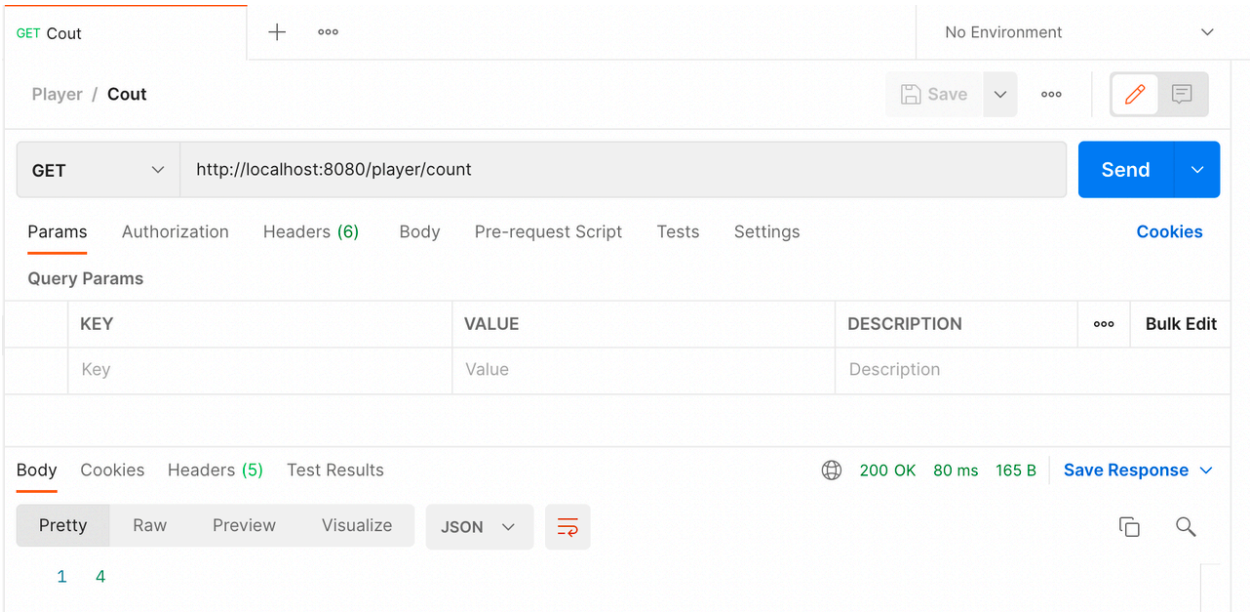

Figure 6: Postman-Count

Player trading

Click on the **Trade** tab and the **Send** button to send a PUT request to `http://localhost:8080/player/trade`. The request parameters are the seller's ID `sellID`, the buyer's ID `buyID`, the number of goods purchased `amount`, the number of coins consumed for the purchase `price`.

The return value is whether the transaction is successful or not. When there are insufficient goods for the seller, insufficient coins for the buyer, or a database error, the database transaction guarantees that the trade is not successful and no player's coins or goods are lost.

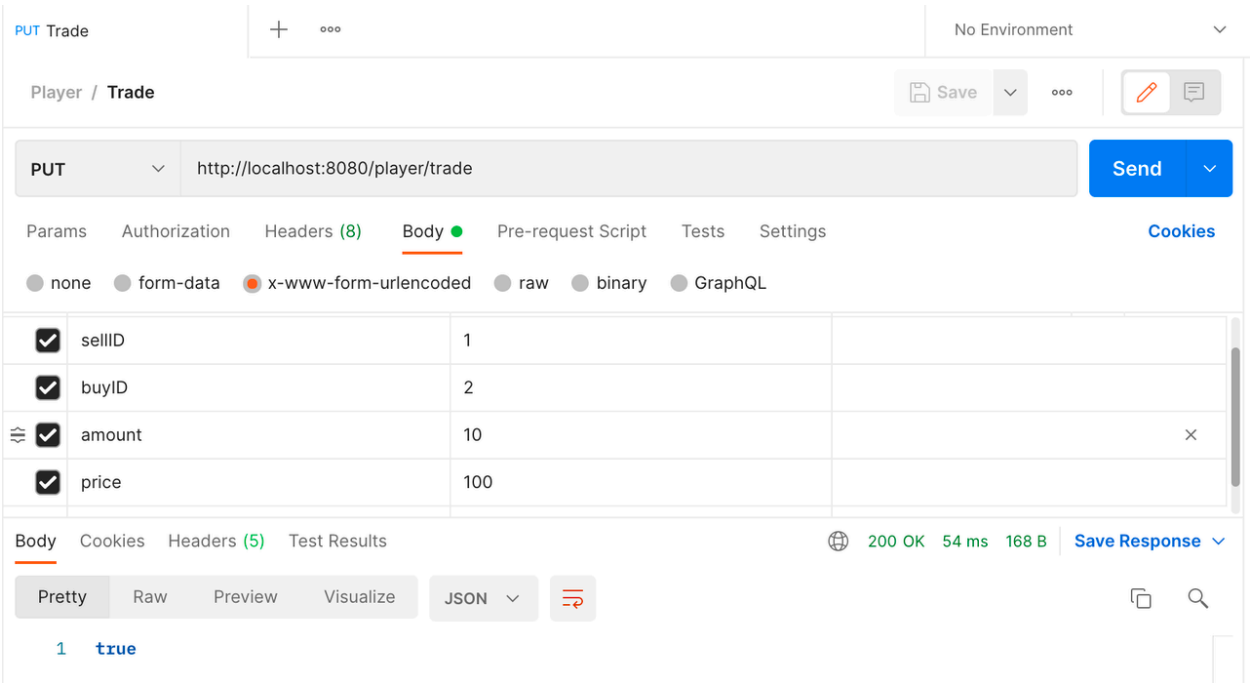

Figure 7: Postman-Trade

4.3.2.6.2 Step 6.2 Using curl requests

You can also use curl to make requests directly.

Create players

To create players, you can send a **POST** request to the `/player` endpoint. For example:

```
curl --location --request POST 'http://localhost:8080/player/' --header '
    ↪ Content-Type: application/json' --data-raw '[{"coins":100,"goods
    ↪ ":20}]'
```

The request uses JSON as the payload. The example above indicates creating a player with 100 `coins` and 20 `goods`. The return value is the number of players created.

```
1
```

Get player information by ID

To get the player information, you can send a **GET** request to the `/player` endpoint. You need to specify the `id` of the player in the path parameter as follows: `/player/{id}`. The following example shows how to get the information of a player with `id` 1:

```
curl --location --request GET 'http://localhost:8080/player/1'
```

The return value is the player's information:

```
{
  "coins": 200,
  "goods": 10,
  "id": 1
}
```

Get player information in bulk by limit

To get the player information in bulk, you can send a **GET** request to the `/player/limit` endpoint. You need to specify the total number of players in the path parameter as follows: `/player/limit/{limit}`. The following example shows how to get the information of up to 3 players:

```
curl --location --request GET 'http://localhost:8080/player/limit/3'
```

The return value is a list of player information:

```
[
  {
    "coins": 200,
    "goods": 10,
    "id": 1
  },
  {
    "coins": 0,
    "goods": 30,
    "id": 2
  },
  {
    "coins": 100,
    "goods": 20,
    "id": 3
  }
]
```

Get player information by page

To get paginated player information, you can send a **GET** request to the `/player/page` endpoint. To specify additional parameters, you need to use the URL parameter. The following example shows how to get the information from a page whose `index` is 0, where each page has a maximum `size` of 2 players.

```
curl --location --request GET 'http://localhost:8080/player/page?index=0&
    size=2'
```

The return value is the page with `index` 0, where 2 players are listed per page. In addition, the return value contains pagination information such as offset, total pages, and whether the results are sorted.

```
{
  "content": [
    {
      "coins": 200,
      "goods": 10,
      "id": 1
    },
    {
      "coins": 0,
      "goods": 30,
      "id": 2
    }
  ],
  "empty": false,
  "first": true,
  "last": false,
  "number": 0,
  "numberOfElements": 2,
  "pageable": {
    "offset": 0,
    "pageNumber": 0,
    "pageSize": 2,
    "paged": true,
    "sort": {
      "empty": true,
      "sorted": false,
      "unsorted": true
    },
    "unpaged": false
  },
  "size": 2,
  "sort": {
    "empty": true,
    "sorted": false,
    "unsorted": true
  },
  "totalElements": 4,
  "totalPages": 2
}
```

Count players

To get the number of players, you can send a **GET** request to the `/player/count` endpoint:

```
curl --location --request GET 'http://localhost:8080/player/count'
```

The return value is the number of players:

```
4
```

Player trading

To initiate a transaction between players, you can send a **PUT** request to the `/player/trade` endpoint. For example:

```
curl --location --request PUT 'http://localhost:8080/player/trade' \
  --header 'Content-Type: application/x-www-form-urlencoded' \
  --data-urlencode 'sellID=1' \
  --data-urlencode 'buyID=2' \
  --data-urlencode 'amount=10' \
  --data-urlencode 'price=100'
```

The request uses **Form Data** as the payload. The example request indicates that the seller's ID (`sellID`) is 1, the buyer's ID (`buyID`) is 2, the number of goods purchased (`amount`) is 10, and the number of coins consumed for purchase (`price`) is 100.

The return value is whether the transaction is successful or not. When there are insufficient goods for the seller, insufficient coins for the buyer, or a database error, the database transaction guarantees that the trade is not successful and no player's coins or goods are lost.

```
true
```

4.3.2.6.3 Step 6.3 Requests with Shell script

You can download this shell script for testing purposes. The script performs the following operations:

1. Create 10 players in a loop.
2. Get the information of players with the `id` of 1.
3. Get a list of up to 3 players.
4. Get a page of players with the `index` of 0 and the `size` of 2.
5. Get the total number of players.
6. Perform a transaction, where the player with the `id` of 1 is the seller and the player with the `id` of 2 is the buyer, and 10 `goods` are purchased at the cost of 100 `coins`.

You can run this script with `make request` or `./request.sh`. The result should look like this:

```
cheese@CheesedeMacBook-Pro spring-jpa-hibernate % make request
./request.sh
loop to create 10 players:
1111111111

get player 1:
{"id":1,"coins":200,"goods":10}

get players by limit 3:
[{"id":1,"coins":200,"goods":10},{"id":2,"coins":0,"goods":30},{"id":3,"
    ↪ coins":100,"goods":20}]

get first players:
{"content":[{"id":1,"coins":200,"goods":10},{"id":2,"coins":0,"goods":30}],"
    ↪ pageable":{"sort":{"empty":true,"unsorted":true,"sorted":false},"
    ↪ offset":0,"pageNumber":0,"pageSize":2,"paged":true,"unpaged":false},"
    ↪ last":false,"totalPages":7,"totalElements":14,"first":true,"size":2,"
    ↪ number":0,"sort":{"empty":true,"unsorted":true,"sorted":false},"
    ↪ numberOfElements":2,"empty":false}

get players count:
14

trade by two players:
false
```

4.3.2.7 Implementation details

This subsection describes the components in the sample application project.

4.3.2.7.1 Overview

The catalog tree for this example project is shown below (some incomprehensible parts are removed):

```
.
├── pom.xml
├── src
│   └── main
│       └── java
│           └── com
│               └── pingcap
│                   ├── App.java
│                   ├── controller
```

```
                    ├── PlayerController.java
                ├── dao
                    ├── PlayerBean.java
                    ├── PlayerRepository.java
                ├── service
                    ├── PlayerService.java
                    ├── impl
                        ├── PlayerServiceImpl.java
        ├── resources
            ├── application.yml
```

- `pom.xml` declares the project's Maven configuration, such as dependencies and packaging.
- `application.yml` declares the project's user configuration, such as database address, password, and database dialect used.
- `App.java` is the entry point of the project.
- `controller` is the package that exposes the HTTP interface to the outside.
- `service` is the package that implements the interface and logic of the project.
- `dao` is the package that implements the connection to the database and the persistence of the data.

4.3.2.7.2 Configuration

This part briefly describes the Maven configuration in the `pom.xml` file and the user configuration in the `application.yml` file.

Maven configuration

The `pom.xml` file is a Maven configuration file that declares the project's Maven dependencies, packaging methods, and packaging information. You can replicate the process of generating this configuration file by creating a blank application with the same dependency, or copying it directly to your project.

```
<?xml version="1.0" encoding="UTF-8"?>
<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.
    ↪ org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 https://maven.
        ↪ apache.org/xsd/maven-4.0.0.xsd">
    <modelVersion>4.0.0</modelVersion>
    <parent>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-parent</artifactId>
        <version>3.0.1</version>
        <relativePath/> <!-- lookup parent from repository -->
    </parent>
```

```
<groupId>com.pingcap</groupId>
<artifactId>spring-jpa-hibernate</artifactId>
<version>0.0.1</version>
<name>spring-jpa-hibernate</name>
<description>an example for spring boot, jpa, hibernate and TiDB</
    ↪ description>

<properties>
    <java.version>17</java.version>
    <maven.compiler.source>17</maven.compiler.source>
    <maven.compiler.target>17</maven.compiler.target>
</properties>

<dependencies>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-data-jpa</artifactId>
    </dependency>

    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-web</artifactId>
    </dependency>

    <dependency>
        <groupId>mysql</groupId>
        <artifactId>mysql-connector-java</artifactId>
        <scope>runtime</scope>
    </dependency>

    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-test</artifactId>
        <scope>test</scope>
    </dependency>
</dependencies>

<build>
    <plugins>
        <plugin>
            <groupId>org.springframework.boot</groupId>
            <artifactId>spring-boot-maven-plugin</artifactId>
        </plugin>
    </plugins>
</build>
```

```
</project>
```

User configuration

The `application.yml` configuration file declares the user configuration, such as database address, password, and the database dialect used.

```
spring:
  datasource:
    url: jdbc:mysql://localhost:4000/test
    username: root
    #    password: xxx
    driver-class-name: com.mysql.cj.jdbc.Driver
  jpa:
    show-sql: true
    database-platform: org.hibernate.dialect.TiDBDialect
    hibernate:
      ddl-auto: create-drop
```

The configuration is written in YAML. The fields are described as follows:

- `spring.datasource.url` : URL of the database connection.
- `spring.datasource.username` : the database username.
- `spring.datasource.password` : the database password. Empty. You need to comment out or delete this field.
- `spring.datasource.driver-class-name` : the database driver. Because TiDB is compatible with MySQL, use a mysql-connector-java driver class `com.mysql.cj.jdbc`.
- `jpa.show-sql` : when this field is set to `true`, the SQL statements run by JPA are printed.
- `jpa.database-platform` : the selected database dialect. Because the application connects to TiDB, choose **TiDB dialect**. Note that this dialect is only available in Hibernate `6.0.0.Beta2` and later versions, so choose the applicable dependency version.
- `jpa.hibernate.ddl-auto` : `create-drop` creates the table at the beginning of the program and deletes the table on exit. Do not set this option in a production environment. Because this is a sample application, this option is set to minimize the impact on the database data.

4.3.2.7.3 Entry point

The `App.java` file is the entry point:

```
package com.pingcap;

import org.springframework.boot.SpringApplication;
import org.springframework.boot.autoconfigure.SpringBootApplication;
```

```
import org.springframework.boot.context.ApplicationPidFileWriter;

@SpringBootApplication
public class App {
   public static void main(String[] args) {
      SpringApplication springApplication = new SpringApplication(App.class)
         ↪ ;
      springApplication.addListeners(new ApplicationPidFileWriter("spring-
         ↪ jpa-hibernate.pid"));
      springApplication.run(args);
   }
}
```

The entry class starts with the standard configuration annotation `@SpringBootApplication` ↪ for Spring Boot applications. For more information, see Using the `@SpringBootApplication` ↪ Annotation in the Spring Boot official documentation. Then, the program uses the `ApplicationPidFileWriter` to write a PID (process identification number) file called `spring-jpa-hibernate.pid` during application startup. The PID file can be used to close this application from an external source.

4.3.2.7.4 Data access object

The `dao` (Data Access Object) package implements the persistence of data objects.

Entity objects

The `PlayerBean.java` file is an entity object, which corresponds to a table in the database:

```
package com.pingcap.dao;

import jakarta.persistence.*;

/**
 * it's core entity in hibernate
 * @Table appoint to table name
 */
@Entity
@Table(name = "player_jpa")
public class PlayerBean {
    /**
     * @ID primary key
     * @GeneratedValue generated way. this field will use generator named "
        ↪ player_id"
     * @SequenceGenerator using `sequence` feature to create a generator,
     *   and it named "player_jpa_id_seq" in database, initial form 1 (by
        ↪ `initialValue`
```

```
     *   parameter default), and every operator will increase 1 (by `
        ↪ allocationSize`)
     */
    @Id
    @GeneratedValue(generator="player_id")
    @SequenceGenerator(name="player_id", sequenceName="player_jpa_id_seq",
        ↪ allocationSize=1)
    private Long id;

    /**
     * @Column field
     */
    @Column(name = "coins")
    private Integer coins;
    @Column(name = "goods")
    private Integer goods;

    public Long getId() {
        return id;
    }

    public void setId(Long id) {
        this.id = id;
    }

    public Integer getCoins() {
        return coins;
    }

    public void setCoins(Integer coins) {
        this.coins = coins;
    }

    public Integer getGoods() {
        return goods;
    }

    public void setGoods(Integer goods) {
        this.goods = goods;
    }
}
```

The entity class has several annotations that give Hibernate additional information to bind the entity class to the table.

- `@Entity` declares that `PlayerBean` is an entity class.
- `@Table` relates this entity class to the `player_jpa` table using the annotation attribute `name`.
- `@Id` declares that this property is related to the primary key column of the table.
- `@GeneratedValue` indicates that the value of this column is generated automatically and should not be set manually. The attribute `generator` is used to specify the name of the generator as `player_id`.
- `@SequenceGenerator` declares a generator that uses sequence, and uses the annotation attribute `name` to declare the name of the generator as `player_id` (consistent with the name specified in `@GeneratedValue`). The annotation attribute `sequenceName` is used to specify the name of the sequence in the database. Finally, the annotation attribute `allocationSize` is used to declare the sequence's step size to be 1.
- `@Column` declares each private attribute as a column of the `player_jpa` table, and uses the annotation attribute `name` to determine the name of the column corresponding to the attribute.

Repository

To abstract the database layer, Spring applications use the `Repository` interface, or a sub-interface of the `Repository`. This interface maps to a database object, such as a table. JPA implements some pre-built methods, such as `INSERT`, or `SELECT` using the primay key.

```
package com.pingcap.dao;

import jakarta.persistence.LockModeType;
import org.springframework.data.domain.Page;
import org.springframework.data.domain.Pageable;
import org.springframework.data.jpa.repository.JpaRepository;
import org.springframework.data.jpa.repository.Lock;
import org.springframework.data.jpa.repository.Query;
import org.springframework.data.repository.query.Param;
import org.springframework.stereotype.Repository;

import java.util.List;

@Repository
public interface PlayerRepository extends JpaRepository<PlayerBean, Long> {
    /**
     * use HQL to query by page
     * @param pageable a pageable parameter required by hibernate
     * @return player list package by page message
     */
    @Query(value = "SELECT player_jpa FROM PlayerBean player_jpa")
    Page<PlayerBean> getPlayersByPage(Pageable pageable);

    /**
```

```
     * use SQL to query by limit, using named parameter
     * @param limit sql parameter
     * @return player list (max size by limit)
     */
    @Query(value = "SELECT * FROM player_jpa LIMIT :limit", nativeQuery =
        ↪ true)
    List<PlayerBean> getPlayersByLimit(@Param("limit") Integer limit);

    /**
     * query player and add a lock for update
     * @param id player id
     * @return player
     */
    @Lock(value = LockModeType.PESSIMISTIC_WRITE)
    @Query(value = "SELECT player FROM PlayerBean player WHERE player.id = :
        ↪ id")
    // @Query(value = "SELECT * FROM player_jpa WHERE id = :id FOR UPDATE",
        ↪  nativeQuery = true)
    PlayerBean getPlayerAndLock(@Param("id") Long id);
}
```

The `PlayerRepository` interface extends the `JpaRepository` interface used by Spring for JPA data access. The `@Query` annotation is used to tell Hibernate how to implement queries in this interface. Two query syntaxes are used:

- In the `getPlayersByPage` interface, Hibernate Query Language (HQL) is used.
- In the `getPlayersByLimit` interface, native SQL is used. When the interface uses the native SQL syntax, the `@Query` annotation parameter `nativeQuery` must be set to `true`.

In the SQL for the `getPlayersByLimit` annotation, `:limit` is called a named parameter in Hibernate. Hibernate automatically finds and splices the parameter by name within the interface where the annotation resides. You can also use `@Param` to specify a name different from the parameter for injection.

In `getPlayerAndLock`, an annotation `@Lock` is used to declare that pessimistic locking is applied. For details on other locking methods, see Entity Locking. The `@Lock` annotation must be used with `HQL`; otherwise, an error occurs. If you want to use SQL directly for locking, you can use the annotation from the comment:

```
@Query(value = "SELECT * FROM player_jpa WHERE id = :id FOR UPDATE",
    ↪ nativeQuery = true)
```

The SQL statement above uses `FOR UPDATE` to add locks directly. You can also dive deeper into the principles with the TiDB `SELECT` statement.

4.3.2.7.5 Logic implementation

The logic implementation layer is the `service` package, which contains the interfaces and logic implemented by the project.

Interface

The `PlayerService.java` file defines the logical interface and implements the interface rather than writing a class directly. This is to keep the example as close to actual use as possible and to reflect the open-closed principle of the design. You may omit this interface and inject the implementation class directly in the dependency class, but this approach is not recommended.

```
package com.pingcap.service;

import com.pingcap.dao.PlayerBean;
import org.springframework.data.domain.Page;

import java.util.List;

public interface PlayerService {
    /**
     * create players by passing in a List of PlayerBean
     *
     * @param players will create players list
     * @return The number of create accounts
     */
    Integer createPlayers(List<PlayerBean> players);

    /**
     * buy goods and transfer funds between one player and another in one
        ↪ transaction
     * @param sellId sell player id
     * @param buyId buy player id
     * @param amount goods amount, if sell player has not enough goods, the
        ↪  trade will break
     * @param price price should pay, if buy player has not enough coins,
        ↪ the trade will break
     */
    void buyGoods(Long sellId, Long buyId, Integer amount, Integer price)
       ↪ throws RuntimeException;

    /**
     * get the player info by id.
     *
     * @param id player id
     * @return the player of this id
```

```
     */
    PlayerBean getPlayerByID(Long id);

    /**
     * get a subset of players from the data store by limit.
     *
     * @param limit return max size
     * @return player list
     */
    List<PlayerBean> getPlayers(Integer limit);

    /**
     * get a page of players from the data store.
     *
     * @param index page index
     * @param size page size
     * @return player list
     */
    Page<PlayerBean> getPlayersByPage(Integer index, Integer size);

    /**
     * count players from the data store.
     *
     * @return all players count
     */
    Long countPlayers();
}
```

Implementation (Important)

The `PlayerService.java` file implements the `PlayerService` interface, which contains all the data processing logic.

```
package com.pingcap.service.impl;

import com.pingcap.dao.PlayerBean;
import com.pingcap.dao.PlayerRepository;
import com.pingcap.service.PlayerService;
import jakarta.transaction.Transactional;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.data.domain.Page;
import org.springframework.data.domain.PageRequest;
import org.springframework.stereotype.Service;

import java.util.List;
```

```
/**
 * PlayerServiceImpl implements PlayerService interface
 * @Transactional it means every method in this class, will package by a
    ↪ pair of
 *    transaction.begin() and transaction.commit(). and it will be call
 *    transaction.rollback() when method throw an exception
 */
@Service
@Transactional
public class PlayerServiceImpl implements PlayerService {
    @Autowired
    private PlayerRepository playerRepository;

    @Override
    public Integer createPlayers(List<PlayerBean> players) {
        return playerRepository.saveAll(players).size();
    }

    @Override
    public void buyGoods(Long sellId, Long buyId, Integer amount, Integer
        ↪ price) throws RuntimeException {
        PlayerBean buyPlayer = playerRepository.getPlayerAndLock(buyId);
        PlayerBean sellPlayer = playerRepository.getPlayerAndLock(sellId);
        if (buyPlayer == null || sellPlayer == null) {
            throw new RuntimeException("sell or buy player not exist");
        }

        if (buyPlayer.getCoins() < price || sellPlayer.getGoods() < amount)
            ↪ {
            throw new RuntimeException("coins or goods not enough, rollback")
                ↪ ;
        }

        buyPlayer.setGoods(buyPlayer.getGoods() + amount);
        buyPlayer.setCoins(buyPlayer.getCoins() - price);
        playerRepository.save(buyPlayer);

        sellPlayer.setGoods(sellPlayer.getGoods() - amount);
        sellPlayer.setCoins(sellPlayer.getCoins() + price);
        playerRepository.save(sellPlayer);
    }

    @Override
    public PlayerBean getPlayerByID(Long id) {
        return playerRepository.findById(id).orElse(null);
```

```
    }

    @Override
    public List<PlayerBean> getPlayers(Integer limit) {
        return playerRepository.getPlayersByLimit(limit);
    }

    @Override
    public Page<PlayerBean> getPlayersByPage(Integer index, Integer size) {
        return playerRepository.getPlayersByPage(PageRequest.of(index, size)
            ↪ );
    }

    @Override
    public Long countPlayers() {
        return playerRepository.count();
    }
}
```

The `@Service` annotation is used to declare that the lifecycle of this object is managed by `Spring`.

The `PlayerServiceImpl` implementation class also has a `@Transactional` annotation in addition to the `@Service` annotation. When transaction management is enabled in the application (which can be turned on using `@EnableTransactionManagement`, but is turned on by default by `Spring Boot`. You don not need to manually configure it.), `Spring` automatically wraps all objects with the `@Transactional` annotation in a proxy and uses this proxy for object invocation processing.

You can simply assume that when the agent calls a function inside an object with the `@Transactional` annotation:

- At the top of the function, it starts the transaction with `transaction.begin()`.
- When the function returns, it calls `transaction.commit()` to commit the transaction.
- When any runtime error occurs, the agent calls `transaction.rollback()` to roll back.

You can refer to Database Transactions for more information on transactions, or read Understanding the Spring Framework's Declarative Transaction Implementation on the `Spring` website.

In all implementation classes, the `buyGoods` function is requires attention. When the function encounters an illogical operation, it throws an exception and directs Hibernate to perform a transaction rollback to prevent incorrect data.

4.3.2.7.6 External HTTP Interface

The `controller` package exposes the HTTP interface to the outside world and allows access to the service via the REST API.

```
package com.pingcap.controller;

import com.pingcap.dao.PlayerBean;
import com.pingcap.service.PlayerService;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.data.domain.Page;
import org.springframework.lang.NonNull;
import org.springframework.web.bind.annotation.*;

import java.util.List;

@RestController
@RequestMapping("/player")
public class PlayerController {
    @Autowired
    private PlayerService playerService;

    @PostMapping
    public Integer createPlayer(@RequestBody @NonNull List<PlayerBean>
        ↪ playerList) {
        return playerService.createPlayers(playerList);
    }

    @GetMapping("/{id}")
    public PlayerBean getPlayerByID(@PathVariable Long id) {
        return playerService.getPlayerByID(id);
    }

    @GetMapping("/limit/{limit_size}")
    public List<PlayerBean> getPlayerByLimit(@PathVariable("limit_size")
        ↪ Integer limit) {
        return playerService.getPlayers(limit);
    }

    @GetMapping("/page")
    public Page<PlayerBean> getPlayerByPage(@RequestParam Integer index,
        ↪ @RequestParam("size") Integer size) {
        return playerService.getPlayersByPage(index, size);
    }

    @GetMapping("/count")
    public Long getPlayersCount() {
```

```
        return playerService.countPlayers();
    }

    @PutMapping("/trade")
    public Boolean trade(@RequestParam Long sellID, @RequestParam Long buyID
        ↪ , @RequestParam Integer amount, @RequestParam Integer price) {
        try {
            playerService.buyGoods(sellID, buyID, amount, price);
        } catch (RuntimeException e) {
            return false;
        }

        return true;
    }
}
```

`PlayerController` uses annotations as many as possible to demonstrate features. In real projects, keep the style consistent while following the rules of your company or team. The annotations in `PlayerController` are explained as follows:

- `@RestController` declares `PlayerController` as a Web Controller and serializes the return value as `JSON` output.
- `@RequestMapping` maps the URL endpoint to `/player`, that is, this `Web Controller` only listens for requests sent to the `/player` URL.
- `@Autowired` means `Spring` container can autowire relationships between collaborating beans. The declaration requires a `PlayerService` object, which is an interface and does not specify which implementation class to use. This is assembled by Spring. For the rules of this assembly, see The IoC container on Spring's official website.
- `@PostMapping` declares that this function responds to a POST request in HTTP.
  - `@RequestBody` declares that the entire HTTP payload is parsed into the `playerList` parameter.
  - `@NonNull` declares that the parameter must not be null; otherwise, it returns an error.
- `@GetMapping` declares that this function responds to a GET request in HTTP.
  - `@PathVariable` shows that the annotation has placeholders like `{id}` and `{ ↪ limit_size}`, which are bound to the variable annotated by `@PathVariable`. Such binding is based on the annotation attribute `name`. If the annotation attribute `name` is not specified, it is the same as the variable name. The variable name can be omitted, that is, `@PathVariable(name="limit_size")` can be written as `@PathVariable("limit_size")`.
- `@PutMapping` declares that this function responds to a PUT request in HTTP.
- `@RequestParam` declares that this function parses URL parameters, form parameters, and other parameters in the request and binds them to the annotated variables.

4.3.2.8 Create a blank application with the same dependency (optional)

This application is built using Spring Initializr. You can quickly get a blank application with the same dependencies as this sample application by clicking on the following options and changing a few configuration items:

Project

- Maven Project

Language

- Java

Spring Boot

- Latest stable version

Project Metadata

- Group: com.pingcap
- Artifact: spring-jpa-hibernate
- Name: spring-jpa-hibernate
- Package name: com.pingcap
- Packaging: Jar
- Java: 17

Dependencies

- Spring Web
- Spring Data JPA
- MySQL Driver

The complete configuration is as follows:

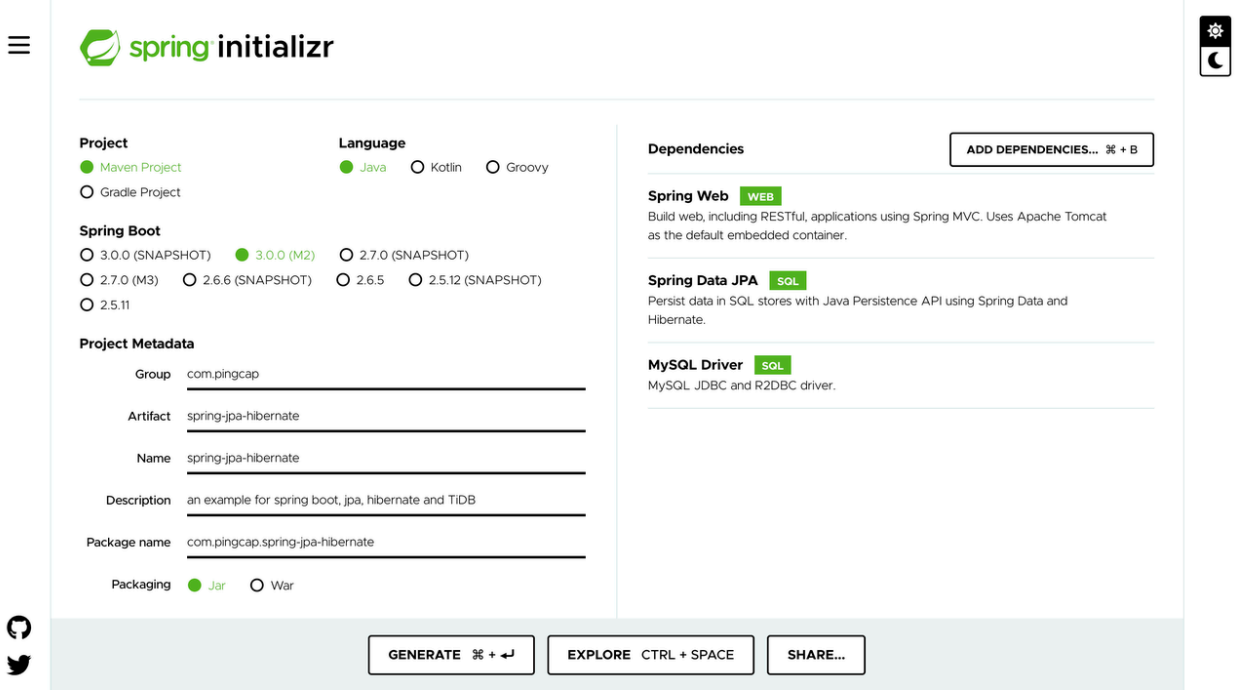

Figure 8: Spring Initializr Configuration

> **Note:**
>
> Although SQL is relatively standardized, each database vendor uses a subset and superset of ANSI SQL defined syntax. This is referred to as the database's dialect. Hibernate handles variations across these dialects through its `org.hibernate.dialect.Dialect` class and the various subclasses for each database vendor.
>
> In most cases, Hibernate will be able to determine the proper Dialect to use by asking some questions of the JDBC Connection during bootstrap. For information on Hibernate's ability to determine the proper Dialect to use (and your ability to influence that resolution), see Dialect resolution.
>
> If for some reason it is not able to determine the proper one or you want to use a custom Dialect, you will need to set the `hibernate.dialect` setting.
>
> —— *Excerpt from the Hibernate official documentation: Database Dialect*

After the configuration, you can get a blank **Spring Boot** application with the same dependencies as the sample application.

4.3.3 Build a Simple CRUD App with TiDB and Java

This document describes how to use TiDB and Java to build a simple CRUD application.

> **Note:**
>
> It is recommended to use Java 8 or a later Java version.
>
> If you want to use Spring Boot for application development, refer to Build the TiDB Application using Spring Boot

4.3.3.1 Step 1. Launch your TiDB cluster

The following introduces how to start a TiDB cluster.

Use a TiDB Cloud Serverless Tier cluster

For detailed steps, see Create a Serverless Tier cluster.

Use a local cluster

For detailed steps, see Deploy a local test cluster or Deploy a TiDB Cluster Using TiUP.

4.3.3.2 Step 2. Get the code

```
git clone https://github.com/pingcap-inc/tidb-example-java.git
```

Compared with Mybatis, the JDBC implementation might be not a best practice, because you need to write error handling logic manually and cannot reuse code easily, which makes your code slightly redundant.

Mybatis is a popular open-source Java class persistence framework. The following uses MyBatis Generator as a Maven plugin to generate the persistence layer code.

Change to the `plain-java-mybatis` directory:

```
cd plain-java-mybatis
```

The structure of this directory is as follows:

```
.
├── Makefile
├── pom.xml
└── src
    └── main
        └── java
            └── com
                └── pingcap
```

```
                ├── MybatisExample.java
                ├── dao
                │   ├── PlayerDAO.java
                ├── model
                │   ├── Player.java
                │   ├── PlayerMapper.java
                │   ├── PlayerMapperEx.java
        ├── resources
            ├── dbinit.sql
            ├── log4j.properties
            ├── mapper
            │   ├── PlayerMapper.xml
            │   ├── PlayerMapperEx.xml
            ├── mybatis-config.xml
            ├── mybatis-generator.xml
```

The automatically generated files are:

- `src/main/java/com/pingcap/model/Player.java`: The `Player` entity class.
- `src/main/java/com/pingcap/model/PlayerMapper.java`: The interface of `PlayerMapper`.
- `src/main/resources/mapper/PlayerMapper.xml`: The XML mapping of `Player`. Mybatis uses this configuration to automatically generate the implementation class of the `PlayerMapper` interface.

The strategy for generating these files is written in `mybatis-generator.xml`, which is the configuration file for Mybatis Generator. There are comments in the following configuration file to describe how to use it.

```
<!DOCTYPE generatorConfiguration PUBLIC
 "-//mybatis.org//DTD MyBatis Generator Configuration 1.0//EN"
 "http://mybatis.org/dtd/mybatis-generator-config_1_0.dtd">

<generatorConfiguration>
    <!--
        <context/> entire document: https://mybatis.org/generator/
            ↪ configreference/context.html

                ↪ to choice.
    -->
    <javaClientGenerator type="XMLMAPPER" targetPackage="com.pingcap.
        ↪ model" targetProject="src/main/java"/>

    <!--
        <table/> entire document: https://mybatis.org/generator/
            ↪ configreference/table.html

        table.tableName: The name of the database table.
        table.domainObjectName: The base name from which generated object
            ↪  names will be generated. If not specified, MBG will
            ↪ generate a name automatically based on the tableName.
        table.enableCountByExample: Signifies whether a count by example
            ↪ statement should be generated.
        table.enableUpdateByExample: Signifies whether an update by
            ↪ example statement should be generated.
        table.enableDeleteByExample: Signifies whether a delete by
            ↪ example statement should be generated.
        table.enableSelectByExample: Signifies whether a select by
            ↪ example statement should be generated.
        table.selectByExampleQueryId: This value will be added to the
            ↪ select list of the select by example statement in this
            ↪ form: "'<value>' as QUERYID".
    -->
    <table tableName="player" domainObjectName="Player"
           enableCountByExample="false" enableUpdateByExample="false"
           enableDeleteByExample="false" enableSelectByExample="false"
           selectByExampleQueryId="false"/>
</context>
```

```
</generatorConfiguration>
```

`mybatis-generator.xml` is included in `pom.xml` as the configuration of `mybatis-generator-maven-plugin`.

```
<plugin>
    <groupId>org.mybatis.generator</groupId>
    <artifactId>mybatis-generator-maven-plugin</artifactId>
    <version>1.4.1</version>
    <configuration>
        <configurationFile>src/main/resources/mybatis-generator.xml</
            ↪ configurationFile>
        <verbose>true</verbose>
        <overwrite>true</overwrite>
    </configuration>

    <dependencies>
        <!-- https://mvnrepository.com/artifact/mysql/mysql-connector-java
            ↪ -->
        <dependency>
        <groupId>mysql</groupId>
        <artifactId>mysql-connector-java</artifactId>
        <version>5.1.49</version>
        </dependency>
    </dependencies>
</plugin>
```

Once included in the Maven plugin, you can delete the old generated files and make new ones using `mvn mybatis-generate`. Or you can use `make gen` to delete the old file and generate a new one at the same time.

> **Note:**
>
> The property `configuration.overwrite` in `mybatis-generator.xml` only ensures that the generated Java code files are overwritten. But the XML mapping files are still written as appended. Therefore, it is recommended to delete the old file before Mybaits Generator generating a new one.

`Player.java` is a data entity class file generated using Mybatis Generator, which is a mapping of database tables in the application. Each property of the `Player` class corresponds to a field in the `player` table.

```
package com.pingcap.model;
```

```
public class Player {
    private String id;

    private Integer coins;

    private Integer goods;

    public Player(String id, Integer coins, Integer goods) {
        this.id = id;
        this.coins = coins;
        this.goods = goods;
    }

    public Player() {
        super();
    }

    public String getId() {
        return id;
    }

    public void setId(String id) {
        this.id = id;
    }

    public Integer getCoins() {
        return coins;
    }

    public void setCoins(Integer coins) {
        this.coins = coins;
    }

    public Integer getGoods() {
        return goods;
    }

    public void setGoods(Integer goods) {
        this.goods = goods;
    }
}
```

`PlayerMapper.java` is a mapping interface file generated using Mybatis Generator. This file only defines the interface, and the implementation classes of interface are automatically

generated using XML or annotations.

```
package com.pingcap.model;

import com.pingcap.model.Player;

public interface PlayerMapper {
    int deleteByPrimaryKey(String id);

    int insert(Player row);

    int insertSelective(Player row);

    Player selectByPrimaryKey(String id);

    int updateByPrimaryKeySelective(Player row);

    int updateByPrimaryKey(Player row);
}
```

`PlayerMapper.xml` is a mapping XML file generated using Mybatis Generator. Mybatis uses this to automatically generate the implementation class of the `PlayerMapper` interface.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE mapper PUBLIC "-//mybatis.org//DTD Mapper 3.0//EN" "http://
    ↪ mybatis.org/dtd/mybatis-3-mapper.dtd">
<mapper namespace="com.pingcap.model.PlayerMapper">
  <resultMap id="BaseResultMap" type="com.pingcap.model.Player">
    <constructor>
      <idArg column="id" javaType="java.lang.String" jdbcType="VARCHAR" />
      <arg column="coins" javaType="java.lang.Integer" jdbcType="INTEGER" />
      <arg column="goods" javaType="java.lang.Integer" jdbcType="INTEGER" />
    </constructor>
  </resultMap>
  <sql id="Base_Column_List">
    id, coins, goods
  </sql>
  <select id="selectByPrimaryKey" parameterType="java.lang.String" resultMap
      ↪ ="BaseResultMap">
    select
    <include refid="Base_Column_List" />
    from player
    where id = #{id,jdbcType=VARCHAR}
  </select>
  <delete id="deleteByPrimaryKey" parameterType="java.lang.String">
    delete from player
```

```
  where id = #{id,jdbcType=VARCHAR}
</delete>
<insert id="insert" parameterType="com.pingcap.model.Player">
  insert into player (id, coins, goods
    )
  values (#{id,jdbcType=VARCHAR}, #{coins,jdbcType=INTEGER}, #{goods,
    ↪ jdbcType=INTEGER}
    )
</insert>
<insert id="insertSelective" parameterType="com.pingcap.model.Player">
  insert into player
  <trim prefix="(" suffix=")" suffixOverrides=",">
    <if test="id != null">
      id,
    </if>
    <if test="coins != null">
      coins,
    </if>
    <if test="goods != null">
      goods,
    </if>
  </trim>
  <trim prefix="values (" suffix=")" suffixOverrides=",">
    <if test="id != null">
      #{id,jdbcType=VARCHAR},
    </if>
    <if test="coins != null">
      #{coins,jdbcType=INTEGER},
    </if>
    <if test="goods != null">
      #{goods,jdbcType=INTEGER},
    </if>
  </trim>
</insert>
<update id="updateByPrimaryKeySelective" parameterType="com.pingcap.model.
  ↪ Player">
  update player
  <set>
    <if test="coins != null">
      coins = #{coins,jdbcType=INTEGER},
    </if>
    <if test="goods != null">
      goods = #{goods,jdbcType=INTEGER},
    </if>
  </set>
```

```
    where id = #{id,jdbcType=VARCHAR}
  </update>
  <update id="updateByPrimaryKey" parameterType="com.pingcap.model.Player">
    update player
    set coins = #{coins,jdbcType=INTEGER},
      goods = #{goods,jdbcType=INTEGER}
    where id = #{id,jdbcType=VARCHAR}
  </update>
</mapper>
```

Since Mybatis Generator needs to generate the source code from the table definition, the table needs to be created first. To create the table, you can use `dbinit.sql`.

```
USE test;
DROP TABLE IF EXISTS player;

CREATE TABLE player (
    `id` VARCHAR(36),
    `coins` INTEGER,
    `goods` INTEGER,
    PRIMARY KEY (`id`)
);
```

Split the interface `PlayerMapperEx` additionally to extend from `PlayerMapper` and write a matching `PlayerMapperEx.xml` file. Avoid changing `PlayerMapper.java` and `PlayerMapper.xml` directly. This is to avoid overwrite by Mybatis Generator.

Define the added interface in `PlayerMapperEx.java`:

```
package com.pingcap.model;

import java.util.List;

public interface PlayerMapperEx extends PlayerMapper {
    Player selectByPrimaryKeyWithLock(String id);

    List<Player> selectByLimit(Integer limit);

    Integer count();
}
```

Define the mapping rules in `PlayerMapperEx.xml`:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE mapper PUBLIC "-//mybatis.org//DTD Mapper 3.0//EN" "http://
    ↪ mybatis.org/dtd/mybatis-3-mapper.dtd">
<mapper namespace="com.pingcap.model.PlayerMapperEx">
```

```
  <resultMap id="BaseResultMap" type="com.pingcap.model.Player">
    <constructor>
      <idArg column="id" javaType="java.lang.String" jdbcType="VARCHAR" />
      <arg column="coins" javaType="java.lang.Integer" jdbcType="INTEGER" />
      <arg column="goods" javaType="java.lang.Integer" jdbcType="INTEGER" />
    </constructor>
  </resultMap>
  <sql id="Base_Column_List">
    id, coins, goods
  </sql>

  <select id="selectByPrimaryKeyWithLock" parameterType="java.lang.String"
     ↪ resultMap="BaseResultMap">
    select
    <include refid="Base_Column_List" />
    from player
    where `id` = #{id,jdbcType=VARCHAR}
    for update
  </select>

  <select id="selectByLimit" parameterType="java.lang.Integer" resultMap="
     ↪ BaseResultMap">
    select
    <include refid="Base_Column_List" />
    from player
    limit #{id,jdbcType=INTEGER}
  </select>

  <select id="count" resultType="java.lang.Integer">
    select count(*) from player
  </select>

</mapper>
```

`PlayerDAO.java` is a class used to manage data, in which `DAO` means Data Access Object. The class defines a set of data manipulation methods for writing data. In it, Mybatis encapsulates a large number of operations such as object mapping and CRUD of basic objects, which greatly simplifies the code.

```
package com.pingcap.dao;

import com.pingcap.model.Player;
import com.pingcap.model.PlayerMapperEx;
import org.apache.ibatis.session.SqlSession;
import org.apache.ibatis.session.SqlSessionFactory;
```

```
import java.util.List;
import java.util.function.Function;

public class PlayerDAO {
    public static class NotEnoughException extends RuntimeException {
        public NotEnoughException(String message) {
            super(message);
        }
    }

    // Run SQL code in a way that automatically handles the
    // transaction retry logic, so we don't have to duplicate it in
    // various places.
    public Object runTransaction(SqlSessionFactory sessionFactory, Function<
        ↪ PlayerMapperEx, Object> fn) {
        Object resultObject = null;
        SqlSession session = null;

```
package com.pingcap;

import com.pingcap.dao.PlayerDAO;
import com.pingcap.model.Player;
import org.apache.ibatis.io.Resources;
import org.apache.ibatis.session.SqlSessionFactory;
import org.apache.ibatis.session.SqlSessionFactoryBuilder;

import java.io.IOException;
import java.io.InputStream;
import java.util.Arrays;
import java.util.Collections;

public class MybatisExample {
```

```
public static void main( String[] args ) throws IOException {
    // 1. Create a SqlSessionFactory based on our mybatis-config.xml
       ↪ configuration
    // file, which defines how to connect to the database.
    InputStream inputStream = Resources.getResourceAsStream("mybatis-
       ↪ config.xml");
    SqlSessionFactory sessionFactory = new SqlSessionFactoryBuilder().
       ↪ build(inputStream);

    // 2. And then, create DAO to manager your data
    PlayerDAO playerDAO = new PlayerDAO();

    // 3. Run some simple examples.

    // Create a player who has 1 coin and 1 goods.
    playerDAO.runTransaction(sessionFactory, playerDAO.createPlayers(
           Collections.singletonList(new Player("test", 1, 1))));

    // Get a player.
    Player testPlayer = (Player)playerDAO.runTransaction(sessionFactory,
       ↪ playerDAO.getPlayerByID("test"));
    System.out.printf("PlayerDAO.getPlayer:\n => id: %s\n => coins: %s\n
       ↪ => goods: %s\n",
           testPlayer.getId(), testPlayer.getCoins(), testPlayer.getGoods
              ↪ ());

    // Count players amount.
    Integer count = (Integer)playerDAO.runTransaction(sessionFactory,
       ↪ playerDAO.countPlayers());
    System.out.printf("PlayerDAO.countPlayers:\n => %d total players\n",
       ↪ count);

    // Print 3 players.
    playerDAO.runTransaction(sessionFactory, playerDAO.printPlayers(3));

    // 4. Getting further.

    // Player 1: id is "1", has only 100 coins.
    // Player 2: id is "2", has 114514 coins, and 20 goods.
    Player player1 = new Player("1", 100, 0);
    Player player2 = new Player("2", 114514, 20);

    // Create two players "by hand", using the INSERT statement on the
       ↪ backend.
    int addedCount = (Integer)playerDAO.runTransaction(sessionFactory,
```

```
                playerDAO.createPlayers(Arrays.asList(player1, player2)));
        System.out.printf("PlayerDAO.createPlayers:\n => %d total inserted
            ↪ players\n", addedCount);

        // Player 1 wants to buy 10 goods from player 2.
        // It will cost 500 coins, but player 1 cannot afford it.
        System.out.println("\nPlayerDAO.buyGoods:\n => this trade will fail")
            ↪ ;
        Integer updatedCount = (Integer)playerDAO.runTransaction(
            ↪ sessionFactory,
                playerDAO.buyGoods(player2.getId(), player1.getId(), 10, 500))
                    ↪ ;
        System.out.printf("PlayerDAO.buyGoods:\n => %d total update players\n
            ↪ ", updatedCount);

        // So player 1 has to reduce the incoming quantity to two.
        System.out.println("\nPlayerDAO.buyGoods:\n => this trade will
            ↪ success");
        updatedCount = (Integer)playerDAO.runTransaction(sessionFactory,
                playerDAO.buyGoods(player2.getId(), player1.getId(), 2, 100));
        System.out.printf("PlayerDAO.buyGoods:\n => %d total update players\n
            ↪ ", updatedCount);
    }
}
```

Compared with Hibernate, the JDBC implementation might be not a best practice, because you need to write error handling logic manually and cannot reuse code easily, which makes your code slightly redundant.

Hibernate is a popular open-source Java ORM, and it supports TiDB dialect starting from `v6.0.0.Beta2`, which fits TiDB features well. The following instructions take `v6.0.0.Beta2` as an example.

Change to the `plain-java-hibernate` directory:

```
cd plain-java-hibernate
```

The structure of this directory is as follows:

```
.
├── Makefile
├── plain-java-hibernate.iml
├── pom.xml
└── src
    └── main
        └── java
            └── com
```

```
            ── pingcap
                ── HibernateExample.java
        ── resources
            ── hibernate.cfg.xml
```

`hibernate.cfg.xml` is the Hibernate configuration file:

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
    <session-factory>

        <!-- Database connection settings -->
        <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
            ↪ Driver</property>
        <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
            ↪ /property>
        <property name="hibernate.connection.url">jdbc:mysql://localhost:4000
            ↪ /test</property>
        <property name="hibernate.connection.username">root</property>
        <property name="hibernate.connection.password"></property>
        <property name="hibernate.connection.autocommit">false</property>

        <!-- Required so a table can be created from the 'PlayerDAO' class
            ↪ -->
        <property name="hibernate.hbm2ddl.auto">create-drop</property>

        <!-- Optional: Show SQL output for debugging -->
        <property name="hibernate.show_sql">true</property>
        <property name="hibernate.format_sql">true</property>
    </session-factory>
</hibernate-configuration>
```

`HibernateExample.java` is the main body of the `plain-java-hibernate`. Compared with JDBC, when using Hibernate, you only need to write the path of the configuration file, because Hibernate avoids differences in database creation between different databases.

`PlayerDAO` is a class used to manage data, in which `DAO` means Data Access Object. The class defines a set of data manipulation methods for writing data. Compared with JDBC, Hibernate encapsulates a large number of operations such as object mapping and CRUD of basic objects, which greatly simplifies the code.

`PlayerBean` is a data entity class that is a mapping for tables. Each property of a `PlayerBean` corresponds to a field in the `player` table. Compared with JDBC, `PlayerBean` in Hibernate adds annotations to indicate mapping relationships for more information.

Change to the `plain-java-jdbc` directory:

```
cd plain-java-jdbc
```

The structure of this directory is as follows:

```
.
├── Makefile
├── plain-java-jdbc.iml
└── pom.xml
```

```
├── src
│   ├── main
│   │   ├── java
│   │   │   ├── com
│   │   │   │   ├── pingcap
│   │   │   │   │   ├── JDBCExample.java
│   │   ├── resources
│   │   │   ├── dbinit.sql
```

You can find initialization statements for the table creation in `dbinit.sql`:

```
USE test;
DROP TABLE IF EXISTS player;

CREATE TABLE player (
    `id` VARCHAR(36),
    `coins` INTEGER,
    `goods` INTEGER,
   PRIMARY KEY (`id`)
);
```

`JDBCExample.java` is the main body of the `plain-java-jdbc`. TiDB is highly compatible with the MySQL protocol, so you need to initialize a MySQL source instance `MysqlDataSource` to connect to TiDB. Then, you can initialize `PlayerDAO` for object management and use it to read, edit, add, and delete data.

`PlayerDAO` is a class used to manage data, in which `DAO` means Data Access Object. The class defines a set of data manipulation methods to provide the ability to write data.

`PlayerBean` is a data entity class that is a mapping for tables. Each property of a `PlayerBean` corresponds to a field in the `player` table.

```
package com.pingcap;

import com.mysql.cj.jdbc.MysqlDataSource;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.util.*;

/**
 * Main class for the basic JDBC example.
 **/
public class JDBCExample
{
```

```
public static class PlayerBean {
    private String id;
    private Integer coins;
    private Integer goods;

    public PlayerBean() {
    }

    public PlayerBean(String id, Integer coins, Integer goods) {
        this.id = id;
        this.coins = coins;
        this.goods = goods;
    }

    public String getId() {
        return id;
    }

    public void setId(String id) {
        this.id = id;
    }

    public Integer getCoins() {
        return coins;
    }

    public void setCoins(Integer coins) {
        this.coins = coins;
    }

    public Integer getGoods() {

    /**
     * Insert randomized account data (id, coins, goods) using the JDBC
        ↪  fast path for
     * bulk inserts. The fastest way to get data into TiDB is using the
     * TiDB Lightning(https://docs.pingcap.com/tidb/stable/tidb-
        ↪ lightning-overview).
     * However, if you must bulk insert from the application using
        ↪ INSERT SQL, the best
     * option is the method shown here. It will require the following:
     *
     *   Add `rewriteBatchedStatements=true` to your JDBC connection
        ↪ settings.
     *   Setting rewriteBatchedStatements to true now causes
        ↪ CallableStatements
     *   with batched arguments to be re-written in the form "CALL
        ↪ (...); CALL (...); ..."
```

```
     *   to send the batch in as few client/server round trips as
         ↪ possible.
     *   https://dev.mysql.com/doc/relnotes/connector-j/5.1/en/news
         ↪ -5-1-3.html
     *
     *   You can see the `rewriteBatchedStatements` param effect logic
         ↪ at
     *   implement function: `com.mysql.cj.jdbc.StatementImpl.
         ↪ executeBatchUsingMultiQueries`
     *
     * @param total Add players amount.
     * @param batchSize Bulk insert size for per batch.
     *
     * @return The number of new accounts inserted.
     */

    mysqlDataSource.setUser("root");
    mysqlDataSource.setPassword("");

    // Or you can use jdbc string instead.
    // mysqlDataSource.setURL("jdbc:mysql://{host}:{port}/test?user={
        ↪ user}&password={password}");

    // 2. And then, create DAO to manager your data.
    PlayerDAO dao = new PlayerDAO(mysqlDataSource);

    // 3. Run some simple example.
```

```
// Create a player, has a coin and a goods.
dao.createPlayers(Collections.singletonList(new PlayerBean("test",
    ↪ 1, 1)));

// Get a player.
PlayerBean testPlayer = dao.getPlayer("test");
System.out.printf("PlayerDAO.getPlayer:\n => id: %s\n => coins: %s\n
    ↪ => goods: %s\n",
        testPlayer.getId(), testPlayer.getCoins(), testPlayer.getGoods
            ↪ ());

// Create players with bulk inserts, insert 1919 players totally,
    ↪ and per batch for 114 players.
int addedCount = dao.bulkInsertRandomPlayers(1919, 114);
System.out.printf("PlayerDAO.bulkInsertRandomPlayers:\n => %d total
    ↪ inserted players\n", addedCount);

// Count players amount.
int count = dao.countPlayers();
System.out.printf("PlayerDAO.countPlayers:\n => %d total players\n",
    ↪ count);

// Print 3 players.
dao.printPlayers(3);

// 4. Getting further.

// Player 1: id is "1", has only 100 coins.
// Player 2: id is "2", has 114514 coins, and 20 goods.
PlayerBean player1 = new PlayerBean("1", 100, 0);
PlayerBean player2 = new PlayerBean("2", 114514, 20);

// Create two players "by hand", using the INSERT statement on the
    ↪ backend.
addedCount = dao.createPlayers(Arrays.asList(player1, player2));
System.out.printf("PlayerDAO.createPlayers:\n => %d total inserted
    ↪ players\n", addedCount);

// Player 1 wants to buy 10 goods from player 2.
// It will cost 500 coins, but player 1 can't afford it.
System.out.println("\nPlayerDAO.buyGoods:\n => this trade will fail")
    ↪ ;
int updatedCount = dao.buyGoods(player2.getId(), player1.getId(),
    ↪ 10, 500);
```

```
        System.out.printf("PlayerDAO.buyGoods:\n => %d total update players\n
            ↪ ", updatedCount);

        // So player 1 have to reduce his incoming quantity to two.
        System.out.println("\nPlayerDAO.buyGoods:\n => this trade will
            ↪ success");
        updatedCount = dao.buyGoods(player2.getId(), player1.getId(), 2, 100)
            ↪ ;
        System.out.printf("PlayerDAO.buyGoods:\n => %d total update players\n
            ↪ ", updatedCount);
    }
}
```

4.3.3.3 Step 3. Run the code

The following content introduces how to run the code step by step.

4.3.3.3.1 Step 3.1 Table initialization

When using Mybatis, you need to initialize the database tables manually. If you are using a local cluster, and MySQL client has been installed locally, you can run it directly in the `plain-java-mybatis` directory:

```
make prepare
```

Or you can execute the following command:

```
mysql --host 127.0.0.1 --port 4000 -u root < src/main/resources/dbinit.sql
```

If you are using a non-local cluster or MySQL client has not been installed, connect to your cluster and run the statement in the `src/main/resources/dbinit.sql` file.

No need to initialize tables manually.

When using JDBC, you need to initialize the database tables manually. If you are using a local cluster, and MySQL client has been installed locally, you can run it directly in the `plain-java-jdbc` directory:

```
make mysql
```

Or you can execute the following command:

```
mysql --host 127.0.0.1 --port 4000 -u root<src/main/resources/dbinit.sql
```

If you are using a non-local cluster or MySQL client has not been installed, connect to your cluster and run the statement in the `src/main/resources/dbinit.sql` file.

4.3.3.3.2 Step 3.2 Modify parameters for TiDB Cloud

If you are using a TiDB Cloud Serverless Tier cluster, modify the `dataSource.url`, `dataSource.username`, `dataSource.password` in `mybatis-config.xml`.

```
<?xml version="1.0" encoding="UTF-8" ?>

                <property name="url" value="jdbc:mysql://127.0.0.1:4000/test"/
                    ↪ >
                <property name="username" value="root"/>
                <property name="password" value=""/>
            </dataSource>
        </environment>
    </environments>

    <mappers>
        <mapper resource="mapper/PlayerMapper.xml"/>
        <mapper resource="mapper/PlayerMapperEx.xml"/>
    </mappers>

</configuration>
```

Suppose that the password you set is `123456`, and the connection parameters you get

from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the parameters in `dataSource` node as follows:

```
<?xml version="1.0" encoding="UTF-8" ?>

<!DOCTYPE configuration
       PUBLIC "-//mybatis.org//DTD Config 3.0//EN"
       "http://mybatis.org/dtd/mybatis-3-config.dtd">

       ...
           <!-- Database pool -->
           <dataSource type="POOLED">
               <property name="driver" value="com.mysql.jdbc.Driver"/>
               <property name="url" value="jdbc:mysql://xxx.tidbcloud.
                   ↪ com:4000/test?sslMode=VERIFY_IDENTITY&amp;
                   ↪ enabledTLSProtocols=TLSv1.2,TLSv1.3"/>
               <property name="username" value="2aEp24QWEDLqRFs.root"/>
               <property name="password" value="123456"/>
           </dataSource>
       ...

</configuration>
```

If you are using a TiDB Cloud Serverless Tier cluster, modify the `hibernate.connection.url`, `hibernate.connection.username`, `hibernate.connection.password` in `hibernate.cfg.xml`.

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
       "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
       "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
   <session-factory>

       <!-- Database connection settings -->
       <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
           ↪ Driver</property>
       <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
           ↪ /property>
       <property name="hibernate.connection.url">jdbc:mysql://localhost:4000
           ↪ /test</property>
```

```
        <property name="hibernate.connection.username">root</property>
        <property name="hibernate.connection.password"></property>
        <property name="hibernate.connection.autocommit">false</property>

        <!-- Required so a table can be created from the 'PlayerDAO' class
            ↪ -->
        <property name="hibernate.hbm2ddl.auto">create-drop</property>

        <!-- Optional: Show SQL output for debugging -->
        <property name="hibernate.show_sql">true</property>
        <property name="hibernate.format_sql">true</property>
    </session-factory>
</hibernate-configuration>
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the parameters as follows:

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
    <session-factory>

        <!-- Database connection settings -->
        <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
            ↪ Driver</property>
        <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
            ↪ /property>
        <property name="hibernate.connection.url">jdbc:mysql://xxx.tidbcloud.
            ↪ com:4000/test?sslMode=VERIFY_IDENTITY&amp;enabledTLSProtocols=
            ↪ TLSv1.2,TLSv1.3</property>
        <property name="hibernate.connection.username">2aEp24QWEDLqRFs.root</
            ↪ property>
        <property name="hibernate.connection.password">123456</property>
        <property name="hibernate.connection.autocommit">false</property>

        <!-- Required so a table can be created from the 'PlayerDAO' class
            ↪ -->
```

```
        <property name="hibernate.hbm2ddl.auto">create-drop</property>

        <!-- Optional: Show SQL output for debugging -->
        <property name="hibernate.show_sql">true</property>
        <property name="hibernate.format_sql">true</property>
    </session-factory>
</hibernate-configuration>
```

If you are using a TiDB Cloud Serverless Tier cluster, modify the parameters of the host, port, user, and password in `JDBCExample.java`:

```
mysqlDataSource.setServerName("localhost");
mysqlDataSource.setPortNumber(4000);
mysqlDataSource.setDatabaseName("test");
mysqlDataSource.setUser("root");
mysqlDataSource.setPassword("");
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the parameters as follows:

```
mysqlDataSource.setServerName("xxx.tidbcloud.com");
mysqlDataSource.setPortNumber(4000);
mysqlDataSource.setDatabaseName("test");
mysqlDataSource.setUser("2aEp24QWEDLqRFs.root");
mysqlDataSource.setPassword("123456");
mysqlDataSource.setSslMode(PropertyDefinitions.SslMode.VERIFY_IDENTITY.name
    ↪ ());
mysqlDataSource.setEnabledTLSProtocols("TLSv1.2,TLSv1.3");
```

4.3.3.3.3 Step 3.3 Run

To run the code, you can run `make prepare`, `make gen`, `make build` and `make run` respectively:

```
make prepare
### this command executes :
### - `mysql --host 127.0.0.1 --port 4000 -u root < src/main/resources/
    ↪ dbinit.sql`
### - `mysql --host 127.0.0.1 --port 4000 -u root -e "TRUNCATE test.player"`
```

```
make gen
### this command executes :
### - `rm -f src/main/java/com/pingcap/model/Player.java`
### - `rm -f src/main/java/com/pingcap/model/PlayerMapper.java`
### - `rm -f src/main/resources/mapper/PlayerMapper.xml`
### - `mvn mybatis-generator:generate`

make build # this command executes `mvn clean package`
make run # this command executes `java -jar target/plain-java-mybatis-0.0.1-
    ↪ jar-with-dependencies.jar`
```

Or you can use the native commands:

```
mysql --host 127.0.0.1 --port 4000 -u root < src/main/resources/dbinit.sql
mysql --host 127.0.0.1 --port 4000 -u root -e "TRUNCATE test.player"
rm -f src/main/java/com/pingcap/model/Player.java
rm -f src/main/java/com/pingcap/model/PlayerMapper.java
rm -f src/main/resources/mapper/PlayerMapper.xml
mvn mybatis-generator:generate
mvn clean package
java -jar target/plain-java-mybatis-0.0.1-jar-with-dependencies.jar
```

Or run the `make` command directly, which is a combination of `make prepare`, `make gen`, `make build` and `make run`.

To run the code, you can run `make build` and `make run` respectively:

```
make build # this command executes `mvn clean package`
make run # this command executes `java -jar target/plain-java-jdbc-0.0.1-jar
    ↪ -with-dependencies.jar`
```

Or you can use the native commands:

```
mvn clean package
java -jar target/plain-java-jdbc-0.0.1-jar-with-dependencies.jar
```

Or run the `make` command directly, which is a combination of `make build` and `make run`.

To run the code, you can run `make build` and `make run` respectively:

```
make build # this command executes `mvn clean package`
make run # this command executes `java -jar target/plain-java-jdbc-0.0.1-jar
    ↪ -with-dependencies.jar`
```

Or you can use the native commands:

```
mvn clean package
java -jar target/plain-java-jdbc-0.0.1-jar-with-dependencies.jar
```

Or run the `make` command directly, which is a combination of `make build` and `make run`.

4.3.3.4 Step 4. Expected output

Mybatis Expected Output

Hibernate Expected Output

JDBC Expected Output

4.3.4 Build a Simple CRUD App with TiDB and Python

This document describes how to use TiDB and Python to build a simple CRUD application.

> **Note:**
>
> It is recommended to use Python 3.10 or a later Python version.

4.3.4.1 Step 1. Launch your TiDB cluster

The following introduces how to start a TiDB cluster.

Use a TiDB Cloud Serverless Tier cluster

For detailed steps, see Create a Serverless Tier cluster.

Use a local cluster

For detailed steps, see Deploy a local test cluster or Deploy a TiDB cluster using TiUP.

4.3.4.2 Step 2. Get the code

```
git clone https://github.com/pingcap-inc/tidb-example-python.git
```

SQLAlchemy is a popular open-source ORM library for Python. The following uses SQLAlchemy 1.44 as an example.

```
import uuid
from typing import List

from sqlalchemy import create_engine, String, Column, Integer, select, func
from sqlalchemy.orm import declarative_base, sessionmaker

engine = create_engine('mysql://root:@127.0.0.1:4000/test')
Base = declarative_base()
```

```
Base.metadata.create_all(engine)
Session = sessionmaker(bind=engine)

class Player(Base):
    __tablename__ = "player"

    id = Column(String(36), primary_key=True)
    coins = Column(Integer)
    goods = Column(Integer)

    def __repr__(self):
        return f'Player(id={self.id!r}, coins={self.coins!r}, goods={self.
            ↪ goods!r})'

def random_player(amount: int) -> List[Player]:
    players = []
    for _ in range(amount):
        players.append(Player(id=uuid.uuid4(), coins=10000, goods=10000))

    return players

def simple_example() -> None:
    with Session() as session:
        # create a player, who has a coin and a goods.
        session.add(Player(id="test", coins=1, goods=1))

        # get this player, and print it.
        get_test_stmt = select(Player).where(Player.id == "test")
        for player in session.scalars(get_test_stmt):
            print(player)

        # create players with bulk inserts.
        # insert 1919 players totally, with 114 players per batch.
        # each player has a random UUID
        player_list = random_player(1919)
        for idx in range(0, len(player_list), 114):
            session.bulk_save_objects(player_list[idx:idx + 114])

        # print the number of players
        count = session.query(func.count(Player.id)).scalar()
        print(f'number of players: {count}')
```

```
        # print 3 players.
        three_players = session.query(Player).limit(3).all()
        for player in three_players:
            print(player)

        session.commit()

def trade_check(session: Session, sell_id: str, buy_id: str, amount: int,
    ↪ price: int) -> bool:
    # sell player goods check
    sell_player = session.query(Player.goods).filter(Player.id == sell_id).
        ↪ with_for_update().one()
    if sell_player.goods < amount:
        print(f'sell player {sell_id} goods not enough')
        return False

    # buy player coins check
    buy_player = session.query(Player.coins).filter(Player.id == buy_id).
        ↪ with_for_update().one()
    if buy_player.coins < price:
        print(f'buy player {buy_id} coins not enough')
        return False

def trade(sell_id: str, buy_id: str, amount: int, price: int) -> None:
    with Session() as session:
        if trade_check(session, sell_id, buy_id, amount, price) is False:
            return

        # deduct the goods of seller, and raise his/her the coins
        session.query(Player).filter(Player.id == sell_id). \
            update({'goods': Player.goods - amount, 'coins': Player.coins +
                ↪ price})
        # deduct the coins of buyer, and raise his/her the goods
        session.query(Player).filter(Player.id == buy_id). \
            update({'goods': Player.goods + amount, 'coins': Player.coins -
                ↪ price})

        session.commit()
        print("trade success")

def trade_example() -> None:
    with Session() as session:
```

```
        # create two players
        # player 1: id is "1", has only 100 coins.
        # player 2: id is "2", has 114514 coins, and 20 goods.
        session.add(Player(id="1", coins=100, goods=0))
        session.add(Player(id="2", coins=114514, goods=20))
        session.commit()

    # player 1 wants to buy 10 goods from player 2.
    # it will cost 500 coins, but player 1 cannot afford it.
    # so this trade will fail, and nobody will lose their coins or goods
    trade(sell_id="2", buy_id="1", amount=10, price=500)

    # then player 1 has to reduce the incoming quantity to 2.
    # this trade will be successful
    trade(sell_id="2", buy_id="1", amount=2, price=100)

    with Session() as session:
        traders = session.query(Player).filter(Player.id.in_(("1", "2"))).
            ↪ all()
        for player in traders:
            print(player)
        session.commit()

simple_example()
trade_example()
```

Compared with using drivers directly, SQLAlchemy provides an abstraction for the specific details of different databases when you create a database connection. In addition, SQLAlchemy encapsulates some operations such as session management and CRUD of basic objects, which greatly simplifies the code.

The `Player` class is a mapping of a table to attributes in the application. Each attribute of `Player` corresponds to a field in the `player` table. To provide SQLAlchemy with more information, the attribute is defined as `id = Column(String(36), primary_key=True)` to indicate the field type and its additional attributes. For example, `id = Column(String(36) ↪ , primary_key=True)` indicates that the `id` attribute is `String` type, the corresponding field in database is `VARCHAR` type, the length is `36`, and it is a primary key.

For more information about how to use SQLAlchemy, refer to SQLAlchemy documentation.

peewee is a popular open-source ORM library for Python. The following uses peewee 3.15.4 as an example.

```
import os
import uuid
```

```
from typing import List

from peewee import *

from playhouse.db_url import connect

db = connect('mysql://root:@127.0.0.1:4000/test')

class Player(Model):
    id = CharField(max_length=36, primary_key=True)
    coins = IntegerField()
    goods = IntegerField()

    class Meta:
        database = db
        table_name = "player"

def random_player(amount: int) -> List[Player]:
    players = []
    for _ in range(amount):
        players.append(Player(id=uuid.uuid4(), coins=10000, goods=10000))

    return players

def simple_example() -> None:
    # create a player, who has a coin and a goods.
    Player.create(id="test", coins=1, goods=1)

    # get this player, and print it.
    test_player = Player.select().where(Player.id == "test").get()
    print(f'id:{test_player.id}, coins:{test_player.coins}, goods:{
        ↪ test_player.goods}')

    # create players with bulk inserts.
    # insert 1919 players totally, with 114 players per batch.
    # each player has a random UUID
    player_list = random_player(1919)
    Player.bulk_create(player_list, 114)

    # print the number of players
    count = Player.select().count()
    print(f'number of players: {count}')
```

```
    # print 3 players.
    three_players = Player.select().limit(3)
    for player in three_players:
        print(f'id:{player.id}, coins:{player.coins}, goods:{player.goods}')

def trade_check(sell_id: str, buy_id: str, amount: int, price: int) -> bool
    ↪ :
    sell_goods = Player.select(Player.goods).where(Player.id == sell_id).get

```

Compared with using drivers directly, peewee provides an abstraction for the specific details of different databases when you create a database connection. In addition, peewee encapsulates some operations such as session management and CRUD of basic objects, which greatly simplifies the code.

The `Player` class is a mapping of a table to attributes in the application. Each attribute of `Player` corresponds to a field in the `player` table. To provide SQLAlchemy with more information, the attribute is defined as `id = Column(String(36), primary_key=True)` to indicate the field type and its additional attributes. For example, `id = Column(String(36)` ↪ `, primary_key=True)` indicates that the `id` attribute is `String` type, the corresponding field in database is `VARCHAR` type, the length is `36`, and it is a primary key.

For more information about how to use peewee, refer to peewee documentation.

mysqlclient is a popular open-source driver for Python. The following uses mysqlclient 2.1.1 as an example. Drivers for Python are more convenient to use than other languages, but they do not shield the underlying implementation and require manual management of transactions. If there are not a lot of scenarios where SQL is required, it is recommended to use ORM, which can help reduce the coupling of your program.

```
import uuid
from typing import List

import MySQLdb
from MySQLdb import Connection
from MySQLdb.cursors import Cursor

def get_connection(autocommit: bool = True) -> MySQLdb.Connection:
    return MySQLdb.connect(
        host="127.0.0.1",
        port=4000,
        user="root",
        password="",
        database="test",
        autocommit=autocommit
    )

The driver has a lower level of encapsulation than ORM, so there are a lot of SQL statements in the program. Unlike ORM, there is no data object in drivers, so the `Player` queried by the driver is represented as a tuple.

For more information about how to use mysqlclient, refer to mysqlclient documentation.

PyMySQL is a popular open-source driver for Python. The following uses PyMySQL 1.0.2 as an example. Drivers for Python are more convenient to use than other languages, but they do not shield the underlying implementation and require manual management of transactions. If there are not a lot of scenarios where SQL is required, it is recommended to use ORM, which can help reduce the coupling of your program.

The driver has a lower level of encapsulation than ORM, so there are a lot of SQL statements in the program. Unlike ORM, there is no data object in drivers, so the `Player` queried by the driver is represented as a tuple.

For more information about how to use mysql-connector-python, refer to mysql-connector-python documentation.

4.3.4.3 Step 3. Run the code

The following content introduces how to run the code step by step.

4.3.4.3.1 Step 3.1 Initialize table

Before running the code, you need to initialize the table manually. If you are using a local TiDB cluster, you can run the following command:

```
mysql --host 127.0.0.1 --port 4000 -u root < player_init.sql
```

```
mycli --host 127.0.0.1 --port 4000 -u root --no-warn < player_init.sql
```

If you are not using a local cluster, or have not installed a MySQL client, connect to your cluster using your preferred method (such as Navicat, DBeaver, or other GUI tools) and run the SQL statements in the `player_init.sql` file.

4.3.4.3.2 Step 3.2 Modify parameters for TiDB Cloud

If you are using a TiDB Cloud Serverless Tier cluster, you need to provide your CA root path and replace `<ca_path>` in the following examples with your CA path. To get the CA root path on your system, refer to Where is the CA root path on my system?.

If you are using a TiDB Cloud Serverless Tier cluster, modify the parameters of the `create_engine` function in `sqlalchemy_example.py`:

```
engine = create_engine('mysql://root:@127.0.0.1:4000/test')
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`

- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `create_engine` as follows:

```
engine = create_engine('mysql://2aEp24QWEDLqRFs.root:123456@xxx.tidbcloud.
    ↪ com:4000/test', connect_args={
    "ssl_mode": "VERIFY_IDENTITY",
    "ssl": {
        "ca": "<ca_path>"
    }
})
```

If you are using a TiDB Cloud Serverless Tier cluster, modify the parameters of the `create_engine` function in `sqlalchemy_example.py`:

```
db = connect('mysql://root:@127.0.0.1:4000/test')
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `connect` as follows:

- When peewee uses PyMySQL as the driver:

```
db = connect('mysql://2aEp24QWEDLqRFs.root:123456@xxx.tidbcloud.com
    ↪ :4000/test',
    ssl_verify_cert=True, ssl_ca="<ca_path>")
```

- When peewee uses mysqlclient as the driver:

```
db = connect('mysql://2aEp24QWEDLqRFs.root:123456@xxx.tidbcloud.com
    ↪ :4000/test',
    ssl_mode="VERIFY_IDENTITY", ssl={"ca": "<ca_path>"})
```

Because peewee will pass parameters to the driver, you need to pay attention to the usage type of the driver when using peewee.

If you are using a TiDB Cloud Serverless Tier cluster, change the `get_connection` function in `mysqlclient_example.py`:

```
def get_connection(autocommit: bool = True) -> MySQLdb.Connection:
    return MySQLdb.connect(
        host="127.0.0.1",
        port=4000,
        user="root",
        password="",
        database="test",
        autocommit=autocommit
    )
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `get_connection` as follows:

```
def get_connection(autocommit: bool = True) -> MySQLdb.Connection:
    return MySQLdb.connect(
        host="xxx.tidbcloud.com",
        port=4000,
        user="2aEp24QWEDLqRFs.root",
        password="123456",
        database="test",
        autocommit=autocommit,
        ssl_mode="VERIFY_IDENTITY",
        ssl={
            "ca": "<ca_path>"
        }
    )
```

If you are using a TiDB Cloud Serverless Tier cluster, change the `get_connection` function in `pymysql_example.py`:

```
def get_connection(autocommit: bool = False) -> Connection:
    return pymysql.connect(host='127.0.0.1',
                           port=4000,
                           user='root',
                           password='',
                           database='test',
                           cursorclass=DictCursor,
                           autocommit=autocommit)
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `get_connection` as follows:

```
def get_connection(autocommit: bool = False) -> Connection:
    return pymysql.connect(host='xxx.tidbcloud.com',
                           port=4000,
                           user='2aEp24QWEDLqRFs.root',
                           password='123546',
                           database='test',
                           cursorclass=DictCursor,
                           autocommit=autocommit,
                           ssl_ca='<ca_path>',
                           ssl_verify_cert=True,
                           ssl_verify_identity=True)
```

If you are using a TiDB Cloud Serverless Tier cluster, change the `get_connection` function in `mysql_connector_python_example.py`:

```
def get_connection(autocommit: bool = True) -> MySQLConnection:
    connection = connect(host='127.0.0.1',
                         port=4000,
                         user='root',
                         password='',
                         database='test')
    connection.autocommit = autocommit
    return connection
```

Suppose that the password you set is `123456`, and the connection parameters you get from the cluster details page are the following:

- Endpoint: `xxx.tidbcloud.com`
- Port: `4000`
- User: `2aEp24QWEDLqRFs.root`

In this case, you can modify the `get_connection` as follows:

```
def get_connection(autocommit: bool = True) -> MySQLConnection:
    connection = connect(
        host="xxx.tidbcloud.com",
```

```
        port=4000,
        user="2aEp24QWEDLqRFs.root",
        password="123456",
        database="test",
        autocommit=autocommit,
        ssl_ca='<ca_path>',
        ssl_verify_identity=True
    )
    connection.autocommit = autocommit
    return connection
```

4.3.4.4.3.3 Step 3.3 Run the code

Before running the code, use the following command to install dependencies:

```
pip3 install -r requirement.txt
```

If you need to run the script multiple times, follow the Table initialization section to initialize the table again before each run.

```
python3 sqlalchemy_example.py
```

```
python3 peewee_example.py
```

```
python3 mysqlclient_example.py
```

```
python3 pymysql_example.py
```

```
python3 mysql_connector_python_example.py
```

4.3.4.4 Step 4. Expected output

SQLAlchemy Expected Output

peewee Expected Output

mysqlclient Expected Output

PyMySQL Expected Output

mysql-connector-python Expected Output

4.4 Connect to TiDB

4.4.1 Choose Driver or ORM

Note:

TiDB provides the following two support levels for drivers and ORMs:

- **Full**: indicates that TiDB is compatible with most features of the tool and maintains compatibility with its newer versions. PingCAP will periodically conduct compatibility tests with the latest version of Third-party tools supported by TiDB.
- **Compatible**: indicates that because the corresponding third-party tool is adapted to MySQL and TiDB is highly compatible with the MySQL protocol, so TiDB can use most features of the tool. However, PingCAP has not completed a full test on all features of the tool, which might lead to some unexpected behaviors.

For more information, refer to Third-Party Tools Supported by TiDB.

TiDB is highly compatible with the MySQL protocol but some features are incompatible with MySQL. For a full list of compatibility differences, see MySQL Compatibility.

4.4.1.1 Java

This section describes how to use drivers and ORM frameworks in Java.

4.4.1.1.1 Java drivers

Support level: **Full**

You can follow the MySQL documentation to download and configure a Java JDBC driver. It is recommended to use MySQL Connector/J 8.0.29 or later with TiDB v6.3.0 and newer.

Tip:

There is a bug in the Connector/J 8.0 versions before 8.0.32, which might cause threads to hang when using TiDB versions earlier than v6.3.0. To avoid this issue, it is recommended that you use either MySQL Connector/J 8.0.32 or a later version, or the TiDB JDBC (see the *TiDB-JDBC* tab).

For an example of how to build a complete application, see Build a Simple CRUD App with TiDB and JDBC.

Support level: **Full**

TiDB-JDBC is a customized Java driver based on MySQL 8.0.29. Compiled based on MySQL official version 8.0.29, TiDB-JDBC fixes the bug of multi-parameter and multi-field EOF in the prepare mode in the original JDBC, and adds features such as automatic TiCDC snapshot maintenance and the SM3 authentication plugin.

Using SM3-based authentication is only supported with the TiDB version of MySQL Connector/J.

If you use Maven, add the following content to the `<dependencies></dependencies>` section in the `pom.xml` file:

```
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>mysql-connector-java</artifactId>
  <version>8.0.29-tidb-1.0.0</version>
</dependency>
```

If you need to enable SM3 authentication, add the following content to the `<dependencies></dependencies>` section in the `pom.xml` file:

```
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>mysql-connector-java</artifactId>
  <version>8.0.29-tidb-1.0.0</version>
</dependency>
<dependency>
    <groupId>org.bouncycastle</groupId>
    <artifactId>bcprov-jdk15on</artifactId>
    <version>1.67</version>
</dependency>
<dependency>
    <groupId>org.bouncycastle</groupId>
    <artifactId>bcpkix-jdk15on</artifactId>
    <version>1.67</version>
</dependency>
```

If you use Gradle, add the following content to `dependencies`:

```
implementation group: 'io.github.lastincisor', name: 'mysql-connector-java',
    ↪  version: '8.0.29-tidb-1.0.0'
implementation group: 'org.bouncycastle', name: 'bcprov-jdk15on', version:
    ↪ '1.67'
implementation group: 'org.bouncycastle', name: 'bcpkix-jdk15on', version:
    ↪ '1.67'
```

4.4.1.1.2 Java ORM frameworks

Note:

- Currently, Hibernate does not support nested transactions.
- Since v6.2.0, TiDB supports savepoint. To use the `Propagation.NESTED` transaction propagation option in `@Transactional`, that is, to set `@Transactional(propagation = Propagation.NESTED)`, make sure that your TiDB is v6.2.0 or later.

Support level: **Full**

To avoid manually managing complex relationships between different dependencies of an application, you can use Gradle or Maven to get all dependencies of your application, including those indirect ones. Note that only Hibernate `6.0.0.Beta2` or above supports the TiDB dialect.

If you are using **Maven**, add the following to your `<dependencies></dependencies>`:

```
<dependency>
    <groupId>org.hibernate.orm</groupId>
    <artifactId>hibernate-core</artifactId>
    <version>6.0.0.CR2</version>
</dependency>

<dependency>
    <groupId>mysql</groupId>
    <artifactId>mysql-connector-java</artifactId>
    <version>5.1.49</version>
</dependency>
```

If you are using **Gradle**, add the following to your `dependencies`:

```
implementation 'org.hibernate:hibernate-core:6.0.0.CR2'
implementation 'mysql:mysql-connector-java:5.1.49'
```

- For an example of using Hibernate to build a TiDB application by native Java, see Build a Simple CRUD App with TiDB and Java.
- For an example of using Spring Data JPA or Hibernate to build a TiDB application by Spring, see Build a TiDB Application using Spring Boot.

In addition, you need to specify the TiDB dialect in your Hibernate configuration file: `org.hibernate.dialect.TiDBDialect`, which is only supported by Hibernate `6.0.0.Beta2` or above. If your `Hibernate` version is earlier than `6.0.0.Beta2`, upgrade it first.

Note:

If you are unable to upgrade your `Hibernate` version, use the MySQL 5.7 dialect `org.hibernate.dialect.MySQL57Dialect` instead. However, this setting might cause unpredictable results and the absence of some TiDB-specific features, such as sequences.

Support level: **Full**

To avoid manually managing complex relationships between different dependencies of an application, you can use Gradle or Maven to get all dependencies of your application, including those indirect dependencies.

If you are using Maven, add the following to your `<dependencies></dependencies>`:

```
<dependency>
    <groupId>org.mybatis</groupId>
    <artifactId>mybatis</artifactId>
    <version>3.5.9</version>
</dependency>

<dependency>
    <groupId>mysql</groupId>
    <artifactId>mysql-connector-java</artifactId>
    <version>5.1.49</version>
</dependency>
```

If you are using Gradle, add the following to your `dependencies`:

```
implementation 'org.mybatis:mybatis:3.5.9'
implementation 'mysql:mysql-connector-java:5.1.49'
```

For an example of using MyBatis to build a TiDB application, see Build a Simple CRUD App with TiDB and Java.

4.4.1.1.3 Java client load balancing

tidb-loadbalance

Support level: **Full**

tidb-loadbalance is a load balancing component on the application side. With tidb-loadbalance, you can automatically maintain the node information of TiDB server and distribute JDBC connections on the client using the tidb-loadbalance policies. Using a direct JDBC connection between the client application and TiDB server has higher performance than using the load balancing component.

Currently, tidb-loadbalance supports the following policies: roundrobin, random, and weight.

> **Note:**
>
> tidb-loadbalance must be used with mysql-connector-j.

If you use Maven, add the following content to the element body of `<dependencies></dependencies>` in the `pom.xml` file:

```
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>mysql-connector-java</artifactId>
  <version>8.0.29-tidb-1.0.0</version>
</dependency>
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>tidb-loadbalance</artifactId>
  <version>0.0.5</version>
</dependency>
```

If you use Gradle, add the following content to `dependencies`:

```
implementation group: 'io.github.lastincisor', name: 'mysql-connector-java',
    ↪  version: '8.0.29-tidb-1.0.0'
implementation group: 'io.github.lastincisor', name: 'tidb-loadbalance',
    ↪ version: '0.0.5'
```

4.4.1.2 Golang

This section describes how to use drivers and ORM frameworks in Golang.

4.4.1.2.1 Golang drivers

go-sql-driver/mysql

Support level: **Full**

To download and configure a Golang driver, refer to the go-sql-driver/mysql documentation.

For an example of how to build a complete application, see Build a Simple CRUD App with TiDB and Golang.

4.4.1.2.2 Golang ORM frameworks

GORM

Support level: **Full**

GORM is a popular ORM framework for Golang. To get all dependencies in your application, you can use the `go get` command.

```
go get -u gorm.io/gorm
go get -u gorm.io/driver/mysql
```

For an example of using GORM to build a TiDB application, see Build a Simple CRUD App with TiDB and Golang.

4.4.1.3 Python

This section describes how to use drivers and ORM frameworks in Python.

4.4.1.3.1 Python drivers

Support level: **Compatible**

You can follow the PyMySQL documentation to download and configure the driver. It is recommended to use PyMySQL 1.0.2 or later versions.

For an example of using PyMySQL to build a TiDB application, see Build a Simple CRUD App with TiDB and Python.

Support level: **Compatible**

You can follow the mysqlclient documentation to download and configure the driver. It is recommended to use mysqlclient 2.1.1 or later versions.

For an example of using mysqlclient to build a TiDB application, see Build a Simple CRUD App with TiDB and Python.

Support level: **Compatible**

You can follow the mysql-connector-python documentation to download and configure the driver. It is recommended to use Connector/Python 8.0.31 or later versions.

For an example of using mysql-connector-python to build a TiDB application, see Build a Simple CRUD App with TiDB and Python.

4.4.1.3.2 Python ORM frameworks

Support level: **Compatible**

SQLAlchemy is a popular ORM framework for Python. To get all dependencies in your application, you can use the `pip install SQLAlchemy==1.4.44` command. It is recommended to use SQLAlchemy 1.4.44 or later versions.

For an example of using SQLAlchemy to build a TiDB application, see Build a Simple CRUD App with TiDB and Python.

Support level: **Compatible**

peewee is a popular ORM framework for Python. To get all dependencies in your application, you can use the `pip install peewee==3.15.4` command. It is recommended to use peewee 3.15.4 or later versions.

For an example of using peewee to build a TiDB application, see Build a Simple CRUD App with TiDB and Python.

4.4.2 Connect to TiDB

TiDB is highly compatible with the MySQL protocol. For a full list of client link parameters, see MySQL Client Options.

TiDB supports the MySQL Client/Server Protocol, which allows most client drivers and ORM frameworks to connect to TiDB just as they connect to MySQL.

4.4.2.1 MySQL

You can choose to use MySQL Client or MySQL Shell based on your personal preferences.

You can connect to TiDB using MySQL Client, which can be used as a command-line tool for TiDB. To install MySQL Client, follow the instructions below for YUM based Linux distributions.

```
sudo yum install mysql
```

After the installation, you can connect to TiDB using the following command:

```
mysql --host <tidb_server_host> --port 4000 -u root -p --comments
```

You can connect to TiDB using MySQL Shell, which can be used as a command-line tool for TiDB. To install MySQL Shell, follow the instructions in the MySQL Shell documentation. After the installation, you can connect to TiDB using the following command:

```
mysqlsh --sql mysql://root@<tidb_server_host>:4000
```

4.4.2.2 JDBC

You can connect to TiDB using the JDBC driver. To do that, you need to create a `MysqlDataSource` or `MysqlConnectionPoolDataSource` object (both objects support the `DataSource` interface), and then set the connection string using the `setURL` function.

For example:

```
MysqlDataSource mysqlDataSource = new MysqlDataSource();
mysqlDataSource.setURL("jdbc:mysql://{host}:{port}/{database}?user={username
    ↪ }&password={password}");
```

For more information on JDBC connections, see the JDBC documentation

4.4.2.2.1 Connection parameters

Parameter name	Description
{username}	A SQL user to connect to the TiDB cluster
{password}	The password of the SQL user
{host}	Host of a TiDB node
{port}	Port that the TiDB node is listening on
{database}	Name of an existing database

For more information about TiDB SQL users, see TiDB User Account Management.

4.4.2.3 Hibernate

You can connect to TiDB using the Hibernate ORM. To do that, you need to set `hibernate.connection.url` in the Hibernate configuration file to a legal TiDB connection string.

For example, if you use a `hibernate.cfg.xml` configuration file, set `hibernate.connection.url` as follows:

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
    <session-factory>
        <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
            ↪ Driver</property>
        <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
            ↪ /property>
        <property name="hibernate.connection.url">jdbc:mysql://{host}:{port
            ↪ }/{database}?user={user}&amp;password={password}</property>
    </session-factory>
</hibernate-configuration>
```

After the configuration is done, you can use the following command to read the configuration file and get the `SessionFactory` object:

```
SessionFactory sessionFactory = new Configuration().configure("hibernate.
    ↪ cfg.xml").buildSessionFactory();
```

Note the following:

- Because the `hibernate.cfg.xml` configuration file is in the XML format and `&` is a special character in XML, you need to change `&` to `&` when configuring the file. For example, you need to change the connection string `hibernate.connection.url` from `jdbc:mysql://{host}:{port}/{database}?user={user}&password={password}` to `jdbc:mysql://{host}:{ port}/{database}?user={user}&password={password}`.
- It is recommended that you use the `TiDB` dialect by setting `hibernate.dialect` to `org.hibernate.dialect.TiDBDialect`.
- Hibernate supports TiDB dialects starting from `6.0.0.Beta2`, so it is recommended that you use Hibernate `6.0.0.Beta2` or a later version to connect to TiDB.

For more information about Hibernate connection parameters, see Hibernate documentation.

4.4.2.3.1 Connection parameters

Parameter name	Description
`{username}`	A SQL user to connect to the TiDB cluster
`{password}`	The password of the SQL user
`{host}`	Host of a TiDB node
`{port}`	Port that the TiDB node is listening on
`{database}`	Name of an existing database

For more information about TiDB SQL users, see TiDB User Account Management.

For more information about TiDB SQL users, see TiDB User Account Management.

4.4.3 Connection Pools and Connection Parameters

This document describes how to configure connection pools and connection parameters when you use a driver or ORM framework to connect to TiDB.

If you are interested in more tips about Java application development, see Best Practices for Developing Java Applications with TiDB

4.4.3.1 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least). Because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

Java has many connection pool implementations such as HikariCP, tomcat-jdbc, druid, c3p0, and dbcp. TiDB does not limit which connection pool you use, so you can choose whichever you like for your application.

4.4.3.1.1 Configure the number of connections

It is a common practice that the connection pool size is well adjusted according to the application's own needs. Take HikariCP as an example:

- **maximumPoolSize**: The maximum number of connections in the connection pool. If this value is too large, TiDB consumes resources to maintain useless connections. If this value is too small, the application gets slow connections. Therefore, you need to configure this value according to your application characteristics. For details, see About Pool Sizing.
- **minimumIdle**: The minimum number of idle connections in the connection pool. It is mainly used to reserve some connections to respond to sudden requests when the application is idle. You also need to configure it according to your application characteristics.

The application needs to return the connection after finishing using it. It is recommended that the application uses the corresponding connection pool monitoring (such as **metricRegistry**) to locate connection pool issues in time.

4.4.3.1.2 Probe configuration

The connection pool maintains persistent connections to TiDB. TiDB does not proactively close client connections by default (unless an error is reported), but generally, there are also network proxies such as LVS or HAProxy between the client and TiDB. Usually, these proxies proactively clean up connections that are idle for a certain period. In addition to paying attention to the idle configuration of the proxies, the connection pool also needs to keep alive or probe connections.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
    ↪ . The driver has not received any packets from the server. com.mysql.
    ↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
    ↪ failure
```

If `n` in `n milliseconds ago` is `0` or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as `3600000` in the above example), it is likely that this connection was idle for a long time and then closed by the proxy. The usual solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time.
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections.

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

4.4.3.1.3 Formulas based on experience

According to the About Pool Sizing article of HikariCP, if you have no idea about how to set a proper size for the database connection pool, you can get started with a formula based on experience. Then, based on the performance result of the pool size calculated from the formula, you can further adjust the size to achieve the best performance.

The formula based on experience is as follows:

```
connections = ((core_count * 2) + effective_spindle_count)
```

The description of each parameter in the formula is as follows:

- **connections**: the size of connections obtained.
- **core_count**: the number of CPU cores.
- **effective_spindle_count**: the number of hard drives (not SSD). Because each spinning hard disk can be called a spindle. For example, if you are using a server with a RAID of 16 disks, the **effective_spindle_count** should be 16. Because **HDD** usually can handle only one request at a time, the formula here is actually measuring how many concurrent I/O requests your server can manage.

In particular, pay attention to the following note below the formula.

```
A formula which has held up pretty well across a lot of
    ↪ benchmarks for years is
that for optimal throughput the number of active connections
    ↪ should be somewhere
near ((core_count * 2) + effective_spindle_count). Core count
    ↪ should not include
HT threads, even if hyperthreading is enabled. Effective
    ↪ spindle count is zero if
the active data set is fully cached, and approaches the actual
    ↪ number of spindles
as the cache hit rate falls. ... There hasn't been any analysis
    ↪  so far regarding
how well the formula works with SSDs.
```

This note indicates that:

- **core_count** is the number of physical cores, regardless of whether you enable Hyper-Threading or not.
- When data is fully cached, you need to set **effective_spindle_count** to `0`. As the hit rate of cache decreases, the count is closer to the actual number of `HDD`.
- **Whether the formula works for *SSD* is not tested and unknown.**

When using SSDs, it is recommended that you use the following formula based on experience instead:

```
connections = (number of cores * 4)
```

Therefore, you can set the maximum connection size of the initial connection pool to `cores * 4` in the case of SSDs and further adjust the size to tune the performance.

4.4.3.1.4 Tuning direction

As you can see, a size calculated from the formulas based on experience is just a recommended base value. To get the optimal size on a specific machine, you need to try other values around the base value and test the performance.

Here are some basic rules to help you get the optimal size:

- If your network or storage latency is high, increase your maximum number of connections to reduce the latency waiting time. Once a thread is blocked by latency, other threads can take over and continue processing.
- If you have multiple services deployed on your server and each service has a separate connection pool, consider the sum of the maximum number of connections to all connection pools.

4.4.3.2 Connection parameters

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

4.4.3.2.1 JDBC API

For JDBC API usage, see JDBC official tutorial. This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter

changes. Therefore, it is recommended to use Prepared Statements instead of regular execution from a text file and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` ↪ is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see MySQL JDBC parameters.

Use Batch API

For batch inserts, you can use the `addBatch/executeBatch` API. The `addBatch()` ↪ method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

> **Note:**
>
> In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.
>
> If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see Batch-related parameters.

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and saves them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time and waits until the client's memory is ready and it requests for the next batch.

Usually, there are two kinds of processing methods in JDBC:

- Set **FetchSize** to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

  When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise,

the error `No statements may be issued when any streaming result sets are open and in use on a given connection. Ensure that you have called .close()on any active streaming result sets before attempting more queries.` is returned.

To avoid such an error in queries before the client finishes reading or closes `resultset`, you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- To use Cursor Fetch, first set `FetchSize` as a positive integer and configure `useCursorFetch=true` in the JDBC URL.

TiDB supports both methods, but it is preferred that you use the first method, because it is a simpler implementation and has a better execution efficiency.

4.4.3.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces MySQL Connector/J's parameter configurations (If you use MariaDB, see MariaDB's parameter configurations). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to `Prepare`.

- **useServerPrepStmts**

  useServerPrepStmts is set to `false` by default, that is, even if you use the Prepare API, the "prepare" operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

  To verify that this setting already takes effect, you can do:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
  - If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

- **cachePrepStmts**

  Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the "prepare" operation is not even as efficient as text file execution. To solve this, it is recommended that after setting

`useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

- **prepStmtCacheSqlLimit**

  After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` ↪ configuration (the default value is `256`). This configuration controls the maximum length of the Prepared Statements cached on the client.

  The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

  You need to check whether this setting is too small if you:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
  - And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` ↪ is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

- **prepStmtCacheSize**

  prepStmtCacheSize controls the number of cached Prepared Statements (the default value is `25`). If your application requires "preparing" many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

  To verify that this setting already takes effect, you can do:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
  - If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements` ↪ `=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare("INSERT INTO `t` (a) values(?)");
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
INSERT INTO `t` (`a`) VALUES(10);
INSERT INTO `t` (`a`) VALUES(11);
INSERT INTO `t` (`a`) VALUES(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
INSERT INTO `t` (`a`) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple "values" keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
INSERT INTO `t` (`a`) VALUES (10) ON DUPLICATE KEY UPDATE `a` = 10;
INSERT INTO `t` (`a`) VALUES (11) ON DUPLICATE KEY UPDATE `a` = 11;
INSERT INTO `t` (`a`) VALUES (12) ON DUPLICATE KEY UPDATE `a` = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
INSERT INTO `t` (`a`) VALUES (10) ON DUPLICATE KEY UPDATE `a` = VALUES(`a`)
    ↪ ;
INSERT INTO `t` (`a`) VALUES (11) ON DUPLICATE KEY UPDATE `a` = VALUES(`a`)
    ↪ ;
INSERT INTO `t` (`a`) VALUES (12) ON DUPLICATE KEY UPDATE `a` = VALUES(`a`)
    ↪ ;
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
INSERT INTO `t` (`a`) VALUES (10), (11), (12) ON DUPLICATE KEY UPDATE a =
    ↪ VALUES(`a`);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
UPDATE `t` SET `a` = 10 WHERE `id` = 1; UPDATE `t` SET `a` = 11 WHERE `id`
    ↪ = 2; UPDATE `t` SET `a` = 12 WHERE `id` = 3;
```

In addition, because of a client bug, if you want to configure `rewriteBatchedStatements=true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Integrate parameters

Through monitoring, you might notice that although the application only performs `INSERT` operations to the TiDB cluster, there are a lot of redundant `SELECT` statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` includes a group of configurations. To get the detailed configurations in MySQL Connector/J 8.0 and those in MySQL Connector/J 5.1, see mysql-connector-j 8.0 and mysql-connector-j 5.1 respectively.

After it is configured, you can check the monitoring to see a decreased number of `SELECT` statements.

Timeout-related parameters

TiDB provides two MySQL-compatible parameters to control the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. Since TiDB v5.4, the default value of `wait_timeout` is `28800` seconds, which is 8 hours. For TiDB versions earlier than v5.4, the default value is `0`, which means the timeout is unlimited. The default value of `max_execution_time` is `0`, which means the maximum execution time of a SQL statement is unlimited.

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables=wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

4.5 Design Database Schema

4.5.1 TiDB Database Schema Design Overview

This document provides the basics of TiDB database schema design, including the objects in TiDB, access control, database schema changes, and object limitations.

In the subsequent documents, Bookshop will be taken as an example to show you how to design a database and perform data read and write operations in a database.

4.5.1.1 Objects in TiDB

To distinguish some general terms, here is a brief agreement on the terms used in TiDB:

- To avoid confusion with the generic term database, **database** in this document refers to a logical object, **TiDB** refers to TiDB itself, and **cluster** refers to a deployed instance of TiDB.
- TiDB uses MySQL-compatible syntax, in which **schema** means the generic term schema instead of a logical object in a database. For more information, see MySQL documentation. Make sure that you note this difference if you are migrating from databases that have schemas as logical objects (for example, PostgreSQL, Oracle, and Microsoft SQL Server).

4.5.1.1.1 Database

A database in TiDB is a collection of objects such as tables and indexes.

TiDB comes with a default database named `test`. However, it is recommended that you create your own database instead of using the `test` database.

4.5.1.1.2 Table

A table is a collection of related data in a database.

Each table consists of **rows** and **columns**. Each value in a row belongs to a specific **column**. Each column allows only a single data type. To further qualify columns, you can add some constraints. To accelerate calculations, you can add generated columns (experimental feature).

4.5.1.1.3 Index

An index is a copy of selected columns in a table. You can create an index using one or more columns of a table. With indexes, TiDB can quickly locate data without having to search every row in a table every time, which greatly improves your query performance.

There are two common types of indexes:

- **Primary Key**: indexes on the primary key column.
- **Secondary Index**: indexes on non-primary key columns.

Note:

In TiDB, the default definition of **Primary Key** is different from that in InnoDB (a common storage engine of MySQL).

- In InnoDB, the definition of **Primary Key** is unique, not null, and a **clustered index**.
- In TiDB, the definition of **Primary Key** is unique and not null. But the primary key is not guaranteed to be a **clustered index**. To specify whether the primary key is a clustered index, you can add non-reserved keywords `CLUSTERED` or `NONCLUSTERED` after `PRIMARY KEY` in a `CREATE TABLE` statement. If a statement does not explicitly specify these keywords, the default behavior is controlled by the system variable `@@global.tidb_enable_clustered_index`. For more information, see Clustered Indexes.

Specialized indexes

To improve query performance of various user scenarios, TiDB provides you with some specialized types of indexes. For details of each type, see the following links:

- Expression indexes (Experimental)
- Columnar storage (TiFlash)
- RocksDB engine

- Titan plugin

- Invisible indexes
- Composite `PRIMARY KEY`
- Unique indexes
- Clustered indexes on integer `PRIMARY KEY`
- Clustered indexes on composite or non-integer key

4.5.1.1.4 Other supported logical objects

TiDB supports the following logical objects at the same level as **table**:

- View: a view acts as a virtual table, whose schema is defined by the `SELECT` statement that creates the view.
- Sequence: a sequence generates and stores sequential data.
- Temporary table: a table whose data is not persistent.

4.5.1.2 Access Control

TiDB supports both user-based and role-based access control. To allow users to view, modify, or delete data objects and data schemas, you can either grant privileges to users directly or grant privileges to users through roles.

4.5.1.3 Database schema changes

As a best practice, it is recommended that you use a MySQL client or a GUI client instead of a driver or ORM to execute database schema changes.

4.5.1.4 Object limitations

This section lists the object limitations on identifier length, a single table, and string types. For more information, see TiDB Limitations.

4.5.1.4.1 Limitations on identifier length

Identifier type	Maximum length (number of characters allowed)
Database	64
Table	64
Column	64
Index	64
View	64
Sequence	64

4.5.1.4.2 Limitations on a single table

Type	Upper limit (default value)
Columns	Defaults to 1017 and can be adjusted up to 4096
Indexes	Defaults to 64 and can be adjusted up to 512
Partitions	8192
Size of a single line	6 MB by default.
Size of a single column in a line	6 MB

You can adjust the size limit of a single line via the **txn-entry-size-limit** configuration item.

4.5.1.4.3 Limitations on string types

Type	Upper limit
CHAR	256 characters

Type	Upper limit
BINARY	256 characters
VARBINARY	65535 characters
VARCHAR	16383 characters
TEXT	6 MB
BLOB	6 MB

4.5.1.4.4 Number of rows

TiDB supports an **unlimited** number of rows by adding nodes to the cluster. For the relevant principles, see TiDB Best Practices.

4.5.2 Create a Database

This document describes how to create a database using SQL and various programming languages and lists the rules of database creation. In this document, the Bookshop application is taken as an example to walk you through the steps of database creation.

4.5.2.1 Before you start

Before creating a database, do the following:

- Build a TiDB Cluster in TiDB Cloud (Serverless Tier).
- Read Schema Design Overview.

4.5.2.2 What is database

Database objects in TiDB contain **tables**, **views**, **sequences**, and other objects.

4.5.2.3 Create databases

To create a database, you can use the `CREATE DATABASE` statement.

For example, to create a database named `bookshop` if it does not exist, use the following statement:

```
CREATE DATABASE IF NOT EXISTS `bookshop`;
```

For more information and examples of the `CREATE DATABASE` statement, see the CREATE DATABASE document.

To execute the library build statement as the `root` user, run the following command:

```
mysql
    -u root \
    -h {host} \
```

```
    -P {port} \
    -p {password} \
    -e "CREATE DATABASE IF NOT EXISTS bookshop;"
```

4.5.2.4 View databases

To view the databases in a cluster, use the `SHOW DATABASES` statement.

For example:

```
mysql
    -u root \
    -h {host} \
    -P {port} \
    -p {password} \
    -e "SHOW DATABASES;"
```

The following is an example output:

```
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
| PERFORMANCE_SCHEMA |
| bookshop           |
| mysql              |
| test               |
+--------------------+
```

4.5.2.5 Rules in database creation

- Follow the Database Naming Conventions and name your database meaningfully.
- TiDB comes with a default database named `test`. However, it is not recommended that you use it in a production environment if you do not have to. You can create your own database using the `CREATE DATABASE` statement and change the current database using the `USE {databasename};` statement in a SQL session.
- Use the `root` user to create objects such as database, roles, and users. Grant only the necessary privileges to roles and users.
- As a best practice, it is recommended that you use a **MySQL command-line client** or a **MySQL GUI client** instead of a driver or ORM to execute database schema changes.

4.5.2.6 Next step

After creating a database, you can add **tables** to it. For more information, see Create a Table.

4.5.3 Create a Table

This document introduces how to create tables using the SQL statement and the related best practices. An example of the TiDB-based Bookshop application) is provided to illustrate the best practices.

4.5.3.1 Before you start

Before reading this document, make sure that the following tasks are completed:

- Build a TiDB Cluster in TiDB Cloud (Serverless Tier).
- Read Schema Design Overview.
- Create a Database.

4.5.3.2 What is a table

A table is a logical object in TiDB cluster that is subordinate to the database. It is used to store the data sent from SQL statements. Tables save data records in the form of rows and columns. A table has at least one column. If you have defined `n` columns, each row of data has exactly the same fields as the `n` columns.

4.5.3.3 Name a table

The first step for creating a table is to give your table a name. Do not use meaningless names that will cause great distress to yourself or your colleagues in the future. It is recommended that you follow your company or organization's table naming convention.

The `CREATE TABLE` statement usually takes the following form:

```
CREATE TABLE {table_name} ( {elements} );
```

Parameter description

- `{table_name}`: The name of the table to be created.
- `{elements}`: A comma-separated list of table elements, such as column definitions and primary key definitions.

Suppose you need to create a table to store the user information in the `bookshop` database.

Note that you cannot execute the following SQL statement yet because not a single column has been added.

```
CREATE TABLE `bookshop`.`users` (
);
```

4.5.3.4 Define columns

A **column** is subordinate to a table. Each table has at least one column. Columns provide a structure to a table by dividing the values in each row into small cells of a single data type.

Column definitions typically take the following form.

```
{column_name} {data_type} {column_qualification}
```

Parameter description

- `{column_name}`: The column name.
- `{data_type}`: The column data type.
- `{column_qualification}`: Column qualifications, such as **column-level constraints** or generated column (experimental feature) clauses.

You can add some columns to the `users` table, such as the unique identifier `id`, `balance` and `nickname`.

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint,
  `nickname` varchar(100),
  `balance` decimal(15,2)
);
```

In the above statement, a field is defined with the name `id` and the type bigint. This is used to represent a unique user identifier. This means that all user identifiers should be of the `bigint` type.

Then, a field named `nickname` is defined, which is the varchar type, with a length limit of 100 characters. This means that the `nicknames` of the users use the `varchar` type and are not longer than 100 characters.

Finally, a field named `balance` is added, which is the decimal type, with a **precision** of `15` and a **scale** of `2`. **Precision** represents the total number of digits in the field, and **scale** represents the number of decimal places. For example, `decimal(5,2)` means a precision of `5` and a scale of `2`, with the range from `-999.99` to `999.99`. `decimal(6,1)` means a precision of `6` and a scale of `1`, with the range from `-99999.9` to `99999.9`. **decimal** is a fixed-point types, which can be used to store numbers accurately. In scenarios where accurate numbers are needed (for example, user property-related), make sure that you use the **decimal** type.

TiDB supports many other column data types, including the integer types, floating-point types, fixed-point types, date and time types, and the enum type. You can refer to the supported column data types and use the **data types** that match the data you want to save in the database.

To make it a bit more complex, you can define a `books` table which will be the core of the `bookshop` data. The `books` table contains fields for the book's ids, titles, types (for example, magazine, novel, life, arts), stock, prices, and publication dates.

```
CREATE TABLE `bookshop`.`books` (
  `id` bigint NOT NULL,
  `title` varchar(100),
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports'),
  `published_at` datetime,
  `stock` int,
  `price` decimal(15,2)
);
```

This table contains more data types than the `users` table.

- int: It is recommended to use the type of right size to avoid using too much disk or even affecting performance (too large a type range) or data overflow (too small a data type range).
- datetime: The **datetime** type can be used to store time values.
- enum: The enum type can be used to store a limited selection of values.

4.5.3.5 Select primary key

A primary key is a column or a set of columns in a table whose values uniquely identify a row in the table.

> **Note:**
>
> The default definition of **primary key** in TiDB is different from that in InnoDB(the common storage engine of MySQL).
>
> - In **InnoDB**: A **primary key** is unique, not null, and **index clustered**.
> - In TiDB: A **primary key** is unique and is not null. But the primary key is not guaranteed to be a **clustered index**. Instead, another set of keywords `CLUSTERED` / `NONCLUSTERED` additionally controls whether the **primary key** is a **clustered index**. If the keyword is not specified, it is controlled by the system variable `@@global.tidb_enable_clustered_index`, as described in clustered indexes.

The **primary key** is defined in the `CREATE TABLE` statement. The primary key constraint requires that all constrained columns contain only non-NULL values.

A table can be created without a **primary key** or with a non-integer **primary key**. In this case, TiDB creates a `_tidb_rowid` as an **implicit primary key**. The implicit primary

key `_tidb_rowid`, because of its monotonically increasing nature, might cause write hotspots in write-intensive scenarios. Therefore, if your application is write-intensive, consider sharding data using the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` parameters. However, this might lead to read amplification, so you need to make your own trade-off.

When the **primary key** of a table is an integer type and `AUTO_INCREMENT` is used, hotspots cannot be avoided by using `SHARD_ROW_ID_BITS`. If you need to avoid hotspots and do not need a continuous and incremental primary key, you can use `AUTO_RANDOM` instead of `AUTO_INCREMENT` to eliminate row ID continuity.

For more information on how to handle hotspot issues, refer to Troubleshoot Hotspot Issues.

Following the guidelines for selecting primary key, the following example shows how an `AUTO_RANDOM` primary key is defined in the `users` table.

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM,
  `balance` decimal(15,2),
  `nickname` varchar(100),
  PRIMARY KEY (`id`)
);
```

4.5.3.6 Clustered or not

TiDB supports the clustered index feature since v5.0. This feature controls how data is stored in tables containing primary keys. It provides TiDB the ability to organize tables in a way that can improve the performance of certain queries.

The term clustered in this context refers to the organization of how data is stored and not a group of database servers working together. Some database management systems refer to clustered indexes as index-organized tables (IOT).

Currently, tables ***containing primary*** keys in TiDB are divided into the following two categories:

- `NONCLUSTERED`: The primary key of the table is non-clustered index. In tables with non-clustered indexes, the keys for row data consist of internal `_tidb_rowid` implicitly assigned by TiDB. Because primary keys are essentially unique indexes, tables with non-clustered indexes need at least two key-value pairs to store a row, which are:
  - `_tidb_rowid` (key) - row data (value)
  - Primary key data (key) - `_tidb_rowid` (value)
- `CLUSTERED`: The primary key of the table is clustered index. In tables with clustered indexes, the keys for row data consist of primary key data given by the user. Therefore, tables with clustered indexes need only one key-value pair to store a row, which is:
  - Primary key data (key) - row data (value)

As described in select primary key, **clustered indexes** are controlled in TiDB using the keywords `CLUSTERED` and `NONCLUSTERED`.

> **Note:**
>
> TiDB supports clustering only by a table's `PRIMARY KEY`. With clustered indexes enabled, the terms *the* `PRIMARY KEY` and *the clustered index* might be used interchangeably. `PRIMARY KEY` refers to the constraint (a logical property), and clustered index describes the physical implementation of how the data is stored.

Following the guidelines for selecting clustered index, the following example creates a table with an association between `books` and `users`, which represents the `ratings` of a `book` by `users`. The example creates the table and constructs a composite primary key using `book_id` and `user_id`, and creates a **clustered index** on that **primary key**.

```
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint,
  `user_id` bigint,
  `score` tinyint,
  `rated_at` datetime,
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED
);
```

4.5.3.7 Add column constraints

In addition to primary key constraints, TiDB also supports other **column constraints** such as NOT NULL constraint, UNIQUE KEY constraint, and `DEFAULT`. For complete constraints, refer to the TiDB constraints document.

4.5.3.7.1 Set default value

To set a default value on a column, use the `DEFAULT` constraint. The default value allows you to insert data without specifying a value for each column.

You can use `DEFAULT` together with supported SQL functions to move the calculation of defaults out of the application layer, thus saving resources of the application layer. The resources consumed by the calculation do not disappear and are moved to the TiDB cluster. Commonly, you can insert data with the default time. The following exemplifies setting the default value in the `ratings` table:

```
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint,
  `user_id` bigint,
```

```
  `score` tinyint,
  `rated_at` datetime DEFAULT NOW(),
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED
);
```

In addition, if the current time is also filled in by default when the data is being updated, the following statements can be used (but only the current time related statements can be filled in after `ON UPDATE`, and more options are supported after `DEFAULT`):

```
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint,
  `user_id` bigint,
  `score` tinyint,
  `rated_at` datetime DEFAULT NOW() ON UPDATE NOW(),
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED
);
```

4.5.3.7.2 Prevent duplicate values

If you need to prevent duplicate values in a column, you can use the `UNIQUE` constraint.

For example, to make sure that users' nicknames are unique, you can rewrite the table creation SQL statement for the `users` table like this:

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM,
  `balance` decimal(15,2),
  `nickname` varchar(100) UNIQUE,
  PRIMARY KEY (`id`)
);
```

If you try to insert the same `nickname` in the `users` table, an error is returned.

4.5.3.7.3 Prevent null values

If you need to prevent null values in a column, you can use the `NOT NULL` constraint.

Take user nicknames as an example. To ensure that a nickname is not only unique but is also not null, you can rewrite the SQL statement for creating the `users` table as follows:

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM,
  `balance` decimal(15,2),
  `nickname` varchar(100) UNIQUE NOT NULL,
  PRIMARY KEY (`id`)
);
```

4.5.3.8 Use HTAP capabilities

> **Note:**
>
> The steps provided in this guide is ***ONLY*** for quick start in the test environment. For production environments, refer to explore HTAP.

Suppose that you want to perform OLAP analysis on the `ratings` table using the `bookshop` application, for example, to query **whether the rating of a book has a significant correlation with the time of the rating**, which is to analyze whether the user's rating of the book is objective or not. Then you need to query the `score` and `rated_at` fields of the entire `ratings` table. This operation is resource-intensive for an OLTP-only database. Or you can use some ETL or other data synchronization tools to export the data from the OLTP database to a dedicated OLAP database for analysis.

In this scenario, TiDB, an **HTAP (Hybrid Transactional and Analytical Processing)** database that supports both OLTP and OLAP scenarios, is an ideal one-stop database solution.

4.5.3.8.1 Replicate column-based data

Currently, TiDB supports two data analysis engines, **TiFlash** and **TiSpark**. For the large data scenarios (100 T), **TiFlash MPP** is recommended as the primary solution for HTAP, and **TiSpark** as a complementary solution.

To learn more about TiDB HTAP capabilities, refer to the following documents: Quick Start Guide for TiDB HTAP and Explore HTAP.

In this example, TiFlash has been chosen as the data analysis engine for the `bookshop` database.

TiFlash does not automatically replicate data after deployment. Therefore, you need to manually specify the tables to be replicated:

```
ALTER TABLE {table_name} SET TIFLASH REPLICA {count};
```

Parameter description

- `{table_name}`: The table name.
- `{count}`: The number of replicated replicas. If it is 0, replicated replicas are deleted.

TiFlash will then replicate the table. When a query is performed, TiDB automatically selects TiKV (row-based) or TiFlash (column-based) for the query based on cost optimization. Alternatively, you can manually specify whether the query uses a **TiFlash** replica. To learn how to specify it, refer to Use TiDB to read TiFlash replicas.

4.5.3.8.2 An example of using HTAP capabilities

The `ratings` table opens 1 replica of TiFlash:

```
ALTER TABLE `bookshop`.`ratings` SET TIFLASH REPLICA 1;
```

> **Note:**
>
> If your cluster does not contain **TiFlash** nodes, this SQL statement will report an error: `1105 - the tiflash replica count: 1 should be less than the total tiflash server count: 0`. You can use Build a TiDB Cluster in TiDB Cloud (Serverless Tier) to create a Serverless Tier cluster that includes **TiFlash**.

Then you can go on to perform the following query:

```
SELECT HOUR(`rated_at`), AVG(`score`) FROM `bookshop`.`ratings` GROUP BY
    ↪ HOUR(`rated_at`);
```

You can also execute the `EXPLAIN ANALYZE` statement to see whether this statement is using the **TiFlash**:

```
EXPLAIN ANALYZE SELECT HOUR(`rated_at`), AVG(`score`) FROM `bookshop`.`
    ↪ ratings` GROUP BY HOUR(`rated_at`);
```

Running results:

```

When the field `cop[tiflash]` appears, it means that the task is sent to **TiFlash** for processing.

4.5.3.9 Execute the `CREATE TABLE` statement

After creating all the tables as above rules, our database initialization script should look like this. If you need to see the table information in detail, please refer to Description of the Tables.

To name the database initialization script `init.sql` and save it, you can execute the following statement to initialize the database.

```
mysql
    -u root \
```

```
    -h {host} \
    -P {port} \
    -p {password} \
    < init.sql
```

To view all tables under the `bookshop` database, use the `SHOW TABLES` statement.

```
SHOW TABLES IN `bookshop`;
```

Running results:

```
+--------------------+
| Tables_in_bookshop |
+--------------------+
| authors            |
| book_authors       |
| books              |
| orders             |
| ratings            |
| users              |
+--------------------+
```

4.5.3.10 Guidelines to follow when creating a table

This section provides guidelines you need to follow when creating a table.

4.5.3.10.1 Guidelines to follow when naming a table

- Use a **fully-qualified** table name (for example, `CREATE TABLE {database_name}.` ↪ `{table_name}`). If you do not specify the database name, TiDB uses the current database in your **SQL session**. If you do not use `USE {databasename};` to specify the database in your SQL session, TiDB returns an error.
- Use meaningful table names. For example, if you need to create a user table, you can use names: `user`, `t_user`,`users`, or follow your company or organization's naming convention. If your company or organization does not have a naming convention, you can refer to the table naming convention. Do not use such table names as: `t1`, `table1`.
- Multiple words are separated by an underscore, and it is recommended that the name is no more than 32 characters.
- Create a separate `DATABASE` for tables of different business modules and add comments accordingly.

4.5.3.10.2 Guidelines to follow when defining columns

- Check the data types supported by columns and organize your data according to the data type restrictions. Select the appropriate type for the data you plan to store in the column.

- Check the guidelines to follow for selecting primary keys and decide whether to use primary key columns.
- Check the guidelines to follow for selecting clustered indexes and decide whether to specify **clustered indexes**.
- Check adding column constraints and decide whether to add constraints to the columns.
- Use meaningful column names. It is recommended that you follow your company or organization's table naming convention. If your company or organization does not have a corresponding naming convention, refer to the column naming convention.

4.5.3.10.3 Guidelines to follow when selecting primary key

- Define a **primary key** or **unique index** within the table.
- Try to select meaningful **columns** as **primary keys**.
- For performance reasons, try to avoid storing extra-wide tables. It is not recommended that the number of table fields is over `60` and that the total data size of a single row is over `64K`. It is recommended to split fields with too much data length to another table.
- It is not recommended to use complex data types.
- For the fields to be joined, ensure that the data types are consistent and avoid implicit conversion.
- Avoid defining **primary keys** on a single monotonic data column. If you use a single monotonic data column (for example, a column with the `AUTO_INCREMENT` attribute) to define the **primary key**, it might impact the write performance. If possible, use `AUTO_RANDOM` instead of `AUTO_INCREMENT`, which discards the continuous and incremental attribute of the primary key.
- If you really need to create an index on a single monotonic data column at write-intensive scenarios, instead of defining this monotonic data column as the **primary key**, you can use `AUTO_RANDOM` to create the **primary key** for that table, or use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` to shard `_tidb_rowid`.

4.5.3.10.4 Guidelines to follow when selecting clustered index

- Follow guidelines for selecting primary key to build **clustered indexes**.
- Compared to tables with non-clustered indexes, tables with clustered indexes offer greater performance and throughput advantages in the following scenarios:
  - When data is inserted, the clustered index reduces one write of the index data from the network.
  - When a query with an equivalent condition only involves the primary key, the clustered index reduces one read of index data from the network.
  - When a query with a range condition only involves the primary key, the clustered index reduces multiple reads of index data from the network.
  - When a query with an equivalent or range condition only involves the primary key prefix, the clustered index reduces multiple reads of index data from the network.

- On the other hand, tables with clustered indexes might have the following issues:
  - There might be write hotspot issues when you insert a large number of primary keys with close values. Follow the guidelines to follow when selecting primary key.
  - The table data takes up more storage space if the data type of the primary key is larger than 64 bits, especially when there are multiple secondary indexes.
- To control the default behavior of whether to use clustered indexes, you can explicitly specify whether to use clustered indexes instead of using the system variable `@@global.tidb_enable_clustered_index` and the configuration `alter-primary-key`.

4.5.3.10.5 Guidelines to follow when executing the `CREATE TABLE` statement

- It is not recommended to use a client-side Driver or ORM to perform database schema changes. It is recommended to use a MySQL client or use a GUI client to perform database schema changes. In this document, the **MySQL client** is used to pass in SQL files to perform database schema changes in most scenarios.
- Follow the SQL development specification for creating and deleting tables. It is recommended to wrap the build and delete statements inside the business application to add judgment logic.

4.5.3.11 One more step

Note that all the tables that have been created in this document do not contain secondary indexes. For a guide to add secondary indexes, refer to Creating Secondary Indexes.

4.5.4 Create a Secondary Index

This document describes how to create a secondary index using SQL and various programming languages and lists the rules of index creation. In this document, the Bookshop application is taken as an example to walk you through the steps of secondary index creation.

4.5.4.1 Before you start

Before creating a secondary index, do the following:

- Build a TiDB Cluster in TiDB Cloud (Serverless Tier).
- Read Schema Design Overview.
- Create a Database.
- Create a Table.

4.5.4.2 What is secondary index

A secondary index is a logical object in a TiDB cluster. You can simply regard it as a sorting type of data that TiDB uses to improve the query performance. In TiDB, creating a secondary index is an online operation, which does not block any data read and write operations on a table. For each index, TiDB creates references for each row in a table and sorts the references by selected columns instead of by data directly.

For more information about secondary indexes, see Secondary Indexes.

In TiDB, you can either add a secondary index to an existing table or create a secondary index when creating a new table.

4.5.4.3 Add a secondary index to an existing table

To add a secondary index to an existing table, you can use the CREATE INDEX statement as follows:

```
CREATE INDEX {index_name} ON {table_name} ({column_names});
```

Parameter description:

- `{index_name}`: the name of a secondary index.
- `{table_name}`: the table name.
- `{column_names}`: the names of the columns to be indexed, separated by semi-colon commas.

4.5.4.4 Create a secondary index when creating a new table

To create a secondary index at the same time as table creation, you can add a clause containing the `KEY` keyword to the end of the CREATE TABLE statement:

```
KEY `{index_name}` (`{column_names}`)
```

Parameter description:

- `{index_name}`: the name of a secondary index.
- `{column_names}`: the names of the columns to be indexed, separated by semi-colon commas.

4.5.4.5 Rules in secondary index creation

See Best Practices for Indexing.

4.5.4.6 Example

Suppose you want the `bookshop` application to support **searching for all books published in a given year**.

The fields in the `books` table are as follows:

Field name	Type	Field description
id	bigint(20)	Unique ID of the book
title	varchar(100)	Book title
type	enum	Types of books (for example, magazines, animations, and teaching aids)
stock	bigint(20)	Stock
price	decimal(15,2)	Price
published_at	datetime	Date of publishing

The `books` table is created using the following SQL statement:

```
CREATE TABLE `bookshop`.`books` (
  `id` bigint(20) AUTO_RANDOM NOT NULL,
  `title` varchar(100) NOT NULL,
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports') NOT NULL,
  `published_at` datetime NOT NULL,
  `stock` int(11) DEFAULT '0',
  `price` decimal(15,2) DEFAULT '0.0',
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

To support the searching by year feature, you need to write a SQL statement to **search for all books published in a given year**. Taking 2022 as an example, write a SQL statement as follows:

```
SELECT * FROM `bookshop`.`books` WHERE `published_at` >= '2022-01-01
    ↪ 00:00:00' AND `published_at` < '2023-01-01 00:00:00';
```

To check the execution plan of the SQL statement, you can use the `EXPLAIN` statement.

```
EXPLAIN SELECT * FROM `bookshop`.`books` WHERE `published_at` >= '
    ↪ 2022-01-01 00:00:00' AND `published_at` < '2023-01-01 00:00:00';
```

The following is an example output of the execution plan:

```
+-------------------------+----------+-----------+---------------+-----------------------
    ↪
| id                      | estRows  | task      | access object | operator info
    ↪
    ↪ |
+-------------------------+----------+-----------+---------------+-----------------------
    ↪
| TableReader_7           | 346.32   | root      |               | data:Selection_6
    ↪
    ↪ |
```

```
|  └─Selection_6         | 346.32  | cop[tikv] |            | ge(bookshop.
   ↪ books.published_at, 2022-01-01 00:00:00.000000), lt(bookshop.books.
   ↪ published_at, 2023-01-01 00:00:00.000000) |
|    └─TableFullScan_5   | 20000.00 | cop[tikv] | table:books | keep order:
   ↪ false
   ↪
   ↪ |
+------------------------+----------+-----------+--------------+--------------------
   ↪
3 rows in set (0.61 sec)
```

In the example output, **TableFullScan** is displayed in the `id` column, which means that TiDB is ready to do a full table scan on the `books` table in this query. In the case of a large amount of data, however, a full table scan might be quite slow and cause a fatal impact.

To avoid such impact, you can add an index for the `published_at` column to the `books` table as follows:

```
CREATE INDEX `idx_book_published_at` ON `bookshop`.`books` (`bookshop`.`
   ↪ books`.`published_at`);
```

After adding the index, execute the `EXPLAIN` statement again to check the execution plan.

The following is an example output.

```
+------------------------------+---------+-----------+------------------------------
   ↪
| id                           | estRows | task    | access object
   ↪                                      | operator info
   ↪                                               |
+------------------------------+---------+-----------+------------------------------
   ↪
| IndexLookUp_10               | 146.01 | root     |
   ↪                                                 |
   ↪                                                                  |
|  └─IndexRangeScan_8(Build)  | 146.01 | cop[tikv] | table:books, index:
   ↪ idx_book_published_at(published_at) | range:[2022-01-01
   ↪ 00:00:00,2023-01-01 00:00:00), keep order:false |
|  └─TableRowIDScan_9(Probe)  | 146.01 | cop[tikv] | table:books
   ↪                                      | keep order:false
   ↪                                            |
+------------------------------+---------+-----------+------------------------------
   ↪
3 rows in set (0.18 sec)
```

In the output, **IndexRangeScan** is displayed instead of **TableFullScan**, which means that TiDB is ready to use indexes to do this query.

The words such as **TableFullScan** and **IndexRangeScan** in the execution plan are operators in TiDB. For more information about execution plans and operators, see TiDB Query Execution Plan Overview.

The execution plan does not return the same operator every time. This is because TiDB uses a **Cost-Based Optimization (CBO)** approach, in which an execution plan depends on both rules and data distribution. For more information about TiDB SQL performance, see SQL Tuning Overview.

> **Note:**
>
> TiDB also supports explicit use of indexes when querying, and you can use Optimizer Hints or SQL Plan Management (SPM) to artificially control the use of indexes. But if you do not know well about indexes, optimizer hints, or SPM, **DO NOT** use this feature to avoid any unexpected results.

To query the indexes on a table, you can use the SHOW INDEXES statement:

```
SHOW INDEXES FROM `bookshop`.`books`;
```

The following is an example output:

```
+-------+------------+----------------------+--------------+--------------+-----------+
   ↪
| Table | Non_unique | Key_name             | Seq_in_index | Column_name |
   ↪ Collation | Cardinality | Sub_part | Packed | Null | Index_type |
   ↪ Comment | Index_comment | Visible | Expression | Clustered |
+-------+------------+----------------------+--------------+--------------+-----------+
   ↪
| books |          0 | PRIMARY              |            1 | id          | A
   ↪         |           0 |     NULL | NULL |      | BTREE     |         |
   ↪               | YES     | NULL       | YES       |
| books |          1 | idx_book_published_at |            1 | published_at | A
   ↪       |           0 |     NULL | NULL |      | BTREE     |         |
   ↪               | YES     | NULL       | NO        |
+-------+------------+----------------------+--------------+--------------+-----------+
   ↪
2 rows in set (1.63 sec)
```

4.5.4.7 Next step

After creating a database and adding tables and secondary indexes to it, you can start adding the data write and read features to your application.

4.6 Write Data

4.6.1 Insert Data

This document describes how to insert data into TiDB by using the SQL language with different programming languages.

4.6.1.1 Before you start

Before reading this document, you need to prepare the following:

- Build a TiDB Cluster in TiDB Cloud (Serverless Tier).
- Read Schema Design Overview, Create a Database, Create a Table, and Create Secondary Indexes

4.6.1.2 Insert rows

There are two ways to insert multiple rows of data. For example, if you need to insert **3** players' data.

- A **multi-line insertion statement**:

```
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (1, 1000, 1), (2,
    ↪  230, 2), (3, 300, 5);
```

- Multiple **single-line insertion statements**:

```
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (1, 1000, 1);
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (2, 230, 2);
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (3, 300, 5);
```

Generally the `multi-line insertion statement` runs faster than the multiple `single ↪ -line insertion statements`.

```
CREATE TABLE `player` (`id` INT, `coins` INT, `goods` INT);
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (1, 1000, 1), (2, 230,
    ↪  2);
```

For more information on how to use this SQL, see Connecting to a TiDB Cluster and follow the steps to enter the SQL statement after connecting to a TiDB cluster using a client.

```java
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource
try (Connection connection = ds.getConnection()) {
    connection.setAutoCommit(false);

    PreparedStatement pstmt = connection.prepareStatement("INSERT INTO
        ↪ player (id, coins, goods) VALUES (?, ?, ?)"))

    // first player
    pstmt.setInt(1, 1);
    pstmt.setInt(2, 1000);
    pstmt.setInt(3, 1);
    pstmt.addBatch();

    // second player
    pstmt.setInt(1, 2);
    pstmt.setInt(2, 230);
    pstmt.setInt(3, 2);
    pstmt.addBatch();

    pstmt.executeBatch();
    connection.commit();
} catch (SQLException e) {
    e.printStackTrace();
}
```

Due to the default MySQL JDBC Driver settings, you need to change some parameters to get better bulk insert performance.

Parameter	Means	Recommended Scenario	Recommended Configuration
`useServerPrepStmts` ↪	Whether to use the server side to enable prepared statements	When you need to use a prepared statement more than once	`true`
`cachePrepStmts` ↪	Whether the client caches prepared statements	`useServerPrepStmts=true` 时	`true`

Parameter	Means	Recommended Scenario	Recommended Configuration
`prepStmtCacheSqlLimit` ↪	Maximum size of a prepared statement (256 characters by default)	When the prepared statement is greater than 256 characters	Configured according to the actual size of the prepared statement
`prepStmtCacheSize` ↪	Maximum number of prepared statement caches (25 by default)	When the number of prepared statements is greater than 25	Configured according to the actual number of prepared statements
`rewriteBatchedStatements` ↪	Whether to rewrite **Batched** statements	When batch operations are required	`true`
`allowMultiQueries` ↪	Support batch operations	Because a client bug requires this to be set when `rewriteBatchedStatements = true` and `useServerPrepStmts = true`	`true`

MySQL JDBC Driver also provides an integrated configuration: `useConfigs`. When it is configured with `maxPerformance`, it is equivalent to configuring a set of configurations. Taking `mysql:mysql-connector-java:8.0.28` as an example, `useConfigs=maxPerformance` contains:

```
cachePrepStmts=true
cacheCallableStmts=true
cacheServerConfiguration=true
useLocalSessionState=true
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false
connectionAttributes=none
```

```
useInformationSchema=true
```

You can check `mysql-connector-java-{version}.jar!/com/mysql/cj/configurations/maxPerformance.properties` to get the configurations contained in `useConfigs=maxPerformance` for the corresponding version of MySQL JDBC Driver.

The following is a typical scenario of JDBC connection string configurations. In this example, Host: `127.0.0.1`, Port: `4000`, User name: `root`, Password: null, Default database: `test`:

```
jdbc:mysql://127.0.0.1:4000/test?user=root&useConfigs=maxPerformance&useServerPrepStmts=true&prepStmtCacheSqlLimit=2048&prepStmtCacheSize=256&rewriteBatchedStatements=true&allowMultiQueries=true
```

For complete examples in Java, see:

- Build a simple CRUD application with TiDB and Java - using JDBC
- Build a simple CRUD application with TiDB and Java - using Hibernate
- Build the TiDB application using Spring Boot

```
package main

import (
    "database/sql"
    "strings"

    _ "github.com/go-sql-driver/mysql"
)

type Player struct {
    ID    string
    Coins int
    Goods int
}

func bulkInsertPlayers(db *sql.DB, players []Player, batchSize int) error {
    tx, err := db.Begin()
    if err != nil {
        return err
    }

    stmt, err := tx.Prepare(buildBulkInsertSQL(batchSize))
    if err != nil {
        return err
    }
```

```
    defer stmt.Close()

    for len(players) > batchSize {
        if _, err := stmt.Exec(playerToArgs(players[:batchSize])...); err !=
            ↪ nil {
            tx.Rollback()
            return err
        }

        players = players[batchSize:]
    }

    if len(players) != 0 {
        if _, err := tx.Exec(buildBulkInsertSQL(len(players)), playerToArgs(
            ↪ players)...); err != nil {
            tx.Rollback()
            return err
        }
    }

    if err := tx.Commit(); err != nil {
        tx.Rollback()
        return err
    }

    return nil
}

func playerToArgs(players []Player) []interface{} {
    var args []interface{}
    for _, player := range players {
        args = append(args, player.ID, player.Coins, player.Goods)
    }
    return args
}

func buildBulkInsertSQL(amount int) string {
    return "INSERT INTO player (id, coins, goods) VALUES (?, ?, ?)" +
        ↪ strings.Repeat(",(?,?,?)", amount-1)
}
```

For complete examples in Golang, see:

- Use go-sql-driver/mysql to build a simple CRUD application with TiDB and Golang

- Use GORM to build a simple CRUD application with TiDB and Golang

```
import MySQLdb
connection = MySQLdb.connect(
    host="127.0.0.1",
    port=4000,
    user="root",
    password="",
    database="bookshop",
    autocommit=True
)

with get_connection(autocommit=True) as connection:
    with connection.cursor() as cur:
        player_list = random_player(1919)
        for idx in range(0, len(player_list), 114):
            cur.executemany("INSERT INTO player (id, coins, goods) VALUES (%s
                ↪ , %s, %s)", player_list[idx:idx + 114])
```

For complete examples in Python, see:

- Use PyMySQL to build a simple CRUD application with TiDB and Python
- Use mysqlclient to build a simple CRUD application with TiDB and Python
- Use mysql-connector-python to build a simple CRUD application with TiDB and Python
- Use SQLAlchemy to build a simple CRUD application with TiDB and Python
- Use peewee to build a simple CRUD application with TiDB and Python

4.6.1.3 Bulk-Insert

If you need to quickly import a large amount of data into a TiDB cluster, it is recommended that you use a range of tools provided by **PingCAP** for data migration. Using the `INSERT` statement is not the best way, because it is not efficient and requires to handle exceptions and other issues on your own.

The following are the recommended tools for bulk-insert:

- Data export: Dumpling. You can export MySQL or TiDB data to local or Amazon S3.

- Data import: TiDB Lightning. You can import **Dumpling** exported data, a **CSV** file, or Migrate Data from Amazon Aurora to TiDB. It also supports reading data from a local disk or Amazon S3 cloud disk.

- Data replication: TiDB Data Migration. You can replicate MySQL, MariaDB, and Amazon Aurora databases to TiDB. It also supports merging and migrating the sharded instances and tables from the source databases.
- Data backup and restore: Backup & Restore (BR). Compared to **Dumpling**, **BR** is more suitable for ***big data*** scenario.

4.6.1.4 Avoid hotspots

When designing a table, you need to consider if there is a large number of insert operations. If so, you need to avoid hotspots during table design. See the Select primary key section and follow the Rules when selecting primary key.

For more information on how to handle hotspot issues, see Troubleshoot Hotspot Issues.

4.6.1.5 Insert data to a table with the `AUTO_RANDOM` primary key

If the primary key of the table you insert has the `AUTO_RANDOM` attribute, then by default the primary key cannot be specified. For example, in the `bookshop` database, you can see that the `id` field of the `users` table contains the `AUTO_RANDOM` attribute.

In this case, you **cannot** use SQL like the following to insert:

```
INSERT INTO `bookshop`.`users` (`id`, `balance`, `nickname`) VALUES (1,
    ↪ 0.00, 'nicky');
```

An error will occur:

```
ERROR 8216 (HY000): Invalid auto random: Explicit insertion on auto_random
    ↪ column is disabled. Try to set @@allow_auto_random_explicit_insert =
    ↪ true.
```

It is not recommended to manually specify the `AUTO_RANDOM` column during insertion time.

There are two solutions to handle this error:

- (Recommended) Remove this column from the insert statement and use the `AUTO_RANDOM` value that TiDB initialized for you. This fits the semantics of `AUTO_RANDOM`.

  ```
  INSERT INTO `bookshop`.`users` (`balance`, `nickname`) VALUES (0.00, '
      ↪ nicky');
  ```

- If you are sure that you ***must*** specify this column, then you can use the `SET` statement to allow the column of `AUTO_RANDOM` to be specified during insertion time by changing the user variable.

  ```
  SET @@allow_auto_random_explicit_insert = true;
  INSERT INTO `bookshop`.`users` (`id`, `balance`, `nickname`) VALUES
      ↪ (1, 0.00, 'nicky');
  ```

4.6.1.6 Use HTAP

In TiDB, HTAP capabilities save you from performing additional operations when inserting data. There is no additional insertion logic. TiDB automatically guarantees data consistency. All you need to do is turn on column-oriented replica synchronization after creating the table, and use the column-oriented replica to speed up your queries directly.

4.6.2 Update Data

This document describes how to use the following SQL statements to update the data in TiDB with various programming languages:

- UPDATE: Used to modify the data in the specified table.
- INSERT ON DUPLICATE KEY UPDATE: Used to insert data and update this data if there is a primary key or unique key conflict. It is **not recommended** to use this statement if there are multiple unique keys (including primary keys). This is because this statement updates the data once it detects any unique key (including primary key) conflict. When there are more than one row conflicts, it updates only one row.

4.6.2.1 Before you start

Before reading this document, you need to prepare the following:

- Build a TiDB Cluster in TiDB Cloud (Serverless Tier).
- Read Schema Design Overview, Create a Database, Create a Table, and Create Secondary Indexes.
- If you want to `UPDATE` data, you need to insert data first.

4.6.2.2 Use `UPDATE`

To update an existing row in a table, you need to use an `UPDATE` statement with a `WHERE` clause to filter the columns for updating.

> **Note:**
>
> If you need to update a large number of rows, for example, more than ten thousand, it is recommended that you do ***NOT*** doing a complete update at once, but rather updating a portion at a time iteratively until all rows are updated. You can write scripts or programs to loop this operation. See Bulk-update for details.

4.6.2.2.1 `UPDATE` SQL syntax

In SQL, the `UPDATE` statement is generally in the following form:

```
UPDATE {table} SET {update_column} = {update_value} WHERE {filter_column} =
    ↪ {filter_value}
```

Parameter Name	Description
`{table}`	Table Name
`{update_column}`	Column names to be updated
`{update_value}`	Column values to be updated
`{filter_column}`	Column names matching filters
`{filter_value}`	Column values matching filters

For detailed information, see UPDATE syntax.

4.6.2.2.2 `UPDATE` best practices

The following are some best practices for updating data:

- Always specify the `WHERE` clause in the `UPDATE` statement. If the `UPDATE` statement does not have a `WHERE` clause, TiDB will update ***ALL ROWS*** in the table.
- Use bulk-update when you need to update a large number of rows (for example, more than ten thousand). Because TiDB limits the size of a single transaction (txn-total-size-limit, 100 MB by default), too many data updates at once will result in holding locks for too long (pessimistic transactions) or cause conflicts (optimistic transactions).

4.6.2.2.3 `UPDATE` example

Suppose an author changes her name to **Helen Haruki**. You need to change the authors table. Assume that her unique `id` is **1**, and the filter should be: `id = 1`.

```
UPDATE `authors` SET `name` = "Helen Haruki" WHERE `id` = 1;
```

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource
try (Connection connection = ds.getConnection()) {
    PreparedStatement pstmt = connection.prepareStatement("UPDATE `authors`
        ↪ SET `name` = ? WHERE `id` = ?");
    pstmt.setString(1, "Helen Haruki");
    pstmt.setInt(2, 1);
    pstmt.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

4.6.2.3 Use `INSERT ON DUPLICATE KEY UPDATE`

If you need to insert new data into a table, but if there are unique key (a primary key is also a unique key) conflicts, the first conflicted record will be updated. You can use `INSERT ... ON DUPLICATE KEY UPDATE ...` statement to insert or update.

4.6.2.3.1 `INSERT ON DUPLICATE KEY UPDATE` SQL Syntax

In SQL, the `INSERT ... ON DUPLICATE KEY UPDATE ...` statement is generally in the following form:

```
INSERT INTO {table} ({columns}) VALUES ({values})
    ON DUPLICATE KEY UPDATE {update_column} = {update_value};
```

Parameter Name	Description
{table}	Table name
{columns}	Column names to be inserted
{values}	Column values to be inserted
{update_column}	Column names to be updated
{update_value}	Column values to be updated

4.6.2.3.2 `INSERT ON DUPLICATE KEY UPDATE` best practices

- Use `INSERT ON DUPLICATE KEY UPDATE` only for a table with one unique key. This statement updates the data if any ***UNIQUE KEY*** (including the primary key) conflicts are detected. If there are more than one row of conflicts, only one row will be updated. Therefore, it is not recommended to use the `INSERT ON DUPLICATE KEY UPDATE` statement in tables with multiple unique keys unless you can guarantee that there is only one row of conflict.
- Use this statement when you create data or update data.

4.6.2.3.3 `INSERT ON DUPLICATE KEY UPDATE` example

For example, you need to update the ratings table to include the user's ratings for the book. If the user has not yet rated the book, a new rating will be created. If the user has already rated it, his previous rating will be updated.

In the following example, the primary key is the joint primary keys of `book_id` and `user_id`. A user `user_id = 1` gives a rating of `5` to a book `book_id = 1000`.

```
INSERT INTO `ratings`
    (`book_id`, `user_id`, `score`, `rated_at`)
VALUES
    (1000, 1, 5, NOW())
ON DUPLICATE KEY UPDATE `score` = 5, `rated_at` = NOW();
```

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource

try (Connection connection = ds.getConnection()) {
    PreparedStatement p = connection.prepareStatement("INSERT INTO `ratings`
        ↪ (`book_id`, `user_id`, `score`, `rated_at`)
VALUES (?, ?, ?, NOW()) ON DUPLICATE KEY UPDATE `score` = ?, `rated_at` =
    ↪ NOW()");
    p.setInt(1, 1000);
    p.setInt(2, 1);
    p.setInt(3, 5);
    p.setInt(4, 5);
    p.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

4.6.2.4 Bulk-update

When you need to update multiple rows of data in a table, you can use `INSERT ON DUPLICATE KEY UPDATE` with the `WHERE` clause to filter the data that needs to be updated.

However, if you need to update a large number of rows (for example, more than ten thousand), it is recommended that you update the data iteratively, that is, updating only a portion of the data at each iteration until the update is complete. This is because TiDB limits the size of a single transaction (txn-total-size-limit, 100 MB by default). Too many data updates at once will result in holding locks for too long (pessimistic transactions, or causing conflicts (optimistic transactions). You can use a loop in your program or script to complete the operation.

This section provides examples of writing scripts to handle iterative updates. This example shows how a combination of `SELECT` and `UPDATE` should be done to complete a bulk-update.

4.6.2.4.1 Write bulk-update loop

First, you should write a `SELECT` query in a loop of your application or script. The return value of this query can be used as the primary key for the rows that need to be updated. Note that when defining this `SELECT` query, you need to use the `WHERE` clause to filter the rows that need to be updated.

4.6.2.4.2 Example

Suppose that you have had a lot of book ratings from users on your `bookshop` website over the past year, but the original design of a 5-point scale has resulted in a lack of differentiation

in book ratings. Most books are rated `3`. You decide to switch from a 5-point scale to a 10-point scale to differentiate ratings.

You need to multiply by `2` the data in the `ratings` table from the previous 5-point scale, and add a new column to the ratings table to indicate whether the rows have been updated. Using this column, you can filter out rows that have been updated in `SELECT`, which will prevent the script from crashing and updating the rows multiple times, resulting in unreasonable data.

For example, you create a column named `ten_point` with the data type BOOL as an identifier of whether it is a 10-point scale:

```
ALTER TABLE `bookshop`.`ratings` ADD COLUMN `ten_point` BOOL NOT NULL
    ↪ DEFAULT FALSE;
```

> **Note:**
>
> This bulk-update application uses the **DDL** statements to make schema changes to the data tables. All DDL change operations for TiDB are executed online. For more information, see ADD COLUMN.

In Golang, a bulk-update application is similar to the following:

```
package main

import (
    "database/sql"
    "fmt"
    _ "github.com/go-sql-driver/mysql"
    "strings"
    "time"
)

func main() {
    db, err := sql.Open("mysql", "root:@tcp(127.0.0.1:4000)/bookshop")
    if err != nil {
        panic(err)
    }
    defer db.Close()

    bookID, userID := updateBatch(db, true, 0, 0)
    fmt.Println("first time batch update success")
    for {
        time.Sleep(time.Second)
```

```
        bookID, userID = updateBatch(db, false, bookID, userID)
        fmt.Printf("batch update success, [bookID] %d, [userID] %d\n", bookID
            ↪ , userID)
    }
}

// updateBatch select at most 1000 lines data to update score
func updateBatch(db *sql.DB, firstTime bool, lastBookID, lastUserID int64) (
    ↪ bookID, userID int64) {
    // select at most 1000 primary keys in five-point scale data
    var err error
    var rows *sql.Rows

    if firstTime {
        rows, err = db.Query("SELECT `book_id`, `user_id` FROM `bookshop`.`
            ↪ ratings` " +
            "WHERE `ten_point` != true ORDER BY `book_id`, `user_id` LIMIT
                ↪ 1000")
    } else {
        rows, err = db.Query("SELECT `book_id`, `user_id` FROM `bookshop`.`
            ↪ ratings` "+
            "WHERE `ten_point` != true AND `book_id` > ? AND `user_id` > ? "+
            "ORDER BY `book_id`, `user_id` LIMIT 1000", lastBookID,
                ↪ lastUserID)
    }

    if err != nil || rows == nil {
        panic(fmt.Errorf("error occurred or rows nil: %+v", err))
    }

    // joint all id with a list
    var idList []interface{}
    for rows.Next() {
        var tempBookID, tempUserID int64
        if err := rows.Scan(&tempBookID, &tempUserID); err != nil {
            panic(err)
        }
        idList = append(idList, tempBookID, tempUserID)
        bookID, userID = tempBookID, tempUserID
    }

    bulkUpdateSql := fmt.Sprintf("UPDATE `bookshop`.`ratings` SET `ten_point
        ↪ ` = true, "+
        "`score` = `score` * 2 WHERE (`book_id`, `user_id`) IN (%s)",
            ↪ placeHolder(len(idList)))
```

```
    db.Exec(bulkUpdateSql, idList...)

    return bookID, userID
}

// placeHolder format SQL place holder
func placeHolder(n int) string {
    holderList := make([]string, n/2, n/2)
    for i := range holderList {
        holderList[i] = "(?,?)"
    }
    return strings.Join(holderList, ",")
}
```

In each iteration, `SELECT` queries in order of the primary key. It selects primary key values for up to 1000 rows that have not been updated to the 10-point scale (`ten_point` is `false`). Each `SELECT` statement selects primary keys larger than the largest of the previous `SELECT` results to prevent duplication. Then, it uses bulk-update, multiples its `score` column by 2, and sets `ten_point` to `true`. The purpose of updating `ten_point` is to prevent the update application from repeatedly updating the same row in case of restart after crashing, which can cause data corruption. `time.Sleep(time.Second)` in each loop makes the update application pause for 1 second to prevent the update application from consuming too many hardware resources.

In Java (JDBC), a bulk-update application might be similar to the following:

Code:

```
package com.pingcap.bulkUpdate;

import com.mysql.cj.jdbc.MysqlDataSource;

import java.sql.*;
import java.util.LinkedList;
import java.util.List;
import java.util.concurrent.TimeUnit;

public class BatchUpdateExample {
    static class UpdateID {
        private Long bookID;
        private Long userID;

        public UpdateID(Long bookID, Long userID) {
            this.bookID = bookID;
            this.userID = userID;
        }
```

```
    public Long getBookID() {
        return bookID;
    }

    public void setBookID(Long bookID) {
        this.bookID = bookID;
    }

    public Long getUserID() {
        return userID;
    }

    public void setUserID(Long userID) {
        this.userID = userID;
    }

    @Override
    public String toString() {
        return "[bookID] " + bookID + ", [userID] " + userID ;
    }
}

public static void main(String[] args) throws InterruptedException {
    // Configure the example database connection.

    // Create a mysql data source instance.
    MysqlDataSource mysqlDataSource = new MysqlDataSource();

    // Set server name, port, database name, username and password.
    mysqlDataSource.setServerName("localhost");
    mysqlDataSource.setPortNumber(4000);
    mysqlDataSource.setDatabaseName("bookshop");
    mysqlDataSource.setUser("root");
    mysqlDataSource.setPassword("");

    UpdateID lastID = batchUpdate(mysqlDataSource, null);

    System.out.println("first time batch update success");
    while (true) {
        TimeUnit.SECONDS.sleep(1);
        lastID = batchUpdate(mysqlDataSource, lastID);
        System.out.println("batch update success, [lastID] " + lastID);
    }
}
```

```
public static UpdateID batchUpdate (MysqlDataSource ds, UpdateID lastID)
    ↪ {
    try (Connection connection = ds.getConnection()) {
        UpdateID updateID = null;

        PreparedStatement selectPs;

        if (lastID == null) {
            selectPs = connection.prepareStatement(
                    "SELECT `book_id`, `user_id` FROM `bookshop`.`ratings`
                        ↪ " +
                    "WHERE `ten_point` != true ORDER BY `book_id`, `user_id
                        ↪ ` LIMIT 1000");
        } else {
            selectPs = connection.prepareStatement(
                    "SELECT `book_id`, `user_id` FROM `bookshop`.`ratings`
                        ↪ "+
                        "WHERE `ten_point` != true AND `book_id` > ? AND `
                            ↪ user_id` > ? "+
                        "ORDER BY `book_id`, `user_id` LIMIT 1000");

            selectPs.setLong(1, lastID.getBookID());
            selectPs.setLong(2, lastID.getUserID());
        }

        List<Long> idList = new LinkedList<>();
        ResultSet res = selectPs.executeQuery();
        while (res.next()) {
            updateID = new UpdateID(
                    res.getLong("book_id"),
                    res.getLong("user_id")
            );
            idList.add(updateID.getBookID());
            idList.add(updateID.getUserID());
        }

        if (idList.isEmpty()) {
            System.out.println("no data should update");
            return null;
        }

        String updateSQL = "UPDATE `bookshop`.`ratings` SET `ten_point` =
            ↪ true, "+
                "`score` = `score` * 2 WHERE (`book_id`, `user_id`) IN ("
                    ↪ +
```

```
                placeHolder(idList.size() / 2) + ")";
            PreparedStatement updatePs = connection.prepareStatement(
                ↪ updateSQL);
            for (int i = 0; i < idList.size(); i++) {
                updatePs.setLong(i + 1, idList.get(i));
            }
            int count = updatePs.executeUpdate();
            System.out.println("update " + count + " data");

            return updateID;
        } catch (SQLException e) {
            e.printStackTrace();
        }

        return null;
    }

    public static String placeHolder(int n) {
        StringBuilder sb = new StringBuilder();
        for (int i = 0; i < n ; i++) {
            sb.append(i == 0 ? "(?,?)" : ",(?,?)");
        }

        return sb.toString();
    }
}
```

- `hibernate.cfg.xml` configuration:

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
    <session-factory>

        <!-- Database connection settings -->
        <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
            ↪ Driver</property>
        <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
            ↪ /property>
        <property name="hibernate.connection.url">jdbc:mysql://localhost:4000
            ↪ /movie</property>
        <property name="hibernate.connection.username">root</property>
```

```
        <property name="hibernate.connection.password"></property>
        <property name="hibernate.connection.autocommit">false</property>
        <property name="hibernate.jdbc.batch_size">20</property>

        <!-- Optional: Show SQL output for debugging -->
        <property name="hibernate.show_sql">true</property>
        <property name="hibernate.format_sql">true</property>
    </session-factory>
</hibernate-configuration>
```

In each iteration, `SELECT` queries in order of the primary key. It selects primary key values for up to `1000` rows that have not been updated to the 10-point scale (`ten_point` is `false`). Each `SELECT` statement selects primary keys larger than the largest of the previous `SELECT` results to prevent duplication. Then, it uses bulk-update, multiples its `score` column by `2`, and sets `ten_point` to `true`. The purpose of updating `ten_point` is to prevent the update application from repeatedly updating the same row in case of restart after crashing, which can cause data corruption. `TimeUnit.SECONDS.sleep(1);` in each loop makes the update application pause for 1 second to prevent the update application from consuming too many hardware resources.

4.6.3 Delete Data

This document describes how to use the DELETE SQL statement to delete the data in TiDB.

4.6.3.1 Before you start

Before reading this document, you need to prepare the following:

- Build a TiDB Cluster in TiDB Cloud (Serverless Tier)
- Read Schema Design Overview, Create a Database, Create a Table, and Create Secondary Indexes
- Insert Data

4.6.3.2 SQL syntax

The `DELETE` statement is generally in the following form:

```
DELETE FROM {table} WHERE {filter}
```

Parameter Name	Description
`{table}`	Table name
`{filter}`	Matching conditions of the filter

This example only shows a simple use case of `DELETE`. For detailed information, see DELETE syntax.

4.6.3.3 Best practices

The following are some best practices to follow when you delete data:

- Always specify the `WHERE` clause in the `DELETE` statement. If the `WHERE` clause is not specified, TiDB will delete ***ALL ROWS*** in the table.

- Use bulk-delete when you delete a large number of rows (for example, more than ten thousand), because TiDB limits the size of a single transaction (txn-total-size-limit, 100 MB by default).

- If you delete all the data in a table, do not use the `DELETE` statement. Instead, use the `TRUNCATE` statement.
- For performance considerations, see Performance Considerations.
- In scenarios where large batches of data need to be deleted, Non-Transactional bulk-delete can significantly improve performance. However, this will lose the transactional of the deletion and therefore **CANNOT** be rolled back. Make sure that you select the correct operation.

4.6.3.4 Example

Suppose you find an application error within a specific time period and you need to delete all the data for the ratings within this period, for example, from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`. In this case, you can use the `SELECT` statement to check the number of records to be deleted.

```
SELECT COUNT(*) FROM `ratings` WHERE `rated_at` >= "2022-04-15 00:00:00"
    ↪ AND `rated_at` <= "2022-04-15 00:15:00";
```

If more than 10,000 records are returned, use Bulk-Delete to delete them.

If fewer than 10,000 records are returned, use the following example to delete them.

In SQL, the example is as follows:

```
DELETE FROM `ratings` WHERE `rated_at` >= "2022-04-15 00:00:00" AND `
    ↪ rated_at` <= "2022-04-15 00:15:00";
```

In Java, the example is as follows:

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource

try (Connection connection = ds.getConnection()) {
    String sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at` >= ? AND
        ↪  `rated_at` <= ?";
```

```
    PreparedStatement preparedStatement = connection.prepareStatement(sql);
    Calendar calendar = Calendar.getInstance();
    calendar.set(Calendar.MILLISECOND, 0);

    calendar.set(2022, Calendar.APRIL, 15, 0, 0, 0);
    preparedStatement.setTimestamp(1, new Timestamp(calendar.getTimeInMillis
        ↪ ()));

    calendar.set(2022, Calendar.APRIL, 15, 0, 15, 0);
    preparedStatement.setTimestamp(2, new Timestamp(calendar.getTimeInMillis
        ↪ ()));

    preparedStatement.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

In Golang, the example is as follows:

```
package main

import (
    "database/sql"
    "fmt"
    "time"

    _ "github.com/go-sql-driver/mysql"
)

func main() {
    db, err := sql.Open("mysql", "root:@tcp(127.0.0.1:4000)/bookshop")
    if err != nil {
        panic(err)
    }
    defer db.Close()

    startTime := time.Date(2022, 04, 15, 0, 0, 0, 0, time.UTC)
    endTime := time.Date(2022, 04, 15, 0, 15, 0, 0, time.UTC)

    bulkUpdateSql := fmt.Sprintf("DELETE FROM `bookshop`.`ratings` WHERE `
        ↪ rated_at` >= ? AND `rated_at` <= ?")
    result, err := db.Exec(bulkUpdateSql, startTime, endTime)
    if err != nil {
        panic(err)
    }
```

```
    _, err = result.RowsAffected()
    if err != nil {
        panic(err)
    }
}
```

In Python, the example is as follows:

```
import MySQLdb
import datetime
import time
connection = MySQLdb.connect(
    host="127.0.0.1",
    port=4000,
    user="root",
    password="",
    database="bookshop",
    autocommit=True
)
with connection:
    with connection.cursor() as cursor:
        start_time = datetime.datetime(2022, 4, 15)
        end_time = datetime.datetime(2022, 4, 15, 0, 15)
        delete_sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at` >= %s
            ↪ AND `rated_at` <= %s"
        affect_rows = cursor.execute(delete_sql, (start_time, end_time))
        print(f'delete {affect_rows} data')
```

The `rated_at` field is of the `DATETIME` type in Date and Time Types. You can assume that it is stored as a literal quantity in TiDB, independent of the time zone. On the other hand, the `TIMESTAMP` type stores a timestamp and thus displays a different time string in a different time zone.

> **Note:**
>
> Like MySQL, the `TIMESTAMP` data type is affected by the year 2038 problem. It is recommended to use the `DATETIME` type if you store values larger than 2038.

4.6.3.5 Performance considerations

4.6.3.5.1 TiDB GC mechanism

TiDB does not delete the data immediately after you run the `DELETE` statement. Instead, it marks the data as ready for deletion. Then it waits for TiDB GC (Garbage Collection) to clean up the outdated data. Therefore, the `DELETE` statement ***DOES NOT*** immediately reduce disk usage.

GC is triggered once every 10 minutes by default. Each GC calculates a time point called **safe_point**. Any data earlier than this time point will not be used again, so TiDB can safely clean it up.

For more information, see GC mechanism.

4.6.3.5.2 Update statistical information

TiDB uses statistical information to determine index selection. There is a high risk that the index is not correctly selected after a large volume of data is deleted. You can use manual collection to update the statistics. It provides the TiDB optimizer with more accurate statistical information for SQL performance optimization.

4.6.3.6 Bulk-delete

When you need to delete multiple rows of data from a table, you can choose the `DELETE` example and use the `WHERE` clause to filter the data that needs to be deleted.

However, if you need to delete a large number of rows (more than ten thousand), it is recommended that you delete the data in an iterative way, that is, deleting a portion of the data at each iteration until the deletion is completed. This is because TiDB limits the size of a single transaction (`txn-total-size-limit`, 100 MB by default). You can use loops in your programs or scripts to perform such operations.

This section provides an example of writing a script to handle an iterative delete operation that demonstrates how you should do a combination of `SELECT` and `DELETE` to complete a bulk-delete.

4.6.3.6.1 Write a bulk-delete loop

You can write a `DELETE` statement in the loop of your application or script, use the `WHERE` clause to filter data, and use `LIMIT` to constrain the number of rows to be deleted in a single statement.

4.6.3.6.2 Bulk-delete example

Suppose you find an application error within a specific time period. You need to delete all the data for the rating within this period, for example, from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`, and more than 10,000 records are written in 15 minutes. You can perform as follows.

In Java, the bulk-delete example is as follows:

```
package com.pingcap.bulkDelete;

import com.mysql.cj.jdbc.MysqlDataSource;

import java.sql.*;
import java.util.*;
import java.util.concurrent.TimeUnit;

public class BatchDeleteExample
{
    public static void main(String[] args) throws InterruptedException {
        // Configure the example database connection.

        // Create a mysql data source instance.
        MysqlDataSource mysqlDataSource = new MysqlDataSource();

        // Set server name, port, database name, username and password.
        mysqlDataSource.setServerName("localhost");
        mysqlDataSource.setPortNumber(4000);
        mysqlDataSource.setDatabaseName("bookshop");
        mysqlDataSource.setUser("root");
        mysqlDataSource.setPassword("");

        while (true) {
            batchDelete(mysqlDataSource);
            TimeUnit.SECONDS.sleep(1);
        }
    }

    public static void batchDelete (MysqlDataSource ds) {
        try (Connection connection = ds.getConnection()) {
            String sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at`
                ↪ >= ? AND `rated_at` <= ? LIMIT 1000";
            PreparedStatement preparedStatement = connection.prepareStatement
                ↪ (sql);
            Calendar calendar = Calendar.getInstance();
            calendar.set(Calendar.MILLISECOND, 0);

            calendar.set(2022, Calendar.APRIL, 15, 0, 0, 0);
            preparedStatement.setTimestamp(1, new Timestamp(calendar.
                ↪ getTimeInMillis()));

            calendar.set(2022, Calendar.APRIL, 15, 0, 15, 0);
            preparedStatement.setTimestamp(2, new Timestamp(calendar.
```

```
                ↪ getTimeInMillis()));

            int count = preparedStatement.executeUpdate();
            System.out.println("delete " + count + " data");
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

In each iteration, `DELETE` deletes up to 1000 rows from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`.

In Golang, the bulk-delete example is as follows:

```
package main

import (
    "database/sql"
    "fmt"
    "time"

    _ "github.com/go-sql-driver/mysql"
)

func main() {
    db, err := sql.Open("mysql", "root:@tcp(127.0.0.1:4000)/bookshop")
    if err != nil {
        panic(err)
    }
    defer db.Close()

    affectedRows := int64(-1)
    startTime := time.Date(2022, 04, 15, 0, 0, 0, 0, time.UTC)
    endTime := time.Date(2022, 04, 15, 0, 15, 0, 0, time.UTC)

    for affectedRows != 0 {
        affectedRows, err = deleteBatch(db, startTime, endTime)
        if err != nil {
            panic(err)
        }
    }
}

// deleteBatch delete at most 1000 lines per batch
func deleteBatch(db *sql.DB, startTime, endTime time.Time) (int64, error) {
```

```
    bulkUpdateSql := fmt.Sprintf("DELETE FROM `bookshop`.`ratings` WHERE `
        ↪ rated_at` >= ? AND `rated_at` <= ? LIMIT 1000")
    result, err := db.Exec(bulkUpdateSql, startTime, endTime)
    if err != nil {
        return -1, err
    }
    affectedRows, err := result.RowsAffected()
    if err != nil {
        return -1, err
    }

    fmt.Printf("delete %d data\n", affectedRows)
    return affectedRows, nil
}
```

In each iteration, `DELETE` deletes up to 1000 rows from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`.

In Python, the bulk-delete example is as follows:

```
import MySQLdb
import datetime
import time
connection = MySQLdb.connect(
    host="127.0.0.1",
    port=4000,
    user="root",
    password="",
    database="bookshop",
    autocommit=True
)
with connection:
    with connection.cursor() as cursor:
        start_time = datetime.datetime(2022, 4, 15)
        end_time = datetime.datetime(2022, 4, 15, 0, 15)
        affect_rows = -1
        while affect_rows != 0:
            delete_sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at`
                ↪ >= %s AND `rated_at` <= %s LIMIT 1000"
            affect_rows = cursor.execute(delete_sql, (start_time, end_time))
            print(f'delete {affect_rows} data')
            time.sleep(1)
```

In each iteration, `DELETE` deletes up to 1000 rows from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`.

4.6.3.7 Non-transactional bulk-delete

> **Note:**
>
> Since v6.1.0, TiDB supports the non-transactional DML statements. This feature is not available for versions earlier than TiDB v6.1.0.

4.6.3.7.1 Prerequisites of non-transactional bulk-delete

Before using the non-transactional bulk-delete, make sure you have read the Non-Transactional DML statements documentation first. The non-transactional bulk-delete improves the performance and ease of use in batch data processing scenarios but compromises transactional atomicity and isolation.

Therefore, you should use it carefully to avoid serious consequences (such as data loss) due to mishandling.

4.6.3.7.2 SQL syntax for non-transactional bulk-delete

The SQL syntax for non-transactional bulk-delete statement is as follows:

```
BATCH ON {shard_column} LIMIT {batch_size} {delete_statement};
```

Parameter Name	Description
`{shard_column}`	The column used to divide batches.
`{batch_size}`	Control the size of each batch.
`{delete_statement}`	The `DELETE` statement.

The preceding example only shows a simple use case of a non-transactional bulk-delete statement. For detailed information, see Non-transactional DML Statements.

4.6.3.7.3 Example of non-transactional bulk-delete

In the same scenario as the Bulk-delete example, the following SQL statement shows how to perform a non-transactional bulk-delete:

```
BATCH ON `rated_at` LIMIT 1000 DELETE FROM `ratings` WHERE `rated_at` >= "
    ↪ 2022-04-15 00:00:00" AND `rated_at` <= "2022-04-15 00:15:00";
```

4.6.4 Prepared Statements

A prepared statement templatizes multiple SQL statements in which only parameters are different. It separates the SQL statements from the parameters. You can use it to improve

the following aspects of SQL statements:

- **Security**: Because parameters and statements are separated, the risk of SQL injection attacks is avoided.
- **Performance**: Because the statement is parsed in advance on the TiDB server, only parameters are passed for subsequent executions, saving the cost of parsing the entire SQL statements, splicing SQL statement strings, and network transmission.

In most applications, SQL statements can be enumerated. You can use a limited number of SQL statements to complete data queries for the entire application. So using a prepared statement is a best practice.

4.6.4.1 SQL syntax

This section describes the SQL syntax for creating, running and deleting a prepared statement.

4.6.4.1.1 Create a prepared statement

```
PREPARE {prepared_statement_name} FROM '{prepared_statement_sql}';
```

Parameter Name	Description
{prepared_statement_name}	name of the prepared statement
{prepared_statement_sql}	the prepared statement SQL with a question mark as a placeholder

See PREPARE statement for more information.

4.6.4.1.2 Use the prepared statement

A prepared statement can only use **user variables** as parameters, so use the SET statement to set the variables before the EXECUTE statement can call the prepared statement.

```
SET @{parameter_name} = {parameter_value};
EXECUTE {prepared_statement_name} USING @{parameter_name};
```

Parameter Name	Description
{parameter_name}	user variable name
{parameter_value}	user variable value
{prepared_statement_name}	The name of the preprocessing statement, which must be the same as the name defined in the Create a prepared statement

See the EXECUTE statement for more information.

4.6.4.1.3 Delete the prepared statement

```
DEALLOCATE PREPARE {prepared_statement_name};
```

Parameter Name	Description
{ prepared_statement_name }	The name of the preprocessing statement, which must be the same as the name defined in the Create a prepared statement

See the DEALLOCATE statement for more information.

4.6.4.2 Examples

This section describes two examples of prepared statements: SELECT data and INSERT data.

4.6.4.2.1 SELECT example

For example, you need to query a book with id = 1 in the bookshop application.

```
PREPARE `books_query` FROM 'SELECT * FROM `books` WHERE `id` = ?';
```

Running result:

```
Query OK, 0 rows affected (0.01 sec)
```

```
SET @id = 1;
```

Running result:

```
Query OK, 0 rows affected (0.04 sec)
```

```
EXECUTE `books_query` USING @id;
```

Running result:

```
+---------+---------------------------------+--------+---------------------+-------+----
    ↪
| id      | title                           | type   | published_at        | stock |
    ↪ price |
+---------+---------------------------------+--------+---------------------+-------+----
    ↪
| 1       | The Adventures of Pierce Wehner | Comics | 1904-06-06 20:46:25 |
    ↪ 586 | 411.66 |
```

```
+---------+----------------------------------+--------+--------------------+-------+----
    ↪
1 row in set (0.05 sec)
```

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource
try (Connection connection = ds.getConnection()) {
    PreparedStatement preparedStatement = connection.prepareStatement("
        ↪ SELECT * FROM `books` WHERE `id` = ?");
    preparedStatement.setLong(1, 1);

    ResultSet res = preparedStatement.executeQuery();
    if(!res.next()) {
        System.out.println("No books in the table with id 1");
    } else {
        // got book's info, which id is 1
        System.out.println(res.getLong("id"));
        System.out.println(res.getString("title"));
        System.out.println(res.getString("type"));
    }
} catch (SQLException e) {
    e.printStackTrace();
}
```

4.6.4.2.2 `INSERT` example

Using the books table as an example, you need to insert a book with `title = TiDB Developer Guide`, `type = Science & Technology`, `stock = 100`, `price = 0.0`, and `published_at = NOW()` (current time of insertion). Note that you don't need to specify the `AUTO_RANDOM` attribute in the **primary key** of the `books` table. For more information about inserting data, see Insert Data.

```
PREPARE `books_insert` FROM 'INSERT INTO `books` (`title`, `type`, `stock`,
    ↪ `price`, `published_at`) VALUES (?, ?, ?, ?, ?);';
```

Running result:

```
Query OK, 0 rows affected (0.03 sec)
```

```
SET @title = 'TiDB Developer Guide';
SET @type = 'Science & Technology';
SET @stock = 100;
SET @price = 0.0;
SET @published_at = NOW();
```

Running result:

```
Query OK, 0 rows affected (0.04 sec)
```

```
EXECUTE `books_insert` USING @title, @type, @stock, @price, @published_at;
```

Running result:

```
Query OK, 1 row affected (0.03 sec)
```

```
try (Connection connection = ds.getConnection()) {
    String sql = "INSERT INTO `books` (`title`, `type`, `stock`, `price`, `
        ↪ published_at`) VALUES (?, ?, ?, ?, ?);";
    PreparedStatement preparedStatement = connection.prepareStatement(sql);

    preparedStatement.setString(1, "TiDB Developer Guide");
    preparedStatement.setString(2, "Science & Technology");
    preparedStatement.setInt(3, 100);
    preparedStatement.setBigDecimal(4, new BigDecimal("0.0"));
    preparedStatement.setTimestamp(5, new Timestamp(Calendar.getInstance().
        ↪ getTimeInMillis()));

    preparedStatement.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

As you can see, JDBC helps you control the life cycle of prepared statements and you don't need to manually create, use, or delete prepared statements in your application. However, note that because TiDB is compatible with MySQL, the default configuration for using MySQL JDBC Driver on the client-side is not to enable the ***server-side*** prepared statement option, but to use the client-side prepared statement.

The following configurations help you use the TiDB server-side prepared statements under JDBC:

Parameter	Means	Recommended Scenario	Recommended Configuration
`useServerPrepStmts` ↪	When set to `true`, it means to use the server side to enable prepared statements	When you need to use a prepared statement more than once	`true`

Parameter	Means	Recommended Scenario	Recommended Configuration
`cachePrepStmts`	Whether the client caches prepared statements	`useServerPrepStmts=true` 时	`true`
`prepStmtCacheSqlLimit`	Maximum size of a prepared statement (256 characters by default)	When the prepared statement is greater than 256 characters	Configured according to the actual size of the prepared statement
`prepStmtCacheSize`	Maximum number of prepared statements (25 by default)	When the number of prepared statements is greater than 25	Configured according to the actual number of prepared statements

The following is a typical scenario of JDBC connection string configurations. Host: `127.0.0.1`, Port: `4000`, User name: `root`, Password: null, Default database: `test`:

```
jdbc:mysql://127.0.0.1:4000/test?user=root&useConfigs=maxPerformance&
    ↪ useServerPrepStmts=true&prepStmtCacheSqlLimit=2048&prepStmtCacheSize
    ↪ =256&rewriteBatchedStatements=true&allowMultiQueries=true
```

You can also see the insert rows chapter if you need to change other JDBC parameters when inserting data.

For a complete example in Java, see:

- Build a Simple CRUD App with TiDB and Java - Using JDBC
- Build a Simple CRUD App with TiDB and Java - Using Hibernate
- Build the TiDB Application using Spring Boot

4.7 Read Data

4.7.1 Query Data from a Single Table

This document describes how to use SQL and various programming languages to query data from a single table in a database.

4.7.1.1 Before you begin

The following content takes the Bookshop application as an example to show how to query data from a single table in TiDB.

Before querying data, make sure that you have completed the following steps:

1. Build a TiDB cluster (using TiDB Cloud or TiUP is recommended).

2. Import table schema and sample data of the Bookshop application.
3. Connect to TiDB.

4.7.1.2 Execute a simple query

In the database of the Bookshop application, the `authors` table stores the basic information of authors. You can use the `SELECT ... FROM ...` statement to query data from the database.

Execute the following SQL statement in a MySQL client:

```
SELECT id, name FROM authors;
```

The output is as follows:

```
+------------+--------------------------+
| id         | name                     |
+------------+--------------------------+
|       6357 | Adelle Bosco             |
|     345397 | Chanelle Koepp           |
|     807584 | Clementina Ryan          |
|     839921 | Gage Huel                |
|     850070 | Ray Armstrong            |
|     850362 | Ford Waelchi             |
|     881210 | Jayme Gutkowski          |
|    1165261 | Allison Kuvalis          |
|    1282036 | Adela Funk               |
...
| 4294957408 | Lyla Nitzsche            |
+------------+--------------------------+
20000 rows in set (0.05 sec)
```

In Java, to store the basic information of authors, you can declare a class `Author`. You should choose appropriate Java data types according to the Data types and Value range in the database. For example:

- Use a variable of type `Int` to store data of type `int`.
- Use a variable of type `Long` to store data of type `bigint`.
- Use a variable of type `Short` to store data of type `tinyint`.
- Use a variable of type `String` to store data of type `varchar`.

```
public class Author {
    private Long id;
    private String name;
    private Short gender;
    private Short birthYear;
    private Short deathYear;

    public Author() {}

     // Skip the getters and setters.
}
```

```
public class AuthorDAO {

    // Omit initialization of instance variables.

    public List<Author> getAuthors() throws SQLException {
        List<Author> authors = new ArrayList<>();

        try (Connection conn = ds.getConnection()) {
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("SELECT id, name FROM authors");
            while (rs.next()) {
                Author author = new Author();
                author.setId(rs.getLong("id"));
                author.setName(rs.getString("name"));
                authors.add(author);
            }
        }
        return authors;
    }
}
```

- After connecting to TiDB using the JDBC driver, you can create a `Statement` object with `conn.createStatus()`.

- Then call `stmt.executeQuery("query_sql")` to initiate a database query request to TiDB.
- The query results are stored in a `ResultSet` object. By traversing `ResultSet`, the returned results can be mapped to the `Author` object.

4.7.1.3 Filter results

To filter query results, you can use the `WHERE` statement.

For example, the following command queries authors who were born in 1998 among all authors:

Add filter conditions in the `WHERE` statement:

```
SELECT * FROM authors WHERE birth_year = 1998;
```

In Java, you can use the same SQL to handle data query requests with dynamic parameters.

This can be done by concatenating parameters into a SQL statement. However, this method poses a potential SQL Injection risk to the security of the application.

To deal with such queries, use a Prepared statement instead of a normal statement.

```
public List<Author> getAuthorsByBirthYear(Short birthYear) throws
    ↪ SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        PreparedStatement stmt = conn.prepareStatement("""
        SELECT * FROM authors WHERE birth_year = ?;
        """);
        stmt.setShort(1, birthYear);
        ResultSet rs = stmt.executeQuery();
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.1.4 Sort results

To sort query results, you can use the `ORDER BY` statement.

For example, the following SQL statement is to get a list of the youngest authors by sorting the `authors` table in descending order (`DESC`) according to the `birth_year` column.

```
SELECT id, name, birth_year
FROM authors
ORDER BY birth_year DESC;
```

```
public List<Author> getAuthorsSortByBirthYear() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
            SELECT id, name, birth_year
            FROM authors
            ORDER BY birth_year DESC;
            """);

        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            author.setBirthYear(rs.getShort("birth_year"));
            authors.add(author);
        }
    }
    return authors;
}
```

The result is as follows:

```
+-----------+-----------------------+------------+
| id        | name                  | birth_year |
+-----------+-----------------------+------------+
| 83420726  | Terrance Dach         | 2000       |
| 57938667  | Margarita Christiansen | 2000  |
| 77441404  | Otto Dibbert          | 2000       |
| 61338414  | Danial Cormier        | 2000       |
| 49680887  | Alivia Lemke          | 2000       |
| 45460101  | Itzel Cummings        | 2000       |
| 38009380  | Percy Hodkiewicz      | 2000       |
| 12943560  | Hulda Hackett         | 2000       |
| 1294029   | Stanford Herman       | 2000       |
| 111453184 | Jeffrey Brekke        | 2000       |
...
300000 rows in set (0.23 sec)
```

4.7.1.5 Limit the number of query results

To limit the number of query results, you can use the `LIMIT` statement.

```
SELECT id, name, birth_year
FROM authors
ORDER BY birth_year DESC
LIMIT 10;
```

```
public List<Author> getAuthorsWithLimit(Integer limit) throws SQLException
    ↪ {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        PreparedStatement stmt = conn.prepareStatement("""
            SELECT id, name, birth_year
            FROM authors
            ORDER BY birth_year DESC
            LIMIT ?;
            """);
        stmt.setInt(1, limit);
        ResultSet rs = stmt.executeQuery();
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            author.setBirthYear(rs.getShort("birth_year"));
            authors.add(author);
        }
    }
    return authors;
}
```

The result is as follows:

```
+-----------+-----------------------+------------+
| id        | name                  | birth_year |
+-----------+-----------------------+------------+
| 83420726  | Terrance Dach         | 2000       |
| 57938667  | Margarita Christiansen | 2000  |
| 77441404  | Otto Dibbert          | 2000       |
| 61338414  | Danial Cormier        | 2000       |
| 49680887  | Alivia Lemke          | 2000       |
| 45460101  | Itzel Cummings        | 2000       |
| 38009380  | Percy Hodkiewicz      | 2000       |
| 12943560  | Hulda Hackett         | 2000       |
| 1294029   | Stanford Herman       | 2000       |
| 111453184 | Jeffrey Brekke        | 2000       |
+-----------+-----------------------+------------+
```

```
10 rows in set (0.11 sec)
```

With the `LIMIT` statement, the query time is significantly reduced from `0.23 sec` to `0.11 sec` in this example. For more information, see TopN and Limit.

4.7.1.6 Aggregate queries

To have a better understanding of the overall data situation, you can use the `GROUP BY` statement to aggregate query results.

For example, if you want to know which years there are more authors born, you can group the `authors` table by the `birth_year` column, and then count for each year:

```
SELECT birth_year, COUNT (DISTINCT id) AS author_count
FROM authors
GROUP BY birth_year
ORDER BY author_count DESC;
```

```
public class AuthorCount {
    private Short birthYear;
    private Integer authorCount;

    public AuthorCount() {}

     // Skip the getters and setters.
}

public List<AuthorCount> getAuthorCountsByBirthYear() throws SQLException {
    List<AuthorCount> authorCounts = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
            SELECT birth_year, COUNT(DISTINCT id) AS author_count
            FROM authors
            GROUP BY birth_year
            ORDER BY author_count DESC;
            """);

        while (rs.next()) {
            AuthorCount authorCount = new AuthorCount();
            authorCount.setBirthYear(rs.getShort("birth_year"));
            authorCount.setAuthorCount(rs.getInt("author_count"));
            authorCounts.add(authorCount);
        }
    }
    return authorCount;
```

```
}
```

The result is as follows:

```
+------------+--------------+
| birth_year | author_count |
+------------+--------------+
|       1932 |          317 |
|       1947 |          290 |
|       1939 |          282 |
|       1935 |          289 |
|       1968 |          291 |
|       1962 |          261 |
|       1961 |          283 |
|       1986 |          289 |
|       1994 |          280 |
...
|       1972 |          306 |
+------------+--------------+
71 rows in set (0.00 sec)
```

In addition to the `COUNT` function, TiDB also supports other aggregate functions. For more information, see Aggregate (GROUP BY) Functions.

4.7.2 Multi-table Join Queries

In many scenarios, you need to use one query to get data from multiple tables. You can use the `JOIN` statement to combine the data from two or more tables.

4.7.2.1 Join types

This section describes the Join types in detail.

4.7.2.1.1 INNER JOIN

The join result of an inner join returns only rows that match the join condition.

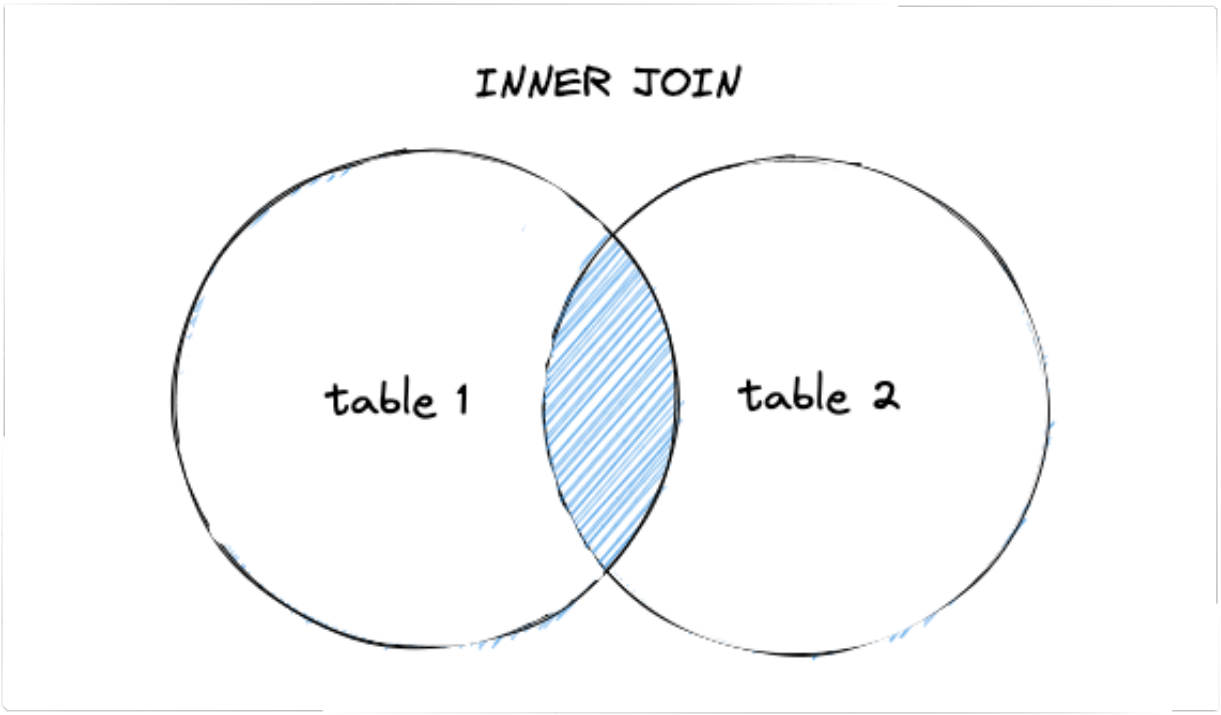

Figure 9: Inner Join

For example, if you want to know the most prolific author, you need to join the author table named `authors` with the book author table named `book_authors`.

In the following SQL statement, use the keyword `JOIN` to declare that you want to join the rows of the left table `authors` and the right table `book_authors` as an inner join with the join condition `a.id = ba.author_id`. The result set will only contain rows that satisfy the join condition. If an author has not written any books, then his record in `authors` table will not satisfy the join condition and will therefore not appear in the result set.

```
SELECT ANY_VALUE(a.id) AS author_id, ANY_VALUE(a.name) AS author_name,
    ↪ COUNT(ba.book_id) AS books
FROM authors a
JOIN book_authors ba ON a.id = ba.author_id
GROUP BY ba.author_id
ORDER BY books DESC
LIMIT 10;
```

The query results are as follows:

```
+-----------+---------------+-------+
| author_id | author_name   | books |
+-----------+---------------+-------+
|  431192671 | Emilie Cassin |  7 |
```

```
|  865305676 | Nola Howell |    7 |
|  572207928 | Lamar Koch  |    6 |
| 3894029860 | Elijah Howe |    6 |
| 1150614082 | Cristal Stehr |  6 |
| 4158341032 | Roslyn Rippin |  6 |
| 2430691560 | Francisca Hahn | 6 |
| 3346415350 | Leta Weimann |   6 |
| 1395124973 | Albin Cole  |    6 |
| 2768150724 | Caleb Wyman |    6 |
+------------+---------------+-------+
10 rows in set (0.01 sec)
```

```java
public List<Author> getTop10AuthorsOrderByBooks() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
        SELECT ANY_VALUE(a.id) AS author_id, ANY_VALUE(a.name) AS author_name
            ↪ , COUNT(ba.book_id) AS books
        FROM authors a
        JOIN book_authors ba ON a.id = ba.author_id
        GROUP BY ba.author_id
        ORDER BY books DESC
        LIMIT 10;
        """);
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("author_id"));
            author.setName(rs.getString("author_name"));
            author.setBooks(rs.getInt("books"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.2.1.2 LEFT OUTER JOIN

The left outer join returns all the rows in the left table and the values in the right table that match the join condition. If no rows are matched in the right table, it will be filled with `NULL`.

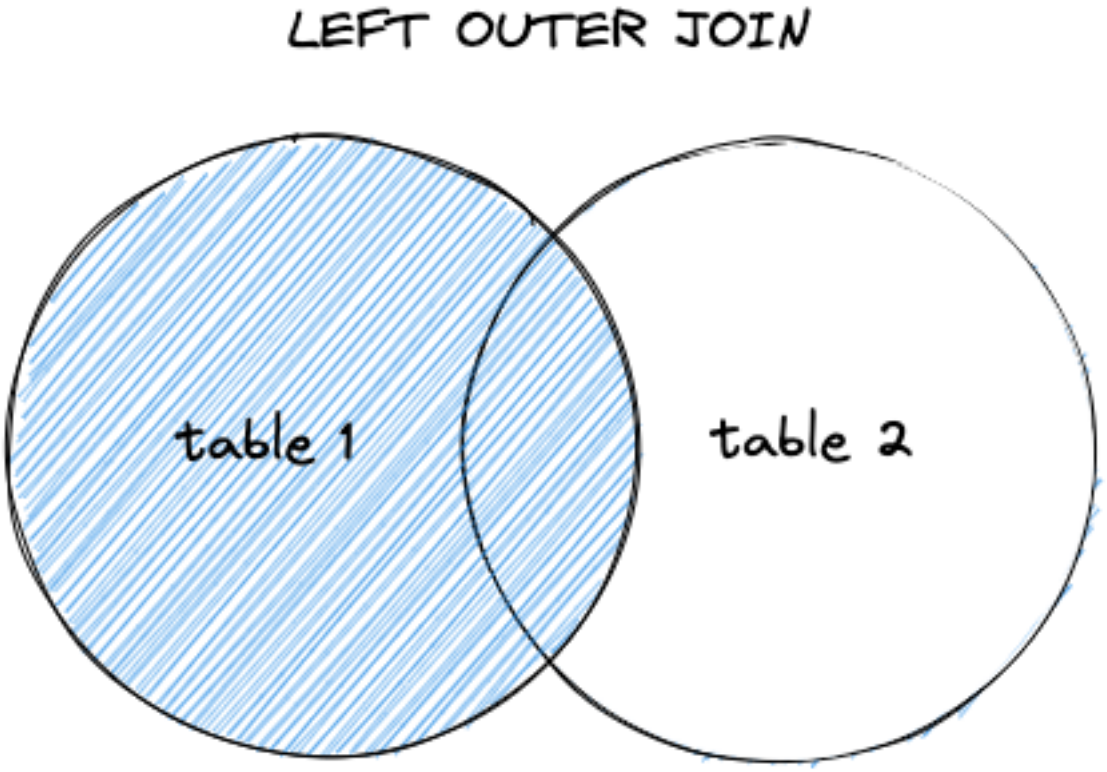

Figure 10: Left Outer Join

In some cases, you want to use multiple tables to complete the data query, but do not want the data set to become too small because the join condition are not met.

For example, on the homepage of the Bookshop app, you want to display a list of new books with average ratings. In this case, the new books may not have been rated by anyone yet. Using inner joins will cause the information of these unrated books to be filtered out, which is not what you expect.

In the following SQL statement, use the `LEFT JOIN` keyword to declare that the left table `books` will be joined to the right table `ratings` in a left outer join, thus ensuring that all rows in the `books` table are returned.

```
SELECT b.id AS book_id, ANY_VALUE(b.title) AS book_title, AVG(r.score) AS
    ↪ average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id
ORDER BY b.published_at DESC
LIMIT 10;
```

The query results are as follows:

```
+-----------+---------------------------------+---------------+
```

```
| book_id   | book_title                    | average_score |
+-----------+-------------------------------+---------------+
| 3438991610 | The Documentary of lion      |        2.7619 |
| 3897175886 | Torey Kuhn                   |        3.0000 |
| 1256171496 | Elmo Vandervort              |        2.5500 |
| 1036915727 | The Story of Munchkin        |        2.0000 |
|  270254583 | Tate Kovacek                 |        2.5000 |
| 1280950719 | Carson Damore                |        3.2105 |
| 1098041838 | The Documentary of grasshopper |      2.8462 |
| 1476566306 | The Adventures of Vince Sanford | 2.3529 |
| 4036300890 | The Documentary of turtle    |        2.4545 |
| 1299849448 | Antwan Olson                 |        3.0000 |
+-----------+-------------------------------+---------------+
10 rows in set (0.30 sec)
```

It seems that the latest published book already has a lot of ratings. To verify the above method, let's delete all the ratings of the book *The Documentary of lion* through the SQL statement:

```
DELETE FROM ratings WHERE book_id = 3438991610;
```

Query again. The book *The Documentary of lion* still appears in the result set, but the `average_score` column calculated from `score` of the right table `ratings` is filled with `NULL`.

```
+-----------+-------------------------------+---------------+
| book_id   | book_title                    | average_score |
+-----------+-------------------------------+---------------+
| 3438991610 | The Documentary of lion      |          NULL |
| 3897175886 | Torey Kuhn                   |        3.0000 |
| 1256171496 | Elmo Vandervort              |        2.5500 |
| 1036915727 | The Story of Munchkin        |        2.0000 |
|  270254583 | Tate Kovacek                 |        2.5000 |
| 1280950719 | Carson Damore                |        3.2105 |
| 1098041838 | The Documentary of grasshopper |      2.8462 |
| 1476566306 | The Adventures of Vince Sanford | 2.3529 |
| 4036300890 | The Documentary of turtle    |        2.4545 |
| 1299849448 | Antwan Olson                 |        3.0000 |
+-----------+-------------------------------+---------------+
10 rows in set (0.30 sec)
```

What happens if you use `INNER JOIN`? It's up to you to have a try.

```
public List<Book> getLatestBooksWithAverageScore() throws SQLException {
    List<Book> books = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
```

```
        ResultSet rs = stmt.executeQuery("""
        SELECT b.id AS book_id, ANY_VALUE(b.title) AS book_title, AVG(r.score
            ↪ ) AS average_score
        FROM books b
        LEFT JOIN ratings r ON b.id = r.book_id
        GROUP BY b.id
        ORDER BY b.published_at DESC
        LIMIT 10;
        """);
        while (rs.next()) {
            Book book = new Book();
            book.setId(rs.getLong("book_id"));
            book.setTitle(rs.getString("book_title"));
            book.setAverageScore(rs.getFloat("average_score"));
            books.add(book);
        }
    }
    return books;
}
```

4.7.2.1.3 RIGHT OUTER JOIN

A right outer join returns all the records in the right table and the values in the left table that match the join condition. If there is no matching value, it is filled with `NULL`.

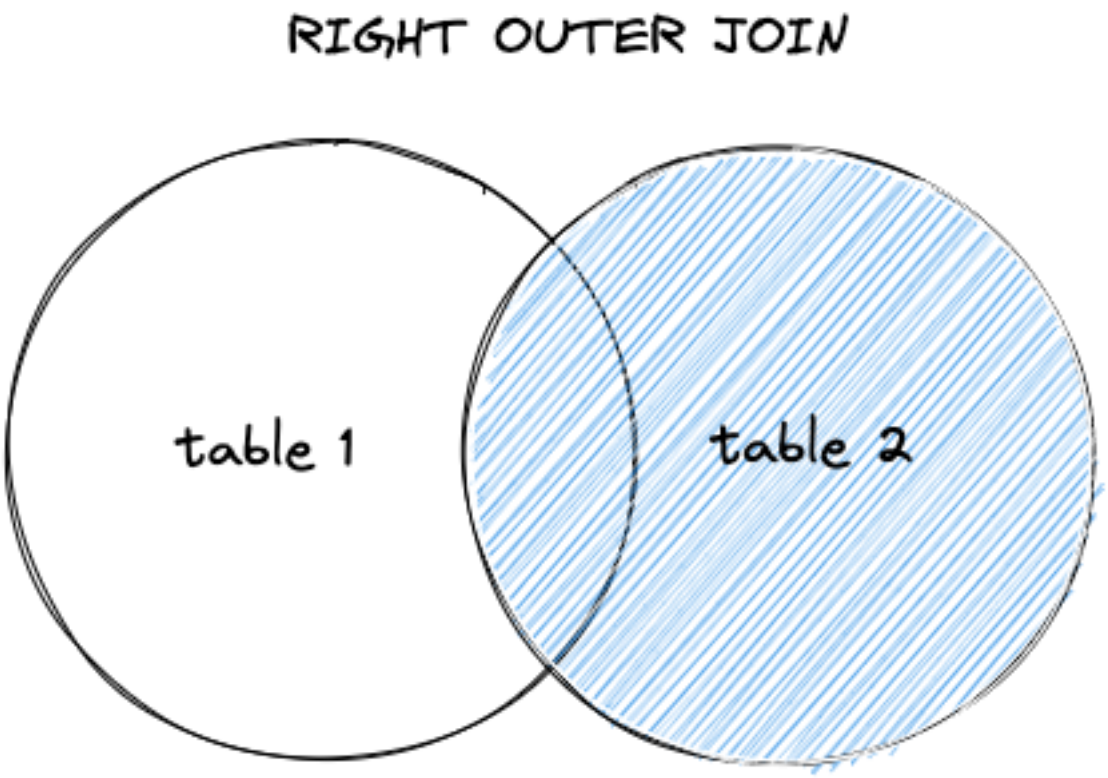

Figure 11: Right Outer Join

4.7.2.1.4 CROSS JOIN

When the join condition is constant, the inner join between the two tables is called a cross join. A cross join joins every record of the left table to all the records of the right table. If the number of records in the left table is `m` and the number of records in the right table is `n`, then `m \* n` records will be generated in the result set.

4.7.2.1.5 LEFT SEMI JOIN

TiDB does not support `LEFT SEMI JOIN table_name` at the SQL syntax level. But at the execution plan level, subquery-related optimizations will use `semi join` as the default join method for rewritten equivalent JOIN queries.

4.7.2.2 Implicit join

Before the `JOIN` statement that explicitly declared a join was added to the SQL standard, it was possible to join two or more tables in a SQL statement using the `FROM t1, t2` clause, and specify the conditions for the join using the `WHERE t1.id = t2.id` clause. You can understand it as an implicit join, which uses the inner join to join tables.

4.7.2.3 Join related algorithms

TiDB supports the following general table join algorithms.

- Index Join
- Hash Join
- Merge Join

The optimizer selects an appropriate join algorithm to execute based on the factors such as the data volume in the joined table. You can see which algorithm the query uses for Join by using the `EXPLAIN` statement.

If the optimizer of TiDB does not execute according to the optimal join algorithm, you can use Optimizer Hints to force TiDB to use a better join algorithm.

For example, assuming the example for the left join query above executes faster using the Hash Join algorithm, which is not chosen by the optimizer, you can append the hint `/*+ HASH_JOIN(b, r)*/` after the `SELECT` keyword. Note that If the table has an alias, use the alias in the hint.

```
EXPLAIN SELECT /*+ HASH_JOIN(b, r) */ b.id AS book_id, ANY_VALUE(b.title)
    ↪ AS book_title, AVG(r.score) AS average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id
ORDER BY b.published_at DESC
LIMIT 10;
```

Hints related to join algorithms:

- MERGE_JOIN(t1_name [, tl_name ...])
- INL_JOIN(t1_name [, tl_name ...])
- INL_HASH_JOIN(t1_name [, tl_name ...])
- HASH_JOIN(t1_name [, tl_name ...])

4.7.2.4 Join orders

In real business scenarios, join statements of multiple tables are very common. The execution efficiency of join is related to the order of each table in join. TiDB uses the Join Reorder algorithm to determine the order in which multiple tables are joined.

If the join order selected by the optimizer is not optimal as expected, you can use `STRAIGHT_JOIN` to enforce TiDB to join queries in the order of the tables used in the `FROM` clause.

```
EXPLAIN SELECT *
FROM authors a STRAIGHT_JOIN book_authors ba STRAIGHT_JOIN books b
WHERE b.id = ba.book_id AND ba.author_id = a.id;
```

For more information about the implementation details and limitations of this Join Reorder algorithm, see Introduction to Join Reorder Algorithm.

- Introduction to Join Reorder

4.7.3 Subquery

This document introduces subquery statements and categories in TiDB.

4.7.3.1 Overview

An subquery is a query within another SQL query. With subquery, the query result can be used in another query.

The following takes the Bookshop application as an example to introduce subquery.

4.7.3.2 Subquery statement

In most cases, there are five types of subqueries:

- Scalar Subquery, such as `SELECT (SELECT s1 FROM t2)FROM t1`.
- Derived Tables, such as `SELECT t1.s1 FROM (SELECT s1 FROM t2)t1`.
- Existential Test, such as `WHERE NOT EXISTS(SELECT ... FROM t2)`, `WHERE t1.a IN (SELECT ... FROM t2)`.
- Quantified Comparison, such as `WHERE t1.a = ANY(SELECT ... FROM t2)`, `WHERE t1.a = ANY(SELECT ... FROM t2)`.
- Subquery as a comparison operator operand, such as `WHERE t1.a > (SELECT ... FROM t2)`.

4.7.3.3 Category of subquery

The subquery can be categorized as Correlated Subquery and Self-contained Subquery. TiDB treats these two types differently.

Whether a subquery is correlated or not depends on whether it refers to columns used in its outer query.

4.7.3.3.1 Self-contained subquery

For a self-contained subquery that uses subquery as operand of comparison operators (`>`, `>=`, `<` , `<=` , `=` , or `!=`), the inner subquery queries only once, and TiDB rewrites it as a constant during the execution plan phase.

For example, to query authors in the `authors` table whose age is greater than the average age, you can use a subquery as a comparison operator operand.

```
SELECT * FROM authors a1 WHERE (IFNULL(a1.death_year, YEAR(NOW())) - a1.
    ↪ birth_year) > (
    SELECT
        AVG(IFNULL(a2.death_year, YEAR(NOW())) - a2.birth_year) AS
            ↪ average_age
    FROM
        authors a2
)
```

The inner subquery is executed before TiDB executes the above query:

```
SELECT AVG(IFNULL(a2.death_year, YEAR(NOW())) - a2.birth_year) AS
    ↪ average_age FROM authors a2;
```

Suppose the result of the query is 34, that is, the average age is 34, and 34 will be used as a constant to replace the original subquery.

```
SELECT * FROM authors a1
WHERE (IFNULL(a1.death_year, YEAR(NOW())) - a1.birth_year) > 34;
```

The result is as follows:

```
+--------+------------------+--------+------------+------------+
| id     | name             | gender | birth_year | death_year |
+--------+------------------+--------+------------+------------+
| 13514 | Kennith Kautzer | 1     | 1956      | 2018      |
| 13748 | Dillon Langosh  | 1     | 1985      | NULL      |
| 99184 | Giovanny Emmerich | 1   | 1954      | 2012      |
| 180191 | Myrtie Robel   | 1     | 1958      | 2009      |
| 200969 | Iva Renner     | 0     | 1977      | NULL      |
| 209671 | Abraham Ortiz  | 0     | 1943      | 2016      |
| 229908 | Wellington Wiza | 1    | 1932      | 1969      |
| 306642 | Markus Crona   | 0     | 1969      | NULL      |
| 317018 | Ellis McCullough | 0   | 1969      | 2014      |
| 322369 | Mozelle Hand   | 0     | 1942      | 1977      |
| 325946 | Elta Flatley   | 0     | 1933      | 1986      |
| 361692 | Otho Langosh   | 1     | 1931      | 1997      |
| 421294 | Karelle VonRueden | 0  | 1977      | NULL      |
...
```

For self-contained subqueries such as Existential Test and Quantified Comparison, TiDB rewrites and replaces them with equivalent queries for better performance. For more information, see Subquery Related Optimizations.

4.7.3.3.2 Correlated subquery

For correlated subquery, because the inner subquery references the columns from the outer query, each subquery is executed once for each row of the outer query. That is, assuming that the outer query gets 10 million results, the subquery will also be executed 10 million times, which will consume more time and resources.

Therefore, in the process of processing, TiDB will try to Decorrelate of Correlated Subquery to improve the query efficiency at the execution plan level.

The following statement is to query authors who are older than the average age of other authors of the same gender.

```
SELECT * FROM authors a1 WHERE (IFNULL(a1.death_year, YEAR(NOW())) - a1.
    ↪ birth_year) > (
    SELECT
        AVG(
            IFNULL(a2.death_year, YEAR(NOW())) - IFNULL(a2.birth_year, YEAR(
                ↪ NOW()))
        ) AS average_age
    FROM
        authors a2
    WHERE a1.gender = a2.gender
);
```

TiDB rewrites it to an equivalent `join` query:

```
SELECT *
FROM
    authors a1,
    (
        SELECT
            gender, AVG(
                IFNULL(a2.death_year, YEAR(NOW())) - IFNULL(a2.birth_year,
                    ↪ YEAR(NOW()))
            ) AS average_age
        FROM
            authors a2
        GROUP BY gender
    ) a2
WHERE
    a1.gender = a2.gender
    AND (IFNULL(a1.death_year, YEAR(NOW())) - a1.birth_year) > a2.
        ↪ average_age;
```

As a best practice, in actual development, it is recommended to avoid querying through a correlated subquery if you can write another equivalent query with better performance.

- Subquery Optimization in TiDB

4.7.4 Paginate Results

To page through a large query result, you can get your desired part in a "paginated" manner.

4.7.4.1 Paginate query results

In TiDB, you can paginate query results using the `LIMIT` statement. For example:

```
SELECT * FROM table_a t ORDER BY gmt_modified DESC LIMIT offset, row_count;
```

`offset` indicates the beginning number of records and `row_count` indicates the number of records per page. TiDB also supports `LIMIT row_count OFFSET offset` syntax.

When pagination is used, it is recommended that you sort query results with the `ORDER BY` statement unless there is a need to display data randomly.

For example, to let users of the Bookshop application view the latest published books in a paginated manner, you can use the `LIMIT 0, 10` statement, which returns the first page of the result list, with a maximum of 10 records per page. To get the second page, you can change the statement to `LIMIT 10, 10`.

```
SELECT *
FROM books
ORDER BY published_at DESC
LIMIT 0, 10;
```

In application development, the backend program receives the `page_number` parameter (which means the number of the page being requested) and the `page_size` parameter (which controls how many records per page) from the frontend instead of the `offset` parameter. Therefore, some conversions needed to be done before querying.

```
public List<Book> getLatestBooksPage(Long pageNumber, Long pageSize) throws
    ↪ SQLException {
    pageNumber = pageNumber < 1L ? 1L : pageNumber;
    pageSize = pageSize < 10L ? 10L : pageSize;
    Long offset = (pageNumber - 1) * pageSize;
    Long limit = pageSize;
    List<Book> books = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        PreparedStatement stmt = conn.prepareStatement("""
        SELECT id, title, published_at
        FROM books
        ORDER BY published_at DESC
```

```
            LIMIT ?, ?;
            """);
            stmt.setLong(1, offset);
            stmt.setLong(2, limit);
            ResultSet rs = stmt.executeQuery();
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setPublishedAt(rs.getDate("published_at"));
                books.add(book);
            }
        }
        return books;
    }
```

4.7.4.2 Paging batches for single-field primary key tables

Usually, you can write a pagination SQL statement using a primary key or unique index to sort results and the `offset` keyword in the `LIMIT` clause to split pages by a specified row count. Then the pages are wrapped into independent transactions to achieve flexible paging updates. However, the disadvantage is also obvious. As the primary key or unique index needs to be sorted, a larger offset consumes more computing resources, especially in the case of a large volume of data.

The following introduces a more efficient paging batching method:

First, sort the data by primary key and call the window function `row_number()` to generate a row number for each row. Then, call the aggregation function to group row numbers by the specified page size and calculate the minimum and maximum values of each page.

```
SELECT
    floor((t.row_num - 1) / 1000) + 1 AS page_num,
    min(t.id) AS start_key,
    max(t.id) AS end_key,
    count(*) AS page_size
FROM (
    SELECT id, row_number() OVER (ORDER BY id) AS row_num
    FROM books
) t
GROUP BY page_num
ORDER BY page_num;
```

The result is as follows:

```
+----------+------------+------------+-----------+
```

```
| page_num | start_key | end_key | page_size |
+----------+-----------+-----------+-----------+
|        1 |    268996 | 213168525 |    1000 |
|        2 |  213210359 | 430012226 |    1000 |
|        3 |  430137681 | 647846033 |    1000 |
|        4 |  647998334 | 848878952 |    1000 |
|        5 |  848899254 | 1040978080 |   1000 |
...
|       20 | 4077418867 | 4294004213 |  1000 |
+----------+-----------+-----------+-----------+
20 rows in set (0.01 sec)
```

Next, use the `WHERE id BETWEEN start_key AND end_key` statement to query the data of each slice. To update data more efficiently, you can use the above slice information when modifying the data.

To delete the basic information of all books on page 1, replace the `start_key` and `end_key` with values of page 1 in the above result:

```
DELETE FROM books
WHERE
    id BETWEEN 268996 AND 213168525
ORDER BY id;
```

In Java, define a `PageMeta` class to store page meta information.

```
public class PageMeta<K> {
    private Long pageNum;
    private K startKey;
    private K endKey;
    private Long pageSize;

    // Skip the getters and setters.

}
```

Define a `getPageMetaList()` method to get the page meta information list, and then define a `deleteBooksByPageMeta()` method to delete data in batches according to the page meta information.

```
public class BookDAO {
    public List<PageMeta<Long>> getPageMetaList() throws SQLException {
        List<PageMeta<Long>> pageMetaList = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT
```

```
                floor((t.row_num - 1) / 1000) + 1 AS page_num,
                min(t.id) AS start_key,
                max(t.id) AS end_key,
                count(*) AS page_size
            FROM (
                SELECT id, row_number() OVER (ORDER BY id) AS row_num
                FROM books
            ) t
            GROUP BY page_num
            ORDER BY page_num;
            """);
            while (rs.next()) {
                PageMeta<Long> pageMeta = new PageMeta<>();
                pageMeta.setPageNum(rs.getLong("page_num"));
                pageMeta.setStartKey(rs.getLong("start_key"));
                pageMeta.setEndKey(rs.getLong("end_key"));
                pageMeta.setPageSize(rs.getLong("page_size"));
                pageMetaList.add(pageMeta);
            }
        }
        return pageMetaList;
    }

    public void deleteBooksByPageMeta(PageMeta<Long> pageMeta) throws
        ↪ SQLException {
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("DELETE FROM books
                ↪  WHERE id >= ? AND id <= ?");
            stmt.setLong(1, pageMeta.getStartKey());
            stmt.setLong(2, pageMeta.getEndKey());
            stmt.executeUpdate();
        }
    }
}
```

The following statement is to delete the data on page 1:

```
List<PageMeta<Long>> pageMetaList = bookDAO.getPageMetaList();
if (pageMetaList.size() > 0) {
    bookDAO.deleteBooksByPageMeta(pageMetaList.get(0));
}
```

The following statement is to delete all book data in batches by paging:

```
List<PageMeta<Long>> pageMetaList = bookDAO.getPageMetaList();
pageMetaList.forEach((pageMeta) -> {
```

```
    try {
        bookDAO.deleteBooksByPageMeta(pageMeta);
    } catch (SQLException e) {
        e.printStackTrace();
    }
});
```

This method significantly improves the efficiency of batch processing by avoiding wasting computing resources caused by frequent data sorting operations.

4.7.4.3 Paging batches for composite primary key tables

4.7.4.3.1 Non-clustered index table

For non-clustered index tables (also known as "non-index-organized tables"), the internal field `_tidb_rowid` can be used as a pagination key, and the pagination method is the same as that of single-field primary key tables.

> **Tip:**
>
> You can use the `SHOW CREATE TABLE users;` statement to check whether the table primary key uses clustered index.

For example:

```
SELECT
    floor((t.row_num - 1) / 1000) + 1 AS page_num,
    min(t._tidb_rowid) AS start_key,
    max(t._tidb_rowid) AS end_key,
    count(*) AS page_size
FROM (
    SELECT _tidb_rowid, row_number () OVER (ORDER BY _tidb_rowid) AS row_num
    FROM users
) t
GROUP BY page_num
ORDER BY page_num;
```

The result is as follows:

```
+----------+-----------+---------+-----------+
| page_num | start_key | end_key | page_size |
+----------+-----------+---------+-----------+
|        1 |         1 |    1000 |      1000 |
```

```
|       2 |     1001 |   2000 |     1000 |
|       3 |     2001 |   3000 |     1000 |
|       4 |     3001 |   4000 |     1000 |
|       5 |     4001 |   5000 |     1000 |
|       6 |     5001 |   6000 |     1000 |
|       7 |     6001 |   7000 |     1000 |
|       8 |     7001 |   8000 |     1000 |
|       9 |     8001 |   9000 |     1000 |
|      10 |     9001 |   9990 |      990 |
+---------+----------+--------+----------+
10 rows in set (0.00 sec)
```

4.7.4.3.2 Clustered index table

For clustered index tables (also known as "index-organized tables"), you can use the `concat` function to concatenate values of multiple columns as a key, and then use a window function to query the paging information.

It should be noted that the key is a string at this time, and you must ensure that the length of the string is always the same, to obtain the correct `start_key` and `end_key` in the slice through the `min` and `max` aggregation function. If the length of the field for string concatenation is not fixed, you can use the `LPAD` function to pad it.

For example, you can implement a paging batch for the data in the `ratings` table as follows:

Create the meta information table by using the following statement. As the key concatenated by `book_id` and `user_id`, which are `bigint` types, is unable to convert to the same length, the `LPAD` function is used to pad the length with `0` according to the maximum bits 19 of `bigint`.

```
SELECT
    floor((t1.row_num - 1) / 10000) + 1 AS page_num,
    min(mvalue) AS start_key,
    max(mvalue) AS end_key,
    count(*) AS page_size
FROM (
    SELECT
        concat('(', LPAD(book_id, 19, 0), ',', LPAD(user_id, 19, 0), ')') AS
            ↪  mvalue,
        row_number() OVER (ORDER BY book_id, user_id) AS row_num
    FROM ratings
) t1
GROUP BY page_num
ORDER BY page_num;
```

Note:

The preceding SQL statement is executed as `TableFullScan`. When the data volume is large, the query will be slow, and you can use TiFlash to speed up it.

The result is as follows:

```
+----------+-----------------------------------------+-----------------------------
    ↪
| page_num | start_key                               | end_key
    ↪                                | page_size |
+----------+-----------------------------------------+-----------------------------
    ↪
|        1 | (0000000000000268996,0000000000092104804) |
    ↪ (0000000000140982742,0000000000374645100) | 10000 |
|        2 | (0000000000140982742,0000000000456757551) |
    ↪ (0000000000287195082,0000000004053200550) | 10000 |
|        3 | (0000000000287196791,0000000000191962769) |
    ↪ (0000000000434010216,0000000000237646714) | 10000 |
|        4 | (0000000000434010216,0000000000375066168) |
    ↪ (0000000000578893327,0000000002167504460) | 10000 |
|        5 | (0000000000578893327,0000000002457322286) |
    ↪ (0000000000718287668,0000000001502744628) | 10000 |
...
|       29 | (0000000004002523918,0000000000902930986) |
    ↪ (0000000004147203315,0000000004090920746) | 10000 |
|       30 | (0000000004147421329,0000000000319181561) |
    ↪ (0000000004294004213,0000000003586311166) | 9972 |
+----------+-----------------------------------------+-----------------------------
    ↪
30 rows in set (0.28 sec)
```

To delete all rating records on page 1, replace the `start_key` and `end_key` with values of page 1 in the above result:

```
SELECT * FROM ratings
WHERE
    (book_id > 268996 AND book_id < 140982742)
    OR (
        book_id = 268996 AND user_id >= 92104804
    )
    OR (
```

```
        book_id = 140982742 AND user_id <= 374645100
    )
ORDER BY book_id, user_id;
```

4.7.5 Views

This document describes how to use views in TiDB.

4.7.5.1 Overview

TiDB supports views. A view acts as a virtual table, whose schema is defined by the `SELECT` statement that creates the view.

- You can create views to expose only safe fields and data to users, which ensures the security of sensitive fields and data in the underlying tables.
- You can create views for complex queries that are frequently used to make complex queries easier and more convenient.

4.7.5.2 Create a view

In TiDB, a complex query can be defined as a view with the `CREATE VIEW` statement. The syntax is as follows:

```
CREATE VIEW view_name AS query;
```

Note that you cannot create a view with the same name as an existing view or table.

For example, the multi-table join query gets a list of books with average ratings by joining the `books` table and the `ratings` table through a `JOIN` statement.

For the convenience of subsequent queries, you can define the query as a view using the following statement:

```
CREATE VIEW book_with_ratings AS
SELECT b.id AS book_id, ANY_VALUE(b.title) AS book_title, AVG(r.score) AS
    ↪ average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id;
```

4.7.5.3 Query views

Once a view is created, you can use the `SELECT` statement to query the view just like a normal table.

```
SELECT * FROM book_with_ratings LIMIT 10;
```

When TiDB queries a view, it queries the `SELECT` statement associated with the view.

4.7.5.4 Update views

Currently, the view in TiDB does not support the `ALTER VIEW view_name AS query;`, you can "update" a view in the following two ways:

- Delete the old view with the `DROP VIEW view_name;` statement, and then update the view by creating a new view with the `CREATE VIEW view_name AS query;` statement.
- Use the `CREATE OR REPLACE VIEW view_name AS query;` statement to overwrite an existing view with the same name.

```
CREATE OR REPLACE VIEW book_with_ratings AS
SELECT b.id AS book_id, ANY_VALUE(b.title), ANY_VALUE(b.published_at) AS
    ↪ book_title, AVG(r.score) AS average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id;
```

4.7.5.5 Get view related information

4.7.5.5.1 Using the `SHOW CREATE TABLE|VIEW view_name` statement

```
SHOW CREATE VIEW book_with_ratings\G
```

The result is as follows:

```
*************************** 1. row ***************************
             View: book_with_ratings
      Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`%` SQL
          ↪ SECURITY DEFINER VIEW `book_with_ratings` (`book_id`, `
          ↪ ANY_VALUE(b.title)`, `book_title`, `average_score`) AS SELECT
          ↪  `b`.`id` AS `book_id`,ANY_VALUE(`b`.`title`) AS `ANY_VALUE(b
          ↪ .title)`,ANY_VALUE(`b`.`published_at`) AS `book_title`,AVG(`r
          ↪ `.`score`) AS `average_score` FROM `bookshop`.`books` AS `b`
          ↪ LEFT JOIN `bookshop`.`ratings` AS `r` ON `b`.`id`=`r`.`
          ↪ book_id` GROUP BY `b`.`id`
character_set_client: utf8mb4
collation_connection: utf8mb4_general_ci
1 row in set (0.00 sec)
```

4.7.5.5.2 Query the `INFORMATION_SCHEMA.VIEWS` table

```
SELECT * FROM information_schema.views WHERE TABLE_NAME = '
    ↪ book_with_ratings'\G
```

The result is as follows:

```
*************************** 1. row ***************************
       TABLE_CATALOG: def
        TABLE_SCHEMA: bookshop
          TABLE_NAME: book_with_ratings
     VIEW_DEFINITION: SELECT `b`.`id` AS `book_id`,ANY_VALUE(`b`.`title`) AS
        ↪  `ANY_VALUE(b.title)`,ANY_VALUE(`b`.`published_at`) AS `
        ↪ book_title`,AVG(`r`.`score`) AS `average_score` FROM `bookshop`.`
        ↪ books` AS `b` LEFT JOIN `bookshop`.`ratings` AS `r` ON `b`.`id`=`
        ↪ r`.`book_id` GROUP BY `b`.`id`
       CHECK_OPTION: CASCADED
       IS_UPDATABLE: NO
            DEFINER: root@%
      SECURITY_TYPE: DEFINER
CHARACTER_SET_CLIENT: utf8mb4
COLLATION_CONNECTION: utf8mb4_general_ci
1 row in set (0.00 sec)
```

4.7.5.6 Drop views

Use the `DROP VIEW view_name;` statement to drop a view.

```
DROP VIEW book_with_ratings;
```

4.7.5.7 Limitation

For limitations of views in TiDB, see Limitations of Views.

- TiFlink: Strongly Consistent Materialized Views Using TiKV and Flink

4.7.6 Temporary Tables

Temporary tables can be thought of as a technique for reusing query results.

If you want to know something about the eldest authors in the Bookshop application, you might write multiple queries that use the list of eldest authors.

For example, you can use the following statement to get the top 50 eldest authors from the `authors` table:

```
SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth_year) AS
    ↪ age
FROM authors a
ORDER BY age DESC
LIMIT 50;
```

The result is as follows:

```
+------------+--------------------+------+
| id         | name               | age |
+------------+--------------------+------+
| 4053452056 | Dessie Thompson |  80 |
| 2773958689 | Pedro Hansen    |  80 |
| 4005636688 | Wyatt Keeling   |  80 |
| 3621155838 | Colby Parker    |  80 |
| 2738876051 | Friedrich Hagenes | 80 |
| 2299112019 | Ray Macejkovic  |  80 |
| 3953661843 | Brandi Williamson | 80 |
...
| 4100546410 | Maida Walsh     |  80 |
+------------+--------------------+------+
50 rows in set (0.01 sec)
```

For the convenience of subsequent queries, you need to cache the result of this query. When using general tables for storage, you should pay attention to how to avoid the table name duplication problem between different sessions, and the need of cleaning up intermediate results in time, as these tables might not be used after a batch query.

4.7.6.1 Create a temporary table

To cache intermediate results, the temporary tables feature is introduced in TiDB v5.3.0. TiDB automatically drops a local temporary table after a session ends, which frees you from worrying about the management trouble caused by increasing intermediate results.

4.7.6.1.1 Types of temporary tables

Temporary tables in TiDB are divided into two types: local temporary tables and global temporary tables.

- For a local temporary table, the table definition and data in the table are visible only to the current session. This type is suitable for temporarily storing intermediate data in the session.
- For a global temporary table, the table definition is visible to the entire TiDB cluster, and the data in the table is visible only to the current transaction. This type is suitable for temporarily storing intermediate data in a transaction.

4.7.6.1.2 Create a local temporary table

Before creating a local temporary table, you need to add `CREATE TEMPORARY TABLES` permission to the current database user.

You can create a temporary table using the `CREATE TEMPORARY TABLE <table_name>` statement. The default type is a local temporary table, which is visible only to the current session.

```
CREATE TEMPORARY TABLE top_50_eldest_authors (
    id BIGINT,
    name VARCHAR(255),
    age INT,
    PRIMARY KEY(id)
);
```

After creating the temporary table, you can use the `INSERT INTO table_name SELECT ...` statement to insert the results of the above query into the temporary table you just created.

```
INSERT INTO top_50_eldest_authors
SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth_year) AS
    ↪ age
FROM authors a
ORDER BY age DESC
LIMIT 50;
```

The result is as follows:

```
Query OK, 50 rows affected (0.03 sec)
Records: 50 Duplicates: 0 Warnings: 0
```

```
public List<Author> getTop50EldestAuthorInfo() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        stmt.executeUpdate("""
            CREATE TEMPORARY TABLE top_50_eldest_authors (
                id BIGINT,
                name VARCHAR(255),
                age INT,
                PRIMARY KEY(id)
            );
        """);

        stmt.executeUpdate("""
            INSERT INTO top_50_eldest_authors
```

```
            SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.
                ↪ birth_year) AS age
            FROM authors a
            ORDER BY age DESC
            LIMIT 50;
        """);

        ResultSet rs = stmt.executeQuery("""
            SELECT id, name FROM top_50_eldest_authors;
        """);

        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.6.1.3 Create a global temporary table

To create a global temporary table, you can add the `GLOBAL` keyword and end with `ON COMMIT DELETE ROWS`, which means the table will be deleted after the current transaction ends.

```
CREATE GLOBAL TEMPORARY TABLE IF NOT EXISTS top_50_eldest_authors_global (
    id BIGINT,
    name VARCHAR(255),
    age INT,
    PRIMARY KEY(id)
) ON COMMIT DELETE ROWS;
```

When inserting data to global temporary tables, you must explicitly declare the start of the transaction via `BEGIN`. Otherwise, the data will be cleared after the `INSERT INTO` statement is executed. Because in the Auto Commit mode, the transaction is automatically committed after the `INSERT INTO` statement is executed, and the global temporary table is cleared when the transaction ends.

When using global temporary tables, you need to turn off Auto Commit mode first. In Java, you can do this with the `conn.setAutoCommit(false);` statement, and you can commit the transaction explicitly with `conn.commit();`. The data added to the global temporary table during the transaction will be cleared after the transaction is committed or canceled.

```
public List<Author> getTop50EldestAuthorInfo() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        conn.setAutoCommit(false);

        Statement stmt = conn.createStatement();
        stmt.executeUpdate("""
            CREATE GLOBAL TEMPORARY TABLE IF NOT EXISTS top_50_eldest_authors
                ↪  (
                id BIGINT,
                name VARCHAR(255),
                age INT,
                PRIMARY KEY(id)
            ) ON COMMIT DELETE ROWS;
        """);

        stmt.executeUpdate("""
            INSERT INTO top_50_eldest_authors
            SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.
                ↪ birth_year) AS age
            FROM authors a
            ORDER BY age DESC
            LIMIT 50;
        """);

        ResultSet rs = stmt.executeQuery("""
            SELECT id, name FROM top_50_eldest_authors;
        """);

        conn.commit();
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.6.2 View temporary tables

With the `SHOW [FULL] TABLES` statement, you can view a list of existing global temporary tables, but you cannot see any local temporary tables in the list. For now, TiDB does

not have a similar `information_schema.INNODB_TEMP_TABLE_INFO` system table for storing temporary table information.

For example, you can see the global temporary table `top_50_eldest_authors_global` in the table list, but not the `top_50_eldest_authors` table.

```
+------------------------------+------------+
| Tables_in_bookshop           | Table_type |
+------------------------------+------------+
| authors                      | BASE TABLE |
| book_authors                 | BASE TABLE |
| books                        | BASE TABLE |
| orders                       | BASE TABLE |
| ratings                      | BASE TABLE |
| top_50_eldest_authors_global | BASE TABLE |
| users                        | BASE TABLE |
+------------------------------+------------+
9 rows in set (0.00 sec)
```

4.7.6.3 Query a temporary table

Once the temporary table is ready, you can query it as a normal data table:

```
SELECT * FROM top_50_eldest_authors;
```

You can reference data from temporary tables to your query via Multi-table join queries:

```
EXPLAIN SELECT ANY_VALUE(ta.id) AS author_id, ANY_VALUE(ta.age), ANY_VALUE(
    ↪ ta.name), COUNT(*) AS books
FROM top_50_eldest_authors ta
LEFT JOIN book_authors ba ON ta.id = ba.author_id
GROUP BY ta.id;
```

Different from view, querying a temporary table gets data directly from the temporary table instead of executing the original query used in the data insert. In some cases, this can improve the query performance.

4.7.6.4 Drop a temporary table

A local temporary table in a session is automatically dropped after the **session** ends, along with both data and table schema. A global temporary table in a transaction is automatically cleared at the end of the **transaction**, but the table schema remains and needs to be deleted manually.

To manually drop local temporary tables, use the `DROP TABLE` or `DROP TEMPORARY TABLE` syntax. For example:

```
DROP TEMPORARY TABLE top_50_eldest_authors;
```

To manually drop global temporary tables, use the `DROP TABLE` or `DROP GLOBAL TEMPORARY TABLE` syntax. For example:

```
DROP GLOBAL TEMPORARY TABLE top_50_eldest_authors_global;
```

4.7.6.5 Limitation

For limitations of temporary tables in TiDB, see Compatibility restrictions with other TiDB features.

4.7.6.6 Read more

- Temporary Tables

4.7.7 Common Table Expression

In some transaction scenarios, due to application complexity, you might need to write a single SQL statement of up to 2,000 lines. The statement probably contains a lot of aggregations and multi-level subquery nesting. Maintaining such a long SQL statement can be a developer's nightmare.

To avoid such a long SQL statement, you can simplify queries by using Views or cache intermediate query results by using Temporary tables.

This document introduces the Common Table Expression (CTE) syntax in TiDB, which is a more convenient way to reuse query results.

Since TiDB v5.1, TiDB supports the CTE of the ANSI SQL99 standard and recursion. With CTE, you can write SQL statements for complex application logic more efficiently and maintain the code much easier.

4.7.7.1 Basic use

A Common Table Expression (CTE) is a temporary result set that can be referred to multiple times within a SQL statement to improve the statement readability and execution efficiency. You can apply the `WITH` statement to use CTE.

Common Table Expressions can be classified into two types: non-recursive CTE and recursive CTE.

4.7.7.1.1 Non-recursive CTE

Non-recursive CTE can be defined using the following syntax:

```
WITH <query_name> AS (
    <query_definition>
)
SELECT ... FROM <query_name>;
```

For example, if you want to know how many books each of the 50 oldest authors have written, take the following steps:

Change the statement in temporary tables to the following:

```
WITH top_50_eldest_authors_cte AS (
    SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth_year)
        ↪ AS age
    FROM authors a
    ORDER BY age DESC
    LIMIT 50
)
SELECT
    ANY_VALUE(ta.id) AS author_id,
    ANY_VALUE(ta.age) AS author_age,
    ANY_VALUE(ta.name) AS author_name,
    COUNT(*) AS books
FROM top_50_eldest_authors_cte ta
LEFT JOIN book_authors ba ON ta.id = ba.author_id
GROUP BY ta.id;
```

The result is as follows:

```
+------------+------------+--------------------+-------+
| author_id | author_age | author_name    | books |
+------------+------------+--------------------+-------+
| 1238393239 |      80 | Araceli Purdy    |     1 |
|  817764631 |      80 | Ivory Davis      |     3 |
| 3093759193 |      80 | Lysanne Harris   |     1 |
| 2299112019 |      80 | Ray Macejkovic   |     4 |
...
+------------+------------+--------------------+-------+
50 rows in set (0.01 sec)
```

```
public List<Author> getTop50EldestAuthorInfoByCTE() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
            WITH top_50_eldest_authors_cte AS (
                SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.
                    ↪ birth_year) AS age
                FROM authors a
                ORDER BY age DESC
                LIMIT 50
            )
```

```
            SELECT
                ANY_VALUE(ta.id) AS author_id,
                ANY_VALUE(ta.name) AS author_name,
                ANY_VALUE(ta.age) AS author_age,
                COUNT(*) AS books
            FROM top_50_eldest_authors_cte ta
            LEFT JOIN book_authors ba ON ta.id = ba.author_id
            GROUP BY ta.id;
        """);
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("author_id"));
            author.setName(rs.getString("author_name"));
            author.setAge(rs.getShort("author_age"));
            author.setBooks(rs.getInt("books"));
            authors.add(author);
        }
    }
    return authors;
}
```

It can be found that the author "Ray Macejkovic" wrote 4 books. With the CTE query, you can further get the order and rating information of these 4 books as follows:

```
WITH books_authored_by_rm AS (
    SELECT *
    FROM books b
    LEFT JOIN book_authors ba ON b.id = ba.book_id
    WHERE author_id = 2299112019
), books_with_average_ratings AS (
    SELECT
        b.id AS book_id,
        AVG(r.score) AS average_rating
    FROM books_authored_by_rm b
    LEFT JOIN ratings r ON b.id = r.book_id
    GROUP BY b.id
), books_with_orders AS (
    SELECT
        b.id AS book_id,
        COUNT(*) AS orders
    FROM books_authored_by_rm b
    LEFT JOIN orders o ON b.id = o.book_id
    GROUP BY b.id
)
SELECT
```

```
    b.id AS `book_id`,
    b.title AS `book_title`,
    br.average_rating AS `average_rating`,
    bo.orders AS `orders`
FROM
    books_authored_by_rm b
    LEFT JOIN books_with_average_ratings br ON b.id = br.book_id
    LEFT JOIN books_with_orders bo ON b.id = bo.book_id
;
```

The result is as follows:

```
+------------+------------------------+---------------+--------+
| book_id    | book_title             | average_rating | orders |
+------------+------------------------+---------------+--------+
|  481008467 | The Documentary of goat |    2.0000 |    16 |
| 2224531102 | Brandt Skiles          |        2.7143 |    17 |
| 2641301356 | Sheridan Bashirian     |        2.4211 |    12 |
| 4154439164 | Karson Streich         |        2.5833 |    19 |
+------------+------------------------+---------------+--------+
4 rows in set (0.06 sec)
```

Three CTE blocks, which are separated by `,`, are defined in this SQL statement.

First, check out the books written by the author (ID is `2299112019`) in the CTE block `books_authored_by_rm`. Then find the average rating and order for these books respectively in `books_with_average_ratings` and `books_with_orders`. Finally, aggregate the results by the `JOIN` statement.

Note that the query in `books_authored_by_rm` executes only once, and then TiDB creates a temporary space to cache its result. When the queries in `books_with_average_ratings` ↪ and `books_with_orders` refer to `books_authored_by_rm`, TiDB gets its result directly from this temporary space.

> **Tip:**
>
> If the efficiency of the default CTE queries is not good, you can use the `MERGE` ↪ `()` hint to expand the CTE subquery to the outer query to improve the efficiency.

4.7.7.1.2 Recursive CTE

Recursive CTE can be defined using the following syntax:

```
WITH RECURSIVE <query_name> AS (
    <query_definition>
)
SELECT ... FROM <query_name>;
```

A classic example is to generate a set of Fibonacci numbers with recursive CTE:

```
WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
(
  SELECT 1, 0, 1
  UNION ALL
  SELECT n + 1, next_fib_n, fib_n + next_fib_n FROM fibonacci WHERE n < 10
)
SELECT * FROM fibonacci;
```

The result is as follows:

```
+------+-------+------------+
| n    | fib_n | next_fib_n |
+------+-------+------------+
|    1 |     0 |          1 |
|    2 |     1 |          1 |
|    3 |     1 |          2 |
|    4 |     2 |          3 |
|    5 |     3 |          5 |
|    6 |     5 |          8 |
|    7 |     8 |         13 |
|    8 |    13 |         21 |
|    9 |    21 |         34 |
|   10 |    34 |         55 |
+------+-------+------------+
10 rows in set (0.00 sec)
```

4.7.8 Read Replica Data

4.7.8.1 Follower Read

This document introduces how to use Follower Read to optimize query performance.

4.7.8.1.1 Introduction

TiDB uses Region as the basic unit to distribute data to all nodes in the cluster. A Region can have multiple replicas, and the replicas are divided into a leader and multiple followers. When the data on the leader changes, TiDB will update the data to the followers synchronously.

By default, TiDB only reads and writes data on the leader of the same Region. When a read hotspot occurs in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader and improve the throughput of the whole system by balancing the load among multiple followers.

4.7.8.1.2 When to use

You can visually analyze whether your application has a hotspot Region on the TiDB Dashboard Key Visualizer Page. You can check whether a read hotspot occurs by selecting the "metrics selection box" to `Read (bytes)` or `Read (keys)`.

For more information about handling hotspot, see TiDB Hotspot Problem Handling.

If read hotspots are unavoidable or the changing cost is very high, you can try using the Follower Read feature to better load the balance of reading requests to the follower Region.

4.7.8.1.3 Enable Follower Read

To enable Follower Read, set the variable `tidb_replica_read` (default value is `leader`) to `follower` or `leader-and-follower`:

```
SET [GLOBAL] tidb_replica_read = 'follower';
```

For more details about this variable, see Follower Read Usage.

In Java, to enable Follower Read, define a `FollowerReadHelper` class.

```
public enum FollowReadMode {
    LEADER("leader"),
    FOLLOWER("follower"),
    LEADER_AND_FOLLOWER("leader-and-follower");

    private final String mode;

    FollowReadMode(String mode) {
        this.mode = mode;
    }

    public String getMode() {
        return mode;
    }
```

```
}

public class FollowerReadHelper {

    public static void setSessionReplicaRead(Connection conn, FollowReadMode
        ↪ mode) throws SQLException {
        if (mode == null) mode = FollowReadMode.LEADER;
        PreparedStatement stmt = conn.prepareStatement(
            "SET @@tidb_replica_read = ?;"
        );
        stmt.setString(1, mode.getMode());
        stmt.execute();
    }

    public static void setGlobalReplicaRead(Connection conn, FollowReadMode
        ↪ mode) throws SQLException {
        if (mode == null) mode = FollowReadMode.LEADER;
        PreparedStatement stmt = conn.prepareStatement(
            "SET GLOBAL @@tidb_replica_read = ?;"
        );
        stmt.setString(1, mode.getMode());
        stmt.execute();
    }

}
```

When reading data from the Follower node, use the `setSessionReplicaRead(conn, ↪ FollowReadMode.LEADER_AND_FOLLOWER)` method to enable the Follower Read feature, which can balance the load between the Leader node and the Follower node in the current session. When the connection is disconnected, it will be restored to the original mode.

```
public static class AuthorDAO {

    // Omit initialization of instance variables...

    public void getAuthorsByFollowerRead() throws SQLException {
        try (Connection conn = ds.getConnection()) {
            // Enable the follower read feature.
            FollowerReadHelper.setSessionReplicaRead(conn, FollowReadMode.
                ↪ LEADER_AND_FOLLOWER);

            // Read the authors list for 100000 times.
            Random random = new Random();
            for (int i = 0; i < 100000; i++) {
                Integer birthYear = 1920 + random.nextInt(100);
```

```
                List<Author> authors = this.getAuthorsByBirthYear(birthYear);
                System.out.println(authors.size());
            }
        }
    }

    public List<Author> getAuthorsByBirthYear(Integer birthYear) throws
        ↪ SQLException {
        List<Author> authors = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("SELECT id, name
                ↪ FROM authors WHERE birth_year = ?");
            stmt.setInt(1, birthYear);
            ResultSet rs = stmt.executeQuery();
            while (rs.next()) {
                Author author = new Author();
                author.setId( rs.getLong("id"));
                author.setName(rs.getString("name"));
                authors.add(author);
            }
        }
        return authors;
    }
}
```

4.7.8.2 Stale Read

Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism, you can read the corresponding historical data at a specific time or within a specified time range, and thus save the latency caused by data replication between storage nodes. When you are using Stale Read, TiDB randomly selects a replica for data reading, which means that all replicas are available for data reading.

In practice, consider carefully whether it is appropriate to enable Stale Read in TiDB based on the usage scenarios. Do not enable Stale Read if your application cannot tolerate reading non-real-time data.

TiDB provides three levels of Stale Read: statement level, transaction level, and session level.

4.7.8.2.1 Introduction

In the Bookshop application, you can query the latest published books and their prices through the following SQL statement:

```
SELECT id, title, type, price FROM books ORDER BY published_at DESC LIMIT
    ↪ 5;
```

The result is as follows:

```
+------------+-----------------------------+----------------------+--------+
    ↪
| id         | title                       | type                 | price |
+------------+-----------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel               | 100.00 |
| 1064253862 | Collin Rolfson              | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat      | Magazine             | 159.75 |
|  893930596 | Myrl Hills                  | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman                 | Life                 | 477.91 |
+------------+-----------------------------+----------------------+--------+
    ↪
5 rows in set (0.02 sec)
```

In the list at this time (2022-04-20 15:20:00), the price of *The Story of Droolius Caesar* is 100.0.

At the same time, the seller found that the book was very popular and raised the price of the book to 150.0 through the following SQL statement:

```
UPDATE books SET price = 150 WHERE id = 3181093216;
```

The result is as follows:

```
Query OK, 1 row affected (0.00 sec)
Rows matched: 1 Changed: 1 Warnings: 0
```

By querying the latest books list, you can see that the price of this book has increased.

```
+------------+-----------------------------+----------------------+--------+
    ↪
| id         | title                       | type                 | price |
+------------+-----------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel               | 150.00 |
| 1064253862 | Collin Rolfson              | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat      | Magazine             | 159.75 |
|  893930596 | Myrl Hills                  | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman                 | Life                 | 477.91 |
```

```
+-----------+----------------------------+----------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

If it is not necessary to use the latest data, you can query with Stale Read, which might return outdated data, to avoid the latency caused by data replication during a strongly consistent read.

Assuming that in the Bookshop application, the real-time price of a book is not required on the book lists page but only required on the book details and order pages. Stale Read can be used to improve throughout of the application.

4.7.8.2.2 Statement level

To query the price of a book before a specific time, add an `AS OF TIMESTAMP <datetime > ↪` clause in the above query statement.

```
SELECT id, title, type, price FROM books AS OF TIMESTAMP '2022-04-20
    ↪ 15:20:00' ORDER BY published_at DESC LIMIT 5;
```

The result is as follows:

```
+-----------+----------------------------+----------------------+--------+
    ↪
| id        | title                      | type                 | price |
+-----------+----------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel          | 100.00 |
| 1064253862 | Collin Rolfson          | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat  | Magazine             | 159.75 |
|  893930596 | Myrl Hills              | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman             | Life                 | 477.91 |
+-----------+----------------------------+----------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

In addition to specifying an exact time, you can also specify the following:

- `AS OF TIMESTAMP NOW()- INTERVAL 10 SECOND` queries the latest data 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 ↪ 16:45:29')` queries the latest data between `2016-10-08 16:45:26` and `2016-10-08 16:45:29`.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW()-INTERVAL 20 SECOND, NOW())` queries the latest data within 20 seconds.

Note that the specified timestamp or interval cannot be too early or later than the current time.

Expired data will be recycled by Garbage Collection in TiDB, and the data will be retained for a short period before being cleared. The period is called GC Life Time (default 10 minutes). When a GC starts, the current time minus the time period will be used as the **GC Safe Point**. If you try to read the data before GC Safe Point, TiDB will report the following error:

```
ERROR 9006 (HY000): GC life time is shorter than transaction duration...
```

If the given timestamp is a future time, TiDB will report the following error:

```
ERROR 9006 (HY000): cannot set read timestamp to a future time.
```

```
public class BookDAO {

    // Omit some code...

    public List<Book> getTop5LatestBooks() throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT id, title, type, price FROM books ORDER BY published_at
                ↪ DESC LIMIT 5;
            """);
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }
        }
        return books;
    }

    public void updateBookPriceByID(Long id, Double price) throws
        ↪ SQLException {
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("""
            UPDATE books SET price = ? WHERE id = ?;
            """);
            stmt.setDouble(1, price);
```

```
            stmt.setLong(2, id);
            int affects = stmt.executeUpdate();
            if (affects == 0) {
                throw new SQLException("Failed to update the book with id: "
                    ↪ + id);
            }
        }
    }

    public List<Book> getTop5LatestBooksWithStaleRead(Integer seconds)
        ↪ throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("""
            SELECT id, title, type, price FROM books AS OF TIMESTAMP NOW() -
                ↪ INTERVAL ? SECOND ORDER BY published_at DESC LIMIT 5;
            """);
            stmt.setInt(1, seconds);
            ResultSet rs = stmt.executeQuery();
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }
        } catch (SQLException e) {
            if ("HY000".equals(e.getSQLState()) && e.getErrorCode() == 1105)
                ↪ {
                System.out.println("WARN: cannot set read timestamp to a
                    ↪ future time.");
            } else if ("HY000".equals(e.getSQLState()) && e.getErrorCode() ==
                ↪  9006) {
                System.out.println("WARN: GC life time is shorter than
                    ↪ transaction duration.");
            } else {
                throw e;
            }
        }
        return books;
    }
}
```

```
List<Book> top5LatestBooks = bookDAO.getTop5LatestBooks();
```

```
if (top5LatestBooks.size() > 0) {
    System.out.println("The latest book price (before update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    Book book = top5LatestBooks.get(0);
    bookDAO.updateBookPriceByID(book.getId(), book.price + 10);

    top5LatestBooks = bookDAO.getTop5LatestBooks();
    System.out.println("The latest book price (after update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // Use the stale read.
    top5LatestBooks = bookDAO.getTop5LatestBooksWithStaleRead(5);
    System.out.println("The latest book price (maybe stale): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // Try to stale read the data at the future time.
    bookDAO.getTop5LatestBooksWithStaleRead(-5);

    // Try to stale read the data before 20 minutes.
    bookDAO.getTop5LatestBooksWithStaleRead(20 * 60);
}
```

The following result shows that the price returned by Stale Read is 100.00, which is the value before the update.

```
The latest book price (before update): 100.00
The latest book price (after update): 150.00
The latest book price (maybe stale): 100.00
WARN: cannot set read timestamp to a future time.
WARN: GC life time is shorter than transaction duration.
```

4.7.8.2.3 Transaction level

With the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement, you can start a read-only transaction based on historical time, which reads historical data from a specified historical timestamp.

For example:

```
START TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL 5 SECOND;
```

By querying the latest price of the book, you can see that the price of *The Story of Droolius Caesar* is still 100.0, which is the value before the update.

```
SELECT id, title, type, price FROM books ORDER BY published_at DESC LIMIT
    ↪ 5;
```

The result is as follows:

```
+------------+------------------------------+----------------------+--------+
    ↪
| id         | title                        | type                 | price |
+------------+------------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel                | 100.00 |
| 1064253862 | Collin Rolfson               | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat       | Magazine             | 159.75 |
|  893930596 | Myrl Hills                   | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman                  | Life                 | 477.91 |
+------------+------------------------------+----------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

After the transaction with the `COMMIT;` statement is committed, you can read the latest data.

```
+------------+------------------------------+----------------------+--------+
    ↪
| id         | title                        | type                 | price |
+------------+------------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel                | 150.00 |
| 1064253862 | Collin Rolfson               | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat       | Magazine             | 159.75 |
|  893930596 | Myrl Hills                   | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman                  | Life                 | 477.91 |
+------------+------------------------------+----------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

You can define a helper class for transactions, which encapsulates the command to enable Stale Read at the transaction level as a helper method.

```
public static class StaleReadHelper {

    public static void startTxnWithStaleRead(Connection conn, Integer
        ↪ seconds) throws SQLException {
        conn.setAutoCommit(false);
        PreparedStatement stmt = conn.prepareStatement(
```

```
            "START TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL ?
                ↪ SECOND;"
        );
        stmt.setInt(1, seconds);
        stmt.execute();
    }

}
```

Then define a method to enable the Stale Read feature through a transaction in the `BookDAO` class. Use the method to query instead of adding `AS OF TIMESTAMP` to the query statement.

```
public class BookDAO {

    // Omit some code...

    public List<Book> getTop5LatestBooksWithTxnStaleRead(Integer seconds)
        ↪ throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            // Start a read only transaction.
            TxnHelper.startTxnWithStaleRead(conn, seconds);

            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT id, title, type, price FROM books ORDER BY published_at
                ↪ DESC LIMIT 5;
            """);
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }

            // Commit transaction.
            conn.commit();
        } catch (SQLException e) {
            if ("HY000".equals(e.getSQLState()) && e.getErrorCode() == 1105)
                ↪ {
                System.out.println("WARN: cannot set read timestamp to a
                    ↪ future time.");
```

```
            } else if ("HY000".equals(e.getSQLState()) && e.getErrorCode() ==
                ↪ 9006) {
                System.out.println("WARN: GC life time is shorter than
                    ↪ transaction duration.");
            } else {
                throw e;
            }
        }
        return books;
    }
}
```

```
List<Book> top5LatestBooks = bookDAO.getTop5LatestBooks();

if (top5LatestBooks.size() > 0) {
    System.out.println("The latest book price (before update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    Book book = top5LatestBooks.get(0);
    bookDAO.updateBookPriceByID(book.getId(), book.price + 10);

    top5LatestBooks = bookDAO.getTop5LatestBooks();
    System.out.println("The latest book price (after update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // Use the stale read.
    top5LatestBooks = bookDAO.getTop5LatestBooksWithTxnStaleRead(5);
    System.out.println("The latest book price (maybe stale): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // After the stale read transaction is committed.
    top5LatestBooks = bookDAO.getTop5LatestBooks();
    System.out.println("The latest book price (after the transaction commit)
        ↪ : " + top5LatestBooks.get(0).getPrice());
}
```

The result is as follows:

```
The latest book price (before update): 100.00
The latest book price (after update): 150.00
The latest book price (maybe stale): 100.00
The latest book price (after the transaction commit): 150
```

With the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement, you can set the opened transaction or the next transaction to be a read-only transaction based on a specified

historical time. The transaction will read historical data based on the provided historical time.

For example, you can use the following `AS OF TIMESTAMP` statement to switch the ongoing transactions to the read-only mode and read historical data 5 seconds ago.

```
SET TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL 5 SECOND;
```

You can define a helper class for transactions, which encapsulates the command to enable Stale Read at the transaction level as a helper method.

```
public static class TxnHelper {

    public static void setTxnWithStaleRead(Connection conn, Integer seconds)
        ↪ throws SQLException {
        PreparedStatement stmt = conn.prepareStatement(
            "SET TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL ?
                ↪ SECOND;"
        );
        stmt.setInt(1, seconds);
        stmt.execute();
    }

}
```

Then define a method to enable the Stale Read feature through a transaction in the `BookDAO` class. Use the method to query instead of adding `AS OF TIMESTAMP` to the query statement.

```
public class BookDAO {

    // Omit some code...

    public List<Book> getTop5LatestBooksWithTxnStaleRead2(Integer seconds)
        ↪ throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            StaleReadHelper.setTxnWithStaleRead(conn, seconds);

            // Start a read only transaction.
            conn.setAutoCommit(false);

            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT id, title, type, price FROM books ORDER BY published_at
                ↪ DESC LIMIT 5;
            """);
```

```
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }

            // Commit transaction.
            conn.commit();
        } catch (SQLException e) {
            if ("HY000".equals(e.getSQLState()) && e.getErrorCode() == 1105)
                ↪ {
                System.out.println("WARN: cannot set read timestamp to a
                    ↪ future time.");
            } else if ("HY000".equals(e.getSQLState()) && e.getErrorCode() ==
                ↪  9006) {
                System.out.println("WARN: GC life time is shorter than
                    ↪ transaction duration.");
            } else {
                throw e;
            }
        }
        return books;
    }
}
```

4.7.8.2.4 Session level

To support reading historical data, TiDB has introduced a new system variable `tidb_read_staleness` since v5.4. you can use it to set the range of historical data that the current session is allowed to read. Its data type is `int` and its scope is `SESSION`.

Enable Stale Read in a session:

```
SET @@tidb_read_staleness="-5";
```

For example, if the value is set to `-5` and TiKV has the corresponding historical data, TiDB selects a timestamp as new as possible within a 5-second time range.

Disable Stale Read in the session:

```
set @@tidb_read_staleness="";
```

```
public static class StaleReadHelper{
```

```
    public static void enableStaleReadOnSession(Connection conn, Integer
        ↪ seconds) throws SQLException {
        PreparedStatement stmt = conn.prepareStatement(
            "SET @@tidb_read_staleness= ?;"
        );
        stmt.setString(1, String.format("-%d", seconds));
        stmt.execute();
    }

    public static void disableStaleReadOnSession(Connection conn) throws
        ↪ SQLException {
        PreparedStatement stmt = conn.prepareStatement(
            "SET @@tidb_read_staleness=\"\";"
        );
        stmt.execute();
    }

}
```

4.7.8.2.5 Read more

- Usage Scenarios of Stale Read
- Read Historical Data Using the `AS OF TIMESTAMP` Clause
- Read Historical Data Using the `tidb_read_staleness` System Variable

4.7.9 HTAP Queries

HTAP stands for Hybrid Transactional and Analytical Processing. Traditionally, databases are often designed for transactional or analytical scenarios, so the data platform often needs to be split into Transactional Processing and Analytical Processing, and the data needs to be replicated from the transactional database to the analytical database for quick response to analytical queries. TiDB databases can perform both transactional and analytical tasks, which greatly simplifies the construction of data platforms and allows users to use fresher data for analysis.

TiDB uses TiKV, a row-based storage engine, for Online Transactional Processing (OLTP), and TiFlash, a columnar storage engine, for Online Analytical Processing (OLAP). The row-based storage engine and the columnar storage engine co-exist for HTAP. Both storage engines can replicate data automatically and keep strong consistency. The row-based storage engine optimizes OLTP performance, and the columnar storage engine optimizes OLAP performance.

The Create a table section introduces how to enable the HTAP capability of TiDB. The following describes how to use HTAP to analyze data faster.

4.7.9.1 Data preparation

Before starting, you can import more sample data via the `tiup demo` command. For example:

```
tiup demo bookshop prepare --users=200000 --books=500000 --authors=100000 --
    ↪ ratings=1000000 --orders=1000000 --host 127.0.0.1 --port 4000 --drop-
    ↪ tables
```

Or you can use the Import function of TiDB Cloud to import the pre-prepared sample data.

4.7.9.2 Window functions

When using a database, in addition to storing your data and providing application features (such as ordering and rating books), you might also need to analyze the data in the database to make further operations and decisions.

The Query data from a single table document introduces how to use aggregate queries to analyze data as a whole. In more complex scenarios, you might want to aggregate the results of multiple aggregation queries into a single query. If you want to know the historical trend of the order amount of a particular book, you can aggregate `sum` for all order data of each month, and then aggregate the `sum` results together to get the historical trend.

To facilitate such analysis, since TiDB v3.0, TiDB supports window functions. For each row of data, this function provides the ability to access data across multiple rows. Different from a regular aggregation query, the window function aggregates rows without merging results set into a single row.

Similar to aggregate functions, you also need to follow a fixed set of syntax when using the window function:

```
SELECT
    window_function() OVER ([partition_clause] [order_clause] [frame_clause
        ↪ ]) AS alias
FROM
    table_name
```

4.7.9.2.1 `ORDER BY` clause

With the aggregate window function `sum()`, you can analyze the historical trend of the order amount of a particular book. For example:

```
WITH orders_group_by_month AS (
  SELECT DATE_FORMAT(ordered_at, '%Y-%c') AS month, COUNT(*) AS orders
  FROM orders
  WHERE book_id = 3461722937
  GROUP BY 1
)
```

```
SELECT
month,
SUM(orders) OVER(ORDER BY month ASC) as acc
FROM orders_group_by_month
ORDER BY month ASC;
```

The `sum()` function accumulates the data in the order specified by the `ORDER BY` statement in the `OVER` clause. The result is as follows:

```
+---------+-------+
| month   | acc   |
+---------+-------+
| 2011-5 |     1 |
| 2011-8 |     2 |
| 2012-1 |     3 |
| 2012-2 |     4 |
| 2013-1 |     5 |
| 2013-3 |     6 |
| 2015-11 |    7 |
| 2015-4 |     8 |
| 2015-8 |     9 |
| 2017-11 |   10 |
| 2017-5 |    11 |
| 2019-5 |    13 |
| 2020-2 |    14 |
+---------+-------+
13 rows in set (0.01 sec)
```

Visualize the above data through a line chart with time as the horizontal axis and cumulative order amount as the vertical axis. You can easily know the historical ordering trend of the book through the change of the slope.

4.7.9.2.2 `PARTITION BY` clause

Suppose that you want to analyze the historical ordering trend of different types of books, and visualize it in the same line chart with multiple series.

You can use the `PARTITION BY` clause to group books by types and count history orders for each type separately.

```
WITH orders_group_by_month AS (
    SELECT
        b.type AS book_type,
        DATE_FORMAT(ordered_at, '%Y-%c') AS month,
        COUNT(*) AS orders
    FROM orders o
    LEFT JOIN books b ON o.book_id = b.id
```

```
    WHERE b.type IS NOT NULL
    GROUP BY book_type, month
), acc AS (
    SELECT
        book_type,
        month,
        SUM(orders) OVER(PARTITION BY book_type ORDER BY book_type, month
            ↪ ASC) as acc
    FROM orders_group_by_month
    ORDER BY book_type, month ASC
)
SELECT * FROM acc;
```

The result is as follows:

```
+-----------------------------+---------+------+
| book_type                   | month   | acc |
+-----------------------------+---------+------+
| Magazine                    | 2011-10 |   1 |
| Magazine                    | 2011-8 |    2 |
| Magazine                    | 2012-5 |    3 |
| Magazine                    | 2013-1 |    4 |
| Magazine                    | 2013-6 |    5 |
...
| Novel                       | 2011-3 |   13 |
| Novel                       | 2011-4 |   14 |
| Novel                       | 2011-6 |   15 |
| Novel                       | 2011-8 |   17 |
| Novel                       | 2012-1 |   18 |
| Novel                       | 2012-2 |   20 |
...
| Sports                      | 2021-4 |   49 |
| Sports                      | 2021-7 |   50 |
| Sports                      | 2022-4 |   51 |
+-----------------------------+---------+------+
1500 rows in set (1.70 sec)
```

4.7.9.2.3 Non-aggregate window functions

TiDB also provides some non-aggregated window functions for more analysis statements.

For example, the Pagination Query document introduces how to use the `row_number()` function to achieve efficient pagination batch processing.

4.7.9.3 Hybrid workload

When using TiDB for real-time online analytical processing in hybrid load scenarios, you only need to provide an entry point of TiDB to your data. TiDB automatically selects different processing engines based on the specific business.

4.7.9.3.1 Create TiFlash replicas

TiDB uses the row-based storage engine, TiKV, by default. To use the columnar storage engine, TiFlash, see Enable HTAP capability. Before querying data through TiFlash, you need to create TiFlash replicas for `books` and `orders` tables using the following statement:

```
ALTER TABLE books SET TIFLASH REPLICA 1;
ALTER TABLE orders SET TIFLASH REPLICA 1;
```

You can check the progress of the TiFlash replicas using the following statement:

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '
    ↪ bookshop' and TABLE_NAME = 'books';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '
    ↪ bookshop' and TABLE_NAME = 'orders';
```

A `PROGRESS` column of 1 indicates that the progress is 100% complete, and a `AVAILABLE` column of 1 indicates that the replica is currently available.

```
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| bookshop     | books      |      143 |             1 |                 |         1 |
    ↪         1 |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
1 row in set (0.07 sec)
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| bookshop     | orders     |      147 |             1 |                 |         1 |
    ↪         1 |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
1 row in set (0.07 sec)
```

After replicas are added, you can use the `EXPLAIN` statement to check the execution plan of the above window function `PARTITION BY` clause. If `cop[tiflash]` appears in the execution plan, it means that the TiFlash engine has started to work.

Then, execute the sample SQL statement in `PARTITION BY` clause again. The result is as follows:

```
+-----------------------------+---------+------+
| book_type                   | month   | acc |
+-----------------------------+---------+------+
| Magazine                    | 2011-10 |   1 |
| Magazine                    | 2011-8 |    2 |
| Magazine                    | 2012-5 |    3 |
| Magazine                    | 2013-1 |    4 |
| Magazine                    | 2013-6 |    5 |
...
| Novel                       | 2011-3 |   13 |
| Novel                       | 2011-4 |   14 |
| Novel                       | 2011-6 |   15 |
| Novel                       | 2011-8 |   17 |
| Novel                       | 2012-1 |   18 |
| Novel                       | 2012-2 |   20 |
...
| Sports                      | 2021-4 |   49 |
| Sports                      | 2021-7 |   50 |
| Sports                      | 2022-4 |   51 |
+-----------------------------+---------+------+
1500 rows in set (0.79 sec)
```

By comparing the two execution results, you can find that the query speed is significantly improved with TiFlash (the improvement is more significant with a large volume of data). This is because a window function usually relies on a full table scan for some columns, and columnar TiFlash is more suitable to handle this type of analytical task than row-based TiKV. For TiKV, if you use primary keys or indexes to reduce the number of rows to be queried, the queries can be fast too and consume fewer resources compared with TiFlash.

4.7.9.3.2 Specify a query engine

TiDB uses the Cost Based Optimizer (CBO) to automatically choose whether to use TiFlash replicas based on cost estimates. However, if you are sure whether your query is transactional or analytical, you can specify the query engine to be used with Optimizer Hints.

To specify which engine to be used in a query, you can use the `/*+ read_from_storage(engine_name[table_name])*/` hint as in the following statement.

Note:

- If a table has an alias, use the alias instead of the table name in the hint, otherwise, the hint does not work.
- The `read_from_storage` hint does not work for common table expression.

```
WITH orders_group_by_month AS (
    SELECT
        /*+ read_from_storage(tikv[o]) */
        b.type AS book_type,
        DATE_FORMAT(ordered_at, '%Y-%c') AS month,
        COUNT(*) AS orders
    FROM orders o
    LEFT JOIN books b ON o.book_id = b.id
    WHERE b.type IS NOT NULL
    GROUP BY book_type, month
), acc AS (
    SELECT
        book_type,
        month,
        SUM(orders) OVER(PARTITION BY book_type ORDER BY book_type, month
            ↪ ASC) as acc
    FROM orders_group_by_month mo
    ORDER BY book_type, month ASC
)
SELECT * FROM acc;
```

You can use the `EXPLAIN` statement to check the execution plan of the above SQL statement. If `cop[tiflash]` and `cop[tikv]` appear in the task column at the same time, it means that TiFlash and TiKV are both scheduled to complete this query. Note that TiFlash and TiKV storage engines usually use different TiDB nodes, so the two query types are not affected by each other.

For more information about how TiDB chooses to use TiFlash, see Use TiDB to read TiFlash replicas

4.7.10 FastScan

> **Warning:**
>
> This feature is experimental and its form and usage may change in subsequent versions.

This document describes how to use FastScan to speed up queries in Online Analytical Processing (OLAP) scenarios.

By default, TiFlash guarantees the precision of query results and data consistency. With the feature FastScan, TiFlash provides more efficient query performance, but does not guarantee the accuracy of query results and data consistency.

Some OLAP scenarios allow for some tolerance to the accuracy of the query results. In these cases, if you need higher query performance, you can enable the FastScan feature at the session or global level. You can choose whether to enable the FastScan feature by configuring the variable `tiflash_fastscan`.

4.7.10.1 Enable and disable FastScan

By default, the variable is `tiflash_fastscan=OFF` at the session level and global level, that is, the FastScan feature is not enabled. You can view the variable information by using the following statement.

```
show variables like 'tiflash_fastscan';

+------------------+-------+
| Variable_name  | Value |
+------------------+-------+
| tiflash_fastscan | OFF |
+------------------+-------+
```

```
show global variables like 'tiflash_fastscan';

+------------------+-------+
| Variable_name  | Value |
+------------------+-------+
| tiflash_fastscan | OFF |
+------------------+-------+
```

You can configure the variable `tiflash_fastscan` at the session level and global level. If you need to enable FastScan in the current session, you can do so with the following statement:

```
set session tiflash_fastscan=ON;
```

You can also set `tiflash_fastscan` at the global level. The new setting will take effect in new sessions, but will not take effect in the current and previous sessions. Besides, in new sessions, `tiflash_fastscan` of the session level and global level will both take the new value.

```
set global tiflash_fastscan=ON;
```

You can disable FastScan using the following statement.

```
set session tiflash_fastscan=OFF;
set global tiflash_fastscan=OFF;
```

4.7.10.2 Mechanism of FastScan

Data in the storage layer of TiFlash is stored in two layers: Delta layer and Stable layer.

By default, FastScan is not enabled, and the TableScan operator processes data in the following steps:

1. Read data: create separate data streams in the Delta layer and Stable layer to read the respective data.
2. Sort Merge: merge the data streams created in step 1. Then return the data after sorting in (handle, version) order.
3. Range Filter: according to the data range, filter the data generated in step 2, and then return the data.
4. MVCC + Column Filter: filter the data generated in step 3 through MVCC and filter out unneeded columns, and then return the data.

FastScan gains faster query speed by sacrificing some data consistency. Step 2 and the MVCC part in step 4 in the normal scan process are omitted in FastScan, thus improving query performance.

4.8 Transaction

4.8.1 Transaction overview

TiDB supports complete distributed transactions, providing optimistic transactions and pessimistic transactions (introduced in TiDB 3.0). This article mainly introduces transaction statements, optimistic transactions and pessimistic transactions, transaction isolation levels, and application-side retry and error handling in optimistic transactions.

4.8.1.1 Common statements

This chapter introduces how to use transactions in TiDB. The following example demonstrates the process of a simple transaction:

Bob wants to transfer $20 to Alice. This transaction includes two operations:

- Bob's account is reduced by $20.
- Alice's account is increased by $20.

Transactions can ensure that both of the above operations are executed successfully or both fail.

Insert some sample data into the table using the `users` table in the bookshop database:

```
INSERT INTO users (id, nickname, balance)
  VALUES (2, 'Bob', 200);
INSERT INTO users (id, nickname, balance)
  VALUES (1, 'Alice', 100);
```

Run the following transactions and explain what each statement means:

```
BEGIN;
  UPDATE users SET balance = balance - 20 WHERE nickname = 'Bob';
  UPDATE users SET balance = balance + 20 WHERE nickname= 'Alice';
COMMIT;
```

After the above transaction is executed successfully, the table should look like this:

```
+----+--------------+---------+
| id | account_name | balance |
+----+--------------+---------+
|  1 | Alice        |  120.00 |
|  2 | Bob          |  180.00 |
+----+--------------+---------+
```

4.8.1.1.1 Start a transaction

To explicitly start a new transaction, you can use either `BEGIN` or `START TRANSACTION`.

```
BEGIN;
```

```
START TRANSACTION;
```

The default transaction mode of TiDB is pessimistic. You can also explicitly specify the optimistic transaction model:

```
BEGIN OPTIMISTIC;
```

Enable the pessimistic transaction mode:

```
BEGIN PESSIMISTIC;
```

If the current session is in the middle of a transaction when the above statement is executed, TiDB commits the current transaction first, and then starts a new transaction.

4.8.1.1.2 Commit a transaction

You can use the `COMMIT` statement to commit all modifications made by TiDB in the current transaction.

```
COMMIT;
```

Before enabling optimistic transactions, make sure that your application can properly handle errors that may be returned by a `COMMIT` statement. If you are not sure how your application will handle it, it is recommended to use the pessimistic transaction mode instead.

4.8.1.1.3 Roll back a transaction

You can use the `ROLLBACK` statement to roll back modifications of the current transaction.

```
ROLLBACK;
```

In the previous transfer example, if you roll back the entire transaction, Alice's and Bob's balances will remain unchanged, and all modifications of the current transaction are canceled.

```
TRUNCATE TABLE `users`;

INSERT INTO `users` (`id`, `nickname`, `balance`) VALUES (1, 'Alice', 100),
    ↪  (2, 'Bob', 200);

SELECT * FROM `users`;
+----+--------------+---------+
| id | nickname   | balance |
+----+--------------+---------+
|  1 | Alice      |  100.00 |
|  2 | Bob        |  200.00 |
+----+--------------+---------+

BEGIN;
  UPDATE `users` SET `balance` = `balance` - 20 WHERE `nickname`='Bob';
  UPDATE `users` SET `balance` = `balance` + 20 WHERE `nickname`='Alice';
ROLLBACK;

SELECT * FROM `users`;
```

```
+----+-------------+---------+
| id | nickname    | balance |
+----+-------------+---------+
|  1 | Alice       |  100.00 |
|  2 | Bob         |  200.00 |
+----+-------------+---------+
```

The transaction is also automatically rolled back if the client connection is stopped or closed.

4.8.1.2 Transaction isolation levels

The transaction isolation levels are the basis of database transaction processing. The "I" (Isolation) in **ACID** refers to the isolation of the transactions.

The SQL-92 standard defines four isolation levels:

- read uncommitted (`READ UNCOMMITTED`)
- read committed (`READ COMMITTED`)
- repeatable read (`REPEATABLE READ`)
- serializable (`SERIALIZABLE`).

See the table below for details:

Isolation Level	Dirty Write	Dirty Read	Fuzzy Read	Phantom
READ UNCOMMITTED	Not Possible	Possible	Possible	Possible
READ COMMITTED	Not Possible	Not possible	Possible	Possible
REPEATABLE READ	Not Possible	Not possible	Not possible	Possible
SERIALIZABLE	Not Possible	Not possible	Not possible	Not possible

TiDB supports the following isolation levels: `READ COMMITTED` and `REPEATABLE READ`:

```
mysql> SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
ERROR 8048 (HY000): The isolation level 'READ-UNCOMMITTED' is not supported
    ↪ . Set tidb_skip_isolation_level_check=1 to skip this error
mysql> SET TRANSACTION ISOLATION LEVEL READ COMMITTED;
Query OK, 0 rows affected (0.00 sec)

mysql> SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;
Query OK, 0 rows affected (0.00 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 8048 (HY000): The isolation level 'SERIALIZABLE' is not supported.
    ↪ Set tidb_skip_isolation_level_check=1 to skip this error
```

TiDB implements Snapshot Isolation (SI) level consistency, also known as "repeatable read" for consistency with MySQL. This isolation level is different from ANSI Repeatable Read Isolation Level and MySQL Repeatable Read Isolation Level. For more details, see TiDB Transaction Isolation Levels.

4.8.2 Optimistic Transactions and Pessimistic Transactions

The optimistic transaction model commits the transaction directly, and rolls back when there is a conflict. By contrast, the pessimistic transaction model tries to lock the resources that need to be modified before actually committing the transaction, and only starts committing after ensuring that the transaction can be successfully executed.

The optimistic transaction model is suitable for scenarios with low conflict rates, because the direct commit has a high probability of success. But once a transaction conflict occurs, the cost of rollback is relatively high.

The advantage of the pessimistic transaction model is that for scenarios with high conflict rates, the cost of locking ahead is less than the cost of rollback afterwards. Moreover, it can solve the problem that multiple concurrent transactions fail to commit due to conflicts. However, the pessimistic transaction model is not as efficient as the optimistic transaction model in scenarios with low conflict rates.

The pessimistic transaction model is more intuitive and easier to implement on the application side. The optimistic transaction model requires complex application-side retry mechanisms.

The following is an example of a bookshop. It uses an example of buying books to show the pros and cons of optimistic and pessimistic transactions. The process of buying books mainly consists of the following:

1. Update the stock quantity
2. Create an order
3. Make the payment

These operations must either all succeed or all fail. You must ensure that overselling does not happen in the case of concurrent transactions.

4.8.2.1 Pessimistic transactions

The following code uses two threads to simulate the process that two users buy the same book in a pessimistic transaction mode. There are 10 books left in the bookstore. Bob buys 6 books, and Alice buys 4 books. They complete the orders at nearly the same time. As a result, all books in inventory are sold out.

Because you use multiple threads to simulate the situation that multiple users insert data simultaneously, you need to use a connection object with safe threads. Here use Java's popular connection pool HikariCP for demo.

`sql.DB` in Golang is concurrency-safe, so there is no need to import a third-party package.

To adapt TiDB transactions, write a toolkit util according to the following code:

```
package util

import (
    "context"
    "database/sql"
)

type TiDBSqlTx struct {
    *sql.Tx
    conn       *sql.Conn
    pessimistic bool
}

func TiDBSqlBegin(db *sql.DB, pessimistic bool) (*TiDBSqlTx, error) {
    ctx := context.Background()
    conn, err := db.Conn(ctx)
    if err != nil {
        return nil, err
    }
    if pessimistic {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "pessimistic
            ↪ ")
    } else {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "optimistic")
    }
    if err != nil {
        return nil, err
    }
    tx, err := conn.BeginTx(ctx, nil)
    if err != nil {
        return nil, err
    }
    return &TiDBSqlTx{
        conn:       conn,
        Tx:         tx,
        pessimistic: pessimistic,
    }, nil
}

func (tx *TiDBSqlTx) Commit() error {
    defer tx.conn.Close()
    return tx.Tx.Commit()
```

```
}

func (tx *TiDBSqlTx) Rollback() error {
    defer tx.conn.Close()
    return tx.Tx.Rollback()
}
```

To ensure thread safety, you can use the mysqlclient driver to open multiple connections that are not shared between threads.

4.8.2.1.1 Write a pessimistic transaction example

Configuration file

If you use Maven to manage the package, in the `<dependencies>` node in `pom.xml`, add the following dependencies to import `HikariCP`, and set the packaging target, and the main class of the JAR package startup. The following is an example of `pom.xml`.

```
<?xml version="1.0" encoding="UTF-8"?>

<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.
    ↪ org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.
      ↪ org/xsd/maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>

  <groupId>com.pingcap</groupId>
  <artifactId>plain-java-txn</artifactId>
  <version>0.0.1</version>

  <name>plain-java-jdbc</name>

  <properties>
    <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
    <maven.compiler.source>17</maven.compiler.source>
    <maven.compiler.target>17</maven.compiler.target>
  </properties>

  <dependencies>
    <dependency>
      <groupId>junit</groupId>
      <artifactId>junit</artifactId>
      <version>4.13.2</version>
      <scope>test</scope>
    </dependency>
```

```
    <!-- https://mvnrepository.com/artifact/mysql/mysql-connector-java -->
    <dependency>
      <groupId>mysql</groupId>
      <artifactId>mysql-connector-java</artifactId>
      <version>8.0.28</version>
    </dependency>

    <dependency>
      <groupId>com.zaxxer</groupId>
      <artifactId>HikariCP</artifactId>
      <version>5.0.1</version>
    </dependency>
  </dependencies>

  <build>
    <plugins>
      <plugin>
        <groupId>org.apache.maven.plugins</groupId>
        <artifactId>maven-assembly-plugin</artifactId>
        <version>3.3.0</version>
        <configuration>
          <descriptorRefs>
            <descriptorRef>jar-with-dependencies</descriptorRef>
          </descriptorRefs>
          <archive>
            <manifest>
              <mainClass>com.pingcap.txn.TxnExample</mainClass>
            </manifest>
          </archive>

        </configuration>
        <executions>
          <execution>
            <id>make-assembly</id>
            <phase>package</phase>
            <goals>
              <goal>single</goal>
            </goals>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>

</project>
```

Coding

Then write the code:

```
package com.pingcap.txn;

import com.zaxxer.hikari.HikariDataSource;

import java.math.BigDecimal;
import java.sql.*;
import java.util.Arrays;
import java.util.concurrent.*;

public class TxnExample {
    public static void main(String[] args) throws SQLException,
        ↪ InterruptedException {
        System.out.println(Arrays.toString(args));
        int aliceQuantity = 0;
        int bobQuantity = 0;

        for (String arg: args) {
            if (arg.startsWith("ALICE_NUM")) {
                aliceQuantity = Integer.parseInt(arg.replace("ALICE_NUM=", "")
                    ↪ );
            }

            if (arg.startsWith("BOB_NUM")) {
                bobQuantity = Integer.parseInt(arg.replace("BOB_NUM=", ""));
            }
        }

        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/bookshop?
            ↪ useServerPrepStmts=true&cachePrepStmts=true");
        ds.setUsername("root");
        ds.setPassword("");

        // prepare data
        Connection connection = ds.getConnection();
        createBook(connection, 1L, "Designing Data-Intensive Application", "
            ↪ Science & Technology",

bob_thread.start()
alice_thread.start()
bob_thread.join(timeout=10)
alice_thread.join(timeout=10)
```

The Python example already includes optimistic transactions.

4.8.2.1.2 An example that does not involve overselling

Run the sample program:

```
mvn clean package
```

```
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=6
```

```
go build -o bin/txn
./bin/txn -a 4 -b 6
```

```
OPTIMISTIC=False ALICE=4 BOB=6 python3 txn_example.py
```

SQL logs:

```
/* txn 1 */ BEGIN PESSIMISTIC
    /* txn 2 */ BEGIN PESSIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
        ↪  `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
        ↪  VALUES (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
        ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 6 WHERE `id` = 1 AND `
    ↪ stock` - 6 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 6)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 600.0 WHERE `id` = 1
/* txn 1 */ COMMIT
```

Finally, check that the order is created, the user balance is deducted, and the book inventory is deducted as expected.

```
mysql> SELECT * FROM `books`;
+--
    ↪ --+--------------------------------------+--------------------+-------------

+------+---------+---------+---------+---------------------+
2 rows in set (0.01 sec)

mysql> SELECT * FROM users;
+----+---------+----------+
| id | balance | nickname |
+----+---------+----------+
|  1 | 9400.00 | Bob      |
|  2 | 9600.00 | Alice    |
+----+---------+----------+
2 rows in set (0.00 sec)
```

4.8.2.1.3 An example that prevents overselling

The task in this example is more challenging. Suppose there are 10 books left in stock. Bob buys 7 books, Alice buys 4 books, and they place orders almost at the same time. What will happen? You can reuse the code from the previous example to solve this challenge, and change Bob's purchase quantity from 6 to 7.

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=7
```

```
go build -o bin/txn
./bin/txn -a 4 -b 7
```

```
OPTIMISTIC=False ALICE=4 BOB=7 python3 txn_example.py
```

```
/* txn 1 */ BEGIN PESSIMISTIC
    /* txn 2 */ BEGIN PESSIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
        ↪ `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
        ↪ values (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
        ↪ = 2
```

```
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 7 WHERE `id` = 1 AND `
    ↪ stock` - 7 >= 0
/* txn 1 */ ROLLBACK
```

Since `txn 2` preemptively gets the lock resource and updates the stock, the return value of `affected_rows` in `txn 1` is 0, and it enters the `rollback` process.

Let's check the order creation, user balance deduction, and book inventory deduction. Alice successfully ordered 4 books, Bob failed to order 7 books, and the remaining 6 books are in stock as expected.

```
mysql> SELECT * FROM books;
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
| id | title                                | type                | published_at
    ↪      | stock | price |
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
    ↪ 2018-09-01 00:00:00 | 6 | 100.00 |
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
1 row in set (0.00 sec)

mysql> SELECT * FROM orders;
+------+---------+---------+---------+---------------------+
| id   | book_id | user_id | quality | ordered_at          |
+------+---------+---------+---------+---------------------+
| 1001 |       1 |       1 |       4 | 2022-04-19 11:03:03 |
+------+---------+---------+---------+---------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM users;
+----+----------+----------+
| id | balance | nickname |
+----+----------+----------+
|  1 | 10000.00 | Bob      |
|  2 |  9600.00 | Alice    |
+----+----------+----------+
2 rows in set (0.01 sec)
```

4.8.2.2 Optimistic transactions

The following code uses two threads to simulate the process that two users buy the same book in an optimistic transaction, just like the pessimistic transaction example. There are 10 books left in inventory. Bob buys 6 and Alice buys 4. They complete the order at about the same time. In the end, no books are left in inventory.

4.8.2.2.1 Write an optimistic transaction example

Coding

```
package com.pingcap.txn.optimistic;

import com.zaxxer.hikari.HikariDataSource;

import java.math.BigDecimal;
import java.sql.*;
import java.util.Arrays;
import java.util.concurrent.*;

public class TxnExample {
    public static void main(String[] args) throws SQLException,
        ↪ InterruptedException {
        System.out.println(Arrays.toString(args));
        int aliceQuantity = 0;
        int bobQuantity = 0;

        for (String arg: args) {
            if (arg.startsWith("ALICE_NUM")) {
                aliceQuantity = Integer.parseInt(arg.replace("ALICE_NUM=", "")
                    ↪ );
            }

            if (arg.startsWith("BOB_NUM")) {
                bobQuantity = Integer.parseInt(arg.replace("BOB_NUM=", ""));
            }
        }

        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/bookshop?
            ↪ useServerPrepStmts=true&cachePrepStmts=true");
        ds.setUsername("root");
        ds.setPassword("");

        // prepare data
        Connection connection = ds.getConnection();
```

```
        createBook(connection, 1L, "Designing Data-Intensive Application", "
            ↪ Science & Technology",
                Timestamp.valueOf("2018-09-01 00:00:00"), new BigDecimal(100)
                    ↪ , 10);
        createUser(connection, 1L, "Bob", new BigDecimal(10000));
        createUser(connection, 2L, "Alice", new BigDecimal(10000));

        CountDownLatch countDownLatch = new CountDownLatch(2);
        ExecutorService threadPool = Executors.newFixedThreadPool(2);

        final int finalBobQuantity = bobQuantity;
        threadPool.execute(() -> {

                                ↪ times. retry for " + e.getMessage());
                            buy(ds, threadID, orderID, bookID, userID,
                                ↪ quantity, retryTimes - 1);
                        }
                    }
                }
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Configuration changes

Change the startup class in `pom.xml`:

```
<mainClass>com.pingcap.txn.TxnExample</mainClass>
```

Change it to the following to point to the optimistic transaction example.

```
<mainClass>com.pingcap.txn.optimistic.TxnExample</mainClass>
```

The Golang example in the Write a pessimistic transaction example section already supports optimistic transactions and can be used directly without changes.

The Python example in the Write a pessimistic transaction example section already supports optimistic transactions and can be used directly without changes.

4.8.2.2.2 An example that does not involve overselling

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=6
```

```
go build -o bin/txn
./bin/txn -a 4 -b 6 -o true
```

```
OPTIMISTIC=True ALICE=4 BOB=6 python3 txn_example.py
```

SQL statement execution process:

```
    /* txn 2 */ BEGIN OPTIMISTIC
/* txn 1 */ BEGIN OPTIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
```

```
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
       ↪  `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
       ↪  VALUES (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
       ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 for UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 6 WHERE `id` = 1 AND `
    ↪ stock` - 6 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 6)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 600.0 WHERE `id` = 1
retry 1 times for 9007 Write conflict, txnStartTS=432618733006225412,
    ↪ conflictStartTS=432618733006225411, conflictCommitTS
    ↪ =432618733006225414, key={tableID=126, handle=1} primary={tableID
    ↪ =114, indexID=1, indexValues={1, 1000, }} [try again later]
/* txn 1 */ BEGIN OPTIMISTIC
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 6 WHERE `id` = 1 AND `
    ↪ stock` - 6 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 6)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 600.0 WHERE `id` = 1
/* txn 1 */ COMMIT
```

In the optimistic transaction mode, because the intermediate state is not necessarily correct, it is not possible to judge whether a statement is successfully executed through `affected_rows` as in the pessimistic transaction mode. You need to regard the transaction as a whole, and judge whether the current transaction has a write conflict by checking whether the final `COMMIT` statement returns an exception.

As you can see from the above SQL log, because two transactions are executed concurrently and the same record is modified, a `9007 Write conflict` exception is thrown after `txn 1` COMMIT. For write conflicts in the optimistic transaction mode, you can safely retry on the application side. After one retry, the data is committed successfully. The final execution result is as expected:

```
mysql> SELECT * FROM books;
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
| id | title                                | type               | published_at
    ↪      | stock | price |
+--
    ↪ --+--------------------------------------+--------------------+-------------
```

```
    ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
    ↪ 2018-09-01 00:00:00 | 0 | 100.00 |
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
1 row in set (0.01 sec)

mysql> SELECT * FROM orders;
+------+---------+---------+---------+---------------------+
| id   | book_id | user_id | quality | ordered_at    |
+------+---------+---------+---------+---------------------+
| 1000 |       1 |       1 |       6 | 2022-04-19 03:18:19 |
| 1001 |       1 |       1 |       4 | 2022-04-19 03:18:17 |
+------+---------+---------+---------+---------------------+
2 rows in set (0.01 sec)

mysql> SELECT * FROM users;
+----+---------+----------+
| id | balance | nickname |
+----+---------+----------+
|  1 | 9400.00 | Bob    |
|  2 | 9600.00 | Alice  |
+----+---------+----------+
2 rows in set (0.00 sec)
```

4.8.2.2.3 An example that prevents overselling

This section describes an optimistic transaction example that prevents overselling. Suppose there are 10 books left in inventory. Bob buys 7 books,and Alice buys 4 books. They place orders almost at the same time. What will happen? You can reuse the code from the optimistic transaction example to address this requirement. Change Bob's purchases from 6 to 7.

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=7
```

```
go build -o bin/txn
./bin/txn -a 4 -b 7 -o true
```

```
OPTIMISTIC=True ALICE=4 BOB=7 python3 txn_example.py
```

```
/* txn 1 */ BEGIN OPTIMISTIC
    /* txn 2 */ BEGIN OPTIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
       ↪  `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
       ↪  VALUES (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
       ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 7 WHERE `id` = 1 AND `
    ↪ stock` - 7 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 7)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 700.0 WHERE `id` = 1
retry 1 times for 9007 Write conflict, txnStartTS=432619094333980675,
    ↪ conflictStartTS=432619094333980676, conflictCommitTS
    ↪ =432619094333980678, key={tableID=126, handle=1} primary={tableID
    ↪ =114, indexID=1, indexValues={1, 1000, }} [try again later]
/* txn 1 */ BEGIN OPTIMISTIC
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
Fail -> out of stock
/* txn 1 */ ROLLBACK
```

You can see from the above SQL log that `txn 1` is retried on the application side due to a write conflict in the first execution. By comparing the latest snapshots, you can find that the stock is running out. The application side throws `out of stock`, and ends abnormally.

```
mysql> SELECT * FROM books;
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
| id | title                                | type               | published_at
    ↪      | stock | price |
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
    ↪ 2018-09-01 00:00:00 | 6 | 100.00 |
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
1 row in set (0.00 sec)
```

```
mysql> SELECT * FROM orders;
+------+---------+---------+---------+---------------------+
| id   | book_id | user_id | quality | ordered_at          |
+------+---------+---------+---------+---------------------+
| 1001 |       1 |       1 |       4 | 2022-04-19 03:41:16 |
+------+---------+---------+---------+---------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM users;
+----+----------+----------+
| id | balance | nickname |
+----+----------+----------+
|  1 | 10000.00 | Bob      |
|  2 |  9600.00 | Alice    |
+----+----------+----------+
2 rows in set (0.00 sec)
```

4.8.3 Transaction Restraints

This document briefly introduces the transaction restraints in TiDB.

4.8.3.1 Isolation levels

The isolation levels supported by TiDB are **RC (Read Committed)** and **SI (Snapshot Isolation)**, where **SI** is basically equivalent to the **RR (Repeatable Read)** isolation level.

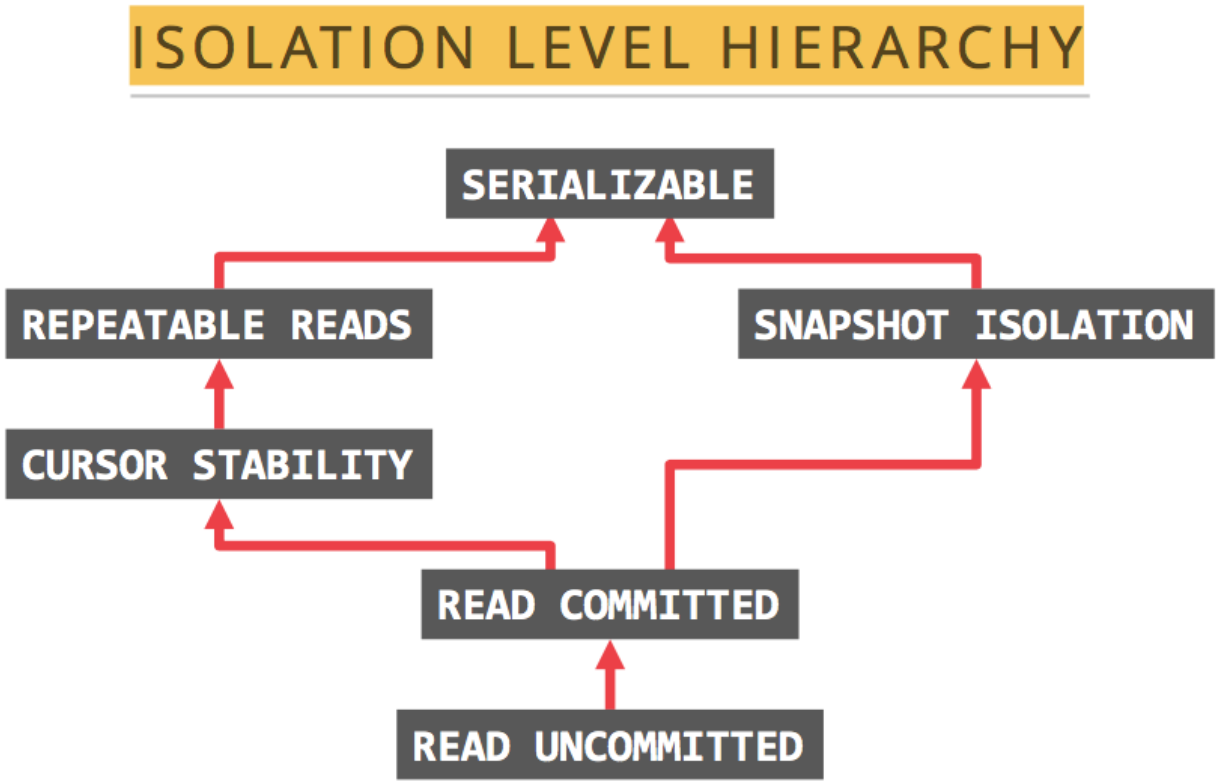

Figure 12: isolation level

4.8.3.2 Snapshot Isolation can avoid phantom reads

The `SI` isolation level of TiDB can avoid **Phantom Reads**, but the `RR` in ANSI/ISO SQL standard cannot.

The following two examples show what **phantom reads** is.

- Example 1: **Transaction A** first gets `n` rows according to the query, and then **Transaction B** changes `m` rows other than these `n` rows or adds `m` rows that match the query of **Transaction A**. When **Transaction A** runs the query again, it finds that there are `n+m` rows that match the condition. It is like a phantom, so it is called a **phantom read**.
- Example 2: **Admin A** changes the grades of all students in the database from specific scores to ABCDE grades, but **Admin B** inserts a record with a specific score at this time. When **Admin A** finishes changing and finds that there is still a record (the one inserted by **Admin B**) that has not been changed yet. That is a **phantom read**.

4.8.3.3 SI cannot avoid write skew

TiDB's SI isolation level cannot avoid **write skew** exceptions. You can use the `SELECT FOR UPDATE` syntax to avoid **write skew** exceptions.

A **write skew** exception occurs when two concurrent transactions read different but related records, and then each transaction updates the data it reads and eventually commits the transaction. If there is a constraint between these related records that cannot be modified concurrently by multiple transactions, then the end result will violate the constraint.

For example, suppose you are writing a doctor shift management program for a hospital. Hospitals typically require several doctors to be on call at the same time, but the minimum requirement is that at least one doctor is on call. Doctors can drop their shifts (for example, if they are feeling sick) as long as at least one doctor is on call during that shift.

Now there is a situation where doctors `Alice` and `Bob` are on call. Both are feeling sick, so they decide to take sick leave. They happen to click the button at the same time. Let's simulate this process with the following program:

```
package com.pingcap.txn.write.skew;

import com.zaxxer.hikari.HikariDataSource;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Semaphore;

public class EffectWriteSkew {
    public static void main(String[] args) throws SQLException,
        ↪ InterruptedException {
        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/test?useServerPrepStmts=
            ↪ true&cachePrepStmts=true");
        ds.setUsername("root");

        // prepare data
        Connection connection = ds.getConnection();
        createDoctorTable(connection);
        createDoctor(connection, 1, "Alice", true, 123);
        createDoctor(connection, 2, "Bob", true, 123);
        createDoctor(connection, 3, "Carol", false, 123);

        Semaphore txn1Pass = new Semaphore(0);
        CountDownLatch countDownLatch = new CountDownLatch(2);
        ExecutorService threadPool = Executors.newFixedThreadPool(2);

        threadPool.execute(() -> {
```

```
            askForLeave(ds, txn1Pass, 1, 1);
            countDownLatch.countDown();
        });

        threadPool.execute(() -> {
            askForLeave(ds, txn1Pass, 2, 2);
            countDownLatch.countDown();
        });

        countDownLatch.await();
    }

    public static void createDoctorTable(Connection connection) throws
        ↪ SQLException {
        connection.createStatement().executeUpdate("CREATE TABLE `doctors` ("
            ↪ +
                "    `id` int(11) NOT NULL," +
                "    `name` varchar(255) DEFAULT NULL," +
                "    `on_call` tinyint(1) DEFAULT NULL," +
                "    `shift_id` int(11) DEFAULT NULL," +
                "    PRIMARY KEY (`id`)," +
                "    KEY `idx_shift_id` (`shift_id`)" +
                "  ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
                    ↪ ");
    }

    public static void createDoctor(Connection connection, Integer id,
        ↪ String name, Boolean onCall, Integer shiftID) throws SQLException
        ↪ {
        PreparedStatement insert = connection.prepareStatement(
                "INSERT INTO `doctors` (`id`, `name`, `on_call`, `shift_id`)
                    ↪ VALUES (?, ?, ?, ?)");
        insert.setInt(1, id);
        insert.setString(2, name);
        insert.setBoolean(3, onCall);
        insert.setInt(4, shiftID);
        insert.executeUpdate();
    }

    public static void askForLeave(HikariDataSource ds, Semaphore txn1Pass,
        ↪ Integer txnID, Integer doctorID) {
        try(Connection connection = ds.getConnection()) {
            try {
                connection.setAutoCommit(false);
```

```
            String comment = txnID == 2 ? " " : "" + "/* txn #{txn_id} */
                ↪ ";
            connection.createStatement().executeUpdate(comment + "BEGIN");

            // Txn 1 should be waiting for txn 2 done
            if (txnID == 1) {
                txn1Pass.acquire();
            }

            PreparedStatement currentOnCallQuery = connection.
                ↪ prepareStatement(comment +
                    "SELECT COUNT(*) AS `count` FROM `doctors` WHERE `
                        ↪ on_call` = ? AND `shift_id` = ?");
            currentOnCallQuery.setBoolean(1, true);
            currentOnCallQuery.setInt(2, 123);
            ResultSet res = currentOnCallQuery.executeQuery();

            if (!res.next()) {
                throw new RuntimeException("error query");
            } else {
                int count = res.getInt("count");
                if (count >= 2) {
                    // If current on-call doctor has 2 or more, this
                        ↪ doctor can leave
                    PreparedStatement insert = connection.prepareStatement(
                        ↪  comment +
                            "UPDATE `doctors` SET `on_call` = ? WHERE `id` =
                                ↪  ? AND `shift_id` = ?");
                    insert.setBoolean(1, false);
                    insert.setInt(2, doctorID);
                    insert.setInt(3, 123);
                    insert.executeUpdate();

                    connection.commit();
                } else {
                    throw new RuntimeException("At least one doctor is on
                        ↪ call");
                }
            }

            // Txn 2 done, let txn 1 run again
            if (txnID == 2) {
                txn1Pass.release();
            }
        } catch (Exception e) {
```

```
                // If got any error, you should roll back, data is priceless
                connection.rollback();
                e.printStackTrace();
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

To adapt TiDB transactions, write a util according to the following code:

```
package main

import (
    "database/sql"
    "fmt"
    "sync"

    "github.com/pingcap-inc/tidb-example-golang/util"

    _ "github.com/go-sql-driver/mysql"
)

func main() {
    openDB("mysql", "root:@tcp(127.0.0.1:4000)/test", func(db *sql.DB) {
        writeSkew(db)
    })
}

func openDB(driverName, dataSourceName string, runnable func(db *sql.DB)) {
    db, err := sql.Open(driverName, dataSourceName)
    if err != nil {
        panic(err)
    }
    defer db.Close()

    runnable(db)
}

func writeSkew(db *sql.DB) {
    err := prepareData(db)
    if err != nil {
        panic(err)
    }
```

```
    waitingChan, waitGroup := make(chan bool), sync.WaitGroup{}

    waitGroup.Add(1)
    go func() {
        defer waitGroup.Done()
        err = askForLeave(db, waitingChan, 1, 1)
        if err != nil {
            panic(err)
        }
    }()

    waitGroup.Add(1)
    go func() {
        defer waitGroup.Done()
        err = askForLeave(db, waitingChan, 2, 2)
        if err != nil {
            panic(err)
        }
    }()

    waitGroup.Wait()
}

func askForLeave(db *sql.DB, waitingChan chan bool, goroutineID, doctorID
    ↪ int) error {
    txnComment := fmt.Sprintf("/* txn %d */ ", goroutineID)
    if goroutineID != 1 {
        txnComment = "\t" + txnComment
    }

    txn, err := util.TiDBSqlBegin(db, true)
    if err != nil {
        return err
    }
    fmt.Println(txnComment + "start txn")

    // Txn 1 should be waiting until txn 2 is done.
    if goroutineID == 1 {
        <-waitingChan
    }

    txnFunc := func() error {
        queryCurrentOnCall := "SELECT COUNT(*) AS `count` FROM `doctors`
            ↪ WHERE `on_call` = ? AND `shift_id` = ?"
```

```
        rows, err := txn.Query(queryCurrentOnCall, true, 123)
        if err != nil {
            return err
        }
        defer rows.Close()
        fmt.Println(txnComment + queryCurrentOnCall + " successful")

        count := 0
        if rows.Next() {
            err = rows.Scan(&count)
            if err != nil {
                return err
            }
        }
        rows.Close()

        if count < 2 {
            return fmt.Errorf("at least one doctor is on call")
        }

        shift := "UPDATE `doctors` SET `on_call` = ? WHERE `id` = ? AND `
            ↪ shift_id` = ?"
        _, err = txn.Exec(shift, false, doctorID, 123)
        if err == nil {
            fmt.Println(txnComment + shift + " successful")
        }
        return err
    }

    err = txnFunc()
    if err == nil {
        txn.Commit()
        fmt.Println("[runTxn] commit success")
    } else {
        txn.Rollback()
        fmt.Printf("[runTxn] got an error, rollback: %+v\n", err)
    }

    // Txn 2 is done. Let txn 1 run again.
    if goroutineID == 2 {
        waitingChan <- true
    }

    return nil
}
```

```
func prepareData(db *sql.DB) error {
    err := createDoctorTable(db)
    if err != nil {
        return err
    }

    err = createDoctor(db, 1, "Alice", true, 123)
    if err != nil {
        return err
    }
    err = createDoctor(db, 2, "Bob", true, 123)
    if err != nil {
        return err
    }
    err = createDoctor(db, 3, "Carol", false, 123)
    if err != nil {
        return err
    }
    return nil
}

func createDoctorTable(db *sql.DB) error {
    _, err := db.Exec("CREATE TABLE IF NOT EXISTS `doctors` (" +
        "    `id` int(11) NOT NULL," +
        "    `name` varchar(255) DEFAULT NULL," +
        "    `on_call` tinyint(1) DEFAULT NULL," +
        "    `shift_id` int(11) DEFAULT NULL," +
        "    PRIMARY KEY (`id`)," +
        "    KEY `idx_shift_id` (`shift_id`)" +
        "  ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin")
    return err
}

func createDoctor(db *sql.DB, id int, name string, onCall bool, shiftID int)
    ↪  error {
    _, err := db.Exec("INSERT INTO `doctors` (`id`, `name`, `on_call`, `
        ↪ shift_id`) VALUES (?, ?, ?, ?)",
        id, name, onCall, shiftID)
    return err
}
```

SQL log:

```
/* txn 1 */ BEGIN
```

```
    /* txn 2 */ BEGIN
    /* txn 2 */ SELECT COUNT(*) as `count` FROM `doctors` WHERE `on_call` =
       ↪  1 AND `shift_id` = 123
    /* txn 2 */ UPDATE `doctors` SET `on_call` = 0 WHERE `id` = 2 AND `
       ↪ shift_id` = 123
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT COUNT(*) AS `count` FROM `doctors` WHERE `on_call` = 1
    ↪ and `shift_id` = 123
/* txn 1 */ UPDATE `doctors` SET `on_call` = 0 WHERE `id` = 1 AND `shift_id
    ↪ ` = 123
/* txn 1 */ COMMIT
```

Running result:

```
mysql> SELECT * FROM doctors;
+----+-------+---------+----------+
| id | name | on_call | shift_id |
+----+-------+---------+----------+
|  1 | Alice |       0 |      123 |
|  2 | Bob   |       0 |      123 |
|  3 | Carol |       0 |      123 |
+----+-------+---------+----------+
```

In both transactions, the application first checks if two or more doctors are on call; if so, it assumes that one doctor can safely take leave. Since the database uses the snapshot isolation, both checks return `2`, so both transactions move on to the next stage. `Alice` updates her record to be off duty, and so does `Bob`. Both transactions are successfully committed. Now there are no doctors on duty which violates the requirement that at least one doctor should be on call. The following diagram (quoted from ***Designing Data-Intensive Applications***) illustrates what actually happens.

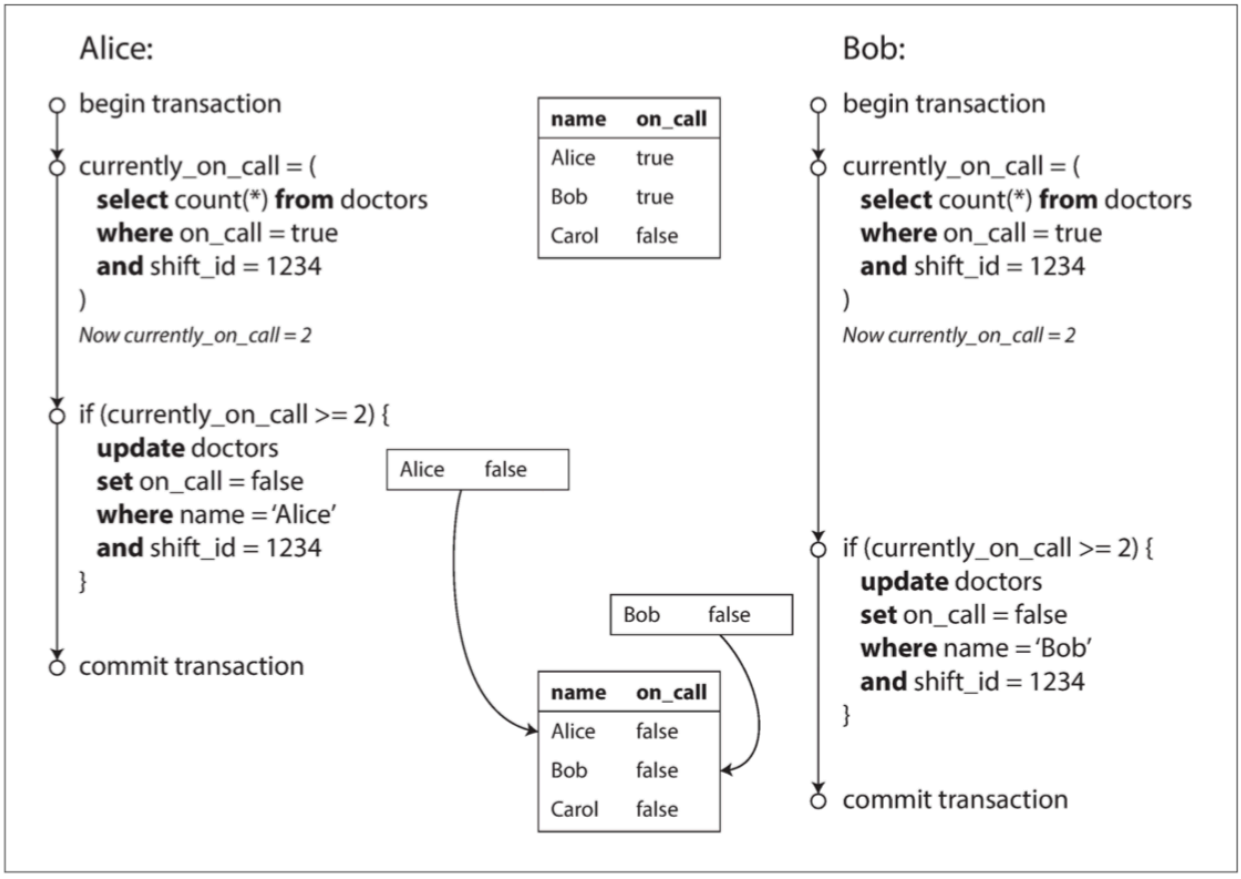

Figure 13: Write Skew

Now let's change the sample program to use `SELECT FOR UPDATE` to avoid the write skew problem:

```
package com.pingcap.txn.write.skew;

import com.zaxxer.hikari.HikariDataSource;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Semaphore;

public class EffectWriteSkew {
    public static void main(String[] args) throws SQLException,
```

```
        ↪ InterruptedException {
        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/test?useServerPrepStmts=
            ↪ true&cachePrepStmts=true");
        ds.setUsername("root");

        // prepare data
        Connection connection = ds.getConnection();
        createDoctorTable(connection);
        createDoctor(connection, 1, "Alice", true, 123);
        createDoctor(connection, 2, "Bob", true, 123);
        createDoctor(connection, 3, "Carol", false, 123);

        Semaphore txn1Pass = new Semaphore(0);
        CountDownLatch countDownLatch = new CountDownLatch(2);
        ExecutorService threadPool = Executors.newFixedThreadPool(2);

        threadPool.execute(() -> {
            askForLeave(ds, txn1Pass, 1, 1);
            countDownLatch.countDown();
        });

        threadPool.execute(() -> {
            askForLeave(ds, txn1Pass, 2, 2);
            countDownLatch.countDown();
        });

        countDownLatch.await();
    }

    public static void createDoctorTable(Connection connection) throws
        ↪ SQLException {
        connection.createStatement().executeUpdate("CREATE TABLE `doctors` ("
            ↪  +
                "    `id` int(11) NOT NULL," +
                "    `name` varchar(255) DEFAULT NULL," +
                "    `on_call` tinyint(1) DEFAULT NULL," +

    /* txn 2 */ COMMIT
/* txn 1 */ SELECT COUNT(*) AS `count` FROM `doctors` WHERE `on_call` = 1
    ↪ FOR UPDATE
At least one doctor is on call
/* txn 1 */ ROLLBACK
```

Running result:

```
mysql> SELECT * FROM doctors;
+----+-------+---------+----------+
| id | name | on_call | shift_id |
+----+-------+---------+----------+
|  1 | Alice |       1 |      123 |
|  2 | Bob   |       0 |      123 |
|  3 | Carol |       0 |      123 |
+----+-------+---------+----------+
```

4.8.3.4 Support for `savepoint` and nested transactions

The `PROPAGATION_NESTED` propagation behavior supported by **Spring** triggers a nested transaction, which is a child transaction that is started independently of the current transaction. A `savepoint` is recorded when the nested transaction starts. If the nested transaction fails, the transaction will roll back to the `savepoint` state. The nested transaction is part of the outer transaction and will be committed together with the outer transaction.

The following example demonstrates the `savepoint` mechanism:

```
mysql> BEGIN;
mysql> INSERT INTO T2 VALUES(100);
mysql> SAVEPOINT svp1;
mysql> INSERT INTO T2 VALUES(200);
mysql> ROLLBACK TO SAVEPOINT svp1;
mysql> RELEASE SAVEPOINT svp1;
mysql> COMMIT;
mysql> SELECT * FROM T2;
+------+
|  ID  |
+------+
|  100 |
+------+
```

> **Note:**
>
> Since v6.2.0, TiDB supports the `savepoint` feature. If your TiDB cluster is earlier than v6.2.0, your TiDB cluster does not support the `PROPAGATION_NESTED` behavior. If your applications are based on the **Java Spring** framework that use the `PROPAGATION_NESTED` propagation behavior, you need to adapt it on the application side to remove the logic for nested transactions.

4.8.3.5 Large transaction restrictions

The basic principle is to limit the size of the transaction. At the KV level, TiDB has a restriction on the size of a single transaction. At the SQL level, one row of data is mapped to one KV entry, and each additional index will add one KV entry. The restriction is as follows at the SQL level:

- The maximum single row record size is `120 MB`. You can configure it by `performance.txn-entry-size-limit` for TiDB v5.0 and later versions. The value is `6 MB` for earlier versions.
- The maximum single transaction size supported is `10 GB`. You can configure it by `performance.txn-total-size-limit` for TiDB v4.0 and later versions. The value is `100 MB` for earlier versions.

Note that for both the size restrictions and row restrictions, you should also consider the overhead of encoding and additional keys for the transaction during the transaction execution. To achieve optimal performance, it is recommended to write one transaction every 100 ~ 500 rows.

4.8.3.6 Auto-committed `SELECT FOR UPDATE` statements do NOT wait for locks

Currently locks are not added to auto-committed `SELECT FOR UPDATE` statements. The effect is shown in the following figure:

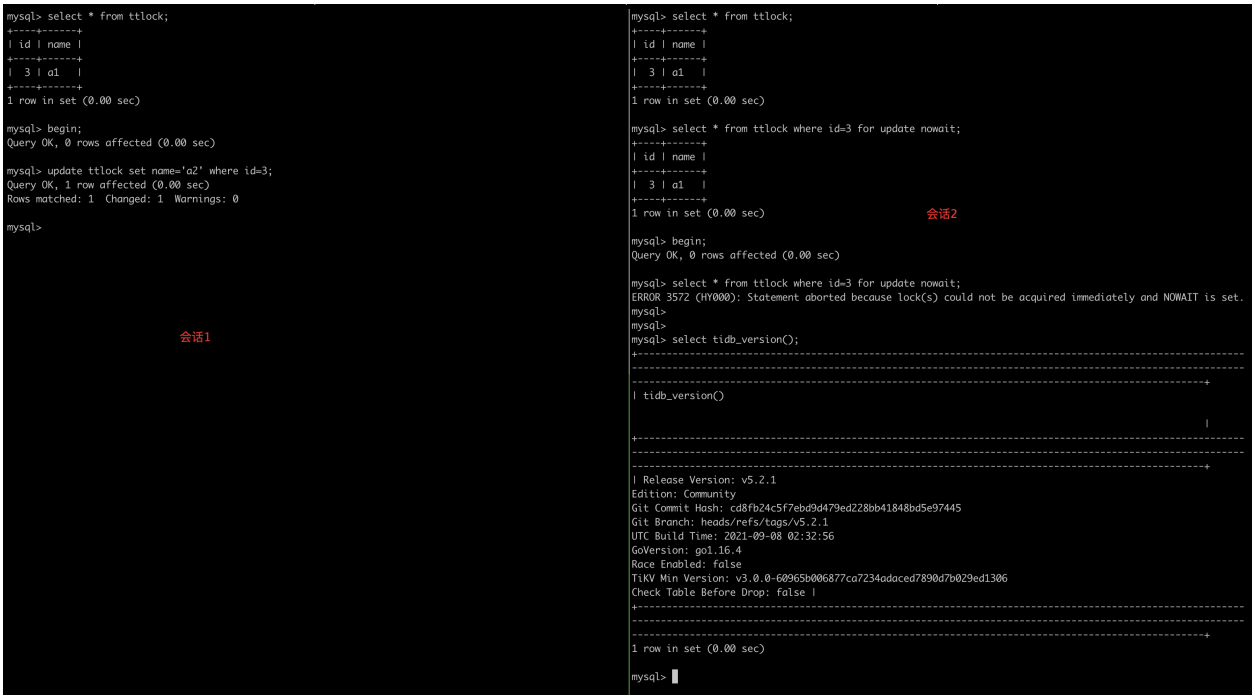

Figure 14: The situation in TiDB

This is a known incompatibility issue with MySQL. You can solve this issue by using the explicit `BEGIN;COMMIT;` statements.

4.8.4 Handle Transaction Errors

This document introduces how to handle transaction errors, such as deadlocks and application retry errors.

4.8.4.1 Deadlocks

The following error in your application indicates a deadlock issue:

```
ERROR 1213: Deadlock found when trying to get lock; try restarting
    ↪ transaction
```

A deadlock occurs when two or more transactions are waiting for each other to release the lock they already hold, or the inconsistent lock order results in a loop waiting for the lock resources.

The following is an example of a deadlock using the table `books` in the `bookshop` database:

First, insert 2 rows into the table `books`:

```
INSERT INTO books (id, title, stock, published_at) VALUES (1, 'book-1', 10,
    ↪ now()), (2, 'book-2', 10, now());
```

In TiDB pessimistic transaction mode, if two clients execute the following statements respectively, a deadlock will occur:

Client-A	Client-B
BEGIN;	
	BEGIN;
UPDATE books SET stock=stock-1 WHERE id=1;	
	UPDATE books SET s
UPDATE books SET stock=stock-1 WHERE id=2; – execution will be blocked	
	UPDATE books SET s

After client-B encounters a deadlock error, TiDB automatically rolls back the transaction in client-B. Updating `id=2` in client-A will be executed successfully. You can then run `COMMIT` to finish the transaction.

4.8.4.1.1 Solution 1: avoid deadlocks

To get better performance, you can avoid deadlocks at the application level by adjusting the business logic or schema design. In the example above, if client-B also uses the same update order as client-A, that is, they update books with `id=1` first, and then update books with `id=2`. The deadlock can then be avoided:

Client-A	Client-B
BEGIN;	
	BEGIN;
UPDATE books SET stock=stock-1 WHERE id=1;	
	UPDATE books SET stock=stock-1 WHERE id=1
UPDATE books SET stock=stock-1 WHERE id=2;	
COMMIT;	
	UPDATE books SET stock=stock-1 WHERE id=2
	COMMIT;

Alternatively, you can update 2 books with 1 SQL statement, which can also avoid the deadlock and execute more efficiently:

```
UPDATE books SET stock=stock-1 WHERE id IN (1, 2);
```

4.8.4.1.2 Solution 2: reduce transaction granularity

If you only update 1 book in each transaction, you can also avoid deadlocks. However, the trade-off is that too small transaction granularity may affect performance.

4.8.4.1.3 Solution 3: use optimistic transactions

There are no deadlocks in the optimistic transaction model. But in your application, you need to add the optimistic transaction retry logic in case of failure. For details, see Application retry and error handling.

4.8.4.1.4 Solution 4: retry

Add the retry logic in the application as suggested in the error message. For details, see Application retry and error handling.

4.8.4.2 Application retry and error handling

Although TiDB is as compatible as possible with MySQL, the nature of its distributed system leads to certain differences. One of them is the transaction model.

The Adapters and ORMs that developers use to connect with databases are tailored for traditional databases such as MySQL and Oracle. In these databases, transactions rarely fail to commit at the default isolation level, so retry mechanisms are not required. When a transaction fails to commit, these clients abort due to an error, as it is treated as an exception in these databases.

Different from traditional databases such as MySQL, in TiDB, if you use the optimistic transaction model and want to avoid commit failure, you need to add a mechanism to handle related exceptions in your applications.

The following Python pseudocode shows how to implement application-level retries. It does not require your driver or ORM to implement advanced retry logic. It can be used in any programming language or environment.

Your retry logic must follow the following rules:

- Throws an error if the number of failed retries reaches the `max_retries` limit.
- Use `try ... catch ...` to catch SQL execution exceptions. Retry when encountering the following errors. Roll back when encountering other errors.
  - `Error 8002: can not retry select for update statement`: SELECT FOR UPDATE write conflict error
  - `Error 8022: Error: KV error safe to retry`: transaction commit failed error.
  - `Error 8028: Information schema is changed during the execution of the statement`: Table schema has been changed by DDL operation, resulting in an error in the transaction commit.

  - `Error 9007: Write conflict`: Write conflict error, usually caused by multiple transactions modifying the same row of data when the optimistic transaction mode is used.

- `COMMIT` the transaction at the end of the try block.

For more information about error codes, see Error Codes and Troubleshooting.

```
while True:
    n++
    if n == max_retries:
        raise("did not succeed within #{n} retries")
    try:
        connection.execute("your sql statement here")
        connection.exec('COMMIT')
        break
    catch error:
        if (error.code != "9007" && error.code != "8028" && error.code != "
            ↪ 8002" && error.code != "8022"):
            raise error
        else:
            connection.exec('ROLLBACK')

            # Capture the error types that require application-side retry,
            # wait for a short period of time,
            # and exponentially increase the wait time for each transaction
                ↪ failure
            sleep_ms = int(((1.5 ** n) + rand) * 100)
            sleep(sleep_ms) # make sure your sleep() takes milliseconds
```

> **Note:**
>
> If you frequently encounter `Error 9007: Write conflict`, you may need to check your schema design and the data access patterns of your workload to find the root cause of the conflict and try to avoid conflicts by a better design.

For information about how to troubleshoot and resolve transaction conflicts, see Troubleshoot Lock Conflicts.

4.9 Optimize

4.9.1 Overview of Optimizing SQL Performance

This document introduces how to optimize the performance of SQL statements in TiDB. To get good performance, you can start with the following aspects:

- SQL performance tuning
- Schema design: Based on your application workload patterns, you might need to change the table schema to avoid transaction contention or hot spots.

4.9.1.1 SQL performance tuning

To get good SQL statement performance, you can follow these guidelines:

- Scan as few rows as possible. It is recommended to scan only the data you need and avoid scanning excess data.
- Use the right index. Ensure that there is a corresponding index for the column in the `WHERE` clause in SQL. If not, the statement entails a full table scan and thus causes poor performance.
- Use the right join type. It is important to choose the right join type based on the relative size of the tables involved in the query. In general, TiDB's cost-based optimizer picks the best-performing join type. However, in a few cases, you might need to manually specify a better join type.
- Use the right storage engine. For hybrid OLTP and OLAP workloads, the TiFlash engine is recommended. For details, see HTAP Query.

4.9.1.2 Schema design

After tuning SQL performance, if your application still cannot get good performance, you might need to check your schema design and data access patterns to avoid the following issues:

- Transaction contention. For how to diagnose and resolve transaction contention, see Troubleshoot Lock Conflicts.
- Hot spots. For how to diagnose and resolve hot spots, see Troubleshoot Hotspot Issues.

4.9.1.2.1 See also

- SQL Performance Tuning

4.9.2 SQL Performance Tuning

This document introduces some common reasons for slow SQL statements and techniques for tuning SQL performance.

4.9.2.1 Before you begin

You can use `tiup demo import` to prepare data:

```
tiup demo bookshop prepare --host 127.0.0.1 --port 4000 --books 1000000
```

Or using the Import feature of TiDB Cloud to import the pre-prepared sample data.

4.9.2.2 Issue: Full table scan

The most common reason for slow SQL queries is that the `SELECT` statements perform full table scan or use incorrect indexes.

When TiDB retrieves a small number of rows from a large table based on a column that is not the primary key or in the secondary index, the performance is usually poor:

```
SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
| id         | title      | type                 | published_at       | stock |
    ↪ price |
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
| 65670536   | Marian Yost | Arts                | 1950-04-09 06:28:58 | 542 |
    ↪ 435.01 |
| 1164070689 | Marian Yost | Education & Reference | 1916-05-27 12:15:35 |
    ↪ 216 | 328.18 |
| 1414277591 | Marian Yost | Arts                | 1932-06-15 09:18:14 | 303 |
    ↪ 496.52 |
| 2305318593 | Marian Yost | Arts                | 2000-08-15 19:40:58 | 398 |
    ↪ 402.90 |
| 2638226326 | Marian Yost | Sports              | 1952-04-02 12:40:37 | 191 |
    ↪ 174.64 |
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
5 rows in set
Time: 0.582s
```

To understand why this query is slow, you can use `EXPLAIN` to see the execution plan:

```
EXPLAIN SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
   ↪ ------------------+-----------+----------+--------------+-------------------
   ↪
| id                | estRows   | task     | access object | operator info
   ↪                    |
+--
   ↪ ------------------+-----------+----------+--------------+-------------------
   ↪
| TableReader_7     | 1.27      | root     |               | data:Selection_6
   ↪                    |
|  ─Selection_6     | 1.27      | cop[tikv] |              | eq(bookshop.books.
   ↪ title, "Marian Yost") |
|    ─TableFullScan_5 | 1000000.00 | cop[tikv] | table:books | keep order:
   ↪ false               |
+--
   ↪ ------------------+-----------+----------+--------------+-------------------
   ↪
```

As can be seen from `TableFullScan_5` in the execution plan, TiDB performs a full table scan on the `books` table and checks whether `title` satisfies the condition for each row. The `estRows` value of `TableFullScan_5` is `1000000.00`, which means the optimizer estimates that this full table scan takes `1000000.00` rows of data.

For more information about the usage of `EXPLAIN`, see EXPLAIN Walkthrough.

4.9.2.2.1 Solution: Use secondary index

To speed up this query above, add a secondary index on the `books.title` column:

```
CREATE INDEX title_idx ON books (title);
```

The query execution is much faster:

```
SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
   ↪ ----------+------------+----------------------+-------------------+-------+-
   ↪
| id         | title      | type                 | published_at      | stock |
   ↪ price |
+--
   ↪ ----------+------------+----------------------+-------------------+-------+-
   ↪
| 1164070689 | Marian Yost | Education & Reference | 1916-05-27 12:15:35 |
   ↪ 216 | 328.18 |
```

```
| 1414277591 | Marian Yost | Arts            | 1932-06-15 09:18:14 | 303 |
    ↪ 496.52 |
| 2305318593 | Marian Yost | Arts            | 2000-08-15 19:40:58 | 398 |
    ↪ 402.90 |
| 2638226326 | Marian Yost | Sports          | 1952-04-02 12:40:37 | 191 |
    ↪ 174.64 |
| 65670536   | Marian Yost | Arts            | 1950-04-09 06:28:58 | 542 |
    ↪ 435.01 |
+--
    ↪ ----------+-------------+----------------------+---------------------+-------+-
    ↪
5 rows in set
Time: 0.007s
```

To understand why the performance is improved, use `EXPLAIN` to see the new execution plan:

```
EXPLAIN SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
    ↪ -----------------------+---------+-----------+---------------------------------
    ↪
| id                        | estRows | task      | access object
    ↪                      | operator info                                    |
+--
    ↪ -----------------------+---------+-----------+---------------------------------
    ↪
| IndexLookUp_10            | 1.27    | root      |
    ↪                                  |
    ↪                                                      |
|  ─IndexRangeScan_8(Build) | 1.27 | cop[tikv] | table:books, index:
    ↪ title_idx(title) | range:["Marian Yost","Marian Yost"], keep order:
    ↪ false |
|  ─TableRowIDScan_9(Probe) | 1.27 | cop[tikv] | table:books
    ↪                     | keep order:false                                 |
+--
    ↪ -----------------------+---------+-----------+---------------------------------
    ↪
```

As can be seen from `IndexLookup_10` in the execution plan, TiDB queries the data by the `title_idx` index. Its `estRows` value is `1.27`, which means that the optimizer estimates that only `1.27` rows are scanned. The estimated rows scanned are much fewer than the `1000000.00` rows of data in the full table scan.

The `IndexLookup_10` execution plan is to first use the `IndexRangeScan_8` operator to read the index data that meets the condition through the `title_idx` index, and then use the

`TableLookup_9` operator to query the corresponding rows according to the Row ID stored in the index data.

For more information on the TiDB execution plan, see TiDB Query Execution Plan Overview.

4.9.2.2.2 Solution: Use covering index

If the index is a covering index, which contains all the columns queried by the SQL statements, scanning the index data is sufficient for the query.

For example, in the following query, you only need to query the corresponding `price` based on `title`:

```
SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
+-------------+--------+
| title      | price |
+-------------+--------+
| Marian Yost | 435.01 |
| Marian Yost | 328.18 |
| Marian Yost | 496.52 |
| Marian Yost | 402.90 |
| Marian Yost | 174.64 |
+-------------+--------+
5 rows in set
Time: 0.007s
```

Because the `title_idx` index only contains data in the `title` column, TiDB still needs to first scan the index data and then query the `price` column from the table.

```
EXPLAIN SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
+--
    ↪ ------------------------+---------+-----------+-----------------------------
    ↪
| id                     | estRows | task    | access object
    ↪                   | operator info                                  |
+--
    ↪ ------------------------+---------+-----------+-----------------------------
    ↪
| IndexLookUp_10         | 1.27    | root      |
    ↪                                  |
    ↪                                                 |
|  ─IndexRangeScan_8(Build) | 1.27 | cop[tikv] | table:books, index:
    ↪ title_idx(title) | range:["Marian Yost","Marian Yost"], keep order:
    ↪ false |
```

```
|  └─TableRowIDScan_9(Probe) | 1.27 | cop[tikv] | table:books
   ↪                  | keep order:false                                |
+--
   ↪ ----------------------+---------+-----------+-------------------------------
   ↪
```

To optimize the performance, drop the `title_idx` index and create a new covering index `title_price_idx`:

```
ALTER TABLE books DROP INDEX title_idx;
```

```
CREATE INDEX title_price_idx ON books (title, price);
```

Because the `price` data is stored in the `title_price_idx` index, the following query only needs to scan the index data:

```
EXPLAIN SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
--
   ↪ -----------------+---------+-----------+-----------------------------------
   ↪
| id                | estRows | task    | access object
   ↪                              | operator info
   ↪                                 |
+--
   ↪ -----------------+---------+-----------+-----------------------------------
   ↪
| IndexReader_6     | 1.27    | root      |
   ↪                                                 | index:IndexRangeScan_5
   ↪                           |
|  └─IndexRangeScan_5 | 1.27 | cop[tikv] | table:books, index:
   ↪ title_price_idx(title, price) | range:["Marian Yost","Marian Yost"],
   ↪ keep order:false |
+--
   ↪ -----------------+---------+-----------+-----------------------------------
   ↪
```

Now this query runs faster:

```
SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
+-------------+--------+
| title       | price |
+-------------+--------+
| Marian Yost | 174.64 |
| Marian Yost | 328.18 |
```

```
| Marian Yost | 402.90 |
| Marian Yost | 435.01 |
| Marian Yost | 496.52 |
+-------------+--------+
5 rows in set
Time: 0.004s
```

Since the `books` table will be used in later examples, drop the `title_price_idx` index:

```
ALTER TABLE books DROP INDEX title_price_idx;
```

4.9.2.2.3 Solution: Use primary index

If a query uses the primary key to filter data, the query runs fast. For example, the primary key of the `books` table is the `id` column, so you can use the `id` column to query data:

```
SELECT * FROM books WHERE id = 896;
```

```
+--
    ↪ ---+---------------+---------------------+--------------------+-------+------
    ↪
| id  | title         | type                | published_at       | stock | price
    ↪ |
+--
    ↪ ---+---------------+---------------------+--------------------+-------+------
    ↪
| 896 | Kathryne Doyle | Science & Technology | 1969-03-18 01:34:15 | 468 |
    ↪ 281.32 |
+--
    ↪ ---+---------------+---------------------+--------------------+-------+------
    ↪
1 row in set
Time: 0.004s
```

Use `EXPLAIN` to see the execution plan:

```
EXPLAIN SELECT * FROM books WHERE id = 896;
```

```
+-------------+---------+------+---------------+---------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+---------------+---------------+
| Point_Get_1 | 1.00 | root | table:books | handle:896 |
+-------------+---------+------+---------------+---------------+
```

`Point_Get` is a very fast execute plan.

4.9.2.3 Use the right join type

See JOIN Execution Plan.

4.9.2.3.1 See also

- Explain Statements That Use Indexes

4.9.3 Performance Tuning Best Practices

This document introduces some best practices for using TiDB databases.

4.9.3.1 DML best practices

This section describes the best practices involved when you use DML with TiDB.

4.9.3.1.1 Use multi-row statements

When you need to modify multiple rows of table, it is recommended to use multi-row statements:

```
INSERT INTO t VALUES (1, 'a'), (2, 'b'), (3, 'c');

DELETE FROM t WHERE id IN (1, 2, 3);
```

It is not recommended to use multiple single-row statements:

```
INSERT INTO t VALUES (1, 'a');
INSERT INTO t VALUES (2, 'b');
INSERT INTO t VALUES (3, 'c');

DELETE FROM t WHERE id = 1;
DELETE FROM t WHERE id = 2;
DELETE FROM t WHERE id = 3;
```

4.9.3.1.2 Use `PREPARE`

When you need to execute a SQL statement for multiple times, it is recommended to use the `PREPARE` statement to avoid the overhead of repeatedly parsing the SQL syntax.

```
func BatchInsert(db *sql.DB) error {
    stmt, err := db.Prepare("INSERT INTO t (id) VALUES (?), (?), (?), (?),
        ↪ (?)")
    if err != nil {
        return err
```

```
    }
    for i := 0; i < 1000; i += 5 {
        values := []interface{}{i, i + 1, i + 2, i + 3, i + 4}
        _, err = stmt.Exec(values...)
        if err != nil {
            return err
        }
    }
    return nil
}
```

```
public void batchInsert(Connection connection) throws SQLException {
    PreparedStatement statement = connection.prepareStatement(
            "INSERT INTO `t` (`id`) VALUES (?), (?), (?), (?), (?)");
    for (int i = 0; i < 1000; i ++) {
        statement.setInt(i % 5 + 1, i);

        if (i % 5 == 4) {
            statement.executeUpdate();
        }
    }
}
```

Do not execute the `PREPARE` statement repeatedly. Otherwise, the execution efficiency cannot be improved.

4.9.3.1.3 Only query the columns you need

If you do not need data from all columns, do not use `SELECT *` to return all columns data. The following query is inefficient:

```
SELECT * FROM books WHERE title = 'Marian Yost';
```

You should only query the columns you need. For example:

```
SELECT title, price FROM books WHERE title = 'Marian Yost';
```

4.9.3.1.4 Use bulk delete

When you delete a large amount of data, it is recommended to use bulk delete.

4.9.3.1.5 Use bulk update

When you update a large amount of data, it is recommended to use bulk update.

4.9.3.1.6 Use `TRUNCATE` instead of `DELETE` for full table data

When you need to delete all data from a table, it is recommended to use the `TRUNCATE` statement:

```
TRUNCATE TABLE t;
```

It is not recommended to use `DELETE` for full table data:

```
DELETE FROM t;
```

4.9.3.2 DDL best practices

This section describes the best practices involved when using TiDB's DDL.

4.9.3.2.1 Primary key best practices

See the rules to follow when selecting the primary key.

4.9.3.3 Index best practices

See Index Best Practices.

4.9.3.3.1 Add index best practices

TiDB supports the online index add operation. You can use ADD INDEX or CREATE INDEX statement to add an index. It does not block data reads and writes in the table. You can adjust the concurrency and the batch size during the `re-organize` phase of the index add operation by modifying the following system variables:

- `tidb_ddl_reorg_worker_cnt`
- `tidb_ddl_reorg_batch_size`

To reduce the impact on the online application, the default speed of add index operation is slow. When the target column of add index operation only involves read load or is not directly related to online workload, you can appropriately increase the value of the above variables to speed up the add index operation:

```
SET @@global.tidb_ddl_reorg_worker_cnt = 16;
SET @@global.tidb_ddl_reorg_batch_size = 4096;
```

When the target column of the add index operation is updated frequently (including `UPDATE`, `INSERT` and `DELETE`), increasing the above variables causes more write conflicts, which impacts the online workload. Accordingly, the add index operation might take a long time to complete due to constant retries. In this case, it is recommended to decrease the value of the above variables to avoid write conflicts with the online application:

```
SET @@global.tidb_ddl_reorg_worker_cnt = 4;
SET @@global.tidb_ddl_reorg_batch_size = 128;
```

4.9.3.4 Transaction conflicts

For how to locate and resolve transaction conflicts, see Troubleshoot Lock Conflicts.

4.9.3.5 Best practices for developing Java applications with TiDB

See Best Practices for Developing Java Applications with TiDB.

4.9.3.5.1 See also

- Highly Concurrent Write Best Practices

4.9.4 Best Practices for Indexing

This document introduces some best practices for creating and using indexes in TiDB.

4.9.4.1 Before you begin

This section takes the `books` table in the bookshop database as an example.

```
CREATE TABLE `books` (
  `id` bigint(20) AUTO_RANDOM NOT NULL,
  `title` varchar(100) NOT NULL,
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports') NOT NULL,
  `published_at` datetime NOT NULL,
  `stock` int(11) DEFAULT '0',
  `price` decimal(15,2) DEFAULT '0.0',
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

4.9.4.2 Best practices for creating indexes

- Creating a combined index with multiple columns, which is an optimization called covering index optimization. **Covering index optimization** allows TiDB to query data directly on indexes, which helps improve performance.
- Avoid creating a secondary index on columns that you do not query often. A useful secondary index can speed up queries, but be aware that it also has side effects. Each time you add an index, an additional Key-Value is added when you insert a row. The more indexes you have, the slower you write, and the more space it consumes. In addition, too many indexes affect optimizer runtime, and inappropriate indexes can mislead the optimizer. So, more indexes do not always mean better performance.

- Create an appropriate index based on your application. In principle, create indexes only on the columns to be used in queries to improve performance. The following cases are suitable for creating an index:

  - Columns with a high distinction degree can significantly reduce the number of filtered rows. For example, it is recommended to create an index on the personal ID number, but not on the gender.
  - Use combined indexes when querying with multiple conditions. Note that columns with equivalent conditions need to be placed in the front of the combined index. Here is an example: if the `select* from t where c1 = 10 and c2 = 100 and c3 > 10` query is frequently used, consider creating a combined index `Index cidx (c1, c2, c3)`, so that a index prefix can be constructed to scan by query conditions.

- Name your secondary index meaningfully, and it is recommended to follow the table naming conventions of your company or organization. If such naming conventions do not exist, follow the rules in Index Naming Specification.

4.9.4.3 Best practices for using indexes

- Indexes are to speed up queries, so make sure that the existing indexes are actually used by some queries. If an index is not used by any query, the index is meaningless, and you need to drop it.

- When using a combined index, follow the left-prefix rule.

  Suppose that you create a new combined index on the `title` and `published_at` columns:

  ```
  CREATE INDEX title_published_at_idx ON books (title, published_at);
  ```

  The following query can still use the combined index:

  ```
  SELECT * FROM books WHERE title = 'database';
  ```

  However, the following query cannot use the combined index because the condition for the leftmost first column in the index is not specified:

  ```
  SELECT * FROM books WHERE published_at = '2018-08-18 21:42:08';
  ```

- When using an index column as a condition in a query, do not use calculation, function, or type conversion on it, which will prevent the TiDB optimizer from using the index.

  Suppose that you create a new index on the time type column `published_at`:

  ```
  CREATE INDEX published_at_idx ON books (published_at);
  ```

  However, the following query cannot use the index on `published_at`:

```
SELECT * FROM books WHERE YEAR(published_at)=2022;
```

To use the index on `published_at`, you can rewrite the query as follows, which avoids using any function on the index column:

```
SELECT * FROM books WHERE published_at >= '2022-01-01' AND
    ↪ published_at < '2023-01-01';
```

You can also use an expression index to create an expression index for `YEAR(Published at)` in the query condition:

```
CREATE INDEX published_year_idx ON books ((YEAR(published_at)));
```

Now, if you execute the `SELECT * FROM books WHERE YEAR(published_at)=2022;` query, the query can use the `published_year_idx` index to speed up the execution.

> **Warning:**
>
> Currently, expression index is an experimental feature, and it needs to be enabled in the TiDB configuration file. For more details, see expression index.

- Try to use a covering index, in which the columns in the index contain the columns to be queried, and avoid querying all columns with `SELECT *` statements.

  The following query only needs to scan the index `title_published_at_idx` to get the data:

  ```
  SELECT title, published_at FROM books WHERE title = 'database';
  ```

  Although the following query statement can use the combined index `(title, published_at)`, it causes an extra cost to query the non-indexed column, which requires TiDB to query row data according to the reference stored in the index data (usually the primary key information).

  ```
  SELECT * FROM books WHERE title = 'database';
  ```

- A query cannot use indexes when the query condition contains `!=` or `NOT IN`. For example, the following query cannot use any indexes:

  ```
  SELECT * FROM books WHERE title != 'database';
  ```

- A query cannot use indexes if the `LIKE` condition starts with wildcard `%` in the query. For example, the following query cannot use any indexes:

  ```
  SELECT * FROM books WHERE title LIKE '%database';
  ```

- When the query condition has multiple indexes available, and you know which index is the best in practice, it is recommended to use Optimizer Hint to force the TiDB optimizer to use this index. This can prevent the TiDB optimizer from selecting the wrong index due to inaccurate statistics or other problems.

  In the following query, assuming that indexes `id_idx` and `title_idx` are available on the column `id` and `title` respectively, if you know that `id_idx` is better, you can use `USE INDEX` hint in SQL to force the TiDB optimizer to use the `id_idx` index.

```
SELECT * FROM t USE INDEX(id_idx) WHERE id = 1 and title = 'database';
```

- When using the `IN` expression in a query condition, it is recommended that the number of value matched after it does not exceed 300, otherwise the execution efficiency will be poor.

4.9.5 Other Optimization Methods

4.9.5.1 Avoid Implicit Type Conversions

This document introduces the rules and possible consequences of implicit type conversions in TiDB and how to avoid implicit type conversions.

4.9.5.1.1 Conversion rules

When the data types on the two sides of the predicate in a SQL statement do not match, TiDB implicitly convert the data types on one or both sides to a compatible data type for predicate operations.

The rules for implicit type conversion in TiDB are as follows:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`. The NULL-safe `<=>` equivalent comparison operator does not require conversion, because NULL `<=>` NULL results in `true`.
- If both arguments in the comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- If no comparison is made with numbers, the hexadecimal value is treated as a binary string.
- If one of the arguments is a decimal value, the comparison depends on the other argument. If the other argument is a decimal or integer value, the argument is compared with the decimal value. If the other argument is a floating-point value, the argument is compared with the floating-point value.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed.
- In all other cases, the arguments are compared as floating-point numbers (the `DOUBLE` type).

4.9.5.1.2 Consequences caused by implicit type conversion

Implicit type conversions increase the usability of human-computer interaction. However, avoid using implicit type conversions in application code, because they might lead to the following issues:

- Index invalidity
- Loss of precision

Index invalidity

In the following case, `account_id` is the primary key and its data type is `varchar`. In the execution plan, this SQL statement has an implicit type conversion and cannot use the index.

```
DESC SELECT * FROM `account` WHERE `account_id`=6010000000009801;
+--
   ↪ ----------------------+---------------+----------+--------------+----------
   ↪
| id                    | estRows       | task     | access object | operator
   ↪ info                                       |
+--
   ↪ ----------------------+---------------+----------+--------------+----------
   ↪
| TableReader_7         | 8000628000.00 | root     |               | data:
   ↪ Selection_6                                |
| ─Selection_6          | 8000628000.00 | cop[tikv] |              | eq(cast(
   ↪ findpt.account.account_id), 6.010000000009801e+15) |
|   ─TableFullScan_5    | 10000785000.00 | cop[tikv] | table:account | keep
   ↪ order:false                                |
+--
   ↪ ----------------------+---------------+----------+--------------+----------
   ↪
3 rows in set (0.00 sec)
```

Brief description of run results: From the above execution plan, the `Cast` operator is visible.

Loss of precision

In the following case, the data type of the `a` field is `decimal(32,0)`. In the execution plan, an implicit type conversion occurs, and both the decimal field and the string constant are converted to the double type. Because the precision of the double type is not as high as decimal, there is a loss of precision. In this case, the SQL statement incorrectly filters the result set out of range.

```
DESC SELECT * FROM `t1` WHERE `a` BETWEEN '12123123' AND '
   ↪ 111122221111111200000';
```

```
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                                                                |
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
| TableReader_7         | 0.80    | root      |               | data:Selection_6
   ↪                                                                |
|  ─Selection_6         | 0.80    | cop[tikv] |               | ge(cast(findpt.t1
   ↪ .a), 1.2123123e+07), le(cast(findpt.t1.a), 1.1112222111111112e+21) |
|    ─TableFullScan_5   | 1.00    | cop[tikv] | table:t1    | keep order:false,
   ↪  stats:pseudo                                                  |
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
3 rows in set (0.00 sec)
```

Brief description of run results: From the above execution plan, the `Cast` operator is visible.

```
SELECT * FROM `t1` WHERE `a` BETWEEN '12123123' AND '1111222211111111200000
   ↪ ';
+-----------------------+
| a                     |
+-----------------------+
| 1111222211111111222211 |
+-----------------------+
1 row in set (0.01 sec)
```

Brief description of run results: The above execution gives a wrong result.

4.9.5.2 Unique Serial Number Generation

This document introduces the unique serial number generation scheme to help developers who generate their own unique IDs.

4.9.5.2.1 Auto-increment column

`AUTO_INCREMENT` is a column attribute of many RDBMSs that are compatible with the MySQL protocol. With the `AUTO_INCREMENT` attribute, a database can automatically assign values to this column without user intervention. As the number of records in the table increases, the value of this column automatically increments and are guaranteed to be unique. In most scenarios, `AUTO_INCREMENT` columns are used as proxy primary keys with no actual meaning.

The limitation of `AUTO_INCREMENT` columns is that the column must be of the integer type and the values assigned to them must be integer. If the serial numbers required by the application are sliced by letters, numbers, and other characters, it is difficult for the user to get the auto-increment numbers required in the serial number through the `AUTO_INCREMENT` column.

4.9.5.2.2 Sequence

A **Sequence** is a database object that an application can invoke to produce incremental sequence values. Applications can flexibly use the sequence values to assign values to one or more tables. Applications can also use the sequence values for more complex processing to produce a combination of text and numbers. This approach gives some tracking and classification meaning to proxy keys.

Sequence is available starting with TiDB v4.0. For details, refer to sequence documentation.

4.9.5.2.3 Snowflake-like solutions

Snowflake is a distributed ID generation solution proposed by Twitter. There are several implementations, the more popular ones are Baidu's **uid-generator** and Meituan's **leaf**. This section uses `uid-generator` as an example.

The 64-bit ID structure generated by `uid-generator` is as follows:

```
| sign | delta seconds | worker node id | sequencs |
|------|---------------|----------------|----------|
| 1bit |    28bits     | 22bits         | 13bits   |
```

- sign: Fixed length of 1 bit. Fixed to `0` to indicate that the generated ID is always a positive number.
- delta seconds: 28 bits by default. The current time, presented as an incremental value in seconds relative to a preset time base (defaults to `2016-05-20`). 28 bits can support up to about 8.7 years.
- worker node id: 22 bits by default. Represents the machine ID, usually obtained from a centralized ID generator when the application process is started. Common centralized ID generators include auto-increment columns and ZooKeeper. The default allocation policy is discard-as-you-go, and the process re-acquires a new worker node ID on restart. 22 bits can support up to about 4.2 million starts.
- sequence: 13 bits by default. The sequence of concurrency per second. 13 bits can support 8192 concurrent sequences per second.

4.9.5.2.4 Number allocation solution

The number allocation solution can be understood as bulk acquisition of auto-increment IDs from the database. This scheme requires a sequence number generation table, with each row representing a sequence object. An example of table definition is as follows:

Field Name	Field Type	Field Description
`SEQ_NAME` ↪	varchar(128)	The name of the sequence, used to distinguish different applications.
`MAX_ID`	bigint(20)	The maximum value of the current sequence that has been allocated.
`STEP`	int(11)	The step, which indicates the length of each assigned segment.

Every time, the application gets a segment of sequence numbers at the configured step. It updates the database at the same time to persist the maximum value of the current sequence that has been allocated. The processing and allocation of sequence numbers are completed in the application's memory. After a segment of sequence numbers is used up, the application gets a new segment of sequence numbers, which effectively alleviates the pressure on the database write. In practice, you can also adjust the step to control the frequency of database updates.

Finally, note that the IDs generated by the above two solutions are not random enough to be directly used as **primary keys** for TiDB tables. In practice, you can perform bit-reverse on the generated IDs to get more random new IDs.

4.10 Troubleshoot

4.10.1 SQL or Transaction Issues

This document introduces problems that may occur during application development and related documents.

4.10.1.1 Troubleshoot SQL query problems

If you want to improve SQL query performance, follow the instructions in SQL Performance Tuning to solve performance problems such as full table scans and missing indexes.

If you still have performance issues, see the following documents:

- Analyze Slow Queries
- Identify Expensive Queries Using Top SQL

If you have questions about SQL operations, see SQL FAQs.

4.10.1.2 Troubleshoot transaction issues

See Handle transaction errors.

4.10.1.3 See also

- Unsupported features

- Cluster Management FAQs
- TiDB FAQs

4.10.2 Unstable Result Set

This document describes how to solve unstable result set errors.

4.10.2.1 GROUP BY

For convenience, MySQL "extends" the `GROUP BY` syntax to allow the `SELECT` clause to refer to non-aggregated fields not declared in the `GROUP BY` clause, that is, the `NON-FULL GROUP BY` syntax. In other databases, this is considered a syntax ***ERROR*** because it causes unstable result sets.

For example, you have two tables:

- `stu_info` stores the student information
- `stu_score` stores the student test scores.

Then you can write a SQL query statement like this:

```
SELECT
    `a`.`class`,
    `a`.`stuname`,
    max( `b`.`courscore` )
FROM
    `stu_info` `a`
    JOIN `stu_score` `b` ON `a`.`stuno` = `b`.`stuno`
GROUP BY
    `a`.`class`,
    `a`.`stuname`
ORDER BY
    `a`.`class`,
    `a`.`stuname`;
```

Result:

```
+-----------+-------------+-----------------+
| class     | stuname     | max(b.courscore) |
+-----------+-------------+-----------------+
| 2018_CS_01 | MonkeyDLuffy |        95.5 |
| 2018_CS_03 | PatrickStar |        99.0 |
| 2018_CS_03 | SpongeBob |          95.0 |
+-----------+-------------+-----------------+
3 rows in set (0.00 sec)
```

The `a.class` and `a.stuname` fields are specified in the `GROUP BY` statement, and the selected columns are `a.class`, `a.stuname` and `b.courscore`. The only column that is not in the `GROUP BY` condition, `b.courscore`, is also specified with a unique value using the `max()` function. There is ***ONLY ONE*** result that satisfies this SQL statement without any ambiguity, which is called the `FULL GROUP BY` syntax.

A counterexample is the `NON-FULL GROUP BY` syntax. For example, in these two tables, write the following SQL query (delete `a.stuname` in `GROUP BY`).

```
SELECT
    `a`.`class`,
    `a`.`stuname`,
    max( `b`.`courscore` )
FROM
    `stu_info` `a`
    JOIN `stu_score` `b` ON `a`.`stuno` = `b`.`stuno`
GROUP BY
    `a`.`class`
ORDER BY
    `a`.`class`,
    `a`.`stuname`;
```

Then two values that match this SQL are returned.

The first returned value:

```
    sql    +-----------+-------------+-----------------------+ | class |
↪ stuname    | max( `b`.`courscore` )| +-----------+-------------+-------------------
↪  | 2018_CS_01 | MonkeyDLuffy |         95.5 |    | 2018_CS_03 | PatrickStar
↪  |              99.0 |   +-----------+-------------+-----------------------+
↪
```

The second returned value:

```
    sql    +-----------+-------------+-----------------+ | class | stuname
↪     | max(b.courscore)|  +-----------+-------------+-----------------+
↪  | 2018_CS_01 | MonkeyDLuffy |     95.5 |    | 2018_CS_03 | SpongeBob |
↪           99.0 |   +-----------+-------------+-----------------+
```

There are two results because you did ***NOT*** specify how to get the value of the `a.stuname` field in SQL, and two results are both satisfied by SQL semantics. It results in an unstable result set. Therefore, if you want to guarantee the stability of the result set of the `GROUP BY` statement, use the `FULL GROUP BY` syntax.

MySQL provides a `sql_mode` switch `ONLY_FULL_GROUP_BY` to control whether to check the `FULL GROUP BY` syntax or not. TiDB is also compatible with this `sql_mode` switch.

```
mysql> select a.class, a.stuname, max(b.courscore) from stu_info a join
    ↪ stu_score b on a.stuno=b.stuno group by a.class order by a.class, a.
    ↪ stuname;
+-----------+-------------+------------------+
| class     | stuname     | max(b.courscore) |
+-----------+-------------+------------------+
| 2018_CS_01 | MonkeyDLuffy |        95.5 |
| 2018_CS_03 | PatrickStar |        99.0 |
+-----------+-------------+------------------+
2 rows in set (0.01 sec)

mysql> set @@sql_mode='STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION,
    ↪ ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.01 sec)

mysql> select a.class, a.stuname, max(b.courscore) from stu_info a join
    ↪ stu_score b on a.stuno=b.stuno group by a.class order by a.class, a.
    ↪ stuname;
ERROR 1055 (42000): Expression #2 of ORDER BY is not in GROUP BY clause and
    ↪  contains nonaggregated column '' which is not functionally dependent
    ↪  on columns in GROUP BY clause; this is incompatible with sql_mode=
    ↪ only_full_group_by
```

Run results: The above example shows the effect when you set `ONLY_FULL_GROUP_BY` for `sql_mode`.

4.10.2.2 ORDER BY

In SQL semantics, the result set is output in order only if the `ORDER BY` syntax is used. For a single-instance database, since the data is stored on one server, the results of multiple executions are often stable without data reorganization. Some databases (especially the MySQL InnoDB storage engine) can even output the result sets in order of the primary key or index.

As a distributed database, TiDB stores data on multiple servers. In addition, the TiDB layer does not cache data pages, so the result set order of SQL statements without `ORDER BY` is easily perceived as unstable. To output a sequential result set, you need to explicitly add the order field into the `ORDER BY` clause, which conforms to SQL semantics.

In the following example, only one field is added to the `ORDER BY` clause, and TiDB only sorts the results by that one field.

```
mysql> select a.class, a.stuname, b.course, b.courscore from stu_info a
    ↪ join stu_score b on a.stuno=b.stuno order by a.class;
+------------+-------------+------------------------+-----------+
| class      | stuname     | course                 | courscore |
+------------+-------------+------------------------+-----------+

+------------+-------------+------------------------+-----------+
```

```
36 rows in set (0.01 sec)
```

Results are unstable when the `ORDER BY` values are the same. To reduce randomness, `ORDER BY` values should be unique. If you can't guarantee the uniqueness, you need to add more `ORDER BY` fields until the combination of the `ORDER BY` fields in `ORDER BY` is unique, then the result will be stable.

4.10.2.3 The result set is unstable because order by is not used in `GROUP_CONCAT()`

The result set is unstable because TiDB reads data from the storage layer in parallel, so the result set order returned by `GROUP_CONCAT()` without `ORDER BY` is easily perceived as unstable.

To let `GROUP_CONCAT()` get the result set output in order, you need to add the sorting fields to the `ORDER BY` clause, which conforms to the SQL semantics. In the following example, `GROUP_CONCAT()` that splices `customer_id` without `ORDER BY` causes an unstable result set.

1. Excluded `ORDER BY`

   First query:

```
sql   mysql> select GROUP_CONCAT( customer_id SEPARATOR ',' )FROM customer
↪  where customer_id like '200002%'; +-----------------------------------------------
↪  | GROUP_CONCAT(customer_id SEPARATOR ',')        |   +-----------------------------
↪  | 20000200992,20000200993,20000200994,20000200995,20000200996,20000200...
↪  | +-------------------------------------------------------------------------+
↪
```

   Second query:

```
sql   mysql> select GROUP_CONCAT( customer_id SEPARATOR ',' )FROM customer
↪  where customer_id like '200002%'; +-----------------------------------------------
↪  | GROUP_CONCAT(customer_id SEPARATOR ',')        |   +-----------------------------
↪  | 20000203040,20000203041,20000203042,20000203043,20000203044,20000203...
↪  | +-------------------------------------------------------------------------+
↪
```

2. Include `ORDER BY`

   First query:

```
sql   mysql> select GROUP_CONCAT( customer_id order by customer_id
↪ SEPARATOR ',' )FROM customer where customer_id like '200002%'; +--------------------
↪  | GROUP_CONCAT(customer_id SEPARATOR ',')     |   +-------------------------------
↪  | 20000200000,20000200001,20000200002,20000200003,20000200004,20000200...
↪  | +-------------------------------------------------------------------------+
↪
```

Second query:

```
sql   mysql> select GROUP_CONCAT( customer_id order by customer_id
↪ SEPARATOR ',' )FROM customer where customer_id like '200002%'; +--------------------
↪  | GROUP_CONCAT(customer_id SEPARATOR ',')      |   +-------------------------------
↪  | 20000200000,20000200001,20000200002,20000200003,20000200004,20000200...
↪  | +-------------------------------------------------------------------------+
↪
```

4.10.2.4 Unstable results in `SELECT * FROM T LIMIT N`

The returned result is related to the distribution of data on the storage node (TiKV). If multiple queries are performed, different storage units (Regions) of the storage nodes (TiKV) return results at different speeds, which can cause unstable results.

4.10.3 Timeouts in TiDB

This document describes various timeouts in TiDB to help you troubleshoot errors.

4.10.3.1 GC timeout

TiDB's transaction implementation uses the MVCC (Multiple Version Concurrency Control) mechanism. When the newly written data overwrites the old data, the old data will not be replaced, but kept together with the newly written data. The versions are distinguished by the timestamp. TiDB uses the mechanism of periodic Garbage Collection (GC) to clean up the old data that is no longer needed.

By default, each MVCC version (consistency snapshots) is kept for 10 minutes. Transactions that take longer than 10 minutes to read will receive an error `GC life time is ↪ shorter than transaction duration`.

If you need longer read time, for example, when you are using **Mydumper** for full backups (**Mydumper** backs up consistent snapshots), you can adjust the value of `tikv_gc_life_time` in the `mysql.tidb` table in TiDB to increase the MVCC version retention time. Note that `tikv_gc_life_time` takes effect globally and immediately. Increasing the value will increase the life time of all existing snapshots, and decreasing it will immediately shorten the life time of all snapshots. Too many MVCC versions will impact TiKV's processing efficiency. So you need to change `tikv_gc_life_time` back to the previous setting in time after doing a full backup with **Mydumper**.

For more information about GC, see GC Overview.

4.10.3.2 Transaction timeout

GC does not affect ongoing transactions. However, there is still an upper limit to the number of pessimistic transactions that can run, with a limit on the transaction timeout and a limit on the memory used by the transaction. You can modify the transaction timeout by `max-txn-ttl` under the `[performance]` category of the TiDB profile, `60` minutes by default.

SQL statements such as `INSERT INTO t10 SELECT * FROM t1` are not affected by GC, but will be rolled back due to timeout after exceeding `max-txn-ttl`.

4.10.3.3 SQL execution timeout

TiDB also provides a system variable (`max_execution_time`, `0` by default, indicating no limit) to limit the execution time of a single SQL statement. `max_execution_time` currently takes effect for all types of statements, not just the `SELECT` statements. The unit is `ms`, but the actual precision is at the `100ms` level instead of the millisecond level.

4.10.3.4 JDBC query timeout

MySQL JDBC's query timeout setting for `setQueryTimeout()` does ***NOT*** work for TiDB, because the client sends a `KILL` command to the database when it detects the timeout. However, the tidb-server is load balanced, and it will not execute this `KILL` command to avoid termination of the connection on a wrong tidb-server. You need to use `MAX_EXECUTION_TIME` to check the query timeout effect.

TiDB provides the following MySQL-compatible timeout control parameters.

- **wait_timeout**, controls the non-interactive idle timeout for the connection to Java applications. Since TiDB v5.4, the default value of `wait_timeout` is `28800` seconds, which is 8 hours. For TiDB versions earlier than v5.4, the default value is `0`, which means the timeout is unlimited.
- **interactive_timeout**, controls the interactive idle timeout for the connection to Java applications. The value is `8 hours` by default.
- **max_execution_time**, controls the timeout for SQL execution in the connection. The value is `0` by default, which allows the connection to be infinitely busy, that is, an SQL statement is executed for an infinitely long time.

However, in a real production environment, idle connections and indefinitely executing SQL statements have a negative effect on both the database and the application. You can avoid idle connections and indefinitely executing SQL statements by configuring these two session-level variables in your application's connection string. For example, set the following:

- `sessionVariables=wait_timeout=3600` (1 hour)
- `sessionVariables=max_execution_time=300000` (5 minutes)

4.11 Reference

4.11.1 Bookshop Example Application

Bookshop is a virtual online bookstore application through which you can buy books of various categories and rate the books you have read.

To make your reading on the application developer guide more smoothly, we present the example SQL statements based on the table structures and data of the Bookshop application. This document focuses on the methods of importing the table structures and data as well as the definitions of the table structures.

4.11.1.1 Import table structures and data

You can import Bookshop table structures and data either via TiUP or via the import feature of TiDB Cloud.

4.11.1.1.1 Method 1: Via `tiup demo`

If your TiDB cluster is deployed using TiUP or you can connect to your TiDB server, you can quickly generate and import sample data for the Bookshop application by running the following command:

```
tiup demo bookshop prepare
```

By default, this command enables your application to connect to port `4000` on address `127.0.0.1`, enables you to log in as the `root` user without a password, and creates a table structure in the database named `bookshop`.

Configure connection information

The following table lists the connection parameters. You can change their default settings to match your environment.

Parameter	Abbreviation	Default value	Description
`--password`	`-p`	None	Database user password
`--host`	`-H`	`127.0.0.1`	Database address
`--port`	`-P`	`4000`	Database port
`--db`	`-D`	`bookshop`	Database name
`--user`	`-U`	`root`	Database user

For example, if you want to connect to a database on TiDB Cloud, you can specify the connection information as follows:

```
tiup demo bookshop prepare -U <username> -H <endpoint> -P 4000 -p <password>
```

Set the data volume

You can specify the volume of data to be generated in each database table by configuring the following parameters:

Parameter	Default value	Description
`--users`	`10000`	The number of rows of data to be generated in the `users` table
`--authors`	`20000`	The number of rows to be generated in the `authors` table

Parameter	Default value	Description
`--books`	20000	The number of rows of data to be generated in the `books` table
`--orders`	300000	The number of rows of data to be generated in the `orders` table
`--ratings`	300000	The number of rows of data to be generated in the `ratings` table

For example, the following command is executed to generate:

- 200,000 rows of user information via the `--users` parameter
- 500,000 rows of book information via the `--books` parameter
- 100,000 rows of author information via the `--authors` parameter
- 1,000,000 rows of rating records via the `--ratings` parameter
- 1,000,000 rows of order records via the `--orders` parameter

```
tiup demo bookshop prepare --users=200000 --books=500000 --authors=100000 --
    ↪ ratings=1000000 --orders=1000000 --drop-tables
```

You can delete the original table structure through the `--drop-tables` parameter. For more parameter descriptions, run the `tiup demo bookshop --help` command.

4.11.1.1.2 Method 2: Via TiDB Cloud Import

On the cluster detail page of TiDB Cloud, click **Import Data** in the **Import** area to enter the **Data Import** page. On this page, perform the following steps to import the Bookshop sample data from AWS S3 to TiDB Cloud.

1. Select **SQL File** for **Data Format**.
2. Copy the following **Bucket URI** and **Role ARN** to the corresponding input boxes:

   Bucket URI:

   ```
   s3://developer.pingcap.com/bookshop/
   ```

   Role ARN:

   ```
   ```

   arn:aws:iam::494090988690:role/s3-tidb-cloud-developer-access
   ```
   ```

3. Click **Next** to go to the **File and filter** step to confirm the information of the files to be imported.
4. Click **Next** again to go to the **Preview** step to confirm the preview of the data to be imported.

   In this example, the following data is generated in advance:

- 200,000 rows of user information
- 500,000 rows of book information
- 100,000 rows of author information
- 1,000,000 rows of rating records
- 1,000,000 rows of order records

5. Click **Start Import** to start the import process and wait for TiDB Cloud to complete the import.

For more information about how to import or migrate data to TiDB Cloud, see TiDB Cloud Migration Overview.

4.11.1.1.3 View data import status

After the import is completed, you can view the data volume information of each table by executing the following SQL statement:

```
SELECT
    CONCAT(table_schema,'.',table_name) AS 'Table Name',
    table_rows AS 'Number of Rows',
    CONCAT(ROUND(data_length/(1024*1024*1024),4),'G') AS 'Data Size',
    CONCAT(ROUND(index_length/(1024*1024*1024),4),'G') AS 'Index Size',
    CONCAT(ROUND((data_length+index_length)/(1024*1024*1024),4),'G') AS '
        ↪ Total'
FROM
    information_schema.TABLES
WHERE table_schema LIKE 'bookshop';
```

The result is as follows:

```
+----------------------+---------------+-----------+------------+---------+
    ↪
| Table Name           | Number of Rows | Data Size | Index Size | Total |
+----------------------+---------------+-----------+------------+---------+
    ↪
| bookshop.orders      |       1000000 | 0.0373G | 0.0075G  | 0.0447G |
| bookshop.book_authors |    1000000 | 0.0149G | 0.0149G  | 0.0298G |
| bookshop.ratings     |       4000000 | 0.1192G | 0.1192G  | 0.2384G |
| bookshop.authors     |        100000 | 0.0043G | 0.0000G  | 0.0043G |
| bookshop.users       |        195348 | 0.0048G | 0.0021G  | 0.0069G |
| bookshop.books       |       1000000 | 0.0546G | 0.0000G  | 0.0546G |
+----------------------+---------------+-----------+------------+---------+
    ↪
6 rows in set (0.03 sec)
```

4.11.1.2 Description of the tables

This section describes the database tables of the Bookshop application in detail.

4.11.1.2.1 `books` table

This table stores the basic information of books.

Field name	Type	Description
id	bigint(20)	Unique ID of a book
title	varchar(100)	Title of a book
type	enum	Type of a book (for example, magazine, animation, or teaching aids)
stock	bigint(20)	Stock
price	decimal(15,2)	Price
published_at	datetime	Date of publish

4.11.1.2.2 `authors` table

This table stores basic information of authors.

Field name	Type	Description
id	bigint(20)	Unique ID of an author
name	varchar(100)	Name of an author
gender	tinyint(1)	Biological gender (0: female, 1: male, NULL: unknown)
birth_year	smallint(6)	Year of birth
death_year	smallint(6)	Year of death

4.11.1.2.3 `users` table

This table stores information of Bookshop users.

Field name	Type	Description
id	bigint(20)	Unique ID of a user
balance	decimal(15,2)	Balance
nickname	varchar(100)	Nickname

4.11.1.2.4 `ratings` table

This table stores records of user ratings on books.

Field name	Type	Description
book_id	bigint	Unique ID of a book (linked to books)
user_id	bigint	User's unique identifier (linked to users)
score	tinyint	User rating (1-5)

Field name	Type	Description
rated_at	datetime	Rating time

4.11.1.2.5 `book_authors` table

An author may write multiple books, and a book may involve more than one author. This table stores the correspondence between books and authors.

Field name	Type	Description
book_id	bigint(20)	Unique ID of a book (linked to books)
author_id	bigint(20)	Unique ID of an author (Link to authors)

4.11.1.2.6 `orders` table

This table stores user purchase information.

Field name	Type	Description
id	bigint(20)	Unique ID of an order
book_id	bigint(20)	Unique ID of a book (linked to books)
user_id	bigint(20)	User unique identifier (associated with users)
quantity	tinyint(4)	Purchase quantity
ordered_at	datetime	Purchase time

4.11.1.3 Database initialization script `dbinit.sql`

If you want to manually create database table structures in the Bookshop application, run the following SQL statements:

```
CREATE DATABASE IF NOT EXISTS `bookshop`;

DROP TABLE IF EXISTS `bookshop`.`books`;
CREATE TABLE `bookshop`.`books` (
  `id` bigint(20) AUTO_RANDOM NOT NULL,
  `title` varchar(100) NOT NULL,
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports') NOT NULL,
  `published_at` datetime NOT NULL,
  `stock` int(11) DEFAULT '0',
  `price` decimal(15,2) DEFAULT '0.0',
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`authors`;
```

```
CREATE TABLE `bookshop`.`authors` (
  `id` bigint(20) AUTO_RANDOM NOT NULL,
  `name` varchar(100) NOT NULL,
  `gender` tinyint(1) DEFAULT NULL,
  `birth_year` smallint(6) DEFAULT NULL,
  `death_year` smallint(6) DEFAULT NULL,
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`book_authors`;
CREATE TABLE `bookshop`.`book_authors` (
  `book_id` bigint(20) NOT NULL,
  `author_id` bigint(20) NOT NULL,
  PRIMARY KEY (`book_id`,`author_id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`ratings`;
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint NOT NULL,
  `user_id` bigint NOT NULL,
  `score` tinyint NOT NULL,
  `rated_at` datetime NOT NULL DEFAULT NOW() ON UPDATE NOW(),
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED,
  UNIQUE KEY `uniq_book_user_idx` (`book_id`,`user_id`)
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
ALTER TABLE `bookshop`.`ratings` SET TIFLASH REPLICA 1;

DROP TABLE IF EXISTS `bookshop`.`users`;
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `balance` decimal(15,2) DEFAULT '0.0',
  `nickname` varchar(100) UNIQUE NOT NULL,
  PRIMARY KEY (`id`)
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`orders`;
CREATE TABLE `bookshop`.`orders` (
  `id` bigint(20) AUTO_RANDOM NOT NULL,
  `book_id` bigint(20) NOT NULL,
  `user_id` bigint(20) NOT NULL,
  `quality` tinyint(4) NOT NULL,
  `ordered_at` datetime NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
    ↪ CURRENT_TIMESTAMP,
  PRIMARY KEY (`id`) CLUSTERED,
  KEY `orders_book_id_idx` (`book_id`)
```

```
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

4.11.2 Guidelines

4.11.2.1 Object Naming Convention

This document introduces the rules to name database objects, such as database, table, index, and user.

4.11.2.1.1 General rules

- It is recommended to use meaningful English words separated by underscores.
- Use only letters, numbers, and underscores in a name.
- Avoid using TiDB reserved words, such as `group` and `order`, as column names.
- It is recommended to use lowercase letters for all database objects.

4.11.2.1.2 Database naming convention

It is recommended to differentiate database names by business, product, or other metrics and use no more than 20 characters in a database name. For example, you can name a temporary library as `tmp_crm` or a test library as `test_crm`.

4.11.2.1.3 Table naming convention

- Use the same prefix for tables of the same business or module, and make sure that the table name is self-explanatory as much as possible.
- Separate words in a name by underscores. It is recommended to use no more than 32 characters in a table name.
- It is recommended to annotate the purpose of the table for a better understanding. For example:
  - Temporary table: `tmp_t_crm_relation_0425`
  - Backup table: `bak_t_crm_relation_20170425`
  - Temporary table of business operations: `tmp_st_{business code}_{creator abbreviation}_{date}`
  - Record table of accounts period: `t_crm_ec_record_YYYY{MM}{dd}`
- Create separate databases for tables of different business modules and add annotations accordingly.

4.11.2.1.4 Column naming convention

- The column naming is the actual meaning or abbreviation of the column.
- It is recommended to use the same column name between tables with the same meaning.
- It is recommended to add annotations to columns and specify named values for enumerated types, such as "0: offline, 1: online".
- It is recommended to name the boolean column as `is_{description}`. For example, the column of a `member` table that indicates whether the member is enabled, can be named as `is_enabled`.
- It is not recommended to name a column with more than 30 characters, and the number of columns should be less than 60.
- Avoid using TiDB reserved words as column names, such as `order`, `from`, and `desc`. To check whether a keyword is reserved, see TiDB keywords.

4.11.2.1.5 Index naming convention

- Primary key index: `pk_{table_name_abbreviation}_{field_name_abbreviation}`
- Unique index: `uk_{table_name_abbreviation}_{field_name_abbreviation}`
- Common index: `idx_{table_name_abbreviation}_{field_name_abbreviation}`
- Column name with multiple words: use meaningful abbreviations

4.11.2.2 SQL Development Specifications

This document introduces some general development specifications for using SQL.

4.11.2.2.1 Create and delete tables

- Basic principle: under the premise of following the table naming convention, it is recommended that the application internally packages the table creation and deletion statements and adds judgment logic to prevent abnormal interruption of business processes.
- Details: `create table if not exists table_name` or `drop table if exists table_name` statements are recommended to add `if` judgments to avoid abnormal interruptions caused by SQL commands running abnormally on the application side.

4.11.2.2.2 `SELECT *` usage

- Basic principle: avoid using `SELECT *` for queries.
- Details: select the appropriate columns as required and avoid using `SELECT *` to read all fields because such operations consume network bandwidth. Consider adding the queried fields to the index to make effective use of the covering index.

4.11.2.2.3 Use functions on fields

- Basic principle: You can use related functions on the queried fields. To avoid index failure, do not use any functions on the filtered fields in the `WHERE` clause, including data type conversion functions. You may consider using the expression index.
- Detailed description:

  NOT recommended:

```
SELECT gmt_create
FROM ...
WHERE DATE_FORMAT(gmt_create, '%Y%m%d %H:%i:%s') = '20090101 00:00:00'
```

  Recommended:

```
SELECT DATE_FORMAT(gmt_create, '%Y%m%d %H:%i:%s')
FROM ...
WHERE gmt_create = str_to_date('20090101 00:00:00', '%Y%m%d %H:%i:%s')
```

4.11.2.2.4 Other specifications

- Do not perform mathematical operations or functions on the index column in the `WHERE` condition.
- Replace `OR` with `IN` or `UNION`. The number of `IN` must be less than `300`.
- Avoid using the `%` prefix for fuzzy prefix queries.
- If the application uses **Multi Statements** to execute SQL, that is, multiple SQLs are joined with semicolons and sent to the client for execution at once, TiDB only returns the result of the first SQL execution.
- When you use expressions, check if the expressions support computing push-down to the storage layer (TiKV or TiFlash). If not, you should expect more memory consumption and even OOM at the TiDB layer. Computing that can be pushe down the storage layer is as follows:
  - TiFlash supported push-down calculations.
  - TiKV - List of Expressions for Pushdown.
  - Predicate push down.

4.11.3 Legacy Docs

4.11.3.1 App Development for Django

> **Note:**
>
> This legacy document is outdated and will not be updated thereafter. You can see Developer Guide Overview for more details.

This tutorial shows you how to build a simple Python application based on TiDB and Django. The sample application to build here is a simple CRM tool where you can add, query, and update customer and order information.

4.11.3.1.1 Step 1. Start a TiDB cluster

Start a pseudo TiDB cluster on your local storage:

```
docker run -p 127.0.0.1:$LOCAL_PORT:4000 pingcap/tidb:v5.1.0
```

The above command starts a temporary and single-node cluster with mock TiKV. The cluster listens on the port `$LOCAL_PORT`. After the cluster is stopped, any changes already made to the database are not persisted.

> **Note:**
>
> To deploy a "real" TiDB cluster for production, see the following guides:
>
> - Deploy TiDB using TiUP for On-Premises
> - Deploy TiDB on Kubernetes
>
> You can also use TiDB Cloud, a fully-managed Database-as-a-Service (DBaaS) of TiDB.

4.11.3.1.2 Step 2. Create a database

1. In the SQL shell, create the `django` database that your application will use:

   ```
   CREATE DATABASE django;
   ```

2. Create a SQL user for your application:

   ```
   CREATE USER <username> IDENTIFIED BY <password>;
   ```

   Take note of the username and password. You will use them in your application code when initializing the project.

3. Grant necessary permissions to the SQL user you have just created:

   ```
   GRANT ALL ON django.* TO <username>;
   ```

4.11.3.1.3 Step 3. Set virtual environments and initialize the project

1. Use Poetry, a dependency and package manager in Python, to set virtual environments and initialize the project.

   Poetry can isolate system dependencies from other dependencies and avoid dependency pollution. Use the following command to install Poetry.

```
pip install --user poetry
```

2. Initialize the development environment using Poetry:

```
poetry init --no-interaction --dependency django
poetry run django-admin startproject tidb_example

mv pyproject.toml ./tidb_example
cd tidb_example

poetry add django-tidb

poetry shell
```

3. Modify the configuration file. The configuration in `tidb_example/settings.py` is as follows.

```
USE_TZ = True

DATABASES = {
    'default': {
        'ENGINE': 'django.db.backends.sqlite3',
        'NAME': BASE_DIR / 'db.sqlite3',
    }
}

DEFAULT_AUTO_FIELD = 'django.db.models.BigAutoField'
```

   Modify the configuration above as follows. This is used for connection to TiDB.

```
USE_TZ = False

DATABASES = {
    'default': {
        'ENGINE': 'django_tidb',
        'NAME': 'django',
        'USER': 'root',
        'PASSWORD': '',
        'HOST': '127.0.0.1',
```

```
        'PORT': 4000,
    },
}

DEFAULT_AUTO_FIELD = 'django.db.models.AutoField'
```

4.11.3.1.4 Step 4. Write the application logic

After you have configured the application's database connection, you can start building out the application. To write the application logic, you need to build the models, build the controller, and define the URL routes.

1. Build models that are defined in a file called `models.py`. You can copy the sample code below and paste it into a new file.

```
from django.db import models

class Orders(models.Model):
    id = models.AutoField(primary_key=True)
    username = models.CharField(max_length=250)
    price = models.FloatField()
```

2. Build class-based views in a file called `views.py`. You can copy the sample code below and paste it into a new file.

```
from django.http import JsonResponse, HttpResponse
from django.utils.decorators import method_decorator
from django.views.generic import View
from django.views.decorators.csrf import csrf_exempt
from django.db import Error, OperationalError
from django.db.transaction import atomic
from functools import wraps
import json
import sys
import time

from .models import *

def retry_on_exception(view, num_retries=3, on_failure=HttpResponse(
    ↪ status=500), delay_=0.5, backoff_=1.5):
    @wraps(view)
    def retry(*args, **kwargs):
        delay = delay_
        for i in range(num_retries):
            try:
```

```
                return view(*args, **kwargs)
            except Exception as e:
                return on_failure
    return retry

class PingView(View):
    def get(self, request, *args, **kwargs):
        return HttpResponse("python/django", status=200)

@method_decorator(csrf_exempt, name='dispatch')
class OrderView(View):
    def get(self, request, id=None, *args, **kwargs):
        if id is None:
            orders = list(Orders.objects.values())
        else:
            orders = list(Orders.objects.filter(id=id).values())
        return JsonResponse(orders, safe=False)

    @retry_on_exception
    @atomic
    def post(self, request, *args, **kwargs):
        form_data = json.loads(request.body.decode())
        username = form_data['username']
        price = form_data['price']
        c = Orders(username=username, price=price)
        c.save()
        return HttpResponse(status=200)

    @retry_on_exception
    @atomic
    def delete(self, request, id=None, *args, **kwargs):
        if id is None:
            return HttpResponse(status=404)
        Orders.objects.filter(id=id).delete()
        return HttpResponse(status=200)
```

3. Define URL routes in a file called `urls.py`. The `django-admin` command-line tool has generated this file when you create the Django project, so the file should already exist in `tidb_example/tidb_example`. You can copy the sample code below and paste it into the existing `urls.py` file.

```
from django.contrib import admin
```

```
from django.urls import path
from django.conf.urls import url

from .views import OrderView, PingView

urlpatterns = [
    path('admin/', admin.site.urls),

    url('ping/', PingView.as_view()),

    url('order/', OrderView.as_view(), name='order'),
    url('order/<int:id>/', OrderView.as_view(), name='order'),
]
```

4.11.3.1.5 Step 5. Set up and run the Django application

In the top `tidb_example` directory, use the `manage.py` script to create Django migrations that initialize the database for the application:

```
python manage.py makemigrations tidb_example
python manage.py migrate tidb_example
python manage.py migrate
```

Then start the application:

```
python3 manage.py runserver 0.0.0.0:8000
```

To test the application by inserting some example data, run the following commands:

```
curl --request POST '127.0.0.1:8000/order/' \
--data-raw '{
    "uid": 1,
    "price": 3.12
}'

curl --request PATCH '127.0.0.1:8000/order/' --data-raw '{ "oid": 1, "price"
    ↪ : 312 }'

curl --request GET '127.0.0.1:8000/order/' --data-raw '{ "oid": 1 }'
```

To verify whether the data insertion is successful, open the terminal with the SQL shell to check:

```
MySQL root@127.0.0.1:(none)> select * from django.tidb_example_orders;
+-----+-----+-------+
| oid | uid | price |
```

```
+-----+-----+-------+
| 1   | 1   | 312.0 |
+-----+-----+-------+
1 row in set
Time: 0.008s
```

The result above shows that the data insertion is successful. Then you can delete the inserted data:

```
curl --request DELETE '127.0.0.1:8000/order/' --data-raw '{ "oid": 1 }'
```

4.12 Cloud Native Development Environment

4.12.1 Gitpod

With Gitpod, you can get a full development environment in your browser with the click of a button or link, and you can write code right away.

Gitpod is an open-source Kubernetes application (GitHub repository address: https://github.com/gitpod-io/gitpod) for direct-to-code development environments, which spins up fresh, automated development environments for each task, in the cloud, in seconds. It enables you to describe your development environment as code and start instant, remote and cloud-based development environments directly from your browser or your Desktop IDE.

4.12.1.1 Quick start

1. Fork the example code repository pingcap-inc/tidb-example-java for TiDB application development.
2. Start your Gitpod workspace by prefixing the URL of the sample code repository with `https://gitpod.io/#` in the address bar of your browser.

- For example, `https://gitpod.io/#https://github.com/pingcap-inc/tidb-example-java`.
- You can configure environment variables in the URL. For example, `https://gitpod.io/#targetFile=spring-jpa-hibernate_Makefile,targetMode=spring-jpa-hibernate/https://github.com/pingcap-inc/tidb-example-java`.

3. Log in and start the workspace using one of the providers listed. For example, `Github`.

4.12.1.2 Use the default Gitpod configuration and environment

After completing the quick-start steps, it will take a while for Gitpod to set up your workspace.

Take the Spring Boot Web application as an example. You can create a new workspace by the `https://gitpod.io/#targetFile=spring-jpa-hibernate_Makefile,targetMode=spring-jpa-hibernate/https://github.com/pingcap-inc/tidb-example-java` URL.

After that, you will see a page similar to the following:

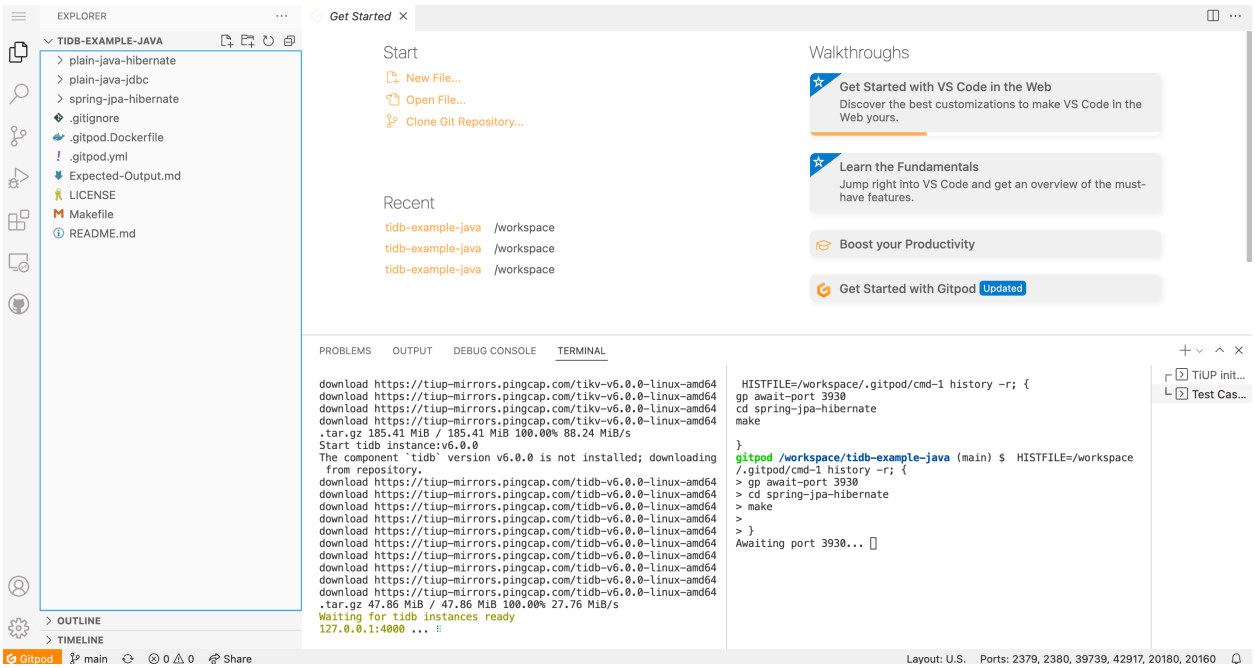

Figure 15: playground gitpod workspace init

This scenario in the page uses TiUP to build a TiDB Playground. You can check the progress on the left side of the terminal area.

Once the TiDB Playground is ready, another `Spring JPA Hibernate` task will run. You can check the progress on the right side of the terminal area.

After all these tasks are finished, you will see a page similar to the following. On this page, check the `REMOTE EXPLORER` area in the left navigation pane (Gitpod supports URL-based port forwarding) and find the URL of your port `8080`.

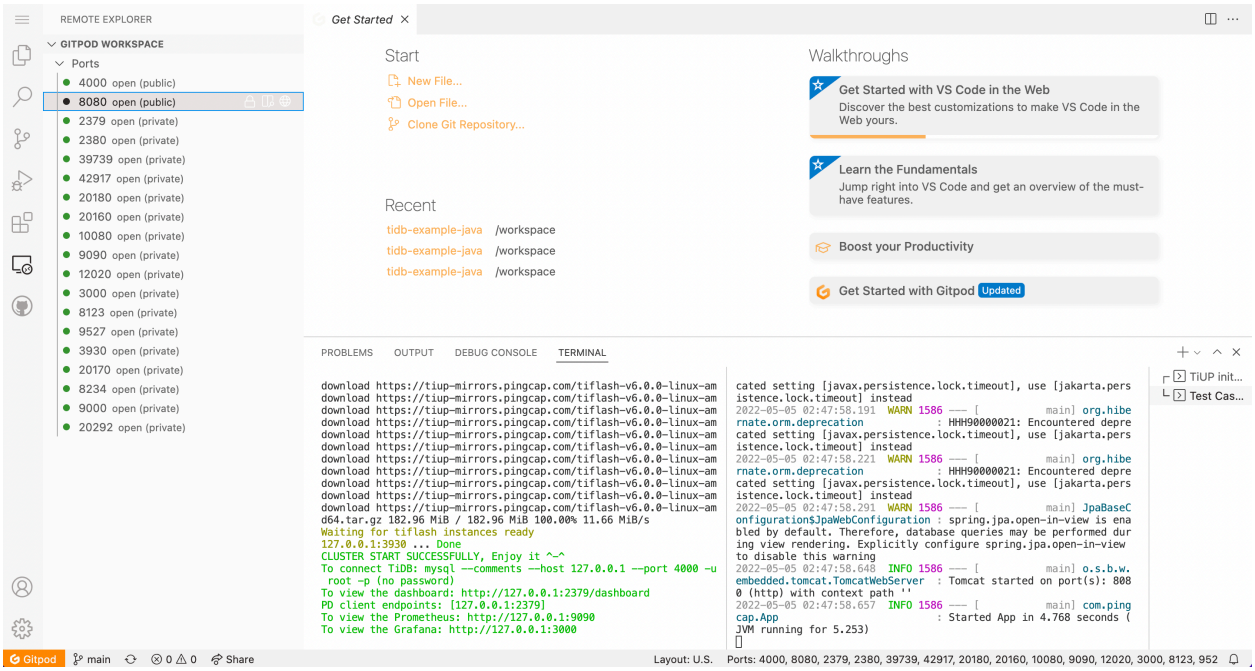

Figure 16: playground gitpod workspace ready

You can test the API by sending an HTTP request. Make sure to replace the `http://localhost:8080` URL with the one you found in the `REMOTE EXPLORER` area.

4.12.1.3 Using custom Gitpod configuration and Docker image

4.12.1.3.1 Customize Gitpod configurations

Referring to example.gitpod.yml, create a `.gitpod.yml` file in the root directory of your project to configure the Gitpod workspace.

```
### This configuration file was automatically generated by Gitpod.
### Please adjust to your needs (see https://www.gitpod.io/docs/config-gitpod-file)
### and commit this file to your remote git repository to share the goodness with others.

### image:
###   file: .gitpod.Dockerfile

tasks:
  - name: Open Target File
    command: |
      if [ -n "$targetFile" ]; then code ${targetFile//[_]//}; fi
  - name: TiUP init playground
```

```
    command: |
      $HOME/.tiup/bin/tiup playground
  - name: Test Case
    openMode: split-right
    init: echo "*** Waiting for TiUP Playground Ready! ***"
    command: |
      gp await-port 3930
      if [ "$targetMode" == "plain-java-jdbc" ]
      then
        cd plain-java-jdbc
        code src/main/resources/dbinit.sql
        code src/main/java/com/pingcap/JDBCExample.java
        make mysql
      elif [ "$targetMode" == "plain-java-hibernate" ]
      then
        cd plain-java-hibernate
        make
      elif [ "$targetMode" == "spring-jpa-hibernate" ]
      then
        cd spring-jpa-hibernate
        make
      fi
ports:
  - port: 8080
    visibility: public
  - port: 4000
    visibility: public
  - port: 2379-36663
    onOpen: ignore
```

4.12.1.3.2 Customize Gitpod Docker images

By default, Gitpod uses a standard Docker image named Workspace-Full as the basis for the workspace. Workspaces launched from this default image are pre-installed with Docker, Go, Java, Node.js, C/C++, Python, Ruby, Rust, PHP, and tools such as Homebrew, Tailscale, and Nginx.

You can use a public Docker image or a Dockerfile and also install any required dependencies for your project.

For example, you can use a Dockerfile (see also Example `.gitpod.Dockerfile`) as follows:

```
FROM gitpod/workspace-java-17

RUN sudo apt install mysql-client -y
```

```
RUN curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

Then, you need to update `.gitpod.yml`:

```
### This configuration file was automatically generated by Gitpod.
### Please adjust to your needs (see https://www.gitpod.io/docs/config-
    ↪ gitpod-file)
### and commit this file to your remote git repository to share the goodness
    ↪  with others.

image:
  # Import your Dockerfile here.
  file: .gitpod.Dockerfile

tasks:
  - name: Open Target File
    command: |
      if [ -n "$targetFile" ]; then code ${targetFile//[_]//}; fi
  - name: TiUP init playground
    command: |
      $HOME/.tiup/bin/tiup playground
  - name: Test Case
    openMode: split-right
    init: echo "*** Waiting for TiUP Playground Ready! ***"
    command: |
      gp await-port 3930
      if [ "$targetMode" == "plain-java-jdbc" ]
      then
        cd plain-java-jdbc
        code src/main/resources/dbinit.sql
        code src/main/java/com/pingcap/JDBCExample.java
        make mysql
      elif [ "$targetMode" == "plain-java-hibernate" ]
      then
        cd plain-java-hibernate
        make
      elif [ "$targetMode" == "spring-jpa-hibernate" ]
      then
        cd spring-jpa-hibernate
        make
      fi
ports:
  - port: 8080
    visibility: public
```

```
- port: 4000
  visibility: public
- port: 2379-36663
  onOpen: ignore
```

4.12.1.3.3 Apply changes

After completing the configuration of the `.gitpod.yml` file, make sure that the latest code is available in your corresponding GitHub repository.

Visit `https://gitpod.io/#<YOUR_REPO_URL>` to create a new Gitpod workspace with the latest code applied.

Visit `https://gitpod.io/workspaces` for all established workspaces.

4.12.1.4 Summary

Gitpod provides a complete, automated, and pre-configured cloud-native development environment. You can develop, run, and test code directly in the browser without any local configurations.

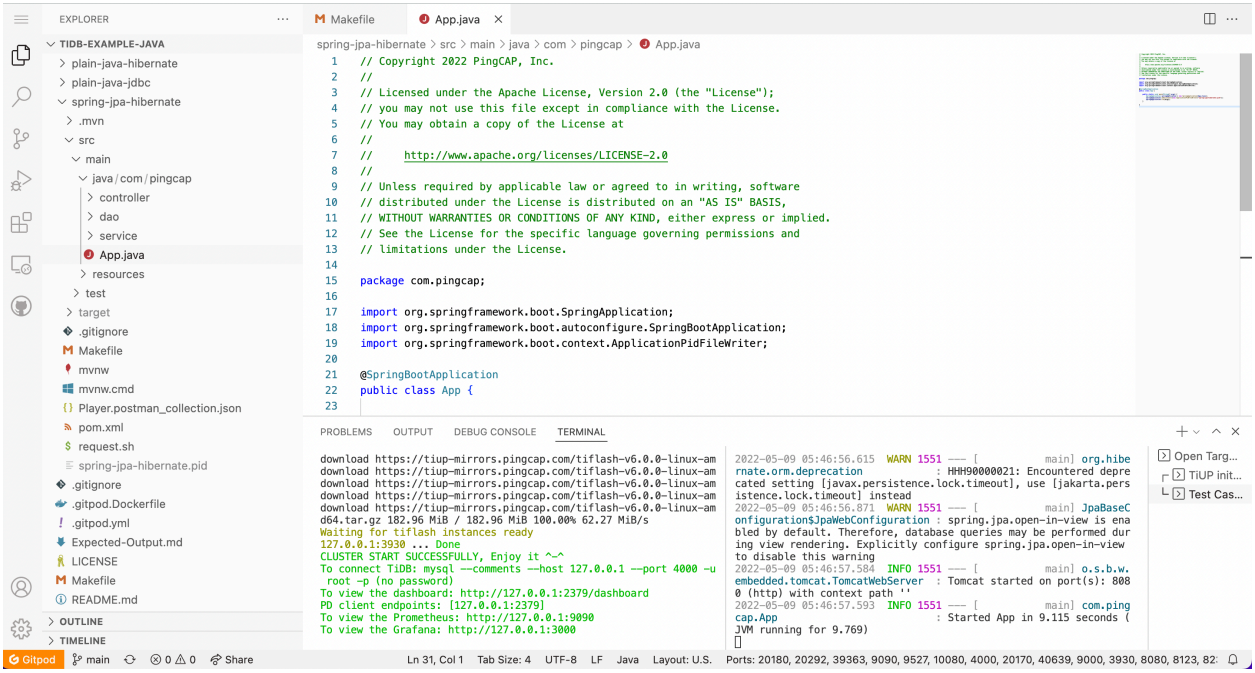

Figure 17: playground gitpod summary

4.13 Third-Party Support

4.13.1 Third-Party Tools Supported by TiDB

> **Note:**
>
> This document only lists common third-party tools supported by TiDB. Some other third-party tools are not listed, not because they are not supported, but because PingCAP is not sure whether they use features that are incompatible with TiDB.

TiDB is highly compatible with the MySQL protocol, so most of the MySQL drivers, ORM frameworks, and other tools that adapt to MySQL are compatible with TiDB. This document focuses on these tools and their support levels for TiDB.

4.13.1.1 Support Level

PingCAP works with the community and provides the following support levels for third-party tools:

- ***Full***: Indicates that TiDB is already compatible with most functionalities of the corresponding third-party tool, and maintains compatibility with its newer versions. PingCAP will periodically conduct compatibility tests with the latest version of the tool.
- ***Compatible***: Indicates that because the corresponding third-party tool is adapted to MySQL and TiDB is highly compatible with the MySQL protocol, so TiDB can use most features of the tool. However, PingCAP has not completed a full test on all features of the tool, which might lead to some unexpected behaviors.

> **Note:**
>
> Unless specified, support for Application retry and error handling is not included for **Driver** or **ORM frameworks**.

If you encounter problems when connecting to TiDB using the tools listed in this document, please submit an issue on GitHub with details to promote support on this tool.

4.13.1.2 Driver

```

4.13.2 Known Incompatibility Issues with Third-Party Tools

Note:

The Unsupported features section lists the unsupported features in TiDB, including:

- Stored procedures and functions
- Triggers
- Events
- User-defined functions
- `FOREIGN KEY` constraints
- `SPATIAL` functions, data types and indexes
- `XA` syntax

> The preceding unsupported features are expected behavior and are not listed in this document. For more details, see MySQL Compatibility.

The incompatibility issues listed in this document are found in some third-party tools supported by TiDB.

4.13.2.1 General incompatibility

4.13.2.1.1 `SELECT CONNECTION_ID()` returns a 64-bit integer in TiDB

Description

The `SELECT CONNECTION_ID()` function returns a 64-bit integer in TiDB, such as `2199023260887`, while it returns a 32-bit integer in MySQL, such as `391650`.

Way to avoid

In a TiDB application, to avoid data overflow, you should use a 64-bit integer or string type to store the result of `SELECT CONNECTION_ID()`. For example, you can use `Long` or `String` in Java and use `string` in JavaScript or TypeScript.

4.13.2.1.2 TiDB does not maintain `Com_*` counters

Description

MySQL maintains a series of server status variables starting with `Com_` to keep track of the total number of operations you have performed on the database. For example, `Com_select` records the total number of `SELECT` statements initiated by MySQL since it was last started (even if the statements were not queried successfully). TiDB does not maintain these variables. You can use the statement SHOW GLOBAL STATUS LIKE 'Com_%' to see the difference between TiDB and MySQL.

Way to avoid

Do not use these variables. One common scenario is monitoring. TiDB is well observable and does not require querying from server status variables. For custom monitoring tools, refer to TiDB Monitoring Framework Overview.

4.13.2.1.3 TiDB distinguishes between `TIMESTAMP` and `DATETIME` in error messages

Description

TiDB error messages distinguish between `TIMESTAMP` and `DATETIME`, while MySQL does not, and returns them all as `DATETIME`. That is, MySQL incorrectly converts `TIMESTAMP` type error messages to `DATETIME` type.

Way to avoid

Do not use the error messages for string matching. Instead, use Error Codes for troubleshooting.

4.13.2.1.4 TiDB does not support the `CHECK TABLE` statement

Description

The `CHECK TABLE` statement is not supported in TiDB.

Way to avoid

To check the consistency of data and corresponding indexes, you can use the `ADMIN CHECK [TABLE|INDEX]` statement in TiDB.

4.13.2.2 Compatibility with MySQL JDBC

The test version is MySQL Connector/J 8.0.29.

4.13.2.2.1 The default collation is inconsistent

Description

The collations of MySQL Connector/J are stored on the client side and distinguished by the server version.

The following table lists known client-side and server-side collation inconsistencies in character sets:

Character	Client-side default collation	Server-side default collation
`ascii`	`ascii_general_ci`	`ascii_bin`
`latin1`	`latin1_swedish_ci`	`latin1_bin`
`utf8mb4`	`utf8mb4_0900_ai_ci`	`utf8mb4_bin`

Way to avoid

Set the collation manually, and do not rely on the client-side default collation. The client-side default collation is stored by the MySQL Connector/J configuration file.

4.13.2.2.2 The `NO_BACKSLASH_ESCAPES` parameter does not take effect

Description

In TiDB, you cannot use the `NO_BACKSLASH_ESCAPES` parameter without escaping the `\` character. For more details, track this issue.

Way to avoid

Do not use `NO_BACKSLASH_ESCAPES` with `\` in TiDB, but use `\\` in SQL statements.

4.13.2.2.3 The `INDEX_USED` related parameters are not supported

Description

TiDB does not set the `SERVER_QUERY_NO_GOOD_INDEX_USED` and `SERVER_QUERY_NO_INDEX_USED` parameters in the protocol. This will cause the following parameters to be returned inconsistently with the actual situation:

- `com.mysql.cj.protocol.ServerSession.noIndexUsed()`
- `com.mysql.cj.protocol.ServerSession.noGoodIndexUsed()`

Way to avoid

Do not use the `noIndexUsed()` and `noGoodIndexUsed()` functions in TiDB.

4.13.2.2.4 The `enablePacketDebug` parameter is not supported

Description

TiDB does not support the enablePacketDebug parameter. It is a MySQL Connector/J parameter used for debugging that will keep the buffer of the data packet. This might cause the connection to close unexpectedly. **DO NOT** turn it on.

Way to avoid

Do not set the `enablePacketDebug` parameter in TiDB.

4.13.2.2.5 The UpdatableResultSet is not supported

Description

TiDB does not support `UpdatableResultSet`. **DO NOT** specify the `ResultSet.CONCUR_UPDATABLE` parameter and **DO NOT** update data inside the `ResultSet`.

Way to avoid

To ensure data consistency by transaction, you can use `UPDATE` statements to update data.

4.13.2.3 MySQL JDBC bugs

4.13.2.3.1 `useLocalTransactionState` and `rewriteBatchedStatements` are true at the same time will cause the transaction to fail to commit or roll back

Description

When the `useLocalTransactionState` and `rewriteBatchedStatements` parameters are set to `true` at the same time, the transaction might fail to commit. You can reproduce with this code.

Way to avoid

> **Note:**
>
> This bug has been reported to MySQL JDBC. To keep track of the process, you can follow this Bug Report.

DO NOT turn on `useLocalTransactionState` as this might prevent transactions from being committed or rolled back.

4.13.2.3.2 Connector is incompatible with the server version earlier than 5.7.5

Description

The database connection might hang under certain conditions when using MySQL Connector/J 8.0.29 with a MySQL server < 5.7.5 or a database using the MySQL server < 5.7.5 protocol (such as TiDB earlier than v6.3.0). For more details, see the Bug Report.

Way to avoid

This is a known issue. As of October 12, 2022, MySQL Connector/J has not fixed the issue.

TiDB fixes it in the following ways:

- Client side: This bug has been fixed in **pingcap/mysql-connector-j** and you can use the pingcap/mysql-connector-j instead of the official MySQL Connector/J.
- Server side: This compatibility issue has been fixed since TiDB v6.3.0 and you can upgrade the server to v6.3.0 or later versions.

4.13.2.4 Compatibility with Sequelize

The compatibility information described in this section is based on Sequelize v6.21.4.

According to the test results, TiDB supports most of the Sequelize features (using `MySQL` as the dialect).

Unsupported features are:

- Foreign key constraints (including many-to-many relationships) are not supported.
- `GEOMETRY` is not supported.
- Modification of integer primary key is not supported.
- `PROCEDURE` is not supported.
- The `READ-UNCOMMITTED` and `SERIALIZABLE` isolation levels are not supported.
- Modification of a column's `AUTO_INCREMENT` attribute is not allowed by default.
- `FULLTEXT`, `HASH`, and `SPATIAL` indexes are not supported.

4.13.2.4.1 Modification of integer primary key is not supported

Description

Modification of integer primary key is not supported. TiDB uses primary key as an index for data organization if the primary key is integer type. Refer to Issue #18090 and Clustered Indexes for more details.

4.13.2.4.2 The `READ-UNCOMMITTED` and `SERIALIZABLE` isolation levels are not supported

Description

TiDB does not support the `READ-UNCOMMITTED` and `SERIALIZABLE` isolation levels. If the isolation level is set to `READ-UNCOMMITTED` or `SERIALIZABLE`, TiDB throws an error.

Way to avoid

Use only the isolation level that TiDB supports: `REPEATABLE-READ` or `READ-COMMITTED`.

If you want TiDB to be compatible with other applications that set the `SERIALIZABLE` isolation level but not depend on `SERIALIZABLE`, you can set `tidb_skip_isolation_level_check` to `1`. In such case, TiDB ignores the unsupported isolation level error.

4.13.2.4.3 Modification of a column's `AUTO_INCREMENT` attribute is not allowed by default

Description

Adding or removing the `AUTO_INCREMENT` attribute of a column via `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE` command is not allowed by default.

Way to avoid

Refer to the restrictions of `AUTO_INCREMENT`.

To allow the removal of the `AUTO_INCREMENT` attribute, set `@@tidb_allow_remove_auto_inc` to `true`.

4.13.2.4.4 `FULLTEXT`, `HASH`, and `SPATIAL` indexes are not supported

Description

`FULLTEXT`, `HASH`, and `SPATIAL` indexes are not supported.

4.13.3 Integrate TiDB with ProxySQL

This document provides a high-level introduction to ProxySQL, describes how to integrate ProxySQL with TiDB in a development environment and a production environment, and demonstrates the key integration benefits through the scenario of query routing.

If you are interested in learning more about TiDB and ProxySQL, you can find some useful links as follows:

- TiDB Cloud
- TiDB Developer Guide
- ProxySQL Documentation

4.13.3.1 What is ProxySQL?

ProxySQL is a high-performance, open-source SQL proxy. It has a flexible architecture and can be deployed in several different ways, making it ideal for a variety of use cases. For example, ProxySQL can be used to improve performance by caching frequently-accessed data.

ProxySQL is designed from the ground up to be fast, efficient, and easy to use. It is fully compatible with MySQL, and supports all of the features you would expect from a high quality SQL proxy. In addition, ProxySQL comes with a number of unique features that make it an ideal choice for a wide range of applications.

4.13.3.2 Why ProxySQL integration?

- ProxySQL can help boost application performance by reducing latency when interacting with TiDB. Irrespective of what you are building, whether it is a scalable application using serverless functions like Lambda, where the workload is nondeterministic and can spike, or if you are building an application to execute queries that load tons of data. By leveraging powerful capabilities of ProxySQL such as connection pooling and caching frequently-used queries, applications can gain immediate benefits.
- ProxySQL can act as an additional layer of application security protection against SQL vulnerabilities such as SQL injection with the help of query rules, an easy-to-configure feature available in ProxySQL.
- As both ProxySQL and TiDB are open-source projects, you can get the benefits of zero vendor lock-in.

4.13.3.3 Deployment architecture

The most obvious way to deploy ProxySQL with TiDB is to add ProxySQL as a standalone intermediary between the application layer and TiDB. However, the scalability and failure tolerance are not guaranteed, and it also adds additional latency due to network hop. To avoid these problems, an alternate deployment architecture is to deploy ProxySQL as a sidecar as below:

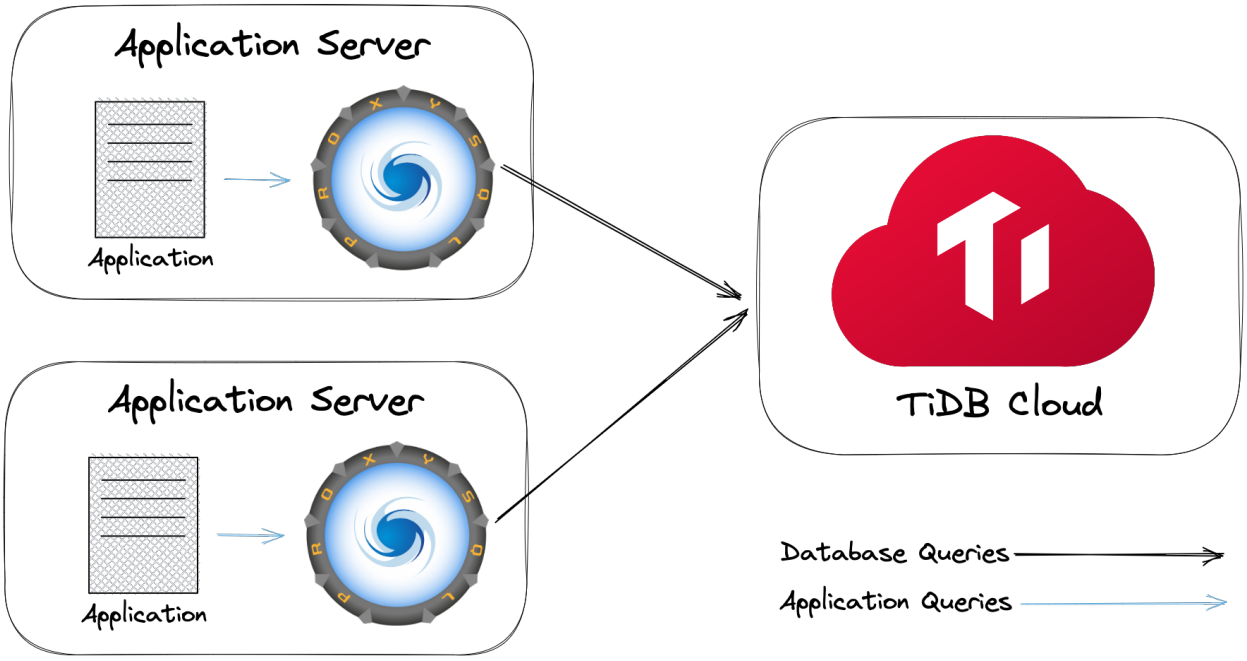

Figure 18: proxysql-client-side-tidb-cloud

Note:

The preceding illustration is only for reference. You must adapt it according to your actual deployment architecture.

4.13.3.4 Development environment

This section describes how to integrate TiDB with ProxySQL in a development environment. To get started with the ProxySQL integration, you can choose either of the following options depending on your TiDB cluster type after you have all the prerequisites in place.

- Option 1: Integrate TiDB Cloud with ProxySQL
- Option 2: Integrate TiDB (self-hosted) with ProxySQL

4.13.3.4.1 Prerequisites

Depending on the option you choose, you might need the following packages:

- Git
- Docker

- Python 3
- Docker Compose
- MySQL Client

You can follow the installation instructions as below:

1. Download and start Docker (the Docker Desktop already includes the Docker Compose).
2. Run the following command to install Python and `mysql-client`:

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/
    ↪ install/HEAD/install.sh)"
brew install python mysql-client
```

```
curl -fsSL https://get.docker.com | bash -s docker
yum install -y git python39 docker-ce docker-ce-cli containerd.io docker-
    ↪ compose-plugin mysql
systemctl start docker
```

- Download and install Git.

    1. Download the **64-bit Git for Windows Setup** package from the Git Windows Download page.
    2. Install the Git package by following the setup wizard. You can click **Next** for a few times to use the default installation settings.

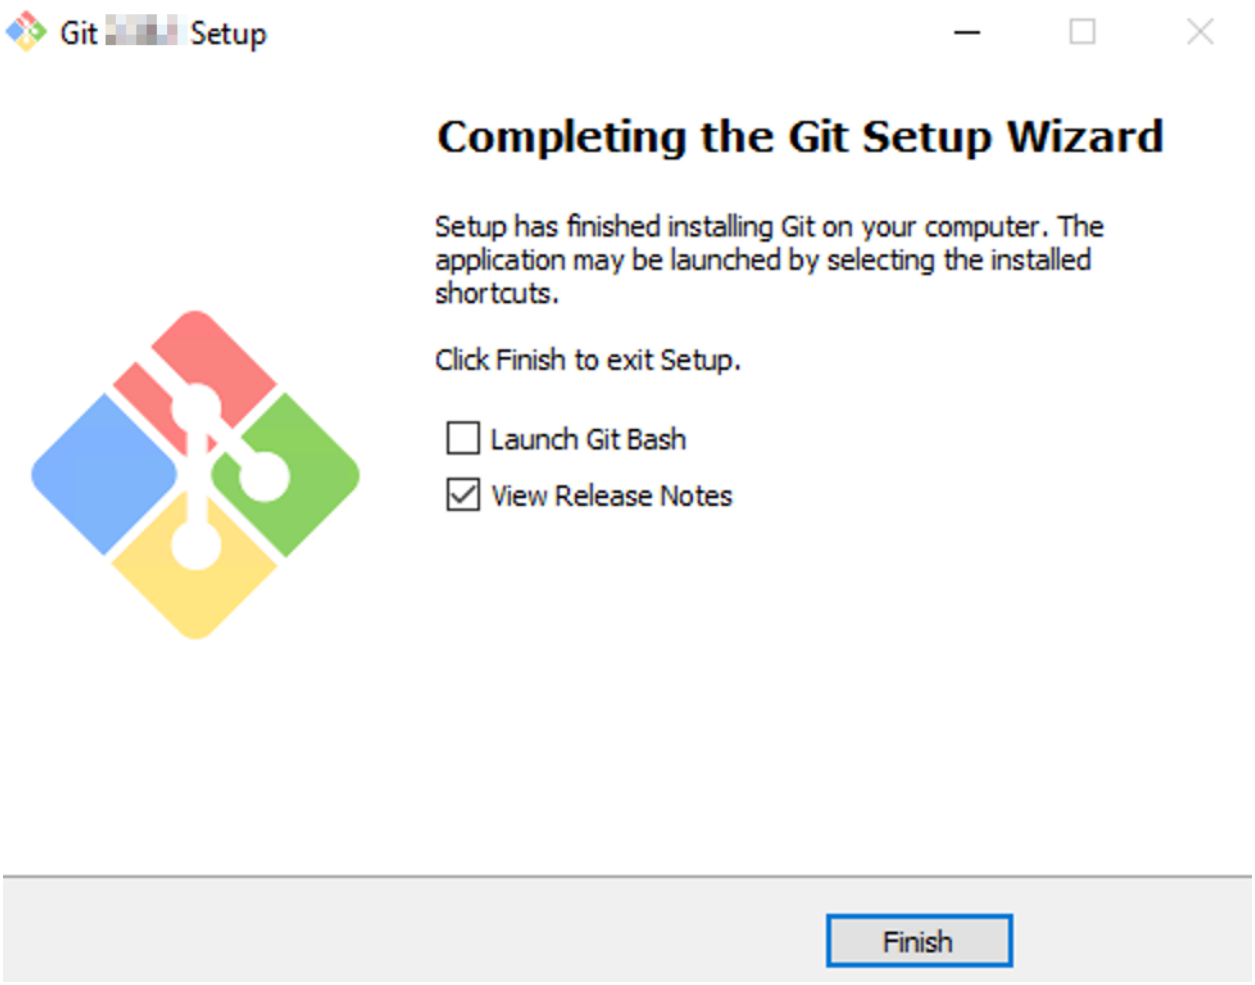

Figure 19: proxysql-windows-git-install

- Download and install MySQL Shell.

    1. Download the ZIP file of MySQL Installer from the MySQL Community Server Download page.
    2. Unzip the file, and locate `mysql.exe` in the `bin` folder. You need to add the path of the `bin` folder to the system variable and set it into the `PATH` variable at Git Bash:

    ```
    echo 'export PATH="(your bin folder)":$PATH' >>~/.bash_profile
    source ~/.bash_profile
    ```

    For example:

    ```
    echo 'export PATH="/c/Program Files (x86)/mysql-8.0.31-winx64/bin"
        ↪ :$PATH' >>~/.bash_profile
    source ~/.bash_profile
    ```

- Download and install Docker.

    1. Download Docker Desktop installer from the Docker Download page.
    2. Double-click the installer to run it. After the installation is completed, you will be prompted for a restart.

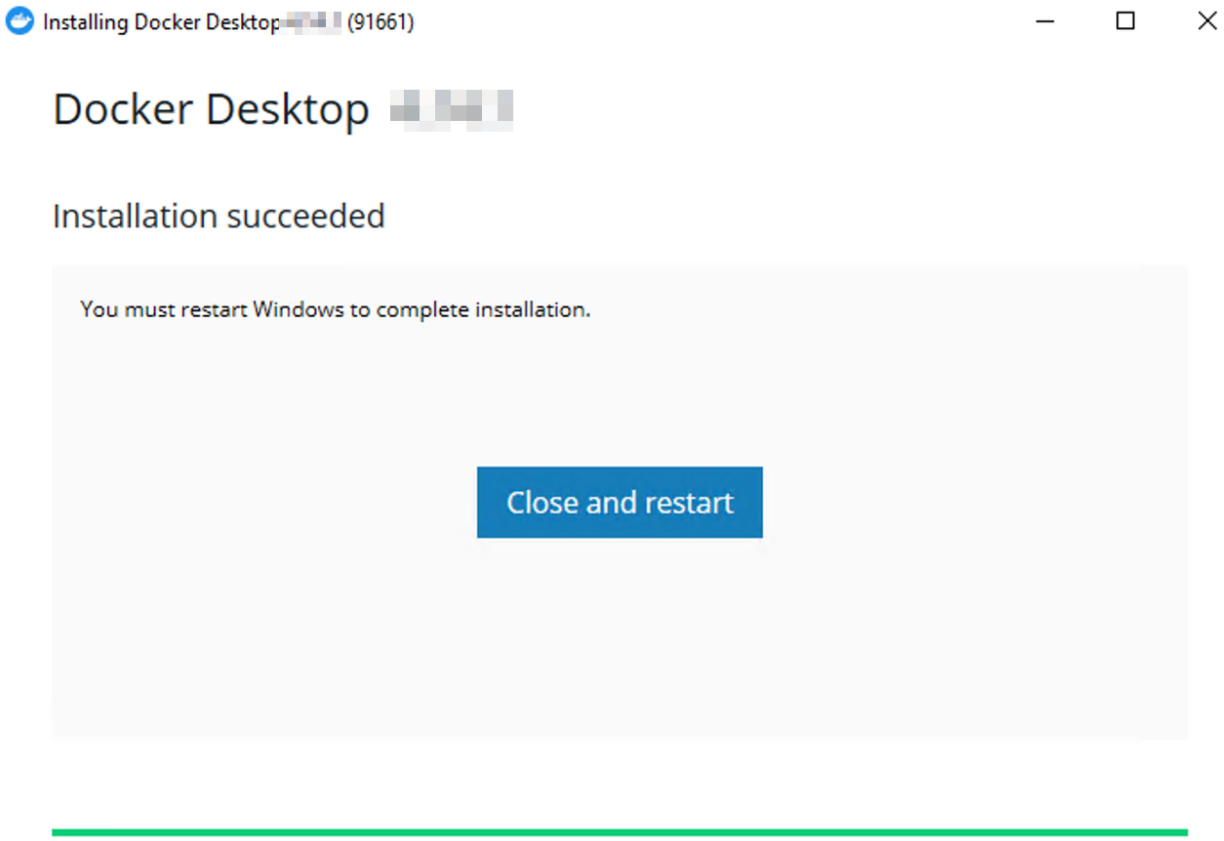

Figure 20: proxysql-windows-docker-install

- Download the latest Python 3 installer from the Python Download page and run it.

4.13.3.4.2 Option 1: Integrate TiDB Cloud with ProxySQL

For this integration, you will be using the ProxySQL Docker image along with a TiDB Serverless Tier cluster. The following steps will set up ProxySQL on port `16033`, so make sure this port is available.

Step 1. Create a TiDB Cloud Serverless Tier cluster

1. Create a free TiDB Serverless Tier cluster. Remember the root password that you set for your cluster.

2. Get your cluster hostname, port, and username for later use.

    1. On the Clusters page, click your cluster name to go to the cluster overview page.
    2. On the cluster overview page, locate the **Connection** pane, and then copy the `Endpoint`, `Port`, and `User` fields, where the `Endpoint` is your cluster hostname.

Step 2. Generate ProxySQL configuration files

1. Clone the integration example code repository for TiDB and ProxySQL:

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

2. Change to the `tidb-cloud-connect` folder:

```
cd tidb-proxysql-integration/example/tidb-cloud-connect
```

```
cd tidb-proxysql-integration/example/tidb-cloud-connect
```

```
cd tidb-proxysql-integration/example/tidb-cloud-connect
```

3. Generate ProxySQL configuration files by running `proxysql-config.py`:

```
python3 proxysql-config.py
```

```
python3 proxysql-config.py
```

```
python proxysql-config.py
```

When prompted, enter the endpoint of your cluster for `Serverless Tier Host`, and then enter the username and the password of your cluster.

The following is an example output. You will see that three configuration files are generated under the current `tidb-cloud-connect` folder.

```
[Begin] generating configuration files..
tidb-cloud-connect.cnf generated successfully.
proxysql-prepare.sql generated successfully.
proxysql-connect.py generated successfully.
[End] all files generated successfully and placed in the current folder
    ↪ .
```

Step 3. Configure ProxySQL

1. Start Docker. If Docker has already started, skip this step:

   Double-click the icon of the installed Docker to start it.

   ```
   systemctl start docker
   ```

   Double-click the icon of the installed Docker to start it.

2. Pull the ProxySQL image and start a ProxySQL container in the background:

   ```
   docker compose up -d
   ```

   ```
   docker compose up -d
   ```

   ```
   docker compose up -d
   ```

3. Integrate with ProxySQL by running the following command, which executes `proxysql -prepare.sql` inside **ProxySQL Admin Interface**:

   ```
   docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -P6032 < ./proxysql-prepare.sql"
   ```

   ```
   docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -P6032 < ./proxysql-prepare.sql"
   ```

   ```
   docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -P6032 < ./proxysql-prepare.sql"
   ```

Note:

The `proxysql-prepare.sql` script does the following:

1. Adds a user using the username and password of your cluster.
2. Assigns the user to the monitoring account.
3. Adds your TiDB Serverless Tier cluster to the list of hosts.
4. Enables a secure connection between ProxySQL and the TiDB Serverless Tier cluster.

To have a better understanding, it is strongly recommended that you check the `proxysql-prepare.sql` file. To learn more about ProxySQL configuration, see ProxySQL documentation.

The following is an example output. You will see that the hostname of your cluster is shown in the output, which means that the connectivity between ProxySQL and the TiDB Serverless Tier cluster is established.

```
*************************** 1. row ***************************
   hostgroup_id: 0
       hostname: gateway01.us-west-2.prod.aws.tidbcloud.com
           port: 4000
       gtid_port: 0
           status: ONLINE
           weight: 1
       compression: 0
   max_connections: 1000
max_replication_lag: 0
           use_ssl: 1
   max_latency_ms: 0
           comment:
```

Step 4. Connect to your TiDB cluster through ProxySQL

1. To connect to your TiDB cluster, run `proxysql-connect.py`. The script will automatically launch the MySQL client and use the username and password you specified in Step 2 for connection.

```
python3 proxysql-connect.py
```

```
python3 proxysql-connect.py
```

```
python proxysql-connect.py
```

2. After connecting to your TiDB cluster, you can use the following SQL statement to validate the connection:

```
SELECT VERSION();
```

   If the TiDB version is displayed, you are successfully connected to your TiDB Serverless Tier cluster through ProxySQL. To exit from the MySQL client anytime, enter `quit` and press enter.

> **Note:**
>
> ***For Debugging:*** If you are unable to connect to the cluster, check the files `tidb-cloud-connect.cnf`, `proxysql-prepare.sql`, and `proxysql-connect.py`. Make sure that the server information you provided is available and correct.

3. To stop and remove containers, and go to the previous directory, run the following command:

```
docker compose down
cd -
```

```
docker compose down
cd -
```

```
docker compose down
cd -
```

4.13.3.4.3 Option 2: Integrate TiDB (self-hosted) with ProxySQL

For this integration, you will set up an environment using Docker images of TiDB and ProxySQL. You are encouraged to try other ways of installing TiDB (self-hosted) in your own interest.

The following steps will set up ProxySQL and TiDB on ports `6033` and `4000` respectively, so make sure these ports are available.

1. Start Docker. If Docker has already started, skip this step:

   Double-click the icon of the installed Docker to start it.

   ```
   systemctl start docker
   ```

   Double-click the icon of the installed Docker to start it.

2. Clone the integration example code repository for TiDB and ProxySQL:

   ```
   git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
   ```

   ```
   git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
   ```

   ```
   git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
   ```

3. Pull the latest images of ProxySQL and TiDB:

   ```
   cd tidb-proxysql-integration && docker compose pull
   ```

   ```
   cd tidb-proxysql-integration && docker compose pull
   ```

   ```
   cd tidb-proxysql-integration && docker compose pull
   ```

4. Start an integrated environment using both TiDB and ProxySQL running as containers:

   ```
   docker compose up -d
   ```

```
docker compose up -d
```

```
docker compose up -d
```

To log in to the ProxySQL `6033` port, you can use the `root` username with an empty password.

5. Connect to TiDB via ProxySQL:

```
mysql -u root -h 127.0.0.1 -P 6033
```

```
mysql -u root -h 127.0.0.1 -P 6033
```

```
mysql -u root -h 127.0.0.1 -P 6033
```

6. After connecting to your TiDB cluster, you can use the following SQL statement to validate the connection:

```
SELECT VERSION();
```

If the TiDB version is displayed, you are successfully connected to your TiDB containers through ProxySQL.

7. To stop and remove containers, and go to the previous directory, run the following command:

```
docker compose down
cd -
```

```
docker compose down
cd -
```

```
docker compose down
cd -
```

4.13.3.5 Production environment

For a production environment, it is recommended that you use TiDB Cloud directly for a fully-managed experience.

4.13.3.5.1 Prerequisite

Download and install a MySQL client. For example, MySQL Shell.

4.13.3.5.2 Integrate TiDB Cloud with ProxySQL on CentOS

ProxySQL can be installed on many different platforms. The following takes CentOS as an example.

For a full list of supported platforms and the corresponding version requirements, see ProxySQL documentation.

Step 1. Create a TiDB Cloud Dedicated Tier cluster

For detailed steps, see Create a TiDB Cluster.

Step 2. Install ProxySQL

1. Add ProxySQL to the YUM repository:

```
cat > /etc/yum.repos.d/proxysql.repo << EOF
[proxysql]
name=ProxySQL YUM repository
baseurl=https://repo.proxysql.com/ProxySQL/proxysql-2.4.x/centos/\
    ↪ $releasever
gpgcheck=1
gpgkey=https://repo.proxysql.com/ProxySQL/proxysql-2.4.x/repo_pub_key
EOF
```

2. Install ProxySQL:

```
yum install -y proxysql
```

3. Start ProxySQL:

```
systemctl start proxysql
```

To learn more about the supported platforms of ProxySQL and their installation, refer to ProxySQL README or ProxySQL installation documentation.

Step 3. Configure ProxySQL

To use ProxySQL as a proxy for TiDB, you need to configure ProxySQL. To do so, you can either execute SQL statements inside ProxySQL Admin Interface (recommended) or use the configuration file.

> **Note:**
>
> The following sections list only the required configuration items of ProxySQL. For a comprehensive list of configurations, see ProxySQL documentation.

Option 1: Configure ProxySQL using the Admin Interface

1. Reconfigure ProxySQL's internals using the standard ProxySQL Admin interface, accessible via any MySQL command line client (available by default on port `6032`):

```
mysql -u admin -padmin -h 127.0.0.1 -P6032 --prompt 'ProxySQL Admin> '
```

   The above step will take you to the ProxySQL admin prompt.

2. Configure the TiDB clusters to be used, where you can add one or multiple TiDB clusters to ProxySQL. The following statement will add one TiDB Cloud Dedicated Tier cluster for example. You need to replace `<tidb cloud dedicated cluster host ↪ >` and `<tidb cloud dedicated cluster port>` with your TiDB Cloud endpoint and port (the default port is `4000`).

```
INSERT INTO mysql_servers(hostgroup_id, hostname, port)
VALUES
  (
    0,
    '<tidb cloud dedicated cluster host>',
    <tidb cloud dedicated cluster port>
  );
LOAD mysql servers TO runtime;
SAVE mysql servers TO DISK;
```

Note:

- `hostgroup_id`: specify an ID of the hostgroup. ProxySQL manages clusters using hostgroup. To distribute SQL traffic to these clusters evenly, you can configure several clusters that need load balancing to the same hostgroup. To distinguish the clusters, such as for read and write purposes, you can configure them to use different hostgroups.
- `hostname`: the endpoint of the TiDB cluster.
- `port`: the port of the TiDB cluster.

3. Configure Proxy login users to make sure that the users have appropriate permissions on the TiDB cluster. In the following statements, you need to replace '*tidb cloud dedicated cluster username*' and '*tidb cloud dedicated cluster password*' with the actual username and password of your cluster.

```
INSERT INTO mysql_users(
  username, password, active, default_hostgroup,
  transaction_persistent
)
VALUES
  (
    '<tidb cloud dedicated cluster username>',
```

```
    '<tidb cloud dedicated cluster password>',
    1, 0, 1
  );
LOAD mysql users TO runtime;
SAVE mysql users TO DISK;
```

Note:

- `username`: TiDB username.
- `password`: TiDB password.
- `active`: controls whether the user is active. `1` indicates that the user is **active** and can be used for login, while `0` indicates that the user is inactive.
- `default_hostgroup`: the default hostgroup used by the user, where SQL traffic is distributed unless the query rule overrides the traffic to a specific hostgroup.
- `transaction_persistent`: `1` indicates a persistent transaction. When a user starts a transaction within a connection, all query statements are routed to the same hostgroup until the transaction is committed or rolled back.

Option 2: Configure ProxySQL using a configuration file

This option should only be considered as an alternate method for configuring ProxySQL. For more information, see Configuring ProxySQL through the config file.

1. Delete any existing SQLite database (where configurations are stored internally):

```
rm /var/lib/proxysql/proxysql.db
```

Warning:

If you delete the SQLite database file, any configuration changes made using ProxySQL Admin interface will be lost.

2. Modify the configuration file `/etc/proxysql.cnf` according to your need. For example:

```
mysql_servers:
(
    {
        address="<tidb cloud dedicated cluster host>"
        port=<tidb cloud dedicated cluster port>
        hostgroup=0
```

```
        max_connections=2000
    }
)

mysql_users:
(
    {
        username = "<tidb cloud dedicated cluster username>"
        password = "<tidb cloud dedicated cluster password>"
        default_hostgroup = 0
        max_connections = 1000
        default_schema = "test"
        active = 1
        transaction_persistent = 1
    }
)
```

In the preceding example:

- `address` and `port`: specify the endpoint and port of your TiDB Cloud cluster.
- `username` and `password`: specify the username and password of your TiDB Cloud cluster.

3. Restart ProxySQL:

```
systemctl restart proxysql
```

After the restart, the SQLite database will be created automatically.

Warning:

Do not run ProxySQL with default credentials in production. Before starting the `proxysql` service, you can change the defaults in the `/etc/proxysql.cnf` file by changing the `admin_credentials` variable.

4.13.3.6 Typical scenario

This section takes query routing as an example to show some of the benefits that you can leverage by integrating ProxySQL with TiDB.

4.13.3.6.1 Query rules

Databases can be overloaded by high traffic, faulty code, or malicious spam. With query rules of ProxySQL, you can respond to these issues quickly and effectively by rerouting, rewriting, or rejecting queries.

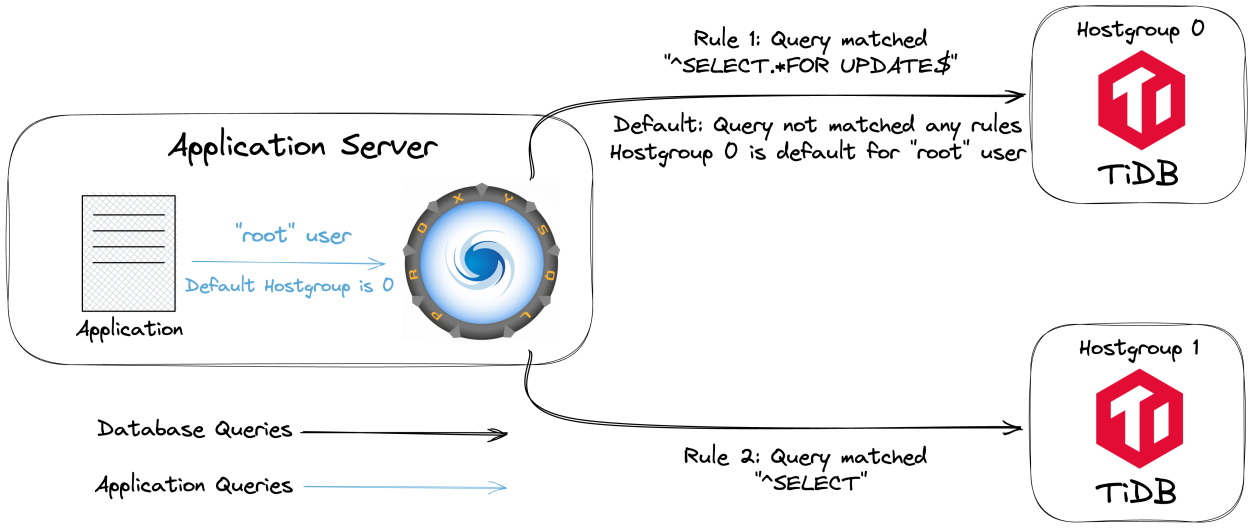

Figure 21: proxysql-client-side-rules

> **Note:**
>
> In the following steps, you will be using the container images of TiDB and ProxySQL to configure query rules. If you have not pulled them, you can check the integration section for detailed steps.

1. Clone the integration example code repository for TiDB and ProxySQL. Skip this step if you have already cloned it in the previous steps.

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

2. Change to the example directory for ProxySQL rules:

```
cd tidb-proxysql-integration/example/proxy-rule-admin-interface
```

```
cd tidb-proxysql-integration/example/proxy-rule-admin-interface
```

```
cd tidb-proxysql-integration/example/proxy-rule-admin-interface
```

3. Run the following command to start two TiDB containers and a ProxySQL container:

```
docker compose up -d
```

```
docker compose up -d
```

```
docker compose up -d
```

If everything goes well, the following containers are started:

- Two Docker containers of TiDB clusters exposed via ports 4001, 4002
- One ProxySQL Docker container exposed via port 6034.

4. In the two TiDB containers, using `mysql` to create a table with a similar schema definition and then insert different data (`'tidb-server01-port-4001'`, `'tidb-server02-port-4002'`) to identify these containers.

```
mysql -u root -h 127.0.0.1 -P 4001 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server01-port
    ↪ -4001');
EOF

mysql -u root -h 127.0.0.1 -P 4002 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server02-port
    ↪ -4002');
EOF
```

```
mysql -u root -h 127.0.0.1 -P 4001 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server01-port
    ↪ -4001');
EOF

mysql -u root -h 127.0.0.1 -P 4002 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
```

```
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server02-port
    ↪ -4002');
EOF
```

```
mysql -u root -h 127.0.0.1 -P 4001 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server01-port
    ↪ -4001');
EOF

mysql -u root -h 127.0.0.1 -P 4002 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server02-port
    ↪ -4002');
EOF
```

5. Configure ProxySQL by running the following command, which executes `proxysql-prepare.sql` inside ProxySQL Admin Interface to establish a proxy connection between the TiDB containers and ProxySQL.

```
docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -
    ↪ P6032 < ./proxysql-prepare.sql"
```

```
docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -
    ↪ P6032 < ./proxysql-prepare.sql"
```

```
docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -
    ↪ P6032 < ./proxysql-prepare.sql"
```

Note:

The `proxysql-prepare.sql` does the following:

- Adds the TiDB clusters in ProxySQL with `hostgroup_id` as `0` and `1`.
- Adds a user `root` with an empty password and sets `default_hostgroup` as `0`.
- Adds the rule `^SELECT.*FOR UPDATE$` with `rule_id` as `1` and `destination_hostgroup` as `0`. If a SQL statement matches this rule, the request will be forwarded to the TiDB cluster with `hostgroup` as `0`.

- Adds the rule `^SELECT` with `rule_id` as `2` and `destination_hostgroup` as `1`. If a SQL statement matches this rule, the request will be forwarded to the TiDB cluster with `hostgroup` as `1`.

To have a better understanding, it is strongly recommended that you check the `proxysql-prepare.sql` file. To learn more about ProxySQL configuration, see ProxySQL documentation.

The following is some additional information about how ProxySQL patterns match query rules:

- ProxySQL tries to match the rules one by one in the ascending order of `rule_id`.
- `^` symbol matches the beginning of a SQL statement and `$` matches the end.

For more information about ProxySQL regular expression and pattern matching, see mysql-query_processor_regex in ProxySQL documentation.

For a full list of parameters, see mysql_query_rules in ProxySQL documentation.

6. Verify the configuration and check whether the query rules work.

    1. Log into ProxySQL MySQL Interface as the `root` user:

    ```
    mysql -u root -h 127.0.0.1 -P 6034
    ```

    ```
    mysql -u root -h 127.0.0.1 -P 6034
    ```

    ```
    mysql -u root -h 127.0.0.1 -P 6034
    ```

    2. Execute the following SQL statements:

        - Execute a `SELECT` statement:

        ```
        SELECT * FROM test.tidb_server;
        ```

        This statement will match rule_id `2` and forward the statement to the TiDB cluster on `hostgroup 1`.

        - Execute a `SELECT ... FOR UPDATE` statement:

        ```
        SELECT * FROM test.tidb_server FOR UPDATE;
        ```

        This statement will match rule_id `1` and forward the statement to the TiDB cluster on `hostgroup 0`.

        - Start a transaction:

```
BEGIN;
INSERT INTO test.tidb_server (server_name) VALUES ('insert this
    ↪ and rollback later');
SELECT * FROM test.tidb_server;
ROLLBACK;
```

In this transaction, the `BEGIN` statement will not match any rules. It uses the default hostgroup (`hostgroup 0` in this example). Because ProxySQL enables user transaction_persistent by default, which will execute all statements within the same transaction in the same hostgroup, the `INSERT` and `SELECT * FROM test.tidb_server;` statements will also be forwarded to the TiDB cluster `hostgroup 0`.

The following is an example output. If you get a similar output, you have successfully configured the query rules with ProxySQL.

```
+-------------------------+
| server_name             |
+-------------------------+
| tidb-server02-port-4002 |
+-------------------------+
+-------------------------+
| server_name             |
+-------------------------+
| tidb-server01-port-4001 |
+-------------------------+
+--------------------------------+
| server_name                    |
+--------------------------------+
| tidb-server01-port-4001        |
| insert this and rollback later |
+--------------------------------+
```

3. To exit from the MySQL client anytime, enter `quit` and press enter.

7. To stop and remove containers, and go to the previous directory, run the following command:

```
docker compose down
cd -
```

```
docker compose down
cd -
```

```
docker compose down
cd -
```

4.13.4 Integrate TiDB with Amazon AppFlow

Amazon AppFlow is a fully managed API integration service that you use to connect your software as a service (SaaS) applications to AWS services, and securely transfer data. With Amazon AppFlow, you can import and export data from and to TiDB into many types of data providers, such as Salesforce, Amazon S3, LinkedIn, and GitHub. For more information, see Supported source and destination applications in AWS documentation.

This document describes how to integrate TiDB with Amazon AppFlow and takes integrating a TiDB Cloud Serverless Tier cluster as an example.

If you do not have a TiDB cluster, you can create a Serverless Tier cluster, which is free and can be created in approximately 30 seconds.

4.13.4.1 Prerequisites

- Git
- JDK 11 or above
- Maven 3.8 or above
- AWS CLI version 2
- AWS Serverless Application Model Command Line Interface (AWS SAM CLI) 1.58.0 or above
- An AWS Identity and Access Management (IAM) user with the following requirements:
  - The user can access AWS using an access key.
  - The user has the following permissions:
    * `AWSCertificateManagerFullAccess`: used for reading and writing the AWS Secrets Manager.
    * `AWSCloudFormationFullAccess`: SAM CLI uses AWS CloudFormation to proclaim the AWS resources.
    * `AmazonS3FullAccess`: AWS CloudFormation uses Amazon S3 to publish.
    * `AWSLambda_FullAccess`: currently, AWS Lambda is the only way to implement a new connector for Amazon AppFlow.
    * `IAMFullAccess`: SAM CLI needs to create a `ConnectorFunctionRole` for the connector.
- A SalesForce account.

4.13.4.2 Step 1. Register a TiDB connector

4.13.4.2.1 Clone the code

Clone the integration example code repository for TiDB and Amazon AppFlow:

```
git clone https://github.com/pingcap-inc/tidb-appflow-integration
```

4.13.4.2.2 Build and upload a Lambda

1. Build the package:

```
cd tidb-appflow-integration
mvn clean package
```

2. (Optional) Configure your AWS access key ID and secret access key if you have not.

```
aws configure
```

3. Upload your JAR package as a Lambda:

```
sam deploy --guided
```

Note:

- The `--guided` option uses prompts to guide you through the deployment. Your input will be stored in a configuration file, which is `samconfig.toml` by default.
- `stack_name` specifies the name of AWS Lambda that you are deploying.
- This prompted guide uses AWS as the cloud provider of TiDB Cloud Serverless Tier. To use Amazon S3 as the source or destination, you need to set the `region` of AWS Lambda as the same as that of Amazon S3.
- If you have already run `sam deploy --guided` before, you can just run `sam deploy` instead, and SAM CLI will use the configuration file `samconfig.toml` to simplify the interaction.

If you see a similar output as follows, this Lambda is successfully deployed.

```
Successfully created/updated stack - <stack_name> in <region>
```

4. Go to the AWS Lambda console, and you can see the Lambda that you just uploaded. Note that you need to select the correct region in the upper-right corner of the window.

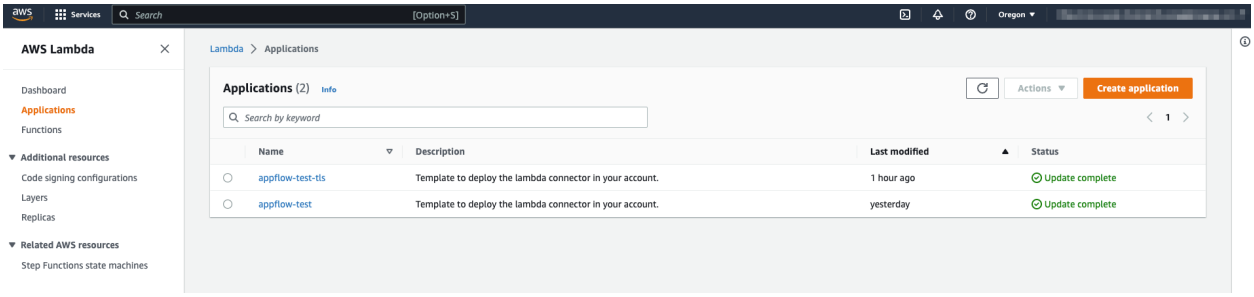

Figure 22: lambda dashboard

4.13.4.2.3 Use Lambda to register a connector

1. In the AWS Management Console, navigate to Amazon AppFlow > Connectors and click **Register new connector**.

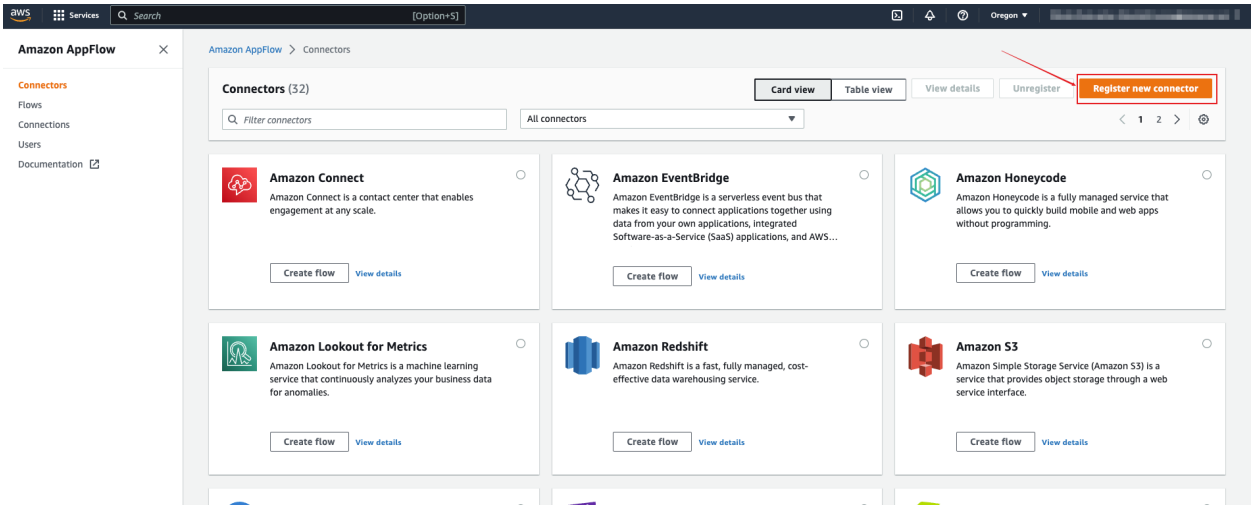

Figure 23: register connector

2. In the **Register a new connector** dialog, choose the Lambda function you uploaded and specify the connector label using the connector name.

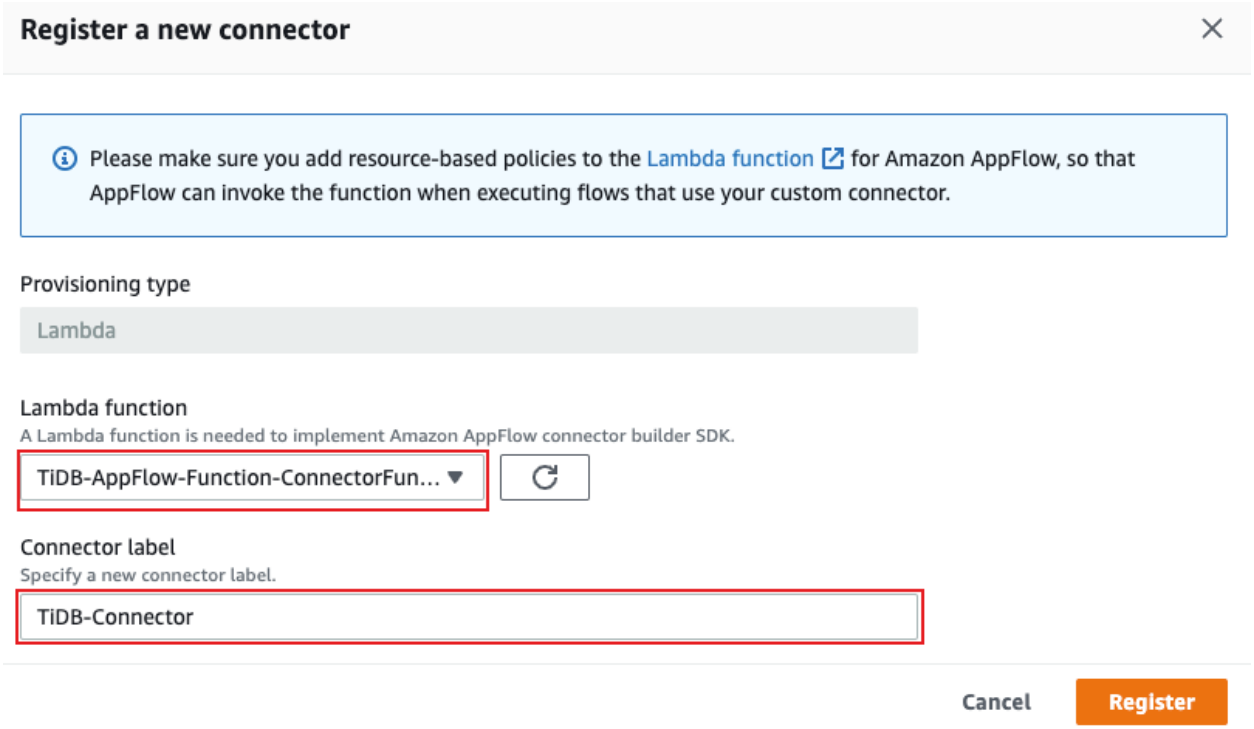

Figure 24: register connector dialog

3. Click **Register**. Then, a TiDB connector is registered successfully.

4.13.4.3 Step 2. Create a flow

Navigate to Amazon AppFlow > Flows and click **Create flow**.

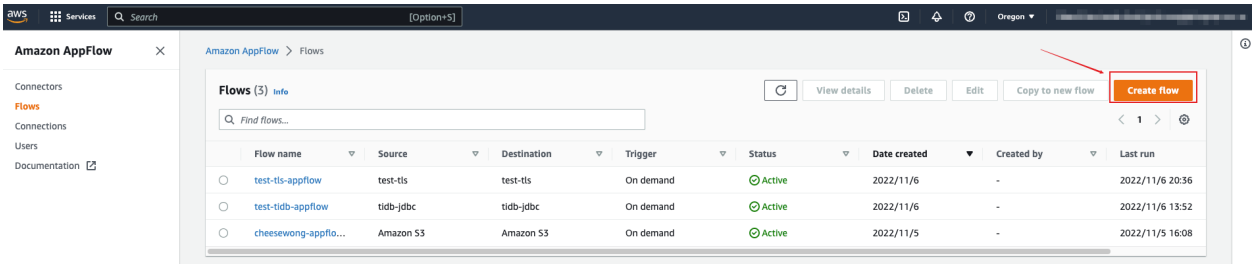

Figure 25: create flow

4.13.4.3.1 Set the flow name

Enter the flow name, and then click **Next**.

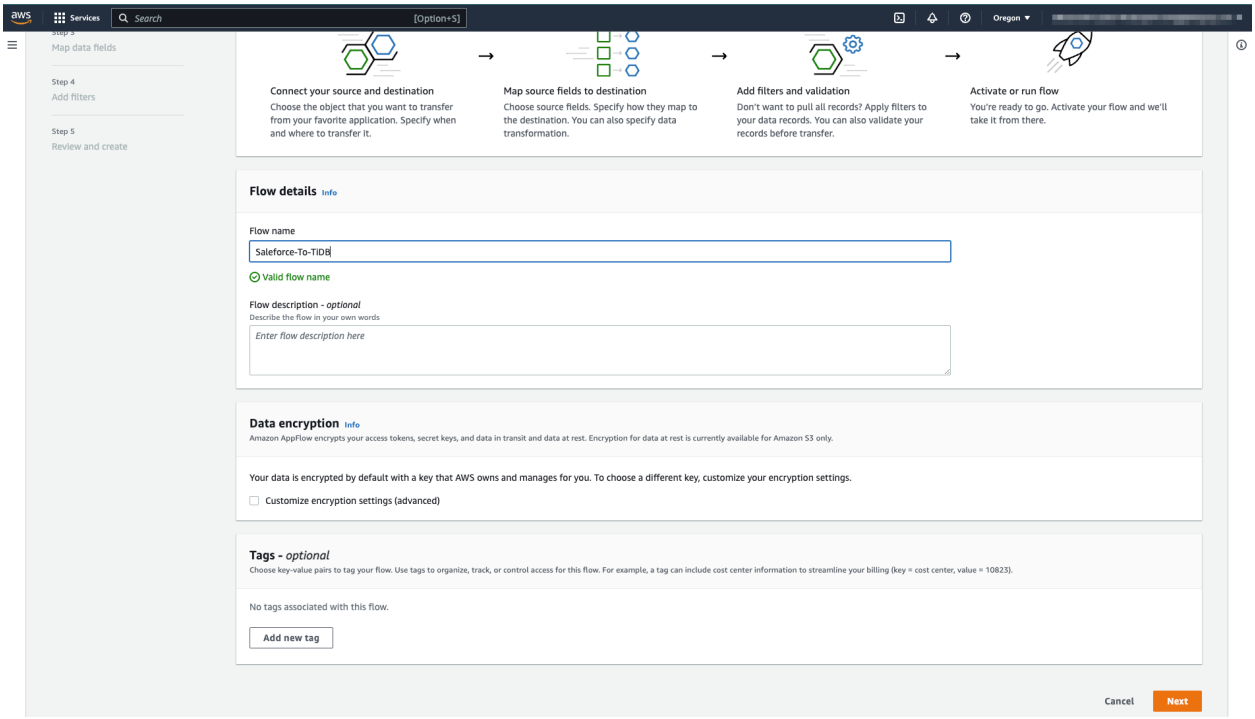

Figure 26: name flow

4.13.4.3.2 Set the source and destination tables

Choose the **Source details** and **Destination details**. TiDB connector can be used in both of them.

1. Choose the source name. This document uses **Salesforce** as an example source.

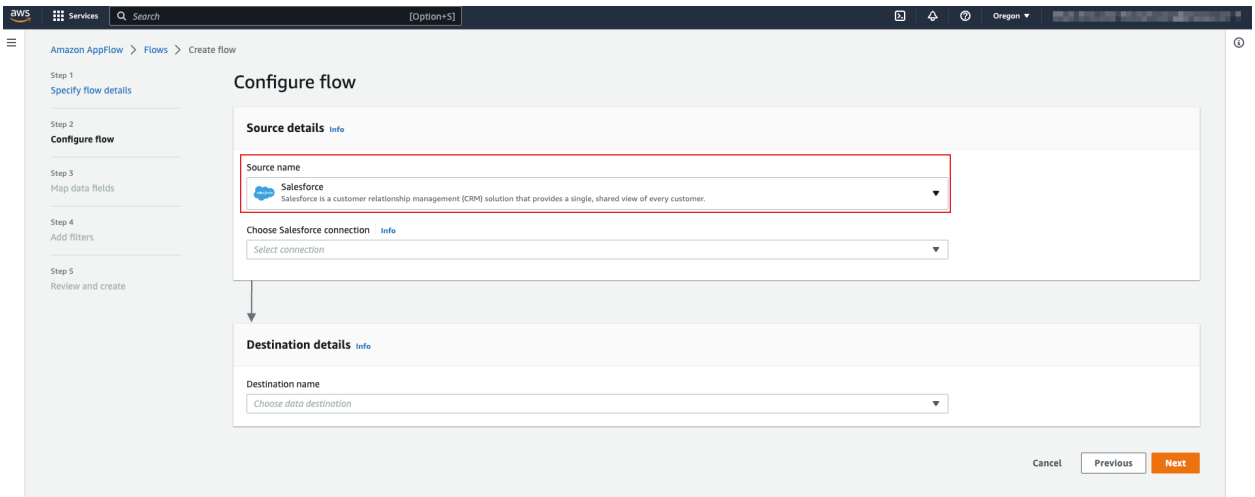

Figure 27: salesforce source

After you register to Salesforce, Salesforce will add some example data to your platform. The following steps will use the **Account** object as an example source object.

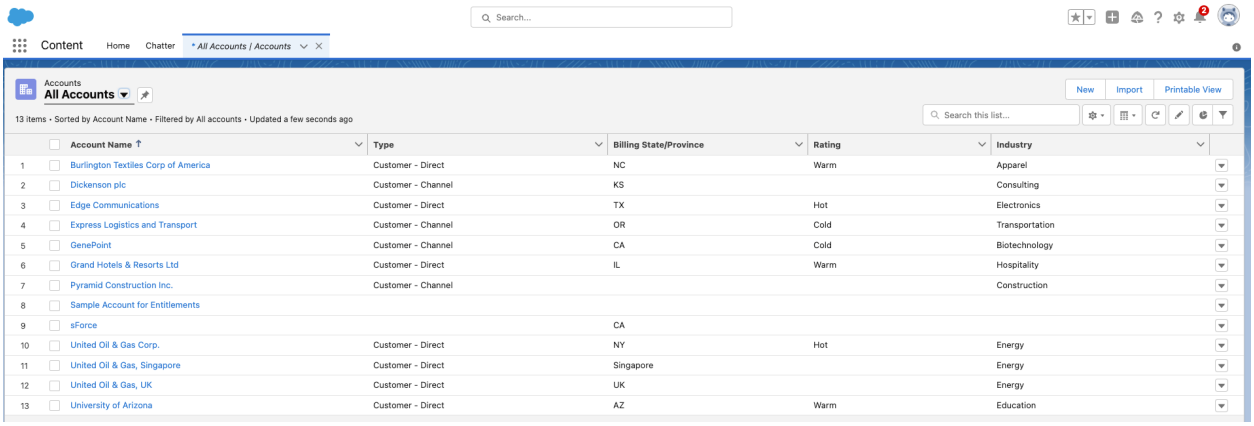

Figure 28: salesforce data

2. Click **Connect**.

    1. In the **Connect to Salesforce** dialog, specify the name of this connection, and then click **Continue**.

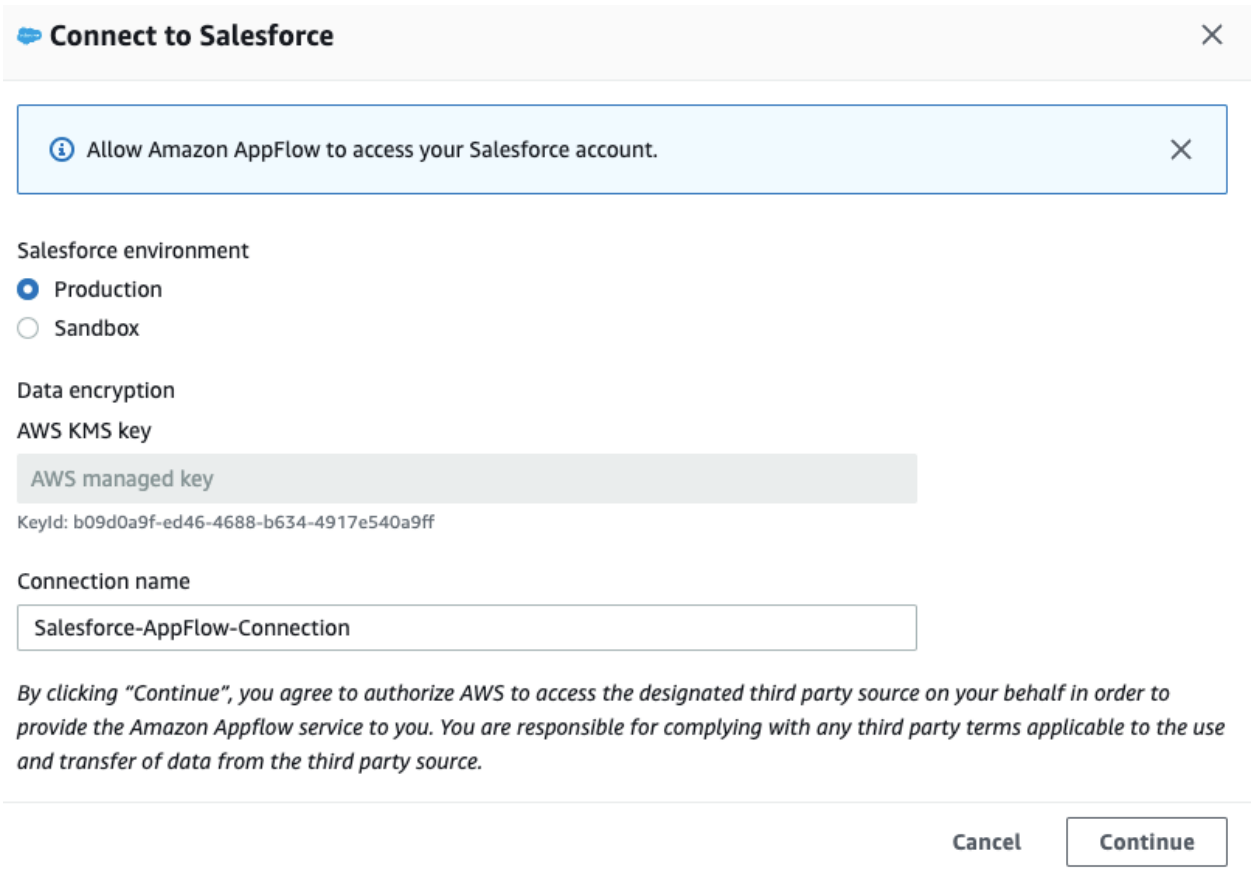

Figure 29: connect to salesforce

2. Click **Allow** to confirm that AWS can read your Salesforce data.

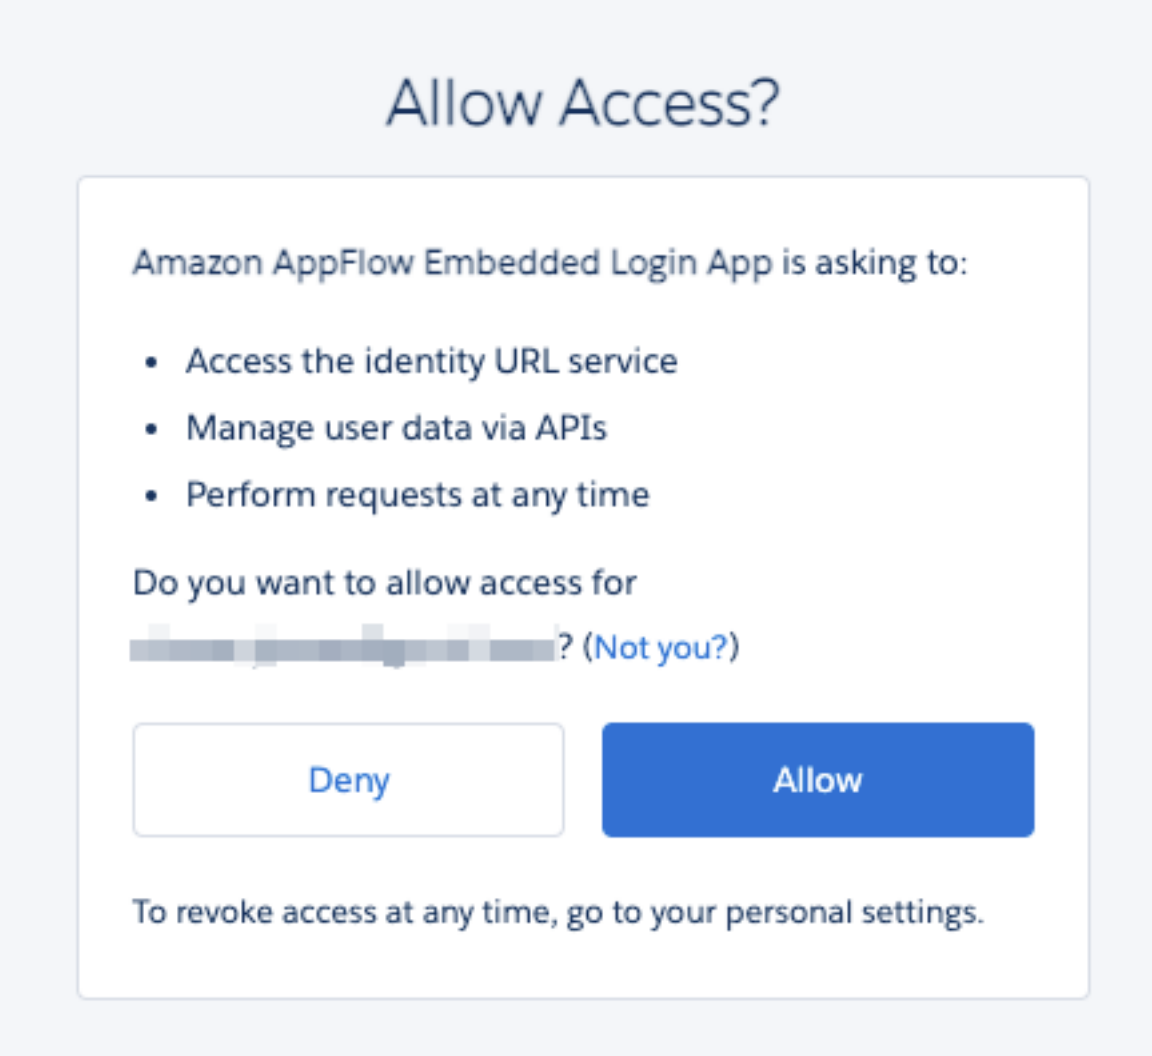

Figure 30: allow salesforce

> **Note:**
> If your company has already used the Professional Edition of Salesforce, the REST API is not enabled by default. You might need to register a new Developer Edition to use the REST API. For more information, refer to Salesforce Forum Topic.

3. In the **Destination details** area, choose **TiDB-Connector** as the destination. The **Connect** button is displayed.

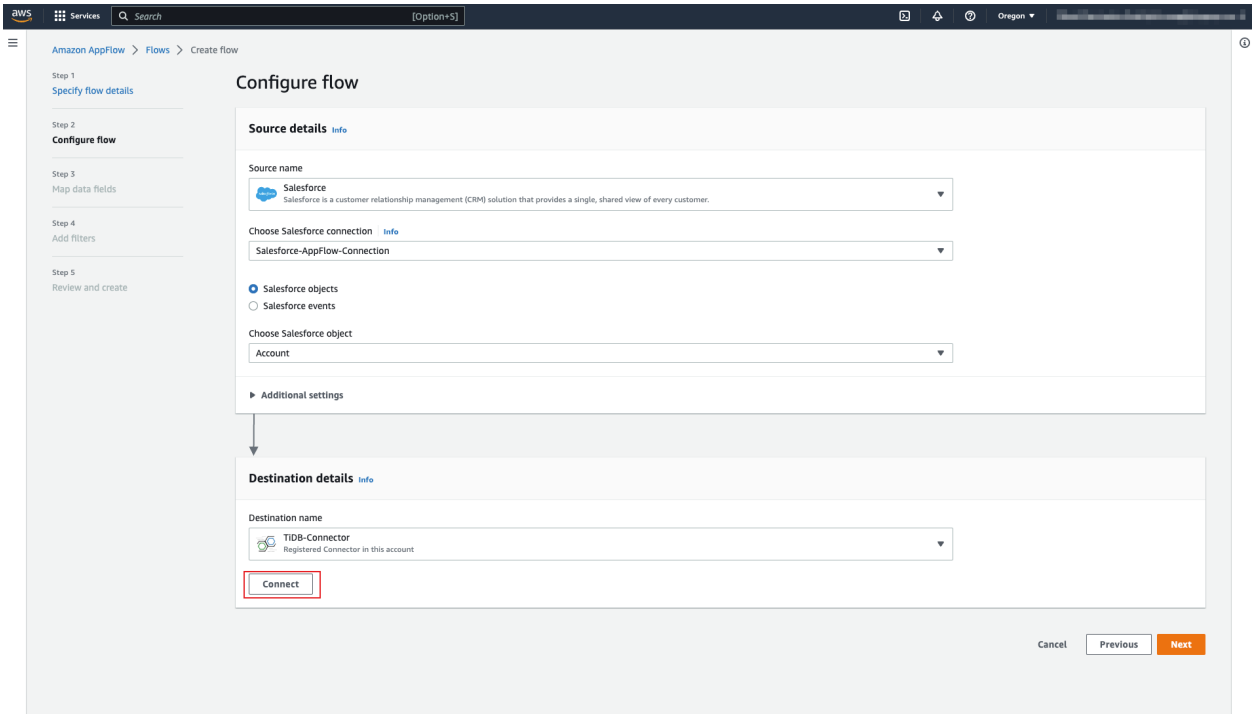

Figure 31: tidb dest

4. Before clicking **Connect**, you need to create a `sf_account` table in TiDB for the Salesforce **Account** object. Note that this table schema is different from the sample data in Tutorial of Amazon AppFlow.

```
CREATE TABLE `sf_account` (
    `id` varchar(255) NOT NULL,
    `name` varchar(150) NOT NULL DEFAULT '',
    `type` varchar(150) NOT NULL DEFAULT '',
    `billing_state` varchar(255) NOT NULL DEFAULT '',
    `rating` varchar(255) NOT NULL DEFAULT '',
    `industry` varchar(255) NOT NULL DEFAULT '',
    PRIMARY KEY (`id`)
);
```

5. After the `sf_account` table is created, click **Connect**. A connection dialog is displayed.

6. In the **Connect to TiDB-Connector** dialog, enter the connection properties of the TiDB cluster. If you use a TiDB Cloud Serverless Tier cluster, you need to set the **TLS** option to `Yes`, which lets the TiDB connector use the TLS connection. Then, click **Connect**.

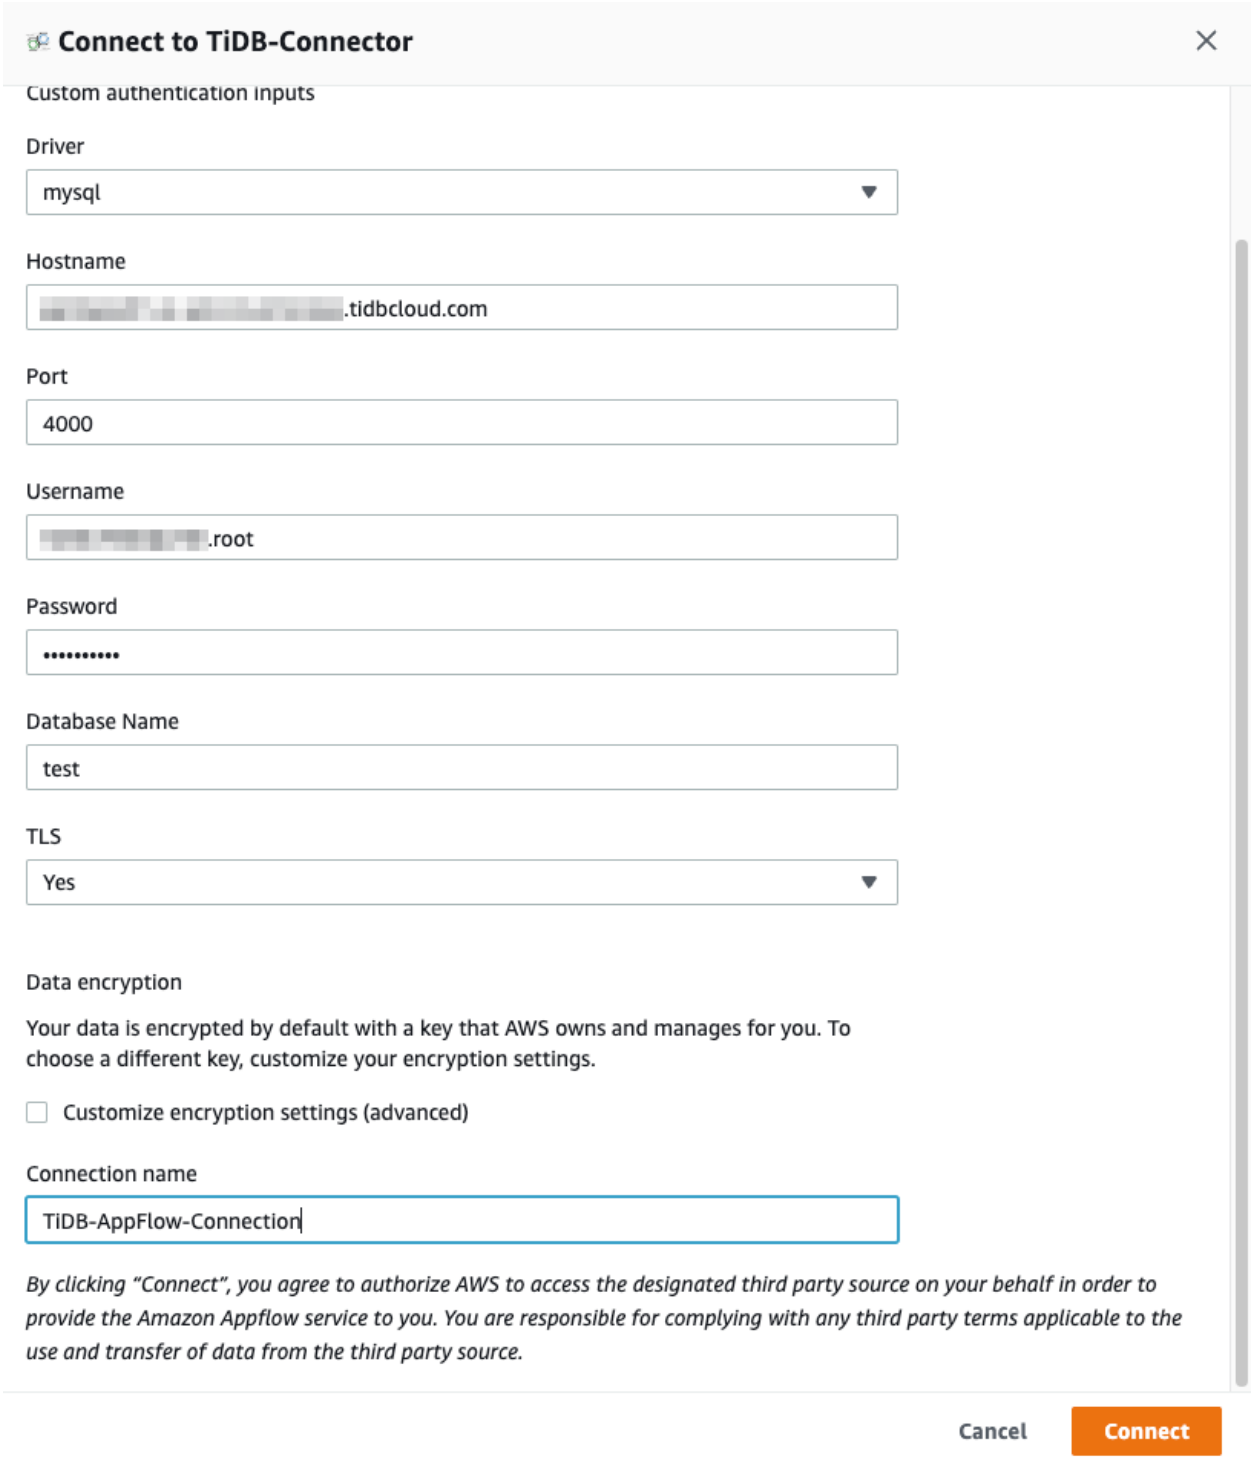

Figure 32: tidb connection message

7. Now you can get all tables in the database that you specified for connection. Choose the **sf_account** table from the drop-down list.

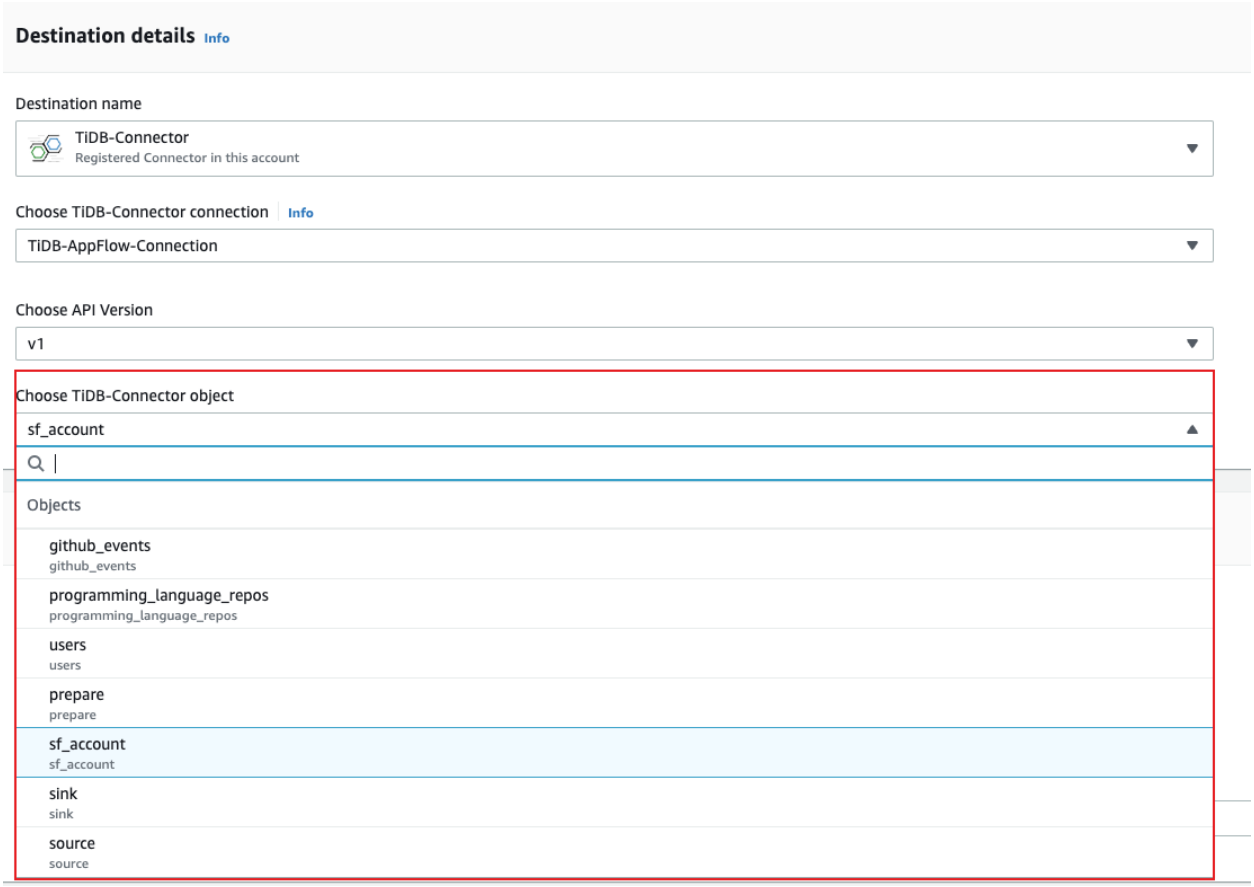

Figure 33: database

The following screenshot shows the configurations to transfer data from the Salesforce **Account** object to the `sf_account` table in TiDB:

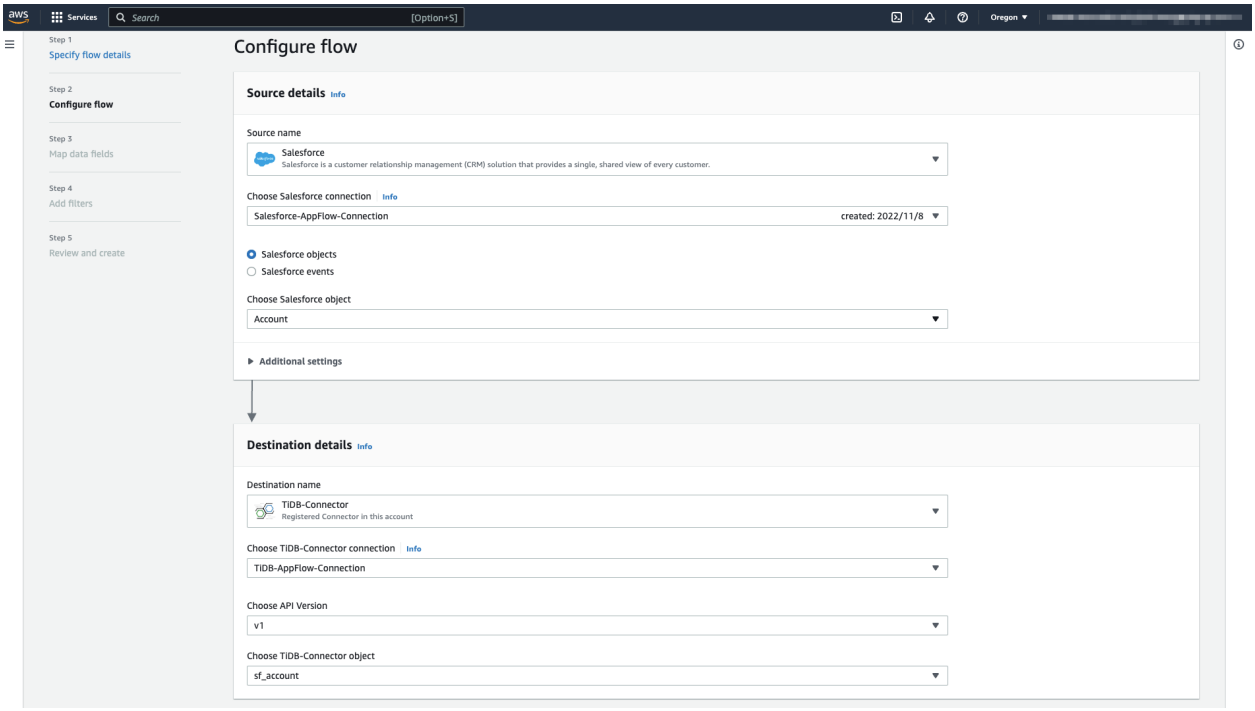

Figure 34: complete flow

8. In the **Error handling** area, choose **Stop the current flow run**. In the **Flow trigger** area, choose the **Run on demand** trigger type, which means you need to run the flow manually. Then, click **Next**.

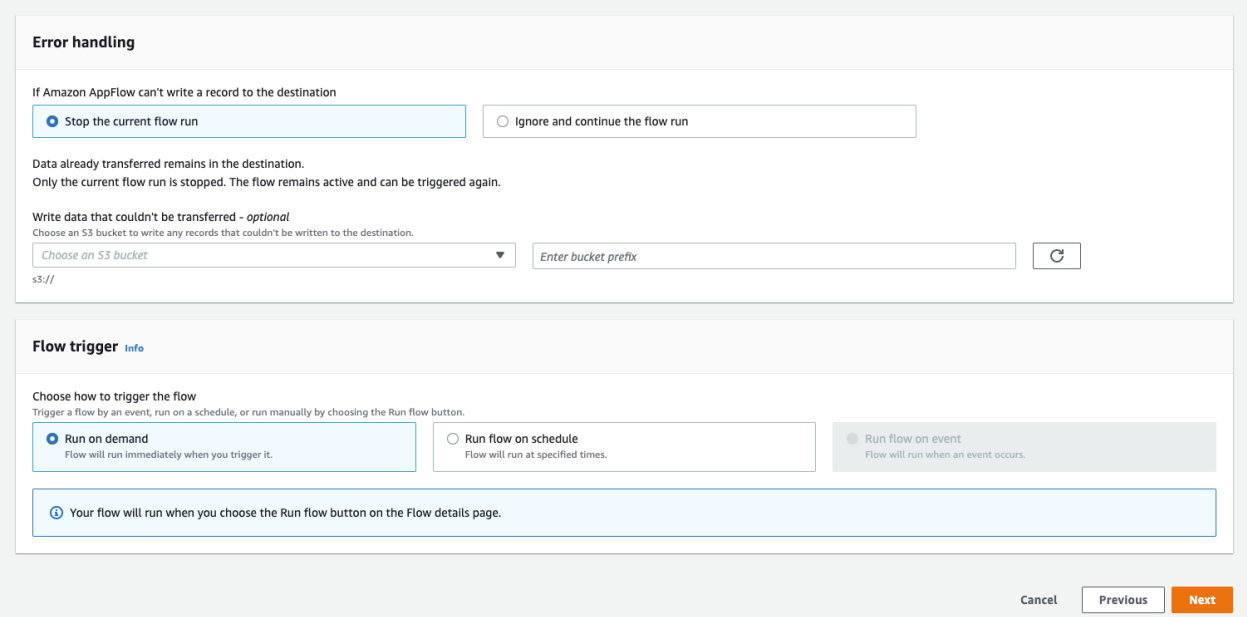

Figure 35: complete step1

4.13.4.3.3 Set mapping rules

Map the fields of the **Account** object in Salesforce to the `sf_account` table in TiDB, and then click **Next**.

- The `sf_account` table is newly created in TiDB and it is empty.

```
test> SELECT * FROM sf_account;
+----+------+------+---------------+--------+----------+
| id | name | type | billing_state | rating | industry |
+----+------+------+---------------+--------+----------+
+----+------+------+---------------+--------+----------+
```

- To set a mapping rule, you can select a source field name on the left, and select a destination field name on the right. Then, click **Map fields**, and a rule is set.

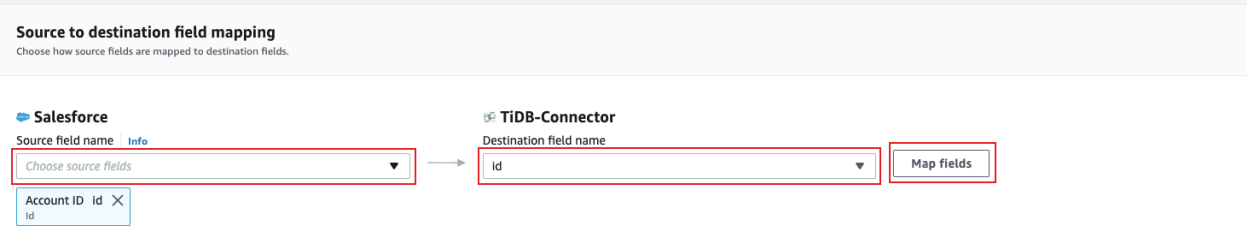

Figure 36: add mapping rule

- The following mapping rules (Source field name -> Destination field name) are needed in this document:

  - Account ID -> id
  - Account Name -> name
  - Account Type -> type
  - Billing State/Province -> billing_state
  - Account Rating -> rating
  - Industry -> industry

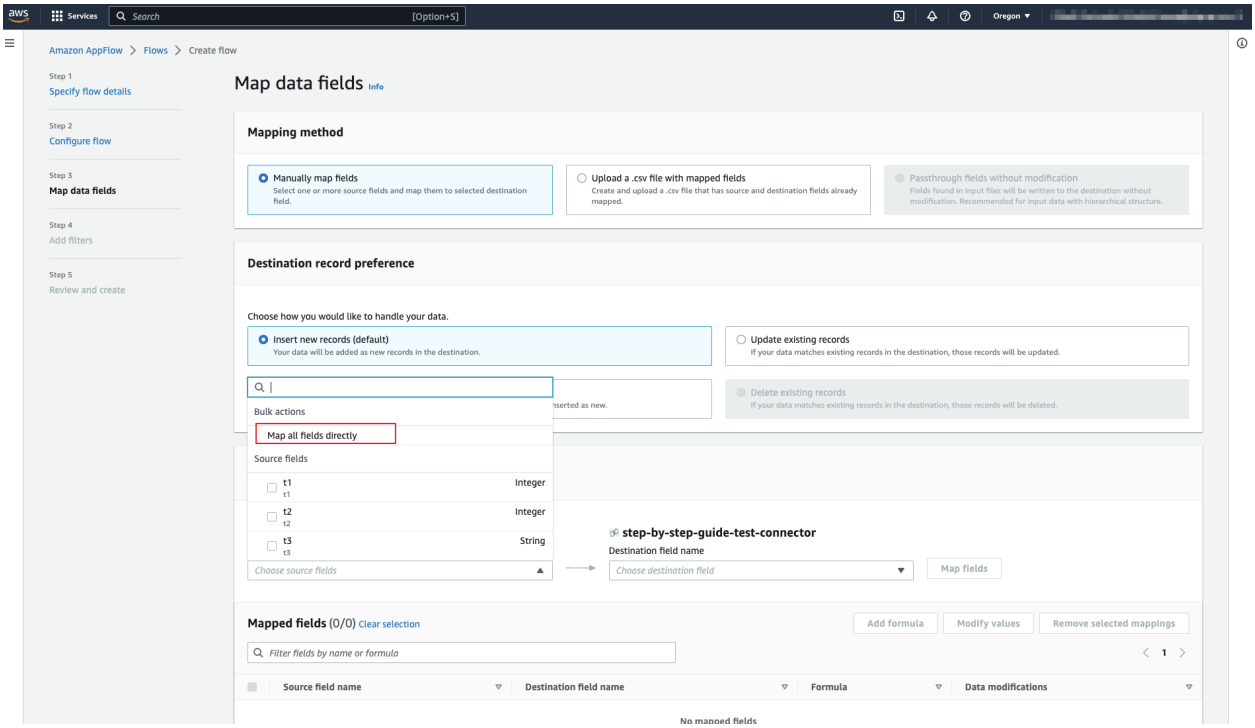

Figure 37: mapping a rule

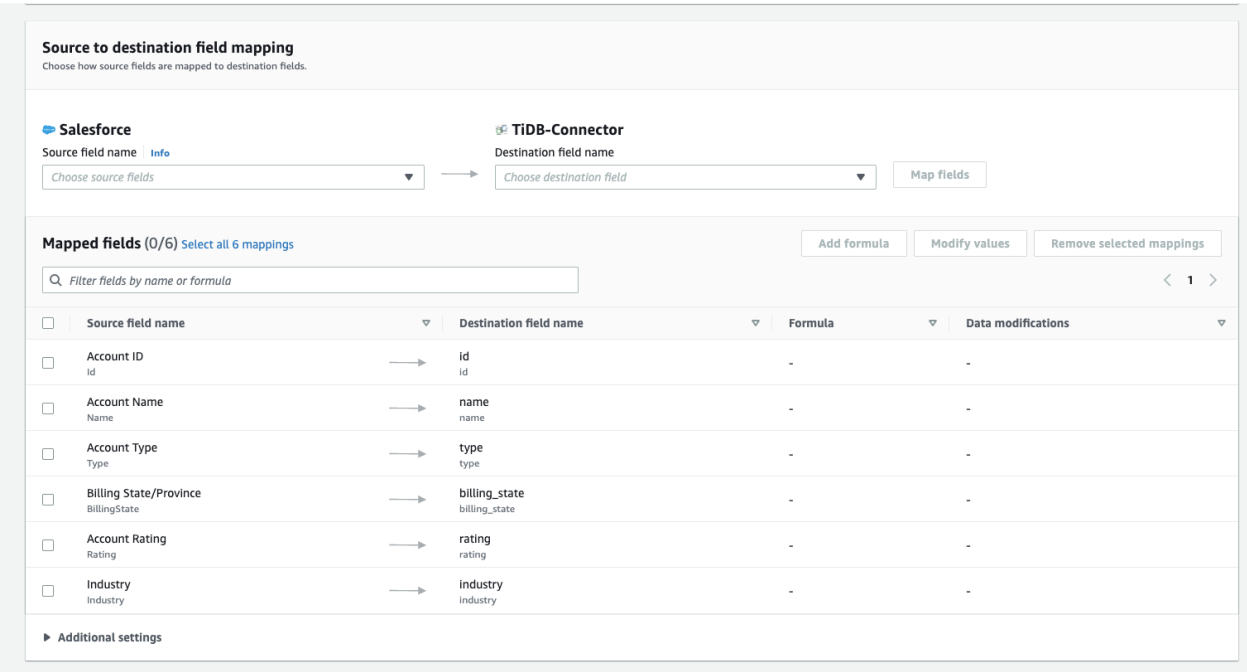

Figure 38: show all mapping rules

4.13.4.3.4 (Optional) Set filters

If you want to add some filters to your data fields, you can set them here. Otherwise, skip this step and click **Next**.

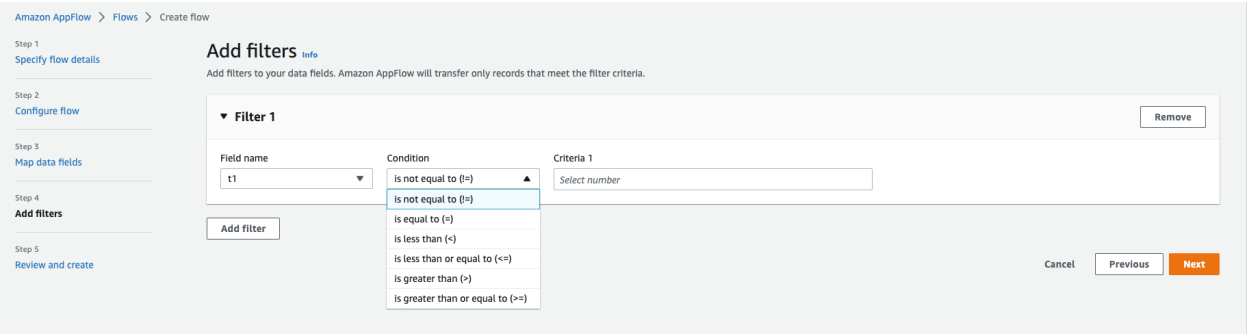

Figure 39: filters

4.13.4.3.5 Confirm and create the flow

Confirm the information of the flow to be created. If everything looks fine, click **Create flow**.

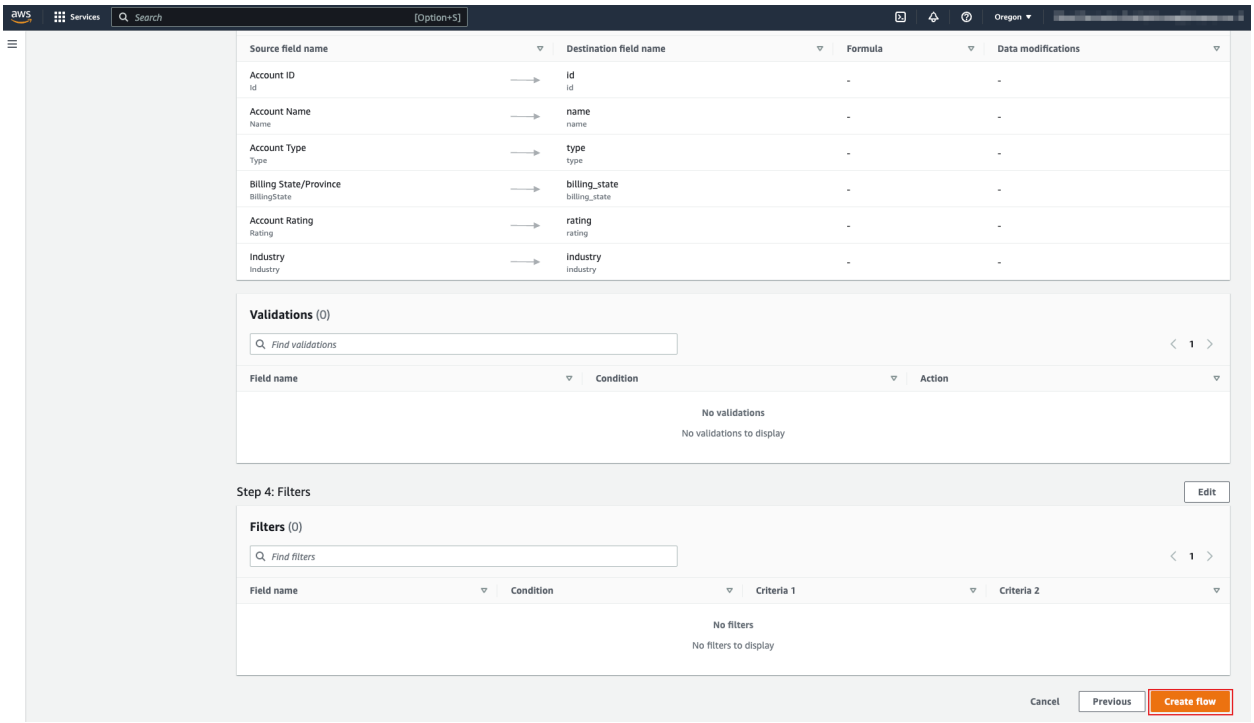

Figure 40: review

4.13.4.4 Step 3. Run the flow

On the page of the newly created flow, click **Run flow** in the upper-right corner.

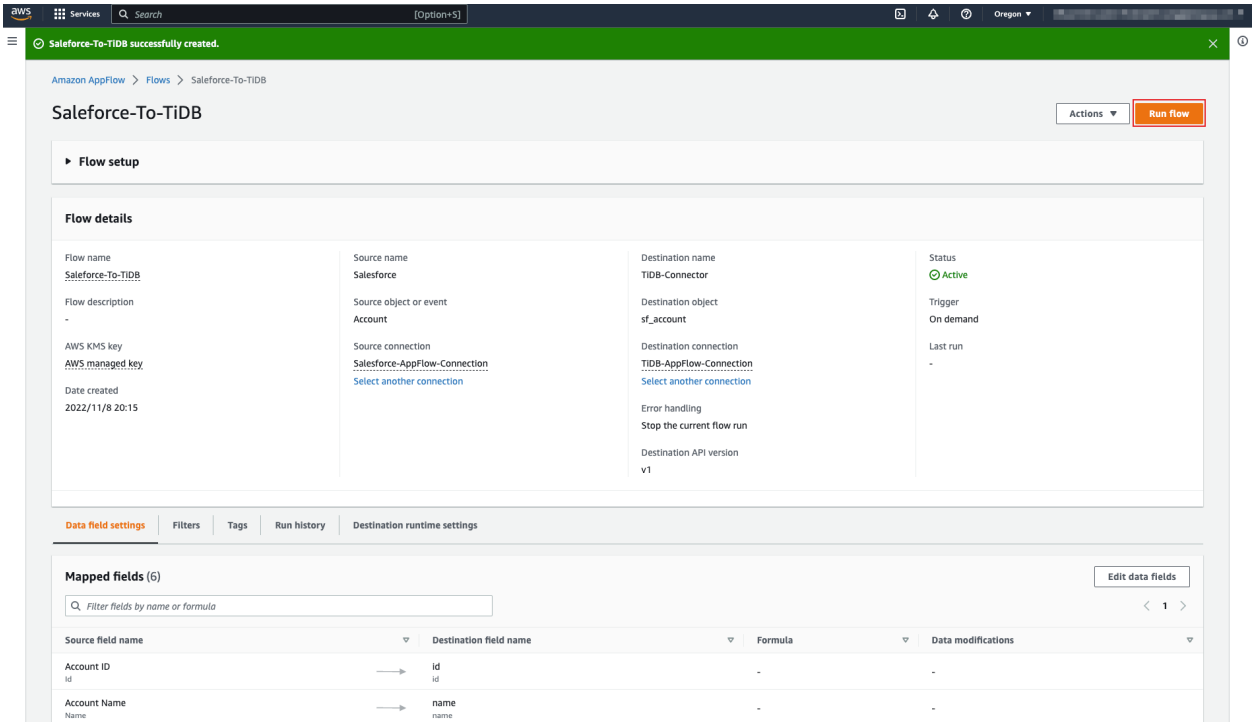

Figure 41: run flow

The following screenshot shows an example that the flow runs successfully:

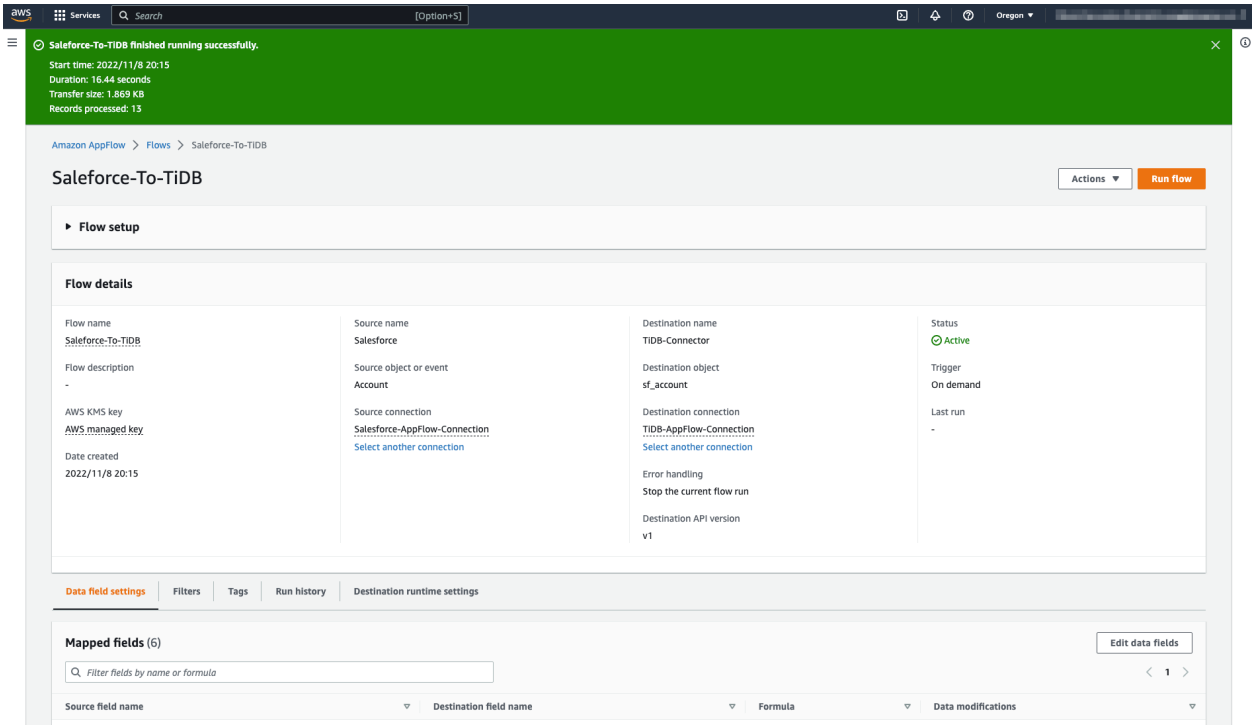

Figure 42: run success

Query the `sf_account` table, and you can see that the records from the Salesforce **Account** object have been written to it:

```
test> SELECT * FROM sf_account;
+--
    ↪ ------------------+----------------------------------------+-------------------+--
    ↪
| id                 | name                                   | type              |
    ↪ billing_state | rating | industry  |

```

4.13.4.5 Noteworthy things

- If anything goes wrong, you can navigate to the CloudWatch page on the AWS Management Console to get logs.
- The steps in this document are based on Building custom connectors using the Amazon AppFlow Custom Connector SDK.
- TiDB Cloud Serverless Tier is **NOT** a production environment.
- To prevent excessive length, the examples in this document only show the `Insert` strategy, but `Update` and `Upsert` strategies are also tested and can be used.

5 Deploy

5.1 Software and Hardware Recommendations

As an open source distributed NewSQL database with high performance, TiDB can be deployed in the Intel architecture server, ARM architecture server, and major virtualization environments and runs well. TiDB supports most of the major hardware networks and Linux operating systems.

5.1.1 OS and platform requirements

Operating systems	Supported CPU architectures
Red Hat Enterprise Linux 8.4 or a later 8.x version	x86_64 ARM 64
Red Hat Enterprise Linux 7.3 or a later 7.x version CentOS 7.3 or a later 7.x version	x86_64 ARM 64
Amazon Linux 2	x86_64 ARM 64
Kylin Euler V10 SP1/SP2	x86_64 ARM 64
UOS V20	x86_64 ARM 64
macOS Catalina or later	x86_64 ARM 64
Oracle Enterprise Linux 7.3 or a later 7.x version	x86_64
Ubuntu LTS 18.04 or later	x86_64
CentOS 8 Stream	x86_64 ARM 64
Debian 9 (Stretch) or later	x86_64
Fedora 35 or later	x86_64
openSUSE Leap later than v15.3 (not including Tumbleweed)	x86_64
SUSE Linux Enterprise Server 15	x86_64

Note:

- For Oracle Enterprise Linux, TiDB supports the Red Hat Compatible Kernel (RHCK) and does not support the Unbreakable Enterprise Kernel provided by Oracle Enterprise Linux.
- According to CentOS Linux EOL, the upstream support for CentOS Linux 8 ended on December 31, 2021. CentOS Stream 8 continues to be supported by the CentOS organization.
- Support for Ubuntu 16.04 will be removed in future versions of TiDB. Upgrading to Ubuntu 18.04 or later is strongly recommended.
- If you are using the 32-bit version of an operating system listed in the preceding table, TiDB **is not guaranteed** to be compilable, buildable or deployable on the 32-bit operating system and the corresponding CPU architecture, or TiDB does not actively adapt to the 32-bit operating system.
- Other operating system versions not mentioned above might work but are not officially supported.

5.1.2 Software recommendations

5.1.2.1 Control machine

Software	Version
sshpass	1.06 or later
TiUP	1.5.0 or later

Note:

It is required that you deploy TiUP on the control machine to operate and manage TiDB clusters.

5.1.2.2 Target machines

Software	Version
sshpass	1.06 or later
numa	2.0.12 or later
tar	any

5.1.3 Server recommendations

You can deploy and run TiDB on the 64-bit generic hardware server platform in the Intel x86-64 architecture or on the hardware server platform in the ARM architecture. The requirements and recommendations about server hardware configuration (ignoring the resources occupied by the operating system itself) for development, test, and production environments are as follows:

5.1.3.1 Development and test environments

Component	CPU	Memory	Local Storage	Network	Instance Number (Minimum Requirement)
TiDB	8 core+	16 GB+	No special requirements	Gigabit network card	1 (can be deployed on the same machine with PD)
PD	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	1 (can be deployed on the same machine with TiDB)
TiKV	8 core+	32 GB+	SAS, 200 GB+	Gigabit network card	3
TiFlash	32 core+	64 GB+	SSD, 200 GB+	Gigabit network card	1
TiCDC	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	1

Note:

- In the test environment, the TiDB and PD instances can be deployed on the same server.
- For performance-related test, do not use low-performance storage and network hardware configuration, in order to guarantee the correctness of the test result.
- For the TiKV server, it is recommended to use NVMe SSDs to ensure faster reads and writes.
- If you only want to test and verify the features, follow Quick Start Guide for TiDB to deploy TiDB on a single machine.

- The TiDB server uses the disk to store server logs, so there are no special requirements for the disk type and capacity in the test environment.
- Starting from v6.3.0, to deploy TiFlash under the Linux AMD64 architecture, the CPU must support the AVX2 instruction set. Ensure that `cat /proc/cpuinfo | grep avx2` has output. To deploy TiFlash under the Linux ARM64 architecture, the CPU must support the ARMv8 instruction set architecture. Ensure that `cat /proc/cpuinfo | grep 'crc32' | grep 'asimd'` has output. By using the instruction set extensions, TiFlash's vectorization engine can deliver better performance.

5.1.3.2 Production environment

Component	CPU	Memory	Hard Disk Type	Network	Instance N
TiDB	16 core+	48 GB+	SAS	10 Gigabit network card (2 preferred)	
PD	8 core+	16 GB+	SSD	10 Gigabit network card (2 preferred)	
TiKV	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
TiFlash	48 core+	128 GB+	1 or more SSDs	10 Gigabit network card (2 preferred)	
TiCDC	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
Monitor	8 core+	16 GB+	SAS	Gigabit network card	

Note:

- In the production environment, the TiDB and PD instances can be deployed on the same server. If you have a higher requirement for performance and reliability, try to deploy them separately.
- It is strongly recommended to use higher configuration in the production environment.
- It is recommended to keep the size of TiKV hard disk within 2 TB if you are using PCIe SSDs or within 1.5 TB if you are using regular SSDs.

Before you deploy TiFlash, note the following items:

- TiFlash can be deployed on multiple disks.
- It is recommended to use a high-performance SSD as the first disk of the TiFlash data directory to buffer the real-time replication of TiKV data. The performance of this disk should not be lower than that of TiKV, such as PCI-E SSD. The disk capacity should be no less than 10% of the total capacity; otherwise, it might become the bottleneck

of this node. You can deploy ordinary SSDs for other disks, but note that a better PCI-E SSD brings better performance.

- It is recommended to deploy TiFlash on different nodes from TiKV. If you must deploy TiFlash and TiKV on the same node, increase the number of CPU cores and memory, and try to deploy TiFlash and TiKV on different disks to avoid interfering each other.
- The total capacity of the TiFlash disks is calculated in this way: `the data volume of the entire TiKV cluster to be replicated / the number of TiKV replicas * the number of TiFlash replicas`. For example, if the overall planned capacity of TiKV is 1 TB, the number of TiKV replicas is 3, and the number of TiFlash replicas is 2, then the recommended total capacity of TiFlash is `1024 GB / 3 * 2`. You can replicate only the data of some tables. In such case, determine the TiFlash capacity according to the data volume of the tables to be replicated.

Before you deploy TiCDC, note that it is recommended to deploy TiCDC on PCIe-SSD disks larger than 1 TB.

5.1.4 Network requirements

As an open source distributed NewSQL database, TiDB requires the following network port configuration to run. Based on the TiDB deployment in actual environments, the administrator can open relevant ports in the network side and host side.

Component	Default Port	Description
TiDB	4000	the communication port for the application and DBA tools

Component	Default Port	Description
TiDB	10080	the communication port to report TiDB status
TiKV	20160	the TiKV communication port
TiKV	20180	the communication port to report TiKV status
PD	2379	the communication port between TiDB and PD

Component	Default Port	Description
PD	2380	the inter-node com-mu-nica-tion port within the PD clus-ter
TiFlash	9000	the Ti-Flash TCP ser-vice port
TiFlash	8123	the Ti-Flash HTTP ser-vice port
TiFlash	3930	the Ti-Flash RAFT and Co-pro-ces-sor ser-vice port

Component	Default Port	Description
TiFlash	20170	the TiFlash Proxy service port
TiFlash	20292	the port for Prometheus to pull TiFlash Proxy metrics
TiFlash	8234	the port for Prometheus to pull TiFlash metrics
Pump	8250	the Pump communication port
Drainer	8249	the Drainer communication port

Component	Default Port	Description
TiCDC	8300	the TiCDC communication port
Monitoring	9090	the communication port for the Prometheus service
Monitoring	12020	the communication port for the Ng-Monitoring service

Component	Default Port	Description
Node_exporter	9100	the communication port to report the system information of every TiDB cluster node
Blackbox_exporter	9115	the Blackbox_exporter communication port, used to monitor the ports in the TiDB cluster

Component	Default Port	Description
Grafana	3000	the port for the external Web monitoring service and client (Browser) access
Alertmanager	9093	the port for the alert web service
Alertmanager	9094	the alert communication port

5.1.5 Disk space requirements

Component	Disk space requirement	Healthy disk usage
TiDB	At least 30 GB for the log disk	Lower than 90%
PD	At least 20 GB for the data disk and for the log disk, respectively	Lower than 90%

Component	Disk space requirement	Healthy disk usage
TiKV	At least 100 GB for the data disk and for the log disk, respectively	Lower than 80%
TiFlash	At least 100 GB for the data disk and at least 30 GB for the log disk, respectively	Lower than 80%

| TiUP |

Control machine: No more than 1 GB space is required for deploying a TiDB cluster of a single version. The space required increases if TiDB clusters of multiple versions are deployed.

Deployment servers (machines where the TiDB components run): TiFlash occupies about 700 MB space and other components (such as PD, TiDB, and TiKV) occupy about 200 MB space respectively. During the cluster deployment process, the TiUP cluster requires less than 1 MB of temporary space (`/tmp` directory) to store temporary files.

| N/A | | Ngmonitoring |

Conprof: 3 x 1 GB x Number of components (each component occupies about 1 GB per day, 3 days in total) + 20 GB reserved space

Top SQL: 30 x 50 MB x Number of components (each component occupies about 50 MB per day, 30 days in total)

Conprof and Top SQL share the reserved space

| N/A |

5.1.6 Web browser requirements

TiDB relies on Grafana to provide visualization of database metrics. A recent version of Internet Explorer, Chrome or Firefox with Javascript enabled is sufficient.

5.2 TiDB Environment and System Configuration Check

This document describes the environment check operations before deploying TiDB. The following steps are ordered by priorities.

5.2.1 Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV

For production deployments, it is recommended to use NVMe SSD of EXT4 filesystem to store TiKV data. This configuration is the best practice, whose reliability, security, and stability have been proven in a large number of online scenarios.

Log in to the target machines using the `root` user account.

Format your data disks to the ext4 filesystem and add the `nodelalloc` and `noatime` mount options to the filesystem. It is required to add the `nodelalloc` option, or else the TiUP deployment cannot pass the precheck. The `noatime` option is optional.

Note:

If your data disks have been formatted to ext4 and have added the mount options, you can uninstall it by running the `umount /dev/nvme0n1p1` command, skip directly to the fifth step below to edit the `/etc/fstab` file, and add the options again to the filesystem.

Take the `/dev/nvme0n1` data disk as an example:

1. View the data disk.

```
fdisk -l
```

```
Disk /dev/nvme0n1: 1000 GB
```

2. Create the partition.

```
parted -s -a optimal /dev/nvme0n1 mklabel gpt -- mkpart primary ext4 1
    ↪ -1
```

Note:

Use the `lsblk` command to view the device number of the partition: for a NVMe disk, the generated device number is usually `nvme0n1p1`; for a regular disk (for example, `/dev/sdb`), the generated device number is usually `sdb1`.

3. Format the data disk to the ext4 filesystem.

```
mkfs.ext4 /dev/nvme0n1p1
```

4. View the partition UUID of the data disk.

   In this example, the UUID of nvme0n1p1 is `c51eb23b-195c-4061-92a9-3fad812cc12f`.

```
lsblk -f
```

```
NAME   FSTYPE LABEL UUID                                 MOUNTPOINT
sda
 ─sda1 ext4        237b634b-a565-477b-8371-6dff0c41f5ab /boot
 ─sda2 swap        f414c5c0-f823-4bb1-8fdf-e531173a72ed
 ─sda3 ext4        547909c1-398d-4696-94c6-03e43e317b60 /
sr0
nvme0n1
 ─nvme0n1p1 ext4       c51eb23b-195c-4061-92a9-3fad812cc12f
```

5. Edit the `/etc/fstab` file and add the `nodelalloc` mount options.

```
vi /etc/fstab
```

```
UUID=c51eb23b-195c-4061-92a9-3fad812cc12f /data1 ext4 defaults,
    ↪ nodelalloc,noatime 0 2
```

6. Mount the data disk.

```
mkdir /data1 && \
mount -a
```

7. Check using the following command.

```
mount -t ext4
```

```
/dev/nvme0n1p1 on /data1 type ext4 (rw,noatime,nodelalloc,data=ordered)
```

If the filesystem is ext4 and `nodelalloc` is included in the mount options, you have successfully mount the data disk ext4 filesystem with options on the target machines.

5.2.2 Check and disable system swap

TiDB needs sufficient memory space for operation. When memory is insufficient, using swap as a buffer might degrade performance. Therefore, it is recommended to disable the system swap permanently by executing the following commands:

```
echo "vm.swappiness = 0">> /etc/sysctl.conf
swapoff -a && swapon -a
sysctl -p
```

Note:

- Executing `swapoff -a` and then `swapon -a` is to refresh swap by dumping data to memory and cleaning up swap. If you drop the swappiness change and execute only `swapoff -a`, swap will be enabled again after you restart the system.
- `sysctl -p` is to make the configuration effective without restarting the system.

5.2.3 Check and stop the firewall service of target machines

In TiDB clusters, the access ports between nodes must be open to ensure the transmission of information such as read and write requests and data heartbeats. In common online scenarios, the data interaction between the database and the application service and between the database nodes are all made within a secure network. Therefore, if there are no special security requirements, it is recommended to stop the firewall of the target machine. Otherwise, refer to the port usage and add the needed port information to the allowlist of the firewall service.

The rest of this section describes how to stop the firewall service of a target machine.

1. Check the firewall status. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo firewall-cmd --state
sudo systemctl status firewalld.service
```

2. Stop the firewall service.

```
sudo systemctl stop firewalld.service
```

3. Disable automatic start of the firewall service.

```
sudo systemctl disable firewalld.service
```

4. Check the firewall status.

```
sudo systemctl status firewalld.service
```

5.2.4 Check and install the NTP service

TiDB is a distributed database system that requires clock synchronization between nodes to guarantee linear consistency of transactions in the ACID model.

At present, the common solution to clock synchronization is to use the Network Time Protocol (NTP) services. You can use the `pool.ntp.org` timing service on the Internet, or build your own NTP service in an offline environment.

To check whether the NTP service is installed and whether it synchronizes with the NTP server normally, take the following steps:

1. Run the following command. If it returns `running`, then the NTP service is running.

```
sudo systemctl status ntpd.service
```

```
ntpd.service - Network Time Service
Loaded: loaded (/usr/lib/systemd/system/ntpd.service; disabled; vendor
    ↪ preset: disabled)
Active: active (running) since — 2017-12-18 13:13:19 CST; 3s ago
```

- If it returns `Unit ntpd.service could not be found.`, then try the following command to see whether your system is configured to use `chronyd` instead of `ntpd` to perform clock synchronization with NTP:

  ```
  sudo systemctl status chronyd.service
  ```

  ```
  chronyd.service - NTP client/server
  Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled;
      ↪ vendor preset: enabled)
  Active: active (running) since Mon 2021-04-05 09:55:29 EDT; 3 days
      ↪ ago
  ```

  If the result shows that neither `chronyd` nor `ntpd` is configured, it means that neither of them is installed in your system. You should first install `chronyd` or `ntpd` and ensure that it can be automatically started. By default, `ntpd` is used.

  If your system is configured to use `chronyd`, proceed to step 3.

2. Run the `ntpstat` command to check whether the NTP service synchronizes with the NTP server.

> **Note:**
> For the Ubuntu system, you need to install the `ntpstat` package.

```
ntpstat
```

- If it returns `synchronised to NTP server` (synchronizing with the NTP server), then the synchronization process is normal.

  ```
  synchronised to NTP server (85.199.214.101) at stratum 2
  time correct to within 91 ms
  polling server every 1024 s
  ```

- The following situation indicates the NTP service is not synchronizing normally:

  ```
  unsynchronised
  ```

- The following situation indicates the NTP service is not running normally:

```
Unable to talk to NTP daemon. Is it running?
```

3. Run the `chronyc tracking` command to check wheter the Chrony service synchronizes with the NTP server.

> **Note:**
> This only applies to systems that use Chrony instead of NTPd.

```
chronyc tracking
```

- If the command returns `Leap status     : Normal`, the synchronization process is normal.

```
Reference ID    : 5EC69F0A (ntp1.time.nl)
Stratum         : 2
Ref time (UTC)  : Thu May 20 15:19:08 2021
System time     : 0.000022151 seconds slow of NTP time
Last offset     : -0.000041040 seconds
RMS offset      : 0.000053422 seconds
Frequency       : 2.286 ppm slow
Residual freq   : -0.000 ppm
Skew            : 0.012 ppm
Root delay      : 0.012706812 seconds
Root dispersion : 0.000430042 seconds
Update interval : 1029.8 seconds
Leap status     : Normal
```

- If the command returns the following result, an error occurs in the synchronization:

```
Leap status     : Not synchronised
```

- If the command returns the following result, the `chronyd` service is not running normally:

```
506 Cannot talk to daemon
```

To make the NTP service start synchronizing as soon as possible, run the following command. Replace `pool.ntp.org` with your NTP server.

```
sudo systemctl stop ntpd.service && \
sudo ntpdate pool.ntp.org && \
sudo systemctl start ntpd.service
```

To install the NTP service manually on the CentOS 7 system, run the following command:

```
sudo yum install ntp ntpdate && \
sudo systemctl start ntpd.service && \
sudo systemctl enable ntpd.service
```

5.2.5 Check and configure the optimal parameters of the operating system

For TiDB in the production environment, it is recommended to optimize the operating system configuration in the following ways:

1. Disable THP (Transparent Huge Pages). The memory access pattern of databases tends to be sparse rather than consecutive. If the high-level memory fragmentation is serious, higher latency will occur when THP pages are allocated.
2. Set the I/O Scheduler of the storage media to `noop`. For the high-speed SSD storage media, the kernel's I/O scheduling operations can cause performance loss. After the Scheduler is set to `noop`, the performance is better because the kernel directly sends I/O requests to the hardware without other operations. Also, the noop Scheduler is better applicable.
3. Choose the `performance` mode for the cpufrequ module which controls the CPU frequency. The performance is maximized when the CPU frequency is fixed at its highest supported operating frequency without dynamic adjustment.

Take the following steps to check the current operating system configuration and configure optimal parameters:

1. Execute the following command to see whether THP is enabled or disabled:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
[always] madvise never
```

> **Note:**
>
> If `[always] madvise never` is output, THP is enabled. You need to disable it.

2. Execute the following command to see the I/O Scheduler of the disk where the data directory is located. Assume that you create data directories on both sdb and sdc disks:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
noop [deadline] cfq
noop [deadline] cfq
```

> **Note:**
>
> If `noop [deadline] cfq` is output, the I/O Scheduler for the disk is in the `deadline` mode. You need to change it to `noop`.

3. Execute the following command to see the `ID_SERIAL` of the disk:

```
udevadm info --name=/dev/sdb | grep ID_SERIAL
```

```
E: ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81
E: ID_SERIAL_SHORT=6d0946606d79f90025f3e09a0c1f9e81
```

> **Note:**
>
> If multiple disks are allocated with data directories, you need to execute the above command several times to record the `ID_SERIAL` of each disk.

4. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
```

```
analyzing CPU 0:
current policy: frequency should be within 1.20 GHz and 3.10 GHz.
            The governor "powersave" may decide which speed to use
               ↪ within this range.
```

> **Note:**
>
> If `The governor "powersave"` is output, the power policy of the cpufreq module is `powersave`. You need to modify it to `performance`. If you use a virtual machine or a cloud host, the output is usually `Unable to` ↪ `determine current policy`, and you do not need to change anything.

5. Configure optimal parameters of the operating system:

    - Method one: Use tuned (Recommended)

1. Execute the `tuned-adm list` command to see the tuned profile of the current operating system:

```
tuned-adm list
```

```
Available profiles:
- balanced                  - General non-specialized tuned
    ↪ profile
- desktop                   - Optimize for the desktop use-case
- hpc-compute               - Optimize for HPC compute workloads
- latency-performance       - Optimize for deterministic
    ↪ performance at the cost of increased power consumption
- network-latency           - Optimize for deterministic
    ↪ performance at the cost of increased power consumption,
    ↪ focused on low latency network performance
- network-throughput        - Optimize for streaming network
    ↪ throughput, generally only necessary on older CPUs or 40G
    ↪ + networks
- powersave                 - Optimize for low power consumption
- throughput-performance    - Broadly applicable tuning that
    ↪ provides excellent performance across a variety of common
    ↪  server workloads
- virtual-guest             - Optimize for running inside a
    ↪ virtual guest
- virtual-host              - Optimize for running KVM guests
Current active profile: balanced
```

The output `Current active profile: balanced` means that the tuned profile of the current operating system is `balanced`. It is recommended to optimize the configuration of the operating system based on the current profile.

2. Create a new tuned profile:

```
mkdir /etc/tuned/balanced-tidb-optimal/
vi /etc/tuned/balanced-tidb-optimal/tuned.conf
```

```
[main]
include=balanced

[cpu]
governor=performance

[vm]
transparent_hugepages=never

[disk]
devices_udev_regex=(ID_SERIAL=36d0946606d79f90025f3e09a0c1fc035
    ↪ )|(ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81)
```

```
elevator=noop
```

The output `include=balanced` means to add the optimization configuration of the operating system to the current `balanced` profile.

3. Apply the new tuned profile:

```
tuned-adm profile balanced-tidb-optimal
```

- Method two: Configure using scripts. Skip this method if you already use method one.

1. Execute the `grubby` command to see the default kernel version:

> **Note:**
> Install the `grubby` package first before you execute `grubby`.

```
grubby --default-kernel
```

```
/boot/vmlinuz-3.10.0-957.el7.x86_64
```

2. Execute `grubby --update-kernel` to modify the kernel configuration:

```
grubby --args="transparent_hugepage=never" --update-kernel /
    ↪ boot/vmlinuz-3.10.0-957.el7.x86_64
```

> **Note:**
> `--update-kernel` is followed by the actual default kernel version.

3. Execute `grubby --info` to see the modified default kernel configuration:

```
grubby --info /boot/vmlinuz-3.10.0-957.el7.x86_64
```

> **Note:**
> `--info` is followed by the actual default kernel version.

```
index=0
kernel=/boot/vmlinuz-3.10.0-957.el7.x86_64
args="ro crashkernel=auto rd.lvm.lv=centos/root rd.lvm.lv=
    ↪ centos/swap rhgb quiet LANG=en_US.UTF-8
    ↪ transparent_hugepage=never"
root=/dev/mapper/centos-root
initrd=/boot/initramfs-3.10.0-957.el7.x86_64.img
title=CentOS Linux (3.10.0-957.el7.x86_64) 7 (Core)
```

4. Modify the current kernel configuration to immediately disable THP:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

5. Configure the I/O Scheduler in the udev script:

```
vi /etc/udev/rules.d/60-tidb-schedulers.rules
```

```
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
    ↪ d0946606d79f90025f3e09a0c1fc035", ATTR{queue/scheduler}="
    ↪ noop"
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
    ↪ d0946606d79f90025f3e09a0c1f9e81", ATTR{queue/scheduler}="
    ↪ noop"
```

6. Apply the udev script:

```
udevadm control --reload-rules
udevadm trigger --type=devices --action=change
```

7. Create a service to configure the CPU power policy:

```
cat >> /etc/systemd/system/cpupower.service << EOF
[Unit]
Description=CPU performance
[Service]
Type=oneshot
ExecStart=/usr/bin/cpupower frequency-set --governor
    ↪ performance
[Install]
WantedBy=multi-user.target
EOF
```

8. Apply the CPU power policy configuration service:

```
systemctl daemon-reload
systemctl enable cpupower.service
systemctl start cpupower.service
```

6. Execute the following command to verify the THP status:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
always madvise [never]
```

7. Execute the following command to verify the I/O Scheduler of the disk where the data directory is located:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
[noop] deadline cfq
[noop] deadline cfq
```

8. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
  ```
```

analyzing CPU 0: current policy: frequency should be within 1.20 GHz and 3.10 GHz. The governor "performance" may decide which speed to use within this range. "'

9. Execute the following commands to modify the `sysctl` parameters:

```
echo "fs.file-max = 1000000">> /etc/sysctl.conf
echo "net.core.somaxconn = 32768">> /etc/sysctl.conf
echo "net.ipv4.tcp_tw_recycle = 0">> /etc/sysctl.conf
echo "net.ipv4.tcp_syncookies = 0">> /etc/sysctl.conf
echo "vm.overcommit_memory = 1">> /etc/sysctl.conf
sysctl -p
```

10. Execute the following command to configure the user's `limits.conf` file:

```
cat << EOF >>/etc/security/limits.conf
tidb           soft    nofile         1000000
tidb           hard    nofile         1000000
tidb           soft    stack         32768
tidb           hard    stack         32768
EOF
```

5.2.6 Manually configure the SSH mutual trust and sudo without password

This section describes how to manually configure the SSH mutual trust and sudo without password. It is recommended to use TiUP for deployment, which automatically configure SSH mutual trust and login without password. If you deploy TiDB clusters using TiUP, ignore this section.

1. Log in to the target machine respectively using the `root` user account, create the `tidb` user and set the login password.

```
useradd tidb && \
passwd tidb
```
```

2. To configure sudo without password, run the following command, and add `tidb ALL =(ALL)NOPASSWD: ALL` to the end of the file:

```
visudo
```

```
tidb ALL=(ALL) NOPASSWD: ALL
```

3. Use the `tidb` user to log in to the control machine, and run the following command. Replace `10.0.1.1` with the IP of your target machine, and enter the `tidb` user password of the target machine as prompted. After the command is executed, SSH mutual trust is already created. This applies to other machines as well. Newly created `tidb` users do not have the `.ssh` directory. To create such a directory, execute the command that generates the RSA key. To deploy TiDB components on the control machine, configure mutual trust for the control machine and the control machine itself.

```
ssh-keygen -t rsa
ssh-copy-id -i ~/.ssh/id_rsa.pub 10.0.1.1
```

4. Log in to the control machine using the `tidb` user account, and log in to the IP of the target machine using `ssh`. If you do not need to enter the password and can successfully log in, then the SSH mutual trust is successfully configured.

```
ssh 10.0.1.1
```

```
[tidb@10.0.1.1 ~]$
```

5. After you log in to the target machine using the `tidb` user, run the following command. If you do not need to enter the password and can switch to the `root` user, then sudo without password of the `tidb` user is successfully configured.

```
sudo -su root
```

```
[root@10.0.1.1 tidb]#
```

5.2.7 Install the `numactl` tool

This section describes how to install the NUMA tool. In online environments, because the hardware configuration is usually higher than required, to better plan the hardware resources, multiple instances of TiDB or TiKV can be deployed on a single machine. In such scenarios, you can use NUMA tools to prevent the competition for CPU resources which might cause reduced performance.

Note:

- Binding cores using NUMA is a method to isolate CPU resources and is suitable for deploying multiple instances on highly configured physical machines.
- After completing deployment using `tiup cluster deploy`, you can use the `exec` command to perform cluster level management operations.

To install the NUMA tool, take either of the following two methods:

Method 1: Log in to the target node to install NUMA. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo yum -y install numactl
```

Method 2: Install NUMA on an existing cluster in batches by running the `tiup cluster exec` command.

1. Follow Deploy a TiDB Cluster Using TiUP to deploy a cluster `tidb-test`. If you have installed a TiDB cluster, you can skip this step.

```
tiup cluster deploy tidb-test v6.1.0 ./topology.yaml --user root [-p]
    ↪ [-i /home/root/.ssh/gcp_rsa]
```

2. Run the `tiup cluster exec` command using the `sudo` privilege to install NUMA on all the target machines in the `tidb-test` cluster:

```
tiup cluster exec tidb-test --sudo --command "yum -y install numactl"
```

To get help information of the `tiup cluster exec` command, run the `tiup cluster exec --help` command.

5.3 Plan Cluster Topology

5.3.1 Minimal Deployment Topology

This document describes the minimal deployment topology of TiDB clusters.

5.3.1.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	2	16 VCore 32 GiB 100 GiB for storage	10.0.1.1 10.0.1.2	Default port Global directory configuration
PD	3	4 VCore 8 GiB 100 GiB for storage	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32 GiB 2 TiB (NVMe SSD) for storage	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8 GiB 500 GiB (SSD) for storage	10.0.1.10	Default port Global directory configuration

5.3.1.1.1 Topology templates

- The simple template for the minimal topology
- The complex template for the minimal topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.2 TiFlash Deployment Topology

This document describes the deployment topology of TiFlash based on the minimal TiDB topology.

TiFlash is a columnar storage engine, and gradually becomes the standard cluster topology. It is suitable for real-time HTAP applications.

5.3.2.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
TiFlash	1	32 VCore 64 GB 2TB (nvme ssd) * 1	10.0.1.11	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.10	Default port Global directory configuration

5.3.2.1.1 Topology templates

- The simple template for the TiFlash topology
- The complex template for the TiFlash topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.2.1.2 Key parameters

- To enable the Placement Rules feature of PD, set the value of `replication.enable-placement-rules` in the configuration template to `true`.
- The instance level `"-host"` configuration in `tiflash_servers` only supports IP, not domain name.
- For detailed TiFlash parameter description, see TiFlash Configuration.

> **Note:**
>
> - You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
> - If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.3 TiCDC Deployment Topology

> **Note:**
>
> TiCDC is a feature for general availability (GA) since v4.0.6. You can use it in the production environment.

This document describes the deployment topology of TiCDC based on the minimal cluster topology.

TiCDC is a tool for replicating the incremental data of TiDB, introduced in TiDB 4.0. It supports multiple downstream platforms, such as TiDB, MySQL, and MQ. Compared with TiDB Binlog, TiCDC has lower latency and native high availability.

5.3.3.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
CDC	3	8 VCore 16GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.4	Default port Global directory configuration

5.3.3.1.1 Topology templates

- The simple template for the TiCDC topology
- The complex template for the TiCDC topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.4 TiDB Binlog Deployment Topology

This document describes the deployment topology of TiDB Binlog based on the minimal TiDB topology.

TiDB Binlog is the widely used component for replicating incremental data. It provides near real-time backup and replication.

5.3.4.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32 GB	10.0.1.1 10.0.1.2 10.0.1.3	Default port configuration; Enable `enable_binlog` ↪ ; Enable `ignore` ↪ - ↪ `error` ↪

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	4 VCore 8 GB	10.0.1.4 10.0.1.5 10.0.1.6	Default port configuration
TiKV	3	16 VCore 32 GB	10.0.1.7 10.0.1.8 10.0.1.9	Default port configuration
Pump	3	8 VCore 16GB	10.0.1.1 10.0.1.2 10.0.1.3	Default port configuration; Set GC time to 7 days

Instance	Count	Physical machine configuration	IP	Configuration
Drainer	1	8 VCore 16GB	10.0.1.12	Default port configuration; Set the default initialization commitTS -1 as the latest timestamp; Configure the downstream target TiDB as `10.0.1.12:4000` ↪

5.3.4.1.1 Topology templates

- The simple template for the TiDB Binlog topology (with `mysql` as the downstream type)
- The simple template for the TiDB Binlog topology (with `file` as the downstream type)
- The complex template for the TiDB Binlog topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.4.1.2 Key parameters

The key parameters in the topology configuration templates are as follows:

- `server_configs.tidb.binlog.enable: true`
  - Enables the binlog service.
  - Default value: `false`.
- `server_configs.tidb.binlog.ignore-error: true`
  - It is recommended to enable this configuration in high availability scenarios.
  - If set to `true`, when an error occurs, TiDB stops writing data into binlog, and adds `1` to the value of the `tidb_server_critical_error_total` monitoring metric.
  - If set to `false`, when TiDB fails to write data into binlog, the whole TiDB service is stopped.
- `drainer_servers.config.syncer.db-type`

  The downstream type of TiDB Binlog. Currently, `mysql`, `tidb`, `kafka`, and `file` are supported.
- `drainer_servers.config.syncer.to`

  The downstream configuration of TiDB Binlog. Depending on different `db-type`s, you can use this configuration item to configure the connection parameters of the downstream database, the connection parameters of Kafka, and the file save path. For details, refer to TiDB Binlog Configuration File.

Note:

- When editing the configuration file template, if you do not need custom ports or directories, modify the IP only.

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.5 TiSpark Deployment Topology

Warning:

TiSpark support in the TiUP cluster is deprecated. It is **NOT** recommended to use it.

This document introduces the TiSpark deployment topology and how to deploy TiSpark based on the minimum cluster topology.

TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer complex OLAP queries. It brings benefits of both the Spark platform and the distributed TiKV cluster to TiDB and makes TiDB a one-stop solution for both online transactions and analytics.

For more information about the TiSpark architecture and how to use it, see TiSpark User Guide.

5.3.5.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiSpark	3	8 VCore 16GB * 1	10.0.1.21 (master) 10.0.1.22 (worker) 10.0.1.23 (worker)	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.11	Default port Global directory configuration

5.3.5.2 Topology templates

- Simple TiSpark topology template
- Complex TiSpark topology template

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.5.3 Prerequisites

TiSpark is based on the Apache Spark cluster, so before you start the TiDB cluster that contains TiSpark, you must ensure that Java Runtime Environment (JRE) 8 is installed on the server that deploys TiSpark. Otherwise, TiSpark cannot be started.

TiUP does not support installing JRE automatically. You need to install it on your own. For detailed installation instruction, see How to download and install prebuilt OpenJDK packages.

If JRE 8 has already been installed on the deployment server but is not in the path of the system's default package management tool, you can specify the path of the JRE environment to be used by setting the `java_home` parameter in the topology configuration. This parameter corresponds to the `JAVA_HOME` system environment variable.

5.3.6 Geo-Distributed Deployment Topology

This document takes the typical architecture of three data centers (DC) in two cities as an example, and introduces the geo-distributed deployment architecture and the key configuration. The cities used in this example are Shanghai (referred to as `sha`) and Beijing (referred to as `bja` and `bjb`).

5.3.6.1 Topology information

Instance	Count	Physical machine configuration	BJ IP	SH IP	Configuration
TiDB	5	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3 10.0.1.4	10.0.1.5	Default port Global directory configuration
PD	5	4 VCore 8GB * 1	10.0.1.6 10.0.1.7 10.0.1.8 10.0.1.9	10.0.1.10	Default port Global directory configuration
TiKV	5	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.11 10.0.1.12 10.0.1.13 10.0.1.14	10.0.1.15	Default port Global directory configuration

Instance	Count	Physical machine configuration	BJ IP	SH IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.16		Default port Global directory configuration

5.3.6.1.1 Topology templates

- The geo-distributed topology template

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.6.1.2 Key parameters

This section describes the key parameter configuration of the TiDB geo-distributed deployment.

TiKV parameters

- The gRPC compression format (`none` by default):

  To increase the transmission speed of gRPC packages between geo-distributed target nodes, set this parameter to `gzip`.

```
server.grpc-compression-type: gzip
```

- The label configuration:

  Since TiKV is deployed across different data centers, if the physical machines go down, the Raft Group might lose three of the default five replicas, which causes the cluster

unavailability. To address this issue, you can configure the labels to enable the smart scheduling of PD, which ensures that the Raft Group does not allow three replicas to be located in TiKV instances on the same machine in the same cabinet of the same data center.

- The TiKV configuration:

  The same host-level label information is configured for the same physical machine.

```
config:
  server.labels:
    zone: bj
    dc: bja
    rack: rack1
    host: host2
```

- To prevent remote TiKV nodes from launching unnecessary Raft elections, it is required to increase the minimum and maximum number of ticks that the remote TiKV nodes need to launch an election. The two parameters are set to `0` by default.

```
raftstore.raft-min-election-timeout-ticks: 1000
raftstore.raft-max-election-timeout-ticks: 1020
```

PD parameters

- The PD metadata information records the topology of the TiKV cluster. PD schedules the Raft Group replicas on the following four dimensions:

```
replication.location-labels: ["zone","dc","rack","host"]
```

- To ensure high availability of the cluster, adjust the number of Raft Group replicas to be `5`:

```
replication.max-replicas: 5
```

- Forbid the remote TiKV Raft replica being elected as Leader:

```
label-property:
     reject-leader:
       - key: "dc"
         value: "sha"
```

> **Note:**
>
> Since TiDB 5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

For the further information about labels and the number of Raft Group replicas, see Schedule Replicas by Topology Labels.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.7 Hybrid Deployment Topology

This document describes the topology and key parameters of the TiKV and TiDB hybrid deployment.

The hybrid deployment is usually used in the following scenario:

The deployment machine has multiple CPU processors with sufficient memory. To improve the utilization rate of the physical machine resources, multiple instances can be deployed on a single machine, that is, TiDB and TiKV's CPU resources are isolated through NUMA node bindings. PD and Prometheus are deployed together, but their data directories need to use separate file systems.

5.3.7.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	6	32 VCore 64GB	10.0.1.1 10.0.1.2 10.0.1.3	Configure NUMA to bind CPU cores

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	16 VCore 32 GB	10.0.1.4 10.0.1.5 10.0.1.6	Configure the `location_labels` parameter

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	6	32 VCore 64GB	10.0.1.7 10.0.1.8 10.0.1.9	1. Separate the instance-level port and status_port; 2. Configure the global parameters `readpool` ↪ , `storage` ↪ and `raftstore` ↪ ; 3. Configure labels of the instance-level host; 4. Con-
				569

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.10	Default configuration

5.3.7.1.1 Topology templates

- The simple template for the hybrid deployment
- The complex template for the hybrid deployment

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.7.1.2 Key parameters

This section introduces the key parameters when you deploy multiple instances on a single machine, which is mainly used in scenarios when multiple instances of TiDB and TiKV are deployed on a single machine. You need to fill in the results into the configuration template according to the calculation methods provided below.

- Optimize the configuration of TiKV
  - To configure `readpool` to be self-adaptive to the thread pool. By configuring the `readpool.unified.max-thread-count` parameter, you can make `readpool.storage` and `readpool.coprocessor` share a unified thread pool, and set the self-adaptive switch respectively.
    * Enable `readpool.storage` and `readpool.coprocessor`:

```
readpool.storage.use-unified-pool: true
readpool.coprocessor.use-unified-pool: true
```

    * The calculation method:

```
readpool.unified.max-thread-count = cores * 0.8 / the number of
    ↪ TiKV instances
```

  - To configure the storage CF (all RocksDB column families) to be self-adaptive to memory. By configuring the `storage.block-cache.capacity` parameter, you can make CF automatically balance the memory usage.
    * `storage.block-cache` enables the CF self-adaptation by default. You do not need to modify it.

    ```
    storage.block-cache.shared: true
    ```

    * The calculation method:

    ```
    storage.block-cache.capacity = (MEM_TOTAL * 0.5 / the number of
        ↪ TiKV instances)
    ```

  - If multiple TiKV instances are deployed on the same physical disk, add the `capacity` parameter in the TiKV configuration:

```
raftstore.capacity = disk total capacity / the number of TiKV
    ↪ instances
```

- The label scheduling configuration

  Since multiple instances of TiKV are deployed on a single machine, if the physical machines go down, the Raft Group might lose two of the default three replicas, which causes the cluster unavailability. To address this issue, you can use the label to enable the smart scheduling of PD, which ensures that the Raft Group has more than two replicas in multiple TiKV instances on the same machine.

  - The TiKV configuration

    The same host-level label information is configured for the same physical machine:

```
config:
  server.labels:
    host: tikv1
```

  - The PD configuration

    To enable PD to identify and scheduling Regions, configure the labels type for PD:

```
pd:
  replication.location-labels: ["host"]
```

- `numa_node` core binding

- In the instance parameter module, configure the corresponding `numa_node` parameter and add the number of CPU cores.
- Before using NUMA to bind cores, make sure that the numactl tool is installed, and confirm the information of CPUs in the physical machines. After that, configure the parameters.
- The `numa_node` parameter corresponds to the `numactl --membind` configuration.

Note:

- When editing the configuration file template, modify the required parameter, IP, port, and directory.
- Each component uses the global `<deploy_dir>/<components_name>-<port>` as their `deploy_dir` by default. For example, if TiDB specifies the `4001` port, its `deploy_dir` is `/tidb-deploy/tidb-4001` by default. Therefore, in multi-instance scenarios, when specifying a non-default port, you do not need to specify the directory again.
- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.4 Install and Start

5.4.1 Deploy a TiDB Cluster Using TiUP

TiUP is a cluster operation and maintenance tool introduced in TiDB 4.0. TiUP provides TiUP cluster, a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

TiUP supports deploying TiDB, TiFlash, TiDB Binlog, TiCDC, and the monitoring system. This document introduces how to deploy TiDB clusters of different topologies.

Note:

TiDB, TiUP and TiDB Dashboard share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.

5.4.1.1 Step 1. Prerequisites and precheck

Make sure that you have read the following documents:

- Hardware and software requirements
- Environment and system configuration check

5.4.1.2 Step 2. Deploy TiUP on the control machine

You can deploy TiUP on the control machine in either of the two ways: online deployment and offline deployment.

5.4.1.2.1 Deploy TiUP online

Log in to the control machine using a regular user account (take the `tidb` user as an example). Subsequent TiUP installation and cluster management can be performed by the `tidb` user.

1. Install TiUP by running the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Set TiUP environment variables:

    1. Redeclare the global environment variables:

    ```
    source .bash_profile
    ```

    2. Confirm whether TiUP is installed:

    ```
    which tiup
    ```

3. Install the TiUP cluster component:

```
tiup cluster
```

4. If TiUP is already installed, update the TiUP cluster component to the latest version:

```
tiup update --self && tiup update cluster
```

    If `Update successfully!` is displayed, the TiUP cluster is updated successfully.

5. Verify the current version of your TiUP cluster:

```
tiup --binary cluster
```

5.4.1.2.2 Deploy TiUP offline

Perform the following steps in this section to deploy a TiDB cluster offline using TiUP:

Prepare the TiUP offline component package

Method 1: On the official download page, select the offline mirror package (TiUP offline package included) of the target TiDB version. Note that you need to download the server package and toolkit package at the same time.

Method 2: Manually pack an offline component package using `tiup mirror clone`. The detailed steps are as follows:

1. Install the TiUP package manager online.

    1. Install the TiUP tool:

    ```
    curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.
        ↪ com/install.sh | sh
    ```

    2. Redeclare the global environment variables:

    ```
    source .bash_profile
    ```

    3. Confirm whether TiUP is installed:

    ```
    which tiup
    ```

2. Pull the mirror using TiUP.

    1. Pull the needed components on a machine that has access to the Internet:

    ```
    tiup mirror clone tidb-community-server-${version}-linux-amd64 ${
        ↪ version} --os=linux --arch=amd64
    ```

    The command above creates a directory named `tidb-community-server-` ↪ `${version}-linux-amd64` in the current directory, which contains the component package necessary for starting a cluster.

    2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

    ```
    tar czvf tidb-community-server-${version}-linux-amd64.tar.gz tidb-
        ↪ community-server-${version}-linux-amd64
    ```

    `tidb-community-server-${version}-linux-amd64.tar.gz` is an independent offline environment package.

3. Customize the offline mirror, or adjust the contents of an existing offline mirror.

    If you want to adjust an existing offline mirror (such as adding a new version of a component), take the following steps:

1. When pulling an offline mirror, you can get an incomplete offline mirror by specifying specific information via parameters, such as the component and version information. For example, you can pull an offline mirror that includes only the offline mirror of TiUP v1.11.0 and TiUP Cluster v1.11.0 by running the following command:

```
tiup mirror clone tiup-custom-mirror-v1.11.0 --tiup v1.11.0 --
    ↪ cluster v1.11.0
```

   If you only need the components for a particular platform, you can specify them using the `--os` or `--arch` parameters.

2. Refer to the step 2 of "Pull the mirror using TiUP", and send this incomplete offline mirror to the control machine in the isolated environment.

3. Check the path of the current offline mirror on the control machine in the isolated environment. If your TiUP tool is of a recent version, you can get the current mirror address by running the following command:

```
tiup mirror show
```

   If the output of the above command indicates that the `show` command does not exist, you might be using an older version of TiUP. In this case, you can get the current mirror address from `$HOME/.tiup/tiup.toml`. Record this mirror address. In the following steps, `${base_mirror}` is used to refer to this address.

4. Merge an incomplete offline mirror into an existing offline mirror:

   First, copy the `keys` directory in the current offline mirror to the `$HOME/.tiup` directory:

```
cp -r ${base_mirror}/keys $HOME/.tiup/
```

   Then use the TiUP command to merge the incomplete offline mirror into the mirror in use:

```
tiup mirror merge tiup-custom-mirror-v1.11.0
```

5. When the above steps are completed, check the result by running the `tiup list` command. In this document's example, the outputs of both `tiup list tiup` and `tiup list cluster` show that the corresponding components of `v1.11.0` are available.

Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following commands:

```
tar xzvf tidb-community-server-${version}-linux-amd64.tar.gz && \
sh tidb-community-server-${version}-linux-amd64/local_install.sh && \
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically runs the `tiup mirror set tidb-community-server-${version}-linux-amd64` command to set the current mirror address to `tidb-community-server-${version}-linux-amd64`.

Merge offline packages

If you download the offline packages from the official download page, you need to merge the server package and the toolkit package into an offline mirror. If you manually package the offline component packages using the `tiup mirror clone` command, you can skip this step.

Run the following commands to merge the offline toolkit package into the server package directory:

```
tar xf tidb-community-toolkit-${version}-linux-amd64.tar.gz
ls -ld tidb-community-server-${version}-linux-amd64 tidb-community-toolkit-${version}-linux-amd64
cd tidb-community-server-${version}-linux-amd64/
cp -rp keys ~/.tiup/
tiup mirror merge ../tidb-community-toolkit-${version}-linux-amd64
```

To switch the mirror to another directory, run the `tiup mirror set <mirror-dir>` command. To switch the mirror to the online environment, run the `tiup mirror set https://tiup-mirrors.pingcap.com` command.

5.4.1.3 Step 3. Initialize cluster topology file

Run the following command to create a cluster topology file:

```
tiup cluster template > topology.yaml
```

In the following two common scenarios, you can generate recommended topology templates by running commands:

- For hybrid deployment: Multiple instances are deployed on a single machine. For details, see Hybrid Deployment Topology.

  ```
  tiup cluster template --full > topology.yaml
  ```

- For geo-distributed deployment: TiDB clusters are deployed in geographically distributed data centers. For details, see Geo-Distributed Deployment Topology.

  ```
  tiup cluster template --multi-dc > topology.yaml
  ```

Run `vi topology.yaml` to see the configuration file content:

```
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/tidb-deploy"
  data_dir: "/tidb-data"
server_configs: {}
pd_servers:
  - host: 10.0.1.4
  - host: 10.0.1.5
  - host: 10.0.1.6
tidb_servers:
  - host: 10.0.1.7
  - host: 10.0.1.8
  - host: 10.0.1.9
tikv_servers:
  - host: 10.0.1.1
  - host: 10.0.1.2
  - host: 10.0.1.3
monitoring_servers:
  - host: 10.0.1.4
grafana_servers:
  - host: 10.0.1.4
alertmanager_servers:
  - host: 10.0.1.4
```

The following examples cover seven common scenarios. You need to modify the configuration file (named `topology.yaml`) according to the topology description and templates in the corresponding links. For other scenarios, edit the configuration template accordingly.

Application	Configuration task	Configuration template	Topology description
OLTP	Deploy minimal topology	Simple minimal configuration template Full minimal configuration template	This is the basic cluster topology, including tidb-server, tikv-server, and pd-server.

Application	Configuration task	Configuration template	Topology description
HTAP	Deploy the TiFlash topology	Simple TiFlash configuration template	This is to deploy TiFlash along with the minimal cluster topology. TiFlash is a columnar storage engine, and gradually becomes a standard cluster topology.
		Full TiFlash configuration template	

Application	Configuration task	Configuration template	Topology description
Replicate incremental data using TiCDC	Deploy the TiCDC topology	Simple TiCDC configuration template Full TiCDC configuration template	This is to deploy TiCDC along with the minimal cluster topology. TiCDC supports multiple downstream platforms, such as TiDB, MySQL, and MQ.

Application	Configuration task	Configuration template	Topology description
Replicate incremental data using TiDB Binlog	Deploy the TiDB Binlog topology	Simple TiDB Binlog configuration template (MySQL as downstream) Simple TiDB Binlog configuration template (Files as downstream) Full TiDB Binlog configuration template	This is to deploy TiDB Binlog along with the minimal cluster topology.

Application	Configuration task	Configuration template	Topology description
Use OLAP on Spark	Deploy the TiSpark topology	Simple TiSpark configuration template Full TiSpark configuration template	This is to deploy TiSpark along with the minimal cluster topology. TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer the OLAP queries. Currently, TiUP cluster's support

Deploy multiple instances on a single machine	Deploy a hybrid topology	Simple configuration template for hybrid deployment Full configuration template for hybrid deployment	The deployment topologies also apply when you need to add extra configurations for the directory, port, resource ratio, and label.

Application	Configuration task	Configuration template	Topology description
Deploy TiDB clusters across data centers	Deploy a geo-distributed deployment topology	Configuration template for geo-distributed deployment	This topology takes the typical architecture of three data centers in two cities as an example. It introduces the geo-distributed deployment architecture and the key configura-

Application task	Configuration template	Configuration file generation	Topology description

Note:

- For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
- For parameters that should be effective on a specific node, configure these parameters in the `config` of this node.
- Use `.` to indicate the subcategory of the configuration, such as `log.slow-threshold`. For more formats, see TiUP configuration template.
- If you need to specify the user group name to be created on the target machine, see this example.

For more configuration description, see the following configuration examples:

- TiDB `config.toml.example`
- TiKV `config.toml.example`
- PD `config.toml.example`
- TiFlash `config.toml.example`

5.4.1.4 Step 4. Run the deployment command

Note:

You can use secret keys or interactive passwords for security authentication when you deploy TiDB using TiUP:

- If you use secret keys, specify the path of the keys through `-i` or `--identity_file`.
- If you use passwords, add the `-p` flag to enter the password interaction window.
- If password-free login to the target machine has been configured, no authentication is required.

> In general, TiUP creates the user and group specified in the `topology.yaml` file on the target machine, with the following exceptions:
>
> - The user name configured in `topology.yaml` already exists on the target machine.
> - You have used the `--skip-create-user` option in the command line to explicitly skip the step of creating the user.

Before you run the `deploy` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

1. Check for potential risks:

```
tiup cluster check ./topology.yaml --user root [-p] [-i /home/root/.ssh
    ↪ /gcp_rsa]
```

2. Enable automatic repair:

```
tiup cluster check ./topology.yaml --apply --user root [-p] [-i /home/
    ↪ root/.ssh/gcp_rsa]
```

3. Deploy a TiDB cluster:

```
tiup cluster deploy tidb-test v6.4.0 ./topology.yaml --user root [-p]
    ↪ [-i /home/root/.ssh/gcp_rsa]
```

In the `tiup cluster deploy` command above:

- `tidb-test` is the name of the TiDB cluster to be deployed.
- `v6.4.0` is the version of the TiDB cluster to be deployed. You can see the latest supported versions by running `tiup list tidb`.
- `topology.yaml` is the initialization configuration file.
- `--user root` indicates logging into the target machine as the `root` user to complete the cluster deployment. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]` are optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

At the end of the output log, you will see `Deployed cluster` `` `tidb-test` `` `successfully`. This indicates that the deployment is successful.

5.4.1.5 Step 5. Check the clusters managed by TiUP

```
tiup cluster list
```

TiUP supports managing multiple TiDB clusters. The preceding command outputs information of all the clusters currently managed by TiUP, including the cluster name, deployment user, version, and secret key information:

5.4.1.6 Step 6. Check the status of the deployed TiDB cluster

For example, run the following command to check the status of the `tidb-test` cluster:

```
tiup cluster display tidb-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down`/`inactive`), and directory information.

5.4.1.7 Step 7. Start a TiDB cluster

Since TiUP cluster v1.9.0, safe start is introduced as a new start method. Starting a database using this method improves the security of the database. It is recommended that you use this method.

After safe start, TiUP automatically generates a password for the TiDB root user and returns the password in the command-line interface.

> **Note:**
>
> - After safe start of a TiDB cluster, you cannot log in to TiDB using a root user without a password. Therefore, you need to record the password returned in the command output for future logins.
> - The password is generated only once. If you do not record it or you forgot it, refer to Forget the `root` password to change the password.

Method 1: Safe start

```
tiup cluster start tidb-test --init
```

If the output is as follows, the start is successful:

```
Started cluster `tidb-test` successfully.
The root password of TiDB database has been changed.
The new password is: 'y_+3Hwp=*AWz8971s6'.
Copy and record it to somewhere safe, it is only displayed once, and will
    ↪ not be stored.
```

```
The generated password can NOT be got again in future.
```

Method 2: Standard start

```
tiup cluster start tidb-test
```

If the output log includes `Started cluster `tidb-test` successfully`, the start is successful. After standard start, you can log in to a database using a root user without a password.

5.4.1.8 Step 8. Verify the running status of the TiDB cluster

```
tiup cluster display tidb-test
```

If the output log shows `Up` status, the cluster is running properly.

5.4.1.9 See also

If you have deployed TiFlash along with the TiDB cluster, see the following documents:

- Use TiFlash
- Maintain a TiFlash Cluster
- TiFlash Alert Rules and Solutions
- Troubleshoot TiFlash

If you have deployed TiCDC along with the TiDB cluster, see the following documents:

- Manage TiCDC Cluster and Replication Tasks
- Troubleshoot TiCDC
- TiCDC FAQs

5.4.2 Deploy a TiDB Cluster on Kubernetes

You can use TiDB Operator to deploy TiDB clusters on Kubernetes. TiDB Operator is an automatic operation system for TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB on Kubernetes documentation is independent of the TiDB documentation. For detailed steps on how to deploy TiDB clusters on Kubernetes using TiDB Operator, see TiDB on Kubernetes documentation.

5.5 Check Cluster Status

After a TiDB cluster is deployed, you need to check whether the cluster runs normally. This document introduces how to check the cluster status using TiUP commands, TiDB Dashboard and Grafana, and how to log into the TiDB database to perform simple SQL operations.

5.5.1 Check the TiDB cluster status

This section describes how to check the TiDB cluster status using TiUP commands, TiDB Dashboard, and Grafana.

5.5.1.1 Use TiUP

Use the `tiup cluster display <cluster-name>` command to check the cluster status. For example:

```
tiup cluster display tidb-test
```

Expected output: If the `Status` information of each node is `Up`, the cluster runs normally.

5.5.1.2 Use TiDB Dashboard

1. Log in to TiDB Dashboard at `${pd-ip}:${pd-port}/dashboard`. The username and password is the same as that of the TiDB `root` user. If you have modified the `root` password, enter the modified password. The password is empty by default.

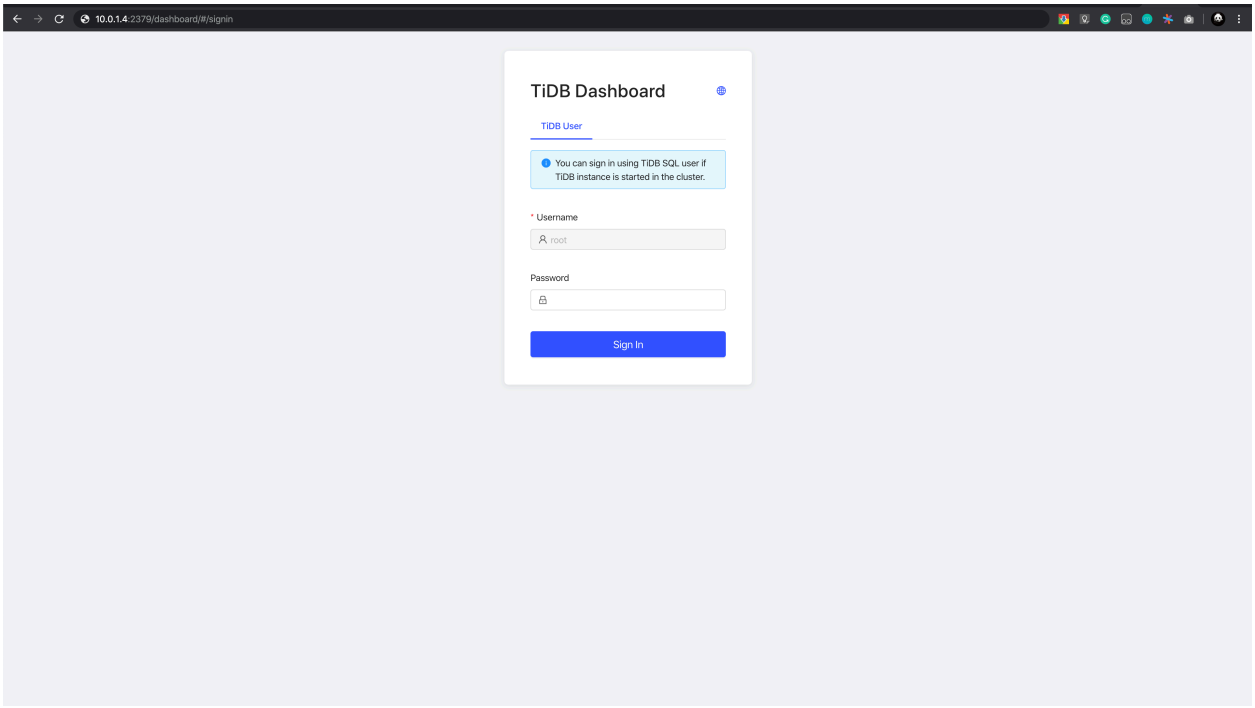

Figure 43: TiDB-Dashboard

2. The home page displays the node information in the TiDB cluster.

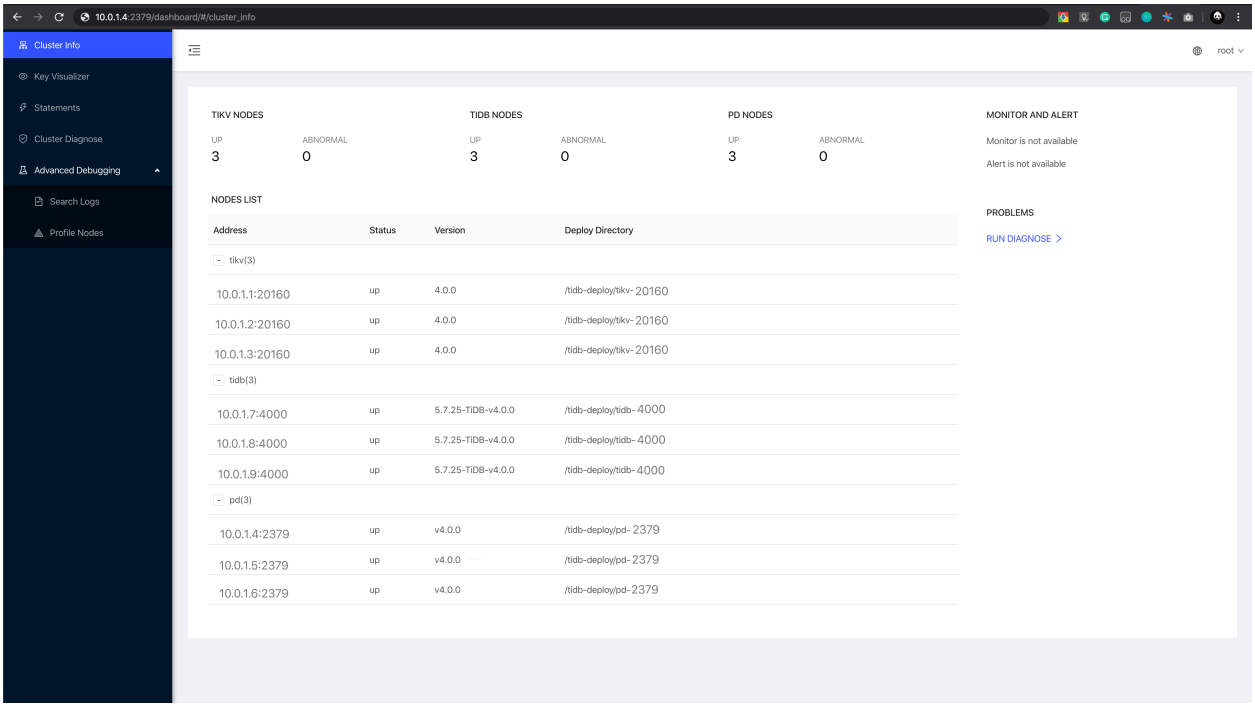

Figure 44: TiDB-Dashboard-status

5.5.1.3 Use Grafana

1. Log in to the Grafana monitoring at `${Grafana-ip}:3000`. The default username and password are both `admin`.

2. To check the TiDB port status and load monitoring information, click **Overview**.

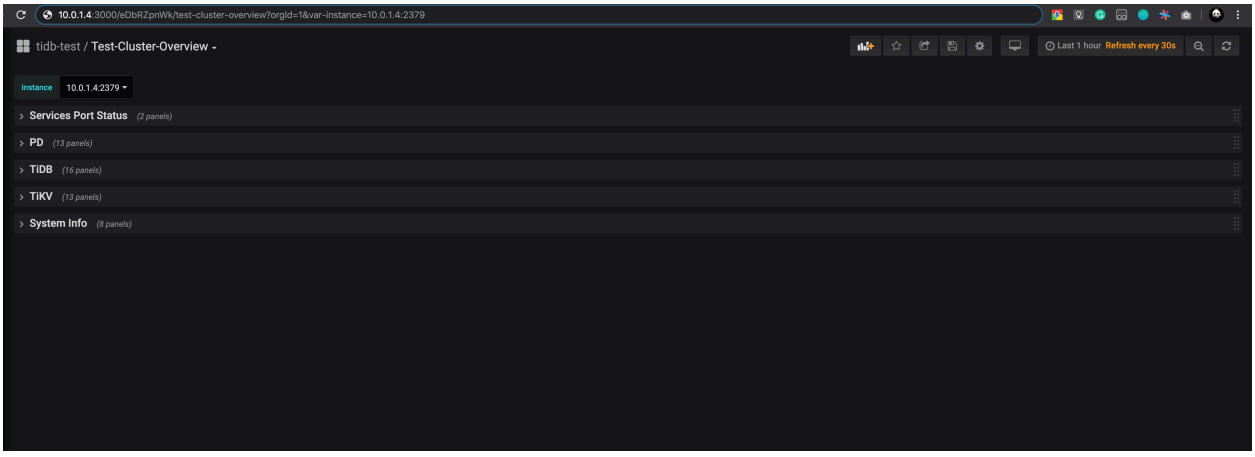

Figure 45: Grafana-overview

5.5.2 Log in to the database and perform simple operations

> **Note:**
>
> Install the MySQL client before you log in to the database.

Log in to the database by running the following command:

```
mysql -u root -h ${tidb_server_host_IP_address} -P 4000
```

`${tidb_server_host_IP_address}` is one of the IP addresses set for `tidb_servers` when you initialize the cluster topology file, such as `10.0.1.7`.

The following information indicates successful login:

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.7.25-TiDB-v5.0.0 TiDB Server (Apache License 2.0)
    ↪ Community Edition, MySQL 5.7 compatible
Copyright (c) 2000, 2015, Oracle and/or its affiliates. All rights reserved
    ↪ .

affiliates. Other names may be trademarks of their respective
owners.

Type 'help;' or '\h' for help. Type '\c' to clear the current input
    ↪ statement.
```

5.5.2.1 Database operations

- Check the version of TiDB:

  ```
  select tidb_version()\G
  ```

  Expected output:

  ```
  *************************** 1. row ***************************
  tidb_version(): Release Version: v5.0.0
  Edition: Community
  Git Commit Hash: 689a6b6439ae7835947fcaccf329a3fc303986cb
  Git Branch: HEAD
  UTC Build Time: 2020-05-28 11:09:45
  GoVersion: go1.13.4
  ```

```
Race Enabled: false
TiKV Min Version: v3.0.0-60965b006877ca7234adaced7890d7b029ed1306
Check Table Before Drop: false
1 row in set (0.00 sec)
```

- Create a database named `pingcap`:

```
create database pingcap;
```

Expected output:

```
Query OK, 0 rows affected (0.10 sec)
```

Switch to the `pingcap` database:

```
use pingcap;
```

Expected output:

```
Database changed
```

- Create a table named `tab_tidb`:

```
CREATE TABLE `tab_tidb` (
`id` int(11) NOT NULL AUTO_INCREMENT,
`name` varchar(20) NOT NULL DEFAULT '',
`age` int(11) NOT NULL DEFAULT 0,
`version` varchar(20) NOT NULL DEFAULT '',
PRIMARY KEY (`id`),
KEY `idx_age` (`age`));
```

Expected output:

```
Query OK, 0 rows affected (0.11 sec)
```

- Insert data:

```
insert into `tab_tidb` values (1,'TiDB',5,'TiDB-v5.0.0');
```

Expected output:

```
Query OK, 1 row affected (0.03 sec)
```

- View the entries in `tab_tidb`:

```
select * from tab_tidb;
```

Expected output:

```
+----+------+-----+-------------+
| id | name | age | version |
+----+------+-----+-------------+
|  1 | TiDB |  5 | TiDB-v5.0.0 |
+----+------+-----+-------------+
1 row in set (0.00 sec)
```

- View the store state, `store_id`, capacity, and uptime of TiKV:

```
select STORE_ID,ADDRESS,STORE_STATE,STORE_STATE_NAME,CAPACITY,AVAILABLE
    ↪ ,UPTIME from INFORMATION_SCHEMA.TIKV_STORE_STATUS;
```

Expected output:

```
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-
    ↪
| STORE_ID | ADDRESS         | STORE_STATE | STORE_STATE_NAME | CAPACITY
    ↪  | AVAILABLE | UPTIME    |

    ↪
|        1 | 10.0.1.1:20160 |        0 | Up              | 49.98GiB | 46.3
    ↪ GiB | 5h21m52.474864026s |
|        4 | 10.0.1.2:20160 |        0 | Up              | 49.98GiB |
    ↪ 46.32GiB | 5h21m52.522669177s |
|        5 | 10.0.1.3:20160 |        0 | Up              | 49.98GiB |
    ↪ 45.44GiB | 5h21m52.713660541s |
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-
    ↪
3 rows in set (0.00 sec)
```

- Exit TiDB:

```
exit
```

Expected output:

```
Bye
```

5.6 Test Cluster Performance

5.6.1 How to Test TiDB Using Sysbench

It is recommended to use Sysbench 1.0 or later, which can be downloaded here.

5.6.1.1 Test plan

5.6.1.1.1 TiDB configuration

Higher log level means fewer logs to be printed and thus positively influences TiDB performance. Specifically, you can add the following command in the TiUP configuration file:

```
server_configs:
  tidb:
    log.level: "error"
```

It is also recommended to make sure `tidb_enable_prepared_plan_cache` is enabled and that you allow sysbench to use prepared statements by *not* using `--db-ps-mode=disabled`. See the SQL Prepared Execution Plan Cache for documentation about what the SQL plan cache does and how to monitor it.

5.6.1.1.2 TiKV configuration

Higher log level also means better performance for TiKV.

There are multiple Column Families on TiKV cluster which are mainly used to store different types of data, including Default CF, Write CF, and Lock CF. For the Sysbench test, you only need to focus on Default CF and Write CF. The Column Family that is used to import data has a constant proportion among TiDB clusters:

Default CF : Write CF = 4 : 1

Configuring the block cache of RocksDB on TiKV should be based on the machine's memory size, in order to make full use of the memory. To deploy a TiKV cluster on a 40GB virtual machine, it is recommended to configure the block cache as follows:

```
server_configs:
  tikv:
    log-level: "error"
    rocksdb.defaultcf.block-cache-size: "24GB"
    rocksdb.writecf.block-cache-size: "6GB"
```

You can also configure TiKV to share block cache:

```
server_configs:
  tikv:
    storage.block-cache.capacity: "30GB"
```

For more detailed information on TiKV performance tuning, see Tune TiKV Performance.

5.6.1.2 Test process

> **Note:**
>
> The test in this document was performed without load balancing tools such as HAproxy. We run the Sysbench test on individual TiDB node and added the results up. The load balancing tools and the parameters of different versions might also impact the performance.

5.6.1.2.1 Sysbench configuration

This is an example of the Sysbench configuration file:

```
mysql-host={TIDB_HOST}
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads={8, 16, 32, 64, 128, 256}
report-interval=10
db-driver=mysql
```

The above parameters can be adjusted according to actual needs. Among them, `TIDB_HOST` is the IP address of the TiDB server (because we cannot include multiple addresses in the configuration file), `threads` is the number of concurrent connections in the test, which can be adjusted in "8, 16, 32, 64, 128, 256". When importing data, it is recommended to set threads = 8 or 16. After adjusting `threads`, save the file named **config**.

See the following as a sample **config** file:

```
mysql-host=172.16.30.33
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads=16
report-interval=10
db-driver=mysql
```

5.6.1.2.2 Data import

Note:

If you enable the optimistic transaction model (TiDB uses the pessimistic transaction mode by default), TiDB rolls back transactions when a concurrency conflict is found. Setting `tidb_disable_txn_auto_retry` to `off` turns on the automatic retry mechanism after meeting a transaction conflict, which can prevent Sysbench from quitting because of the transaction conflict error.

Before importing the data, it is necessary to make some settings to TiDB. Execute the following command in MySQL client:

```
set global tidb_disable_txn_auto_retry = off;
```

Then exit the client.

Restart MySQL client and execute the following SQL statement to create a database `sbtest`:

```
create database sbtest;
```

Adjust the order in which Sysbench scripts create indexes. Sysbench imports data in the order of "Build Table -> Insert Data -> Create Index", which takes more time for TiDB to import data. Users can adjust the order to speed up the import of data. Suppose that you use the Sysbench version 1.0.20. You can adjust the order in either of the following two ways:

- Download the modified oltp_common.lua file for TiDB and overwrite the `/usr/share/sysbench/oltp_common.lua` file with it.
- In `/usr/share/sysbench/oltp_common.lua`, move the lines 235-240 to be right behind the line 198.

Note:

This operation is optional and is only to save the time consumed by data import.

At the command line, enter the following command to start importing data. The config file is the one configured in the previous step:

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 prepare
```

5.6.1.2.3 Warming data and collecting statistics

To warm data, we load data from disk into the block cache of memory. The warmed data has significantly improved the overall performance of the system. It is recommended to warm data once after restarting the cluster.

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 warmup
```

5.6.1.2.4 Point select test command

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 run
```

5.6.1.2.5 Update index test command

```
sysbench --config-file=config oltp_update_index --tables=32 --table-size
    ↪ =10000000 run
```

5.6.1.2.6 Read-only test command

```
sysbench --config-file=config oltp_read_only --tables=32 --table-size
    ↪ =10000000 run
```

5.6.1.3 Common issues

5.6.1.3.1 TiDB and TiKV are both properly configured under high concurrency, why is the overall performance still low?

This issue often has things to do with the use of a proxy. You can add pressure on single TiDB server, sum each result up and compare the summed result with the result with proxy.

Take HAproxy as an example. The parameter `nbproc` can increase the number of processes it can start at most. Later versions of HAproxy also support `nbthread` and `cpu-map`. All of these can mitigate the negative impact of proxy use on performance.

5.6.1.3.2 Under high concurrency, why is the CPU utilization rate of TiKV still low?

Although the overall CPU utilization rate is low for TiKV, the CPU utilization rate of some modules in the cluster might be high.

The maximum concurrency limits for other modules on TiKV, such as storage readpool, coprocessor, and gRPC, can be adjusted through the TiKV configuration file.

The actual CPU usage can be observed through Grafana's TiKV Thread CPU monitor panel. If there is a bottleneck on the modules, it can be adjusted by increasing the concurrency of the modules.

5.6.1.3.3 Given that TiKV has not yet reached the CPU usage bottleneck under high concurrency, why is TiDB's CPU utilization rate still low?

CPU of NUMA architecture is used on some high-end equipment where cross-CPU access to remote memory will greatly reduce performance. By default, TiDB will use all CPUs of the server, and goroutine scheduling will inevitably lead to cross-CPU memory access.

Therefore, it is recommended to deploy n TiDBs (n is the number of NUMA CPUs) on the server of NUMA architecture, and meanwhile set the TiDB parameter `max-procs` to a value that is the same as the number of NUMA CPU cores.

5.6.2 How to Run TPC-C Test on TiDB

This document describes how to test TiDB using TPC-C.

TPC-C is an online transaction processing (OLTP) benchmark. It tests the OLTP system by using a commodity sales model that involves the following five transactions of different types:

- NewOrder
- Payment
- OrderStatus
- Delivery
- StockLevel

5.6.2.1 Prepare

Before testing, TPC-C Benchmark specifies the initial state of the database, which is the rule for data generation in the database. The `ITEM` table contains a fixed number of 100,000 items, while the number of warehouses can be adjusted. If there are W records in the `WAREHOUSE` table, then:

- The `STOCK` table has W * 100,000 records (Each warehouse corresponds to the stock data of 100,000 items)
- The `DISTRICT` table has W * 10 records (Each warehouse provides services to 10 districts)
- The `CUSTOMER` table has W * 10 * 3,000 records (Each district has 3,000 customers)
- The `HISTORY` table has W * 10 * 3,000 records (Each customer has one transaction history)
- The `ORDER` table has W * 10 * 3,000 records (Each district has 3,000 orders and the last 900 orders generated are added to the `NEW-ORDER` table. Each order randomly generates 5 ~ 15 ORDER-LINE records.

In this document, the testing uses 1,000 warehouses as an example to test TiDB.

TPC-C uses tpmC (transactions per minute) to measure the maximum qualified throughput (MQTh, Max Qualified Throughput). The transactions are the NewOrder transactions and the final unit of measure is the number of new orders processed per minute.

The test in this document is implemented based on go-tpc. You can download the test program using TiUP commands.

```
tiup install bench
```

For detailed usage of the TiUP Bench component, see TiUP Bench.

Assume that you have deployed a TiDB cluster with two TiDB servers located at 172.16.5.140 and 172.16.5.141, and both servers are listening on port 4000. You can run a TPC-C test with the following steps.

5.6.2.2 Load data

Loading data is usually the most time-consuming and problematic stage of the entire TPC-C test. This section provides the following command to load data.

Execute the following TiUP command in Shell:

```
tiup bench tpcc -H 172.16.5.140,172.16.5.141 -P 4000 -D tpcc --warehouses
    ↪ 1000 --threads 20 prepare
```

Based on different machine configurations, this loading process might take a few hours. If the cluster size is small, you can use a smaller `WAREHOUSE` value for the test.

After the data is loaded, you can execute the `tiup bench tpcc -H 172.16.5.140 -P ↪ 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

5.6.2.3 Run the test

Execute the following command to run the test:

```
tiup bench tpcc -H 172.16.5.140,172.16.5.141 -P 4000 -D tpcc --warehouses
    ↪ 1000 --threads 100 --time 10m run
```

During the test, test results are continuously printed on the console:

```
[Current] NEW_ORDER - Takes(s): 4.6, Count: 5, TPM: 65.5, Sum(ms): 4604, Avg
    ↪ (ms): 920, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms): 1500
[Current] ORDER_STATUS - Takes(s): 1.4, Count: 1, TPM: 42.2, Sum(ms): 256,
    ↪ Avg(ms): 256, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
[Current] PAYMENT - Takes(s): 6.9, Count: 5, TPM: 43.7, Sum(ms): 2208, Avg(
    ↪ ms): 441, 90th(ms): 512, 99th(ms): 512, 99.9th(ms): 512
[Current] STOCK_LEVEL - Takes(s): 4.4, Count: 1, TPM: 13.8, Sum(ms): 224,
    ↪ Avg(ms): 224, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
...
```

After the test is finished, the test summary results are printed:

```
[Summary] DELIVERY - Takes(s): 455.2, Count: 32, TPM: 4.2, Sum(ms): 44376,
   ↪ Avg(ms): 1386, 90th(ms): 2000, 99th(ms): 4000, 99.9th(ms): 4000
[Summary] DELIVERY_ERR - Takes(s): 455.2, Count: 1, TPM: 0.1, Sum(ms): 953,
   ↪ Avg(ms): 953, 90th(ms): 1000, 99th(ms): 1000, 99.9th(ms): 1000
[Summary] NEW_ORDER - Takes(s): 487.8, Count: 314, TPM: 38.6, Sum(ms):
   ↪ 282377, Avg(ms): 899, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms):
   ↪ 1500
[Summary] ORDER_STATUS - Takes(s): 484.6, Count: 29, TPM: 3.6, Sum(ms):
   ↪ 8423, Avg(ms): 290, 90th(ms): 512, 99th(ms): 1500, 99.9th(ms): 1500
[Summary] PAYMENT - Takes(s): 490.1, Count: 321, TPM: 39.3, Sum(ms): 144708,
   ↪  Avg(ms): 450, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1500
[Summary] STOCK_LEVEL - Takes(s): 487.6, Count: 41, TPM: 5.0, Sum(ms): 9318,
   ↪  Avg(ms): 227, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1000
```

After the test is finished, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

5.6.2.4 Clean up test data

Execute the following command to clean up the test data:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 cleanup
```

5.6.3 How to Run CH-benCHmark Test on TiDB

This document describes how to test TiDB using CH-benCHmark.

CH-benCHmark is a mixed workload containing both TPC-C and TPC-H tests. It is the most common workload to test HTAP systems. For more information, see The mixed workload CH-benCHmark.

Before running the CH-benCHmark test, you need to deploy TiFlash first, which is a TiDB's HTAP component. After you deploy TiFlash and create TiFlash replicas, TiKV will replicate the latest data of TPC-C online transactions to TiFlash in real time, and the TiDB optimizer will automatically push down OLAP queries from TPC-H workload to the MPP engine of TiFlash for efficient execution.

The CH-benCHmark test in this document is implemented based on go-tpc. You can download the test program using the following TiUP command:

```
tiup install bench
```

For detailed usage of the TiUP Bench component, see TiUP Bench.

5.6.3.1 Load data

5.6.3.1.1 Load TPC-C data

Loading data is usually the most time-consuming and problematic stage of the entire TPC-C test.

Taking 1000 warehouses as an example, you can execute the following TiUP command in shell for data load and test. Note that you need to replace `172.16.5.140` and `4000` in this document with your TiDB host and port values.

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 prepare -T
    ↪ 32
```

Depending on different machine configurations, this loading process might take a few hours. If the cluster size is small, you can use a smaller warehouse value for the test.

After the data is loaded, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 check` command to validate the data correctness.

5.6.3.1.2 Load additional tables and views required for TPC-H

Run the following TiUP command in the shell:

```
tiup bench ch -H 172.16.5.140 -P 4000 -D tpcc prepare
```

The following is the log output:

```
creating nation
creating region
creating supplier
generating nation table
generate nation table done
generating region table
generate region table done
generating suppliers table
generate suppliers table done
creating view revenue1
```

5.6.3.2 Create TiFlash replicas

After TiFlash is deployed, TiFlash does not automatically replicate TiKV data. You need to execute the following SQL statement to create TiFlash replicas for the `tpcc` database. Once the specified TiFlash replicas are created, TiKV automatically replicates the latest data to TiFlash in real-time. In the following example, two TiFlash nodes are deployed in the cluster and the replica number is set to 2.

```
ALTER DATABASE tpcc SET tiflash replica 2;
```

To check whether the replication of all tables in the `tpcc` database is complete, execute the following statement, in which the `WHERE` clause is used to specify the databases and tables to be checked. If you want to check the replication status of all databases, remove the `WHERE` clause from the statement.

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'tpcc
    ↪ ';
```

In the result of the above statement:

- `AVAILABLE` indicates whether the TiFlash replica of a specific table is available or not. `1` means available and `0` means unavailable. Once a replica becomes available, this status does not change anymore.
- `PROGRESS` means the progress of the replication. The value is between `0` and `1`. `1` means that the replication is complete for the TiFlash replica.

5.6.3.3 Collect statistics

To ensure that the TiDB optimizer can generate the optimal execution plan, execute the following SQL statements to collect statistics in advance.

```
analyze table customer;
analyze table district;
analyze table history;
analyze table item;
analyze table new_order;
analyze table order_line;
analyze table orders;
analyze table stock;
analyze table warehouse;
analyze table nation;
analyze table region;
analyze table supplier;
```

5.6.3.4 Run the test

Taking 50 TP concurrency and 1 AP concurrency as an example, execute the following command to run the test:

```
tiup bench ch --host 172.16.5.140 -P4000 --warehouses 1000 run -D tpcc -T 50
    ↪  -t 1 --time 1h
```

During the test, test results are continuously printed on the console. For example:

```
[Current] NEW_ORDER - Takes(s): 10.0, Count: 13524, TPM: 81162.0, Sum(ms):
    ↪ 998317.6, Avg(ms): 73.9, 50th(ms): 71.3, 90th(ms): 100.7, 95th(ms):
    ↪ 113.2, 99th(ms): 159.4, 99.9th(ms): 209.7, Max(ms): 243.3
```

```
[Current] ORDER_STATUS - Takes(s): 10.0, Count: 1132, TPM: 6792.7, Sum(ms):
   ↪ 16196.6, Avg(ms): 14.3, 50th(ms): 13.1, 90th(ms): 24.1, 95th(ms):
   ↪ 27.3, 99th(ms): 37.7, 99.9th(ms): 50.3, Max(ms): 52.4
[Current] PAYMENT - Takes(s): 10.0, Count: 12977, TPM: 77861.1, Sum(ms):
   ↪ 773982.0, Avg(ms): 59.7, 50th(ms): 56.6, 90th(ms): 88.1, 95th(ms):
   ↪ 100.7, 99th(ms): 151.0, 99.9th(ms): 201.3, Max(ms): 243.3
[Current] STOCK_LEVEL - Takes(s): 10.0, Count: 1134, TPM: 6806.0, Sum(ms):
   ↪ 31220.9, Avg(ms): 27.5, 50th(ms): 25.2, 90th(ms): 37.7, 95th(ms):

[Summary] Q5   - Count: 11, Sum(ms): 368301.0, Avg(ms): 33483.5
[Summary] Q6   - Count: 11, Sum(ms): 61702.5, Avg(ms): 5608.9
[Summary] Q7   - Count: 11, Sum(ms): 158928.2, Avg(ms): 14446.3
```

After the test is finished, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 check` command to validate the data correctness.

6 Migrate

6.1 Data Migration Overview

This document gives an overview of the data migration solutions that you can use with TiDB. The data migration solutions are as follows:

- Full data migration.
  - To import Amazon Aurora snapshots, CSV files, or Mydumper SQL files into TiDB, you can use TiDB Lightning to perform the full migration.
  - To export all TiDB data as CSV files or Mydumper SQL files, you can use Dumpling to perform the full migration, which makes data migration from MySQL or MariaDB easier.
  - To migrate all data from a database with a small data size volume (for example, less than 1 TiB), you can also use TiDB Data Migration (DM).
- Quick initialization of TiDB. TiDB Lightning supports quickly importing data and can quickly initialize a specific table in TiDB. Before you use this feature, pay attention that the quick initialization has a great impact on TiDB and the cluster does not provide services during the initialization period.
- Incremental replication. You can use TiDB DM to replicate binlogs from MySQL, MariaDB, or Aurora to TiDB, which greatly reduces the window downtime during the replication period.
- Data replication between TiDB clusters. TiDB supports backup and restore. This feature can initialize a snapshot in an existing TiDB cluster to a new TiDB cluster.
- Incremental replication between TiDB clusters. TiDB supports disaster recovery between homogeneous databases to ensure eventual data consistency of primary and secondary databases after a disaster event. It works only when both primary and secondary clusters are TiDB.

You might choose different migration solutions according to the database type, deployment location, application data size, and application needs. The following sections introduce some common migration scenarios, and you can refer to these sections to determine the most suitable solution according to your needs.

6.1.1 Migrate data from Aurora MySQL to TiDB

When you migrate data from Aurora to a TiDB cluster deployed on AWS, your data migration takes two operations: full data migration and incremental replication. You can choose the corresponding operation according to your application needs.

- Migrate Data from Amazon Aurora to TiDB.

6.1.2 Migrate data from MySQL to TiDB

If cloud storage (S3) service is not used, the network connectivity is good, and the network latency is low, you can use the following method to migrate data from MySQL to TiDB.

- Migrate MySQL of Small Datasets to TiDB

If you have a high demand on migration speed, or if the data size is large (for example, larger than 1 TiB), and you do not allow other applications to write to TiDB during the migration period, you can use TiDB Lightning to quickly import data. Then, you can use DM to replicate incremental data (binlog) based on your application needs.

- Migrate MySQL of Large Datasets to TiDB

6.1.3 Migrate and merge MySQL shards into TiDB

Suppose that your application uses MySQL shards for data storage, and you need to migrate these shards into TiDB as one table. In this case, you can use DM to perform the shard merge and migration.

- Migrate and Merge MySQL Shards of Small Datasets to TiDB

If the data size of the sharded tables is large (for example, larger than 1 TiB), and you do not allow other applications to write to TiDB during the migration period, you can use TiDB Lightning to quickly merge and import the sharded tables. Then, you can use DM to replicate incremental sharding data (binlog) based on your application needs.

- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.1.4 Migrate data from files to TiDB

- Migrate data from CSV files to TiDB
- Migrate data from SQL files to TiDB

6.1.5 Incremental replication between TiDB clusters

You can use TiCDC for incremental data replication between TiDB clusters. For details, refer to TiCDC Overview.

6.1.6 More advanced migration solutions

The following features can improve the migration process and might meet more needs in your application.

- Continuous Replication from Databases that Use gh-ost or pt-osc
- Migrate Data to a Downstream TiDB Table with More Columns
- Filter Binlog Events
- Filter DML Events Using SQL Expressions

6.2 TiDB Migration Tools Overview

TiDB provides multiple data migration tools for different scenarios such as full data migration, incremental data migration, backup and restore, and data replication.

This document introduces the user scenarios, supported upstreams and downstreams, advantages, and limitations of these tools. You can choose the right tool according to your needs.

6.2.1 TiDB Data Migration (DM)

User scenario	Data migration from MySQL-compatible databases to TiDB
Upstream	MySQL, MariaDB, Aurora, MySQL
Downstream	TiDB

| **Advantages** |

A convenient and unified data migration task management tool that supports full data migration and incremental replication

Support filtering tables and operations

Support shard merge and migration

| | **Limitation** | Data import speed is roughly the same as that of TiDB Lightning's logical import mode, and a lot lower than that of TiDB Lightning's physical import mode. So it is recommended to use DM to migrate full data with a size of less than 1 TiB. |

6.2.2 Dumpling

User scenario	Full data export from MySQL or TiDB
Upstream	MySQL, TiDB
Downstream (the output file)	SQL, CSV

| **Advantages** |

Support the table-filter feature that enables you to filter data easier

Support exporting data to Amazon S3

| | **Limitation** |

If you want to restore the exported data to a database other than TiDB, it is recommended to use Dumpling.

If you want to restore the exported data to another TiDB cluster, it is recommended to use Backup & Restore (BR).

|

6.2.3 TiDB Lightning

User scenario	Full data import into TiDB

| **Upstream (the imported source file)** |

Files exported from Dumpling

Parquet files exported by Amazon Aurora or Apache Hive

CSV files

Data from local disks or Amazon S3

| | **Downstream** | TiDB | | **Advantages** |

Support quickly importing a large amount of data and quickly initializing a specific table in a TiDB cluster

Support checkpoints to store the import progress, so that `tidb-lightning` continues importing from where it lefts off after restarting

Support data filtering

| | **Limitation** |

If physical import mode is used for data import, during the import process, the TiDB cluster cannot provide services.

If you do not want the TiDB services to be impacted, perform the data import according to TiDB Lightning logical import mode.

|

6.2.4 Backup & Restore (BR)

User scenario	Migrate a large amount of TiDB custer data by backing up and restoring data
Upstream and Downstream (the output file)	TiDB SST, backup.meta files, backup.lock files

| **Advantages** |

Suitable for migrating data to another TiDB cluster

Support backing up data to an external storage for disaster recovery

| | **Limitation** |

When BR restores data to the upstream cluster of TiCDC or Drainer, the restored data cannot be replicated to the downstream by TiCDC or Drainer.

BR supports operations only between clusters that have the same `new_collations_enabled_on_first_` ↪ value.

|

6.2.5 TiCDC

User scenario	This tool is implemented by pulling TiKV change logs. It can restore cluster data to a consistent state with any upstream TSO, and support other systems to subscribe to data changes.
Upstream	TiDB

	This tool is implemented by pulling TiKV change logs. It can restore cluster data to a consistent state with any upstream TSO, and support other systems to subscribe to data changes.
User scenario	
Downstream	TiDB, MySQL, Kafka, Confluent

	This tool is implemented by pulling TiKV change logs. It can restore cluster data to a consistent state with any upstream TSO, and support other systems to subscribe to data changes.
User scenario	
Advantages	Provide TiCDC Open Protocol

	This tool is implemented by pulling TiKV change logs. It can restore cluster data to a consistent state with any upstream TSO, and support other systems to subscribe to data changes.
User scenario	

| **Limitation** | TiCDC only replicates tables that have at least one valid index. The following scenarios are not supported:

The TiKV cluster that uses RawKV alone.

The DDL operation `CREATE SEQUENCE` and the `SEQUENCE` function in TiDB.

|

6.2.6 TiDB Binlog

User scenario	Incremental replication between TiDB clusters, such as using one TiDB cluster as the secondary cluster of another TiDB cluster
Upstream	TiDB

	Incremental replication between TiDB clusters, such as using one TiDB cluster as the secondary cluster of another TiDB cluster
User scenario	
Downstream (or the output file)	TiDB, MySQL, Kafka, incremental backup files

User scenario	Incremental replication between TiDB clusters, such as using one TiDB cluster as the secondary cluster of another TiDB cluster
Advantages	Support real-time backup and restore. Back up TiDB cluster data to be restored for dis-

User scenario	Incremental replication between TiDB clusters, such as using one TiDB cluster as the secondary cluster of another TiDB cluster
Limitation	TiDB Binlog is incompatible with some TiDB versions. It is recommended that you use TiCDC.

	Incremental replication between TiDB clusters, such as using one TiDB cluster as the secondary cluster of another
User scenario	TiDB cluster

6.2.7 sync-diff-inspector

User scenario	Comparing data stored in the databases with the MySQL protocol
Upstream	TiDB, MySQL
Downstream	TiDB, MySQL
Advantages	Can be used to repair data in the scenario where a small amount of data is inconsistent

Limitation
Online check is not supported for data migration between MySQL and TiDB. JSON, BIT, BINARY, BLOB and other types of data are not supported.

6.2.8 Install tools using TiUP

Since TiDB v4.0, TiUP acts as a package manager that helps you manage different cluster components in the TiDB ecosystem. Now you can manage any cluster component using a single command.

6.2.8.1 Step 1. Install TiUP

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

Redeclare the global environment variable:

```
source ~/.bash_profile
```

6.2.8.2 Step 2. Install components

You can use the following command to see all the available components:

```
tiup list
```

The command output lists all the available components:

```
Available components:
Name          Owner   Description
----          -----   -----------
bench         pingcap Benchmark database with different workloads
br            pingcap TiDB/TiKV cluster backup restore tool
cdc           pingcap CDC is a change data capture tool for TiDB
client        pingcap Client to connect playground
cluster       pingcap Deploy a TiDB cluster for production
ctl           pingcap TiDB controller suite
dm            pingcap Data Migration Platform manager
dmctl         pingcap dmctl component of Data Migration Platform
errdoc        pingcap Document about TiDB errors
pd-recover    pingcap PD Recover is a disaster recovery tool of PD, used to
    ↪ recover the PD cluster which cannot start or provide services
    ↪ normally
playground    pingcap Bootstrap a local TiDB cluster for fun
tidb          pingcap TiDB is an open source distributed HTAP database
    ↪ compatible with the MySQL protocol
tidb-lightning pingcap TiDB Lightning is a tool used for fast full import
    ↪ of large amounts of data into a TiDB cluster
tiup          pingcap TiUP is a command-line component management tool that
    ↪  can help to download and install TiDB platform components to the
    ↪ local system
```

Choose the components to install:

```
tiup install dumpling tidb-lightning
```

> **Note:**
>
> To install a component of a specific version, use the `tiup install <component>[:version]` command.

6.2.8.3 Step 3. Update TiUP and its components (optional)

It is recommended to see the release log and compatibility notes of the new version.

```
tiup update --self && tiup update dm
```

6.2.9 See also

- Deploy TiUP offline
- Download and install tools in binary

6.3 Migration Scenarios

6.3.1 Migrate Data from Amazon Aurora to TiDB

This document describes how to migrate data from Amazon Aurora to TiDB. The migration process uses DB snapshot, which saves a lot of space and time.

The whole migration has two processes:

- Import full data to TiDB using TiDB Lightning
- Replicate incremental data to TiDB using DM (optional)

6.3.1.1 Prerequisites

- Install Dumpling and TiDB Lightning
- Get the target database privileges required for TiDB Lightning.

6.3.1.2 Import full data to TiDB

6.3.1.2.1 Step 1. Export an Aurora snapshot to Amazon S3

1. In Aurora, query the current binlog position by running the following command:

```
mysql> SHOW MASTER STATUS;
```

   The output is similar to the following. Record the binlog name and position for later use.

```
+------------------+----------+--------------+------------------+------------------
    ↪
| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
    ↪ Executed_Gtid_Set |
+------------------+----------+--------------+------------------+------------------
    ↪
| mysql-bin.000002 | 52806 |              |                  |
    ↪                  |
+------------------+----------+--------------+------------------+------------------
    ↪
1 row in set (0.012 sec)
```

2. Export the Aurora snapshot. For detailed steps, refer to Exporting DB snapshot data to Amazon S3.

After you obtain the binlog position, export the snapshot within 5 minutes. Otherwise, the recorded binlog position might be outdated and thus cause data conflict during the incremental replication.

After the two steps above, make sure you have the following information ready:

- The Aurora binlog name and position at the time of the snapshot creation.
- The S3 path where the snapshot is stored, and the SecretKey and AccessKey with access to the S3 path.

6.3.1.2.2 Step 2. Export schema

Because the snapshot file from Aurora does not contain the DDL statements, you need to export the schema using Dumpling and create the schema in the target database using TiDB Lightning. If you want to manually create the schema, you can skip this step.

Export the schema using Dumpling by running the following command. The command includes the `--filter` parameter to only export the desired table schema:

```
tiup dumpling --host ${host} --port 3306 --user root --password ${password}
    ↪ --filter 'my_db1.table[12]' --no-data --output 's3://my-bucket/schema
    ↪ -backup' --filter "mydb.*"
```

The parameters used in the command above are as follows. For more parameters, refer to Dumpling overview.

Parameter	Description
`--user` or `-u`	Aurora MySQL user
`--user`	user
`--password` or `-p`	MySQL user password
`--password`	password
`--port` or `-P`	MySQL port
`--port`	port
`--host` or `-h`	MySQL HP address
`--host`	host
`--thread` or `-t`	The number of threads
`--thread`	thread for export

Parameter	Description
-o, --output-dir	The directory that stores the exported file. Supports local path or external storage URL
-r, --row	The maximum number of rows in a single file

Parameter	Description
`-F`	The maximum size of a single file, in MiB. Recommended value: 256 MiB.
`-B`	Specifies a database to be exported
`-T`	The specified tables list
`-d`	Does not export data. Only exports schema.

Parameter	Description
-f	Exports files that match the filter pattern. Do not use -f and -T at the same time. Refer to table-filter for the syntax.

6.3.1.2.3 Step 3. Create the TiDB Lightning configuration file

Create the `tidb-lightning.toml` configuration file as follows:

```
vim tidb-lightning.toml
```

```
[tidb]

### The target TiDB cluster information.
host = ${host}             # e.g.: 172.16.32.1
port = ${port}             # e.g.: 4000
user = "${user_name}       # e.g.: "root"
```

```
password = "${password}"  # e.g.: "rootroot"
status-port = ${status-port} # Obtains the table schema information from
    ↪ TiDB status port, e.g.: 10080
pd-addr = "${ip}:${port}" # The cluster PD address, e.g.: 172.16.31.3:2379.
    ↪  TiDB Lightning obtains some information from PD. When backend = "
    ↪ local", you must specify status-port and pd-addr correctly. Otherwise
    ↪ , the import will be abnormal.

[tikv-importer]
### "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the target
    ↪ TiDB cluster cannot provide any service.
### "tidb": The "tidb" backend is recommended to import data less than 1 TiB
    ↪ . During the import, the target TiDB cluster can provide service
    ↪ normally.
backend = "local"

### Set the temporary storage directory for the sorted Key-Value files. The
    ↪ directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage, which can use I/O exclusively.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
### The path that stores the snapshot file.
data-source-dir = "${s3_path}" # e.g.: s3://my-bucket/sql-backup

[[mydumper.files]]
### The expression that parses the parquet file.
pattern = '(?i)^(?:[^/]*/)*([a-z0-9_]+)\.([a-z0-9_]+)/(?:[^/]*/)*(?:[a-z0
    ↪ -9\-_.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

If you need to enable TLS in the TiDB cluster, refer to TiDB Lightning Configuration.

6.3.1.2.4 Step 4. Import full data to TiDB

1. Create the tables in the target database using TiDB Lightning:

```
tiup tidb-lightning -config tidb-lightning.toml -d 's3://my-bucket/
    ↪ schema-backup'
```

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a SIGHUP signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

   Pass the SecretKey and AccessKey that have access to the S3 storage path as environment variables to the Dumpling node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After the import starts, you can check the progress of the import by either of the following methods:

   - `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
   - Check progress in the monitoring dashboard.
   - Check progress in the TiDB Lightning web interface.

4. After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If you encounter any problem during the import, refer to TiDB Lightning FAQ for troubleshooting.

6.3.1.3 Replicate incremental data to TiDB (optional)

6.3.1.3.1 Prerequisites

- Install DM.
- Get the source database and target database privileges required for DM.

6.3.1.3.2 Step 1: Create the data source

1. Create the `source1.yaml` file as follows:

```
# Must be unique.
source-id: "mysql-01"
# Configures whether DM-worker uses the global transaction identifier (
    ↪ GTID) to pull binlogs. To enable this mode, the upstream MySQL
    ↪ must also enable GTID. If the upstream MySQL service is
    ↪ configured to switch master between different nodes automatically
    ↪ , GTID mode is required.
enable-gtid: false

from:
  host: "${host}"      # e.g.: 172.16.10.81
  user: "root"
  password: "${password}" # Supported but not recommended to use
      ↪ plaintext password. It is recommended to use `dmctl encrypt` to
      ↪  encrypt the plaintext password before using it.
  port: 3306
```

2. Load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create
    ↪ source1.yaml
```

   The parameters used in the command above are described as follows:

Parameter	Description
--master-addr	The {master-advertise-addr} of any DM-master in the cluster where dmctl is to be connected, e.g.: 172.16.10.71:8261
operate-source	Loads the source, stops the source, or shows the source list.
create	Creates the DM cluster.

6.3.1.3.3 Step 2: Create the migration task

Create the `task1.yaml` file as follows:

```
### Task name. Multiple tasks that are running at the same time must each
    ↪ have a unique name.
name: "test"
### Task mode. Options are:
### - full: only performs full data migration.
```

```
### - incremental: only performs binlog real-time replication.
### - all: full data migration + binlog real-time replication.
task-mode: "incremental"
### The configuration of the target TiDB database.
target-database:
  host: "${host}"               # e.g.: 172.16.10.83
  port: 4000
  user: "root"
  password: "${password}"       # Supported but not recommended to use a
     ↪ plaintext password. It is recommended to use `dmctl encrypt` to
     ↪ encrypt the plaintext password before using it.

### Global configuration for block and allow lists. Each instance can
   ↪ reference the configuration by name.
block-allow-list:                # If the DM version is earlier than v2
   ↪ .0.0-beta.2, use black-white-list.
  listA:                         # Name.
    do-tables:                   # Allow list for the upstream tables to be
       ↪  migrated.
    - db-name: "test_db"         # Name of databases to be migrated.
      tbl-name: "test_table"     # Name of tables to be migrated.

### Configures the data source.
mysql-instances:
  - source-id: "mysql-01"          # Data source ID, i.e., source-id in
     ↪ source1.yaml
    block-allow-list: "listA"      # References the block-allow-list
       ↪ configuration above.
###      syncer-config-name: "global" # Name of the syncer configuration.
    meta:                          # The position where the binlog
       ↪ replication starts when `task-mode` is `incremental` and the
       ↪ downstream database checkpoint does not exist. If the checkpoint
       ↪ exists, the checkpoint is used. If neither the `meta`
       ↪ configuration item nor the downstream database checkpoint exists,
       ↪ the migration starts from the latest binlog position of the
       ↪ upstream.
      binlog-name: "mysql-bin.000004" # The binlog position recorded in "
         ↪ Step 1. Export an Aurora snapshot to Amazon S3". When the
         ↪ upstream database has source-replica switching, GTID mode is
         ↪ required.
      binlog-pos: 109227
      # binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"

### (Optional) If you need to incrementally replicate data that has already
   ↪ been migrated in the full data migration, you need to enable the safe
```

```
  ↪  mode to avoid the incremental data replication error.
# This scenario is common in the following case: the full migration data
   ↪ does not belong to the data source's consistency snapshot, and
   ↪ after that, DM starts to replicate incremental data from a position
   ↪  earlier than the full migration.
# syncers:          # The running configurations of the sync processing
   ↪ unit.
#   global:          # Configuration name.
#     safe-mode: true # If this field is set to true, DM changes INSERT of
   ↪  the data source to REPLACE for the target database, and changes
   ↪ UPDATE of the data source to DELETE and REPLACE for the target
   ↪ database. This is to ensure that when the table schema contains a
   ↪ primary key or unique index, DML statements can be imported
   ↪ repeatedly. In the first minute of starting or resuming an
   ↪ incremental replication task, DM automatically enables the safe
   ↪ mode.
```

The YAML file above is the minimum configuration required for the migration task. For more configuration items, refer to DM Advanced Task Configuration File.

6.3.1.3.4 Step 3. Run the migration task

Before you start the migration task, to reduce the probability of errors, it is recommended to confirm that the configuration meets the requirements of DM by running the `check-task` command:

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

After that, start the migration task by running `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
--master-addr	The {master-advertise-addr} of any DM-master in the cluster where dmctl is to be connected, e.g.: 172.16.10.71:8261
start	Starts the migration task.

If the task fails to start, check the prompt message and fix the configuration. After that, you can re-run the command above to start the task.

If you encounter any problem, refer to DM error handling and DM FAQ.

6.3.1.3.5 Step 4. Check the migration task status

To learn whether the DM cluster has an ongoing migration task and the task status, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to Query Status.

6.3.1.3.6 Step 5. Monitor the task and view logs

To view the history status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when you deployed DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select DM dashboard to view DM-related monitoring metrics.

When DM is running, DM-worker, DM-master, and dmctl print the related information in logs. The log directories of these components are as follows:

- DM-master: specified by the DM-master process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- DM-worker: specified by the DM-worker process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

6.3.1.4 What's next

- Pause the migration task.
- Resume the migration task.
- Stop the migration task.
- Export and import the cluster data source and task configuration.
- Handle failed DDL statements.

6.3.2 Migrate MySQL of Small Datasets to TiDB

This document describes how to use TiDB Data Migration (DM) to migrate MySQL of small datasets to TiDB in the full migration mode and incremental replication mode. "Small datasets" in this document mean data size less than 1 TiB.

The migration speed varies from 30 GB/h to 50 GB/h, depending on multiple factors such as the number of indexes in the table schema, hardware, and network environment.

6.3.2.1 Prerequisites

- Deploy a DM Cluster Using TiUP
- Grant the required privileges for the source database and the target database of DM

6.3.2.2 Step 1. Create the data source

First, create the `source1.yaml` file as follows:

```
### The ID must be unique.
source-id: "mysql-01"
```

```
### Configures whether DM-worker uses the global transaction identifier (
    ↪ GTID) to pull binlogs. To enable GTID, the upstream MySQL must have
    ↪ enabled GTID. If the upstream MySQL has automatic source-replica
    ↪ switching, the GTID mode is required.
enable-gtid: true

from:
  host: "${host}"      # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext password is supported but not
      ↪ recommended. It is recommended to use dmctl encrypt to encrypt the
      ↪ plaintext password before using the password.
  port: 3306
```

Then, load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
`--master-addr`	{advertise-addr} of any DM-master node in the cluster where `dmctl` is to connect. For example, 172.16.10.71:8261.
`operate-source`	Load the source to create the DM cluster.

6.3.2.3 Step 2. Create the migration task

Create the `task1.yaml` file as follows:

```
### Task name. Each of the multiple tasks running at the same time must have a unique name.
name: "test"
```

```
### Task mode. Options are:
### full: only performs full data migration.
### incremental: only performs binlog real-time replication.
### all: full data migration + binlog real-time replication.
task-mode: "all"
### The configuration of the target TiDB database.
target-database:
  host: "${host}"               # For example: 172.16.10.83
  port: 4000
  user: "root"
  password: "${password}"       # Plaintext password is supported but not
     ↪ recommended. It is recommended to use dmctl encrypt to encrypt the
     ↪ plaintext password before using the password.

### The configuration of all MySQL instances of source database required for
   ↪  the current migration task.
mysql-instances:
-
  # The ID of an upstream instance or a replication group
  source-id: "mysql-01"
  # The names of the block list and allow list configuration of the schema
     ↪ name or table name that is to be migrated. These names are used to
     ↪ reference the global configuration of the block and allowlist. For
     ↪ the global configuration, refer to the `block-allow-list`
     ↪ configuration below.
  block-allow-list: "listA"

### The global configuration of blocklist and allowlist. Each instance is
   ↪ referenced by a configuration item name.
block-allow-list:
  listA:                         # name
    do-tables:                   # The allowlist of upstream tables that
       ↪ need to be migrated.
    - db-name: "test_db"         # The schema name of the table to be
       ↪ migrated.
      tbl-name: "test_table"     # The name of the table to be migrated.
```

The above is the minimum task configuration to perform the migration. For more configuration items regarding the task, refer to DM task complete configuration file introduction.

6.3.2.4 Step 3. Start the migration task

To avoid errors, before starting the migration task, it is recommended to use the `check -task` command to check whether the configuration meets the requirements of DM configuration.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Start the migration task by running the following command with `tiup dmctl`.

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
`--master-addr`	`{advertise-addr}` of any DM-master node in the cluster where `dmctl` is to connect. For example: 172.16.10.71:8261.
`start-task`	Start the migration task

If the task fails to start, after changing the configuration according to the returned result,

you can run the `start-task task.yaml` command to restart the task. If you encounter problems, refer to Handle Errors and FAQ.

6.3.2.5 Step 4: Check the migration task status

To learn whether the DM cluster has an ongoing migration task, the task status and some other information, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to Query Status.

6.3.2.6 Step 5. Monitor the task and view logs (optional)

To view the historical status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when deploying DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select the DM dashboard to view DM-related monitoring metrics.

- The log directory of DM-master: specified by the DM-master process parameter `--log-file`. If you have deployd DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- The log directory of DM-worker: specified by the DM-worker process parameter `--log-file`. If you have deployd DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

6.3.2.7 What's next

- Pause the migration task
- Resume the migration task
- Stop the migration task
- Export and import the cluster data source and task configuration
- Handle failed DDL statements

6.3.3 Migrate MySQL of Large Datasets to TiDB

When the data volume to be migrated is small, you can easily use DM to migrate data, both for full migration and incremental replication. However, because DM imports data at a slow speed (30~50 GiB/h), when the data volume is large, the migration might take a long time. "Large datasets" in this document usually mean data around one TiB or more.

This document describes how to migrate large datasets from MySQL to TiDB. The whole migration has two processes:

1. *Full migration*. Use Dumpling and TiDB Lightning to perform the full migration. TiDB Lightning's **local backend** mode can import data at a speed of up to 500 GiB/h.
2. *Incremental replication*. After the full migration is completed, you can replicate the incremental data using DM.

6.3.3.1 Prerequisites

- Install DM.
- Install Dumpling and TiDB Lightning.
- Grant the source database and target database privileges required for DM.
- Grant the target database privileges required for TiDB Lightning.
- Grant the source database privileges required for Dumpling.

6.3.3.2 Resource requirements

Operating system: The example in this document uses fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, `tikv-server`) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU: Because TiDB Lightning consumes high resources, it is recommended to allocate more than 64 GiB of memory and more than 32 CPU cores. To get the best performance, make sure that the CPU core to memory (GiB) ratio is greater than 1:2.

Disk space:

- Dumpling requires a disk space that can store the whole data source (or to store all upstream tables to be exported). SSD is recommended. To calculate the required space, see Downstream storage space requirements.
- During the import, TiDB Lightning needs temporary space to store the sorted key-value pairs. The disk space should be enough to hold the largest single table from the data source.
- If the full data volume is large, you can increase the binlog storage time in the upstream. This is to ensure that the binlogs are not lost during the incremental replication.

Note: It is difficult to calculate the exact data volume exported by Dumpling from MySQL, but you can estimate the data volume by using the following SQL statement to summarize the `data-length` field in the `information_schema.tables` table:

```
/* Calculate the size of all schemas, in MiB. Replace ${schema_name} with
   ↪ your schema name. */
```

```
SELECT table_schema,SUM(data_length)/1024/1024 AS data_length,SUM(
    ↪ index_length)/1024/1024 AS index_length,SUM(data_length+index_length)
    ↪ /1024/1024 AS SUM FROM information_schema.tables WHERE table_schema =
    ↪  "${schema_name}" GROUP BY table_schema;

/* Calculate the size of the largest table, in MiB. Replace ${schema_name}
    ↪  with your schema name. */
SELECT table_name,table_schema,SUM(data_length)/1024/1024 AS data_length,
    ↪ SUM(index_length)/1024/1024 AS index_length,SUM(data_length+
    ↪ index_length)/1024/1024 AS SUM from information_schema.tables WHERE
    ↪ table_schema = "${schema_name}" GROUP BY table_name,table_schema
    ↪ ORDER BY SUM DESC LIMIT 5;
```

6.3.3.2.1 Disk space for the target TiKV cluster

The target TiKV cluster must have enough disk space to store the imported data. In addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has `x 2` because:

- Index might take extra space.
- RocksDB has a space amplification effect.

6.3.3.3 Step 1. Export all data from MySQL

1. Export all data from MySQL by running the following command:

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MiB -B
    ↪ my_db1 -f 'my_db1.table[12]' -o 's3://my-bucket/sql-backup'
```

Dumpling exports data in SQL files by default. You can specify a different file format by adding the `--filetype` option.

The parameters used above are as follows. For more Dumpling parameters, refer to Dumpling Overview.

parameter	description
-	MySQL
↪ user	
↪	
or	
--	
↪ user	
↪	

parameter	Description
- --password or --password	MySQL user password
- -P or --port	MySQL port
- -H or --host	MySQL HP address
- -t or --thread	The number of threads for export

parameter	Description
-o, --output-dir	The directory that stores the exported file. Supports a local path or an external storage URL
-r, --row-number	The maximum number of rows in a single file

parameter	Description
`-F`	The maximum size of a single file, in MiB. Recommended value: 256 MiB.
`-B` or `--database`	Specifies a database to be exported
`-f`	Exports tables that match the filter pattern. Refer to table-filter for the syntax.

Make sure `${data-path}` has the space to store all exported upstream tables. To calculate the required space, see Downstream storage space requirements. To prevent the export from being interrupted by a large table consuming all the spaces, it is strongly recommended to use the `-F` option to limit the size of a single file.

2. View the `metadata` file in the `${data-path}` directory. This is a Dumpling-generated metadata file. Record the binlog position information, which is required for the incremental replication in Step 3.

```
SHOW MASTER STATUS:
Log: mysql-bin.000004
Pos: 109227
GTID:
```

6.3.3.4 Step 2. Import full data to TiDB

1. Create the `tidb-lightning.toml` configuration file:

```
[lightning]
# log.
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the
    ↪ target TiDB cluster cannot provide any service.
# "tidb": The "tidb" backend is recommended to import data less than 1
    ↪ TiB. During the import, the target TiDB cluster can provide
    ↪ service normally. For more information on the backends, refer to
    ↪ https://docs.pingcap.com/tidb/stable/tidb-lightning-backends.
backend = "local"
# Sets the temporary storage directory for the sorted Key-Value files.
    ↪ The directory must be empty, and the storage space must be
    ↪ greater than the size of the dataset to be imported. For better
    ↪ import performance, it is recommended to use a directory
    ↪ different from `data-source-dir` and use flash storage, which can
    ↪  use I/O exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
# The data source directory. The same directory where Dumpling exports
    ↪ data in "Step 1. Export all data from MySQL".
data-source-dir = "${data-path}" # A local path or S3 path. For example
    ↪ , 's3://my-bucket/sql-backup'.
```

```
[tidb]
# The target TiDB cluster information.
host = ${host}             # e.g.: 172.16.32.1
port = ${port}             # e.g.: 4000
user = "${user_name}"      # e.g.: "root"
password = "${password}"   # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs
    ↪ to obtain the table schema information from the TiDB status port.
    ↪  e.g.: 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD
    ↪ . When backend = "local", you must specify status-port and pd-
    ↪ addr correctly. Otherwise, the import will be abnormal.
```

For more information on TiDB Lightning configuration, refer to TiDB Lightning Configuration.

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a SIGHUP signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

   If you import data from S3, pass the SecretKey and AccessKey that have access to the S3 storage path as environment variables to the TiDB Lightning node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After the import starts, you can check the progress of the import by one of the following methods:

   - `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
   - Check progress in the monitoring dashboard.
   - Check progress in the TiDB Lightning web interface.

4. After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

Note:

Whether the import is successful or not, the last line of the log shows `tidb lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

6.3.3.5 Step 3. Replicate incremental data to TiDB

6.3.3.5.1 Add the data source

1. Create a `source1.yaml` file as follows:

```
# Must be unique.
source-id: "mysql-01"

# Configures whether DM-worker uses the global transaction identifier (
    ↪ GTID) to pull binlogs. To enable this mode, the upstream MySQL
    ↪ must also enable GTID. If the upstream MySQL service is
    ↪ configured to switch master between different nodes automatically
    ↪ , GTID mode is required.
enable-gtid: true

from:
  host: "${host}"        # e.g.: 172.16.10.81
  user: "root"
  password: "${password}" # Supported but not recommended to use a
      ↪ plaintext password. It is recommended to use `dmctl encrypt` to
      ↪  encrypt the plaintext password before using it.
  port: 3306
```

2. Load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create
    ↪ source1.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
--master-addr	The {master-addr} of any DM-master in the cluster where dmctl is to be connected, e.g.: 172.16.10.71:8261
operate-source	Loads the source configuration to the DM cluster.

6.3.3.5.2 Add a replication task

1. Edit the `task.yaml` file. Configure the incremental replication mode and the starting point of each data source:

```
name: task-test                     # Task name. Must be globally unique.
task-mode: incremental              # Task mode. The "incremental" mode
    ↪ only performs incremental data replication.
```

```
# Configures the target TiDB database.
target-database:                # The target database instance.
  host: "${host}"               # e.g.: 127.0.0.1
  port: 4000
  user: "root"
  password: "${password}"       # It is recommended to use `dmctl
     ↪ encrypt` to encrypt the plaintext password before using it.

# Use block and allow lists to specify the tables to be replicated.
block-allow-list:               # The collection of filtering rules
   ↪ that matches the tables in the source database instance. If the
   ↪ DM version is earlier than v2.0.0-beta.2, use black-white-list.
  bw-rule-1:                    # The block-allow-list configuration
     ↪ item ID.
    do-dbs: ["${db-name}"]      # Name of databases to be replicated.

# Configures the data source.
mysql-instances:
  - source-id: "mysql-01"       # Data source ID, i.e., source-id in
     ↪ source1.yaml
    block-allow-list: "bw-rule-1" # You can use the block-allow-list
       ↪ configuration above.
    # syncer-config-name: "global" # You can use the syncers
       ↪ incremental data configuration below.
    meta:                       # The position where the binlog
       ↪ replication starts when `task-mode` is `incremental` and the
       ↪ downstream database checkpoint does not exist. If the
       ↪ checkpoint exists, the checkpoint is used. If neither the `
       ↪ meta` configuration item nor the downstream database
       ↪ checkpoint exists, the migration starts from the latest
       ↪ binlog position of the upstream.
      # binlog-name: "mysql-bin.000004" # The binlog position recorded
         ↪ in "Step 1. Export all data from MySQL". If the upstream
         ↪ database service is configured to switch master between
         ↪ different nodes automatically, GTID mode is required.
      # binlog-pos: 109227
      binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"

# (Optional) If you need to incrementally replicate data that has
   ↪ already been migrated in the full data migration, you need to
   ↪ enable the safe mode to avoid the incremental data replication
   ↪ error.
# This scenario is common in the following case: the full migration
   ↪ data does not belong to the data source's consistency snapshot,
```

```
    ↪ and after that, DM starts to replicate incremental data from a
    ↪ position earlier than the full migration.
# syncers:          # The running configurations of the sync processing
    ↪ unit.
#   global:         # Configuration name.
#     safe-mode: true # If this field is set to true, DM changes INSERT
    ↪ of the data source to REPLACE for the target database, and
    ↪ changes UPDATE of the data source to DELETE and REPLACE for the
    ↪ target database. This is to ensure that when the table schema
    ↪ contains a primary key or unique index, DML statements can be
    ↪ imported repeatedly. In the first minute of starting or resuming
    ↪ an incremental replication task, DM automatically enables the
    ↪ safe mode.
```

The YAML above is the minimum configuration required for the migration task. For more configuration items, refer to DM Advanced Task Configuration File.

Before you start the migration task, to reduce the probability of errors, it is recommended to confirm that the configuration meets the requirements of DM by running the `check-task` command:

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

2. Start the migration task by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
--master-addr {advertise-addr}	The advertise-addr of any DM-master in the cluster where dmctl is to be connected, e.g.: 172.16.10.71:8261
start	Starts the task

If the task fails to start, check the prompt message and fix the configuration. After that, you can re-run the command above to start the task.

If you encounter any problem, refer to DM error handling and DM FAQ.

6.3.3.5.3 Check the migration task status

To learn whether the DM cluster has an ongoing migration task and view the task status, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to Query Status.

6.3.3.5.4 Monitor the task and view logs

To view the history status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when you deployed DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select DM dashboard to view DM-related monitoring metrics.

When DM is running, DM-worker, DM-master, and dmctl print the related information in logs. The log directories of these components are as follows:

- DM-master: specified by the DM-master process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- DM-worker: specified by the DM-worker process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

6.3.3.6 What's next

- Pause a Data Migration Task
- Resume a Data Migration Task
- Stop a Data Migration Task
- Export and Import Data Sources and Task Configuration of Clusters
- Handle Failed DDL Statements

6.3.4 Migrate and Merge MySQL Shards of Small Datasets to TiDB

If you want to migrate and merge multiple MySQL database instances upstream to one TiDB database downstream, and the amount of data is not too large, you can use DM to migrate MySQL shards. "Small datasets" in this document usually mean data around or less than one TiB. Through examples in this document, you can learn the operation steps, precautions, and troubleshooting of the migration.

This document applies to migrating MySQL shards less than 1 TiB in total. If you want to migrate MySQL shards with a total of more than 1 TiB of data, it will take a long time to migrate only using DM. In this case, it is recommended that you follow the operation introduced in Migrate and Merge MySQL Shards of Large Datasets to TiDB to perform migration.

This document takes a simple example to illustrate the migration procedure. The MySQL shards of the two data source MySQL instances in the example are migrated to the downstream TiDB cluster.

In this example, both MySQL Instance 1 and MySQL Instance 2 contain the following schemas and tables. In this example, you migrate and merge tables from `store_01` and `store_02` schemas with a `sale` prefix in both instances, into the downstream `sale` table in the `store` schema.

Schema	Table
store_01	sale_01, sale_02
store_02	sale_01, sale_02

Target schemas and tables:

Schema	Table
store	sale

6.3.4.1 Prerequisites

Before starting the migration, make sure you have completed the following tasks:

- Deploy a DM Cluster Using TiUP
- Privileges required by DM-worker

6.3.4.1.1 Check conflicts for the sharded tables

If the migration involves merging data from different sharded tables, primary key or unique index conflicts may occur during the merge. Therefore, before migration, you need to take a deep look at the current sharding scheme from the business point of view, and find a way to avoid the conflicts. For more details, see Handle conflicts between primary keys or unique indexes across multiple sharded tables. The following is a brief description.

In this example, `sale_01` and `sale_02` have the same table structure as follows

```
CREATE TABLE `sale_01` (
  `id` bigint(20) NOT NULL AUTO_INCREMENT,
  `sid` bigint(20) NOT NULL,
  `pid` bigint(20) NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

The `id` column is the primary key, and the `sid` column is the sharding key. The `id` column is auto-incremental, and duplicated multiple sharded table ranges will cause data conflicts. The `sid` can ensure that the index is globally unique, so you can follow the steps in Remove the primary key attribute of the auto-increment primary key to bypasses the `id` column.

```
CREATE TABLE `sale` (
  `id` bigint(20) NOT NULL,
  `sid` bigint(20) NOT NULL,
  `pid` bigint(20) NOT NULL,
```

```
  `comment` varchar(255) DEFAULT NULL,
  INDEX (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

6.3.4.2 Step 1. Load data sources

Create a new data source file called `source1.yaml`, which configures an upstream data source into DM, and add the following content:

```
### Configuration.
source-id: "mysql-01" # Must be unique.
### Specifies whether DM-worker pulls binlogs with GTID (Global Transaction
    ↪ Identifier).
### The prerequisite is that you have already enabled GTID in the upstream
    ↪ MySQL.
### If you have configured the upstream database service to switch master
    ↪ between different nodes automatically, you must enable GTID.
enable-gtid: true
from:
  host: "${host}"        # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext passwords are supported but not
      ↪ recommended. It is recommended that you use dmctl encrypt to encrypt
      ↪  plaintext passwords.
  port: ${port}          # For example: 3306
```

Run the following command in a terminal. Use `tiup dmctl` to load the data source configuration into the DM cluster:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml
```

The parameters are described as follows.

Parameter	Description
--	{
master-addr	advertise addr of any DM-master node in the cluster that dmctl connects to. For example: 172.16.10.71:8261
operate-source	Loads, shows, or stops data sources to the cluster. create: loads data sources to the DM clusters.

Repeat the above steps until all data sources are added to the DM cluster.

6.3.4.3 Step 2. Configure the migration task

Create a task configuration file named `task1.yaml` and writes the following content to it:

```
name: "shard_merge"           # The name of the task. Should be globally
    ↪ unique.
```

```
### Task mode. You can set it to the following:
### - full: Performs only full data migration (incremental replication is
    ↪ skipped)
### - incremental: Only performs real-time incremental replication using
    ↪ binlog. (full data migration is skipped)
### - all: Performs both full data migration and incremental replication.
    ↪ For migrating small to medium amount of data here, use this option.
task-mode: all
### Required for the MySQL shards. By default, the "pessimistic" mode is
    ↪ used.
### If you have a deep understanding of the principles and usage limitations
    ↪  of the optimistic mode, you can also use the "optimistic" mode.
### For more information, see [Merge and Migrate Data from Sharded Tables](
    ↪ https://docs.pingcap.com/tidb/dev/feature-shard-merge/)
shard-mode: "pessimistic"
meta-schema: "dm_meta"                  # A schema will be created in the
    ↪ downstream database to store the metadata
ignore-checking-items: ["auto_increment_ID"] # In this example, there are
    ↪ auto-incremental primary keys upstream, so you do not need to check
    ↪ this item.

target-database:
  host: "${host}"                       # For example: 192.168.0.1
  port: 4000
  user: "root"
  password: "${password}"               # Plaintext passwords are supported
      ↪  but not recommended. It is recommended that you use dmctl encrypt
      ↪ to encrypt plaintext passwords.

mysql-instances:
  -
    source-id: "mysql-01"                               # ID of the data
        ↪ source, which is source-id in source1.yaml
    route-rules: ["sale-route-rule"]                    # Table route rules
        ↪ applied to the data source
    filter-rules: ["store-filter-rule", "sale-filter-rule"] # Binlog event
        ↪ filter rules applied to the data source
    block-allow-list: "log-bak-ignored"                 # Block & Allow Lists
        ↪ rules applied to the data source
  -
    source-id: "mysql-02"
    route-rules: ["sale-route-rule"]
    filter-rules: ["store-filter-rule", "sale-filter-rule"]
    block-allow-list: "log-bak-ignored"
```

```
### Configurations for merging MySQL shards
routes:
  sale-route-rule:
    schema-pattern: "store_*"                          # Merge schemas
       ↪ store_01 and store_02 to the store schema in the downstream
    table-pattern: "sale_*"                            # Merge tables sale_01
       ↪ and sale_02 of schemas store_01 and store_02 to the sale table in
       ↪ the downstream
    target-schema: "store"
    target-table: "sale"
    # Optional. Used for extracting the source information of sharded
       ↪ schemas and tables and writing the information to the user-defined
       ↪  columns in the downstream. If these options are configured, you
       ↪ need to manually create a merged table in the downstream. For
       ↪ details, see the following table routing setting.
    # extract-table:                                   # Extracts and writes
       ↪ the table name suffix without the sale_ part to the c-table column
       ↪  of the merged table. For example, 01 is extracted and written to
       ↪ the c-table column for the sharded table sale_01.
    #   table-regexp: "sale_(.*)"
    #   target-column: "c_table"
    # extract-schema:                                  # Extracts and writes
       ↪ the schema name suffix without the store_ part to the c_schema
       ↪ column of the merged table. For example, 02 is extracted and
       ↪ written to the c_schema column for the sharded schema store_02.
    #   schema-regexp: "store_(.*)"
    #   target-column: "c_schema"
    # extract-source:                                  # Extracts and writes
       ↪ the source instance information to the c_source column of the
       ↪ merged table. For example, mysql-01 is extracted and written to
       ↪ the c_source column for the data source mysql-01.
    #   source-regexp: "(.*)"
    #   target-column: "c_source"

### Filters out some DDL events.
filters:
  sale-filter-rule:       # Filter name.
    schema-pattern: "store_*" # The binlog events or DDL SQL statements of
       ↪ upstream MySQL instance schemas that match schema-pattern are
       ↪ filtered by the rules below.
    table-pattern: "sale_*" # The binlog events or DDL SQL statements of
       ↪ upstream MySQL instance tables that match table-pattern are
       ↪ filtered by the rules below.
    events: ["truncate table", "drop table", "delete"] # The binlog event
       ↪ array.
```

```
    action: Ignore                                    # The string (`Do`/`Ignore
       ↪ `). `Do` is the allow list. `Ignore` is the block list.
  store-filter-rule:
    schema-pattern: "store_*"
    events: ["drop database"]
    action: Ignore

### Block and allow list
block-allow-list:       # filter or only migrate all operations of some
    ↪ databases or some tables.
  log-bak-ignored:      # Rule name.
    do-dbs: ["store_*"]  # The allow list of the schemas to be migrated,
       ↪ similar to replicate-do-db in MySQL.
```

The above example is the minimum configuration to perform the migration task. For more information, see DM Advanced Task Configuration File.

For more information on `routes`, `filters` and other configurations in the task file, see the following documents:

- Table routing
- Block & Allow Table Lists
- Binlog event filter
- Filter Certain Row Changes Using SQL Expressions

6.3.4.4 Step 3. Start the task

Before starting a migration task, run the `check-task` subcommand in `tiup dmctl` to check whether the configuration meets the requirements of DM so as to avoid possible errors.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Run the following command in `tiup dmctl` to start a migration task:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

Parameter	Description
`--master-addr`	`{advertise-addr}` of any DM-master node in the cluster that `dmctl` connects to. For example: `172.16.10.71:8261`
`start-task`	Starts the task.

If the migration task fails to start, modify the configuration information according to the error information, and then run `start-task task.yaml` again to start the migration task. If you encounter problems, see Handle Errors and FAQ.

6.3.4.5 Step 4. Check the task

After starting the migration task, you can use `dmtcl tiup` to run `query-status` to view the status of the task.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

If you encounter errors, use `query-status ${task-name}` to view more detailed information. For details about the query results, task status and sub task status of the `query-status` command, see TiDB Data Migration Query Status.

6.3.4.6 Step 5. Monitor tasks and check logs (optional)

You can view the history of a migration task and internal operational metrics through Grafana or logs.

- Via Grafana

  If Prometheus, Alertmanager, and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. Specifically, enter the IP address and port specified during deployment in Grafana and select the DM dashboard.

- Via logs

  When DM is running, DM-master, DM-worker, and dmctl output logs, which includes information about migration tasks. The log directory of each component is as follows.

  - DM-master log directory: It is specified by the DM-master process parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/`.
  - DM-worker log directory: It is specified by the DM-worker process parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/`.

- Handle Performance Issues
- FAQ

6.3.5 Migrate and Merge MySQL Shards of Large Datasets to TiDB

If you want to migrate a large MySQL dataset (for example, more than 1 TiB) from different partitions into TiDB, and you are able to suspend all the TiDB cluster write operations from your business during the migration, you can use TiDB Lightning to do the

migration quickly. After migration, you can also use TiDB DM to perform incremental replication according to your business needs. "Large datasets" in this document usually mean data around one TiB or more.

This document uses an example to walk through the whole procedure of such kind of migration.

If the data size of the MySQL shards is less than 1 TiB, you can follow the procedure described in Migrate and Merge MySQL Shards of Small Datasets to TiDB, which supports both full and incremental migration and the steps are easier.

The example in this document assumes that you have two databases, `my_db1` and `my_db2`. You use Dumpling to export two tables `table1` and `table2` from `my_db1`, and two tables `table3` and `table4` from `my_db2`, respectively. After that, you use TiDB Lightning to import and merge the four exported tables into the same `table5` from `mydb` in the target TiDB.

In this document, you can migrate data following this procedure:

1. Use Dumpling to export full data. In this example, you export 2 tables respectively from 2 upstream databases:

    - Export `table1` and `table2` from `my_db1`
    - Export `table3` and `table4` from `my_db2`

2. Start TiDB Lightning to migrate data to `mydb.table5` in TiDB.

3. (Optional) Use TiDB DM to perform incremental replication.

6.3.5.1 Prerequisites

Before getting started, see the following documents to prepare for the migration task.

- Deploy a DM Cluster Using TiUP
- Use TiUP to Deploy Dumpling and Lightning
- Downstream privilege requirements for Dumpling
- Downstream privilege requirements for TiDB Lightning
- Downstream storage space for TiDB Lightning
- Privileges required by DM-worker

6.3.5.1.1 Check conflicts for Sharded Tables

If the migration involves merging data from different sharded tables, primary key or unique index conflicts may occur during the merge. Therefore, before migration, you need to take a deep look at the current sharding scheme from the business point of view, and find a way to avoid conflicts. For more details, see Handle conflicts between primary keys or unique indexes across multiple sharded tables. The following is a brief description.

Assume that tables 1~4 have the same table structure as follows.

```
CREATE TABLE `table1` (
  `id` bigint(20) NOT NULL AUTO_INCREMENT,
  `sid` bigint(20) NOT NULL,
  `pid` bigint(20) NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

For those four tables, the `id` column is the primary key. It is auto-incremental, which will cause different sharded tables to generate duplicated `id` ranges and cause the primary key conflict on the target table during the migration. On the other hand, the `sid` column is the sharding key, which ensures that the index is unique globally. So you can remove the unique constraint of the `id` column in the target `table5` to avoid the data merge conflicts.

```
CREATE TABLE `table5` (
  `id` bigint(20) NOT NULL,
  `sid` bigint(20) NOT NULL,
  `pid` bigint(20) NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  INDEX (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

6.3.5.2 Step1. Use Dumpling to export full data

If those multiple sharded tables to be exported are in the same upstream MySQL instance, you can directly use the `-f` parameter of Dumpling to export them in a single operation.

If the sharded tables are stored in different MySQL instances, you can use Dumpling to export them respectively and place the exported results in the same parent directory.

In the following example, both methods are used, and then the exported data is stored in the same parent directory.

First, run the following command to use Dumpling to export `table1` and `table2` from `my_db1`:

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MB -B my_db1 -f
    ↪  'my_db1.table[12]' -o ${data-path}/my_db1
```

The following table describes parameters in the command above. For more information about Dumpling parameters, see Dumpling Overview.

Parameter Description
-u Specifies the user name to use if user is used.
-p Specifies the password to use if password is used.
-P Specifies the port to be used.
-h Specifies the IP address of the data source.

Parameter	Description
-t or --thread	Specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and increases the database's memory consumption. Therefore, it is not recommended to set the number too large. The default value is 4.

Parameter	Description
`-d` or `--output-dir`	Specifies the export output directory of the storage, which supports a local file path or an external storage URL.

Parameter	Description
-r or --row	Specifies the maximum row number of rows in a single file. If you use this parameter, Dumpling enables the in-table concurrency to speed up the export and reduce the memory usage.

Parameter	Description
`--max-file-size`	Specifies the maximum size of a single file. The unit is `MiB`. It is recommended to keep the value to 256 MiB.
`--databases` or `--database`	Specifies databases to be exported

Parameter	Description
-f or --filter	Exports tables that match the filter pattern. For the filter syntax, see table-filter.

Ensure that there is enough free space in `${data-path}`. It is strongly recommended to use the `-F` option to avoid interruptions in the backup process due to oversized single tables.

Then, run the following command to use Dumpling to export `table3` and `table4` from `my_db2`. Note that the path is `${data-path}/my_db2` instead of `${data-path}/my_db1`.

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MB -B my_db2 -f
    ↪  'my_db2.table[34]' -o ${data-path}/my_db2
```

After the preceding procedures, all source data tables are now exported to the `${data-path}` directory. Putting all the exported data on the same directory makes subsequent import by TiDB Lightning convenient.

The starting position information needed for incremental replication is in the `metadata` files in `my_db1` and `my_db2` sub-directories of `${data-path}` directory respectively. They are meta-information files automatically generated by Dumpling. To perform incremental replication, you need to record the binlog locations information in these files.

6.3.5.3 Step 2. Start TiDB Lightning to import full exported data

Before starting TiDB Lightning for migration, it is recommended that you understand how to handle checkpoints, and then choose the appropriate way to proceed according to your needs.

6.3.5.3.1 Checkpoints

Migrating a large volume of data usually takes hours or even days. There is a certain chance that the long-running process is interrupted unexpectedly. It can be very frustrating to redo everything from scratch, even if some part of data has already been imported.

Fortunately, TiDB Lightning provides a feature called `checkpoints`, which makes TiDB Lightning save the import progress as `checkpoints` from time to time, so that an interrupted import task can be resumed from the latest checkpoint upon restart.

If the TiDB Lightning task crashes due to unrecoverable errors (for example, data corruption), it will not pick up from the checkpoint, but will report an error and quit the task. To ensure the safety of the imported data, you must resolve these errors by using the `tidb-lightning-ctl` command before proceeding with other steps. The options include:

- –checkpoint-error-destroy: This option allows you to restart importing data into failed target tables from scratch by destroying all the existing data in those tables first.
- –checkpoint-error-ignore: If migration has failed, this option clears the error status as if no errors ever happened.
- –checkpoint-remove: This option simply clears all checkpoints, regardless of errors.

For more information, see TiDB Lightning Checkpoints.

6.3.5.3.2 Create a target schema

Create `mydb.table5` at downstream.

```
CREATE TABLE `table5` (
  `id` bigint(20) NOT NULL,
  `sid` bigint(20) NOT NULL,
  `pid` bigint(20) NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  INDEX (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

6.3.5.3.3 Start the migration task

Follow these steps to start `tidb-lightning`:

1. Edit the toml file. `tidb-lightning.toml` is used in the following example:

```
[lightning]
# Logs
level = "info"
file = "tidb-lightning.log"
```

```
[mydumper]
data-source-dir = ${data-path}

[tikv-importer]
# Choose a local backend.
# "local": The default mode. It is used for large data volumes greater
    ↪ than 1 TiB. During migration, downstream TiDB cannot provide
    ↪ services.
# "tidb": Used for data volumes less than 1 TiB. During migration,
    ↪ downstream TiDB can provide services normally.
# For more information, see [TiDB Lightning Backends](https://docs.
    ↪ pingcap.com/tidb/stable/tidb-lightning-backends)
backend = "local"
# Set the temporary directory for the sorted key value pairs. It must
    ↪ be empty.
# The free space must be greater than the size of the dataset to be
    ↪ imported.
# It is recommended that you use a directory different from `data-
    ↪ source-dir` to get better migration performance by consuming I/O
    ↪ resources exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

# Set the renaming rules ('routes') from source to target tables, in
    ↪ order to support merging different table shards into a single
    ↪ target table. Here you migrate `table1` and `table2` in `my_db1`,
    ↪  and `table3` and `table4` in `my_db2`, to the target `table5` in
    ↪  downstream `my_db`.
[[mydumper.files]]
pattern = '(^|/)my_db1\.table[1-2]\..*\.sql$'
schema = "my_db"
table = "table5"
type = "sql"

[[mydumper.files]]
pattern = '(^|/)my_db2\.table[3-4]\..*\.sql$'
schema = "my_db"
table = "table5"
type = "sql"

# Information of the target TiDB cluster. For example purposes only.
    ↪ Replace the IP address with your IP address.
[tidb]
# Information of the target TiDB cluster.
# Values here are only for illustration purpose. Replace them with your
    ↪  own values.
```

```
host = ${host}        # For example: "172.16.31.1"
port = ${port}        # For example: 4000
user = "${user_name}" # For example: "root"
password = "${password}" # For example: "rootroot"
status-port = ${status-port} # The table information is read from the
    ↪ status port. For example: 10080
# the IP address of the PD cluster. TiDB Lightning gets some
    ↪ information through the PD cluster.
# For example: "172.16.31.3:2379".
# When backend = "local", make sure that the values of status-port and
    ↪ pd-addr are correct. Otherwise an error will occur.
pd-addr = "${ip}:${port}"
```

2. Run `tidb-lightning`. If you run the program by directly invoking the program name in a shell, the process may quit unexpectedly after receiving a SIGHUP signal. It is recommended that you run the program using tools such as `nohup` or `screen` or `tiup`, and put the process to the shell background. If you migrate from S3, the SecretKey and AccessKey of the account that has access to the Amazon S3 backend store needs to be passed into the Lightning node as environment variables. Reading credential files from `~/.aws/credentials` is also supported. For example:

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After starting the migration task, you can check the progress by using either of the following methods:

- Use `grep` tool to search the keyword `progress` in the log. By default, a message reporting the progress is flushed into the log file every 5 minutes.
- View progress via the monitoring dashboard. For more information, see TiDB Lightning Monitoring.
- View the progress via the Web page. See Web Interface.

After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

Note:

> Whether the migration is successful or not, the last line in the log will always be `tidb lightning exit`. It just means that TiDB Lightning quits normally, and does not guarantee that the importing task is completed successfully.

If you encounter any problems during migration, see TiDB Lightning FAQs.

6.3.5.4 Step 3. (Optional) Use DM to perform incremental replication

To replicate the data changes based on binlog from a specified position in the source database to TiDB, you can use TiDB DM to perform incremental replication.

6.3.5.4.1 Add the data source

Create a new data source file called `source1.yaml`, which configures an upstream data source into DM, and add the following content:

```
### Configuration.
source-id: "mysql-01" # Must be unique.

### Specifies whether DM-worker pulls binlogs with GTID (Global Transaction
    ↪ Identifier).
### The prerequisite is that you have already enabled GTID in the upstream
    ↪ MySQL.
### If you have configured the upstream database service to switch master
    ↪ between different nodes automatically, you must enable GTID.
enable-gtid: true

from:
  host: "${host}"        # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext passwords are supported but not
      ↪ recommended. It is recommended that you use dmctl encrypt to encrypt
      ↪  plaintext passwords.
  port: ${port}          # For example: 3306
```

Run the following command in a terminal. Use `tiup dmctl` to load the data source configuration into the DM cluster:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml
```

The parameters are described as follows.

Parameter	Description
--{advertise-master-addr}	The address of DM-master node in the cluster that dmctl connects to. For example: 172.16.10.71:8261
operate-source	Load data sources to DM clusters.

Repeat the above steps until all MySQL upstream instances are added to the DM as data sources.

6.3.5.4.2 Create a replication task

Edit a task configuration file called `task.yaml`, to configure the incremental replication mode and replication starting point for each data source.

```
name: task-test           # The name of the task. Should be globally unique
  ↪ .
task-mode: incremental    # The mode of the task. "incremental" means full
  ↪ data migration is skipped and only incremental replication is
  ↪ performed.
```

```
### Required for incremental replication from sharded tables. By default,
   ↪ the "pessimistic" mode is used.
### If you have a deep understanding of the principles and usage limitations
   ↪  of the optimistic mode, you can also use the "optimistic" mode.
### For more information, see [Merge and Migrate Data from Sharded Tables](
   ↪ https://docs.pingcap.com/zh/tidb/dev/feature-shard-merge/).

shard-mode: "pessimistic"

### Configure the access information of the target TiDB database instance:
target-database:          # The target database instance
  host: "${host}"         # For example: 127.0.0.1
  port: 4000
  user: "root"
  password: "${password}" # It is recommended to use a dmctl encrypted
     ↪ password.

### Use block-allow-list to configure tables that require sync:
block-allow-list:         # The set of filter rules on matching tables in
   ↪ the data sources, to decide which tables need to migrate and which
   ↪ not. Use the black-white-list if the DM version is earlier than or
   ↪ equal to v2.0.0-beta.2.
  bw-rule-1:              # The ID of the block and allow list rule.
    do-dbs: ["my_db1"]    # The databases to be migrated. Here, my_db1 of
       ↪ instance 1 and my_db2 of instance 2 are configured as two separate
       ↪  rules to demonstrate how to prevent my_db2 of instance 1 from
       ↪ being replicated.
  bw-rule-2:
    do-dbs: ["my_db2"]
routes:                           # Table renaming rules ('routes') from
   ↪ upstream to downstream tables, in order to support merging different
   ↪ sharded table into a single target table.
  route-rule-1:                   # Rule name. Migrate and merge table1 and
     ↪ table2 from my_db1 to the downstream my_db.table5.
    schema-pattern: "my_db1"      # Rule for matching upstream schema names.
       ↪  It supports the wildcards "*" and "?".
    table-pattern: "table[1-2]"   # Rule for matching upstream table names.
       ↪ It supports the wildcards "*" and "?".
    target-schema: "my_db"        # Name of the target schema.
    target-table: "table5"        # Name of the target table.
  route-rule-2:                   # Rule name. Migrate and merge table3 and
     ↪ table4 from my_db2 to the downstream my_db.table5.
    schema-pattern: "my_db2"
    table-pattern: "table[3-4]"
    target-schema: "my_db"
```

```
    target-table: "table5"

### Configure data sources. The following uses two data sources as an
    ↪ example.
mysql-instances:
  - source-id: "mysql-01"         # Data source ID. It is the source-id in
      ↪ source1.yaml.
    block-allow-list: "bw-rule-1" # Use the block and allow list
       ↪ configuration above. Replicate `my_db1` in instance 1.
    route-rules: ["route-rule-1"] # Use the configured routing rule above to
       ↪  merge upstream tables.
###      syncer-config-name: "global" # Use the syncers configuration below.
    meta:                         # The position where the binlog
       ↪ replication starts when `task-mode` is `incremental` and the
       ↪ downstream database checkpoint does not exist. If the checkpoint
       ↪ exists, the checkpoint is used. If neither the `meta`
       ↪ configuration item nor the downstream database checkpoint exists,
       ↪ the migration starts from the latest binlog position of the
       ↪ upstream.
      binlog-name: "${binlog-name}" # The log location recorded in ${data-
         ↪ path}/my_db1/metadata in Step 1. You can either specify binlog-
         ↪ name + binlog-pos or binlog-gtid. When the upstream database
         ↪ service is configured to switch master between different nodes
         ↪ automatically, use binlog GTID here.
      binlog-pos: ${binlog-position}
      # binlog-gtid:              " For example: 09bec856-ba95-11ea-850a-58
         ↪ f2b4af5188:1-9"
  - source-id: "mysql-02"         # Data source ID. It is the source-id in
      ↪ source1.yaml.
    block-allow-list: "bw-rule-2" # Use the block and allow list
       ↪ configuration above. Replicate `my_db2` in instance2.
    route-rules: ["route-rule-2"] # Use the routing rule configured above.

###      syncer-config-name: "global" # Use the syncers configuration below.
    meta:                         # The migration starting point of binlog
       ↪ when task-mode is incremental and there is no checkpoint in the
       ↪ downstream database. If there is a checkpoint, the checkpoint will
       ↪  be used.
      # binlog-name: "${binlog-name}" # The log location recorded in ${data-
         ↪ path}/my_db2/metadata in Step 1. You can either specify binlog-
         ↪ name + binlog-pos or binlog-gtid. When the upstream database
         ↪ service is configured to switch master between different nodes
         ↪ automatically, use binlog GTID here.
      # binlog-pos: ${binlog-position}
      binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"
```

```
### (Optional) If you need to incrementally replicate some data changes that
    ↪  have been covered in the full migration, you need to enable the safe
    ↪  mode to avoid data migration errors during incremental replication.
### This scenario is common when the fully migrated data is not part of a
    ↪ consistent snapshot of the data source, and the incremental data is
    ↪ replicated from a location earlier than the fully migrated data.
### syncers:         # The running parameters of the sync processing unit.
### global:          # Configuration name.
### If set to true, DM changes INSERT to REPLACE, and changes UPDATE to a
    ↪ pair of DELETE and REPLACE for data source replication operations.
### Thus, it can apply DML repeatedly during replication when primary keys
    ↪ or unique indexes exist in the table structure.
### TiDB DM automatically starts safe mode within 1 minute before starting
    ↪ or resuming an incremental replication task.
###   safe-mode: true
```

For more configurations, see DM Advanced Task Configuration File.

Before you start the data migration task, it is recommended to use the `check-task` ↪ subcommand in `tiup dmctl` to check if the configuration meets the DM configuration requirements.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Use `tiup dmctl` to run the following command to start the data migration task.

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters in this command are described as follows.

Parameter	Description
–master-addr	{advertise-addr} address of any DM-master node in the cluster that dmctl connects to. For example: 172.16.10.71:8261
start-task	Starts the data migration task.

If the task fails to start, first make configuration changes according to the prompt messages from the returned result, and then run the `start-task task.yaml` subcommand in `tiup dmctl` to restart the task. If you encounter problems, see Handle Errors and TiDB Data Migration FAQ.

6.3.5.4.3 Check the migration status

You can check if there are running migration tasks in the DM cluster and their status by running the `query-status` command in `tiup dmctl`.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For more information, see Query Status.

6.3.5.4.4 Monitor tasks and view logs

You can view the history of a migration task and internal operational metrics through Grafana or logs.

- Via Grafana

  If Prometheus, Alertmanager, and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. Specifically, enter the IP address and port specified during deployment in Grafana and select the DM dashboard.

- Via logs

  When DM is running, DM-master, DM-worker, and dmctl output logs, which includes information about migration tasks. The log directory of each component is as follows.

  - DM-master log directory: It is specified by the DM-master command line parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/`.
  - DM-worker log directory: It is specified by the DM-worker command line parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/`.

6.3.6 Migrate Data from CSV Files to TiDB

This document describes how to migrate data from CSV files to TiDB.

TiDB Lightning can read data from CSV files and other delimiter formats, such as tab-separated values (TSV). For other flat file data sources, you can also refer to this document and migrate data to TiDB.

6.3.6.1 Prerequisites

- Install TiDB Lightning.
- Get the target database privileges required for TiDB Lightning.

6.3.6.2 Step 1. Prepare the CSV files

Put all the CSV files in the same directory. If you need TiDB Lightning to recognize all CSV files, the file names should meet the following requirements:

- If a CSV file contains the data for an entire table, name the file `${db_name}.${table_name}.csv`.
- If the data of one table is separated into multiple CSV files, append a numeric suffix to these CSV files. For example, `${db_name}.${table_name}.003.csv`. The numeric suffixes can be inconsecutive but must be in ascending order. You also need to add extra zeros before the number to ensure all the suffixes are in the same length.

6.3.6.3 Step 2. Create the target table schema

Because CSV files do not contain schema information, before importing data from CSV files into TiDB, you need to create the target table schema. You can create the target table schema by either of the following two methods:

- **Method 1**: create the target table schema using TiDB Lightning.

  Create SQL files that contain the required DDL statements:

  - Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
  - Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2**: create the target table schema manually.

6.3.6.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the target
    ↪ TiDB cluster cannot provide any service.
### "tidb": The "tidb" backend is recommended to import data less than 1 TiB
    ↪ . During the import, the target TiDB cluster can provide service
    ↪ normally.
backend = "local"
```

```
### Set the temporary storage directory for the sorted Key-Value files. The
    ↪ directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage, which can use I/O exclusively.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
### Directory of the data source.
data-source-dir = "${data-path}" # A local path or S3 path. For example, 's3
    ↪ ://my-bucket/sql-backup'.

### Defines CSV format.
[mydumper.csv]
### Field separator of the CSV file. Must not be empty. If the source file
    ↪ contains fields that are not string or numeric, such as binary, blob,
    ↪  or bit, it is recommended not to usesimple delimiters such as ",",
    ↪ and use an uncommon character combination like "|+|" instead.
separator = ','
### Delimiter. Can be zero or multiple characters.
delimiter = '"'
### Configures whether the CSV file has a table header.
### If this item is set to true, TiDB Lightning uses the first line of the
    ↪ CSV file to parse the corresponding relationship of fields.
header = true
### Configures whether the CSV file contains NULL.
### If this item is set to true, any column of the CSV file cannot be parsed
    ↪  as NULL.
not-null = false
### If `not-null` is set to false (CSV contains NULL),
### The following value is parsed as NULL.
null = '\N'
### Whether to treat the backslash ('\') in the string as an escape
    ↪ character.
backslash-escape = true
### Whether to trim the last separator at the end of each line.
trim-last-separator = false

[tidb]
### The target cluster.
host = ${host}         # e.g.: 172.16.32.1
port = ${port}         # e.g.: 4000
user = "${user_name}"  # e.g.: "root"
password = "${password}" # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs to
```

```
    ↪ obtain the table schema information from the TiDB status port. e.g.:
    ↪ 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD.
    ↪ When backend = "local", you must specify status-port and pd-addr
    ↪ correctly. Otherwise, the import will be abnormal.
```

For more information on the configuration file, refer to TiDB Lightning Configuration.

6.3.6.5 Step 4. Tune the import performance (optional)

When you import data from CSV files with a uniform size of about 256 MiB, TiDB Lightning works in the best performance. However, if you import data from a single large CSV file, TiDB Lightning can only use one thread to process the import by default, which might slow down the import speed.

To speed up the import, you can split a large CSV file into smaller ones. For a CSV file in a common format, before TiDB Lightning reads the entire file, it is hard to quickly locate the beginning and ending positions of each line. Therefore, TiDB Lightning does not automatically split CSV files by default. But if your CSV files to be imported meet certain format requirements, you can enable the `strict-format` mode. In this mode, TiDB Lightning automatically splits a single large CSV file into multiple files, each in about 256 MiB, and processes them in parallel.

> **Note:**
>
> If a CSV file is not in a strict format but the `strict-format` mode is set to `true` by mistake, a field that spans multiple lines will be split into two fields. This causes the parsing to fail, and TiDB Lightning might import the corrupted data without reporting any error.

In a strict-format CSV file, each field only takes up one line. It must meet the following requirements:

- The delimiter is empty.
- Each field does not contain CR (`\r`) or LF (`\n`).

If your CSV file meets the above requirements, you can speed up the import by enabling the `strict-format` mode as follows:

```
[mydumper]
strict-format = true
```

6.3.6.6 Step 5. Import the data

To start the import, run `tidb-lightning`. If you launch the program in the command line, the process might exit unexpectedly after receiving a SIGHUP signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

```
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1 &
```

After the import starts, you can check the progress of the import by either of the following methods:

- `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
- Check progress in the monitoring dashboard.
- Check progress in the TiDB Lightning web interface.

After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb-lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

6.3.6.7 Other file formats

If your data source is in other formats, to migrate data from your data source, you must end the file name with `.csv` and make corresponding changes in the `[mydumper.csv]` section of the `tidb-lightning.toml` configuration file. Here are example changes for common formats:

TSV:

```
### Format example
### ID   Region   Count
### 1    East     32
### 2    South    NULL
### 3    West     10
### 4    North    39
```

```
### Format configuration
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
trim-last-separator = false
```

TPC-H DBGEN:

```
### Format example
### 1|East|32|
### 2|South|0|
### 3|West|10|
### 4|North|39|

### Format configuration
[mydumper.csv]
separator = '|'
delimiter = ''
header = false
not-null = true
backslash-escape = false
trim-last-separator = true
```

6.3.6.8 What's next

- CSV Support and Restrictions.

6.3.7 Migrate Data from SQL Files to TiDB

This document describes how to migrate data from MySQL SQL files to TiDB using TiDB Lightning. For how to generate MySQL SQL files, refer to Export to SQL files using Dumpling.

6.3.7.1 Prerequisites

- Install TiDB Lightning using TiUP
- Grant the required privileges to the target database for TiDB Lightning

6.3.7.2 Step 1. Prepare SQL files

Put all the SQL files in the same directory, like `/data/my_datasource/` or `s3://my-bucket/sql-backup`. TiDB Lightning recursively searches for all `.sql` files in this directory and its subdirectories.

6.3.7.3 Step 2. Define the target table schema

To import data to TiDB, you need to create the table schema for the target database.

If you use Dumpling to export data, the table schema file is automatically exported. For the data exported in other ways, you can create the table schema in one of the following methods:

- **Method 1**: Create the target table schema using TiDB Lightning.

  Create SQL files that contain the required DDL statements:

  - Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
  - Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2**: Create the target table schema manually.

6.3.7.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default. The local backend is used to import large volumes of
    ↪ data (around or more than 1 TiB). During the import, the target TiDB
    ↪ cluster cannot provide any service.
### "tidb": The "tidb" backend can also be used to import small volumes of
    ↪ data (less than 1 TiB). During the import, the target TiDB cluster
    ↪ can provide service normally. For the information about backend mode,
    ↪  refer to https://docs.pingcap.com/tidb/stable/tidb-lightning-
    ↪ backends.

backend = "local"
### Sets the temporary storage directory for the sorted key-value files. The
    ↪  directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage and exclusive I/O for the directory.
```

```
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
### Directory of the data source
data-source-dir = "${data-path}" # Local or S3 path, such as 's3://my-bucket
    ↪ /sql-backup'

[tidb]
### The information of target cluster
host = ${host}             # For example, 172.16.32.1
port = ${port}             # For example, 4000
user = "${user_name}"      # For example, "root"
password = "${password}"   # For example, "rootroot"
status-port = ${status-port} # During the import process, TiDB Lightning
    ↪ needs to obtain table schema information from the "Status Port" of
    ↪ TiDB, such as 10080.
pd-addr = "${ip}:${port}" # The address of the cluster's PD. TiDB Lightning
    ↪  obtains some information through PD, such as 172.16.31.3:2379. When
    ↪ backend = "local", you must correctly specify status-port and pd-addr
    ↪ . Otherwise, the import will encounter errors.
```

For more information about the configuration file, refer to TiDB Lightning Configuration.

6.3.7.5 Step 4. Import the data

To start the import, run `tidb-lightning`. If you launch the program in the command line, the program might exit because of the `SIGHUP` signal. In this case, it is recommended to run the program with a `nohup` or `screen` tool.

If you import the data from S3, you need to pass in `SecretKey` and `AccessKey` of the account as environment variables. The account has the permission to access the S3 backend storage.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1 &
```

TiDB Lightning also supports reading credential files from `~/.aws/credentials`.

After the import is started, you can check the progress in one of the following ways:

- Search the `progress` keyword in the `grep` log, which is updated every 5 minutes by default.
- Use the Grafana dashboard. For details, see TiDB Lightning Monitoring.
- Use web interface. For details, see TiDB Lightning Web Interface.

After the import is completed, TiDB Lightning automatically exits. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> No matter whether the import is successful or not, the last line displays `tidb lightning exit`. It only means that TiDB Lightning has exited normally, not the completion of the task. If you encounter problems during the import process, refer to TiDB Lightning FAQ for troubleshooting.

6.3.8 Migrate from One TiDB Cluster to Another TiDB Cluster

This document describes how to migrate data from one TiDB cluster to another TiDB cluster. This function applies to the following scenarios:

- Split databases: You can split databases when a TiDB cluster is excessively large, or you want to avoid impact between services of a cluster.
- Relocate databases: Physically relocate databases, such as changing the data center.
- Migrate data to a TiDB cluster of a newer version: Migrate data to a TiDB cluster of a newer version to satisfy data security and accuracy requirements.

This document exemplifies the whole migration process and contains the following steps:

1. Set up the environment.
2. Migrate full data.
3. Migrate incremental data.
4. Migrate services to the new TiDB cluster.

6.3.8.1 Step 1. Set up the environment

1. Deploy TiDB clusters.

   Deploy two TiDB clusters, one upstream and the other downstream by using TiUP Playground. For more information, refer to Deploy and Maintain an Online TiDB Cluster Using TiUP.

```
# Create an upstream cluster
tiup --tag upstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 1
# Create a downstream cluster
tiup --tag downstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 1
# View cluster status
tiup status
```

2. Initialize data.

   By default, test databases are created in the newly deployed clusters. Therefore, you can use sysbench to generate test data and simulate data in real scenarios.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=10 --
    ↪ table-size=10000 prepare
```

   In this document, we use sysbench to run the `oltp_write_only` script. This script generates 10 tables in the test database, each with 10,000 rows. The tidb-config is as follows:

```
mysql-host=172.16.6.122 # Replace the value with the IP address of your
    ↪  upstream cluster
mysql-port=4000
mysql-user=root
mysql-password=
db-driver=mysql      # Set database driver to MySQL
mysql-db=test        # Set the database as a test database
report-interval=10   # Set data collection period to 10s
threads=10           # Set the number of worker threads to 10
time=0               # Set the time required for executing the script.
    ↪ 0 indicates time unlimited
rate=100             # Set average TPS to 100
```

3. Simulate service workload.

   In real scenarios, service data is continuously written to the upstream cluster. In this document, we use sysbench to simulate this workload. Specifically, run the following command to enable 10 workers to continuously write data to three tables, sbtest1, sbtest2, and sbtest3, with a total TPS not exceeding 100.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=3 run
```

4. Prepare external storage.

   In full data backup, both the upstream and downstream clusters need to access backup files. It is recommended that you use External storage to store backup files. In this document, Minio is used to simulate an S3-compatible storage service.

```
wget https://dl.min.io/server/minio/release/linux-amd64/minio
chmod +x minio
# Configure access-key access-screct-id to access minio
export HOST_IP='172.16.6.122' # Replace the value with the IP address
    ↪ of your upstream cluster
export MINIO_ROOT_USER='minio'
export MINIO_ROOT_PASSWORD='miniostorage'
# Create the database directory. backup is the bucket name.
mkdir -p data/backup
# Start minio at port 6060
./minio server ./data --address :6060 &
```

The preceding command starts a minio server on one node to simulate S3 services. Parameters in the command are configured as follows:

- Endpoint: `http://${HOST_IP}:6060/`
- Access-key: `minio`
- Secret-access-key: `miniostorage`
- Bucket: `backup`

The access link is as follows:

```
s3://backup?access-key=minio&secret-access-key=miniostorage&endpoint=
    ↪ http://${HOST_IP}:6060&force-path-style=true
```

6.3.8.2 Step 2. Migrate full data

After setting up the environment, you can use the backup and restore functions of BR to migrate full data. BR can be started in three ways. In this document, we use the SQL statements, `BACKUP` and `RESTORE`.

Note:

In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you back up data in off-peak hours, and set `RATE_LIMIT` to a proper value to avoid performance degradation.

If the versions of the upstream and downstream clusters are different, you should check BR compatibility. In this document, we assume that the upstream and downstream clusters are the same version.

1. Disable GC.

   To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before backup. In this way, history data is not deleted.

   Run the following command to disable GC:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=FALSE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+--------------------------+:
| @@global.tidb_gc_enable |
+--------------------------+
|                      0 |
+--------------------------+
1 row in set (0.00 sec)
```

2. Back up data.

   Run the `BACKUP` statement in the upstream cluster to back up data:

```
MySQL [(none)]> BACKUP DATABASE * TO 's3://backup?access-key=minio&
   ↪ secret-access-key=miniostorage&endpoint=http://${HOST_IP}:6060&
   ↪ force-path-style=true' RATE_LIMIT = 120 MB/SECOND;
```

```
+---------------+----------+--------------------+---------------------+------------
   ↪
| Destination | Size     | BackupTS          | Queue Time         |
   ↪ Execution Time    |
+---------------+----------+--------------------+---------------------+------------
   ↪
| s3://backup | 10315858 | 431434047157698561 | 2022-02-25 19:57:59 |
   ↪ 2022-02-25 19:57:59 |
+---------------+----------+--------------------+---------------------+------------
   ↪
1 row in set (2.11 sec)
```

   After the `BACKUP` command is executed, TiDB returns metadata about the backup data. Pay attention to `BackupTS`, because data generated before it is backed up. In this document, we use `BackupTS` as **the end of data check** and **the start of incremental migration scanning by TiCDC**.

3. Restore data.

   Run the `RESTORE` command in the downstream cluster to restore data:

```
mysql> RESTORE DATABASE * FROM 's3://backup?access-key=minio&secret-
    ↪ access-key=miniostorage&endpoint=http://${HOST_IP}:6060&force-
    ↪ path-style=true';
```

```
+--------------+----------+--------------------+---------------------+------------
    ↪
| Destination | Size    | BackupTS          | Queue Time         |
    ↪ Execution Time    |
+--------------+----------+--------------------+---------------------+------------
    ↪
| s3://backup | 10315858 | 431434141450371074 | 2022-02-25 20:03:59 |
    ↪ 2022-02-25 20:03:59 |
+--------------+----------+--------------------+---------------------+------------
    ↪
1 row in set (41.85 sec)
```

4. (Optional) Validate data.

   You can use sync-diff-inspector to check data consistency between upstream and downstream at a certain time. The preceding `BACKUP` output shows that the upstream cluster finishes backup at 431434047157698561. The preceding `RESTORE` output shows that the downstream finishes restoration at 431434141450371074.

```
sync_diff_inspector -C ./config.yaml
```

   For details about how to configure the sync-diff-inspector, see Configuration file description. In this document, the configuration is as follows:

```
# Diff Configuration.
######################### Datasource config #########################
[data-sources]
[data-sources.upstream]
    host = "172.16.6.122" # Replace the value with the IP address of
        ↪ your upstream cluster
    port = 4000
    user = "root"
    password = ""
    snapshot = "431434047157698561" # Set snapshot to the actual backup
        ↪  time (BackupTS in the "Back up data" section in [Step 2.
        ↪ Migrate full data](#step-2-migrate-full-data))
[data-sources.downstream]
    host = "172.16.6.125" # Replace the value with the IP address of
        ↪ your downstream cluster
```

```
    port = 4000
    user = "root"
    password = ""

########################## Task config ##########################
[task]
    output-dir = "./output"
    source-instances = ["upstream"]
    target-instance = "downstream"
    target-check-tables = ["*.*"]
```

6.3.8.3 Step 3. Migrate incremental data

1. Deploy TiCDC.

   After finishing full data migration, deploy and configure a TiCDC to replicate incremental data. In production environments, deploy TiCDC as instructed in Deploy TiCDC. In this document, a TiCDC node has been started upon the creation of the test clusters. Therefore, you can skip the step of deploying TiCDC and proceed with changefeed configuration.

2. Create a changefeed.

   In the upstream cluster, run the following command to create a changefeed from the upstream to the downstream clusters:

```
tiup cdc cli changefeed create --pd=http://172.16.6.122:2379 --sink-uri
    ↪ ="mysql://root:@172.16.6.125:4000" --changefeed-id="upstream-to-
    ↪ downstream" --start-ts="431434047157698561"
```

   In this command, the parameters are as follows:

   - `--pd`: PD address of the upstream cluster
   - `--sink-uri`: URI of the downstream cluster
   - `--changefeed-id`: changefeed ID, must be in the format of a regular expression, [5]+(-[a-zA-Z0-9]+)*$
   - `--start-ts`: start timestamp of the changefeed, must be the backup time (or BackupTS in the "Back up data" section in Step 2. Migrate full data)

   For more information about the changefeed configurations, see Task configuration file.

3. Enable GC.

   In incremental migration using TiCDC, GC only removes history data that is replicated. Therefore, after creating a changefeed, you need to run the following command

[5] a-zA-Z0-9

to enable GC. For details, see What is the complete behavior of TiCDC garbage collection (GC) safepoint?.

To enable GC, run the following command:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=TRUE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+--------------------------+
| @@global.tidb_gc_enable |
+--------------------------+
|                        1 |
+--------------------------+
1 row in set (0.00 sec)
```

6.3.8.4 Step 4. Migrate services to the new TiDB cluster

After creating a changefeed, data written to the upstream cluster is replicated to the downstream cluster with low latency. You can migrate read traffic to the downstream cluster gradually. Observe for a period. If the downstream cluster is stable, you can migrate write traffic to the downstream cluster by performing the following steps:

1. Stop write services in the upstream cluster. Make sure that all upstream data are replicated to downstream before stopping the changefeed.

```
# Stop the changefeed from the upstream cluster to the downstream
   ↪ cluster
tiup cdc cli changefeed pause -c "upstream-to-downstream" --pd=http
   ↪ ://172.16.6.122:2379

# View the changefeed status
tiup cdc cli changefeed list
```

```
[
  {
    "id": "upstream-to-downstream",
    "summary": {
    "state": "stopped", # Ensure that the status is stopped
    "tso": 431747241184329729,
    "checkpoint": "2022-03-11 15:50:20.387", # This time must be later
       ↪ than the time of stopping writing
```

```
    "error": null
    }
  }
]
```

2. Create a changefeed from downstream to upstream. You can leave `start-ts` unspecified so as to use the default setting, because the upstream and downstream data are consistent and there is no new data written to the cluster.

```
tiup cdc cli changefeed create --pd=http://172.16.6.125:2379 --sink-uri
    ↪ ="mysql://root:@172.16.6.122:4000" --changefeed-id="downstream -
    ↪ to-upstream"
```

3. After migrating writing services to the downstream cluster, observe for a period. If the downstream cluster is stable, you can discard the upstream cluster.

6.3.9 Migrate Data from TiDB to MySQL-compatible Databases

This document describes how to migrate data from TiDB clusters to MySQL-compatible databases, such as Aurora, MySQL, and MariaDB. The whole process contains four steps:

1. Set up the environment.
2. Migrate full data.
3. Migrate incremental data.
4. Migrate services to the MySQL-compatible cluster.

6.3.9.1 Step 1. Set up the environment

1. Deploy a TiDB cluster upstream.

   Deploy a TiDB cluster by using TiUP Playground. For more information, refer to Deploy and Maintain an Online TiDB Cluster Using TiUP.

```
# Create a TiDB cluster
tiup playground --db 1 --pd 1 --kv 1 --tiflash 0 --ticdc 1
# View cluster status
tiup status
```

2. Deploy a MySQL instance downstream.

   - In a lab environment, you can use Docker to quickly deploy a MySQL instance by running the following command:

```
docker run --name some-mysql -e MYSQL_ROOT_PASSWORD=my-secret-pw -p
    ↪  3306:3306 -d mysql
```

- In a production environment, you can deploy a MySQL instance by following instructions in Installing MySQL.

3. Simulate service workload.

   In the lab environment, you can use `go-tpc` to write data to the TiDB cluster upstream. This is to generate event changes in the TiDB cluster. Run the following command to create a database named `tpcc` in the TiDB cluster, and then use TiUP bench to write data to this database.

```
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 prepare
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 run --time
    ↪ 300s
```

   For more details about `go-tpc`, refer to How to Run TPC-C Test on TiDB.

6.3.9.2 Step 2. Migrate full data

After setting up the environment, you can use Dumpling to export the full data from the upstream TiDB cluster.

> **Note:**
>
> In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you complete this step in off-peak hours.

1. Disable Garbage Collection (GC).

   To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before exporting full data. In this way, history data is not deleted.

   Run the following command to disable GC:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=FALSE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+-------------------------+:
| @@global.tidb_gc_enable |
+-------------------------+
|                       0 |
+-------------------------+
1 row in set (0.00 sec)
```

2. Back up data.

    1. Export data in SQL format using Dumpling:

    ```
    tiup dumpling -u root -P 4000 -h 127.0.0.1 --filetype sql -t 8 -o
        ↪ ./dumpling_output -r 200000 -F256MiB
    ```

    2. After finishing exporting data, run the following command to check the metadata. `Pos` in the metadata is the TSO of the export snapshot and can be recorded as the BackupTS.

    ```
    cat dumpling_output/metadata
    ```

    ```
    Started dump at: 2022-06-28 17:49:54
    SHOW MASTER STATUS:
            Log: tidb-binlog
            Pos: 434217889191428107
            GTID:
    Finished dump at: 2022-06-28 17:49:57
    ```

3. Restore data.

    Use MyLoader (an open-source tool) to import data to the downstream MySQL instance. For details about how to install and use MyLoader, see MyDumpler/MyLoader. Run the following command to import full data exported by Dumpling to MySQL:

    ```
    myloader -h 127.0.0.1 -P 3306 -d ./dumpling_output/
    ```

4. (Optional) Validate data.

    You can use sync-diff-inspector to check data consistency between upstream and downstream at a certain time.

    ```
    sync_diff_inspector -C ./config.yaml
    ```

    For details about how to configure the sync-diff-inspector, see Configuration file description. In this document, the configuration is as follows:

```
# Diff Configuration.
######################### Datasource config #########################
[data-sources]
[data-sources.upstream]
       host = "127.0.0.1" # Replace the value with the IP address of
          ↪ your upstream cluster
       port = 4000
       user = "root"
       password = ""
       snapshot = "434217889191428107" # Set snapshot to the actual
          ↪ backup time (BackupTS in the "Back up data" section in [
          ↪ Step 2. Migrate full data](#step-2-migrate-full-data))
[data-sources.downstream]
       host = "127.0.0.1" # Replace the value with the IP address of
          ↪ your downstream cluster
       port = 3306
       user = "root"
       password = ""
######################### Task config #########################
[task]
       output-dir = "./output"
       source-instances = ["upstream"]
       target-instance = "downstream"
       target-check-tables = ["*.*"]
```

6.3.9.3 Step 3. Migrate incremental data

1. Deploy TiCDC.

   After finishing full data migration, deploy and configure a TiCDC cluster to replicate incremental data. In production environments, deploy TiCDC as instructed in Deploy TiCDC. In this document, a TiCDC node has been started upon the creation of the test cluster. Therefore, you can skip the step of deploying TiCDC and proceed with the next step to create a changefeed.

2. Create a changefeed.

   In the upstream cluster, run the following command to create a changefeed from the upstream to the downstream clusters:

```
tiup ctl:<cluster-version> cdc changefeed create --pd=http
   ↪ ://127.0.0.1:2379 --sink-uri="mysql://root:@127.0.0.1:3306" --
   ↪ changefeed-id="upstream-to-downstream" --start-ts
   ↪ ="434217889191428107"
```

In this command, the parameters are as follows:

- `--pd`: PD address of the upstream cluster
- `--sink-uri`: URI of the downstream cluster
- `--changefeed-id`: changefeed ID, must be in the format of a regular expression, `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$`
- `--start-ts`: start timestamp of the changefeed, must be the backup time (or BackupTS in the "Back up data" section in Step 2. Migrate full data)

For more information about the changefeed configurations, see Task configuration file.

3. Enable GC.

   In incremental migration using TiCDC, GC only removes history data that is replicated. Therefore, after creating a changefeed, you need to run the following command to enable GC. For details, see What is the complete behavior of TiCDC garbage collection (GC) safepoint.

To enable GC, run the following command:

````
```sql
MySQL [test]> SET GLOBAL tidb_gc_enable=TRUE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```sql
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+-------------------------+
| @@global.tidb_gc_enable |
+-------------------------+
|                       1 |
+-------------------------+
1 row in set (0.00 sec)
```
````

6.3.9.4 Step 4. Migrate services

After creating a changefeed, data written to the upstream cluster is replicated to the downstream cluster with low latency. You can migrate read traffic to the downstream cluster gradually. Observe the read traffic for a period. If the downstream cluster is stable, you can migrate write traffic to the downstream cluster as well in the following steps:

1. Stop write services in the upstream cluster. Make sure that all upstream data are replicated to downstream before stopping the changefeed.

```
# Stop the changefeed from the upstream cluster to the downstream
    ↪ cluster
tiup cdc cli changefeed pause -c "upstream-to-downstream" --pd=http
    ↪ ://172.16.6.122:2379
# View the changefeed status
tiup cdc cli changefeed list
```

```
[
  {
    "id": "upstream-to-downstream",
    "summary": {
    "state": "stopped", # Ensure that the status is stopped
    "tso": 434218657561968641,
    "checkpoint": "2022-06-28 18:38:45.685", # This time should be
       ↪ later than the time of stopping writing
    "error": null
    }
  }
]
```

2. After migrating writing services to the downstream cluster, observe for a period. If the downstream cluster is stable, you can discard the upstream cluster.

6.4 Advanced Migration

6.4.1 Continuous Replication from Databases that Use gh-ost or pt-osc

In production scenarios, table locking during DDL execution can block the reads from or writes to the database to a certain extent. Therefore, online DDL tools are often used to execute DDLs to minimize the impact on reads and writes. Common DDL tools are gh-ost and pt-osc.

When using DM to migrate data from MySQL to TiDB, you can enbale `online-ddl` to allow collaboration of DM and gh-ost or pt-osc.

For the detailed replication instructions, refer to the following documents by scenarios:

- Migrate MySQL of Small Datasets to TiDB

- Migrate MySQL of Large Datasets to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.4.1.1 Enable online-ddl on DM

In the task configuration file of DM, set the global parameter `online-ddl` to `true`, as shown below:

```
### ----------- Global configuration -----------
#### ********* Basic configuration *********
name: test                    # The name of the task. Should be globally
    ↪ unique.
task-mode: all                # The task mode. Can be set to `full`, `
    ↪ incremental`, or `all`.
shard-mode: "pessimistic"     # The shard merge mode. Optional modes are `
    ↪ pessimistic` and `optimistic`. The `pessimistic` mode is used by
    ↪ default. After understanding the principles and restrictions of the "
    ↪ optimistic" mode, you can set it to the "optimistic" mode.
meta-schema: "dm_meta"        # The downstream database that stores the `meta`
    ↪  information.
online-ddl: true              # Enable online-ddl support on DM to support
    ↪ automatic processing of "gh-ost" and "pt-osc" for the upstream
    ↪ database.
```

6.4.1.2 Workflow after enabling online-ddl

After online-ddl is enabled on DM, the DDL statements generated by DM replicating gh-ost or pt-osc will change.

The workflow of gh-ost or pt-osc:

- Create a ghost table according to the table schema of the DDL real table.
- Apply DDLs on the ghost table.
- Replicate the data of the DDL real table to the ghost table.
- After the data are consistent between the two tables, use the rename statement to replace the real table with the ghost table.

The workflow of DM:

- Skip creating the ghost table downstream.
- Record DDLs applied to the ghost table.

- Replicate data only from the ghost table.
- Apply DDLs recorded downstream.

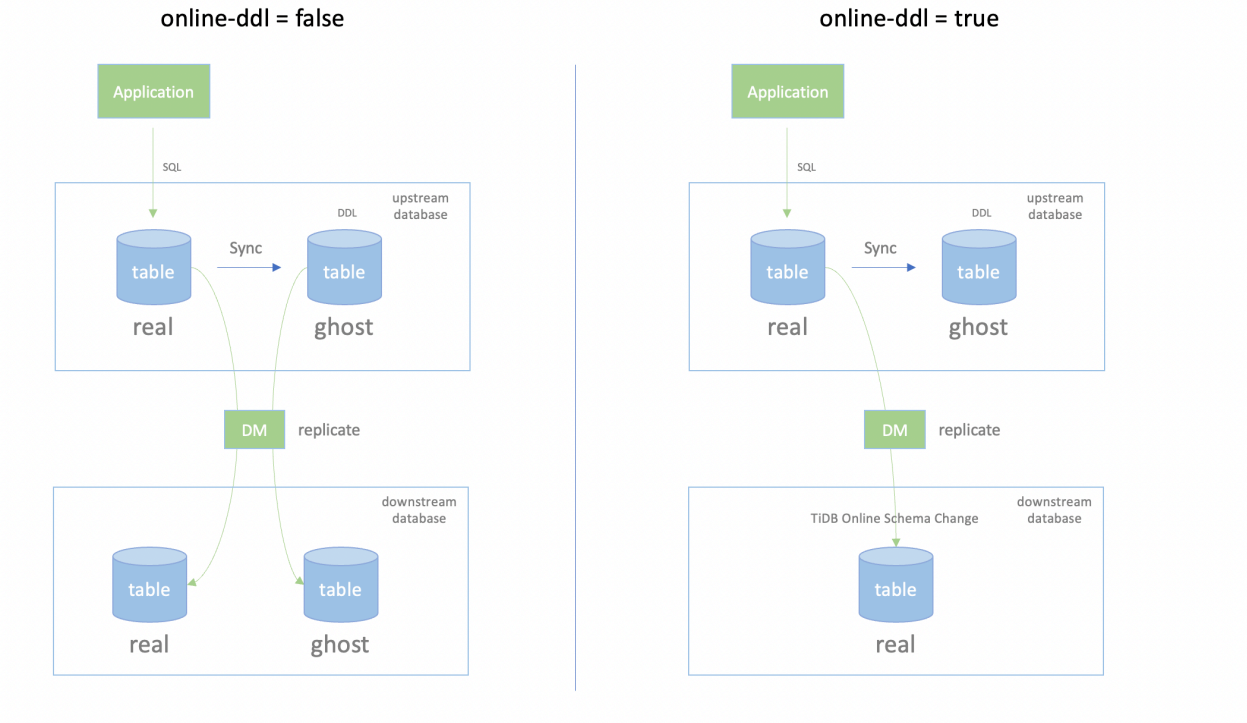

Figure 46: dm-online-ddl

The change in the workflow brings the following advantages:

- The downstream TiDB does not need to create and replicate the ghost table, saving the storage space and network transmission overhead.
- When you migrate and merge data from sharded tables, the RENAME operation is ignored for each sharded ghost table to ensure the correctness of the replication.

6.4.1.3 See also

Working details for DM with online DDL tools

6.4.2 Migrate Data to a Downstream TiDB Table with More Columns

This document provides the additional steps to be taken when you migrate data to a downstream TiDB table with more columns than the corresponding upstream table. For regular migration steps, see the following migration scenarios:

- Migrate MySQL of Small Datasets to TiDB
- Migrate MySQL of Large Datasets to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.4.2.1 Use DM to migrate data to a downstream TiDB table with more columns

When replicating the upstream binlog, DM tries to use the current table schema of the downstream to parse the binlog and generate the corresponding DML statements. If the column number of the table in the upstream binlog does not match the column number in the downstream table schema, the following error occurs:

```
"errors": [
    {
        "ErrCode": 36027,
        "ErrClass": "sync-unit",
        "ErrScope": "internal",
        "ErrLevel": "high",
        "Message": "startLocation: [position: (mysql-bin.000001, 2022), gtid-
            ↪ set:09bec856-ba95-11ea-850a-58f2b4af5188:1-9 ], endLocation: [
            ↪  position: (mysql-bin.000001, 2022), gtid-set: 09bec856-ba95
            ↪ -11ea-850a-58f2b4af5188:1-9]: gen insert sqls failed, schema:
            ↪ log, table: messages: Column count doesn't match value count:
            ↪ 3 (columns) vs 2 (values)",
        "RawCause": "",
        "Workaround": ""
    }
]
```

The following is an example upstream table schema:

```
### Upstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
)
```

The following is an example downstream table schema:

```
### Downstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  `message` varchar(255) DEFAULT NULL, # This is the additional column that
     ↪  only exists in the downstream table.
  PRIMARY KEY (`id`)
)
```

When DM tries to use the downstream table schema to parse the binlog event generated by the upstream, DM reports the above `Column count doesn't match` error.

In such cases, you can use the `binlog-schema` command to set a table schema for the table to be migrated from the data source. The specified table schema needs to correspond to the binlog event data to be replicated by DM. If you are migrating sharded tables, for each sharded table, you need to set a table schema in DM to parse binlog event data. The steps are as follows:

1. Create a SQL file in DM and add the `CREATE TABLE` statement that corresponds to the upstream table schema to the file. For example, save the following table schema to `log.messages.sql`. For DM v6.0 or later versions, you can update the table schema by adding the `--from-source` or `--from-target` flag without creating a SQL file. For details, see Manage Table Schemas of Tables to be Migrated.

```
# Upstream table schema
CREATE TABLE `messages` (
`id` int(11) NOT NULL,
PRIMARY KEY (`id`)
)
```

2. Use the `binlog-schema` command to set the table schema for the table to be migrated from the data source. At this time, the data migration task should be in the Paused state due to the above `Column count doesn't match` error.

```
tiup dmctl --master-addr ${advertise-addr} binlog-schema update -s ${
    ↪ source-id} ${task-name} ${database-name} ${table-name} ${schema-
    ↪ file}
```

   The descriptions of parameters in this command are as follows:

Parameter	Description
`--master-addr`	Specifies the `${advertise-addr}` of any DM-master node in the cluster where dmctl is to be connected. `${advertise-addr}` indicates the address that DM-master advertises to the outside world.

Parameter	Description
`binlog-schema-set`	Manually set the schema information.
`-s`	Specifies the source. `${source-id}` indicates the source ID of MySQL data.

Parameter	Description
`${ task - name } `	Specifies the name of the migration task defined in the `task.yaml` configuration file of the data migration task.

Parameter	Description
`${database-name}`	Specifies the database.
`${table-name}`	Specifies the name of the upstream table.
`${schema-file}`	Specifies the schema file to be set.

For example:

```
tiup dmctl --master-addr 172.16.10.71:8261 binlog-schema update -s
    ↪ mysql-01 task-test -d log -t message log.message.sql
```

3. Use the `resume-task` command to resume the migration task in the Paused state.

```
tiup dmctl --master-addr ${advertise-addr} resume-task ${task-name}
```

4. Use the `query-status` command to confirm that the data migration task is running correctly.

```
tiup dmctl --master-addr ${advertise-addr} query-status resume-task ${
    ↪ task-name}
```

6.4.3 Filter Binlog Events

This document describes how to filter binlog events when you use DM to perform continuous incremental data replication. For the detailed replication instructions, refer to the following documents by scenarios:

- Migrate MySQL of Small Datasets to TiDB
- Migrate MySQL of Large Datasets to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.4.3.1 Configuration

To use binlog event filter, add a `filter` to the task configuration file of DM, as shown below:

```
filters:
  rule-1:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table"]
    sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
    action: Ignore
```

- `schema-pattern/table-pattern`: Filters matching schemas or tables
- `events`: Filters binlog events. Supported events are listed in the table below:

Event	Category	Description
all		Includes all events
all dml		Includes all DML events
all ddl		Includes all DDL events
none		Includes no event
none ddl		Excludes all DDL events
none dml		Excludes all DML events
insert	DML	Insert DML event
update	DML	Update DML event
delete	DML	Delete DML event

Event	Category	Description
create database	DDL	Create database event
drop database	DDL	Drop database event
create table	DDL	Create table event
create index	DDL	Create index event
drop table	DDL	Drop table event
truncate table	DDL	Truncate table event
rename table	DDL	Rename table event
drop index	DDL	Drop index event
alter table	DDL	Alter table event

- `sql-pattern`: Filters specified DDL SQL statements. The matching rule supports using a regular expression.
- `action`: `Do` or `Ignore`
  - `Do`: the allow list. A binlog event is replicated if meeting either of the following two conditions:
    * The event matches the rule setting.
    * sql-pattern has been specified and the SQL statement of the event matches any of the sql-pattern options.
  - `Ignore`: the block list. A binlog event is filtered out if meeting either of the following two conditions:
    * The event matches the rule setting.
    * sql-pattern has been specified and the SQL statement of the event matches any of the sql-pattern options.

  If both `Do` and `Ignore` are configured, `Ignore` has higher priority over `Do`. That is, an event satisfying both `Ignore` and `Do` conditions will be filtered out.

6.4.3.2 Application scenarios

This section describes the application scenarios of binlog event filter.

6.4.3.2.1 Filter out all sharding deletion operations

To filter out all deletion operations, configure a `filter-table-rule` and a `filter-schema-rule`, as shown below:

```
filters:
  filter-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table", "delete"]
```

```
    action: Ignore
  filter-schema-rule:
    schema-pattern: "test_*"
    events: ["drop database"]
    action: Ignore
```

6.4.3.2.2 Migrate only DML operations of sharded schemas and tables

To replicate only DML statements, configure two `Binlog event filter rule`, as shown below:

```
filters:
  do-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["create table", "all dml"]
    action: Do
  do-schema-rule:
    schema-pattern: "test_*"
    events: ["create database"]
    action: Do
```

6.4.3.2.3 Filter out SQL statements not supported by TiDB

To filter out SQL statements not supported by TiDB, configure a `filter-procedure-rule`, as shown below:

```
filters:
  filter-procedure-rule:
    schema-pattern: "*"
    sql-pattern: [".*\\s+DROP\\s+PROCEDURE", ".*\\s+CREATE\\s+PROCEDURE", "
        ↪ ALTER\\s+TABLE[\\s\\S]*ADD\\s+PARTITION", "ALTER\\s+TABLE[\\s\\S]*
        ↪ DROP\\s+PARTITION"]
    action: Ignore
```

> **Warning:**
>
> To avoid filtering out data that needs to be migrated, configure the global filtering rule as strictly as possible.

6.4.3.3 See also

Filter Binlog Events Using SQL Expressions

6.4.4 Filter DML Events Using SQL Expressions

This document introduces how to filter binlog events using SQL expressions when you use DM to perform continuous incremental data replication. For the detailed replication instruction, refer to the following documents:

- Migrate MySQL of Small Datasets to TiDB
- Migrate MySQL of Large Datasets to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

When performing incremental data replication, you can use the Binlog Event Filter to filter certain types of binlog events. For example, you can choose not to replicate `DELETE` events to the downstream for the purposes like archiving and auditing. However, the Binlog Event Filter cannot determine whether to filter the `DELETE` event of a row that requires finer granularity.

To address the issue, since v2.0.5, DM supports using `binlog value filter` in incremental data replication to filter data. Among the DM-supported and `ROW`-formatted binlog, the binlog events carry values of all columns, and you can configure SQL expressions based on these values. If the expression calculates a row change as `TRUE`, DM does not replicate this row change to the downstream.

Similar to Binlog Event Filter, you need to configure `binlog value filter` in the task configuration file. For details, see the following configuration example. For the advanced task configuration and the description, refer to DM advanced task configuration file.

```
name: test
task-mode: all

mysql-instances:
  - source-id: "mysql-replica-01"
    expression-filters: ["even_c"]

expression-filter:
  even_c:
    schema: "expr_filter"
    table: "tbl"
    insert-value-expr: "c % 2 = 0"
```

In the above configuration example, the `even_c` rule is configured and referenced by the data source `mysql-replica-01`. According to this rule, for the `tb1` table in the `expr_filter` ↪ schema, when an even number is inserted into the `c` column (`c % 2 = 0`), this `insert` statement is not replicated to the downstream. The following example shows the effect of this rule.

Incrementally insert the following data in the upstream data source:

```
INSERT INTO tbl(id, c) VALUES (1, 1), (2, 2), (3, 3), (4, 4);
```

Then query the `tb1` table on downstream. You can see that only the rows with odd numbers on `c` are replicated.

```
MySQL [test]> select * from tbl;
+------+------+
| id   | c    |
+------+------+
|    1 |    1 |
|    3 |    3 |
+------+------+
2 rows in set (0.001 sec)
```

6.4.4.1 Configuration parameters and description

- `schema`: The name of the upstream schema to match. Wildcard matching or regular matching is not supported.
- `table`: The name of the upstream table to match. Wildcard matching or regular matching is not supported.
- `insert-value-expr`: Configures an expression that takes effect on values carried by the `INSERT` type binlog events (WRITE_ROWS_EVENT). You cannot use this expression together with `update-old-value-expr`, `update-new-value-expr` or `delete-value-expr` in the same configuration item.
- `update-old-value-expr`: Configures an expression that takes effect on the old values carried by the `UPDATE` type binlog events (UPDATE_ROWS_EVENT). You cannot use this expression together with `insert-value-expr` or `delete-value-expr` in the same configuration item.
- `update-new-value-expr`: Configures an expression that takes effect on the new values carried by the `UPDATE` type binlog events (UPDATE_ROWS_EVENT). You cannot use this expression together with `insert-value-expr` or `delete-value-expr` in the same configuration item.
- `delete-value-expr`: Configures an expression that takes effect on values carried by the `DELETE` type binlog events (DELETE_ROWS_EVENT). You cannot use this expression together with `insert-value-expr`, `update-old-value-expr` or `update-new-value-expr`.

Note:

- You can configure `update-old-value-expr` and `update-new-value-expr` together.

- When `update-old-value-expr` and `update-new-value-expr` are configured together, the rows whose "update + old values" meet `update-old-value-expr` **and** whose "update + new values" meet `update-new-value-expr` are filtered.
- When one of `update-old-value-expr` and `update-new-value-expr` is configured, the configured expression determines whether to filter the **entire row change**, which means that the deletion of old values and the insertion of new values are filtered as a whole.

You can use the SQL expression on one column or on multiple columns. You can also use the SQL functions supported by TiDB, such as `c % 2 = 0`, `a*a + b*b = c*c`, and `ts > NOW()`.

The `TIMESTAMP` default time zone is the time zone specified in the task configuration file. The default value is the time zone of the downstream. You can explicitly specify the time zone in a way like `c_timestamp = '2021-01-01 12:34:56.5678+08:00'`.

You can configure multiple filtering rules under the `expression-filter` configuration item. The upstream data source references the required rule in `expression-filters` to make it effective. When multiple rules are used, if **any** one of the rules are matched, the entire row change is filtered.

Note:

Configuring too many expression filtering rules increases the calculation overhead of DM and slows down the data replication.

7 Integrate

7.1 Data Integration Overview

Data integration means the flow, transfer, and consolidation of data among various data sources. As data grows exponentially in volume and data value is more profoundly explored, data integration has become increasingly popular and urgent. To avoid the situation that TiDB becomes data silos and to integrate data with different platforms, TiCDC offers the capability to replicate TiDB incremental data change logs to other data platforms. This document describes the data integration applications using TiCDC. You can choose an integration solution that suits your business scenarios.

7.1.1 Integrate with Confluent Cloud and Snowflake

You can use TiCDC to replicate incremental data from TiDB to Confluent Cloud, and replicate the data to Snowflake, ksqlDB, and SQL Server via Confluent Cloud. For details, see Integrate with Confluent Cloud and Snowflake.

7.1.2 Integrate with Apache Kafka and Apache Flink

You can use TiCDC to replicate incremental data from TiDB to Apache Kafka, and consume the data using Apache Flink. For details, see Integrate with Apache Kafka and Apache Flink.

7.2 Integration Scenarios

7.2.1 Integrate Data with Confluent Cloud and Snowflake

Confluent is an Apache Kafka-compatible streaming data platform that provides strong data integration capabilities. On this platform, you can access, store, and manage non-stop real-time streaming data.

Starting from TiDB v6.1.0, TiCDC supports replicating incremental data to Confluent in Avro format. This document introduces how to replicate TiDB incremental data to Confluent using TiCDC, and further replicate data to Snowflake, ksqlDB, and SQL Server via Confluent Cloud. The organization of this document is as follows:

1. Quickly deploy a TiDB cluster with TiCDC included.
2. Create a changefeed that replicates data from TiDB to Confluent Cloud.
3. Create Connectors that replicate data from Confluent Cloud to Snowflake, ksqlDB, and SQL Server.
4. Write data to TiDB using go-tpc, and observe data changes in Snowflake, ksqlDB, and SQL Server.

The preceding steps are performed in a lab environment. You can also deploy a cluster in a production environment by referring to these steps.

7.2.1.1 Replicate incremental data to Confluent Cloud

7.2.1.1.1 Step 1. Set up the environment

1. Deploy a TiDB cluster with TiCDC included.

   In a lab or testing environment, you can deploy a TiDB cluster with TiCDC included quickly by using TiUP Playground.

```
tiup playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --tiflash 0 --ticdc
    ↪ 1
# View cluster status
tiup status
```

If TiUP is not installed yet, refer to Install TiUP. In a production environment, you can deploy a TiCDC as instructed in Deploy TiCDC.

2. Register Confluent Cloud and create a Confluent cluster.

   Create a Basic cluster and make it accessible via Internet. For details, see Quick Start for Confluent Cloud.

7.2.1.1.2 Step 2. Create an access key pair

1. Create a cluster API key.

   Sign in to Confluent Cloud. Choose **Data integration** > **API keys** > **Create key**. On the **Select scope for API key** page that is displayed, select **Global access**.

   After creation, a key pair file is generated, as shown below.

```
=== Confluent Cloud API key: xxx-xxxxx ===

API key:
L5WWA4GK4NAT2EQV

API secret:
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bootstrap server:
xxx-xxxxx.ap-east-1.aws.confluent.cloud:9092
```

2. Record the Schema Registry Endpoints.

   In the Confluent Cloud Console, choose **Schema Registry** > **API endpoint**. Record the Schema Registry Endpoints. The following is an example:

```
https://yyy-yyyyy.us-east-2.aws.confluent.cloud
```

3. Create a Schema Registry API key.

   In the Confluent Cloud Console, choose **Schema Registry** > **API credentials**. Click **Edit** and then **Create key**.

   After creation, a key pair file is generated, as shown below:

```
=== Confluent Cloud API key: yyy-yyyyy === API key: 7NBH2CAFM2LMGTH7
↪ API secret: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```

You can also perform this step by using Confluent CLI. For details, see Connect Confluent CLI to Confluent Cloud Cluster.

7.2.1.1.3 Step 3. Create a Kafka changefeed

1. Create a changefeed configuration file.

   As required by Avro and Confluent Connector, incremental data of each table must be sent to an independent topic, and a partition must be dispatched for each event based on the primary key value. Therefore, you need to create a changefeed configuration file `changefeed.conf` with the following contents:

```
[sink]
dispatchers = [
{matcher = ['*.*'], topic = "tidb_{schema}_{table}", partition="index-
    ↪ value"},
]
```

   For detailed description of `dispatchers` in the configuration file, see Customize the rules for Topic and Partition dispatchers of Kafka Sink.

2. Create a changefeed to replicate incremental data to Confluent Cloud:

```
tiup ctl:<cluster-version> cdc changefeed create --pd="http
    ↪ ://127.0.0.1:2379" --sink-uri="kafka://<broker_endpoint>/ticdc-
    ↪ meta?protocol=avro&replication-factor=3&enable-tls=true&auto-
    ↪ create-topic=true&sasl-mechanism=plain&sasl-user=<broker_api_key
    ↪ >&sasl-password=<broker_api_secret>" --schema-registry="https://<
    ↪ schema_registry_api_key>:<schema_registry_api_secret>@<
    ↪ schema_registry_endpoint>" --changefeed-id="confluent-changefeed"
    ↪  --config changefeed.conf
```

   You need to replace the values of the following fields with those created or recorded in Step 2. Create an access key pair:

   - `<broker_endpoint>`
   - `<broker_api_key>`
   - `<broker_api_secret>`
   - `<schema_registry_api_key>`
   - `<schema_registry_api_secret>`
   - `<schema_registry_endpoint>`

   Note that you should encode `<schema_registry_api_secret>` based on HTML URL Encoding Reference before replacing its value. After you replace all the preceding fields, the configuration file is as follows:

```
tiup ctl:<cluster-version> cdc changefeed create --pd="http
    ↪ ://127.0.0.1:2379" --sink-uri="kafka://xxx-xxxxx.ap-east-1.aws.
    ↪ confluent.cloud:9092/ticdc-meta?protocol=avro&replication-factor
    ↪ =3&enable-tls=true&auto-create-topic=true&sasl-mechanism=plain&
    ↪ sasl-user=L5WWA4GK4NAT2EQV&sasl-password=
    ↪ xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx" --schema-registry="https://7
    ↪ NBH2CAFM2LMGTH7:xxxxxxxxxxxxxxxxx@yyy-yyyyy.us-east-2.aws.
    ↪ confluent.cloud" --changefeed-id="confluent-changefeed" --config
    ↪ changefeed.conf
```

- Run the command to create a changefeed.
  - If the changefeed is successfully created, changefeed information, such as changefeed ID, is displayed, as shown below:

    ```
    Create changefeed successfully!
    ID: confluent-changefeed
    Info: {... changfeed info json struct ...}
    ```

  - If no result is returned after you run the command, check the network connectivity between the server where you run the command and Confluent Cloud. For details, see Test connectivity to Confluent Cloud.

3. After creating the changefeed, run the following command to check the changefeed status:

```
tiup ctl:<cluster-version> cdc changefeed list --pd="http
    ↪ ://127.0.0.1:2379"
```

You can refer to Manage TiCDC Cluster and Replication Tasks to manage the changefeed.

7.2.1.1.4 Step 4. Write data to generate change logs

After the preceding steps are done, TiCDC sends change logs of incremental data in the TiDB cluster to Confluent Cloud. This section describes how to write data into TiDB to generate change logs.

1. Simulate service workload.

   To generate change logs in a lab environment, you can use go-tpc to write data to the TiDB cluster. Specifically, run the following command to create a database `tpcc` in the TiDB cluster. Then, use TiUP bench to write data to this new database.

```
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 prepare
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 run --time
    ↪ 300s
```

For more details about go-tpc, refer to How to Run TPC-C Test on TiDB.

2. Observe data in Confluent Cloud.

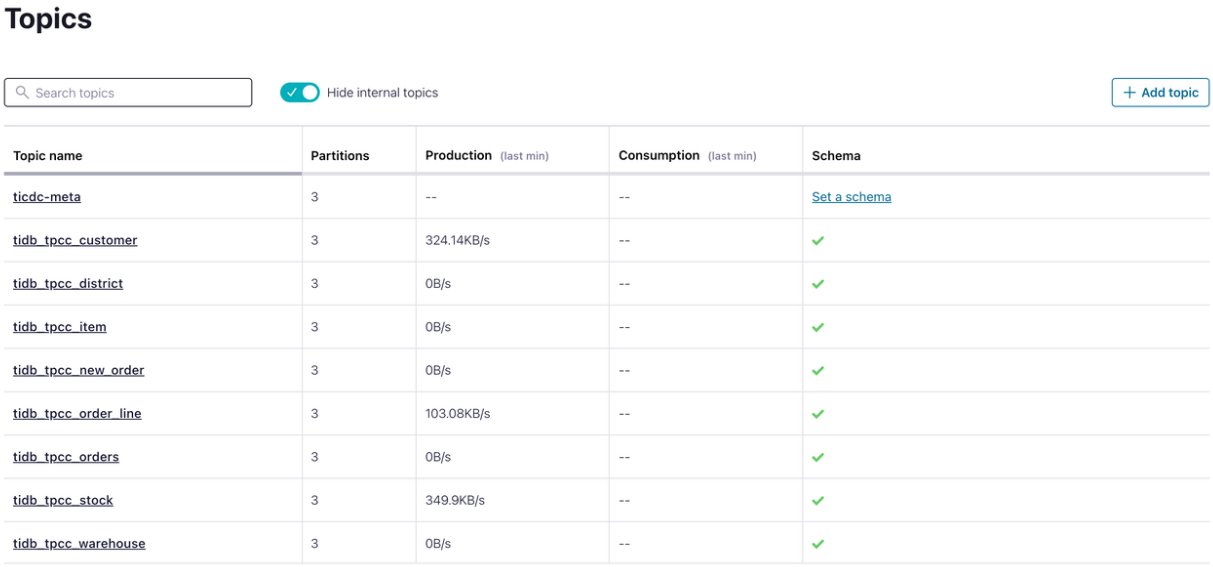

Figure 47: Confluent topics

In the Confluent Cloud Console, click **Topics**. You can see that the target topics have been created and are receiving data. At this time, incremental data of the TiDB database is successfully replicated to Confluent Cloud.

7.2.1.2 Integrate data with Snowflake

Snowflake is a cloud native data warehouse. With Confluent, you can replicate TiDB incremental data to Snowflake by creating Snowflake Sink Connectors.

7.2.1.2.1 Prerequisites

- You have registered and created a Snowflake cluster. See Getting Started with Snowflake.
- Before connecting to the Snowflake cluster, you have generated a private key for it. See Key Pair Authentication & Key Pair Rotation.

7.2.1.2.2 Integration procedure

1. Create a database and a schema in Snowflake.

   In the Snowflake control console, choose **Data** > **Database**. Create a database named `TPCC` and a schema named `TiCDC`.

2. In the Confluent Cloud Console, choose **Data integration** > **Connectors** > **Snowflake Sink**. The page shown below is displayed.

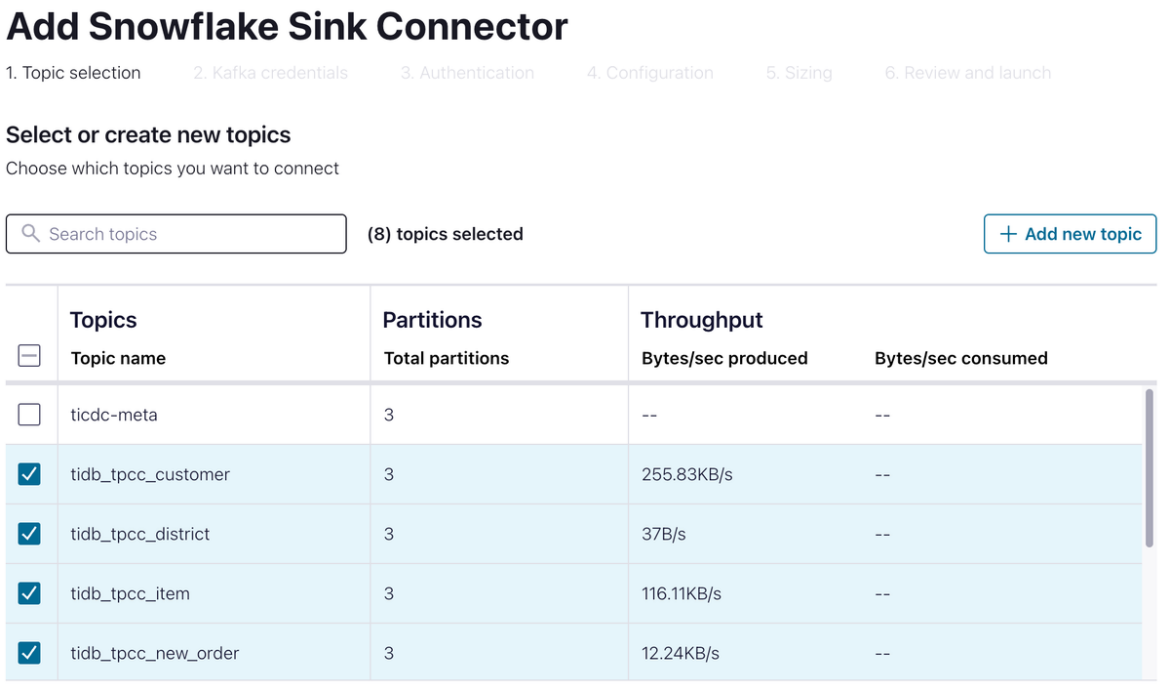

Figure 48: Add snowflake sink connector

3. Select the topic you want to replicate to Snowflake. Then go to the next page.

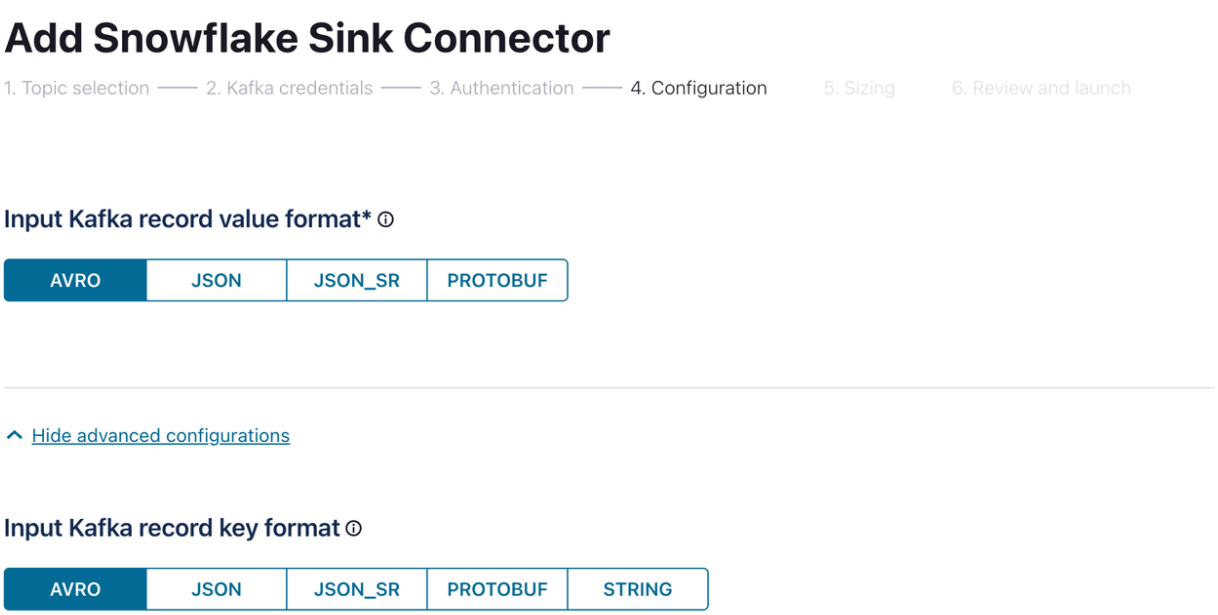

Figure 49: Configuration

4. Specify the authentication information for connecting Snowflake. Fill in **Database name** and **Schema name** with the values you created in the previous step. Then go to the next page.

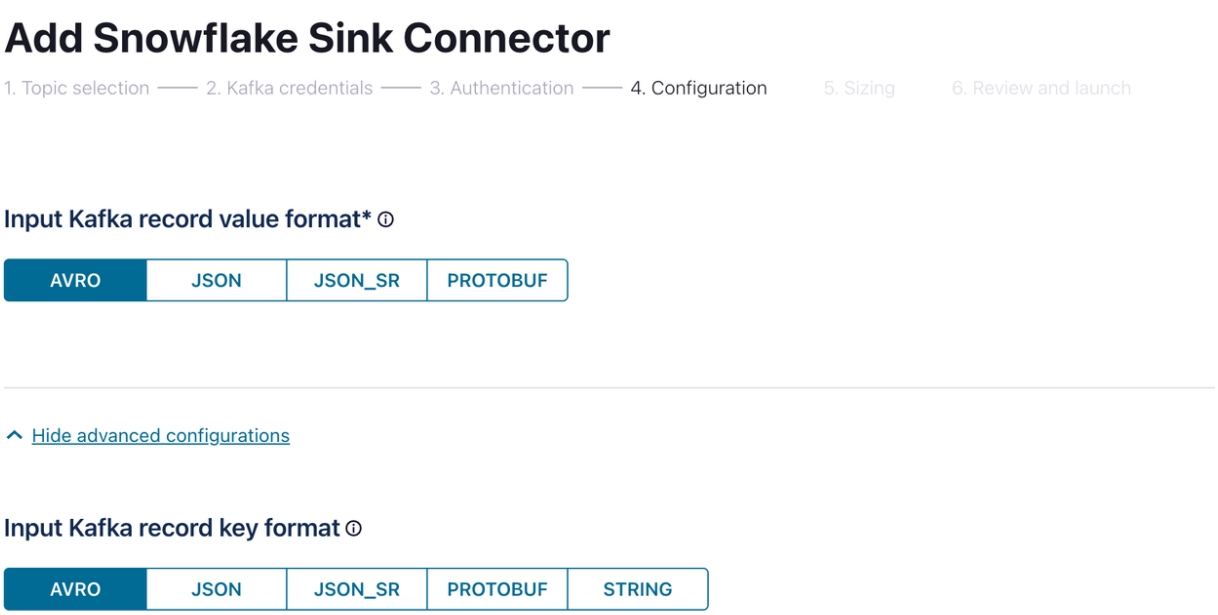

Figure 50: Configuration

5. On the **Configuration** page, select `AVRO` for both **Input Kafka record value format** and **Input Kafka record key format**. Then click **Continue**. Wait until the connector is created and the status becomes **Running**, which might take several minutes.

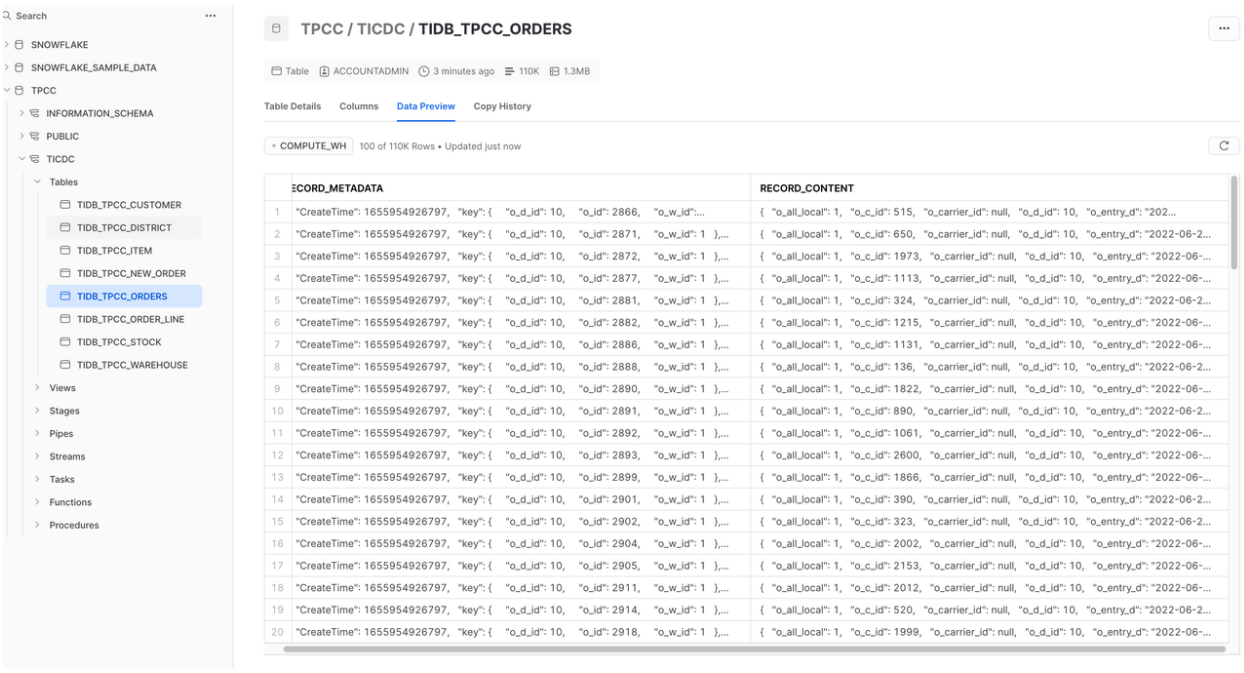

Figure 51: Data preview

6. In the Snowflake console, choose **Data** > **Database** > **TPCC** > **TiCDC**. You can see that TiDB incremental data has been replicated to Snowflake. Data integration with Snowflake is done (see the preceding figure). However, the table structure in Snowflake is different from that in TiDB, and data is inserted into Snowflake incrementally. In most scenarios, you expect the data in Snowflake to be a replica of the data in TiDB, rather than storing TiDB change logs. This problem will be addressed in the next section.

7.2.1.2.3 Create data replicas of TiDB tables in Snowflake

In the previous section, the change logs of TiDB incremental data have been replicated to Snowflake. This section describes how to process these change logs using the TASK and STREAM features of Snowflake according to the event type of `INSERT`, `UPDATE`, and `DELETE` ↪ , and then write them to a table with the same structure as that in upstream, thereby creating a data replica of the TiDB table in Snowflake. The following takes the `ITEM` table as an example.

The structure of the `ITEM` table is as follows:

```
CREATE TABLE `item` (
  `i_id` int(11) NOT NULL,
  `i_im_id` int(11) DEFAULT NULL,
  `i_name` varchar(24) DEFAULT NULL,
  `i_price` decimal(5,2) DEFAULT NULL,
  `i_data` varchar(50) DEFAULT NULL,
```

```
  PRIMARY KEY (`i_id`)
);
```

In Snowflake, there is a table named `TIDB_TEST_ITEM`, which is automatically created by the Confluent Snowflake Sink Connector. The table structure is as follows:

```
create or replace TABLE TIDB_TEST_ITEM (
       RECORD_METADATA VARIANT,
       RECORD_CONTENT VARIANT
);
```

1. In Snowflake, create a table with the same structure as that in TiDB:

   ```
   create or replace table TEST_ITEM (
       i_id INTEGER primary key,
       i_im_id INTEGER,
       i_name VARCHAR,
       i_price DECIMAL(36,2),
       i_data VARCHAR
   );
   ```

2. Create a stream for `TIDB_TEST_ITEM` and set `append_only` to `true` as follows.

   ```
   create or replace stream TEST_ITEM_STREAM on table TIDB_TEST_ITEM
       ↪ append_only=true;
   ```

   In this way, the created stream captures only `INSERT` events in real time. Specifically, when a new change log is generated for `ITEM` in TiDB, the change log will be inserted into `TIDB_TEST_ITEM` and be captured by the stream.

3. Process the data in the stream. According to the event type, insert, update, or delete the stream data in the `TEST_ITEM` table.

   ```
   --Merge data into the TEST_ITEM table
   merge into TEST_ITEM n
     using
         -- Query TEST_ITEM_STREAM
         (SELECT RECORD_METADATA:key as k, RECORD_CONTENT:val as v from
             ↪ TEST_ITEM_STREAM) stm
         -- Match the stream with table on the condition that i_id is equal
         on k:i_id = n.i_id
     -- If the TEST_ITEM table contains a record that matches i_id and v
         ↪ is empty, delete this record
     when matched and IS_NULL_VALUE(v) = true then
         delete
   ```

```
  -- If the TEST_ITEM table contains a record that matches i_id and v
     ↪ is not empty, update this record
  when matched and IS_NULL_VALUE(v) = false then
     update set n.i_data = v:i_data, n.i_im_id = v:i_im_id, n.i_name =
        ↪ v:i_name, n.i_price = v:i_price

  -- If the TEST_ITEM table does not contain a record that matches i_id
     ↪ , insert this record
  when not matched then
     insert
        (i_data, i_id, i_im_id, i_name, i_price)
     values
        (v:i_data, v:i_id, v:i_im_id, v:i_name, v:i_price)
;
```

In the preceding example, the `MERGE INTO` statement of Snowflake is used to match the stream and the table on a specific condition, and then execute corresponding operations, such as deleting, updating, or inserting a record. In this example, three `WHERE` clauses are used for the following three scenarios:

- Delete the record in the table when the stream and the table match and the data in the stream is empty.
- Update the record in the table when the stream and the table match and the data in the stream is not empty.
- Insert the record in the table when the stream and the table do not match.

4. Periodically execute the statement in Step 3 to ensure that data is always up-to-date. You can also use the `SCHEDULED TASK` feature of Snowflake:

```
-- Create a TASK to periodically execute the MERGE INTO statement
create or replace task STREAM_TO_ITEM
    warehouse = test
    -- Execute the TASK every minute
    schedule = '1 minute'
when
    -- Skip the TASK when there is no data in TEST_ITEM_STREAM
    system$stream_has_data('TEST_ITEM_STREAM')
as
-- Merge data into the TEST_ITEM table. The statement is the same as
    ↪ that in the preceding example
merge into TEST_ITEM n
  using
     (select RECORD_METADATA:key as k, RECORD_CONTENT:val as v from
        ↪ TEST_ITEM_STREAM) stm
     on k:i_id = n.i_id
  when matched and IS_NULL_VALUE(v) = true then
```

```
    delete
  when matched and IS_NULL_VALUE(v) = false then
    update set n.i_data = v:i_data, n.i_im_id = v:i_im_id, n.i_name =
      ↪ v:i_name, n.i_price = v:i_price
  when not matched then
    insert
      (i_data, i_id, i_im_id, i_name, i_price)
    values
      (v:i_data, v:i_id, v:i_im_id, v:i_name, v:i_price)
;
```

At this time, you have established a data channel with certain ETL capabilities. Through this data channel, you can replicate TiDB's incremental data change logs to Snowflake, maintain a data replica of TiDB, and use the data in Snowflake.

The last step is to regularly clean up the useless data in the `TIDB_TEST_ITEM` table:

```
-- Clean up the TIDB_TEST_ITEM table every two hours
create or replace task TRUNCATE_TIDB_TEST_ITEM
    warehouse = test
    schedule = '120 minute'
when
    system$stream_has_data('TIDB_TEST_ITEM')
as
    TRUNCATE table TIDB_TEST_ITEM;
```

7.2.1.3 Integrate data with ksqlDB

ksqlDB is a database purpose-built for stream processing applications. You can create ksqlDB clusters on Confluent Cloud and access incremental data replicated by TiCDC.

1. Select **ksqlDB** in the Confluent Cloud Console and create a ksqlDB cluster as instructed.

   Wait until the ksqlDB cluster status is **Running**. This process takes several minutes.

2. In the ksqlDB Editor, run the following command to create a stream to access the `tidb_tpcc_orders` topic:

   ```
   CREATE STREAM orders (o_id INTEGER, o_d_id INTEGER, o_w_id INTEGER,
      ↪ o_c_id INTEGER, o_entry_d STRING, o_carrier_id INTEGER, o_ol_cnt
      ↪  INTEGER, o_all_local INTEGER) WITH (kafka_topic='
      ↪ tidb_tpcc_orders', partitions=3, value_format='AVRO');
   ```

3. Run the following command to check the orders STREAM data:

```
SELECT * FROM ORDERS EMIT CHANGES;
```

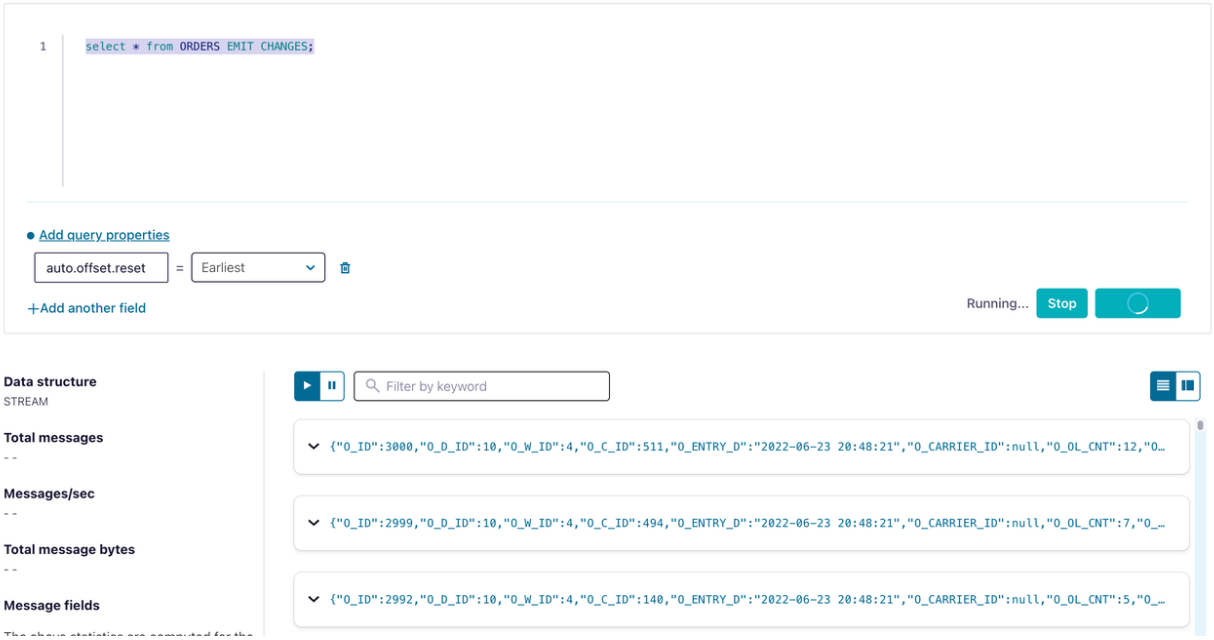

Figure 52: Select from orders

You can see that the incremental data has been replicated to ksqlDB, as shown in the preceding figure. Data integration with ksqlDB is done.

7.2.1.4 Integrate data with SQL Server

Microsoft SQL Server is a relational database management system (RDBMS) developed by Microsoft. With Confluent, you can replicate TiDB incremental data to SQL Server by creating SQL Server Sink Connectors.

1. Connect to SQL Server and create a database named `tpcc`.

```
[ec2-user@ip-172-1-1-1 bin]$ sqlcmd -S 10.61.43.14,1433 -U admin
Password:
1> create database tpcc
2> go
1> select name from master.dbo.sysdatabases
2> go
name
----------------------------------------------------------------------
master
tempdb
```

```
model
msdb
rdsadmin
tpcc
(6 rows affected)
```

2. In the Confluent Cloud Console, choose **Data integration** > **Connectors** > **Microsoft SQL Server Sink**. The page shown below is displayed.

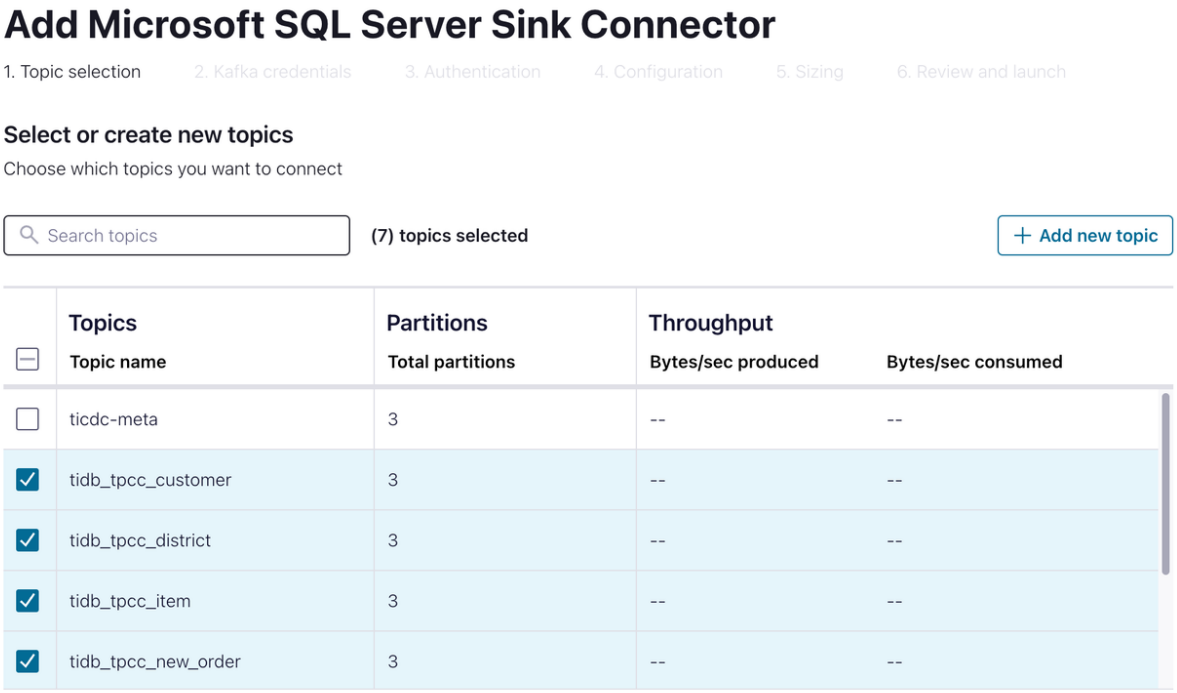

Figure 53: Topic selection

3. Select the topic you want to replicate to SQL Server. Then go to the next page.

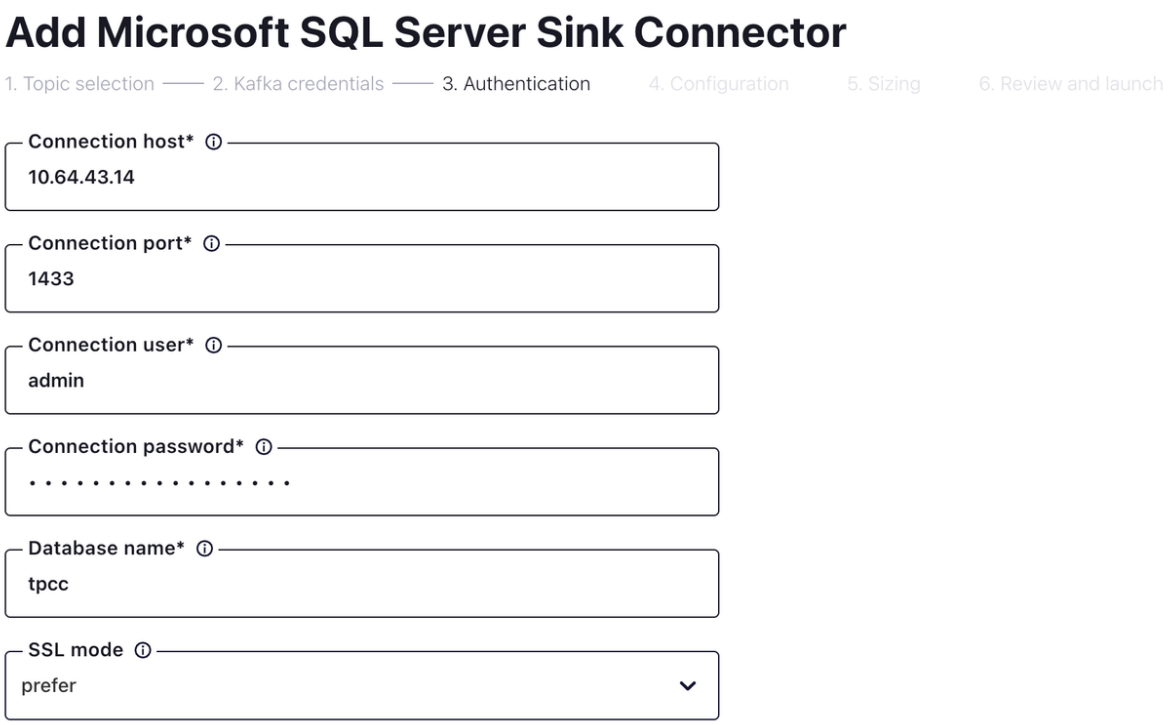

Figure 54: Authentication

4. Fill in the connection and authentication information. Then go to the next page.

5. On the **Configuration** page, configure the following fields and click **Continue**.

Field	Value
Input Kafka record value format	AVRO
Insert mode	UPSERT
Auto create table	true
Auto add columns	true
PK mode	record_key
Input Kafka record key format	AVRO
Delete on null	true

6. After configuration, click **Continue**. Wait until the connector status becomes **Running**, which might take several minutes.

Run Cancel | Disconnect Change Connection | tpcc

```
SELECT TOP (1000) [o_id]
      ,[o_d_id]
      ,[o_w_id]
      ,[o_c_id]
      ,[o_entry_d]
      ,[o_carrier_id]
      ,[o_ol_cnt]
      ,[o_all_local]
  FROM [tpcc].[dbo].[tidb_tpcc_orders]
```

Results Messages

	o_id	o_d_id	o_w_id	o_c_id	o_entry_d	o_carrier_id	o_ol_cnt	o_all_local
1	1	1	1	1860	2022-06-22 22:08:06	3	6	1
2	1	3	1	884	2022-06-22 22:08:06	10	5	1

Figure 55: Results

7. Connect SQL Server and observe the data. You can see that the incremental data has been replicated to SQL Server, as shown in the preceding figure. Data integration with SQL Server is done.

7.2.2 Integrate Data with Apache Kafka and Apache Flink

This document describes how to replicate TiDB data to Apache Kafka and Apache Flink using TiCDC. The organization of this document is as follows:

1. Quickly deploy a TiDB cluster with TiCDC included, and create a Kafka cluster and a Flink cluster.
2. Create a changefeed that replicates data from TiDB to Kafka.
3. Write data to TiDB using go-tpc.
4. Observe data on Kafka console consumer and check that the data is replicated to a specified Kafka topic.
5. (Optional) Configure the Flink cluster to consume Kafka data.

The preceding steps are performed in a lab environment. You can also deploy a cluster in a production environment by referring to these steps.

7.2.2.1 Step 1. Set up the environment

1. Deploy a TiDB cluster with TiCDC included.

   In a lab or testing environment, you can deploy a TiDB cluster with TiCDC included quickly by using TiUP Playground.

   ```
   tiup playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --tiflash 0 --ticdc
       ↪ 1
   # View cluster status
   tiup status
   ```

   If TiUP is not installed yet, refer to Install TiUP. In a production environment, you can deploy a TiCDC as instructed in Deploy TiCDC.

2. Create a Kafka cluster.

   - Lab environment: refer to Apache Kakfa Quickstart to start a Kafka cluster.
   - Production environment: refer to Running Kafka in Production to deploy a Kafka production cluster.

3. (Optional) Create a Flink cluster.

   - Lab environment: refer to Apache Flink First steps to start a Flink cluster.
   - Production environment: refer to Apache Kafka Deployment to deploy a Flink production cluster.

7.2.2.2 Step 2. Create a Kafka changefeed

1. Create a changefeed configuration file.

   As required by Flink, incremental data of each table must be sent to an independent topic, and a partition must be dispatched for each event based on the primary key value. Therefore, you need to create a changefeed configuration file `changefeed.conf` with the following contents:

   ```
   [sink]
   dispatchers = [
   {matcher = ['*.*'], topic = "tidb_{schema}_{table}", partition="index-
       ↪ value"},
   ]
   ```

   For detailed description of `dispatchers` in the configuration file, see Customize the rules for Topic and Partition dispatchers of Kafka Sink.

2. Create a changefeed to replicate incremental data to Kafka:

```
tiup ctl:<cluster-version> cdc changefeed create --pd="http
    ↪ ://127.0.0.1:2379" --sink-uri="kafka://127.0.0.1:9092/kafka-topic
    ↪ -name?protocol=canal-json" --changefeed-id="kafka-changefeed" --
    ↪ config="changefeed.conf"
```

- If the changefeed is successfully created, changefeed information, such as changefeed ID, is displayed, as shown below:

```
Create changefeed successfully!
ID: kafka-changefeed
Info: {... changfeed info json struct ...}
```

- If no result is returned after you run the command, check the network connectivity between the server where you run the command and the Kafka machine specified in the sink URI.

In a production environment, a Kafka cluster has multiple broker nodes. Therefore, you can add the addresses of multiple brokers to the sink UIR. This ensures stable access to the Kafka cluster. When the Kafka cluster is down, the changefeed still works. Suppose that a Kafka cluster has three broker nodes, with IP addresses being 127.0.0.1:9092, 127.0.0.2:9092, and 127.0.0.3:9092, respectively. You can create a changefeed with the following sink URI.

```
tiup ctl:<cluster-version> cdc changefeed create --pd="http
    ↪ ://127.0.0.1:2379" --sink-uri="kafka
    ↪ ://127.0.0.1:9092,127.0.0.2:9092,127.0.0.3:9092/kafka-topic-name?
    ↪ protocol=canal-json&partition-num=3&replication-factor=1&max-
    ↪ message-bytes=1048576" --config="changefeed.conf"
```

3. After creating the changefeed, run the following command to check the changefeed status:

```
tiup ctl:<cluster-version> cdc changefeed list --pd="http
    ↪ ://127.0.0.1:2379"
```

You can refer to Manage TiCDC Cluster and Replication Tasks to manage the changefeed.

7.2.2.3 Step 3. Write data to generate change logs

After the preceding steps are done, TiCDC sends change logs of incremental data in the TiDB cluster to Kafka. This section describes how to write data into TiDB to generate change logs.

1. Simulate service workload.

   To generate change logs in a lab environment, you can use go-tpc to write data to the TiDB cluster. Specifically, run the following command to use TiUP bench to create a `tpcc` database and write data to this new database.

   ```
   tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 prepare
   tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 run --time
       ↪ 300s
   ```

   For more details about go-tpc, refer to How to Run TPC-C Test on TiDB.

2. Consume data in the Kafka topic.

   When a changefeed works normally, it writes data to the Kafka topic. Run `kafka-console-consumer.sh`. You can see that data is successfully written to the Kafka topic.

   ```
   ./bin/kafka-console-consumer.sh --bootstrap-server 127.0.0.1:9092 --
       ↪ from-beginning --topic `${topic-name}`
   ```

At this time, incremental data of the TiDB database is successfully replicated to Kafka. Next, you can use Flink to consume Kafka data. Alternatively, you can develop a Kafka consumer client yourself for specific service scenarios.

7.2.2.4 (Optional) Step 4. Configure Flink to consume Kafka data

1. Install a Flink Kafka connector.

   In the Flink ecosystem, a Flink Kafka connector is used to consume Kafka data and output data to Flink. However, Flink Kafka connectors are not automatically installed. To use it, add a Flink Kafka connector and its dependencies to the Flink installation directory after installing Flink. Specifically, download the following jar files to the `lib` directory of the Flink installation directory. If you have already run the Flink cluster, restart it to load the new plugin.

   - flink-connector-kafka-1.15.0.jar
   - flink-sql-connector-kafka-1.15.0.jar
   - kafka-clients-3.2.0.jar

2. Create a table.

   In the directory where Flink is installed, run the following command to start the Flink SQL client:

   ```
   [root@flink flink-1.15.0]# ./bin/sql-client.sh
   ```

   Then, run the following command to create a table named `tpcc_orders`.

```
CREATE TABLE tpcc_orders (
    o_id INTEGER,
    o_d_id INTEGER,
    o_w_id INTEGER,
    o_c_id INTEGER,
    o_entry_d STRING,
    o_carrier_id INTEGER,
    o_ol_cnt INTEGER,
    o_all_local INTEGER
) WITH (
'connector' = 'kafka',
'topic' = 'tidb_tpcc_orders',
'properties.bootstrap.servers' = '127.0.0.1:9092',
'properties.group.id' = 'testGroup',
'format' = 'canal-json',
'scan.startup.mode' = 'earliest-offset',
'properties.auto.offset.reset' = 'earliest'
)
```

Replace `topic` and `properties.bootstrap.servers` with the actual values in the environment.

3. Query data of the table.

   Run the following command to query data of the `tpcc_orders` table:

```
SELECT * FROM tpcc_orders;
```

   After this command is executed, you can see that there is new data in the table, as shown in the following figure.

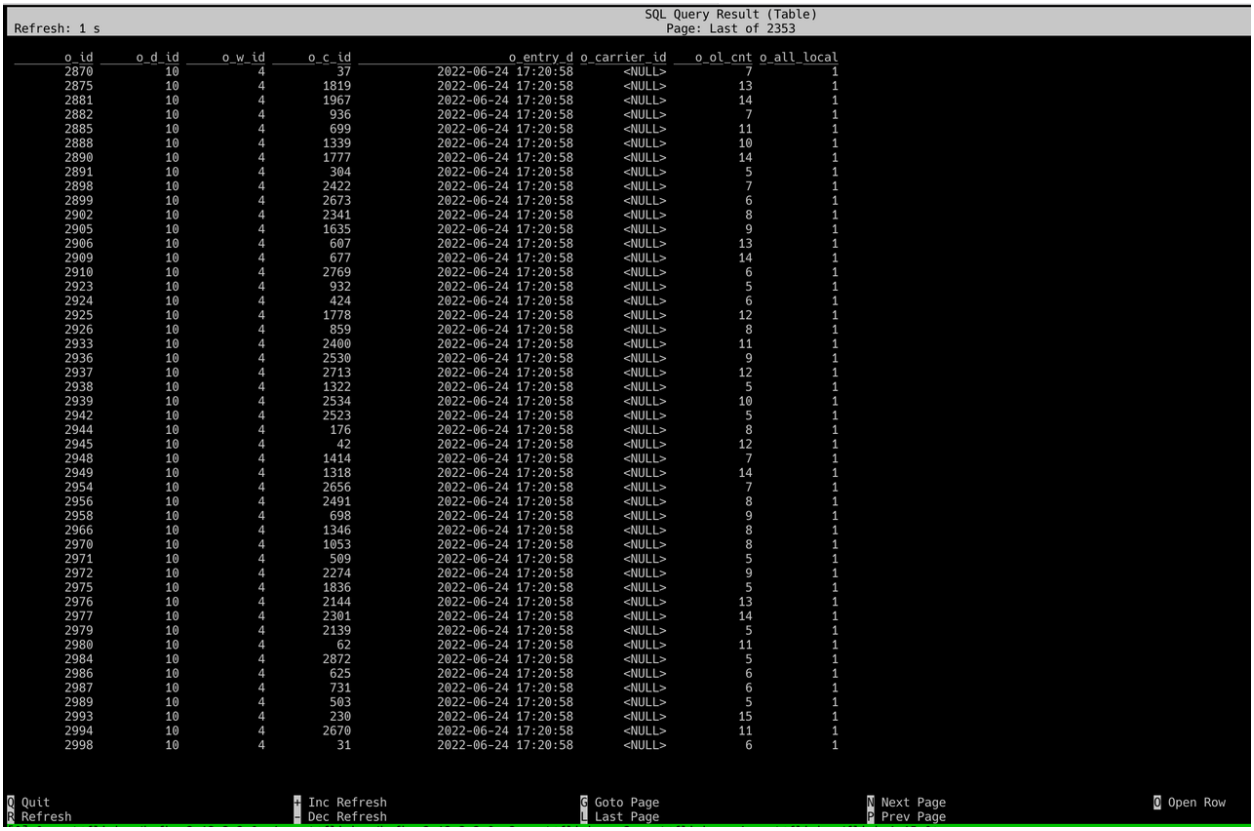

Figure 56: SQL query result

Data integration with Kafka is done.

8 Maintain

8.1 Upgrade

8.1.1 Upgrade TiDB Using TiUP

This document is targeted for the following upgrade paths:

- Upgrade from TiDB 4.0 versions to TiDB 6.4.
- Upgrade from TiDB 5.0-5.4 versions to TiDB 6.4.
- Upgrade from TiDB 6.0 to TiDB 6.4.
- Upgrade from TiDB 6.1 to TiDB 6.4.
- Upgrade from TiDB 6.2 to TiDB 6.4.
- Upgrade from TiDB 6.3 to TiDB 6.4.

Warning:

- You cannot upgrade TiFlash online from versions earlier than 5.3 to 5.3 or later. Instead, you must first stop all the TiFlash instances of the early version, and then upgrade the cluster offline. If other components (such as TiDB and TiKV) do not support an online upgrade, follow the instructions in warnings in Online upgrade.
- **DO NOT** upgrade a TiDB cluster when a DDL statement is being executed in the cluster (usually for the time-consuming DDL statements such as `ADD INDEX` and the column type changes).
- Before the upgrade, it is recommended to use the `ADMIN SHOW DDL` command to check whether the TiDB cluster has an ongoing DDL job. If the cluster has a DDL job, to upgrade the cluster, wait until the DDL execution is finished or use the `ADMIN CANCEL DDL` command to cancel the DDL job before you upgrade the cluster.
- In addition, during the cluster upgrade, **DO NOT** execute any DDL statement. Otherwise, the issue of undefined behavior might occur.

Note:

If your cluster to be upgraded is v3.1 or an earlier version (v3.0 or v2.1), the direct upgrade to v6.4.0 is not supported. You need to upgrade your cluster first to v4.0 and then to v6.4.0.

8.1.1.1 Upgrade caveat

- TiDB currently does not support version downgrade or rolling back to an earlier version after the upgrade.
- For the v4.0 cluster managed using TiDB Ansible, you need to import the cluster to TiUP (`tiup cluster`) for new management according to Upgrade TiDB Using TiUP (v4.0). Then you can upgrade the cluster to v6.4.0 according to this document.
- To update versions earlier than v3.0 to v6.4.0:
  1. Update this version to 3.0 using TiDB Ansible.
  2. Use TiUP (`tiup cluster`) to import the TiDB Ansible configuration.
  3. Update the 3.0 version to 4.0 according to Upgrade TiDB Using TiUP (v4.0).
  4. Upgrade the cluster to v6.4.0 according to this document.
- Support upgrading the versions of TiDB Binlog, TiCDC, TiFlash, and other components.

- When upgrading TiFlash from versions earlier than v6.3.0 to v6.3.0 and later versions, note that the CPU must support the AVX2 instruction set under the Linux AMD64 architecture and the ARMv8 instruction set architecture under the Linux ARM64 architecture. For details, see the description in v6.3.0 Release Notes.
- For detailed compatibility changes of different versions, see the Release Notes of each version. Modify your cluster configuration according to the "Compatibility Changes" section of the corresponding release notes.
- For clusters that upgrade from versions earlier than v5.3 to v5.3 or later versions, the default deployed Prometheus will upgrade from v2.8.1 to v2.27.1. Prometheus v2.27.1 provides more features and fixes a security issue. Compared with v2.8.1, alert time representation in v2.27.1 is changed. For more details, see Prometheus commit for more details.

8.1.1.2 Preparations

This section introduces the preparation works needed before upgrading your TiDB cluster, including upgrading TiUP and the TiUP Cluster component.

8.1.1.2.1 Step 1: Review compatibility changes

Review the compatibility changes in TiDB v6.4.0 release notes. If any changes affect your upgrade, take actions accordingly.

8.1.1.2.2 Step 2: Upgrade TiUP or TiUP offline mirror

Before upgrading your TiDB cluster, you first need to upgrade TiUP or TiUP mirror.

Upgrade TiUP and TiUP Cluster

> **Note:**
>
> If the control machine of the cluster to upgrade cannot access `https://tiup-mirrors.pingcap.com`, skip this section and see Upgrade TiUP offline mirror.

1. Upgrade the TiUP version. It is recommended that the TiUP version is `1.11.0` or later.

```
tiup update --self
tiup --version
```

2. Upgrade the TiUP Cluster version. It is recommended that the TiUP Cluster version is `1.11.0` or later.

```
tiup update cluster
tiup cluster --version
```

Upgrade TiUP offline mirror

> **Note:**
>
> If the cluster to upgrade was deployed not using the offline method, skip this step.

Refer to Deploy a TiDB Cluster Using TiUP - Deploy TiUP offline to download the TiUP mirror of the new version and upload it to the control machine. After executing `local_install.sh`, TiUP will complete the overwrite upgrade.

```
tar xzvf tidb-community-server-${version}-linux-amd64.tar.gz
sh tidb-community-server-${version}-linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

After the overwrite upgrade, run the following command to merge the server and toolkit offline mirrors to the server directory:

```
tar xf tidb-community-toolkit-${version}-linux-amd64.tar.gz
ls -ld tidb-community-server-${version}-linux-amd64 tidb-community-toolkit-$
    ↪ {version}-linux-amd64
cd tidb-community-server-${version}-linux-amd64/
cp -rp keys ~/.tiup/
tiup mirror merge ../tidb-community-toolkit-${version}-linux-amd64
```

After merging the mirrors, run the following command to upgrade the TiUP Cluster component:

```
tiup update cluster
```

Now, the offline mirror has been upgraded successfully. If an error occurs during TiUP operation after the overwriting, it might be that the `manifest` is not updated. You can try `rm -rf ~/.tiup/manifests/*` before running TiUP again.

8.1.1.2.3 Step 3: Edit TiUP topology configuration file

Note:

Skip this step if one of the following situations applies:

- You have not modified the configuration parameters of the original cluster. Or you have modified the configuration parameters using `tiup cluster` but no more modification is needed.
- After the upgrade, you want to use v6.4.0's default parameter values for the unmodified configuration items.

1. Enter the `vi` editing mode to edit the topology file:

```
tiup cluster edit-config <cluster-name>
```

2. Refer to the format of topology configuration template and fill the parameters you want to modify in the `server_configs` section of the topology file.

3. After the modification, enter : + w + q to save the change and exit the editing mode. Enter Y to confirm the change.

Note:

Before you upgrade the cluster to v6.4.0, make sure that the parameters you have modified in v4.0 are compatible in v6.4.0. For details, see TiKV Configuration File.

8.1.1.2.4 Step 4: Check the health status of the current cluster

To avoid the undefined behaviors or other issues during the upgrade, it is recommended to check the health status of Regions of the current cluster before the upgrade. To do that, you can use the `check` sub-command.

```
tiup cluster check <cluster-name> --cluster
```

After the command is executed, the "Region status" check result will be output.

- If the result is "All Regions are healthy", all Regions in the current cluster are healthy and you can continue the upgrade.
- If the result is "Regions are not fully healthy: m miss-peer, n pending-peer" with the "Please fix unhealthy regions before other operations." prompt, some Regions in the current cluster are abnormal. You need to troubleshoot the anomalies until the check result becomes "All Regions are healthy". Then you can continue the upgrade.

8.1.1.3 Upgrade the TiDB cluster

This section describes how to upgrade the TiDB cluster and verify the version after the upgrade.

8.1.1.3.1 Upgrade the TiDB cluster to a specified version

You can upgrade your cluster in one of the two ways: online upgrade and offline upgrade.

By default, TiUP Cluster upgrades the TiDB cluster using the online method, which means that the TiDB cluster can still provide services during the upgrade process. With the online method, the leaders are migrated one by one on each node before the upgrade and restart. Therefore, for a large-scale cluster, it takes a long time to complete the entire upgrade operation.

If your application has a maintenance window for the database to be stopped for maintenance, you can use the offline upgrade method to quickly perform the upgrade operation.

Online upgrade

```
tiup cluster upgrade <cluster-name> <version>
```

For example, if you want to upgrade the cluster to v6.4.0:

```
tiup cluster upgrade <cluster-name> v6.4.0
```

Note:

- An online upgrade upgrades all components one by one. During the upgrade of TiKV, all leaders in a TiKV instance are evicted before stopping the instance. The default timeout time is 5 minutes (300 seconds). The instance is directly stopped after this timeout time.
- You can use the `--force` parameter to upgrade the cluster immediately without evicting the leader. However, the errors that occur during the upgrade will be ignored, which means that you are not notified of any upgrade failure. Therefore, use the `--force` parameter with caution.
- To keep a stable performance, make sure that all leaders in a TiKV instance are evicted before stopping the instance. You can set `--transfer-timeout` to a larger value, for example, `--transfer-timeout 3600` (unit: second).
- To upgrade TiFlash from versions earlier than 5.3 to 5.3 or later, you should stop TiFlash and then upgrade it. The following steps help you upgrade TiFlash without interrupting other components:

1. Stop the TiFlash instance: `tiup cluster stop <cluster-name> -R tiflash`
2. Upgrade the TiDB cluster without restarting it (only updating the files): `tiup cluster upgrade <cluster-name> <version> --offline`
3. Reload the TiDB cluster: `tiup cluster reload <cluster-name>`. After the reload, the TiFlash instance is started and you do not need to manually start it.

- Try to avoid creating a new clustered index table when you apply rolling updates to the clusters using TiDB Binlog.

Offline upgrade

1. Before the offline upgrade, you first need to stop the entire cluster.

```
tiup cluster stop <cluster-name>
```

2. Use the `upgrade` command with the `--offline` option to perform the offline upgrade.

```
tiup cluster upgrade <cluster-name> <version> --offline
```

3. After the upgrade, the cluster will not be automatically restarted. You need to use the `start` command to restart it.

```
tiup cluster start <cluster-name>
```

8.1.1.3.2 Verify the cluster version

Execute the `display` command to view the latest cluster version `TiDB Version`:

```
tiup cluster display <cluster-name>
```

```
Cluster type:     tidb
Cluster name:     <cluster-name>
Cluster version:  v6.4.0
```

Note:

By default, TiUP and TiDB share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.

8.1.1.4 FAQ

This section describes common problems encountered when updating the TiDB cluster using TiUP.

8.1.1.4.1 If an error occurs and the upgrade is interrupted, how to resume the upgrade after fixing this error?

Re-execute the `tiup cluster upgrade` command to resume the upgrade. The upgrade operation restarts the nodes that have been previously upgraded. If you do not want the upgraded nodes to be restarted, use the `replay` sub-command to retry the operation:

1. Execute `tiup cluster audit` to see the operation records:

```
tiup cluster audit
```

   Find the failed upgrade operation record and keep the ID of this operation record. The ID is the `<audit-id>` value in the next step.

2. Execute `tiup cluster replay <audit-id>` to retry the corresponding operation:

```
tiup cluster replay <audit-id>
```

8.1.1.4.2 The evict leader has waited too long during the upgrade. How to skip this step for a quick upgrade?

You can specify `--force`. Then the processes of transferring PD leader and evicting TiKV leader are skipped during the upgrade. The cluster is directly restarted to update the version, which has a great impact on the cluster that runs online. Here is the command:

```
tiup cluster upgrade <cluster-name> <version> --force
```

8.1.1.4.3 How to update the version of tools such as pd-ctl after upgrading the TiDB cluster?

You can upgrade the tool version by using TiUP to install the `ctl` component of the corresponding version:

```
tiup install ctl:v6.4.0
```

8.1.2 Use TiDB Operator

8.1.3 TiFlash v6.2 Upgrade Guide

This document describes the functional changes in TiFlash modules you need to pay attention to when you upgrade TiFlash from earlier versions to v6.2, and recommended actions for you to take.

To learn the standard upgrade process, see the following documents:

- Upgrade TiDB Using TiUP
- Upgrade TiDB on Kubernetes

Note:

- An experimental feature introduced in v6.2.0, FastScan provides more efficient query performance at the cost of strong data consistency. Note that the form and usage of this feature might change in subsequent versions.
- It is not recommended that you upgrade TiDB that includes TiFlash across major versions, for example, from v4.x to v6.x. Instead, you need to upgrade from v4.x to v5.x first, and then to v6.x.
- v4.x is near the end of its life cycle. It is recommended that you upgrade to v5.x or later as soon as possible. For more information, see TiDB Release Support Policy.
- PingCAP does not provide bug fixes for non-LTS versions, such as v6.0. It is recommended that you upgrade to v6.1 and later LTS versions whenever possible.
- To upgrade TiFlash from versions earlier than v5.3.0 to v5.3.0 or later, you should stop TiFlash and then upgrade it. The following steps help you upgrade TiFlash without interrupting other components:
  - Stop the TiFlash instance: `tiup cluster stop <cluster-name> -R tiflash`
  - Upgrade the TiDB cluster without restarting it (only updating the files): `tiup cluster upgrade <cluster-name> <version> --offline`
  - Reload the TiDB cluster: `tiup cluster reload <cluster-name>`. After the reload, the TiFlash instance is started and you do not need to manually start it.

8.1.3.1 From 5.x or v6.0 to v6.1

When you upgrade TiFlash from v5.x or v6.0 to v6.1, pay attention to the functional changes in TiFlash Proxy and dynamic pruning.

8.1.3.1.1 TiFlash Proxy

TiFlash Proxy is upgraded in v6.1.0 (aligned with TiKV v6.0.0). The new version has upgraded the RocksDB version. After you upgrade TiFlash to v6.1, the data format is converted to the new version automatically.

In regular upgrades, the data conversion does not involve any risks. However, if you need to downgrade TiFlash from v6.1 to any earlier version in special scenarios (for example, testing or verification scenarios), the earlier version might fail to parse the new RocksDB configuration. As as result, TiFlash will fail to restart. It is recommended that you fully test and verify the upgrade process and prepare an emergency plan.

Workaround for downgrading TiFlash in testing or other special scenarios

You can forcibly scale in the target TiFlash node and then replicate data from TiKV again. For detailed steps, see Scale in a TiFlash cluster.

8.1.3.1.2 Dynamic pruning

If you do not enable dynamic pruning mode and will not use it in the future, you can skip this section.

- Newly installed TiDB v6.1.0: Dynamic pruning is enabled by default.
- TiDB v6.0 and earlier: Dynamic pruning is disabled by default. The setting of dynamic pruning after an upgrade inherits that of the previous version. That is, dynamic pruning will not be enabled (or disabled) automatically after an upgrade.

  After an upgrade, to enable dynamic pruning, set `tidb_partition_prune_mode` to `dynamic` and manually update GlobalStats of partitioned tables. For details, see Dynamic pruning mode.

8.1.3.2 From v5.x or v6.0 to v6.2

In TiDB v6.2, TiFlash upgrades its data storage format to the V3 version. Therefore, when you upgrade TiFlash from v5.x or v6.0 to v6.2, besides functional changes in TiFlash Proxy and Dynamic pruning, you also need to pay attention to the functional change in PageStorage.

8.1.3.2.1 PageStorage

By default, TiFlash v6.2.0 uses PageStorage V3 version `format_version = 4`. This new data format significantly reduces the peak write I/O traffic. In scenarios with high update traffic and high concurrency or heavy queries, it effectively relieves excessive CPU usage caused by TiFlash data GC. Meanwhile, compared with the earlier storage format, the V3 version significantly reduces space amplification and resource consumption.

- After an upgrade to v6.2.0, as new data is written to the existing TiFlash nodes, earlier data will be gradually converted to the new format.
- However, earlier data cannot be completely converted to the new format during the upgrade, because the conversion consumes a certain amount of system overhead (services are not affected, but you still need to pay attention). After the upgrade, it is recommended that you run the `Compact` command to convert the data to the new format. The steps are as follows:

1. Run the following command for each table containing TiFlash replicas:

```
ALTER TABLE <table_name> COMPACT tiflash replica;
```

2. Restart the TiFlash node.

You can check whether tables still use the old data format on Grafana: **TiFlash-Summary** > **Storage Pool** > **Storage Pool Run Mode**.

- Only V2: Number of tables using PageStorage V2 (including partitions)
- Only V3: Number of tables using PageStorage V3 (including partitions)
- Mix Mode: Number of tables with data format converted from PageStorage V2 to PageStorage V3 (including partitions)

Workaround for downgrading TiFlash in testing or other special scenarios

You can forcibly scale in the target TiFlash node and then replicate data from TiKV again. For detailed steps, see Scale in a TiFlash cluster.

8.1.3.3 From v6.1 to v6.2

When you upgrade TiFlash from v6.1 to v6.2, pay attention to the change in data storage format. For details, see PageStorage.

8.2 Scale

8.2.1 Scale a TiDB Cluster Using TiUP

The capacity of a TiDB cluster can be increased or decreased without interrupting the online services.

This document describes how to scale the TiDB, TiKV, PD, TiCDC, or TiFlash cluster using TiUP. If you have not installed TiUP, refer to the steps in Step 2. Deploy TiUP on the control machine.

To view the current cluster name list, run `tiup cluster list`.

For example, if the original topology of the cluster is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.1.1 Scale out a TiDB/PD/TiKV cluster

This section exemplifies how to add a TiDB node to the `10.0.1.5` host.

> **Note:**
>
> You can take similar steps to add a PD node. Before you add a TiKV node, it is recommended that you adjust the PD scheduling parameters in advance according to the cluster load.

1. Configure the scale-out topology:

> **Note:**
>
> - The port and directory information is not required by default.
> - If multiple instances are deployed on a single machine, you need to allocate different ports and directories for them. If the ports or directories have conflicts, you will receive a notification during deployment or scaling.
> - Since TiUP v1.0.0, the scale-out configuration inherits the global configuration of the original cluster.

Add the scale-out topology configuration in the `scale-out.yaml` file:

```
vi scale-out.yaml
```

```
tidb_servers:
- host: 10.0.1.5
  ssh_port: 22
  port: 4000
  status_port: 10080
  deploy_dir: /data/deploy/install/deploy/tidb-4000
  log_dir: /data/deploy/install/log/tidb-4000
```

Here is a TiKV configuration file template:

```
tikv_servers:
- host: 10.0.1.5
  ssh_port: 22
  port: 20160
  status_port: 20180
  deploy_dir: /data/deploy/install/deploy/tikv-20160
  data_dir: /data/deploy/install/data/tikv-20160
  log_dir: /data/deploy/install/log/tikv-20160
```

Here is a PD configuration file template:

```
pd_servers:
- host: 10.0.1.5
  ssh_port: 22
  name: pd-1
  client_port: 2379
  peer_port: 2380
  deploy_dir: /data/deploy/install/deploy/pd-2379
  data_dir: /data/deploy/install/data/pd-2379
  log_dir: /data/deploy/install/log/pd-2379
```

To view the configuration of the current cluster, run `tiup cluster edit-config <cluster-name>`. Because the parameter configuration of `global` and `server_configs` is inherited by `scale-out.yaml` and thus also takes effect in `scale-out.yaml`.

2. Run the scale-out command:

   Before you run the `scale-out` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

   1. Check for potential risks:

      ```
      tiup cluster check <cluster-name> scale-out.yaml --cluster --user root [-p] [-i /home/root/.ssh/gcp_rsa]
      ```

   2. Enable automatic repair:

      ```
      tiup cluster check <cluster-name> scale-out.yaml --cluster --apply --user root [-p] [-i /home/root/.ssh/gcp_rsa]
      ```

   3. Run the `scale-out` command:

      ```
      tiup cluster scale-out <cluster-name> scale-out.yaml [-p] [-i /home/root/.ssh/gcp_rsa]
      ```

   In the preceding commands:

   - `scale-out.yaml` is the scale-out configuration file.
   - `--user root` indicates logging in to the target machine as the `root` user to complete the cluster scale out. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
   - `[-i]` and `[-p]` are optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

If you see `Scaled cluster <cluster-name> out successfully`, the scale-out operation succeeds.

3. Check the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser to monitor the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	**TiDB** + TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.1.2 Scale out a TiFlash cluster

This section exemplifies how to add a TiFlash node to the `10.0.1.4` host.

> **Note:**
>
> When adding a TiFlash node to an existing TiDB cluster, note the following:
>
> - Confirm that the current TiDB version supports using TiFlash. Otherwise, upgrade your TiDB cluster to v5.0 or later versions.
> - Run the `tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> config set enable-placement-rules true` command to enable the Placement Rules feature. Or run the corresponding command in pd-ctl.

1. Add the node information to the `scale-out.yaml` file:

   Create the `scale-out.yaml` file to add the TiFlash node information.

```
tiflash_servers:
- host: 10.0.1.4
```

   Currently, you can only add IP addresses but not domain names.

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yaml
```

> **Note:**
> The preceding command is based on the assumption that the mutual trust has been configured for the user to run the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD + **TiFlash**
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.1.3 Scale out a TiCDC cluster

This section exemplifies how to add two TiCDC nodes to the `10.0.1.3` and `10.0.1.4` hosts.

1. Add the node information to the `scale-out.yaml` file:

   Create the `scale-out.yaml` file to add the TiCDC node information.

```
cdc_servers:
  - host: 10.0.1.3
    gc-ttl: 86400
    data_dir: /data/deploy/install/data/cdc-8300
  - host: 10.0.1.4
    gc-ttl: 86400
    data_dir: /data/deploy/install/data/cdc-8300
```

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yaml
```

> **Note:**
> The preceding command is based on the assumption that the mutual trust has been configured for the user to run the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + **TiCDC**
10.0.1.4	TiDB + PD + TiFlash + **TiCDC**
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.1.4 Scale in a TiDB/PD/TiKV cluster

This section exemplifies how to remove a TiKV node from the `10.0.1.5` host.

> **Note:**
>
> - You can take similar steps to remove a TiDB or PD node.
> - Because the TiKV, TiFlash, and TiDB Binlog components are taken offline asynchronously and the stopping process takes a long time, TiUP takes them offline in different methods. For details, see Particular handling of components' offline process.
> - The PD Client in TiKV caches the list of PD nodes. The current version of TiKV has a mechanism to automatically and regularly update PD

nodes, which can help mitigate the issue of an expired list of PD nodes cached by TiKV. However, after scaling out PD, you should try to avoid directly removing all PD nodes at once that exist before the scaling. If necessary, before making all the previously existing PD nodes offline, make sure to switch the PD leader to a newly added PD node.

1. View the node ID information:

```
tiup cluster display <cluster-name>
```

```
Starting /root/.tiup/components/cluster/v1.11.0/cluster display <
    ↪ cluster-name>
TiDB Cluster: <cluster-name>
TiDB Version: v6.4.0
ID            Role        Host       Ports                          Status
    ↪  Data Dir             Deploy Dir
--            ----        ----       -----                          ------
    ↪  --------             ----------
10.0.1.3:8300 cdc         10.0.1.3   8300                           Up
    ↪      data/cdc-8300        deploy/cdc-8300
10.0.1.4:8300 cdc         10.0.1.4   8300                           Up

    ↪      data/tikv-20160      deploy/tikv-20160
10.0.1.3:4000 tidb        10.0.1.3   4000/10080                     Up
    ↪      -                    deploy/tidb-4000
10.0.1.4:4000 tidb        10.0.1.4   4000/10080                     Up
    ↪      -                    deploy/tidb-4000
10.0.1.5:4000 tidb        10.0.1.5   4000/10080                     Up
    ↪      -                    deploy/tidb-4000
10.0.1.3:9000 tiflash     10.0.1.3   9000/8123/3930/20170/20292/8234 Up
    ↪  data/tiflash-9000    deploy/tiflash-9000
10.0.1.4:9000 tiflash     10.0.1.4   9000/8123/3930/20170/20292/8234 Up
    ↪  data/tiflash-9000    deploy/tiflash-9000
10.0.1.5:9090 prometheus  10.0.1.5   9090                           Up
    ↪      data/prometheus-9090 deploy/prometheus-9090
```

```
10.0.1.5:3000 grafana    10.0.1.5   3000                          Up
   ↪     -                    deploy/grafana-3000
10.0.1.5:9093 alertmanager 10.0.1.5 9093/9294                    Up
   ↪     data/alertmanager-9093 deploy/alertmanager-9093
```

2. Run the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.5:20160
```

The `--node` parameter is the ID of the node to be taken offline.

If you see `Scaled cluster <cluster-name> in successfully`, the scale-in operation succeeds.

3. Check the cluster status:

The scale-in process takes some time. You can run the following command to check the scale-in status:

```
tiup cluster display <cluster-name>
```

If the node to be scaled in becomes `Tombstone`, the scale-in operation succeeds.

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiFlash + TiCDC
10.0.1.5	TiDB + Monitor **(TiKV is deleted)**
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.1.5 Scale in a TiFlash cluster

This section exemplifies how to remove a TiFlash node from the `10.0.1.4` host.

8.2.1.5.1 1. Adjust the number of replicas of the tables according to the number of remaining TiFlash nodes

1. Query whether any table has TiFlash replicas more than the number of TiFlash nodes after scale-in. `tobe_left_nodes` means the number of TiFlash nodes after scale-in. If the query result is empty, you can start scaling in TiFlash. If the query result is not empty, you need to modify the number of TiFlash replicas of the related table(s).

```
SELECT * FROM information_schema.tiflash_replica WHERE REPLICA_COUNT >
    ↪  'tobe_left_nodes';
```

2. Execute the following statement for all tables with TiFlash replicas more than the number of TiFlash nodes after scale-in. `new_replica_num` must be less than or equal to `tobe_left_nodes`:

```
ALTER TABLE <db-name>.<table-name> SET tiflash replica '
    ↪ new_replica_num';
```

3. Perform step 1 again and make sure that there is no table with TiFlash replicas more than the number of TiFlash nodes after scale-in.

8.2.1.5.2 2. Perform the scale-in operation

Perform the scale-in operation with one of the following solutions.

Solution 1. Use TiUP to remove a TiFlash node

1. Confirm the name of the node to be taken down:

```
tiup cluster display <cluster-name>
```

2. Remove the TiFlash node (assume that the node name is `10.0.1.4:9000` from Step 1):

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:9000
```

Solution 2. Manually remove a TiFlash node

In special cases (such as when a node needs to be forcibly taken down), or if the TiUP scale-in operation fails, you can manually remove a TiFlash node with the following steps.

1. Use the store command of pd-ctl to view the store ID corresponding to this TiFlash node.

    - Enter the store command in pd-ctl (the binary file is under `resources/bin` in the tidb-ansible directory).
    - If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:<cluster-version ↪ > pd`:

```
tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> store
```

> **Note:**
>
> If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

2. Remove the TiFlash node in pd-ctl:

    - Enter `store delete <store_id>` in pd-ctl (`<store_id>` is the store ID of the TiFlash node found in the previous step.
    - If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:<cluster-version > pd`:

    ```
    tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> store
       ↪ delete <store_id>
    ```

> **Note:**
>
> If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

3. Wait for the store of the TiFlash node to disappear or for the `state_name` to become `Tombstone` before you stop the TiFlash process.

4. Manually delete TiFlash data files (the location can be found in the `data_dir` directory under the TiFlash configuration of the cluster topology file).

5. Delete information about the TiFlash node that goes down from the cluster topology using the following command:

    ```
    tiup cluster scale-in <cluster-name> --node <pd_ip>:<pd_port> --force
    ```

> **Note:**
>
> Before all TiFlash nodes in the cluster stop running, if not all tables replicated to TiFlash are canceled, you need to manually clean up the replication rules in PD, or the TiFlash node cannot be taken down successfully.

The steps to manually clean up the replication rules in PD are below:

1. View all data replication rules related to TiFlash in the current PD instance:

```
curl http://<pd_ip>:<pd_port>/pd/api/v1/config/rules/group/tiflash
```

```
[
  {
    "group_id": "tiflash",
    "id": "table-45-r",
    "override": true,
    "start_key": "7480000000000000FF2D5F720000000000FA",
    "end_key": "7480000000000000FF2E00000000000000F8",
    "role": "learner",
    "count": 1,
    "label_constraints": [
      {
        "key": "engine",
        "op": "in",
        "values": [
          "tiflash"
        ]
      }
    ]
  }
]
```

2. Remove all data replication rules related to TiFlash. Take the rule whose `id` is `table-45-r` as an example. Delete it by the following command:

```
curl -v -X DELETE http://<pd_ip>:<pd_port>/pd/api/v1/config/rule/
    ↪ tiflash/table-45-r
```

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

   Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiCDC **(TiFlash is deleted)**
10.0.1.5	TiDB+ Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.1.6 Scale in a TiCDC cluster

This section exemplifies how to remove the TiCDC node from the `10.0.1.4` host.

1. Take the node offline:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

2. View the cluster status:

```
tiup cluster display <cluster-name>
```

   Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + **(TiCDC is deleted)**
10.0.1.5	TiDB + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.2.2 Use TiDB Operator

8.3 Backup and Restore

8.3.1 TiDB Backup & Restore Overview

Based on the Raft protocol and a reasonable deployment topology, TiDB realizes high availability of clusters. When a few nodes in the cluster fail, the cluster can still be available. On this basis, to further ensure data safety, TiDB provides the Backup & Restore (BR) feature as the last resort to recover data from natural disasters and misoperations.

BR satisfies the following requirements:

- Back up cluster data to a disaster recovery (DR) system with an RPO of no more than 10 minutes, reducing data loss in disaster scenarios.
- Handle the cases of misoperations from applications by rolling back data to a time point before the error event.
- Perform history data auditing to meet the requirements of judicial supervision.
- Clone the production environment, which is convenient for troubleshooting, performance tuning, and simulation testing.

8.3.1.1 Before you use

This section describes the prerequisites for using TiDB backup and restore, including restrictions, usage tips and compatibility issues.

8.3.1.1.1 Restrictions

- PITR only supports restoring data to **an empty cluster**.
- PITR only supports cluster-level restore and does not support database-level or table-level restore.
- PITR does not support restoring the data of user tables or privilege tables from system tables.
- BR does not support running multiple backup tasks on a cluster **at the same time**.
- When a PITR is running, you cannot run a log backup task or use TiCDC to replicate data to a downstream cluster.

8.3.1.1.2 Some tips

Snapshot backup:

- It is recommended that you perform the backup operation during off-peak hours to minimize the impact on applications.
- It is recommended that you execute multiple backup or restore tasks one by one. Running multiple backup tasks in parallel leads to low performance. Worse still, a lack of collaboration between multiple tasks might result in task failures and affect cluster performance.

Snapshot restore:

- BR uses resources of the target cluster as much as possible. Therefore, it is recommended that you restore data to a new cluster or an offline cluster. Avoid restoring data to a production cluster. Otherwise, your application will be affected inevitably.

Backup storage and network configuration:

- It is recommended that you store backup data to a storage system that is compatible with Amazon S3, GCS, or Azure Blob Storage.
- You need to ensure that BR, TiKV, and the backup storage system have enough network bandwidth, and that the backup storage system can provide sufficient read and write performance (IOPS). Otherwise, they might become a performance bottleneck during backup and restore.

8.3.1.2 Use backup and restore

The way to use BR varies with the deployment method of TiDB. This document introduces how to use the br command-line tool to back up and restore TiDB cluster data in an on-premise deployment.

For information about how to use this feature in other deployment scenarios, see the following documents:

- Back Up and Restore TiDB Deployed on TiDB Cloud: It is recommended that you create TiDB clusters on TiDB Cloud. TiDB Cloud offers fully managed databases to let you focus on your applications.
- Back Up and Restore Data Using TiDB Operator: If you deploy a TiDB cluster using TiDB Operator on Kubernetes, it is recommended to back up and restore data using Kubernetes CustomResourceDefinition (CRD).

8.3.1.3 BR features

TiDB BR provides the following features:

- Back up cluster data: You can back up full data (**full backup**) of the cluster at a certain time point, or back up the data changes in TiDB (**log backup**, in which log means KV changes in TiKV).
- Restore backup data:
  - You can **restore a full backup** or **specific databases or tables** in a full backup.
  - Based on backup data (full backup and log backup), you can restore the target cluster to any time point of the backup cluster. This type of restore is called point-in-time recovery, or PITR for short.

8.3.1.3.1 Back up cluster data

Full backup backs up all data of a cluster at a specific time point. TiDB supports the following way of full backup:

- Back up cluster snapshots: A snapshot of a TiDB cluster contains transactionally consistent data at a specific time. For details, see Snapshot backup.

Full backup occupies much storage space and contains only cluster data at a specific time point. If you want to choose the restore point as required, that is, to perform point-in-time recovery (PITR), you can use the following two ways of backup at the same time:

- Start log backup. After log backup is started, the task keeps running on all TiKV nodes and backs up TiDB incremental data in small batches to the specified storage periodically.

- Perform snapshot backup regularly. Back up the full cluster data to the backup storage, for example, perform cluster snapshot backup at 0:00 AM every day.

Backup performance and impact on TiDB clusters

- The impact of backup on a TiDB cluster is kept below 20%, and this value can be reduced to 10% or less with the proper configuration of the TiDB cluster. The backup speed of a TiKV node is scalable and ranges from 50 MB/s to 100 MB/s. For more information, see Backup performance and impact.
- When there are only log backup tasks, the impact on the cluster is about 5%. Log backup flushes all the changes generated after the last refresh every 5-10 minutes to the backup storage, which can **achieve a Recovery Point Objective (RPO) of no more than ten minutes**.

8.3.1.3.2 Restore backup data

Corresponding to the backup features, you can perform two types of restore: full restore and PITR.

- Restore a full backup
  - Restore cluster snapshot backup: You can restore snapshot backup data to an empty cluster or a cluster that does not have data conflicts (with the same schema or tables). For details, see Restore snapshot backup. In addition, you can restore specific databases or tables from the backup data and filter out unwanted data. For details, see Restore specific databases or tables from backup data.
- Restore data to any point in time (PITR)
  - By running the `br restore point` command, you can restore the latest snapshot backup data before recovery time point and log backup data to a specified time. BR automatically determines the restore scope, accesses backup data, and restores data to the target cluster in turn.

Restore performance and impact on TiDB clusters

- Data restore is performed at a scalable speed. Generally, the speed is 100 MiB/s per TiKV node. `br` only supports restoring data to a new cluster and uses the resources of the target cluster as much as possible. For more details, see Restore performance and impact.
- On each TiKV node, PITR can restore log data at 30 GiB/h. For more details, see PITR performance and impact.

8.3.1.4 Backup storage

TiDB supports backing up data to Amazon S3, Google Cloud Storage (GCS), Azure Blob Storage, NFS, and other S3-compatible file storage services. For details, see the following documents:

- Specify backup storage in URL
- Configure access privileges to backup storages

8.3.1.5 Compatibility

8.3.1.5.1 Compatibility with other features

Backup and restore might go wrong when some TiDB features are enabled or disabled. If these features are not consistently enabled or disabled during backup and restore, compatibility issues might occur.

Feature	Issue	Solution
GBK charset		BR of versions earlier than v5.4.0 does not support restoring `charset = GBK` tables. No version of BR supports recovering `charset = GBK` tables to TiDB clusters earlier than v5.4.0.

Feature	Issue	Solution
Clustered index	#1565	Make sure that the value of the `tidb_enable_clustered_index` global variable during restore is consistent with that during backup. Otherwise, data inconsistency might occur, such as `default not found` error and inconsistent data index.

Feature	Issue	Solution
New collation	#352	Make sure that the value of the `new_collations_enabled_on_first_bootstrap` variable during restore is consistent with that during backup. Otherwise, inconsistent data index might occur and checksum might fail to pass. For more information, see FAQ - Why does BR report

Feature	Issue	Solution
Global temporary tables		Make sure that you are using v5.3.0 or a later version of BR to back up and restore data. Otherwise, an error occurs in the definition of the backed global temporary tables.

Feature	Issue	Solution
TiDB Lightning Physical Import		If the upstream database uses the physical import mode of TiDB Lightning, data cannot be backed up in log backup. It is recommended to perform a full backup after the data import. For more information, see When the upstream database imports data

Feature	Issue	Solution

8.3.1.5.2 Version compatibility

Before performing backup and restore, BR compares and checks the TiDB cluster version with its own. If there is a major-version mismatch, BR prompts a reminder to exit. To forcibly skip the version check, you can set `--check-requirements=false`. Note that skipping the version check might introduce incompatibility.

Backup version (vertical) Restore version (horizontal)	Restore to TiDB v6.0	Restore to TiDB v6.1	Restore to TiDB v6.2	Restore to TiDB v6.3
TiDB v6.0 snapshot backup	Compatible	Compatible	Compatible	Compatible

Backup version (vertical) Restore version (horizontal)	Restore to TiDB v6.0	Restore to TiDB v6.1	Restore to TiDB v6.2	Restore to TiDB v6.3
TiDB v6.1 snapshot backups	Compatible (A known issue #36379: if backup data contains an empty schema, BR might report an error.)	Compatible	Compatible	Compatible

Backup version (vertical) Restore version (horizontal)	Restore to TiDB v6.0	Restore to TiDB v6.1	Restore to TiDB v6.2	Restore to TiDB v6.3
TiDB v6.2 snapshot backups	Compatible (A known issue #36379: if backup data contains an empty schema, BR might report an error.)	Compatible	Compatible	Compatible

Backup version (vertical) \ Restore version (horizontal)	Restore to TiDB v6.0	Restore to TiDB v6.1	Restore to TiDB v6.2	Restore to TiDB v6.3
TiDB v6.3 snapshot backup	Compatible (A known issue #36379: if backup data contains an empty schema, BR might report an error.)	Compatible	Compatible	Compatible
TiDB v6.3 log backup	N/A	N/A	Incompatible	Compatible

8.3.2 Architecture

8.3.2.1 Overview of TiDB Backup & Restore Architecture

As described in TiDB Backup & Restore Overview, TiDB supports backing up and restoring multiple types of cluster data. You can use Backup & Restore (BR) and TiDB Operator to access these features, and create tasks to back up data from TiKV nodes or restore data to TiKV nodes.

For details about the architecture of each backup and restore feature, see the following documents:

- Full data backup and restore
  - Back up snapshot data
  - Restore snapshot backup data
- Data change log backup
  - Log backup: backup of KV data change
- Point-in-time recovery (PITR)
  - PITR

8.3.2.2 TiDB Snapshot Backup and Restore Architecture

This document introduces the architecture and process of TiDB snapshot backup and restore using a Backup & Restore (BR) tool as an example.

8.3.2.2.1 Architecture

The TiDB snapshot backup and restore architecture is as follows:

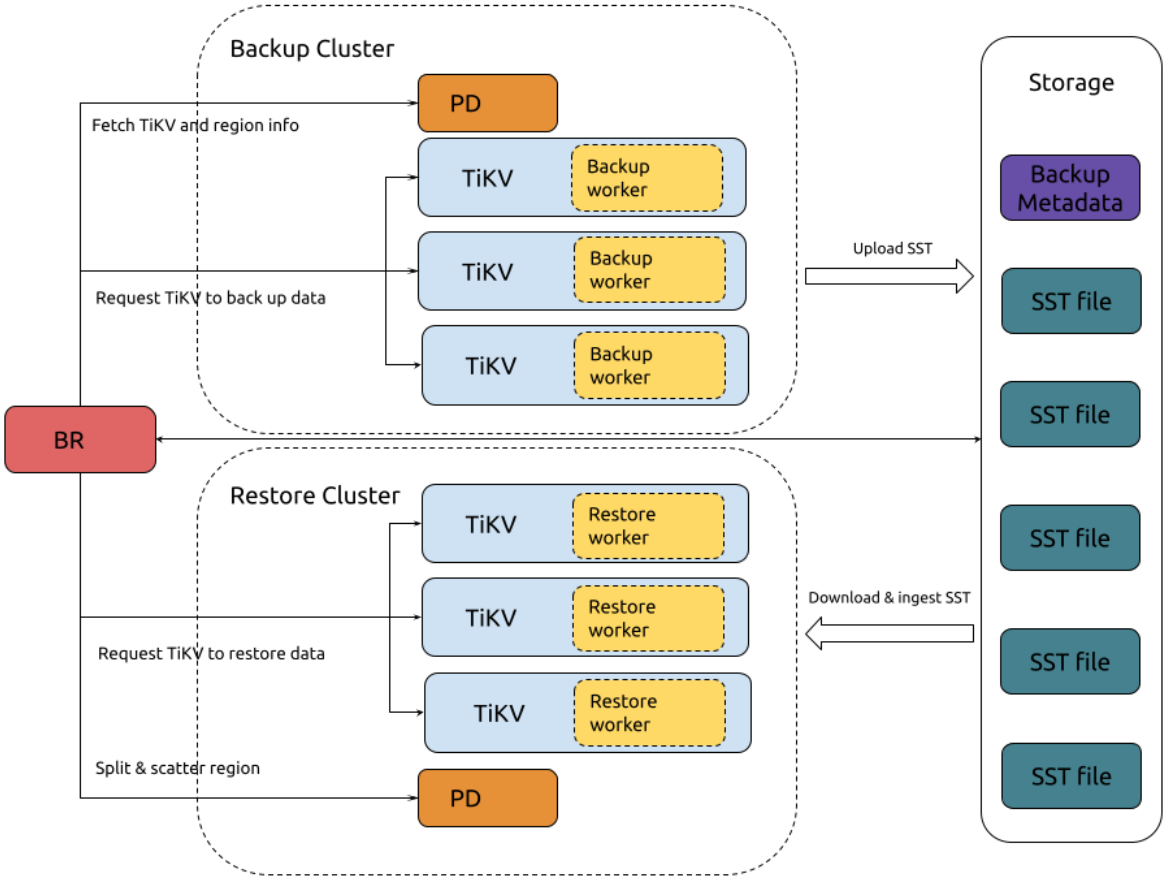

Figure 57: BR snapshot backup and restore architecture

8.3.2.2.2 Process of backup

The process of a cluster snapshot backup is as follows:

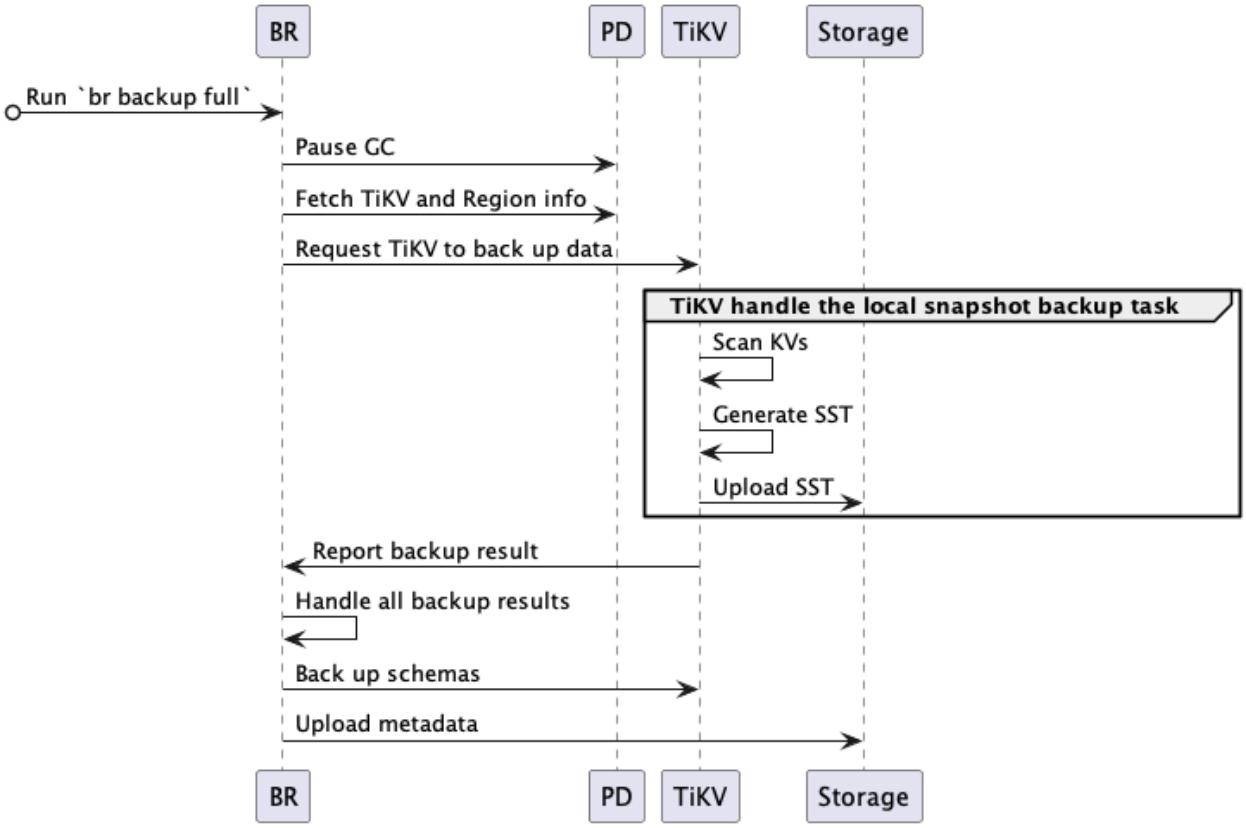

Figure 58: snapshot backup process design

The complete backup process is as follows:

1. BR receives the `br backup full` command.

    - Gets the backup time point and storage path.

2. BR schedules the backup data.

    - **Pause GC**: BR configures the TiDB GC time to prevent the backup data from being cleaned up by TiDB GC mechanism.
    - **Fetch TiKV and Region info**: BR accesses PD to get all TiKV nodes addresses and Region distribution of data.
    - **Request TiKV to back up data**: BR creates a backup request and sends it to all TiKV nodes. The backup request includes the backup time point, Regions to be backed up, and the storage path.

3. TiKV accepts the backup request and initiates a backup worker.

4. TiKV backs up the data.

- **Scan KVs**: the backup worker reads data corresponding to the backup time point from the Region where the leader locates.
- **Generate SST**: the backup worker saves the data to SST files, which are stored in the memory.
- **Upload SST**: the backup worker uploads the SST files to the storage path.

5. BR receives the backup result from each TiKV node.

    - If some data fails to be backed up due to Region changes, for example, a TiKV node is down, BR will retry the backup.
    - If there is any data fails to be backed up and cannot be retried, the backup task fails.
    - After all data is backed up, BR will then back up the metadata.

6. BR backs up the metadata.

    - **Back up schemas**: BR backs up the table schemas and calculates the checksum of the table data.
    - **Upload metadata**: BR generates the backup metadata and uploads it to the storage path. The backup metadata includes the backup timestamp, the table and corresponding backup files, data checksum, and file checksum.

8.3.2.2.3 Process of restore

The process of a cluster snapshot restore is as follows:

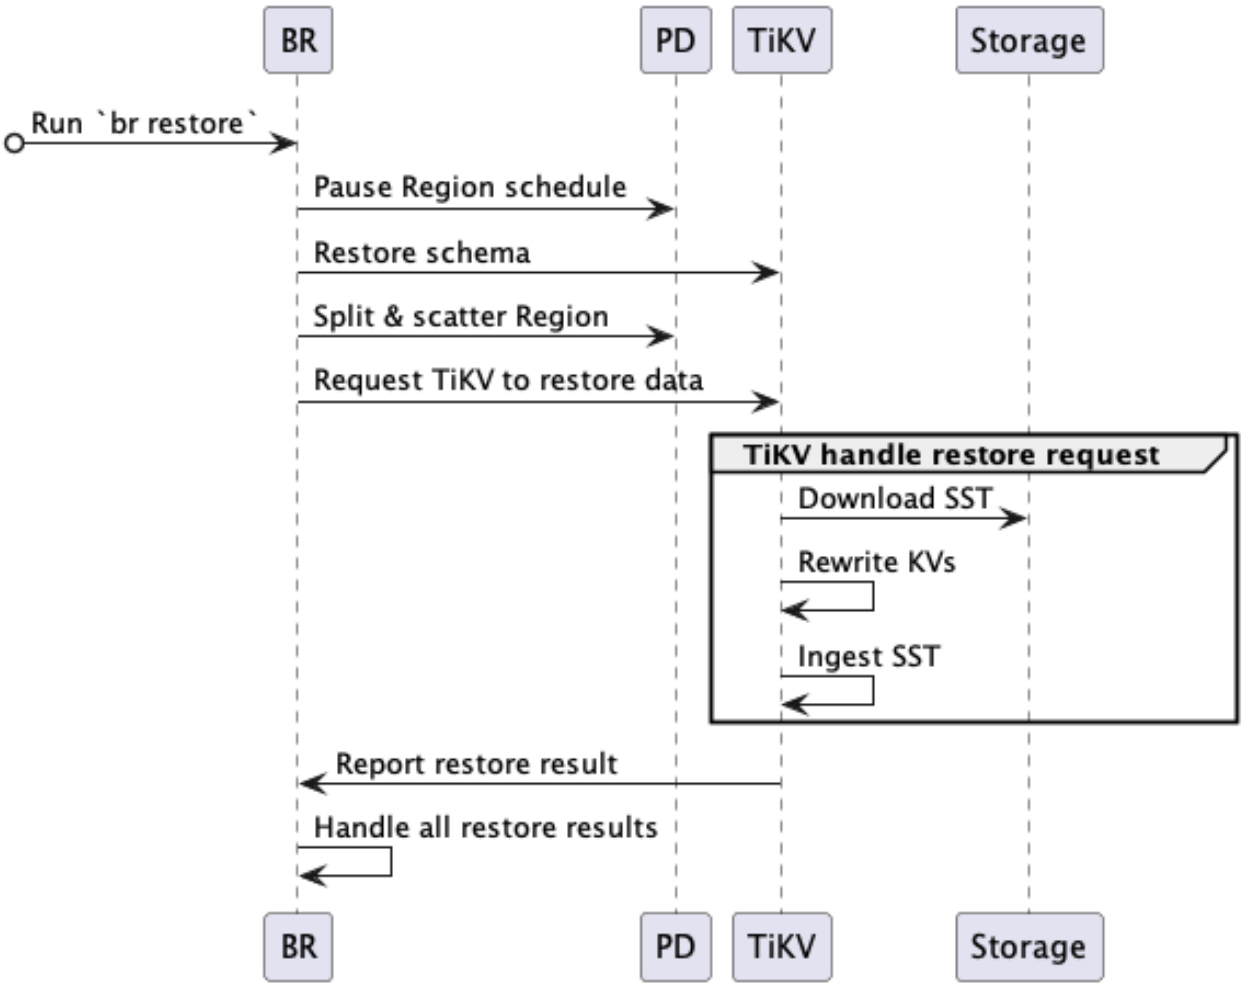

Figure 59: snapshot restore process design

The complete restore process is as follows:

1. BR receives the `br restore` command.

    - Gets the data storage path and the database or table to be restored.
    - Checks whether the table to be restored exists and whether it meets the requirements for restore.

2. BR schedules the restore data.

    - **Pause Region schedule**: BR requests PD to pause the automatic Region scheduling during restore.
    - **Restore schema**: BR gets the schema of the backup data and the database and table to be restored. Note that the ID of a newly created table might be different from that of the backup data.

- **Split & scatter Region**: BR requests PD to allocate Regions (split Region) based on backup data, and schedules Regions to be evenly distributed to storage nodes (scatter Region). Each Region has a specified data range `[start key, end key)`.
- **Request TiKV to restore data**: BR creates a restore request and sends it to the corresponding TiKV nodes according to the result of Region split. The restore request includes the data to be restored and rewrite rules.

3. TiKV accepts the restore request and initiates a restore worker.

    - The restore worker calculates the backup data that needs to be read to restore.

4. TiKV restores the data.

    - **Download SST**: the restore worker downloads corresponding SST files from the storage path to a local directory.
    - **Rewrite KVs**: the restore worker rewrites the KV data according to the new table ID, that is, replace the original table ID in the Key-Value with the new table ID. The restore worker also rewrites the index ID in the same way.
    - **Ingest SST**: the restore worker ingests the processed SST files into RocksDB.
    - **Report restore result**: the restore worker reports the restore result to BR.

5. BR receives the restore result from each TiKV node.

    - If some data fails to be restored due to `RegionNotFound` or `EpochNotMatch`, for example, a TiKV node is down, BR will retry the restore.
    - If there is any data fails to be restored and cannot be retried, the restore task fails.
    - After all data is restored, the restore task succeeds.

8.3.2.2.4 Backup files

Types of backup files

Snapshot backup generates the following types of files:

- `SST` file: stores the data that the TiKV node backs up. The size of an `SST` file equals to that of a Region.
- `backupmeta` file: stores the metadata of a backup task, including the number of all backup files, and the key range, the size, and the Hash (sha256) value of each backup file.
- `backup.lock` file: prevents multiple backup tasks from storing data at the same directory.

Naming format of SST files

When data is backed up to Google Cloud Storage (GCS) or Azure Blob Storage, SST files are named in the format of `storeID_regionID_regionEpoch_keyHash_timestamp_cf`. The fields in the name are explained as follows:

- `storeID` is the TiKV node ID.
- `regionID` is the Region ID.
- `regionEpoch` is the version number of Region.
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a file.
- `timestamp` is the Unix timestamp of an SST file when it is generated by TiKV.
- `cf` indicates the Column Family of RocksDB (only restores data whose `cf` is `default` or `write`).

When data is backed up to Amazon S3 or a network disk, the SST files are named in the format of `regionID_regionEpoch_keyHash_timestamp_cf`. The fields in the name are explained as follows:

- `regionID` is the Region ID.
- `regionEpoch` is the version number of Region.
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a file.
- `timestamp` is the Unix timestamp of an SST file when it is generated by TiKV.
- `cf` indicates the Column Family of RocksDB (only restores data whose `cf` is `default` or `write`).

Storage format of SST files

- For details about the storage format of SST files, see RocksDB BlockBasedTable format.
- For details about the encoding format of backup data in SST files, see mapping of table data to Key-Value.

Structure of backup files

When you back up data to GCS or Azure Blob Storage, the SST files, `backupmeta` files, and `backup.lock` files are stored in the same directory as the following structure:

```
.
└── 20220621
    ├── backupmeta
    ├── backup.lock
    ├── {storeID}-{regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
    ├── {storeID}-{regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
    └── {storeID}-{regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
```

When you back up data to Amazon S3 or a network disk, the SST files are stored in sub-directories based on the `storeID`. The structure is as follows:

```
.
├── 20220621
│   ├── backupmeta
│   ├── backup.lock
│   ├── store1
│   │   └── {regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
│   ├── store100
│   │   └── {regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
│   ├── store2
│   │   └── {regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
│   ├── store3
│   ├── store4
│   └── store5
```

8.3.2.3 TiDB Log Backup and PITR Architecture

This document introduces the architecture and process of TiDB log backup and point-in-time recovery (PITR) using a Backup & Restore (BR) tool as an example.

8.3.2.3.1 Architecture

The log backup and PITR architecture is as follows:

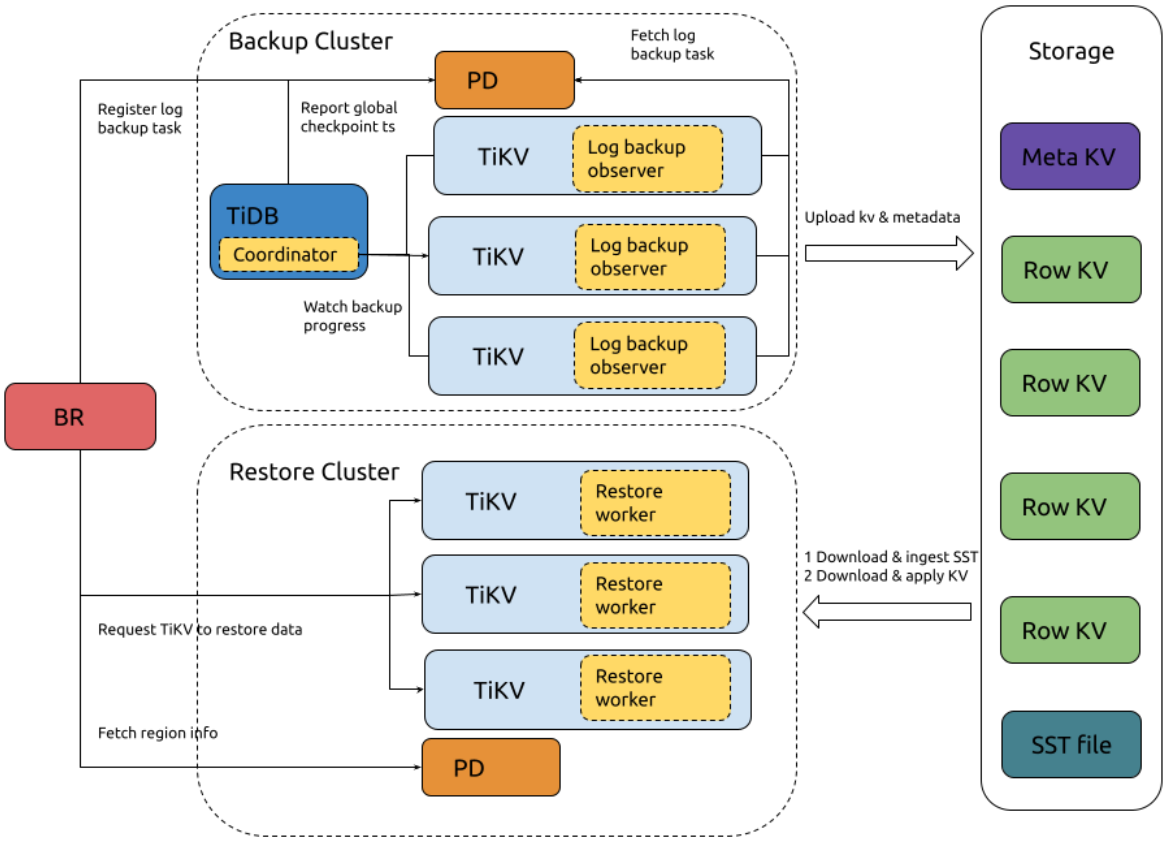

Figure 60: BR log backup and PITR architecture

8.3.2.3.2 Process of log backup

The process of a cluster log backup is as follows:

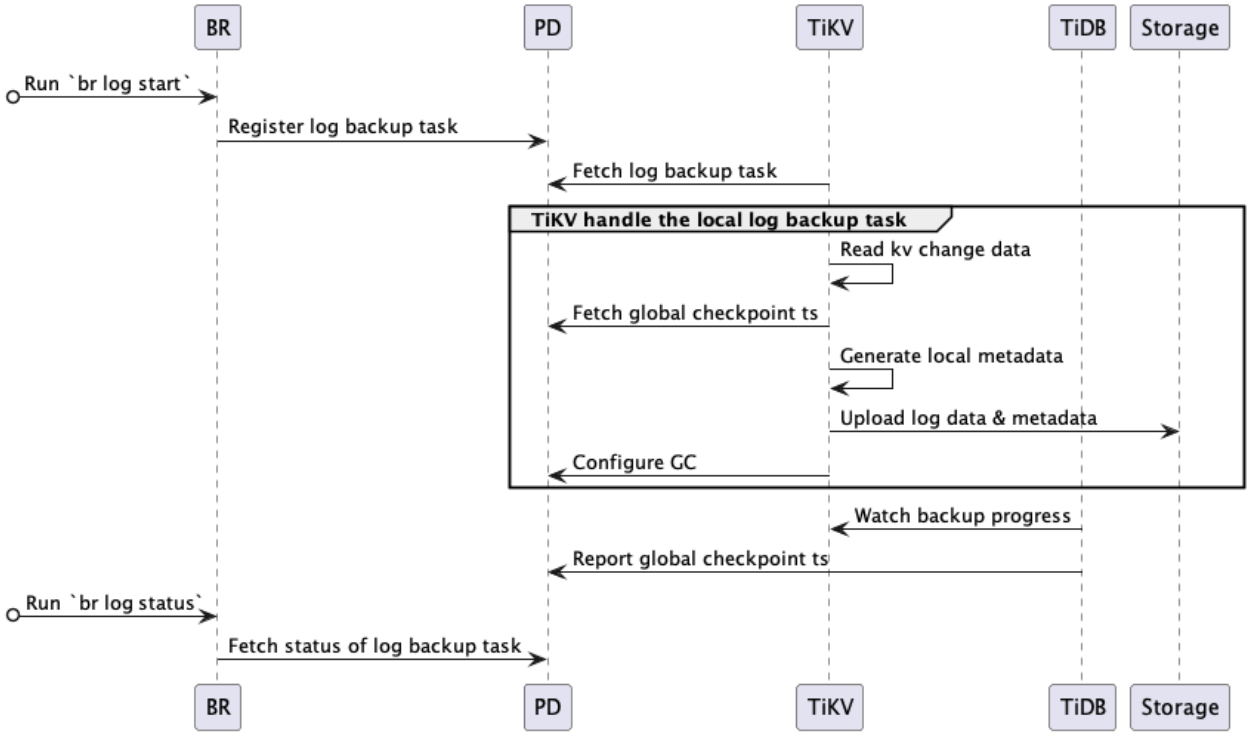

Figure 61: BR log backup process design

System components and key concepts involved in the log backup process:

- **local metadata**: indicates the metadata backed up by a single TiKV node, including local checkpoint ts, global checkpoint ts, and backup file information.
- **local checkpoint ts** (in local metadata): indicates that all logs generated before local checkpoint ts in this TiKV node have been backed up to the target storage.
- **global checkpoint ts**: indicates that all logs generated before global checkpoint ts in all TiKV nodes have been backed up to the target storage. TiDB Coordinator calculates this timestamp by collecting local checkpoint ts of all TiKV node and then reports it to PD.
- **TiDB Coordinator**: a TiDB node is elected as the coordinator, which is responsible for collecting and calculating the progress of the entire log backup task (global checkpoint ts). This component is stateless in design, and after its failure, a new Coordinator is elected from the surviving TiDB nodes.
- **TiKV log backup observer**: runs on each TiKV node in the TiDB cluster, which is responsible for backing up log data. If a TiKV node fails, backing up the data range on it will be taken by other TiKV nodes after region re-election, and these nodes will back up data of the failure range starting from global checkpoint ts.

The complete backup process is as follows:

1. BR receives the `br log start` command.

- BR parses the checkpoint ts (the start time of log backup) and storage path of the backup task.
- **Register log backup task**: BR registers a log backup task in PD.

2. TiKV monitors the creation and update of the log backup task.

- **Fetch log backup task**: The log backup observer of each TiKV node fetches the log backup task from PD and then backs up the log data in the specified range.

3. The log backup observer backs up the KV change logs continuously.

- **Read kv change data**: reads KV change data and then saves the change log to backup files in custom format.
- **Fetch global checkpoint ts**: fetches the global checkpoint ts from PD.
- **Generate local metadata**: generates the local metadata of the backup task, including local checkpoint ts, global checkpoint ts, and backup file information.
- **Upload log data & metadata**: uploads the backup files and local metadata to the target storage periodically.
- **Configure GC**: requests PD to prevent data that have not been backed up (greater than local checkpoint ts) from being recycled by the TiDB GC mechanism.

4. The TiDB Coordinator monitors the progress of the log backup task.

- **Watch backup progress**: gets the backup progress of each Region (Region checkpoint ts) by polling all TiKV nodes.
- **Report global checkpoint ts**: calculates the progress of the entire log backup task (global checkpoint ts) based on the Region checkpoint ts and then reports the global checkpoint ts to PD.

5. PD persists the status of the log backup task, and you can view it using `br log status`.

8.3.2.3.3 Process of PITR

The process of PITR is as follows:

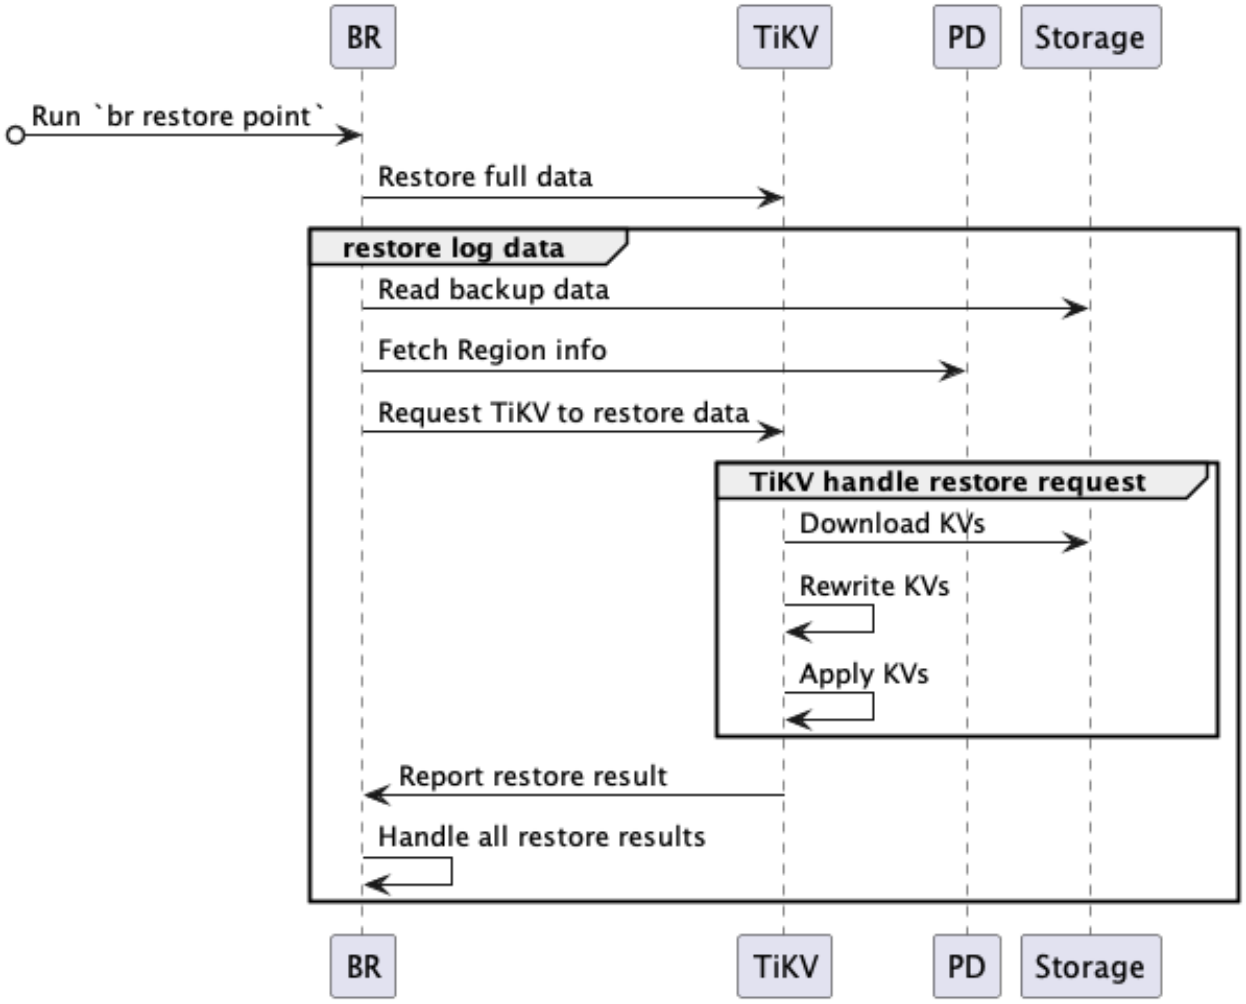

Figure 62: Point-in-time recovery process design

The complete PITR process is as follows:

1. BR receives the `br restore point` command.

- BR parses the full backup data address, log backup data address, and the point-in-time recovery time.
- Queries the restore object (database or table) in the backup data and checks whether the table to be restored exists and meets the restore requirements.

2. BR restores the full backup data.

- Restores full backup data. For more details about the process of snapshot backup data restore, refer to Restore snapshot backup data.

3. BR restores the log backup data.

- **Read backup data**: reads the log backup data and calculates the log backup data that needs to be restored.
- **Fetch Region info**: fetches all Regions distributions by accessing PD.
- **Request TiKV to restore data**: creates a log restore request and sends it to the corresponding TiKV node. The log restore request contains the log backup data information to be restored.

4. TiKV accepts the restore request from BR and initiates a log restore worker.

- The log restore worker gets the log backup data that needs to be restored.

5. TiKV restores the log backup data.

- **Download KVs**: the log restore worker downloads the corresponding backup data from the backup storage to a local directory according to the log restore request.
- **Rewrite KVs**: the log restore worker rewrites the KV data of the backup data according to the table ID of the restore cluster table, that is, replace the original table ID in the Key-Value with the new table ID. The restore worker also rewrites the index ID in the same way.
- **Apply KVs**: the log restore worker writes the processed KV data to the store (RocksDB) through the raft interface.
- **Report restore result**: the log restore worker returns the restore result to BR.

6. BR receives the restore result from each TiKV node.

- If some data fails to be restored due to `RegionNotFound` or `EpochNotMatch`, for example, a TiKV node is down, BR will retry the restore.
- If there is any data fails to be restored and cannot be retried, the restore task fails.
- After all data is restored, the restore task succeeds.

8.3.2.3.4 Log backup files

Log backup generates the following types of files:

- `{min_ts}-{uuid}.log` file: stores the KV change log data of the backup task. The `{min_ts}` is the minimum TSO timestamp of the KV change log data in the file, and the `{uuid}` is generated randomly when the file is created.
- `{checkpoint_ts}-{uuid}.meta` file: is generated every time each TiKV node uploads the log backup data and stores metadata of all log backup data files uploaded this time. The `{checkpoint_ts}` is the log backup checkpoint of the TiKV node, and the global checkpoint is the minimum checkpoint of all TiKV nodes. The `{uuid}` is generated randomly when the file is created.

- `{store_id}.ts` file: this file is updated with global checkpoint ts every time each TiKV node uploads the log backup data. The `{store_id}` is the store ID of the TiKV node.
- `v1_stream_truncate_safepoint.txt` file: stores the timestamp corresponding to the latest backup data in storage that deleted by `br log truncate`.

Structure of backup files

```
.
├── v1
│   ├── backupmeta
│   │   ├── {min_restored_ts}-{uuid}.meta
│   │   └── {checkpoint}-{uuid}.meta
│   ├── global_checkpoint

8.3.3 Use BR

8.3.3.1 Usage Overview of TiDB Backup and Restore

This document describes best practices of using TiDB backup and restore features, including how to choose a backup method, how to manage backup data, and how to install and deploy the backup and restore tool.

8.3.3.1.1 Recommended practices

Before using TiDB backup and restore features, it is recommended that you understand the recommended backup and restore solutions.

How to back up data?

TiDB provides two types of backup. Which one should I use? Full backup contains the full data of a cluster at a certain point in time. Log backup contains the data changes written to TiDB. It is recommended to use both types of backup at the same time:

- Start log backup: Run the `br log start` command to start the log backup task. After that, the task keeps running on all TiKV nodes and backs up TiDB data changes to the specified storage in small batches regularly.
- **Perform snapshot (full) backup regularly**: Run the `br backup full` command to back up the snapshot of the cluster to the specified storage. For example, back up the cluster snapshot at 0:00 AM every day.

How to manage backup data?

BR provides only basic backup and restore features, and does not support backup management. Therefore, you need to decide how to manage backup data on your own, which might involve the following questions?

- Which backup storage system should I choose?
- In which directory should I place the backup data during a backup task?

- In what way should I organize the directory of the full backup data and log backup data?
- How to handle the historical backup data in the storage system?

The following sections will answer these questions one by one.

Choose a backup storage system

It is recommended that you store backup data to Amazon S3, Google Cloud Storage (GCS), or Azure Blob Storage. Using these systems, you do not need to worry about the backup capacity and bandwidth allocation.

If the TiDB cluster is deployed in a self-built data center, the following practices are recommended:

- Build MinIO as the backup storage system, and use the S3 protocol to back up data to MinIO.
- Mount Network File System (NFS, such as NAS) disks to br command-line tool and all TiKV instances, and use the POSIX file system interface to write backup data to the corresponding NFS directory.

> **Note:**
>
> If you do not choose NFS or a storage system that supports Amazon S3, GCS, or Azure Blob Storage protocols, the data backed up is generated at each TiKV node. **Note that this is not the recommended way to use BR**, because collecting the backup data might result in data redundancy and operation and maintenance problems.

Organize the backup data directory

- Store the snapshot backup and log backup in the same directory for unified management, for example, `backup-${cluster-id}`.
- Store each snapshot backup in a directory with the backup date included, for example, `backup-${cluster-id}/fullbackup-202209081330`.
- Store the log backup in a fixed directory, for example, `backup-${cluster-id}/logbackup`. The log backup program creates subdirectories under the `logbackup` directory every day to distinguish the data backed up each day.

Handle historical backup data

Assume that you need to set the life cycle for each backup data, for example, 7 days. Such a life cycle is called **backup retention period**, which will also be mentioned in backup tutorials.

- To perform PITR, you need to restore the full backup before the restore point, and the log backup between the full backup and the restore point. Therefore, **It is recommended to only delete the log backup before the full snapshot**. For log backups that exceed the backup retention period, you can use `br log truncate` command to delete the backup before the specified time point.
- For backup data that exceeds the retention period, you can delete or archive the backup directory.

How to restore data?

- To restore only full backup data, you can use `br restore` to perform a full restore of the specified backup.
- If you have started log backup and regularly performed a full backup, you can run the `br restore point` command to restore data to any time point within the backup retention period.

8.3.3.1.2 Deploy and use BR

To deploy BR, ensure that the following requirements are met:

- BR, TiKV nodes, and the backup storage system provide network bandwidth that is greater than the backup speed. If the target cluster is particularly large, the threshold of backup and restore speed is limited by the bandwidth of the backup network.
- The backup storage system provides sufficient read and write performance (IOPS). Otherwise, they might become a performance bottleneck during backup or restore.
- TiKV nodes have at least two additional CPU cores and high performance disks for backups. Otherwise, the backup might have an impact on the services running on the cluster.
- BR runs on a node with more than 8 cores and 16 GiB memory.

You can use backup and restore features in several ways, such as via the command-line tool, by running SQL commands, and using TiDB Operator. The following sections describe these three methods in detail.

Use br command-line tool (recommended)

TiDB supports backup and restore using br command-line tool.

- You can run the `tiup install br` command to install br command-line tool using TiUP online.
- For details about how to use `br` commands to back up and restore data, refer to the following documents:
  - TiDB Snapshot Backup and Restore Guide

- TiDB Log Backup and PITR Guide
- TiDB Backup and Restore Use Cases

Use SQL statements

TiDB supports full backup and restore using SQL statements:

- `BACKUP`: backs up full snapshot data.
- `RESTORE`: restores snapshot backup data.
- `SHOW BACKUPS|RESTORES`: views the backup and restore progress.

Use TiDB Operator on Kubernetes

On Kubernetes, you can use TiDB Operator to back up TiDB cluster data to Amazon S3, GCS, or Azure Blob Storage, and restore data from the backup data in such systems. For details, see Back Up and Restore Data Using TiDB Operator.

8.3.3.1.3 See also

- TiDB Backup and Restore Overview
- TiDB Backup and Restore Architecture

8.3.3.2 Snapshot Backup and Restore Guide

This document describes how to back up and restore TiDB snapshots using the br command-line tool (hereinafter referred to as `br`). Before backing up and restoring data, you need to install the br command-line tool first.

Snapshot backup is an implementation to back up the entire cluster. It is based on multi-version concurrency control (MVCC) and backs up all data in the specified snapshot to a target storage. The size of the backup data is approximately the size of the compressed single replica in the cluster. After the backup is completed, you can restore the backup data to an empty cluster or a cluster that does not contain conflict data (with the same schema or same tables), restore the cluster to the time point of the snapshot backup, and restore multiple replicas according to the cluster replica settings.

Besides basic backup and restore, snapshot backup and restore also provides the following features:

- Backup data of a specified time point
- Restore data of a specified database or table

8.3.3.2.1 Back up cluster snapshots

Note:

- The following examples assume that Amazon S3 access keys and secret keys are used to authorize permissions. If IAM roles are used to authorize permissions, you need to set `--send-credentials-to-tikv` to `false`.
- If other storage systems or authorization methods are used to authorize permissions, adjust the parameter settings according to Backup Storages.

You can back up a TiDB cluster snapshot by running the `br backup full` command. Run `br backup full --help` to see the help information:

```
tiup br backup full --pd "${PD_IP}:2379" \
    --backupts '2022-09-08 13:30:00' \
    --storage "s3://backup-101/snapshot-202209081330?access-key=${access-key
        ↪ }&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
```

In the preceding command:

- `--backupts`: The time point of the snapshot. The format can be TSO or timestamp, such as `400036290571534337` or `2018-05-11 01:42:23`. If the data of this snapshot is garbage collected, the `br backup` command returns an error and `br` exits. If you leave this parameter unspecified, `br` picks the snapshot corresponding to the backup start time.
- `--storage`: The storage address of the backup data. Snapshot backup supports Amazon S3, Google Cloud Storage, and Azure Blob Storage as backup storage. The preceding command uses Amazon S3 as an example. For more details, see URL format of backup storages.
- `--ratelimit`: The maximum speed **per TiKV** performing backup tasks. The unit is in MiB/s.

During backup, a progress bar is displayed in the terminal as shown below. When the progress bar advances to 100%, the backup task is completed and statistics such as total backup time, average backup speed, and backup data size are displayed.

```
Full Backup
    ↪ <-------------------------------------------------------------------------->
    ↪  100.00%
Checksum
    ↪ <-------------------------------------------------------------------------->
    ↪  100.00%
```

```
*** ["Full Backup success summary"] *** [backup-checksum=3.597416ms] [backup
    ↪ -fast-checksum=2.36975ms] *** [total-take=4.715509333s] [BackupTS
    ↪ =435844546560000000] [total-kv=1131] [total-kv-size=250kB] [average-
    ↪ speed=53.02kB/s] [backup-data-size(after-compressed)=71.33kB] [Size
    ↪ =71330]
```

8.3.3.2.2 Get the backup time point of a snapshot backup

To manage a lot of backups, if you need to get the physical time of a snapshot backup, you can run the following command:

```
tiup br validate decode --field="end-version" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}" | tail -n1
```

The output is as follows, corresponding to the physical time `2022-09-08 13:30:00 ↪ +0800 CST`:

```
435844546560000000
```

8.3.3.2.3 Restore cluster snapshots

You can restore a snapshot backup by running the `br restore full` command. Run `br restore full --help` to see the help information:

The following example restores the preceding backup snapshot to a target cluster:

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

During restore, a progress bar is displayed in the terminal as shown below. When the progress bar advances to 100%, the restore task is completed and statistics such as total restore time, average restore speed, and total data size are displayed.

```
Full Restore
    ↪ <-----------------------------------------------------------------------------
    ↪  100.00%
*** ["Full Restore success summary"] *** [total-take=4.344617542s] [total-kv
    ↪ =5] [total-kv-size=327B] [average-speed=75.27B/s] [restore-data-size(
    ↪ after-compressed)=4.813kB] [Size=4813] [BackupTS=435844901803917314]
```

Restore a database or a table

BR supports restoring partial data of a specified database or table from backup data. This feature allows you to filter out unwanted data and back up only a specific database or table.

Restore a database

To restore a database to a cluster, run the `br restore db` command. The following example restores the `test` database from the backup data to the target cluster:

```
tiup br restore db \
--pd "${PD_IP}:2379" \
--db "test" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

In the preceding command, `--db` specifies the name of the database to be restored.

Restore a table

To restore a single table to a cluster, run the `br restore table` command. The following example restores the `test.usertable` table from the backup data to the target cluster:

```
tiup br restore table --pd "${PD_IP}:2379" \
--db "test" \
--table "usertable" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

In the preceding command, `--db` specifies the name of the database to be restored, and `--table` specifies the name of the table to be restored.

Restore multiple tables with table filter

To restore multiple tables with more complex filter rules, run the `br restore full` command and specify the table filters with `--filter` or `-f`. The following example restores tables that match the `db*.tbl*` filter rule from the backup data to the target cluster:

```
tiup br restore full \
--pd "${PD_IP}:2379" \
--filter 'db*.tbl*' \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

Restore tables in the `mysql` schema

Starting from BR v5.1.0, when you back up snapshots, BR backs up the **system tables** in the `mysql` schema and does not restore them by default. Starting from BR v6.2.0, BR restores **data in some system tables** if you configure `--with-sys-table`.

BR can restore data in the following system tables:

```
+---------------------------------+
| mysql.columns_priv              |
| mysql.db                        |
| mysql.default_roles             |
```

```
| mysql.global_grants          |
| mysql.global_priv            |
| mysql.role_edges             |
| mysql.tables_priv            |
| mysql.user                   |
+------------------------------+
```

BR does not restore the following system tables:

- Statistics tables (`mysql.stats_*`)
- System variable tables (`mysql.tidb` and `mysql.global_variables`)
- Other system tables

When you restore data related to system privilege, note the following:

- BR does not restore user data with `user` as `cloud_admin` and `host` as `'%'`. This user is reserved for TiDB Cloud. Do not create a user or role named `cloud_admin` in your cluster, because the user privileges related to `cloud_admin` cannot be restored correctly.
- Before restoring data, BR checks whether the system tables in the target cluster are compatible with those in the backup data. "Compatible" means that all the following conditions are met:
  - The target cluster has the same system tables as the backup data.
  - The **number of columns** in the system privilege table of the target cluster is the same as that in the backup data. The column order is not important.
  - The columns in the system privilege table of the target cluster are compatible with that in the backup data. If the data type of the column is a type with a length (such as integer and string), the length in the target cluster must be >= the length in the backup data. If the data type of the column is an `ENUM` type, the number of `ENUM` values in the target cluster must be a superset of that in the backup data.

8.3.3.2.4 Performance and impact

Performance and impact of snapshot backup

The backup feature has some impact on cluster performance (transaction latency and QPS). However, you can mitigate the impact by adjusting the number of backup threads `backup.num-threads` or by adding more clusters.

To illustrate the impact of backup, this document lists the test conclusions of several snapshot backup tests:

- (5.3.0 and earlier) When the backup threads of BR on a TiKV node take up 75% of the total CPU of the node, the QPS is reduced by 35% of the original QPS.

- (5.4.0 and later) When there are no more than `8` threads of BR on a TiKV node and the cluster's total CPU utilization does not exceed 80%, the impact of BR tasks on the cluster (write and read) is 20% at most.
- (5.4.0 and later) When there are no more than `8` threads of BR on a TiKV node and the cluster's total CPU utilization does not exceed 75%, the impact of BR tasks on the cluster (write and read) is 10% at most.
- (5.4.0 and later) When there are no more than `8` threads of BR on a TiKV node and the cluster's total CPU utilization does not exceed 60%, BR tasks have little impact on the cluster (write and read).

You can use the following methods to manually control the impact of backup tasks on cluster performance. However, these two methods also reduce the speed of backup tasks while reducing the impact of backup tasks on the cluster.

- Use the `--ratelimit` parameter to limit the speed of backup tasks. Note that this parameter limits the speed of **saving backup files to external storage**. When calculating the total size of backup files, use the `backup data size(after compressed)` as a benchmark.
- Adjust the TiKV configuration item `backup.num-threads` to limit the number of threads used by backup tasks. According to internal tests, when BR uses no more than `8` threads for backup tasks, and the total CPU utilization of the cluster does not exceed 60%, the backup tasks have little impact on the cluster, regardless of the read and write workload.

The impact of backup on cluster performance can be reduced by limiting the backup threads number, but this affects the backup performance. The preceding tests show that the backup speed is proportional to the number of backup threads. When the number of threads is small, the backup speed is about 20 MiB/thread. For example, 5 backup threads on a single TiKV node can reach a backup speed of 100 MiB/s.

Performance and impact of snapshot restore

- During data restore, TiDB tries to fully utilize the TiKV CPU, disk IO, and network bandwidth resources. Therefore, it is recommended to restore the backup data on an empty cluster to avoid affecting the running applications.
- The speed of restoring backup data is much related with the cluster configuration, deployment, and running applications. In internal tests, the restore speed of a single TiKV node can reach 100 MiB/s. The performance and impact of snapshot restore are varied in different user scenarios and should be tested in actual environments.

8.3.3.2.5 See also

- TiDB Backup and Restore Use Cases
- br Command-line Manual
- TiDB Snapshot Backup and Restore Architecture

8.3.3.3 TiDB Log Backup and PITR Guide

A full backup (snapshot backup) contains the full cluster data at a certain point, while TiDB log backup can back up data written by applications to a specified storage in a timely manner. If you want to choose the restore point as required, that is, to perform point-in-time recovery (PITR), you can start log backup and run full backup regularly.

Before you back up or restore data using the br command-line tool (hereinafter referred to as `br`), you need to install `br` first.

8.3.3.3.1 Back up TiDB cluster

Start log backup

> **Note:**
>
> - The following examples assume that Amazon S3 access keys and secret keys are used to authorize permissions. If IAM roles are used to authorize permissions, you need to set `--send-credentials-to-tikv` to `false`.
> - If other storage systems or authorization methods are used to authorize permissions, adjust the parameter settings according to Backup Storages.

To start a log backup, run `br log start`. A cluster can only run one log backup task each time.

```
tiup br log start --task-name=pitr --pd "${PD_IP}:2379" \
--storage 's3://backup-101/logbackup?access-key=${access-key}&secret-access-
    ↪ key=${secret-access-key}"'
```

After the log backup task starts, it runs in the background of the TiDB cluster until you stop it manually. During this process, the TiDB change logs are regularly backed up to the specified storage in small batches. To query the status of the log backup task, run the following command:

```
tiup br log status --task-name=pitr --pd "${PD_IP}:2379"
```

Expected output:

```
  Total 1 Tasks.
> #1 <
    name: pitr
    status:  NORMAL
    start: 2022-05-13 11:09:40.7 +0800
```

```
      end: 2035-01-01 00:00:00 +0800
    storage: s3://backup-101/log-backup
    speed(est.): 0.00 ops/s
checkpoint[global]: 2022-05-13 11:31:47.2 +0800; gap=4m53s
```

Run full backup regularly

The snapshot backup can be used as a method of full backup. You can run `br backup full` to back up the cluster snapshot to the backup storage according to a fixed schedule (for example, every 2 days).

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage 's3://backup-101/snapshot-${date}?access-key=${access-key}&secret-access-key=${secret-access-key}"'
```

8.3.3.3.2 Run PITR

To restore the cluster to any point in time within the backup retention period, you can use `br restore point`. When you run this command, you need to specify the **time point you want to restore**, **the latest snapshot backup data before the time point**, and the **log backup data**. BR will automatically determine and read data needed for the restore, and then restore these data to the specified cluster in order.

```
br restore point --pd "${PD_IP}:2379" \
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-key=${secret-access-key}"' \
--full-backup-storage='s3://backup-101/snapshot-${date}?access-key=${access-key}&secret-access-key=${secret-access-key}"' \
--restored-ts '2022-05-15 18:00:00+0800'
```

During data restore, you can view the progress through the progress bar in the terminal. The restore is divided into two phases, full restore and log restore (restore meta files and restore KV files). After each phase is completed, `br` outputs information such as restore time and data size.

```
Full Restore
    ↪ <-----------------------------------------------------------------------------------------
    ↪  100.00%
*** ["Full Restore success summary"] ****** [total-take=xxx.xxxs] [restore-data-size(after-compressed)=xxx.xxx] [Size=xxxx] [BackupTS={TS}] [
    ↪ total-kv=xxx] [total-kv-size=xxx] [average-speed=xxx]
Restore Meta Files
    ↪ <-----------------------------------------------------------------------------------------
    ↪  100.00%
Restore KV Files
    ↪ <-----------------------------------------------------------------------------------------
    ↪  100.00%
```

```
*** ["restore log success summary"] [total-take=xxx.xx] [restore-from={TS}]
    ↪ [restore-to={TS}] [total-kv-count=xxx] [total-size=xxx]
```

8.3.3.3.3 Clean up outdated data

As described in the Usage Overview of TiDB Backup and Restore:

To perform PITR, you need to restore the full backup before the restore point, and the log backup between the full backup point and the restore point. Therefore, for log backups that exceed the backup retention period, you can use `br log truncate` to delete the backup before the specified time point. **It is recommended to only delete the log backup before the full snapshot**.

The following steps describe how to clean up backup data that exceeds the backup retention period:

1. Get the **last full backup** outside the backup retention period.
2. Use the `validate` command to get the time point corresponding to the backup. Assume that the backup data before 2022/09/01 needs to be cleaned, you should look for the last full backup before this time point and ensure that it will not be cleaned.

```
FULL_BACKUP_TS=`tiup br validate decode --field="end-version" --storage
    ↪  "s3://backup-101/snapshot-${date}?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"| tail -n1`
```

3. Delete log backup data earlier than the snapshot backup `FULL_BACKUP_TS`:

```
tiup br log truncate --until=${FULL_BACKUP_TS} --storage='s3://backup
    ↪ -101/logbackup?access-key=${access-key}&secret-access-key=${
    ↪ secret-access-key}"'
```

4. Delete snapshot data earlier than the snapshot backup `FULL_BACKUP_TS`:

```
rm -rf s3://backup-101/snapshot-${date}
```

8.3.3.3.4 Performance and impact of PITR

Capabilities

- On each TiKV node, PITR can restore snapshot data at a speed of 280 GB/h and log data 30 GB/h.
- BR deletes outdated log backup data at a speed of 600 GB/h.

Note:

The preceding specifications are based on test results from the following two testing scenarios. The actual data might be different.

- Snapshot data restore speed = Snapshot data size / (duration * the number of TiKV nodes)
- Log data restore speed = Restored log data size / (duration * the number of TiKV nodes)

Testing scenario 1 (on TiDB Cloud):

- The number of TiKV nodes (8 core, 16 GB memory): 21
- The number of Regions: 183,000
- New log data created in the cluster: 10 GB/h
- Write (INSERT/UPDATE/DELETE) QPS: 10,000

Testing scenario 2 (on-premises):

- The number of TiKV nodes (8 core, 64 GB memory): 6
- The number of Regions: 50,000
- New log data created in the cluster: 10 GB/h
- Write (INSERT/UPDATE/DELETE) QPS: 10,000

8.3.3.3.5 See also

- TiDB Backup and Restore Use Cases
- br Command-line Manual
- Log Backup and PITR Architecture

8.3.3.4 TiDB Backup and Restore Use Cases

TiDB Snapshot Backup and Restore Guide and TiDB Log Backup and PITR Guide introduce the backup and restore solutions provided by TiDB, namely, snapshot (full) backup and restore, log backup and point-in-time recovery (PITR). This document helps you to quickly get started with the backup and restore solutions of TiDB in specific use cases.

Assume that you have deployed a TiDB production cluster on AWS and the business team requests the following requirements:

- Back up the data changes in a timely manner. When the database encounters a disaster, you can quickly recover the application with minimal data loss (only a few minutes of data loss is tolerable).
- Perform business audits every month at no specific time. When an audit request is received, you must provide a database to query the data at a certain time point of the past month as requested.

With PITR, you can satisfy the preceding requirements.

8.3.3.4.1 Deploy the TiDB cluster and BR

To use PITR, you need to deploy a TiDB cluster >= v6.4.0 and update BR to the same version as the TiDB cluster. This document uses v6.4.0 as an example.

The following table shows the recommended hardware resources for using PITR in a TiDB cluster.

Component	CPU	Memory	Disk	AWS instance	Number of instances
TiDB	8 core+	16 GB+	SAS	c5.2xlarge	2
PD	8 core+	16 GB+	SSD	c5.2xlarge	3
TiKV	8 core+	32 GB+	SSD	m5.2xlarge	3
BR	8 core+	16 GB+	SAS	c5.2xlarge	1
Monitor	8 core+	16 GB+	SAS	c5.2xlarge	1

Note:

- When BR runs backup and restore tasks, it needs to access PD and TiKV. Make sure that BR can connect to all PD and TiKV nodes.
- BR and PD servers must use the same time zone.

Deploy or upgrade a TiDB cluster using TiUP:

- To deploy a new TiDB cluster, refer to Deploy a TiDB cluster.
- If the TiDB cluster is earlier than v6.4.0, upgrade it by referring to Upgrade a TiDB cluster.

Install or upgrade BR using TiUP:

- Install:

```
tiup install br:v6.4.0
```

- Upgrade:

```
tiup update br:v6.4.0
```

8.3.3.4.2 Configure backup storage (Amazon S3)

Before you start a backup task, prepare the backup storage, including the following aspects:

1. Prepare the S3 bucket and directory that stores the backup data.
2. Configure the permissions to access the S3 bucket.
3. Plan the subdirectory that stores each backup data.

The detailed steps are as follows:

1. Create a directory in S3 to store the backup data. The directory in this example is `s3://tidb-pitr-bucket/backup-data`.

    1. Create a bucket. You can choose an existing S3 to store the backup data. If there is none, refer to AWS documentation: Creating a bucket and create an S3 bucket. In this example, the bucket name is `tidb-pitr-bucket`.
    2. Create a directory for your backup data. In the bucket (`tidb-pitr-bucket`), create a directory named `backup-data`. For detailed steps, refer to AWS documentation: Organizing objects in the Amazon S3 console using folders.

2. Configure permissions for BR and TiKV to access the S3 directory. It is recommended to grant permissions using the IAM method, which is the most secure way to access the S3 bucket. For detailed steps, refer to AWS documentation: Controlling access to a bucket with user policies. The required permissions are as follows:

    - TiKV and BR in the backup cluster need `s3:ListBucket`, `s3:PutObject`, and `s3:AbortMultipartUpload` permissions of the `s3://tidb-pitr-bucket/backup-data` directory.
    - TiKV and BR in the restore cluster need `s3:ListBucket` and `s3:GetObject` permissions of the `s3://tidb-pitr-bucket/backup-data` directory.

3. Plan the directory structure that stores the backup data, including the snapshot (full) backup and the log backup.

    - All snapshot backup data are stored in the `s3://tidb-pitr-bucket/backup-data/snapshot-${date}` directory. `${date}` is the start time of the snapshot backup. For example, a snapshot backup starting at 2022/05/12 00:01:30 is stored in `s3://tidb-pitr-bucket/backup-data/snapshot-20220512000130`.
    - Log backup data are stored in the `s3://tidb-pitr-bucket/backup-data/log-backup/` directory.

8.3.3.4.3 Determine the backup policy

To meet the requirements of minimum data loss, quick recovery, and business audits within a month, you can set the backup policy as follows:

- Run the log backup to continuously back up the data change in the database.
- Run a snapshot backup at 00:00 AM every two days.
- Retain the snapshot backup data and log backup data within 30 days and clean up backup data older than 30 days.

8.3.3.4.4 Run log backup

After the log backup task is started, the log backup process runs in the TiKV cluster to continuously send the data change in the database to the S3 storage. To start a log backup task, run the following command:

```
tiup br log start --task-name=pitr --pd="${PD_IP}:2379" \
--storage='s3://tidb-pitr-bucket/backup-data/log-backup'
```

When the log backup task is running, you can query the backup status:

```
tiup br log status --task-name=pitr --pd="${PD_IP}:2379"

  Total 1 Tasks.
> #1 <
    name: pitr
    status:  NORMAL
    start: 2022-05-13 11:09:40.7 +0800
      end: 2035-01-01 00:00:00 +0800
    storage: s3://tidb-pitr-bucket/backup-data/log-backup
    speed(est.): 0.00 ops/s
checkpoint[global]: 2022-05-13 11:31:47.2 +0800; gap=4m53s
```

8.3.3.4.5 Run snapshot backup

You can run snapshot backup tasks on a regular basis using an automatic tool such as crontab. For example, run a snapshot backup at 00:00 every two days.

The following are two snapshot backup examples:

- Run a snapshot backup at 2022/05/14 00:00:00

  ```
  tiup br backup full --pd="${PD_IP}:2379" \
  --storage='s3://tidb-pitr-bucket/backup-data/snapshot-20220514000000' \
  --backupts='2022/05/14 00:00:00'
  ```

- Run a snapshot backup at 2022/05/16 00:00:00

```
tiup br backup full --pd="${PD_IP}:2379" \
--storage='s3://tidb-pitr-bucket/backup-data/snapshot-20220516000000' \
--backupts='2022/05/16 00:00:00'
```

8.3.3.4.6 Run PITR

Assume that you need to query the data at 2022/05/15 18:00:00. You can use PITR to restore a cluster to that time point by restoring a snapshot backup taken at 2022/05/14 and the log backup data between the snapshot and 2022/05/15 18:00:00.

The command is as follows:

```
tiup br restore point --pd="${PD_IP}:2379" \
--storage='s3://tidb-pitr-bucket/backup-data/log-backup' \
--full-backup-storage='s3://tidb-pitr-bucket/backup-data/snapshot
    ↪ -20220514000000' \
--restored-ts '2022-05-15 18:00:00+0800'

Full Restore
    ↪ <-------------------------------------------------------------------------
    ↪  100.00%
[2022/05/29 18:15:39.132 +08:00] [INFO] [collector.go:69] ["Full Restore
    ↪ success summary"] [total-ranges=12] [ranges-succeed=xxx] [ranges-
    ↪ failed=0] [split-region=xxx.xxxµs] [restore-ranges=xxx] [total-take=
    ↪ xxx.xxxs] [restore-data-size(after-compressed)=xxx.xxx] [Size=xxxx] [
    ↪ BackupTS={TS}] [total-kv=xxx] [total-kv-size=xxx] [average-speed=xxx]
Restore Meta Files
    ↪ <-------------------------------------------------------------------------
    ↪  100.00%
Restore KV Files
    ↪ <-------------------------------------------------------------------------
    ↪  100.00%
[2022/05/29 18:15:39.325 +08:00] [INFO] [collector.go:69] ["restore log
    ↪ success summary"] [total-take=xxx.xx] [restore-from={TS}] [restore-to
    ↪ ={TS}] [total-kv-count=xxx] [total-size=xxx]
```

8.3.3.4.7 Clean up outdated data

You can clean up outdated data every two days using an automatic tool such as crontab.

For example, you can run the following commands to clean up outdated data:

- Delete snapshot data earlier than 2022/05/14 00:00:00

```
shell  rm s3://tidb-pitr-bucket/backup-data/snapshot-20220514000000
```

- Delete log backup data earlier than 2022/05/14 00:00:00

```
shell  tiup br log truncate --until='2022-05-14 00:00:00 +0800' --storage
↪ ='s3://tidb-pitr-bucket/backup-data/log-backup'
```

8.3.3.5 Backup Storages

TiDB supports storing backup data to Amazon S3, Google Cloud Storage (GCS), Azure Blob Storage, and NFS. Specifically, you can specify the URL of backup storage in the `--storage` or `-s` parameter of `br` commands. This document introduces the URL format and authentication of different external storage services, and server-side encryption.

8.3.3.5.1 Send credentials to TiKV

CLI parameter	Description	Default value
`--send-credentials-to-tikv`	Controls whether to send credentials obtained by BR to TiKV.	`true`

By default, BR sends a credential to each TiKV node when using Amazon S3, GCS, or Azure Blob Storage as the storage system. This behavior simplifies the configuration and is controlled by the parameter `--send-credentials-to-tikv`(or `-c` in short).

Note that this operation is not applicable to cloud environments. If you use IAM Role authorization, each node has its own role and permissions. In this case, you need to configure `--send-credentials-to-tikv=false` (or `-c=0` in short) to disable sending credentials:

```
./br backup full -c=0 -u pd-service:2379 --storage 's3://bucket-name/prefix'
```

If you back up or restore data using the `BACKUP` and `RESTORE` statements, you can add the `SEND_CREDENTIALS_TO_TIKV = FALSE` option:

```
BACKUP DATABASE * TO 's3://bucket-name/prefix' SEND_CREDENTIALS_TO_TIKV =
    ↪ FALSE;
```

8.3.3.5.2 URL format

URL format description

This section describes the URL format of the storage services:

```
[scheme]://[host]/[path]?[parameters]
```

- `scheme`: `s3`
- `host`: `bucket name`
- `parameters`:
  - `access-key`: Specifies the access key.
  - `secret-access-key`: Specifies the secret access key.
  - `use-accelerate-endpoint`: Specifies whether to use the accelerate endpoint on Amazon S3 (defaults to `false`).
  - `endpoint`: Specifies the URL of custom endpoint for S3-compatible services (for example, `<https://s3.example.com/>`).
  - `force-path-style`: Use path style access rather than virtual hosted style access (defaults to `true`).
  - `storage-class`: Specifies the storage class of the uploaded objects (for example, `STANDARD` or `STANDARD_IA`).
  - `sse`: Specifies the server-side encryption algorithm used to encrypt the uploaded objects (value options: ‘`,AES256, oraws:kms‘).
  - `sse-kms-key-id`: Specifies the KMS ID if `sse` is set to `aws:kms`.
  - `acl`: Specifies the canned ACL of the uploaded objects (for example, `private` or `authenticated-read`).

- `scheme`: `gcs` or `gs`
- `host`: `bucket name`
- `parameters`:
  - `credentials-file`: Specifies the path to the credentials JSON file on the migration tool node.
  - `storage-class`: Specifies the storage class of the uploaded objects (for example, `STANDARD` or `COLDLINE`)
  - `predefined-acl`: Specifies the predefined ACL of the uploaded objects (for example, `private` or `project-private`)

- `scheme`: `azure` or `azblob`
- `host`: `container name`
- `parameters`:
  - `account-name`: Specifies the account name of the storage.
  - `account-key`: Specifies the access key.
  - `access-tier`: Specifies the access tier of the uploaded objects, for example, `Hot`, `Cool`, or `Archive`. The value is `Hot` by default.

URL examples

This section provides some URL examples by using `external` as the `host` parameter (`bucket name` or `container name` in the preceding sections).

Back up snapshot data to Amazon S3

```
./br restore full -u "${PD_IP}:2379" \
--storage "s3://external/backup-20220915?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}"
```

Restore snapshot data from Amazon S3

```
./br restore full -u "${PD_IP}:2379" \
--storage "s3://external/backup-20220915?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}"
```

Back up snapshot data to GCS

```
./br backup full --pd "${PD_IP}:2379" \
--storage "gcs://external/backup-20220915?credentials-file=${credentials-
    ↪ file-path}"
```

Restore snapshot data from GCS

```
./br restore full --pd "${PD_IP}:2379" \
--storage "gcs://external/backup-20220915?credentials-file=${credentials-
    ↪ file-path}"
```

Back up snapshot data to Azure Blob Storage

```
./br backup full -u "${PD_IP}:2379" \
--storage "azure://external/backup-20220915?account-name=${account-name}&
    ↪ account-key=${account-key}"
```

Restore the `test` database from snapshot backup data in Azure Blob Storage

```
./br restore db --db test -u "${PD_IP}:2379" \
--storage "azure://external/backup-20220915account-name=${account-name}&
    ↪ account-key=${account-key}"
```

8.3.3.5.3 Authentication

When storing backup data in a cloud storage system, you need to configure authentication parameters depending on the specific cloud service provider. This section describes the authentication methods used by Amazon S3, GCS, and Azure Blob Storage, and how to configure the accounts used to access the corresponding storage service.

Before backup, configure the following privileges to access the backup directory on S3.

- Minimum privileges for TiKV and Backup & Restore (BR) to access the backup directories during backup: `s3:ListBucket`, `s3:PutObject`, and `s3:AbortMultipartUpload`
- Minimum privileges for TiKV and BR to access the backup directories during restore: `s3:ListBucket` and `s3:GetObject`

If you have not yet created a backup directory, refer to Create a bucket to create an S3 bucket in the specified region. If necessary, you can also create a folder in the bucket by referring to Create a folder.

It is recommended that you configure access to S3 using either of the following ways:

- Method 1: Specify the access key

  If you specify an access key and a secret access key in the URL, authentication is performed using the specified access key and secret access key. Besides specifying the key in the URL, the following methods are also supported:

  - BR reads the environment variables `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` ↪ .
  - BR reads the environment variables `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY`.
  - BR reads the shared credentials file in the path specified by the environment variable `$AWS_SHARED_CREDENTIALS_FILE`.
  - BR reads the shared credentials file in the `~/.aws/credentials` path.

- Method 2: Access based on the IAM role

  Associate an IAM role that can access S3 with EC2 instances where the TiKV and BR nodes run. After the association, BR can directly access the backup directories in S3 without additional settings.

```
br backup full --pd "${PD_IP}:2379" \
--storage "s3://${host}/${path}"
```

You can configure the account used to access GCS by specifying the access key. If you specify the `credentials-file` parameter, the authentication is performed using the specified `credentials-file`. Besides specifying the key in the URL, the following methods are also supported:

- BR reads the file in the path specified by the environment variable `$GOOGLE_APPLICATION_CREDENTIA`
  ↪
- BR reads the file `~/.config/gcloud/application_default_credentials.json`.
- BR obtains the credentials from the metadata server when the cluster is running in GCE or GAE.

- Method 1: Specify the access key

  If you specify `account-name` and `account-key` in the URL, the authentication is performed using the specified access key and secret access key. Besides the method of specifying the key in the URL, BR can also read the key from the environment variable `$AZURE_STORAGE_KEY`.

- Method 2: Use Azure AD for backup and restore

  Configure the environment variables `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` on the node where BR is running.

  – When the cluster is started using TiUP, TiKV uses the systemd service. The following example shows how to configure the preceding three environment variables for TiKV:

> **Note:**
> If this method is used, you need to restart TiKV in step 3. If your cluster cannot be restarted, use **Method 1: Specify the access key** for backup and restore.

1. Suppose that the TiKV port on this node is `24000`, that is, the name of the systemd service is `tikv-24000`:

```
systemctl edit tikv-24000
```

2. Edit the TiKV configuration file to configure the three environment variables:

```
[Service]
Environment="AZURE_CLIENT_ID=aaaaaaaa-aaaa-aaaa-aaaa-
    ↪ aaaaaaaaaaaa"
Environment="AZURE_TENANT_ID=aaaaaaaa-aaaa-aaaa-aaaa-
    ↪ aaaaaaaaaaaa"
Environment="AZURE_CLIENT_SECRET=
    ↪ aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa"
```

3. Reload the configuration and restart TiKV:

```
systemctl daemon-reload
systemctl restart tikv-24000
```

- To configure the Azure AD information for TiKV and BR started with command lines, you only need to check whether the environment variables `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` are configured in the operating environment by running the following commands:

```
echo $AZURE_CLIENT_ID
echo $AZURE_TENANT_ID
echo $AZURE_CLIENT_SECRET
```

- Use BR to back up data to Azure Blob Storage:

```
./br backup full -u "${PD_IP}:2379" \
--storage "azure://external/backup-20220915?account-name=${account-
    ↪ name}"
```

8.3.3.5.4 Server-side encryption

Amazon S3 server-side encryption

BR supports server-side encryption when backing up data to Amazon S3. You can also use an AWS KMS key you create for S3 server-side encryption using BR. For details, see BR S3 server-side encryption.

8.3.3.5.5 Other features supported by the storage service

BR v6.3.0 supports AWS S3 Object Lock. You can enable this feature to prevent backup data from being tampered with or deleted.

8.3.4 BR CLI Manuals

8.3.4.1 br Command-line Manual

This document describes the definition, components, and common options of `br` commands, and how to perform snapshot backup and restore, and log backup and point-in-time recovery (PITR) using `br` commands.

8.3.4.1.1 `br` command-line description

A `br` command consists of sub-commands, options, and parameters. A sub-command is the characters without `-` or `--`. An option is the characters that start with `-` or `--` ↪ . A parameter is the characters that immediately follow behind and are passed to the sub-command or the option.

The following is a complete `br` command:

```
br backup full --pd "${PD_IP}:2379" \
--storage "s3://backup-data/snapshot-202209081330/"
```

Explanations for the preceding command are as follows:

- `backup`: the sub-command of `br`.
- `full`: the sub-command of `br backup`.
- `-s` (or `--storage`): the option that specifies the path where the backup files are stored. `"s3://backup-data/snapshot-202209081330/"` is the parameter of `-s`.
- `--pd`: the option that specifies the PD service address. `"${PD_IP}:2379"` is the parameter of `--pd`.

Commands and sub-commands

A `br` command consists of multiple layers of sub-commands. Currently, br command-line tool has the following sub-commands:

- `br backup`: used to back up the data of the TiDB cluster.
- `br log`: used to start and manage log backup tasks.
- `br restore`: used to restore backup data of the TiDB cluster.

`br backup` and `br restore` include the following sub-commands:

- `full`: used to back up or restore all the cluster data.
- `db`: used to back up or restore a specified database of the cluster.
- `table`: used to back up or restore a single table in the specified database of the cluster.

Common options

- `--pd`: specifies the PD service address. For example, `"${PD_IP}:2379"`.
- `-s` (or `--storage`): specifies the path where the backup files are stored. Amazon S3, Google Cloud Storage (GCS), Azure Blob Storage, and NFS are supported to store backup data. For more details, refer to URL format of backup storages.
- `--ca`: specifies the path to the trusted CA certificate in the PEM format.
- `--cert`: specifies the path to the SSL certificate in the PEM format.
- `--key`: specifies the path to the SSL certificate key in the PEM format.
- `--status-addr`: specifies the listening address through which `br` provides statistics to Prometheus.

8.3.4.1.2 Commands of full backup

To back up cluster data, run the `br backup` command. You can add the `full` or `table` sub-command to specify the scope of your backup operation: the whole cluster (`full`) or a single table (`table`).

- Back up TiDB cluster snapshots
- Back up a database
- Back up a table
- Back up multiple tables with table filter
- Encrypt snapshots

8.3.4.1.3 Commands of log backup

To start log backup and manage log backup tasks, run the `br log` command.

- Start a log backup task
- Query the backup status
- Pause and resume a log backup task
- Stop and restart a log backup task
- Clean up the backup data
- View the backup metadata

8.3.4.1.4 Commands of restoring backup data

To restore cluster data, run the `br restore` command. You can add the `full`, `db`, or `table` sub-command to specify the scope of your restore: the whole cluster (`full`), a single database (`db`), or a single table (`table`).

- Point-in-time recovery
- Restore cluster snapshots
- Restore a database
- Restore a table
- Restore multiple tables with table filter
- Restore encrypted snapshots

8.3.4.2 TiDB Snapshot Backup and Restore Command Manual

This document describes the commands of TiDB snapshot backup and restore according to the application scenarios, including:

- Back up cluster snapshots
- Back up a database
- Back up a table
- Back up multiple tables with table filter
- Encrypt the backup data
- Restore cluster snapshots
- Restore a database
- Restore a table
- Restore multiple tables with table filter
- Restore encrypted snapshots

For more information about snapshot backup and restore, refer to:

- Snapshot Backup and Restore Guide
- Backup and Restore Use Cases

8.3.4.2.1 Back up cluster snapshots

You can back up the latest or specified snapshot of the TiDB cluster using the `br backup full` command. For more information about the command, run the `br backup full --help` command.

```
br backup full \
    --pd "${PD_IP}:2379" \
    --backupts '2022-09-08 13:30:00' \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${access-key}&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
    --log-file backupfull.log
```

In the preceding command:

- `--backupts`: The time point of the snapshot. The format can be TSO or timestamp, such as `400036290571534337` or `2018-05-11 01:42:23`. If the data of this snapshot is garbage collected, the `br backup` command returns an error and 'br' exits. If you leave this parameter unspecified, `br` picks the snapshot corresponding to the backup start time.
- `--ratelimit`: The maximum speed **per TiKV** performing backup tasks. The unit is in MiB/s.
- `--log-file`: The target file where `br` log is written.

During backup, a progress bar is displayed in the terminal, as shown below. When the progress bar advances to 100%, the backup is complete.

```
Full Backup <---------/.....................................................> 17.12%.
```

8.3.4.2.2 Back up a database or a table

Backup & Restore (BR) supports backing up partial data of a specified database or table from a cluster snapshot or incremental data backup. This feature allows you to filter out unwanted data from snapshot backup and incremental data backup, and back up only business-critical data.

Back up a database

To back up a database in a cluster, run the `br backup db` command.

The following example backs up the `test` database to Amazon S3:

```
br backup db \
    --pd "${PD_IP}:2379" \
    --db test \
```

```
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
    --log-file backuptable.log
```

In the preceding command, `--db` specifies the database name, and other parameters are the same as those in Back up TiDB cluster snapshots.

Back up a table

To back up a table in a cluster, run the `br backup table` command.

The following example backs up the `test.usertable` table to Amazon S3:

```
br backup table \
    --pd "${PD_IP}:2379" \
    --db test \
    --table usertable \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
    --log-file backuptable.log
```

In the preceding command, `--db` and `--table` specify the database name and table name respectively, and other parameters are the same as those in Back up TiDB cluster snapshots.

Back up multiple tables with table filter

To back up multiple tables with more criteria, run the `br backup full` command and specify the table filters with `--filter` or `-f`.

The following example backs up tables that match the `db*.tbl*` filter rule to Amazon S3:

```
br backup full \
    --pd "${PD_IP}:2379" \
    --filter 'db*.tbl*' \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
    --log-file backupfull.log
```

8.3.4.2.3 Encrypt the backup data

> **Warning:**
>
> This is an experimental feature. It is not recommended that you use it in the production environment.

BR supports encrypting backup data at the backup side and at the storage side when backing up to Amazon S3. You can choose either encryption method as required.

Since TiDB v5.3.0, you can encrypt backup data by configuring the following parameters:

- `--crypter.method`: Encryption algorithm, which can be `aes128-ctr`, `aes192-ctr`, or `aes256-ctr`. The default value is `plaintext`, indicating that data is not encrypted.
- `--crypter.key`: Encryption key in hexadecimal string format. It is a 128-bit (16 bytes) key for the algorithm `aes128-ctr`, a 24-byte key for the algorithm `aes192-ctr`, and a 32-byte key for the algorithm `aes256-ctr`.
- `--crypter.key-file`: The key file. You can directly pass in the file path where the key is stored as a parameter without passing in the `crypter.key`.

The following is an example:

```
br backup full\
    --pd ${PD_IP}:2379 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --crypter.method aes128-ctr \
    --crypter.key 0123456789abcdef0123456789abcdef
```

Note:

- If the key is lost, the backup data cannot be restored to the cluster.
- The encryption feature needs to be used on `br` and TiDB clusters v5.3.0 or later versions. The encrypted backup data cannot be restored on clusters earlier than v5.3.0.

8.3.4.2.4 Restore cluster snapshots

You can restore a TiDB cluster snapshot by running the `br restore full` command.

```
br restore full \
    --pd "${PD_IP}:2379" \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
    --log-file restorefull.log
```

In the preceding command:

- `--ratelimit`: The maximum speed **per TiKV** performing backup tasks. The unit is in MiB/s.
- `--log-file`: The target file where the `br` log is written.

During restore, a progress bar is displayed in the terminal as shown below. When the progress bar advances to 100%, the restore task is completed. Then `br` will verify the restored data to ensure data security.

```
Full Restore <---------/.....................................................>
    ↪ 17.12%.
```

8.3.4.2.5 Restore a database or a table

You can use `br` to restore partial data of a specified database or table from backup data. This feature allows you to filter out data that you do not need during the restore.

Restore a database

To restore a database to a cluster, run the `br restore db` command.

The following example restores the `test` database from the backup data to the target cluster:

```
br restore db \
    --pd "${PD_IP}:2379" \
    --db "test" \
    --ratelimit 128 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restore_db.log
```

In the preceding command, `--db` specifies the name of the database to be restored and other parameters are the same as those in Restore TiDB cluster snapshots.

> **Note:**
>
> When you restore the backup data, the database name specified by `--db` must be the same as the one specified by `-- db` in the backup command. Otherwise, the restore fails. This is because the metafile of the backup data (`backupmeta` file) records the database name, and you can only restore data to the database with the same name. The recommended method is to restore the backup data to the database with the same name in another cluster.

Restore a table

To restore a single table to a cluster, run the `br restore table` command.

The following example restores the `test.usertable` table from Amazon S3 to the target cluster:

```
br restore table \
    --pd "${PD_IP}:2379" \
    --db "test" \
    --table "usertable" \
    --ratelimit 128 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restore_table.log
```

In the preceding command, `--table` specifies the name of the table to be restored, and other parameters are the same as those in Restore a database.

Restore multiple tables with table filter

To restore multiple tables with more complex filter rules, run the `br restore full` command and specify the table filters with `--filter` or `-f`.

The following example restores tables that match the `db*.tbl*` filter rule from Amazon S3 to the target cluster:

```
br restore full \
    --pd "${PD_IP}:2379" \
    --filter 'db*.tbl*' \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restorefull.log
```

8.3.4.2.6 Restore encrypted snapshots

> **Warning:**
>
> This is an experimental feature. It is not recommended that you use it in the production environment.

After encrypting the backup data, you need to pass in the corresponding decryption parameters to restore the data. Ensure that the decryption algorithm and key are correct. If the decryption algorithm or key is incorrect, the data cannot be restored. The following is an example:

```
br restore full\
    --pd "${PD_IP}:2379" \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --crypter.method aes128-ctr \
    --crypter.key 0123456789abcdef0123456789abcdef
```

8.3.4.3 TiDB Log Backup and PITR Command Manual

This document describes the commands used in TiDB log backup and point-in-time recovery (PITR).

For more information about log backup and PITR, refer to:

- Log Backup and PITR Guide
- Back up and Restore Use Cases

8.3.4.3.1 Perform log backup

You can start and manage log backup using the `br log` command.

```
./br log --help

backup stream log from TiDB/TiKV cluster

Usage:
  br log [command]

Available Commands:
  metadata  get the metadata of log dir
  pause     pause a log backup task
  resume    resume a log backup task
  start     start a log backup task
  status    get status for the log backup task
  stop      stop a log backup task
  truncate  truncate the log data until sometime
```

Each subcommand is described as follows:

- `br log start`: start a log backup task.
- `br log status`: query the status of the log backup task.
- `br log pause`: pause a log backup task.
- `br log resume`: resume a paused log backup task.
- `br log stop`: stop a log backup task and delete the task metadata.

- `br log truncate`: clean up the log backup data from the backup storage.
- `br log metadata`: query the metadata of the log backup data.

Start a backup task

You can run the `br log start` command to start a log backup task. This task runs in the background of your TiDB cluster and automatically backs up the change log of KV storage to the backup storage.

Run `br log start --help` to see the help information:

```
./br log start --help
start a log backup task

Usage:
  br log start [flags]

Flags:
  -h, --help            help for start
  --start-ts string     usually equals last full backupTS, used for backup
     ↪ log. Default value is current ts. support TSO or datetime, e.g.
     ↪ '400036290571534337' or '2018-05-11 01:42:23+0800'.
  --task-name string    The task name for the backup log task.

Global Flags:
 --ca string              CA certificate path for TLS connection
 --cert string            Certificate path for TLS connection
 --key string             Private key path for TLS connection
 -u, --pd strings         PD address (default [127.0.0.1:2379])
 -s, --storage string     specify the url where backup storage, eg, "s3://
    ↪ bucket/path/prefix"
```

The example output only shows the common parameters. These parameters are described as follows:

- `--start-ts`: specifies the start timestamp for the log backup. If this parameter is not specified, the backup program uses the current time as `start-ts`.
- `task-name`: specifies the task name for the log backup. This name is also used to query, pause, and resume the backup task.
- `--ca`, `--cert`, `--key`: specifies the mTLS encryption method to communicate with TiKV and PD.
- `--pd`: specifies the PD address for the backup cluster. BR needs to access PD to start the log backup task.
- `--storage`: specifies the backup storage address. Currently, BR supports Amazon S3, Google Cloud Storage (GCS), or Azure Blob Storage as the storage for log backup. The preceding command uses Amazon S3 as an example. For details, see URL format of backup storages.

Usage example:

```
./br log start --task-name=pitr --pd="${PD_IP}:2379" \
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-
    ↪ key=${secret-access-key}"'
```

Query the backup status

You can run the `br log status` command to query the backup status.

Run `br log status --help` to see the help information:

```
./br log status --help
get status for the log backup task

Usage:
  br log status [flags]

Flags:
  -h, --help         help for status
  --json             Print JSON as the output.
  --task-name string The task name for backup stream log. If default, get
     ↪ status of all of tasks (default "*")

Global Flags:
 --ca string              CA certificate path for TLS connection
 --cert string            Certificate path for TLS connection
 --key string             Private key path for TLS connection
 -u, --pd strings         PD address (default [127.0.0.1:2379])
```

In the example output, `task-name` is used to specify the name of the backup task. The default value is `*`, which means querying the status of all tasks.

Usage example:

```
./br log status --task-name=pitr --pd="${PD_IP}:2379"
```

Expected output:

```
  Total 1 Tasks.
> #1 <
              name: pitr
            status:  NORMAL
             start: 2022-07-14 20:08:03.268 +0800
               end: 2090-11-18 22:07:45.624 +0800
           storage: s3://backup-101/logbackup
      speed(est.): 0.82 ops/s
checkpoint[global]: 2022-07-25 22:52:15.518 +0800; gap=2m52s
```

The output fields are described as follows:

- `status`: the status of the backup task, which can be `NORMAL`, `ERROR`, or `PAUSE`.
- `start`: the start time of the backup task. It is the `start-ts` value specified when the backup task is started.
- `storage`: the backup storage address.
- `speed`: the total QPS of the backup task. QPS means the number of logs backed per second.
- `checkpoint [global]`: all data before this checkpoint is backed up to the backup storage. This is the latest timestamp available for restoring the backup data.
- `error [store]`: the error the log backup program encounters on the storage node.

Pause and resume a backup task

You can run the `br log pause` command to pause a running backup task.

Run `br log pause --help` to see the help information:

```
./br log pause --help
pause a log backup task

Usage:
  br log pause [flags]

Flags:
  --gc-ttl int      the TTL (in seconds) that PD holds for BR's GC
    ↪ safepoint (default 86400)
  -h, --help        help for status
  --task-name string The task name for backup stream log.

Global Flags:
 --ca string              CA certificate path for TLS connection
 --cert string            Certificate path for TLS connection
 --key string             Private key path for TLS connection
 -u, --pd strings         PD address (default [127.0.0.1:2379])
```

Note:

- After the log backup task is paused, to prevent the MVCC data that generates the change log from being deleted, the backup program automatically sets the current backup checkpoint as the service safepoint, which retains MVCC data within the latest 24 hours. If the backup task is paused for more than 24 hours, the corresponding data is garbage collected and is not backed up.

- Retaining too much MVCC data has a negative impact on the storage capacity and performance of the TiDB cluster. Therefore, it is recommended to resume the backup task in time.

Usage example:

```
./br log pause --task-name=pitr --pd="${PD_IP}:2379"
```

You can run the `br log resume` command to resume a paused backup task.

Run `br log resume --help` to see the help information:

```
./br log resume --help
resume a log backup task

Usage:
  br log resume [flags]

Flags:
  -h, --help         help for status
  --task-name string The task name for backup stream log.

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
```

After the backup task is paused for more than 24 hours, running `br log resume` reports an error, and BR prompts that backup data is lost. To handle this error, refer to Backup & Restore FAQs.

Usage example:

```
./br log resume --task-name=pitr --pd="${PD_IP}:2379"
```

Stop and restart a backup task

You can stop a log backup task by running the `br log stop` command and restart a backup task that is stopped by using the original `--storage` directory.

Stop a backup task

You can run the `br log stop` command to stop a log backup task. This command cleans up the task metadata in the backup cluster.

Run `br log stop --help` to see the help information:

```
./br log stop --help
stop a log backup task

Usage:
  br log stop [flags]

Flags:
  -h, --help         help for status
  --task-name string The task name for the backup log task.

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
```

> **Note:**
>
> Use this command with caution. If you need to pause a log backup task, use `br log pause` and `br log resume` instead.

Usage example:

```
./br log stop --task-name=pitr --pd="${PD_IP}:2379"
```

Restart a backup task

After running the `br log stop` command to stop a log backup task, you can create a new log backup task in another `--storage` directory or restart the log backup task in the original `--storage` directory by running the `br log start` command. If you restart the task in the original `--storage` directory, pay attention to the following points:

- Parameters of the `--storage` directory for restarting a task must be the same as the task that is stopped.
- The `--start-ts` does not need to be specified. BR automatically starts the backup from the last backup checkpoint.
- If the task is stopped for a long time and multiple versions of the data have been garbage collected, the error `BR:Backup:ErrBackupGCSafepointExceeded` is reported when you attempt to restart the task. In this case, you have to create a new log backup task in another `--storage` directory.

Clean up backup data

You can run the `br log truncate` command to clean up the outdated or no longer needed log backup data.

Run `br log truncate --help` to see the help information:

```
./br log truncate --help
truncate the incremental log until sometime.

Usage:
  br log truncate [flags]

Flags:
  --dry-run      Run the command but don't really delete the files.
  -h, --help     help for truncate
  --until string Remove all backup data until this TS.(support TSO or
     ↪ datetime, e.g. '400036290571534337' or '2018-05-11 01:42:23+0800'.)
  -y, --yes      Skip all prompts and always execute the command.

Global Flags:
  -s, --storage string     specify the url where backup storage, eg, "s3://
     ↪ bucket/path/prefix"
```

This command only accesses the backup storage and does not access the TiDB cluster. Some parameters are described as follows:

- `--dry-run`: run the command but do not really delete the files.
- `--until`: delete all log backup data before the specified timestamp.
- `--storage`: the backup storage address. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URL format of backup storages.

Usage example:

```
./br log truncate --until='2022-07-26 21:20:00+0800' \
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-
   ↪ key=${secret-access-key}"'
```

Expected output:

```
Reading Metadata... DONE; take = 277.911599ms
We are going to remove 9 files, until 2022-07-26 21:20:00.0000.
Sure? (y/N) y
Clearing data files... DONE; take = 43.504161ms, kv-count = 53, kv-size =
   ↪ 4573(4.573kB)
Removing metadata... DONE; take = 24.038962ms
```

View the backup metadata

You can run the `br log metadata` command to view the backup metadata in the storage system, such as the earliest and latest timestamp that can be restored.

Run `br log metadata --help` to see the help information:

```
./br log metadata --help
get the metadata of log backup storage

Usage:
  br log metadata [flags]

Flags:
  -h, --help     help for metadata

Global Flags:
  -s, --storage string     specify the url where backup storage, eg, "s3://
     ↪ bucket/path/prefix"
```

This command only accesses the backup storage and does not access the TiDB cluster.

The `--storage` parameter is used to specify the backup storage address. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URL format of backup storages.

Usage example:

```
./br log metadata --storage='s3://backup-101/logbackup?access-key=${access-
   ↪ key}&secret-access-key=${secret-access-key}"'
```

Expected output:

```
[2022/07/25 23:02:57.236 +08:00] [INFO] [collector.go:69] ["log metadata"] [
   ↪ log-min-ts=434582449885806593] [log-min-date="2022-07-14 20:08:03.268
   ↪  +0800"] [log-max-ts=434834300106964993] [log-max-date="2022-07-25
   ↪ 23:00:15.618 +0800"]
```

8.3.4.3.2 Restore to a specified point in time (PITR)

You can run the `br restore point` command to perform a PITR on a new cluster or just restore the log backup data.

Run `br restore point --help` to see the help information:

```
./br restore point --help
restore data from log until specify commit timestamp

Usage:
```

```
  br restore point [flags]

Flags:
  --full-backup-storage string specify the backup full storage. fill it if
      ↪ want restore full backup before restore log.
  -h, --help                 help for point
  --restored-ts string       the point of restore, used for log restore.
      ↪ support TSO or datetime, e.g. '400036290571534337' or '2018-05-11
      ↪ 01:42:23+0800'
  --start-ts string          the start timestamp which log restore from.
      ↪ support TSO or datetime, e.g. '400036290571534337' or '2018-05-11
      ↪ 01:42:23+0800'

Global Flags:
 --ca string                CA certificate path for TLS connection
 --cert string              Certificate path for TLS connection
 --key string               Private key path for TLS connection
 -u, --pd strings           PD address (default [127.0.0.1:2379])
 -s, --storage string       specify the url where backup storage, eg, "s3://
     ↪ bucket/path/prefix"
```

The example output only shows the common parameters. These parameters are described as follows:

- `--full-backup-storage`: the storage address for the snapshot (full) backup. To use PITR, specify this parameter and choose the latest snapshot backup before the restore timestamp. To restore only log backup data, you can omit this parameter. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URL format of backup storages.
- `--restored-ts`: the timestamp that you want to restore data to. If this parameter is not specified, BR restores data to the latest timestamp available in the log backup, that is, the checkpoint of the backup data.
- `--start-ts`: the start timestamp that you want to restore log backup data from. If you only need to restore log backup data, you must specify this parameter.
- `--pd`: the PD address of the restore cluster.
- `--ca`, `--cert`, `--key`: specify the mTLS encryption method to communicate with TiKV and PD.
- `--storage`: the storage address for the log backup. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URL format of backup storages.

Usage example:

```
./br restore point --pd="${PD_IP}:2379"
```

```
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-
    ↪ key=${secret-access-key}"'
--full-backup-storage='s3://backup-101/snapshot-202205120000?access-key=${
    ↪ access-key}&secret-access-key=${secret-access-key}"'

Full Restore
    ↪ <-----------------------------------------------------------------------
    ↪  100.00%
*** ***["Full Restore success summary"] ****** [total-take=3.112928252s] [

    ↪ <-----------------------------------------------------------------------
    ↪  100.00%
"restore log success summary"] [total-take=192.955533ms] [restore-from
    ↪ =434693681289625602] [restore-to=434693753549881345] [total-kv-count
    ↪ =33] [total-size=21551]
```

Note:

- You cannot restore the log backup data of a certain time period repeatedly. If you restore the log backup data of a range `[t1=10, t2=20)` repeatedly, the restored data might be inconsistent.
- When you restore log data of different time periods in multiple batches, ensure that the log data is restored in consecutive order. If you restore the log backup data of `[t1, t2)`, `[t2, t3)`, and `[t3, t4)` in consecutive order, the restored data is consistent. However, if you restore `[t1, t2)` and then skip `[t2, t3)` to restore `[t3, t4)`, the restored data might be inconsistent.

8.3.5 References

8.3.5.1 BR Features

8.3.5.1.1 Backup Auto-Tune New in v5.4.0

Before TiDB v5.4.0, when you back up data using Backup & Restore (BR), the number of threads used for backup makes up 75% of the logical CPU cores. Without a speed limit, the backup process can consume a lot of cluster resources, which has a considerable impact on the performance of the online cluster. Although you can reduce the impact of backup by adjusting the size of the thread pool, it is a tedious task to observe the CPU load and manually adjust the thread pool size.

To reduce the impact of backup tasks on the cluster, TiDB v5.4.0 introduces the auto-tune feature, which is enabled by default. When the cluster resource utilization is high, BR automatically limits the resources used by backup tasks and thereby reduces their impact on the cluster. The auto-tune feature is enabled by default.

Usage scenario

If you want to reduce the impact of backup tasks on the cluster, you can enable the auto-tune feature. With this feature enabled, TiDB performs backup tasks as fast as possible without excessively affecting the cluster.

Alternatively, you can limit the backup speed by using the TiKV configuration item `backup.num-threads` or using the parameter `--ratelimit`.

Use auto-tune

The auto-tune feature is enabled by default, without additional configuration.

> **Note:**
>
> For clusters that upgrade from v5.3.x to v5.4.0 or later versions, the auto-tune feature is disabled by default. You need to manually enable it.

To manually enable the auto-tune feature, you need to set the TiKV configuration item `backup.enable-auto-tune` to `true`.

TiKV supports dynamically configuring the auto-tune feature. You can enable or disable the feature without restarting your cluster. To dynamically enable or disable the auto-tune feature, run the following command:

```
tikv-ctl modify-tikv-config -n backup.enable-auto-tune -v <true|false>
```

When you perform backup tasks on an offline cluster, to speed up the backup, you can modify the value of `backup.num-threads` to a larger number using `tikv-ctl`.

Limitations

Auto-tune is a coarse-grained solution for limiting backup speed. It reduces the need for manual tuning. However, because of the lack of fine-grained control, auto-tune might not be able to completely remove the impact of backup on the cluster.

The auto-tune feature has the following issues and corresponding solutions:

- Issue 1: For **write-heavy clusters**, auto-tune might put the workload and backup tasks into a "positive feedback loop": the backup tasks take up too many resources, which causes the cluster to use fewer resources; at this point, auto-tune might mistakenly assume that the cluster is not under heavy workload and thus allowing backup to run faster. In such cases, auto-tune is ineffective.

  - Solution: Manually adjust `backup.num-threads` to a smaller number to limit the number of threads used by backup tasks. The working principle is as follows:

    The backup process includes lots of SST decoding, encoding, compression, and decompression, which consume CPU resources. In addition, previous test cases have shown that during the backup process, the CPU utilization of the thread pool used for backup is close to 100%. This means that the backup tasks take up a lot of CPU resources. By adjusting the number of threads used by the backup tasks, TiKV can limit the CPU cores used by backup tasks, thus reducing the impact of backup tasks on the cluster performance.

- Issue 2: For **clusters with hotspots**, backup tasks on the TiKV node that has hotspots might be excessively limited, which slows down the overall backup process.

  - Solution: Eliminate the hotspot node, or disable auto-tune on the hotspot node (this might reduce the cluster performance).

- Issue 3: For scenarios with **high traffic jitter**, because auto-tune adjusts the speed limit on a fixed interval (1 minute by default), it might not be able to handle high traffic jitter. For details, see `auto-tune-refresh-interval`.

  - Solution: Disable auto-tune.

Implementation

Auto-tune adjusts the size of the thread pool used by backup tasks to ensure that the overall CPU utilization of the cluster does not exceed a specific threshold.

This feature has two related configuration items not listed in the TiKV configuration file. These two configuration items are only for internal tuning. You do **not** need to configure these two configuration items when you perform backup tasks.

- `backup.auto-tune-remain-threads`:

  - Auto-tune controls the resources used by the backup tasks and ensures that at least `backup.auto-tune-remain-threads` cores are available for other tasks on the same node.
  - Default value: `round(0.2 * vCPU)`

- `backup.auto-tune-refresh-interval`:

- Every `backup.auto-tune-refresh-interval` minute(s), auto-tune refreshes the statistics and recalculates the maximum number of CPU cores that backup tasks can use.
- Default value: `1m`

The following is an example of how auto-tune works. `*` denotes a CPU core used by backup tasks. `^` denotes a CPU core used by other tasks. `-` denotes an idle CPU core.

```
|--------| The server has 8 logical CPU cores.
|********| By default, `backup.num-threads` is `4`. Note that auto-tune
   ↪ makes sure that the thread pool size is never larger than `backup.num
   ↪ -threads`.
|^^****--| By default, `auto-tune-remain-threads` = round(8 * 0.2) = 2. Auto
   ↪ -tune adjusts the size of the thread pool to `4`.
|^^^^**--| Because the cluster workload gets higher, auto-tune adjusts the
   ↪ size of the thread pool to `2`. After that, the cluster still has 2
   ↪ idle CPU cores.
```

In the **Backup CPU Utilization** panel, you can see the size of the thread pool adjusted by auto-tune:

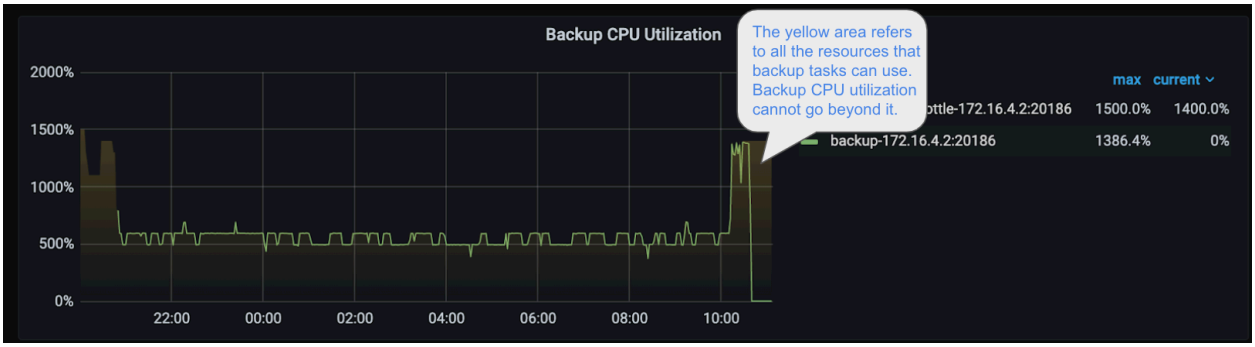

Figure 63: Grafana dashboard example of backup auto-tune metrics

In the image above, the yellow semi-transparent area represents the threads available for backup tasks. You can see the CPU utilization of backup tasks does not go beyond the yellow area.

8.3.5.1.2 Batch Create Table

When restoring data, Backup & Restore (BR) creates databases and tables in the target TiDB cluster and then restores the backup data to the tables. In versions earlier than TiDB v6.0.0, BR uses the serial execution implementation to create tables in the restore process. However, when BR restores data with a large number of tables (nearly 50000), this implementation takes much time on creating tables.

To speed up the table creation process and reduce the time for restoring data, the Batch Create Table feature is introduced in TiDB v6.0.0. This feature is enabled by default.

Note:

- To use the Batch Create Table feature, both TiDB and BR are expected to be of v6.0.0 or later. If either TiDB or BR is earlier than v6.0.0, BR uses the serial execution implementation.
- Suppose that you use a cluster management tool (for example, TiUP), and your TiDB and BR are of v6.0.0 or later versions, or your TiDB and BR are upgraded from a version earlier than v6.0.0 to v6.0.0 or later.

Usage scenario

If you need to restore data with a massive amount of tables, for example, 50000 tables, you can use the Batch Create Table feature to speed up the restore process.

For the detailed effect, see Test for the Batch Create Table Feature.

Use Batch Create Table

BR enables the Batch Create Table feature by default, with the default configuration of `--ddl-batch-size=128` in v6.0.0 or later to speed up the restore process. Therefore, you do not need to configure this parameter. `--ddl-batch-size=128` means creating tables in batches, each batch with 128 tables.

To disable this feature, you can set `--ddl-batch-size` to `1`. See the following example command:

```
br restore full \
--storage local:///br_data/ --pd "${PD_IP}:2379" --log-file restore.log \
--ddl-batch-size=1
```

After this feature is disabled, BR uses the serial execution implementation instead.

Implementation

- Serial execution implementation before v6.0.0:

  When restoring data, BR creates databases and tables in the target TiDB cluster and then restores the backup data to the tables. To create tables, BR calls TiDB internal API first, and then processes table creation tasks, which works similarly to executing the `Create Table` statement. The TiDB DDL owner creates tables sequentially. Once the DDL owner creates a table, the DDL schema version changes correspondingly and each version change is synchronized to other TiDB DDL workers (including BR). Therefore, when restoring a large number of tables, the serial execution implementation is time-consuming.

- Batch create table implementation since v6.0.0:

  By default, BR creates tables in multiple batches, and each batch has 128 tables. Using this implementation, when BR creates one batch of tables, the TiDB schema version only changes once. This implementation significantly increases the speed of table creation.

Feature test

This section describes the test information about the Batch Create Table feature. The test environment is as follows:

- Cluster configurations:
  - 15 TiKV instances. Each TiKV instance is equipped with 16 CPU cores, 80 GB memory, and 16 threads to process RPC requests (`import.num-threads` = 16).
  - 3 TiDB instances. Each TiDB instance is equipped with 16 CPU cores, 32 GB memory.
  - 3 PD instances. Each PD instance is equipped with 16 CPU cores, 32 GB memory.
- The size of data to be restored: 16.16 TB

The test result is as follows:

```
'[2022/03/12 22:37:49.060 +08:00] [INFO] [collector.go:67] ["Full restore
    ↪ success summary"] [total-ranges=751760] [ranges-succeed=751760] [
    ↪ ranges-failed=0] [split-region=1h33m18.078448449s] [restore-ranges
    ↪ =542693] [total-take=1h41m35.471476438s] [restore-data-size(after-
    ↪ compressed)=8.337TB] [Size=8336694965072] [BackupTS
    ↪ =431773933856882690] [total-kv=148015861383] [total-kv-size=16.16TB]
    ↪ [average-speed=2.661GB/s]'
```

From the test result, you can see that the average speed of restoring one TiKV instance is as high as 181.65 MB/s (which equals to `average-speed`/`tikv_count`).

8.3.5.2 Back up and Restore Data Using Dumpling and TiDB Lightning

This document introduces how to use Dumpling and TiDB Lightning to back up and restore full data of TiDB.

If you need to back up a small amount of data (for example, less than 50 GB) and do not require high backup speed, you can use Dumpling to export data from the TiDB database and then use TiDB Lightning to import the data into another TiDB database. For more information about backup and restore, see TiDB Backup & Restore Overview.

8.3.5.2.1 Requirements

- Install and start Dumpling:

```
tiup install dumpling && tiup dumpling
```

- Install and start TiDB Lightning:

```
tiup install tidb lightning && tiup tidb lightning
```

- Grant the source database privileges required for Dumpling
- Grant the target database privileges required for TiDB Lightning

8.3.5.2.2 Resource requirements

Operating system: The example in this document uses fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, `tikv-server`) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU: Because TiDB Lightning consumes high resources, it is recommended to allocate more than 64 GiB of memory and more than 32 CPU cores. To get the best performance, make sure that the CPU core to memory (GiB) ratio is greater than 1:2.

Disk space:

It is recommended to use Amazon S3, Google Cloud Storage (GCS), or Azure Blob Storage as the external storage. With such a cloud storage, you can store backup files quickly without being limited by the disk space.

If you need to save data of one backup task to the local disk, note the following limitations:

- Dumpling requires a disk space that can store the whole data source (or to store all upstream tables to be exported). To calculate the required space, see Downstream storage space requirements.
- During the import, TiDB Lightning needs temporary space to store the sorted key-value pairs. The disk space should be enough to hold the largest single table from the data source.

Note: It is difficult to calculate the exact data volume exported by Dumpling from MySQL, but you can estimate the data volume by using the following SQL statement to summarize the `data-length` field in the `information_schema.tables` table:

```
/* Calculate the size of all schemas, in MiB. Replace ${schema_name} with
    ↪ your schema name. */
SELECT table_schema,SUM(data_length)/1024/1024 AS data_length,SUM(
    ↪ index_length)/1024/1024 AS index_length,SUM(data_length+index_length)
    ↪ /1024/1024 AS SUM FROM information_schema.tables WHERE table_schema =
    ↪  "${schema_name}" GROUP BY table_schema;

/* Calculate the size of the largest table, in MiB. Replace ${schema_name}
    ↪  with your schema name. */
SELECT table_name,table_schema,SUM(data_length)/1024/1024 AS data_length,
    ↪ SUM(index_length)/1024/1024 AS index_length,SUM(data_length+
    ↪ index_length)/1024/1024 AS SUM from information_schema.tables WHERE
    ↪ table_schema = "${schema_name}" GROUP BY table_name,table_schema
    ↪ ORDER BY SUM DESC LIMIT 5;
```

Disk space for the target TiKV cluster

The target TiKV cluster must have enough disk space to store the imported data. In addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has x 2 because:

- Index might take extra space.
- RocksDB has a space amplification effect.

8.3.5.2.3 Use Dumpling to back up full data

1. Run the following command to export full data from TiDB to `s3://my-bucket/sql-backup` in Amazon S3:

   ```
   tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MiB -B
       ↪ my_db1 -f 'my_db1.table[12]' -o 's3://my-bucket/sql-backup'
   ```

   Dumpling exports data in SQL files by default. You can specify a different file format by adding the `--filetype` option.

   For more configurations of Dumpling, see Option list of Dumpling.

2. After the export is completed, you can view the backup files in the directory `s3://my-bucket/sql-backup`.

8.3.5.2.4 Use TiDB Lightning to restore full data

1. Edit the `tidb-lightning.toml` file to import full data backed up using Dumpling from `s3://my-bucket/sql-backup` to the target TiDB cluster:

```
[lightning]
# log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the
    ↪ target TiDB cluster cannot provide any service.
# "tidb": The "tidb" backend is recommended to import data less than 1
    ↪ TiB. During the import, the target TiDB cluster can provide
    ↪ service normally. For more information on the backends, refer to
    ↪ https://docs.pingcap.com/tidb/stable/tidb-lightning-backends.
backend = "local"
# Sets the temporary storage directory for the sorted Key-Value files.
    ↪ The directory must be empty, and the storage space must be
    ↪ greater than the size of the dataset to be imported. For better
    ↪ import performance, it is recommended to use a directory
    ↪ different from `data-source-dir` and use flash storage, which can
    ↪  use I/O exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
# The data source directory. The same directory where Dumpling exports
    ↪ data in "Use Dumpling to back up full data".
data-source-dir = "${data-path}" # A local path or S3 path. For example
    ↪ , 's3://my-bucket/sql-backup'

[tidb]
# The target TiDB cluster information.
host = ${host}             # e.g.: 172.16.32.1
port = ${port}             # e.g.: 4000
user = "${user_name}"      # e.g.: "root"
password = "${password}"   # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs
    ↪ to obtain the table schema information from the TiDB status port.
    ↪  e.g.: 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD
    ↪ . When backend = "local", you must specify status-port and pd-
    ↪ addr correctly. Otherwise, the import will be abnormal.
```

For more information on TiDB Lightning configuration, refer to TiDB Lightning Configuration.

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a `SIGHUP` signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

   If you import data from S3, pass the SecretKey and AccessKey that have access to the S3 storage path as environment variables to the TiDB Lightning node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After the import starts, you can `grep` the keyword `progress` in the log to check the progress of the import. The progress is updated every 5 minutes by default.

4. After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

8.3.5.3 Back Up and Restore RawKV

> **Warning:**
>
> This feature is experimental, without being thoroughly tested. It is NOT recommended that you use it in the production environment.

TiKV and PD can constitute a KV database when used without TiDB, which is called RawKV. Backup & Restore (BR) supports data backup and restore for products that use RawKV. This document describes how to back up and restore RawKV.

8.3.5.3.1 Back up RawKV

In some scenarios, TiKV might run independently of TiDB. Given that, BR supports bypassing the TiDB layer and backing up data in TiKV.

```
br backup raw --pd $PD_ADDR \
    -s "local://$BACKUP_DIR" \
    --start 31 \
    --ratelimit 128 \
    --end 3130303030303030 \
    --format hex \
    --cf default
```

The preceding command backs up all keys between `[0x31, 0x3130303030303030)` in the default CF to `$BACKUP_DIR`.

In this command, the values of `--start` and `--end` are decoded using the format specified by `--format` before being sent to TiKV. Currently, the following formats are available:

- "raw": The input string is directly encoded as a key in binary format.
- "hex": The default encoding format. The input string is treated as a hexadecimal number.
- "escaped": First escape (backslash) the input string, and then encode it into binary format, for example, `abc\xFF\x00\r\n`.

Note:

- If you use the local storage, you **should** copy all back up SST files to every TiKV node in the path specified by `--storage`. Even if each TiKV node eventually only needs to read a part of the SST files, they all need full access to the complete archive because:
  - Data is replicated into multiple peers. When ingesting SSTs, these files have to be present on all peers. This is unlike backup where reading from a single node is enough.
  - Where each peer is scattered to during restoration is random. You have no idea in advance which node will read which file.
- These can be avoided using shared storage, for example, mounting an NFS on the local path, or using S3. With network storage, every node can automatically read every SST file. In this case, the preceding caveats no longer apply.
- Also, note that you can only run one restoration operation for a single cluster at the same time. Otherwise, unexpected behaviors might occur. For details, see FAQs.

8.3.5.3.2 Restore RawKV

Similar to backing up RawKV, you can run the following command to restore RawKV:

```
br restore raw --pd $PD_ADDR \
    -s "local://$BACKUP_DIR" \
    --start 31 \
    --end 3130303030303030 \
    --ratelimit 128 \
    --format hex \
    --cf default
```

In this example, all the backed up keys in the range `[0x31, 0x3130303030303030)` are restored to the TiKV cluster. The coding formats of these keys are identical to that of keys during the backup process.

8.3.5.4 TiDB Incremental Backup and Restore Guide

Incremental data of a TiDB cluster is differentiated data between the starting snapshot and the end snapshot of time period, and the DDLs generated during this period. Compared with full (snapshot) backup data, incremental data is smaller and therefore it is a supplementary to snapshot backup, which reduces the volume of backup data. To perform incremental backup, ensure that MVCC data generated within the specified period is not garbage collected by the TiDB GC mechanism. For example, to perform incremental backup hourly, you must set `tidb_gc_life_time` to a value greater than 1 hour.

> **Warning:**
>
> Development for this feature has stopped. It is recommended that you use log backup and PITR as an alternative.

8.3.5.4.1 Back up incremental data

To back up incremental data, run the `br backup` command with **the last backup timestamp** `--lastbackupts` specified. In this way, br command-line tool automatically backs up incremental data generated between `lastbackupts` and the current time. To get `--lastbackupts`, run the `validate` command. The following is an example:

```
LAST_BACKUP_TS=`tiup br validate decode --field="end-version" --storage "s3
    ↪ ://backup-101/snapshot-202209081330?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}"| tail -n1`
```

The following command backs up the incremental data between `(LAST_BACKUP_TS, current PD timestamp]` and the DDLs generated during this time period:

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330/incr?access-key=${access-
    ↪ key}&secret-access-key=${secret-access-key}" \
--lastbackupts ${LAST_BACKUP_TS} \
--ratelimit 128
```

- `--lastbackupts`: The last backup timestamp.
- `--ratelimit`: The maximum speed **per TiKV** performing backup tasks (in MiB/s).
- `storage`: The storage path of backup data. You need to save the incremental backup data under a different path from the previous snapshot backup. In the preceding example, incremental backup data is saved in the `incr` directory under the full backup data. For details, see Backup storage URL configuration.

8.3.5.4.2 Restore incremental data

When restoring incremental data, make sure that all the data backed up before `LAST_BACKUP_TS` has been restored to the target cluster. Also, because incremental restore updates data, you need to ensure that there are no other writes during the restore. Otherwise, conflicts might occur.

The following command restores the full backup data stored in the `backup-101/snapshot-202209081330` directory:

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

The following command restores the incremental backup data stored in the `backup-101/snapshot-202209081330/incr` directory:

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330/incr?access-key=${access-
    ↪ key}&secret-access-key=${secret-access-key}"
```

8.4 Time Zone Support

The time zone in TiDB is decided by the global `time_zone` system variable and the session `time_zone` system variable. The default value of `time_zone` is `SYSTEM`. The actual time zone corresponding to `System` is configured when the TiDB cluster bootstrap is initialized. The detailed logic is as follows:

- Prioritize the use of the `TZ` environment variable.
- If the `TZ` environment variable fails, extract the time zone from the actual soft link address of `/etc/localtime`.

- If both of the above methods fail, use `UTC` as the system time zone.

You can use the following statement to set the global server `time_zone` value at runtime:

```
SET GLOBAL time_zone = timezone;
```

Each client has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
SET time_zone = timezone;
```

You can use the following statement to view the current values of the global, client-specific and system time zones:

```
SELECT @@global.time_zone, @@session.time_zone, @@global.system_time_zone;
```

To set the format of the value of the `time_zone`:

- The value 'SYSTEM' indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as '+10:00' or '-6:00'.
- The value can be given as a named time zone, such as 'Europe/Helsinki', 'US/Eastern', or 'MET'.

The current session time zone setting affects the display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`.

> **Note:**
>
> Only the values of the Timestamp data type is affected by time zone. This is because the Timestamp data type uses the literal value + time zone information. Other data types, such as Datetime/Date/Time, do not have time zone information, thus their values are not affected by the changes of time zone.

```
create table t (ts timestamp, dt datetime);
```

```
Query OK, 0 rows affected (0.02 sec)
```

```
set @@time_zone = 'UTC';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
insert into t values ('2017-09-30 11:11:11', '2017-09-30 11:11:11');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
set @@time_zone = '+8:00';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+---------------------|---------------------+
| ts                  | dt                  |
+---------------------|---------------------+
| 2017-09-30 19:11:11 | 2017-09-30 11:11:11 |
+---------------------|---------------------+
1 row in set (0.00 sec)
```

In this example, no matter how you adjust the value of the time zone, the value of the Datetime data type is not affected. But the displayed value of the Timestamp data type changes if the time zone information changes. In fact, the value that is stored in the storage does not change, it's just displayed differently according to different time zone setting.

Note:

- Time zone is involved during the conversion of the value of Timestamp and Datetime, which is handled based on the current `time_zone` of the session.
- For data migration, you need to pay special attention to the time zone setting of the primary database and the secondary database.

8.5 Daily Check

As a distributed database, TiDB is more complicated than the stand-alone database in terms of the mechanism, and monitoring items. To help operate and maintain TiDB in a more convenient way, this document introduces some key performance indicators.

8.5.1 Key indicators of TiDB Dashboard

Starting from v4.0, TiDB provides a new operation and maintenance management tool, TiDB Dashboard. This tool is integrated into the PD component. You can access TiDB Dashboard at the default address `http://${pd-ip}:${pd_port}/dashboard`.

TiDB Dashboard simplifies the operation and maintenance of the TiDB database. You can view the running status of the entire TiDB cluster through one interface. The following are descriptions of some performance indicators.

8.5.1.1 Instance panel

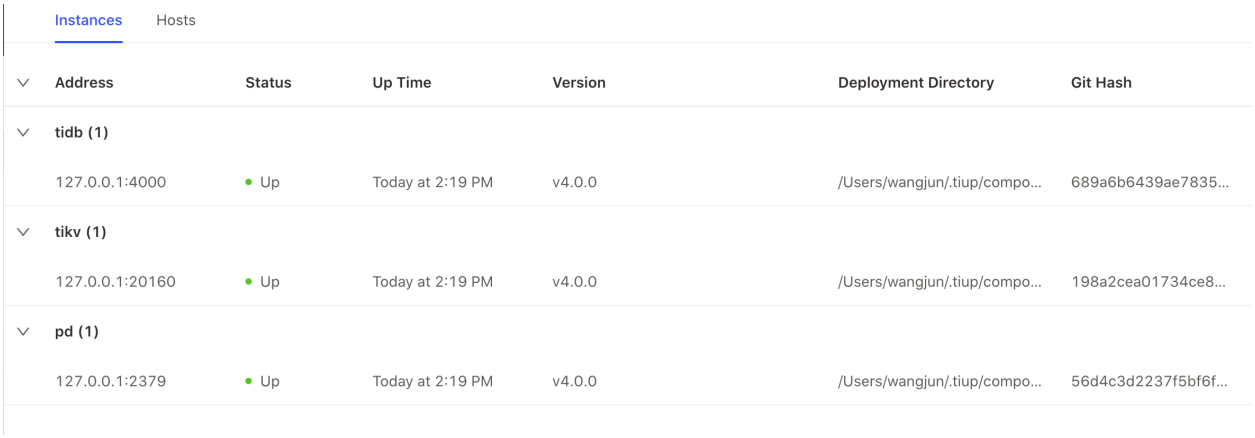

Figure 64: Instance panel

- **Status**: This indicator is used to check whether the status is normal. For an online node, this can be ignored.
- **Up Time**: The key indicator. If you find that the `Up Time` is changed, you need to locate the reason why the component is restarted.
- **Version**, **Deployment Directory**, **Git Hash**: These indicators need to be checked to avoid inconsistent or even incorrect version/deployment directory.

8.5.1.2 Host panel

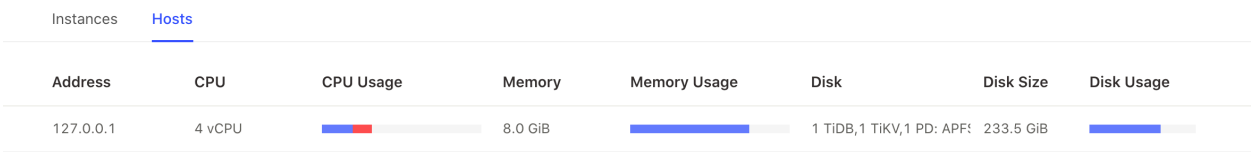

Figure 65: Host panel

You can view the usage of CPU, memory, and disk. When the usage of any resource exceeds 80%, it is recommended to scale out the capacity accordingly.

8.5.1.3 SQL analysis panel

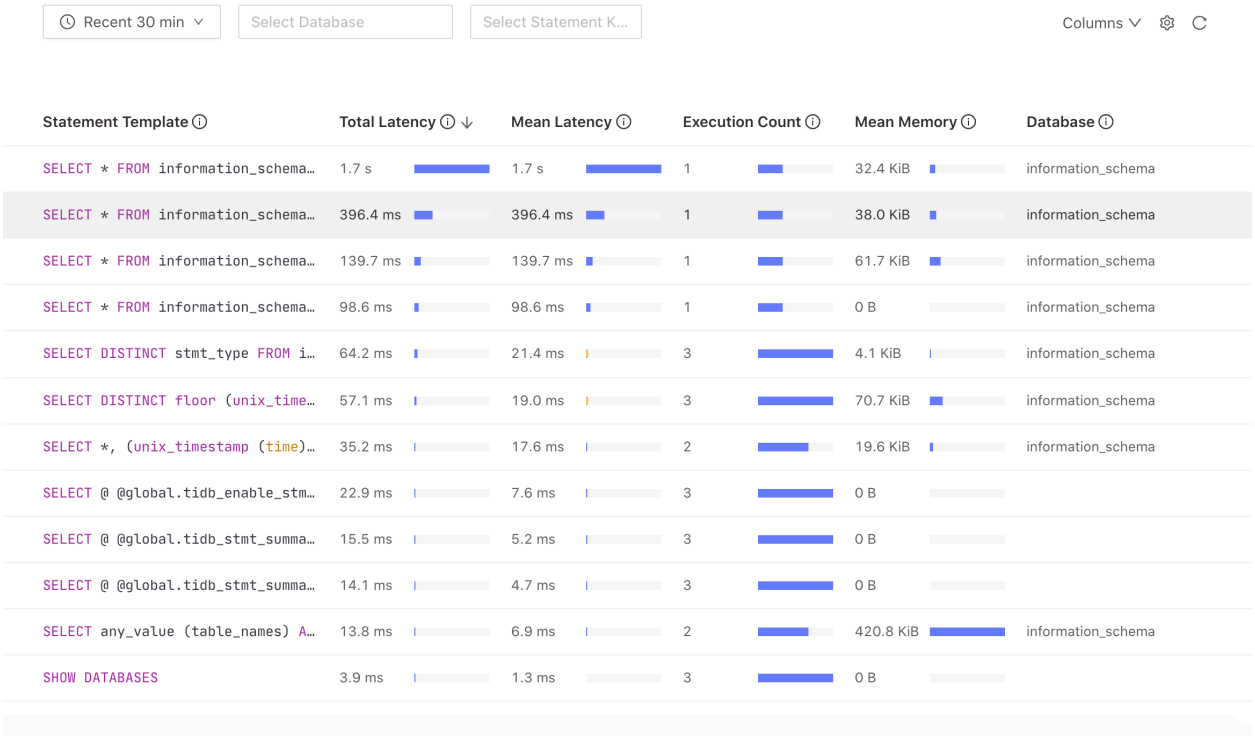

Figure 66: SQL analysis panel

You can locate the slow SQL statement executed in the cluster. Then you can optimize the specific SQL statement.

8.5.1.4 Region panel

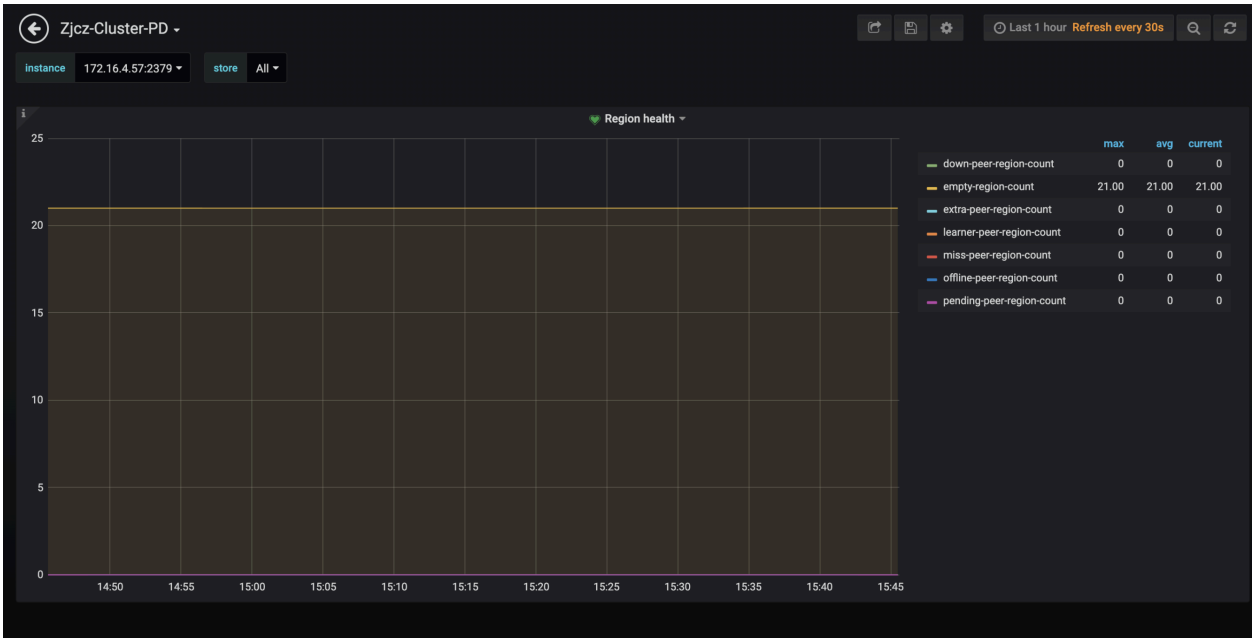

Figure 67: Region panel

- `miss-peer-region-count`: The number of Regions without enough replicas. This value is not always greater than `0`.
- `extra-peer-region-count`: The number of Regions with extra replicas. These Regions are generated during the scheduling process.
- `empty-region-count`: The number of empty Regions, generated by executing the `TRUNCATE TABLE/DROP TABLE` statement. If this number is large, you can consider enabling `Region Merge` to merge Regions across tables.
- `pending-peer-region-count`: The number of Regions with outdated Raft logs. It is normal that a few pending peers are generated in the scheduling process. However, it is not normal if this value is large for a period of time (longer than 30 minutes).
- `down-peer-region-count`: The number of Regions with an unresponsive peer reported by the Raft leader.
- `offline-peer-region-count`: The number of Regions during the offline process.

Generally, it is normal that these values are not `0`. However, it is not normal that they are not `0` for quite a long time.

8.5.1.5 KV Request Duration

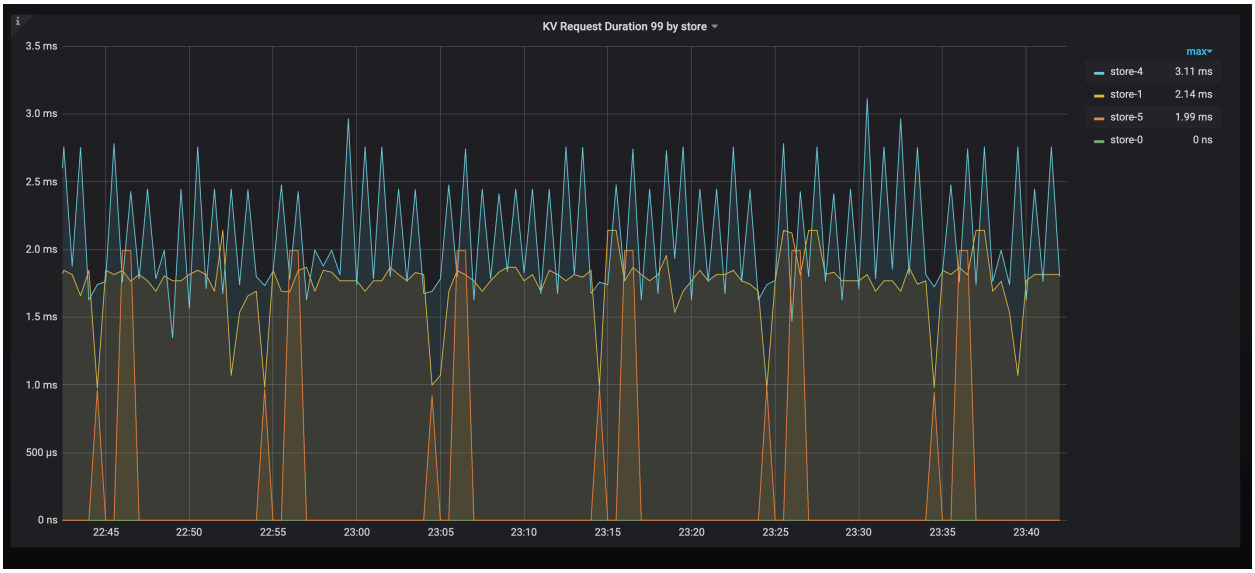

Figure 68: TiKV request duration

The KV request duration 99 in TiKV. If you find nodes with a long duration, check whether there are hot spots, or whether there are nodes with poor performance.

8.5.1.6 PD TSO Wait Duration

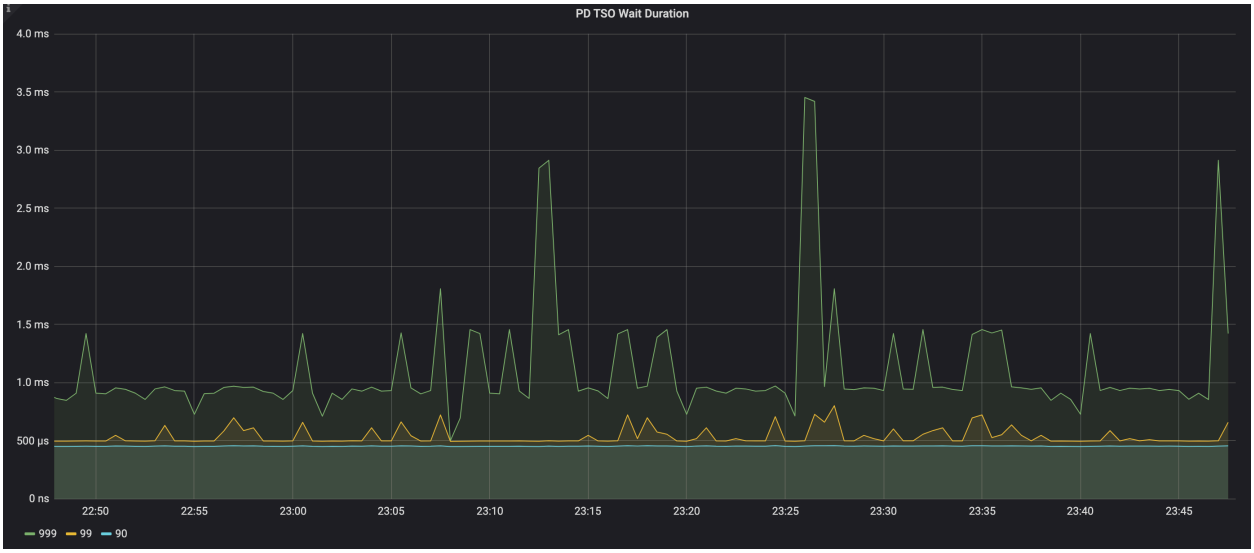

Figure 69: TiDB TSO Wait Duration

The time it takes for TiDB to obtain TSO from PD. The following are reasons for the long wait duration:

- High network latency from TiDB to PD. You can manually execute the ping command to test the network latency.
- High load for the TiDB server.
- High load for the PD server.

8.5.1.7 Overview panel

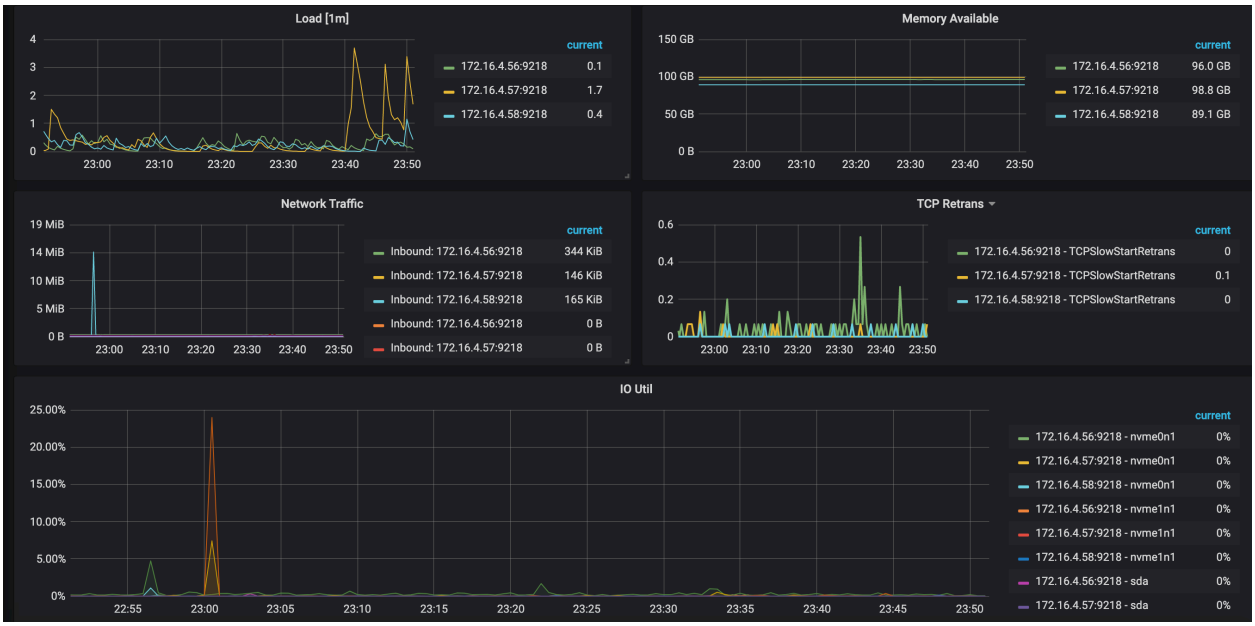

Figure 70: Overview panel

You can view the load, memory available, network traffic, and I/O utilities. When a bottleneck is found, it is recommended to scale out the capacity, or to optimize the cluster topology, SQL, and cluster parameters.

8.5.1.8 Exceptions

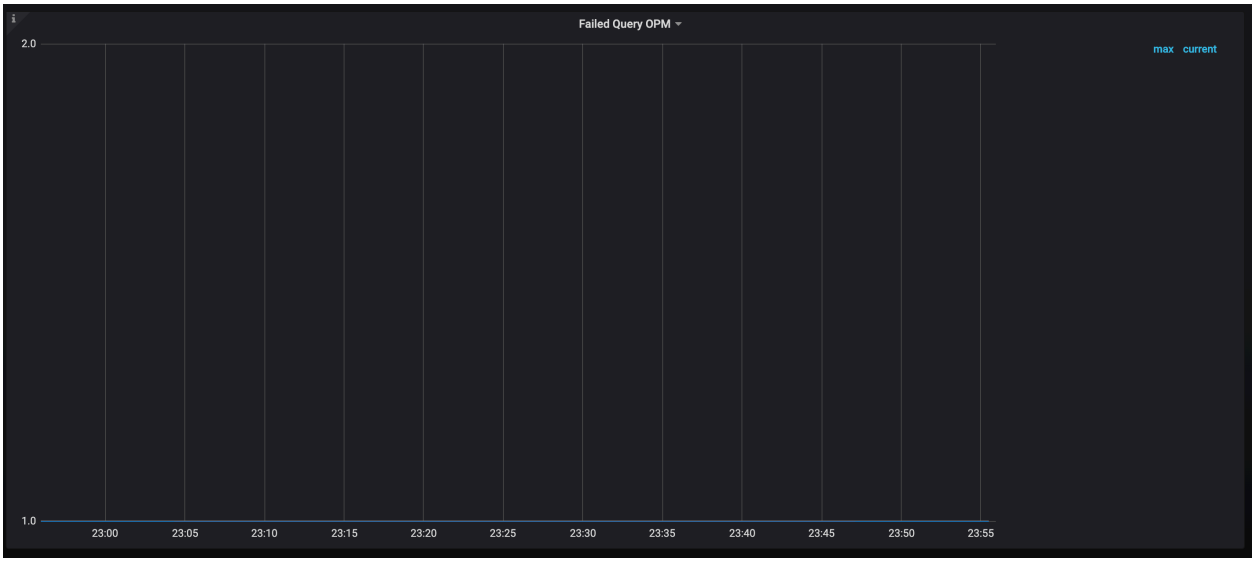

Figure 71: Exceptions

You can view the errors triggered by the execution of SQL statements on each TiDB instance. These include syntax error and primary key conflicts.

8.5.1.9 GC status

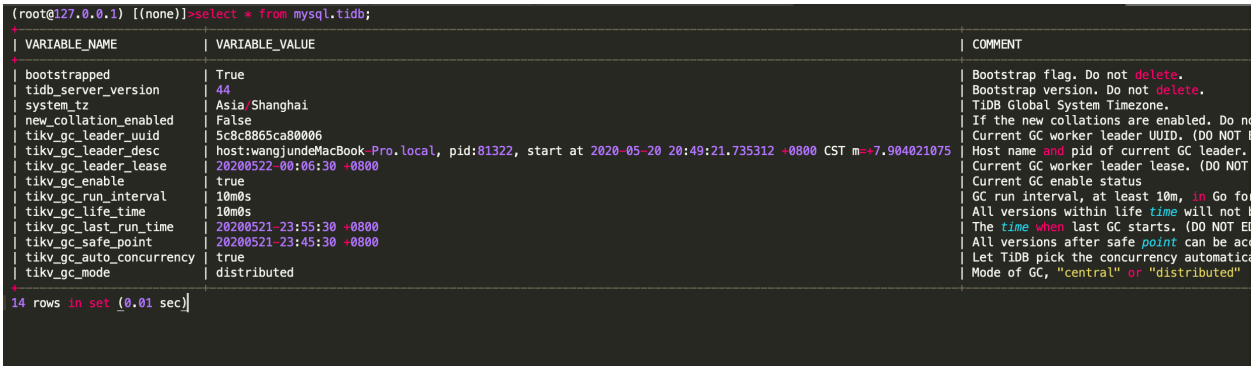

Figure 72: GC status

You can check whether the GC (Garbage Collection) status is normal by viewing the time when the last GC happens. If the GC is abnormal, it might lead to excessive historical data, thereby decreasing the access efficiency.

8.6 Maintain a TiFlash Cluster

This document describes how to perform common operations when you maintain a TiFlash cluster, including checking the TiFlash version. This document also introduces critical logs and a system table of TiFlash.

8.6.1 Check the TiFlash version

There are two ways to check the TiFlash version:

- If the binary file name of TiFlash is `tiflash`, you can check the version by executing the `./tiflash version` command.

  However, to execute the above command, you need to add the directory path which includes the `libtiflash_proxy.so` dynamic library to the `LD_LIBRARY_PATH` environment variable. This is because the running of TiFlash relies on the `libtiflash_proxy.so` dynamic library.

  For example, when `tiflash` and `libtiflash_proxy.so` are in the same directory, you can first switch to this directory, and then use the following command to check the TiFlash version:

```
LD_LIBRARY_PATH=./ ./tiflash version
```

- Check the TiFlash version by referring to the TiFlash log. For the log path, see the `[logger]` part in the `tiflash.toml` file. For example:

```
<information>: TiFlash version: TiFlash 0.2.0 master-375035282451103999
    ↪ f3863c691e2fc2
```

8.6.2 TiFlash critical logs

Log Information	Log Description
`[INFO] [<` `↪ unknown>]` `↪ ["KVStore:` `↪ Start to` `↪ persist [` `↪ region 47,` `↪ applied:` `↪ term 6` `↪ index 10]"]` `↪ [thread_id` `↪ =23]`	Data starts to be replicated (the number in the square brackets at the start of the log refers to the thread ID

Log Information	Log Description
`[DEBUG] [<unknown>] ["CoprocessorHandler : grpc::Status DB::CoprocessorHandler::execute() : Handling DAG request"] [thread_id=30]`	Handling DAG request, that is, TiFlash starts to handle a Coprocessor request
`[DEBUG] [<unknown>] ["CoprocessorHandler : grpc::Status DB::CoprocessorHandler::execute() : Handle DAG request done"] [thread_id=30]`	Handling DAG request done, that is, TiFlash finishes handling a Coprocessor request

You can find the beginning or the end of a Coprocessor request, and then locate the related logs of the Coprocessor request through the thread ID printed at the start of the log.

8.6.3 TiFlash system table

The column names and their descriptions of the `information_schema.tiflash_replica` system table are as follows:

Column Name	Description
TABLE_SCHEMA	Database name
TABLE_NAME	Table name
TABLE_ID	Table ID
REPLICA_COUNT	Number of TiFlash replicas

Column Name	Description
LOCATION_LABELS	The hint for PD, based on which multiple replicas in a Region are scattered
AVAILABLE	Available or not (0/1)
PROGRESS	Replication progress [0.0~1.0]

8.7 TiUP Common Operations

This document describes the following common operations when you operate and maintain a TiDB cluster using TiUP.

- View the cluster list
- Start the cluster
- View the cluster status
- Modify the configuration
- Stop the cluster
- Destroy the cluster

8.7.1 View the cluster list

You can manage multiple TiDB clusters using the TiUP cluster component. When a TiDB cluster is deployed, the cluster appears in the TiUP cluster list.

To view the list, run the following command:

```
tiup cluster list
```

8.7.2 Start the cluster

The components in the TiDB cluster are started in the following order:

PD > TiKV > Pump > TiDB > TiFlash > Drainer > TiCDC > Prometheus > Grafana > Alertmanager

To start the cluster, run the following command:

```
tiup cluster start ${cluster-name}
```

> **Note:**
>
> Replace `${cluster-name}` with the name of your cluster. If you forget the cluster name, check it by running `tiup cluster list`.

You can start only some of the components by adding the `-R` or `-N` parameters in the command. For example:

- This command starts only the PD component:

```
tiup cluster start ${cluster-name} -R pd
```

- This command starts only the PD components on the `1.2.3.4` and `1.2.3.5` hosts:

```
tiup cluster start ${cluster-name} -N 1.2.3.4:2379,1.2.3.5:2379
```

> **Note:**
>
> If you start the specified component by using the `-R` or `-N` parameters, make sure the starting order is correct. For example, start the PD component before the TiKV component. Otherwise, the start might fail.

8.7.3 View the cluster status

After starting the cluster, check the status of each component to ensure that they work normally. TiUP provides the `display` command, so you do not have to log in to every machine to view the component status.

```
tiup cluster display ${cluster-name}
```

8.7.4 Modify the configuration

When the cluster is in operation, if you need to modify the parameters of a component, run the `edit-config` command. The detailed steps are as follows:

1. Open the configuration file of the cluster in the editing mode:

```
tiup cluster edit-config ${cluster-name}
```

2. Configure the parameters:

    - If the configuration is globally effective for a component, edit `server_configs`:

    ```
    server_configs:
      tidb:
        log.slow-threshold: 300
    ```

    - If the configuration takes effect on a specific node, edit the configuration in `config` of the node:

    ```
    tidb_servers:
    - host: 10.0.1.11
      port: 4000
      config:
          log.slow-threshold: 300
    ```

    For the parameter format, see the TiUP parameter template.

    Use `.` to represent the hierarchy of the configuration items.

    For more information on the configuration parameters of components, refer to TiDB `config.toml.example`, TiKV `config.toml.example`, and PD `config.toml.example` ↪ .

3. Rolling update the configuration and restart the corresponding components by running the `reload` command:

    ```
    tiup cluster reload ${cluster-name} [-N <nodes>] [-R <roles>]
    ```

8.7.4.1 Example

If you want to set the transaction size limit parameter (`txn-total-size-limit` in the performance module) to `1G` in tidb-server, edit the configuration as follows:

```
server_configs:
  tidb:
    performance.txn-total-size-limit: 1073741824
```

Then, run the `tiup cluster reload ${cluster-name} -R tidb` command to rolling restart the TiDB component.

8.7.5 Replace with a hotfix package

For normal upgrade, see Upgrade TiDB Using TiUP. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  cluster patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the role
      --transfer-timeout int Timeout in seconds when transferring PD and
          ↪ TiKV store leaders (default 300)

Global Flags:

      --native-ssh      Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

8.7.6 Rename the cluster

After deploying and starting the cluster, you can rename the cluster using the `tiup ↪ cluster rename` command:

```
tiup cluster rename ${cluster-name} ${new-name}
```

Note:

- The operation of renaming a cluster restarts the monitoring system (Prometheus and Grafana).
- After a cluster is renamed, some panels with the old cluster name might remain on Grafana. You need to delete them manually.

8.7.7 Stop the cluster

The components in the TiDB cluster are stopped in the following order (The monitoring component is also stopped):

Alertmanager > Grafana > Prometheus > TiCDC > Drainer > TiFlash > TiDB > Pump > TiKV > PD

To stop the cluster, run the following command:

```
tiup cluster stop ${cluster-name}
```

Similar to the `start` command, the `stop` command supports stopping some of the components by adding the `-R` or `-N` parameters. For example:

- This command stops only the TiDB component:

  ```
  tiup cluster stop ${cluster-name} -R tidb
  ```

- This command stops only the TiDB components on the `1.2.3.4` and `1.2.3.5` hosts:

  ```
  tiup cluster stop ${cluster-name} -N 1.2.3.4:4000,1.2.3.5:4000
  ```

8.7.8 Clean up cluster data

The operation of cleaning up cluster data stops all the services and cleans up the data directory or/and log directory. The operation cannot be reverted, so proceed **with caution**.

- Clean up the data of all services in the cluster, but keep the logs:

  ```
  tiup cluster clean ${cluster-name} --data
  ```

- Clean up the logs of all services in the cluster, but keep the data:

  ```
  tiup cluster clean ${cluster-name} --log
  ```

- Clean up the data and logs of all services in the cluster:

  ```
  tiup cluster clean ${cluster-name} --all
  ```

- Clean up the logs and data of all services except Prometheus:

```
tiup cluster clean ${cluster-name} --all --ignore-role prometheus
```

- Clean up the logs and data of all services except the `172.16.13.11:9000` instance:

```
tiup cluster clean ${cluster-name} --all --ignore-node
    ↪ 172.16.13.11:9000
```

- Clean up the logs and data of all services except the `172.16.13.12` node:

```
tiup cluster clean ${cluster-name} --all --ignore-node 172.16.13.12
```

8.7.9 Destroy the cluster

The destroy operation stops the services and clears the data directory and deployment directory. The operation cannot be reverted, so proceed **with caution**.

```
tiup cluster destroy ${cluster-name}
```

8.8 Modify Configuration Dynamically

This document describes how to dynamically modify the cluster configuration.

You can dynamically update the configuration of components (including TiDB, TiKV, and PD) using SQL statements, without restarting the cluster components. Currently, the method of changing TiDB instance configuration is different from that of changing configuration of other components (such TiKV and PD).

8.8.1 Common Operations

This section describes the common operations of dynamically modifying configuration.

8.8.1.1 View instance configuration

To view the configuration of all instances in the cluster, use the `show config` statement. The result is as follows:

```
show config;
```

```
+--
    ↪ ----+----------------+-------------------------------------------------------------
    ↪
```

```
| Type | Instance     | Name                                                          |
   ↪  Value
   ↪
   ↪ |
+--
   ↪ ----+----------------+---------------------------------------------------------
   ↪
| tidb | 127.0.0.1:4001 | advertise-address                                          |
   ↪  127.0.0.1
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.binlog-socket                                       |
   ↪
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.enable                                              |
   ↪  false
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.ignore-error                                        |
   ↪  false
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.strategy                                            |
   ↪  range
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.write-timeout                                       |
   ↪  15s
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | check-mb4-value-in-utf8                                    |
   ↪  true
   ↪
   ↪ |

...
```

You can filter the result by fields. For example:

```
show config where type='tidb'
show config where instance in (...)
show config where name like '%log%'
show config where type='tikv' and name='log.level'
```

8.8.1.2 Modify TiKV configuration dynamically

> **Note:**
>
> - After dynamically changing TiKV configuration items, the TiKV configuration file is automatically updated. However, you also need to modify the corresponding configuration items by executing `tiup edit-config`; otherwise, operations such as `upgrade` and `reload` will overwrite your changes. For details of modifying configuration items, refer to Modify configuration using TiUP.
> - After executing `tiup edit-config`, you do not need to execute `tiup reload`.

When using the `set config` statement, you can modify the configuration of a single instance or of all instances according to the instance address or the component type.

- Modify the configuration of all TiKV instances:

> **Note:**
>
> It is recommended to wrap variable names in backticks.

```
set config tikv `split.qps-threshold`=1000;
```

- Modify the configuration of a single TiKV instance:

```
set config "127.0.0.1:20180" `split.qps-threshold`=1000;
```

If the modification is successful, `Query OK` is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If an error occurs during the batch modification, a warning is returned:

```
set config tikv `log-level`='warn';
```

```
Query OK, 0 rows affected, 1 warning (0.04 sec)
```

```
show warnings;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | bad request to http://127.0.0.1:20180/config: fail to
    ↪ update, error: "config log-level can not be changed" |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

The batch modification does not guarantee atomicity. The modification might succeed on some instances, while failing on others. If you modify the configuration of the entire TiKV cluster using `set tikv key=val`, your modification might fail on some instances. You can use `show warnings` to check the result.

If some modifications fail, you need to re-execute the corresponding statement or modify each failed instance. If some TiKV instances cannot be accessed due to network issues or machine failure, modify these instances after they are recovered.

If a configuration item is successfully modified, the result is persisted in the configuration file, which will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words, such as `limit` and `key`. For these configuration items, use backtick ` to enclose them. For example, `` `raftstore.raft-log-gc-size-limit` ``.

The following TiKV configuration items can be modified dynamically:

Configuration item	Description
log.level	The log level.

Configuration item	Description
`raftstore.raft-max-inflight-msgs`	The number of Raft logs to be confirmed. If this number is exceeded, the Raft state machine slows down log sending.
`raftstore.raft-log-gc-tick-interval`	The time interval at which the polling task of deleting Raft logs is scheduled

Configuration item	Description
`raftstore.raft-soft-limit`	The soft limit on the maximum allowable number of residual Raft logs
`raftstore.raft-hard-limit`	The hard limit on the allowable number of residual Raft logs

Configuration item	Description
`raftstore.raft-log-gc-size-limit`	The hard limit on the allowable size of residual Raft logs
`raftstore.raft-max-size-per-msg`	The soft limit on the size of a single message packet that is allowed to be generated

Configuration item	Description
`raftstore.raft-entry-max-size`	The hard limit on the maximum size of a single Raft log
`raftstore.raft-entry-cache-life-time`	The maximum remaining time allowed for the log cache in memory

Configuration item	Description
`raftstore.split-region-check-tick-interval`	The time interval at which to check whether the region split is needed
`raftstore.region-max-size`	The maximum value by which the Region data is allowed to exceed before Region split

Configuration item	Description
`raftstore.region-compact-check-interval`	The time interval between which to check whether it is necessary to manually trigger RocksDB compaction
`raftstore.region-compact-check-step`	The number of Regions checked at one time for each round of manual compaction

Configuration item	Description
`raftstore.region-compact-min-tombstones`	The minimum number of tombstones required to trigger RocksDB compaction
`raftstore.region-compact-tombstones-percent`	The proportion of tombstones required to trigger RocksDB compaction

Configuration item	Description
`raftstore.pd-heartbeat-tick-interval`	The time interval for a Region's heartbeat to PD is triggered
`raftstore.store-heartbeat-tick-interval`	The time interval for which store's heartbeat to PD is triggered

Configuration item	Description
`raftstore.snap-mgr-gc-tick-interval`	The time interval at which the recycle of expired snapshot files is triggered
`raftstore.snap-gc-timeout`	The longest time for which a snapshot file is saved

Configuration item	Description
`raftstore.lock-cf-compact-interval`	The time interval at which TiKV triggers a manual compaction for the Lock Column Family
`raftstore.lock-cf-compact-bytes-threshold`	The size at which TiKV triggers a manual compaction for the Lock Column Family

Configuration item	Description
`raftstore.max-messages-per-tick`	The maximum number of messages processed per batch
`raftstore.max-peer-down-duration`	The longest inactive duration allowed for a peer

Configuration item	Description
`raftstore.max-leader-missing-duration`	The longest duration for a peer to be without a leader. If this value is exceeded, the peer verifies with PD whether it has been deleted.

Configuration item	Description
`raftstore.abnormal-leader-missing-duration`	The normal duration for a peer to be without a leader. If this value is exceeded, the peer is seen as abnormal and marked in metrics and logs.

Configuration item	Description
`raftstore.peer-stale-state-check-interval`	The time interval to check whether a peer is out a leader
`raftstore.consistency-check-interval`	The time interval to check consistency (**NOT** recommended because it is not compatible with the garbage collection in TiDB)

Configuration item	Description
`raftstore.raft-base-tick-interval`	The longest trusted period of a Raft leader lease
`raftstore.raft-log-gc-threshold`	The time interval for merge check
`raftstore.raft-log-gc-tick-interval`	The time interval for check expired SST files
`raftstore.raft-max-leader-lease`	The maximum number of Raft logs to compact
`raftstore.region-split-check-diff`	The minimum interval to trigger Raft log compaction
`raftstore.split-region-check-tick-interval`	The minimum interval to import an SST file

Configuration item	Description
`raftstore.local-read-batch-size`	The maximum number of read requests processed in one batch
`raftstore.apply-yield-write-size`	The maximum number of bytes that the Apply thread can write for one FSM (Finite-state Machine) in each round

Configuration item	Description
`raftstore.hibernate-timeout`	The shortest wait duration before entering hibernation upon start. Within this duration, TiKV does not hibernate (not released).

Configuration item	Description
`raftstore.apply-pool-size`	The number of threads in the pool that flushes data to the disk, which is the size of the Apply thread pool

Configuration item	Description
`raftstore.store-pool-size`	The number of threads in the pool that processes Raft, which is the size of the Raftstore thread pool

Configuration item	Description
`raftstore.apply-max-batch-size`	Raft state machines process data write requests in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can execute the requests in one batch.

Configuration item	Description
`raftstore.store-max-batch-size`	Raft state machines process requests for flushing logs into the disk in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can process the requests

Configuration item	Description
`readpool.unified.max-thread-count`	The maximum number of threads in the thread pool that uniformly processes read requests, which is the size of the UnifyReadPool thread pool

Configuration item	Description
`readpool.unified.auto-adjust-pool-size`	Determines whether to automatically adjust the UnifyReadPool thread pool size
`coprocessor.split-region-on-table`	Enables to split Region by table
`coprocessor.batch-split-limit`	The threshold of Region split in batches
`coprocessor.region-max-size`	The maximum size of a Region

Configuration item	Description
`coprocessor.region-split-size`	The size of the newly split Region
`coprocessor.region-max-keys`	The maximum number of keys allowed in a Region
`coprocessor.region-split-keys`	The number of keys in the newly split Region

Configuration item	Description
`pessimistic-txn.wait-for-lock-timeout`	The longest duration that a pessimistic transaction waits for the lock
`pessimistic-txn.wake-up-delay-duration`	The duration after which a pessimistic transaction is woken up
`pessimistic-txn.pipelined`	Determines whether to enable the pipelined pessimistic locking process

Configuration item	Description
`pessimistic-txn.in-memory`	Determines whether to enable the in-memory pessimistic lock
`quota.foreground-cpu-time`	The soft limit on the CPU resources used by TiKV foreground to process read and write requests

Configuration item	Description
`quota.foreground-write-bandwidth`	The soft limit on the bandwidth with which foreground transactions write data
`quota.foreground-read-bandwidth`	The soft limit on the bandwidth with which foreground transactions and the Coprocessor read data

Configuration item	Description
`quota-background-cpu-time`	The soft limit on the CPU resources used by TiKV background to process read and write requests
`quota-background-write-bandwidth`	The soft limit on the bandwidth with which background transactions write data (not effective yet)

Configuration item	Description
`quota_background_read_bandwidth`	The soft limit on the background read bandwidth with which background transactions and the Coprocessor read data (not effective yet)

Configuration item	Description
`quota.enable-auto-tune`	Whether to enable the auto-tuning of quota. If this configuration item is enabled, TiKV dynamically adjusts the quota for the background requests based on the load of TiKV instances.

Configuration item	Description
`quota.max-delay-duration`	The maximum time that a single read or write request is forced to wait before it is processed in the foreground

Configuration item	Description
`gc.ratio-threshold`	The threshold which Region GC is skipped (the number of GC versions/the number of keys)
`gc.batch-keys`	The number of keys processed in one batch

Configuration item	Description
gc.max-write-bytes-per-sec	The maximum bytes that can be written into RocksDB per second
gc.enable-compaction-filter	Whether to enable compaction filter
gc.compaction-filter-skip-version-check	Whether to skip the cluster version check of compaction filter (not released)

Configuration item	Description
{db-name}.max-total-wal-size	The maximum size of total WAL
{db-name}.max-background-jobs	The number of background threads in RocksDB
{db-name}.max-background-flushes	The maximum number of background flush threads in RocksDB
{db-name}.max-open-files	The total number of files that RocksDB can open

Configuration item	Description
{db-name}.compaction-readahead-size	The size of pre-read data during compaction
{db-name}.bytes-per-sync	The rate at which OS incrementally synchronizes files to disk while these files are being written asynchronously

Configuration item	Description
{db-name}.wal-bytes-per-sync	The rate at which OS incrementally synchronizes WAL files to disk while the WAL files are being written
{db-name}.writable-file-max-buffer-size	The maximum buffer size used in WritableFileWriter buffer size

Configuration item	Description
{db-name}.{cf-name}.block-cache-size	The size of a block cache
{db-name}.{cf-name}.write-buffer-size	The size of a memtable
{db-name}.{cf-name}.max-write-buffer-number	The maximum number of memtables

Configuration item	Description
{db-name}.{cf-name}.max-bytes-for-level-base	The maximum number of bytes at base level (L1) for level base
{db-name}.{cf-name}.target-file-size-base	The size of the target file at base level

Configuration item	Description
{db-name}.{cf-name}.level0-file-num-compaction-trigger	The maximum number of files at L0 that trigger compaction
{db-name}.{cf-name}.level0-slowdown-writes-trigger	The maximum number of files at L0 that trigger write stall

Configuration item	Description
{db-name}.{cf-name}.level0-stop-writes-trigger	The maximum number of files at L0 that completely block write
{db-name}.{cf-name}.max-compaction-bytes	The maximum number of bytes written by one compaction

Configuration item	Description
`{db-name}.{cf-name}.max-bytes-for-level-multiplier`	The default amplification multiple for each layer
`{db-name}.{cf-name}.disable-auto-compactions`	Enables or disables automatic compaction

Configuration item	Description
{db-name}.{cf-name}.soft-pending-compaction-bytes-limit	The soft limit on the pending compaction bytes
{db-name}.{cf-name}.hard-pending-compaction-bytes-limit	The hard limit on the pending compaction bytes

Configuration item	Description
`{db-name}.{cf-name}.titan.blob_run_mode`	The mode of processing blob files
`server.grpc-memory-pool-quota`	Limits the memory size that can be used by gRPC
`server.max-grpc-send-msg-len`	Sets the maximum length of a gRPC message that can be sent

Configuration item	Description
`server.snap-max-write-bytes-per-sec`	Sets the maximum allowable disk bandwidth when processing snapshots
`server.concurrent-snap-sender`	Sets the maximum number of snapshots sent at the same time

Configuration item	Description
`server.concurrent-recv-snap-limit`	Sets the maximum number of snapshots received at the same time
`server.raft-msg-max-batch-size`	Sets the maximum number of Raft messages that are contained in a single gRPC message

Configuration item	Description
`server.simplify-metrics`	Controls whether to simplify the sampling monitoring metrics
`storage.block-cache.capacity`	The size of shared block cache (supported since v4.0.3)
`storage.scheduler-worker-pool-size`	The number of threads in the Scheduler thread pool

Configuration item	Description
`backup.num-threads`	The number of backup threads (supported since v4.0.3)

Configuration item	Description
`split-qps-threshold`	The threshold to execute `load-base-split` on a Region. If the QPS of read requests for a Region exceeds `qps-threshold` for 10 consecutive seconds, this Region should be split.

Configuration item	Description
`split-byte-threshold`	The threshold to execute a split on a Region. If the traffic of read requests for a Region exceeds the `byte-threshold` for 10 consecutive seconds, this Region should be split.

Configuration item	Description
`split-region-on-cpu-overload-threshold-ratio`	The threshold to execute load base split on a Region. If the CPU usage in the Unified Read Pool for a Region exceeds the `region-cpu-overload-threshold-ratio` for 10 consecutive seconds, this

Configuration item	Description
`split.split-balance-score`	The parameter of `balance-load` split. The smaller the value is, the more balanced the load is. But setting it too small might cause split

Configuration item	Description
`split.split-contained-score-base`	The parameter of the load base split. The smaller the value, the fewer cross-Region visits after Region split.
`cdc.min-ts-interval`	The time interval at which Resolved TS is forwarded

Configuration item	Description
`cdc.old-value.memory.quota`	The upper limit of memory occupied by the TiCDC Old Value entries
`cdc.sink-memory.quota`	The upper limit of memory occupied by TiCDC data change events

Configuration item	Description
`cdc.incremental-scan-speed-limit`	The speed limit of incremental scanning for historical data
`cdc.incremental-scan-concurrency`	The maximum number of concurrent incremental scanning tasks for historical data

In the table above, parameters with the `{db-name}` or `{db-name}.{cf-name}` prefix are configurations related to RocksDB. The optional values of `db-name` are `rocksdb` and `raftdb`.

- When `db-name` is `rocksdb`, the optional values of `cf-name` are `defaultcf`, `writecf`, `lockcf`, and `raftcf`.
- When `db-name` is `raftdb`, the value of `cf-name` can be `defaultcf`.

For detailed parameter description, refer to TiKV Configuration File.

8.8.1.3 Modify PD configuration dynamically

Currently, PD does not support the separate configuration for each instance. All PD instances share the same configuration.

You can modify the PD configurations using the following statement:

```
set config pd `log.level`='info';
```

If the modification is successful, `Query OK` is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If a configuration item is successfully modified, the result is persisted in etcd instead of in the configuration file; the configuration in etcd will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words. For these configuration items, use backtick ` to enclose them. For example, `` `schedule.leader-schedule-limit` ``.

The following PD configuration items can be modified dynamically:

Configuration item	Description
`log.level`	The log level
`cluster-version`	The cluster version
`schedule.max-merge-region-size`	Controls the size limit of Region Merge (in MiB)

Configuration item	Description
`schedule-max-merge-region-keys`	Specifies the maximum numbers of the Region Merge keys
`schedule-patrol-region-interval`	Determines the frequency which ReplicaChecker checks the health state of a Region

Configuration item	Description
`schedule-split-interval`	Determines the time interval of performing split and merge operations on the same Region
`schedule-max-snapshot-count`	Determines the maximum number of snapshots that a single store can send or receive at the same time

Configuration item	Description
`schedule-max-pending-peer-count`	Determines the maximum number of pending peers in a single store
`schedule-max-store-down-time`	The down-time after which PD judges that the disconnected store cannot be recovered
`schedule-leader-schedule-policy`	Determines the policy of leader scheduling

Configuration item	Description
`schedule-limit`	The number of leader schedule tasks performed at the same time
`schedule-limit`	The number of Region schedule tasks performed at the same time

Configuration item	Description
`schedule-replica-schedule-limit`	The number of Replica scheduling tasks performed at the same time
`schedule-merge-schedule-limit`	The number of Region Merge scheduling tasks performed at the same time

Configuration item	Description
`schedule-hot-region-schedule-limit`	The number of hot Region schedule scheduling tasks performed at the same time
`schedule-hot-region-cache-hits-threshold`	Determines the threshold which a Region is considered a hot spot

Configuration item	Description
`schedule.high-space-ratio`	The threshold ratio of low space ratio, which the capacity of the store is sufficient
`schedule.low-space-ratio`	The threshold ratio of high space ratio, which the capacity of the store is insufficient
`schedule.tolerant-size-ratio`	Controls the balance buffer size ratio

Configuration item	Description
`schedule.enable-remove-down-replica`	Determines whether to enable the feature that automatically removes `DownReplica`
`schedule.enable-replace-offline-replica`	Determines whether to enable the feature that migrates `OfflineReplica`

Configuration item	Description
`schedule-limit`	Determines whether to enable the feature that automatically supplements replicas
`schedule-limit`	Determines whether to enable the feature that removes extra replicas
`schedule-limit`	Determines whether to enable location replacement check

Configuration item	Description
`schedule.enable-cross-table-merge`	Determines whether to enable cross-table merge
`schedule.enable-one-way-merge`	Enables one-way merge, which only allows merging with the next adjacent Region
`replication.max-replicas`	Sets the maximum number of replicas

Configuration item	Description
`replication.location-labels`	The topology information of a TiKV cluster
`replication.enable-placement-rules`	Enables Placement Rules
`replication.strictly-match-label`	Enables the label check
`pd-server.use-region-storage`	Enables independent Region storage

Configuration item	Description
pd-server.max-gap-reset-ts	Sets the maximum interval of resetting timestamp (BR)
pd-server.cluster-key-type	Sets the cluster key type
pd-server.metric-storage	Sets the storage address of the cluster metrics
pd-server.dashboard-address	Sets the dashboard address

Configuration item	Description
`replication.replication-mode`	Sets the backup mode

For detailed parameter description, refer to PD Configuration File.

8.8.1.4 Modify TiDB configuration dynamically

Currently, the method of changing TiDB configuration is different from that of changing TiKV and PD configurations. You can modify TiDB configuration by using system variables.

The following example shows how to dynamically modify `slow-threshold` by using the `tidb_slow_log_threshold` variable.

The default value of `slow-threshold` is 300 ms. You can set it to 200 ms by using `tidb_slow_log_threshold`.

```
set tidb_slow_log_threshold = 200;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select @@tidb_slow_log_threshold;
```

```
+-----------------------------+
| @@tidb_slow_log_threshold |
+-----------------------------+
| 200                       |
+-----------------------------+
1 row in set (0.00 sec)
```

The following TiDB configuration items can be modified dynamically:

Configuration item	SQL variable
`log.enable-slow-log`	`tidb_enable_slow_log`
`log.slow-threshold`	`tidb_slow_log_threshold`
`log.expensive-threshold`	`tidb_expensive_query_time_threshold`

8.8.1.5 Modify TiFlash configuration dynamically

Currently, you can modify the TiFlash configuration `max_threads` by using the system variable `tidb_max_tiflash_threads`, which specifies the maximum concurrency for TiFlash to execute a request.

The default value of `tidb_max_tiflash_threads` is `-1`, indicating that this system variable is invalid and depends on the setting of the TiFlash configuration file. You can set `max_threads` to 10 by using `tidb_max_tiflash_threads`:

```
set tidb_max_tiflash_threads = 10;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select @@tidb_max_tiflash_threads;
```

```
+----------------------------+
| @@tidb_max_tiflash_threads |
+----------------------------+
| 10                         |
+----------------------------+
1 row in set (0.00 sec)
```

8.9 Online Unsafe Recovery

> **Warning:**
>
> Online Unsafe Recovery is a type of lossy recovery. If you use this feature, the integrity of data and data indexes cannot be guaranteed.

When permanently damaged replicas cause part of data on TiKV to be unreadable and unwritable, you can use the Online Unsafe Recovery feature to perform a lossy recovery operation.

8.9.1 Feature description

In TiDB, the same data might be stored in multiple stores at the same time according to the replica rules defined by users. This guarantees that data is still readable and writable even if a single or a few stores are temporarily offline or damaged. However, when most or all replicas of a Region go offline during a short period of time, the Region becomes temporarily unavailable and cannot be read or written.

Suppose that multiple replicas of a data range encounter issues like permanent damage (such as disk damage), and these issues cause the stores to stay offline. In this case, this data range is temporarily unavailable. If you want the cluster back in use and also accept data rewind or data loss, in theory, you can re-form the majority of replicas by manually removing the failed replicas from the group. This allows application-layer services to read and write this data range (might be stale or empty) again.

In this case, if some stores with loss-tolerant data are permanently damaged, you can perform a lossy recovery operation by using Online Unsafe Recovery. When you use this feature, PD automatically pauses Region scheduling (including split and merge), collects the metadata of data shards from all stores, and then, under its global perspective, generates a real-time and complete recovery plan. Then, PD distributes the plan to all surviving stores to make them perform data recovery tasks. In addition, once the data recovery plan is distributed, PD periodically monitors the recovery progress and re-send the plan when necessary.

8.9.2 User scenarios

The Online Unsafe Recovery feature is suitable for the following scenarios:

- The data for application services is unreadable and unwritable, because permanently damaged stores cause the stores to fail to restart.
- You can accept data loss and want the affected data to be readable and writable.
- You want to perform a one-stop online data recovery operation.

8.9.3 Usage

8.9.3.1 Prerequisites

Before using Online Unsafe Recovery, make sure that the following requirements are met:

- The offline stores indeed cause some pieces of data to be unavailable.
- The offline stores cannot be automatically recovered or restarted.

8.9.3.2 Step 1. Specify the stores that cannot be recovered

To trigger automatic recovery, use PD Control to execute `unsafe remove-failed-stores <store_id>[,<store_id>,...]` and specify **all** the TiKV nodes that cannot be recovered, seperated by commas.

```
pd-ctl -u <pd_addr> unsafe remove-failed-stores <store_id1,store_id2,...>
```

If the command returns `Success`, PD Control has successfully registered the task to PD. This only means that the request has been accepted, not that the recovery has been successfully performed. The recovery task is performed in the background. To see the recovery progress, use `show`.

If the command returns `Failed`, PD Control has failed to register the task to PD. The possible errors are as follows:

- `unsafe recovery is running`: There is already an ongoing recovery task.
- `invalid input store x doesn't exist`: The specified store ID does not exist.
- `invalid input store x is up and connected`: The specified store with the ID is still healthy and should not be recovered.

To specify the longest allowable duration of a recovery task, use the `--timeout <seconds >` option. If this option is not specified, the longest duration is 5 minutes by default. When the timeout occurs, the recovery is interrupted and returns an error.

Note:

- Because this command needs to collect information from all peers, it might cause an increase in memory usage (100,000 peers are estimated to use 500 MiB of memory).
- If PD restarts when the command is running, the recovery is interrupted and you need to trigger the task again.
- Once the command is running, the specified stores will be set to the Tombstone status, and you cannot restart these stores.
- When the command is running, all scheduling tasks and split/merge are paused and will be resumed automatically after the recovery is successful or fails.

8.9.3.3 Step 2. Check the recovery progress and wait for the completion

When the above store removal command runs successfully, you can use PD Control to check the removal progress by running `unsafe remove-failed-stores show`.

```
pd-ctl -u <pd_addr> unsafe remove-failed-stores show
```

The recovery process has multiple possible stages:

- `collect report`: The initial stage in which PD collects reports from TiKV and gets global information.
- `tombstone tiflash learner`: Among the unhealthy Regions, delete the TiFlash learners that are newer than other healthy peers, to prevent such an extreme situation and the possible panic.
- `force leader for commit merge`: A special stage. When there is an uncompleted commit merge, `force leader` is first performed on the Regions with commit merge, in case of extreme situations.

- `force leader`: Forces unhealthy Regions to assign a Raft leader among the remaining healthy peers.
- `demote failed voter`: Demotes the Region's failed voters to learners, and then the Regions can select a Raft leader as normal.
- `create empty region`: Creates an empty Region to fill in the space in the key range. This is to resolve the case that the stores with all replicas of some Regions have been damaged.

Each of the above stages is output in the JSON format, including information, time, and a detailed recovery plan. For example:

```
[
    {
        "info": "Unsafe recovery enters collect report stage: failed stores
            ↪ 4, 5, 6",
        "time": "......"
    },
    {
        "info": "Unsafe recovery enters force leader stage",
        "time": "......",
        "actions": {
            "store 1": [
                "force leader on regions: 1001, 1002"
            ],
            "store 2": [
                "force leader on regions: 1003"
            ]
        }
    },
    {
        "info": "Unsafe recovery enters demote failed voter stage",
        "time": "......",
        "actions": {
            "store 1": [
                "region 1001 demotes peers { id:101 store_id:4 }, { id:102
                    ↪ store_id:5 }",
                "region 1002 demotes peers { id:103 store_id:5 }, { id:104
                    ↪ store_id:6 }",
            ],
            "store 2": [
                "region 1003 demotes peers { id:105 store_id:4 }, { id:106
                    ↪ store_id:6 }",
            ]
        }
    },
```

```
    {
        "info": "Collecting reports from alive stores(1/3)",
        "time": "......",
        "details": [
            "Stores that have not dispatched plan: ",
            "Stores that have reported to PD: 4",
            "Stores that have not reported to PD: 5, 6",
        ]
    }
]
```

After PD has successfully dispatched the recovery plan, it waits for TiKV to report the execution results. As you can see in `Collecting reports from alive stores`, the last stage of the above output, this part of the output shows the detailed statuses of PD dispatching recovery plan and receiving reports from TiKV.

The whole recovery process takes multiple stages and one stage might be retried multiple times. Usually, the estimated duration is 3 to 10 periods of store heartbeat (one period of store heartbeat is 10 seconds by default). After the recovery is completed, the last stage in the command output shows `"Unsafe recovery finished"`, the table IDs to which the affected Regions belong (if there is none or RawKV is used, the output does not show the table IDs), and the affected SQL meta Regions. For example:

```
{
    "info": "Unsafe recovery finished",
    "time": "......",
    "details": [
        "Affected table ids: 64, 27",
        "Affected meta regions: 1001",
    ]
}
```

After you get the affected table IDs, you can query `INFORMATION_SCHEMA.TABLES` to view the affected table names.

```
SELECT TABLE_SCHEMA, TABLE_NAME, TIDB_TABLE_ID FROM INFORMATION_SCHEMA.
    ↪ TABLES WHERE TIDB_TABLE_ID IN (64, 27);
```

Note:

- The recovery operation has turned some failed voters to failed learners. Then PD scheduling needs some time to remove these failed learners.
- It is recommended to add new stores in time.

If an error occurs during the task, the last stage in the output shows `"Unsafe recovery failed"` and the error message. For example:

```
{
    "info": "Unsafe recovery failed: <error>",
    "time": "......"
}
```

8.9.3.4 Step 3. Check the consistency of data and index (not required for RawKV)

> **Note:**
>
> Although the data can be read and written, it does not mean that there is no data loss.

After the recovery is completed, the data and index might be inconsistent. Use the SQL command `ADMIN CHECK` to check the data and index consistency of the affected tables

```
ADMIN CHECK TABLE table_name;
```

If there are inconsistent indexes, you can fix the index inconsistency by renaming the old index, creating a new index, and then droping the old index.

1. Rename the old index:

   ```
   ALTER TABLE table_name RENAME INDEX index_name TO index_name_lame_duck
   ;
   ```

2. Create a new index:

   ```
   ALTER TABLE table_name ADD INDEX index_name (column_name);
   ```

3. Drop the old index:

   ```
   ALTER TABLE table_name DROP INDEX index_name_lame_duck;
   ```

8.9.3.5 Step 4: Remove unrecoverable stores (optional)

1. Remove the unrecoverable nodes:

   ```
   tiup cluster scale-in <cluster-name> -N <host> --force
   ```

2. Clean up Tombstone nodes:

```
tiup cluster prune <cluster-name>
```

1. Delete the `PersistentVolumeClaim`.

```
kubectl delete -n ${namespace} pvc ${pvc_name} --wait=false
```

2. Delete the TiKV Pod and wait for newly created TiKV Pods to join the cluster.

```
kubectl delete -n ${namespace} pod ${pod_name}
```

8.10 Replicate Data Between Primary and Secondary Clusters

This document describes how to configure a TiDB primary (upstream) cluster and a TiDB or MySQL secondary (downstream) cluster, and replicate incremental data from the primary cluster to the secondary cluster. The process includes the following steps:

1. Configure a TiDB primary cluster and a TiDB or MySQL secondary cluster.
2. Replicate incremental data from the primary cluster to the secondary cluster.
3. Recover data consistently by using Redo log when the primary cluster is down.

To replicate incremental data from a running TiDB cluster to its secondary cluster, you can use Backup & Restore BR and TiCDC.

8.10.1 Step 1. Set up the environment

1. Deploy TiDB clusters.

   Deploy two TiDB clusters, one upstream and the other downstream by using TiUP Playground. For production environments, deploy the clusters by referring to Deploy and Maintain an Online TiDB Cluster Using TiUP.

   In this document, we deploy the two clusters on two machines:

   - Node A: 172.16.6.123, for deploying the upstream TiDB cluster
   - Node B: 172.16.6.124, for deploying the downstream TiDB cluster

```
# Create an upstream cluster on Node A
tiup --tag upstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 1
# Create a downstream cluster on Node B
tiup --tag downstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 0
# View cluster status
tiup status
```

2. Initialize data.

   By default, test databases are created in the newly deployed clusters. Therefore, you can use sysbench to generate test data and simulate data in real scenarios.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=10 --
    ↪ table-size=10000 prepare
```

   In this document, we use sysbench to run the `oltp_write_only` script. This script generates 10 tables in the upstream database, each with 10,000 rows. The tidb-config is as follows:

```
mysql-host=172.16.6.122 # Replace it with the IP address of your
    ↪ upstream cluster
mysql-port=4000
mysql-user=root
mysql-password=
db-driver=mysql      # Set database driver to MySQL
mysql-db=test        # Set the database as a test database
report-interval=10   # Set data collection period to 10s
threads=10           # Set the number of worker threads to 10
time=0               # Set the time required for executing the script.
    ↪ 0 indicates time unlimited
rate=100             # Set average TPS to 100
```

3. Simulate service workload.

   In real scenarios, service data is continuously written to the upstream cluster. In this document, we use sysbench to simulate this workload. Specifically, run the following command to enable 10 workers to continuously write data to three tables, sbtest1, sbtest2, and sbtest3, with a total TPS not exceeding 100.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=3 run
```

4. Prepare external storage.

   In full data backup, both the upstream and downstream clusters need to access backup files. It is recommended that you use External storage to store backup files. In this example, Minio is used to simulate an S3-compatible storage service.

```
wget https://dl.min.io/server/minio/release/linux-amd64/minio
chmod +x minio
# Configure access-key access-screct-id to access minio
export HOST_IP='172.16.6.123' # Replace it with the IP address of your
    ↪ upstream cluster
export MINIO_ROOT_USER='minio'
export MINIO_ROOT_PASSWORD='miniostorage'
# Create the redo and backup directories. `backup` and `redo` are
    ↪ bucket names.
```

```
mkdir -p data/redo
mkdir -p data/backup
# Start minio at port 6060
nohup ./minio server ./data --address :6060 &
```

The preceding command starts a minio server on one node to simulate S3 services. Parameters in the command are configured as follows:

- Endpoint: `http://${HOST_IP}:6060/`
- Access-key: `minio`
- Secret-access-key: `miniostorage`
- Bucket: `redo`

The link is as follows:

```
s3://backup?access-key=minio&secret-access-key=miniostorage&endpoint=
    ↪ http://${HOST_IP}:6060&force-path-style=true
```

8.10.2 Step 2. Migrate full data

After setting up the environment, you can use the backup and restore functions of BR) to migrate full data. BR can be started in three ways. In this document, we use the SQL statements, `BACKUP` and `RESTORE`.

Note:

- In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you back up data in off-peak hours, and set RATE_LIMIT to a proper value to avoid performance degradation.
- If the versions of the upstream and downstream clusters are different, you should check BR compatibility. In this document, we assume that the upstream and downstream clusters are the same version.

1. Disable GC.

   To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before backup. In this way, history data is not deleted.

   Run the following command to disable GC:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=FALSE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+--------------------------+
| @@global.tidb_gc_enable |
+--------------------------+
|                        0 |
+--------------------------+
1 row in set (0.00 sec)
```

2. Back up data.

   Run the `BACKUP` statement in the upstream cluster to back up data:

```
MySQL [(none)]> BACKUP DATABASE * TO 's3://backup?access-key=minio&
    ↪ secret-access-key=miniostorage&endpoint=http://${HOST_IP}:6060&
    ↪ force-path-style=true' RATE_LIMIT = 120 MB/SECOND;
```

```
+----------------------+----------+--------------------+--------------------+-----
    ↪
| Destination        | Size     | BackupTS         | Queue Time         |
    ↪ Execution Time    |
+----------------------+----------+--------------------+--------------------+-----
    ↪
| local:///tmp/backup/ | 10315858 | 431434047157698561 | 2022-02-25
    ↪ 19:57:59 | 2022-02-25 19:57:59 |
+----------------------+----------+--------------------+--------------------+-----
    ↪
1 row in set (2.11 sec)
```

   After the `BACKUP` command is executed, TiDB returns metadata about the backup data. Pay attention to `BackupTS`, because data generated before it is backed up. In this document, we use `BackupTS` as **the end of data check** and **the start of incremental migration scanning by TiCDC**.

3. Restore data.

   Run the `RESTORE` command in the downstream cluster to restore data:

```
mysql> RESTORE DATABASE * FROM 's3://backup?access-key=minio&secret-
    ↪ access-key=miniostorage&endpoint=http://${HOST_IP}:6060&force-
    ↪ path-style=true';
```

```
+---------------------+---------+-------------------+---------------------+-----
   ↪
| Destination         | Size    | BackupTS          | Queue Time          |
   ↪ Execution Time    |
+---------------------+---------+-------------------+---------------------+-----
   ↪
| local:///tmp/backup/ | 10315858 | 431434141450371074 | 2022-02-25
   ↪ 20:03:59 | 2022-02-25 20:03:59 |
+---------------------+---------+-------------------+---------------------+-----
   ↪
1 row in set (41.85 sec)
```

4. (Optional) Validate data.

   Use sync-diff-inspector to check data consistency between upstream and downstream at a certain time. The preceding `BACKUP` output shows that the upstream cluster finishes backup at 431434047157698561. The preceding `RESTORE` output shows that the downstream finishes restoration at 431434141450371074.

```
sync_diff_inspector -C ./config.yaml
```

   For details about how to configure the sync-diff-inspector, see Configuration file description. In this document, the configuration is as follows:

```
# Diff Configuration.
######################### Global config #########################
check-thread-count = 4
export-fix-sql = true
check-struct-only = false

######################### Datasource config #########################
[data-sources]
[data-sources.upstream]
       host = "172.16.6.123" # Replace it with the IP address of your
          ↪ upstream cluster
       port = 4000
       user = "root"
       password = ""
       snapshot = "431434047157698561" # Set snapshot to the actual
          ↪ backup time
[data-sources.downstream]
       host = "172.16.6.124" # Replace the value with the IP address of
          ↪  your downstream cluster
       port = 4000
       user = "root"
       password = ""
```

```
        snapshot = "431434141450371074" # Set snapshot to the actual
            ↪ restore time

########################## Task config ###########################
[task]
        output-dir = "./output"
        source-instances = ["upstream"]
        target-instance = "downstream"
        target-check-tables = ["*.*"]
```

8.10.3 Step 3. Migrate incremental data

1. Deploy TiCDC.

   After finishing full data migration, deploy and configure a TiCDC to replicate incremental data. In production environments, deploy TiCDC as instructed in Deploy TiCDC. In this document, a TiCDC node has been started upon the creation of the test clusters. Therefore, we skip the step of deploying TiCDC and proceed with changefeed configuration.

2. Create a changefeed.

   Create a changefeed configuration file `changefeed.toml`.

   ```
   [consistent]
   # Consistency level, eventual means enabling consistent replication
   level = "eventual"
   # Use S3 to store redo logs. Other options are local and nfs.
   storage = "s3://redo?access-key=minio&secret-access-key=miniostorage&
       ↪ endpoint=http://172.16.6.125:6060&force-path-style=true"
   ```

   In the upstream cluster, run the following command to create a changefeed from the upstream to the downstream clusters:

   ```
   tiup cdc cli changefeed create --pd=http://172.16.6.122:2379 --sink-uri
       ↪ ="mysql://root:@172.16.6.125:4000" --changefeed-id="primary-to-
       ↪ secondary" --start-ts="431434047157698561"
   ```

   In this command, the parameters are as follows:

   - `--pd`: PD address of the upstream cluster
   - `--sink-uri`: URI of the downstream cluster
   - `--start-ts`: start timestamp of the changefeed, must be the backup time (or BackupTS mentioned in Step 2. Migrate full data)

   For more information about the changefeed configurations, see Task configuration file.

3. Enable GC.

   In incremental migration using TiCDC, GC only removes history data that is replicated. Therefore, after creating a changefeed, you need to run the following command to enable GC. For details, see What is the complete behavior of TiCDC garbage collection (GC) safepoint?.

   To enable GC, run the following command:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=TRUE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+--------------------------+
| @@global.tidb_gc_enable |
+--------------------------+
|                        1 |
+--------------------------+
1 row in set (0.00 sec)
```

8.10.4 Step 4. Simulate a disaster in the upstream cluster

Create a disastrous event in the upstream cluster while it is running. For example, you can terminate the tiup playground process by pressing Ctrl+C.

8.10.5 Step 5. Use redo log to ensure data consistency

Normally, TiCDC concurrently writes transactions to downstream to increase throughout. When a changefeed is interrupted unexpectedly, the downstream may not have the latest data as it is in the upstream. To address inconsistency, run the following command to ensure that the downstream data is consistent with the upstream data.

```
tiup cdc redo apply --storage "s3://redo?access-key=minio&secret-access-key=
    ↪ miniostorage&endpoint=http://172.16.6.123:6060&force-path-style=true"
    ↪  --tmp-dir /tmp/redo --sink-uri "mysql://root:@172.16.6.124:4000"
```

- `--storage`: Location and credential of the redo log in S3
- `--tmp-dir`: Cache directory of the redo log downloaded from S3
- `--sink-uri`: URI of the downstream cluster

8.10.6 Step 6. Recover the primary cluster and its services

After the previous step, the downstream (secondary) cluster has data that is consistent with the upstream (primary) cluster at a specific time. You need to set up new primary and secondary clusters to ensure data reliability.

1. Deploy a new TiDB cluster on Node A as the new primary cluster.

```
tiup --tag upstream playground v5.4.0 --host 0.0.0.0 --db 1 --pd 1 --kv
    ↪  1 --tiflash 0 --ticdc 1
```

2. Use BR to back up and restore data fully from the secondary cluster to the primary cluster.

```
# Back up full data of the secondary cluster
tiup br --pd http://172.16.6.124:2379 backup full --storage ./backup
# Restore full data of the secondary cluster
tiup br --pd http://172.16.6.123:2379 restore full --storage ./backup
```

3. Create a new changefeed to back up data from the primary cluster to the secondary cluster.

```
# Create a changefeed

```

9 Monitor and Alert

9.1 TiDB Monitoring Framework Overview

The TiDB monitoring framework adopts two open source projects: Prometheus and Grafana. TiDB uses Prometheus to store the monitoring and performance metrics and Grafana to visualize these metrics.

9.1.1 About Prometheus in TiDB

As a time series database, Prometheus has a multi-dimensional data model and flexible query language. As one of the most popular open source projects, Prometheus has been adopted by many companies and organizations and has a very active community. PingCAP is one of the active developers and adopters of Prometheus for monitoring and alerting in TiDB, TiKV and PD.

Prometheus consists of multiple components. Currently, TiDB uses the following of them:

- The Prometheus Server to scrape and store time series data
- The client libraries to customize necessary metrics in the application
- An Alertmanager for the alerting mechanism

The diagram is as follows:

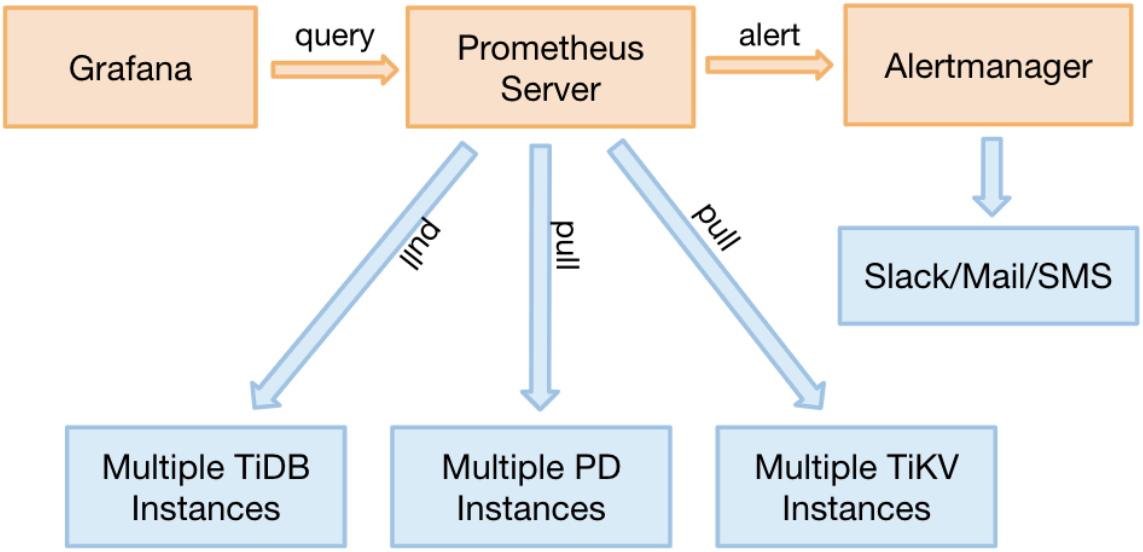

Figure 73: diagram

9.1.2 About Grafana in TiDB

Grafana is an open source project for analyzing and visualizing metrics. TiDB uses Grafana to display the performance metrics as follows:

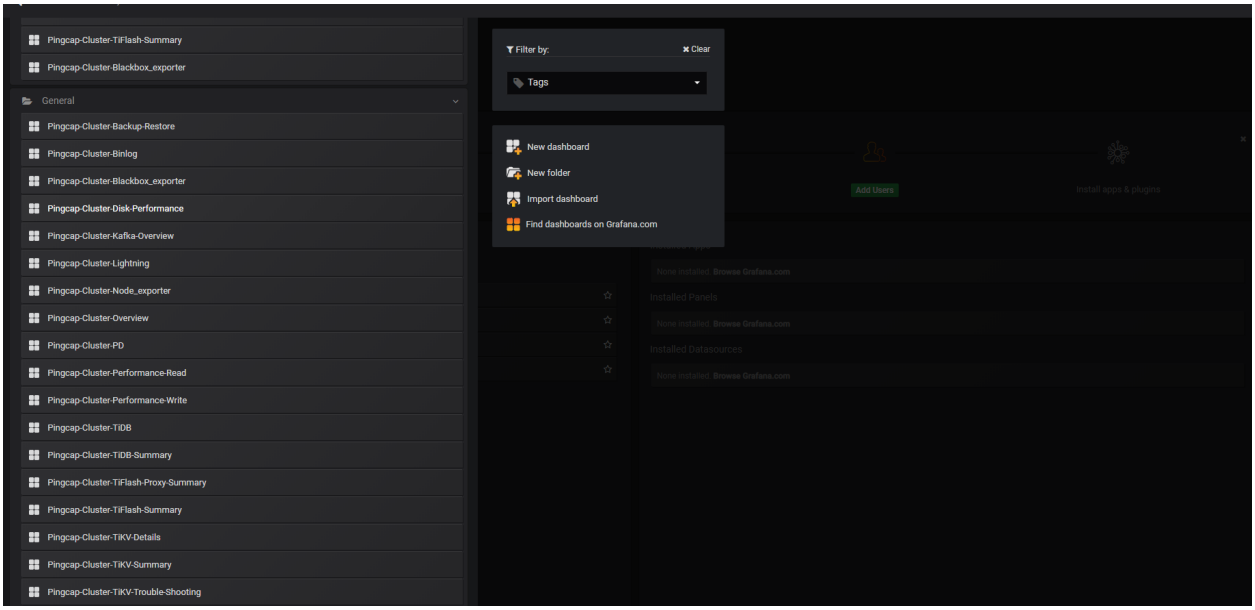

Figure 74: Grafana monitored_groups

- {TiDB_Cluster_name}-Backup-Restore: Monitoring metrics related to backup and restore.
- {TiDB_Cluster_name}-Binlog: Monitoring metrics related to TiDB Binlog.
- {TiDB_Cluster_name}-Blackbox_exporter: Monitoring metrics related to network probe.
- {TiDB_Cluster_name}-Disk-Performance: Monitoring metrics related to disk performance.
- {TiDB_Cluster_name}-Kafka-Overview: Monitoring metrics related to Kafka.
- {TiDB_Cluster_name}-Lightning: Monitoring metrics related to TiDB Lightning.
- {TiDB_Cluster_name}-Node_exporter: Monitoring metrics related to the operating system.
- {TiDB_Cluster_name}-Overview: Monitoring overview related to important components.
- {TiDB_Cluster_name}-PD: Monitoring metrics related to the PD server.
- {TiDB_Cluster_name}-Performance-Read: Monitoring metrics related to read performance.
- {TiDB_Cluster_name}-Performance-Write: Monitoring metrics related to write performance.
- {TiDB_Cluster_name}-TiDB: Detailed monitoring metrics related to the TiDB server.
- {TiDB_Cluster_name}-TiDB-Summary: Monitoring overview related to TiDB.
- {TiDB_Cluster_name}-TiFlash-Proxy-Summary: Monitoring overview of the proxy server that is used to replicate data to TiFlash.
- {TiDB_Cluster_name}-TiFlash-Summary: Monitoring overview related to TiFlash.
- {TiDB_Cluster_name}-TiKV-Details: Detailed monitoring metrics related to the

TiKV server.

- {TiDB_Cluster_name}-TiKV-Summary: Monitoring overview related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Trouble-Shooting: Monitoring metrics related to the TiKV error diagnostics.
- {TiDB_Cluster_name}-TiCDC: Detailed monitoring metrics related to TiCDC.

Each group has multiple panel labels of monitoring metrics, and each panel contains detailed information of multiple monitoring metrics. For example, the **Overview** monitoring group has five panel labels, and each labels corresponds to a monitoring panel. See the following UI:

Figure 75: Grafana Overview

9.2 TiDB Monitoring API

You can use the following types of interfaces to monitor the TiDB cluster status:

- The status interface: this interface uses the HTTP interface to get the component information. Using this interface, you can get the running status of the current TiDB server and the storage information of a table.
- The metrics interface: this interface uses Prometheus to record the detailed information of the various operations in components and views these metrics using Grafana.

9.2.1 Use the status interface

The status interface monitors the basic information of a specific component in the TiDB cluster. It can also act as the monitor interface for Keepalive messages. In addition, the status interface for the Placement Driver (PD) can get the details of the entire TiKV cluster.

9.2.1.1 TiDB server

- TiDB API address: `http://${host}:${port}`
- Default port: `10080`

9.2.1.2 Running status

The following example uses `http://${host}:${port}/status` to get the current status of the TiDB server and to determine whether the server is alive. The result is returned in **JSON** format.

```
curl http://127.0.0.1:10080/status
{
    connections: 0, # The current number of clients connected to the TiDB
        ↪ server.
    version: "5.7.25-TiDB-v3.0.0-beta-250-g778c3f4a5", # The TiDB version
        ↪ number.
    git_hash: "778c3f4a5a716880bcd1d71b257c8165685f0d70" # The Git Hash of
        ↪ the current TiDB code.
}
```

9.2.1.2.1 Storage information

The following example uses `http://${host}:${port}/schema_storage/${db}/${table}` to get the storage information of the specific data table. The result is returned in **JSON** format.

```
curl http://127.0.0.1:10080/schema_storage/mysql/stats_histograms
```

```
{
    "table_schema": "mysql",
    "table_name": "stats_histograms",
    "table_rows": 0,
```

```
    "avg_row_length": 0,
    "data_length": 0,
    "max_data_length": 0,
    "index_length": 0,
    "data_free": 0
}
```

```
curl http://127.0.0.1:10080/schema_storage/test
```

```
[
    {
        "table_schema": "test",
        "table_name": "test",
        "table_rows": 0,
        "avg_row_length": 0,
        "data_length": 0,
        "max_data_length": 0,
        "index_length": 0,
        "data_free": 0
    }
]
```

9.2.1.3 PD server

- PD API address: `http://${host}:${port}/pd/api/v1/${api_name}`
- Default port: 2379
- Details about API names: see PD API doc

The PD interface provides the status of all the TiKV servers and the information about load balancing. See the following example for the information about a single-node TiKV cluster:

```
curl http://127.0.0.1:2379/pd/api/v1/stores
{
  "count": 1, # The number of TiKV nodes.
  "stores": [ # The list of TiKV nodes.
    # The details about the single TiKV node.
    {
      "store": {
        "id": 1,
        "address": "127.0.0.1:20160",
        "version": "3.0.0-beta",
        "state_name": "Up"
      },
```

```
    "status": {
      "capacity": "20 GiB", # The total capacity.
      "available": "16 GiB", # The available capacity.
      "leader_count": 17,
      "leader_weight": 1,
      "leader_score": 17,
      "leader_size": 17,
      "region_count": 17,
      "region_weight": 1,
      "region_score": 17,
      "region_size": 17,
      "start_ts": "2019-03-21T14:09:32+08:00", # The starting timestamp.
      "last_heartbeat_ts": "2019-03-21T14:14:22.961171958+08:00", # The
          ↪ timestamp of the last heartbeat.
      "uptime": "4m50.961171958s"
    }
  }
]
```

9.2.2 Use the metrics interface

The metrics interface monitors the status and performance of the entire TiDB cluster.

- If you use other deployment ways, deploy Prometheus and Grafana before using this interface.

After Prometheus and Grafana are successfully deployed, configure Grafana.

9.3 Deploy Monitoring Services for the TiDB Cluster

This document is intended for users who want to manually deploy TiDB monitoring and alert services.

If you deploy the TiDB cluster using TiUP, the monitoring and alert services are automatically deployed, and no manual deployment is needed.

9.3.1 Deploy Prometheus and Grafana

Assume that the TiDB cluster topology is as follows:

Name	Host IP	Services
Node1	192.168.199.113	PD1, TiDB, node_export, Prometheus, Grafana
Node2	192.168.199.114	PD2, node_export

Name	Host IP	Services
Node3	192.168.199.115	PD3, node_export
Node4	192.168.199.116	TiKV1, node_export
Node5	192.168.199.117	TiKV2, node_export
Node6	192.168.199.118	TiKV3, node_export

9.3.1.1 Step 1: Download the binary package

```
## Downloads the package.
wget https://download.pingcap.org/prometheus-2.27.1.linux-amd64.tar.gz
wget https://download.pingcap.org/node_exporter-v1.3.1-linux-amd64.tar.gz
wget https://download.pingcap.org/grafana-7.5.11.linux-amd64.tar.gz
```

```
## Extracts the package.
tar -xzf prometheus-2.27.1.linux-amd64.tar.gz
tar -xzf node_exporter-v1.3.1-linux-amd64.tar.gz
tar -xzf grafana-7.5.11.linux-amd64.tar.gz
```

9.3.1.2 Step 2: Start node_exporter on Node1, Node2, Node3, and Node4

```
cd node_exporter-v1.3.1-linux-amd64

## Starts the node_exporter service.
$ ./node_exporter --web.listen-address=":9100" \
    --log.level="info" &
```

9.3.1.3 Step 3: Start Prometheus on Node1

Edit the Prometheus configuration file:

```
cd prometheus-2.27.1.linux-amd64 &&
vi prometheus.yml
```

```
...

global:
  scrape_interval:  15s # By default, scrape targets every 15 seconds.
  evaluation_interval: 15s # By default, scrape targets every 15 seconds.
  # scrape_timeout is set to the global default value (10s).
  external_labels:
    cluster: 'test-cluster'
    monitor: "prometheus"

scrape_configs:
```

```
  - job_name: 'overwritten-nodes'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:9100'
      - '192.168.199.114:9100'
      - '192.168.199.115:9100'
      - '192.168.199.116:9100'
      - '192.168.199.117:9100'
      - '192.168.199.118:9100'

  - job_name: 'tidb'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:10080'

  - job_name: 'pd'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:2379'
      - '192.168.199.114:2379'
      - '192.168.199.115:2379'

  - job_name: 'tikv'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.116:20180'
      - '192.168.199.117:20180'
      - '192.168.199.118:20180'

...
```

Start the Prometheus service:

```
$ ./prometheus \
    --config.file="./prometheus.yml" \
    --web.listen-address=":9090" \
    --web.external-url="http://192.168.199.113:9090/" \
    --web.enable-admin-api \
    --log.level="info" \
    --storage.tsdb.path="./data.metrics" \
    --storage.tsdb.retention="15d" &
```

9.3.1.4 Step 4: Start Grafana on Node1

Edit the Grafana configuration file:

```
cd grafana-7.5.11 &&
vi conf/grafana.ini

...

[paths]
data = ./data
logs = ./data/log
plugins = ./data/plugins
[server]
http_port = 3000
domain = 192.168.199.113
[database]
[session]
[analytics]
check_for_updates = true
[security]
admin_user = admin
admin_password = admin
[snapshots]
[users]
[auth.anonymous]
[auth.basic]
[auth.ldap]
[smtp]
[emails]
[log]
mode = file
[log.console]
[log.file]
level = info
format = text
[log.syslog]
[event_publisher]
[dashboards.json]
enabled = false
path = ./data/dashboards
[metrics]
[grafana_net]
url = https://grafana.net

...
```

Start the Grafana service:

```
./bin/grafana-server \
    --config="./conf/grafana.ini" &
```

9.3.2 Configure Grafana

This section describes how to configure Grafana.

9.3.2.1 Step 1: Add a Prometheus data source

1. Log in to the Grafana Web interface.

    - Default address: http://localhost:3000
    - Default account: admin
    - Default password: admin

    Note:
    For the **Change Password** step, you can choose **Skip**.

2. In the Grafana sidebar menu, click **Data Source** within the **Configuration**.
3. Click **Add data source**.
4. Specify the data source information.

    - Specify a **Name** for the data source.
    - For **Type**, select **Prometheus**.
    - For **URL**, specify the Prometheus address.
    - Specify other fields as needed.

5. Click **Add** to save the new data source.

9.3.2.2 Step 2: Import a Grafana dashboard

To import a Grafana dashboard for the PD server, the TiKV server, and the TiDB server, take the following steps respectively:

1. Click the Grafana logo to open the sidebar menu.
2. In the sidebar menu, click **Dashboards** -> **Import** to open the **Import Dashboard** window.

3. Click **Upload .json File** to upload a JSON file (Download TiDB Grafana configuration files from pingcap/tidb, tikv/tikv, and tikv/pd).

> **Note:**
> For the TiKV, PD, and TiDB dashboards, the corresponding JSON files are `tikv_summary.json`, `tikv_details.json`, `tikv_trouble_shooting.json`, `pd.json`, `tidb.json`, and `tidb_summary.json`.

4. Click **Load**.
5. Select a Prometheus data source.
6. Click **Import**. A Prometheus dashboard is imported.

9.3.3 View component metrics

Click **New dashboard** in the top menu and choose the dashboard you want to view.

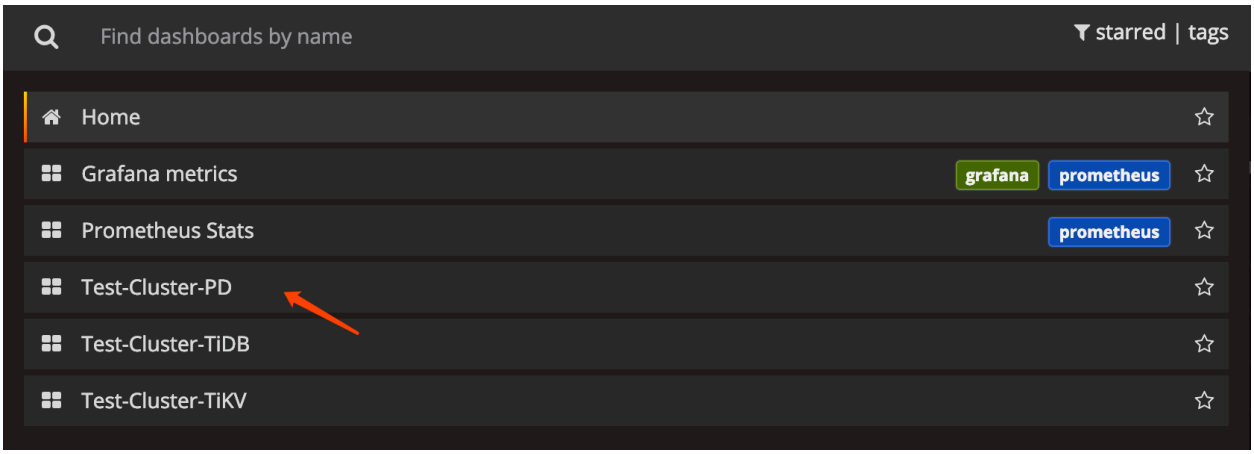

Figure 76: view dashboard

You can get the following metrics for cluster components:

- **TiDB server:**
  - Query processing time to monitor the latency and throughput
  - The DDL process monitoring
  - TiKV client related monitoring
  - PD client related monitoring
- **PD server:**

  - The total number of times that the command executes
  - The total number of times that a certain command fails
  - The duration that a command succeeds
  - The duration that a command fails
  - The duration that a command finishes and returns result

- **TiKV server:**

  - Garbage Collection (GC) monitoring
  - The total number of times that the TiKV command executes
  - The duration that Scheduler executes commands
  - The total number of times of the Raft propose command
  - The duration that Raft executes commands
  - The total number of times that Raft commands fail
  - The total number of times that Raft processes the ready state

Warning:

- Since TiDB v6.0.0, PingCAP no longer maintains MetricsTool. Since v6.1.0, PingCAP no longer maintains the MetricsTool document.
- To export monitoring metrics data, use the PingCAP Clinic diagnostic service to get the information required for diagnosing a TiDB cluster, including the monitoring metrics, logs, cluster topology, configuration, and parameters.

9.4 Export Grafana Snapshots

Metrics data is important in troubleshooting. When you request remote assistance, sometimes the support staff need to view the Grafana dashboards to diagnose problems. MetricsTool can help export snapshots of Grafana dashboards as local files and visualize these snapshots. You can share these snapshots with outsiders and allow them to accurately read out the graphs, without giving out access to other sensitive information on the Grafana server.

9.4.1 Usage

MetricsTool can be accessed from https://metricstool.pingcap.net/. It consists of three sets of tools:

- **Export**: A user script running on the browser's Developer Tool, allowing you to download a snapshot of all visible panels in the current dashboard on any Grafana v6.x.x server.

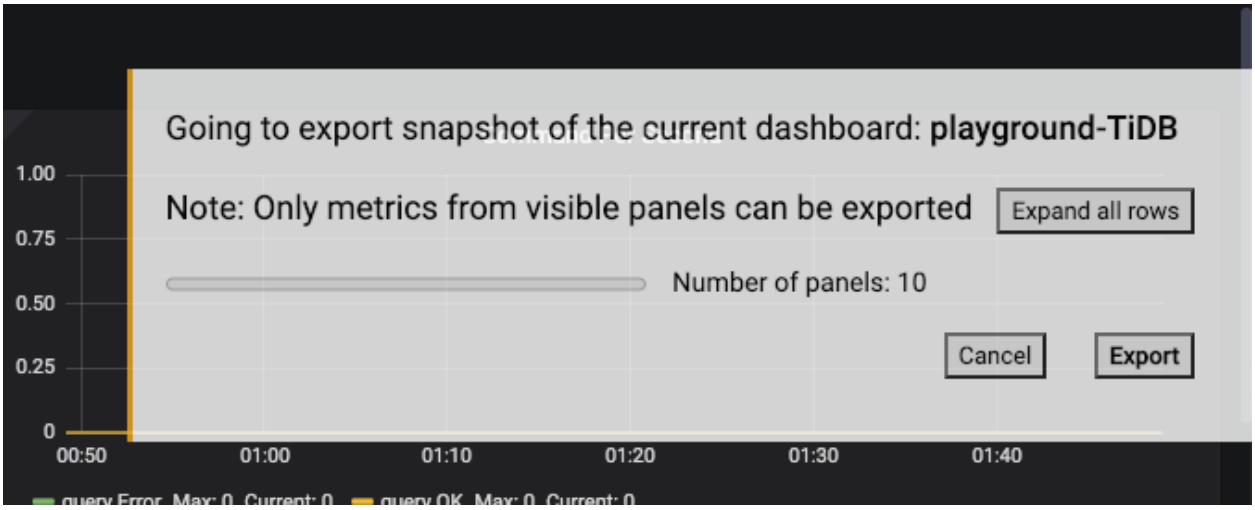

Figure 77: Screenshot of MetricsTool Exporter after running the user script

- **Visualize**: A web page visualizing the exported snapshot files. The visualized snapshots can be operated in the same way as live Grafana dashboards.

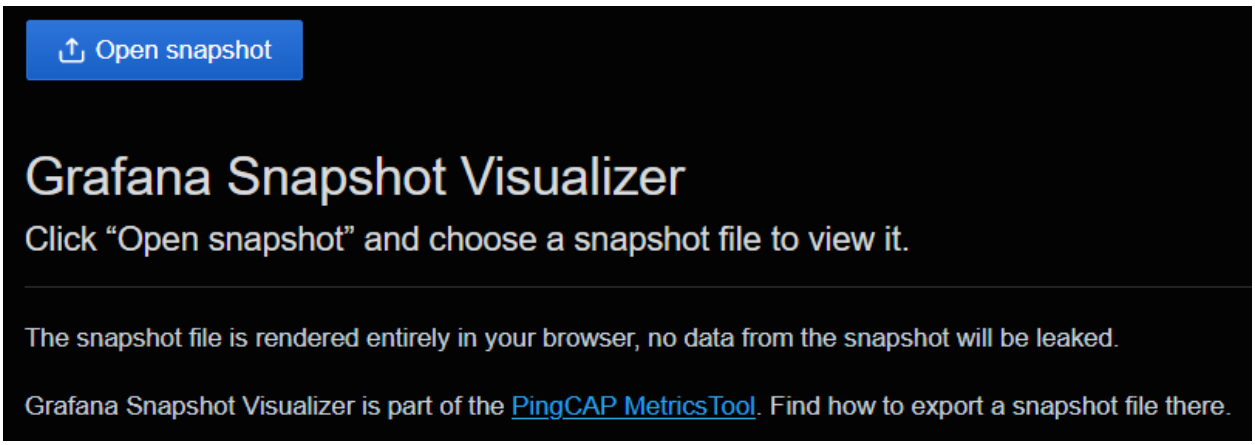

Figure 78: Screenshot of MetricsTool Visualizer

- **Import**: Instructions to import the exported snapshot back into an actual Grafana instance.

9.4.2 FAQs

9.4.2.1 What is the advantage of this tool compared with screenshot or PDF printing?

The snapshot files exported by MetricsTool contain the actual values when they are taken. And the Visualizer allows you to interact with the rendered graphs as if it is a live

Grafana dashboard, supporting operations like toggling series, zooming into a smaller time range, and checking the precise value at a given time. This makes MetricsTool much more powerful than images or PDFs.

9.4.2.2 What are included in the snapshot file?

The snapshot file contains the values of all graphs and panels in the selected time range. It does not save the original metrics from the data sources (and thus you cannot edit the query expression in the Visualizer).

9.4.2.3 Will the Visualizer save the uploaded snapshot files in PingCAP's servers?

No, the Visualizer parses the snapshot files entirely inside your browser. Nothing will be sent to PingCAP. You are free to view snapshot files received from sensitive sources, and no need to worry about these leaking to third parties through the Visualizer.

9.4.2.4 Can it export metrics besides Grafana?

No, we only support Grafana v6.x.x at the moment.

9.4.2.5 Will there be problems to execute the script before all metrics are loaded?

No, the script UI will notify you to wait for all metrics to be loaded. However, you can manually skip waiting and export the snapshot in case of some metrics loading for too long.

9.4.2.6 Can we share a link to a visualized snapshot?

No, but you can share the snapshot file, with instruction on how to use the Visualizer to view it. If you truly need a world-readable URL, you may also try the public `snapshot.raintank.io` service built into Grafana, but make sure all privacy concerns are cleared before doing so.

9.5 TiDB Cluster Alert Rules

This document describes the alert rules for different components in a TiDB cluster, including the rule descriptions and solutions of the alert items in TiDB, TiKV, PD, TiFlash, TiDB Binlog, TiCDC, Node_exporter and Blackbox_exporter.

According to the severity level, alert rules are divided into three categories (from high to low): emergency-level, critical-level, and warning-level. This division of severity levels applies to all alert items of each component below.

Severity level	Description
Emergency-level	The highest severity level at which the service is unavailable. Emergency-level alerts are often caused by a service or node failure. **Manual intervention is required immediately**.

Severity level	Description
Critical-level	Decreased service availability. For the critical-level alerts, a close watch on the abnormal metrics is required.
Warning-level	Warning-level alerts are a reminder for an issue or error.

9.5.1 TiDB alert rules

This section gives the alert rules for the TiDB component.

9.5.1.1 Emergency-level alerts

9.5.1.1.1 `TiDB_schema_error`

- Alert rule:

```
increase(tidb_session_schema_lease_error_total{type="outdated"}[15m])>
↪ 0
```

- Description:

The latest schema information is not reloaded in TiDB within one lease. When TiDB fails to continue providing services, an alert is triggered.

- Solution:

  It is often caused by an unavailable Region or a TiKV timeout. You need to locate the issue by checking the TiKV monitoring items.

9.5.1.1.2 TiDB_tikvclient_region_err_total

- Alert rule:

  `increase(tidb_tikvclient_region_err_total[10m])> 6000`

- Description:

  When TiDB accesses TiKV, a Region error occurs. When the error is reported over 6000 times in 10 minutes, an alert is triggered.

- Solution:

  View the monitoring status of TiKV.

9.5.1.1.3 TiDB_domain_load_schema_total

- Alert rule:

  `increase(tidb_domain_load_schema_total{type="failed"}[10m])> 10`

- Description:

  The total number of failures to reload the latest schema information in TiDB. If the reloading failure occurs over 10 times in 10 minutes, an alert is triggered.

- Solution:

  Same as TiDB_schema_error.

9.5.1.1.4 TiDB_monitor_keep_alive

- Alert rule:

  `increase(tidb_monitor_keep_alive_total[10m])< 100`

- Description:

  Indicates whether the TiDB process still exists. If the number of times for `tidb_monitor_keep_alive_total` increases less than 100 in 10 minutes, the TiDB process might already exit and an alert is triggered.

- Solution:

  - Check whether the TiDB process is out of memory.
  - Check whether the machine has restarted.

9.5.1.2 Critical-level alerts

9.5.1.2.1 TiDB_server_panic_total

- Alert rule:

  `increase(tidb_server_panic_total[10m])> 0`

- Description:

  The number of panicked TiDB threads. When a panic occurs, an alert is triggered. The thread is often recovered, otherwise, TiDB will frequently restart.

- Solution:

  Collect the panic logs to locate the issue.

9.5.1.3 Warning-level alerts

9.5.1.3.1 TiDB_memory_abnormal

- Alert rule:

  `go_memstats_heap_inuse_bytes{job="tidb"} > 1e+10`

- Description:

  The monitoring on the TiDB memory usage. If the usage exceeds 10 G, an alert is triggered.

- Solution:

  Use the HTTP API to troubleshoot the goroutine leak issue.

9.5.1.3.2 TiDB_query_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tidb_server_handle_query_duration_seconds_bucket
  ↪ [1m]))BY (le, instance))> 1
  ```

- Description:

  The latency of handling a request in TiDB. If the ninety-ninth percentile latency exceeds 1 second, an alert is triggered.

- Solution:

  View TiDB logs and search for the `SLOW_QUERY` and `TIME_COP_PROCESS` keywords to locate the slow SQL queries.

9.5.1.3.3 TiDB_server_event_error

- Alert rule:

  ```
  increase(tidb_server_event_total{type=~"server_start|server_hang"}[15m
  ↪ ])> 0
  ```

- Description:

  The number of events that happen in the TiDB service. An alert is triggered when the following events happen:

  1. start: The TiDB service starts.
  2. hang: When a critical-level event (currently there is only one scenario: TiDB cannot write binlog) happens, TiDB enters the `hang` mode and waits to be killed manually.

- Solution:

  - Restart TiDB to recover the service.
  - Check whether the TiDB Binlog service is normal.

9.5.1.3.4 TiDB_tikvclient_backoff_seconds_count

- Alert rule:

  ```
  increase(tidb_tikvclient_backoff_seconds_count[10m])> 10
  ```

- Description:

  The number of retries when TiDB fails to access TiKV. When the retry times is over 10 in 10 minutes, an alert is triggered.

- Solution:

  View the monitoring status of TiKV.

9.5.1.3.5 TiDB_monitor_time_jump_back_error

- Alert rule:

  ```
  increase(tidb_monitor_time_jump_back_total[10m])> 0
  ```

- Description:

  When the time of the machine that holds TiDB rewinds, an alert is triggered.

- Solution:

  Troubleshoot the NTP configurations.

9.5.1.3.6 TiDB_ddl_waiting_jobs

- Alert rule:

  `sum(tidb_ddl_waiting_jobs)> 5`

- Description:

  When the number of DDL tasks pending for execution in TiDB exceeds 5, an alert is triggered.

- Solution:

  Check whether there is any time-consuming `add index` operation that is being executed by running `admin show ddl`.

9.5.2 PD alert rules

This section gives the alert rules for the PD component.

9.5.2.1 Emergency-level alerts

9.5.2.1.1 PD_cluster_down_store_nums

- Alert rule:

  ```
  (sum(pd_cluster_status{type="store_down_count"})by (instance)> 0)and (
  ↪ sum(etcd_server_is_leader)by (instance)> 0)
  ```

- Description:

  PD has not received a TiKV/TiFlash heartbeat for a long time (the default configuration is 30 minutes).

- Solution:

  - Check whether the TiKV/TiFlash process is normal, the network is isolated or the load is too high, and recover the service as much as possible.
  - If the TiKV/TiFlash instance cannot be recovered, you can make it offline.

9.5.2.2 Critical-level alerts

9.5.2.2.1 PD_etcd_write_disk_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_disk_wal_fsync_duration_seconds_bucket
↪ [1m]))by (instance, job, le))> 1
```

- Description:

  If the latency of the fsync operation exceeds 1 second, it indicates that etcd writes data to disk at a lower speed than normal. It might lead to PD leader timeout or failure to store TSO on disk in time, which will shut down the service of the entire cluster.

- Solution:

  - Find the cause of slow writes. It might be other services that overload the system. You can check whether PD itself occupies a large amount of CPU or I/O resources.
  - Try to restart PD or manually transfer leader to another PD to recover the service.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.5.2.2.2 PD_miss_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="miss_peer_region_count"})by (instance)>
↪ 100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  The number of Region replicas is smaller than the value of `max-replicas`.

- Solution:

  - Find the cause of the issue by checking whether there is any TiKV machine that is down or being made offline.
  - Watch the Region health panel and see whether `miss_peer_region_count` is continuously decreasing.

9.5.2.3 Warning-level alerts

9.5.2.3.1 PD_cluster_lost_connect_store_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_disconnected_count"})by (instance)>
↪ 0)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  PD does not receive a TiKV/TiFlash heartbeat within 20 seconds. Normally a TiKV/TiFlash heartbeat comes in every 10 seconds.

- Solution:

  - Check whether the TiKV/TiFlash instance is being restarted.
  - Check whether the TiKV/TiFlash process is normal, the network is isolated, and the load is too high, and recover the service as much as possible.
  - If you confirm that the TiKV/TiFlash instance cannot be recovered, you can make it offline.
  - If you confirm that the TiKV/TiFlash instance can be recovered, but not in the short term, you can consider increasing the value of `max-down-time`. It will prevent the TiKV/TiFlash instance from being considered as irrecoverable and the data from being removed from the TiKV/TiFlash.

9.5.2.3.2 PD_cluster_unhealthy_tikv_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_unhealth_count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  Indicates that there are unhealthy stores. If the situation persists for some time (configured by `max-store-down-time`, defaults to `30m`), the store is likely to change to `Offline` state, which triggers the `PD_cluster_down_store_nums` alert.

- Solution:

  Check the state of the TiKV stores.

9.5.2.3.3 PD_cluster_low_space

- Alert rule:

```
(sum(pd_cluster_status{type="store_low_space_count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  Indicates that there is no sufficient space on the TiKV/TiFlash node.

- Solution:

  - Check whether the space in the cluster is generally insufficient. If so, increase its capacity.

- Check whether there is any issue with Region balance scheduling. If so, it will lead to uneven data distribution.
- Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, and core dump.
- Lower the Region weight of the node to reduce the data volume.
- When it is not possible to release the space, consider proactively making the node offline. This prevents insufficient disk space that leads to downtime.

9.5.2.3.4 PD_etcd_network_peer_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_network_peer_round_trip_time_seconds_bucket
↪ [1m]))by (To, instance, job, le))> 1
```

- Description:

  The network latency between PD nodes is high. It might lead to the leader timeout and TSO disk storage timeout, which impacts the service of the cluster.

- Solution:

  - Check the network and system load status.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.5.2.3.5 PD_tidb_handle_requests_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(pd_client_request_handle_requests_duration_second
↪ {type="tso"}[1m]))by (instance, job, le))> 0.1
```

- Description:

  It takes a longer time for PD to handle the TSO request. It is often caused by a high load.

- Solution:

  - Check the load status of the server.
  - Use pprof to analyze the CPU profile of PD.
  - Manually switch the PD leader.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.5.2.3.6 PD_down_peer_region_nums

- Alert rule:

```
(sum(pd_regions_status{type="down-peer-region-count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  The number of Regions with an unresponsive peer reported by the Raft leader.

- Solution:

  - Check whether there is any TiKV that is down, or that was just restarted, or that is busy.
  - Watch the Region health panel and see whether `down_peer_region_count` is continuously decreasing.
  - Check the network between TiKV servers.

9.5.2.3.7 PD_pending_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="pending-peer-region-count"})by (instance)>
↪  100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  There are too many Regions that have lagged Raft logs. It is normal that scheduling leads to a small number of pending peers, but if the number remains high, there might be an issue.

- Solution:

  - Watch the Region health panel and see whether `pending_peer_region_count` is continuously decreasing.
  - Check the network between TiKV servers, especially whether there is enough bandwidth.

9.5.2.3.8 PD_leader_change

- Alert rule:

```
count(changes(pd_tso_events{type="save"}[10m])> 0)>= 2
```

- Description:

  The PD leader is recently switched.

- Solution:

- Exclude the human factors, such as restarting PD, manually transferring leader, and adjusting leader priority.
- Check the network and system load status.
- If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.5.2.3.9 TiKV_space_used_more_than_80%

- Alert rule:

```
sum(pd_cluster_status{type="storage_size"})/ sum(pd_cluster_status{type
↪ ="storage_capacity"})* 100 > 80
```

- Description:

  Over 80% of the cluster space is occupied.

- Solution:

  - Check whether it is needed to increase capacity.
  - Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, and core dump.

9.5.2.3.10 PD_system_time_slow

- Alert rule:

```
changes(pd_tso_events{type="system_time_slow"}[10m])>= 1
```

- Description:

  The system time rewind might happen.

- Solution:

  Check whether the system time is configured correctly.

9.5.2.3.11 PD_no_store_for_making_replica

- Alert rule:

```
increase(pd_checker_event_count{type="replica_checker", name="no_target_store
↪ "}[1m])> 0
```

- Description:

  There is no appropriate store for additional replicas.

- Solution:

  - Check whether there is enough space in the store.
  - Check whether there is any store for additional replicas according to the label configuration if it is configured.

9.5.2.3.12 PD_cluster_slow_tikv_nums

- Alert rule:

```
sum(pd_cluster_status{type="store_slow_count"})by (instance)> 0)and (
↪ sum(etcd_server_is_leader)by (instance)> 0
```

- Description:

  There is a slow TiKV node. `raftstore.inspect-interval` controls the detection of TiKV slow nodes. For more information, see `raftstore.inspect-interval`.

- Solution:

  - Check whether the performance of the store is proper.
  - Set the `raftstore.inspect-interval` configuration item to a larger value to increase the timeout limit of latency.

9.5.3 TiKV alert rules

This section gives the alert rules for the TiKV component.

9.5.3.1 Emergency-level alerts

9.5.3.1.1 TiKV_memory_used_too_fast

- Alert rule:

```
process_resident_memory_bytes{job=~"tikv",instance=~".*"} - (process_resident_memor
↪ {job=~"tikv",instance=~".*"} offset 5m)> 5*1024*1024*1024
```

- Description:

  Currently, there are no TiKV monitoring items about memory. You can monitor the memory usage of the machines in the cluster by Node_exporter. The above rule indicates that when the memory usage exceeds 5 GB within 5 minutes (the memory is occupied too fast in TiKV), an alert is triggered.

- Solution:

  Adjust the `block-cache-size` value of both `rocksdb.defaultcf` and `rocksdb.` ↪ `writecf`.

9.5.3.1.2 TiKV_GC_can_not_work

- Alert rule:

```
sum(increase(tikv_gcworker_gc_tasks_vec{task="gc"}[1d]))< 1 and (sum(
↪ increase(tikv_gc_compaction_filter_perform[1d]))< 1 and sum(increase
↪ (tikv_engine_event_total{db="kv", cf="write", type="compaction"}[1d
↪ ]))>= 1)
```

- Description:

  GC is not performed successfully on a TiKV instance within 24 hours, which indicates that GC is not working properly. If GC does not run in a short term, it will not cause much trouble; but if GC keeps down, more and more versions are retained, which slows down the query.

- Solution:

  1. Perform `SELECT VARIABLE_VALUE FROM mysql.tidb WHERE VARIABLE_NAME = "tikv_gc_leader_desc"` to locate the `tidb-server` corresponding to the GC leader;
  2. View the log of the `tidb-server`, and grep gc_worker tidb.log;
  3. If you find that the GC worker has been resolving locks (the last log is "start resolve locks") or deleting ranges (the last log is "start delete {number} ranges") during this time, it means the GC process is running normally. Otherwise, get support from PingCAP or the community.

9.5.3.2 Critical-level alerts

9.5.3.2.1 TiKV_server_report_failure_msg_total

- Alert rule:

```
sum(rate(tikv_server_report_failure_msg_total{type="unreachable"}[10m])
↪ )BY (store_id)> 10
```

- Description:

  Indicates that the remote TiKV cannot be connected.

- Solution:

  1. Check whether the network is clear.
  2. Check whether the remote TiKV is down.
  3. If the remote TiKV is not down, check whether the pressure is too high. Refer to the solution in TiKV_channel_full_total.

9.5.3.2.2 TiKV_channel_full_total

- Alert rule:

  `sum(rate(tikv_channel_full_total[10m]))BY (type, instance)> 0`

- Description:

  This issue is often caused by the stuck Raftstore thread and high pressure on TiKV.

- Solution:

  1. Watch the Raft Propose monitor, and see whether the alerted TiKV node has a much higher Raft propose than other TiKV nodes. If so, it means that there are one or more hot spots on this TiKV. You need to check whether the hot spot scheduling can work properly.
  2. Watch the Raft I/O monitor, and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk. One feasible but unsafe solution is setting `sync-log` to `false`.
  3. Watch the Raft Process monitor, and see whether the tick duration is high. If so, you need to add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

9.5.3.2.3 TiKV_write_stall

- Alert rule:

  `delta(tikv_engine_write_stall[10m])> 0`

- Description:

  The write pressure on RocksDB is too high, and a stall occurs.

- Solution:

  1. View the disk monitor, and troubleshoot the disk issues;
  2. Check whether there is any write hot spot on the TiKV;
  3. Set `max-sub-compactions` to a larger value under the `[rocksdb]` and `[raftdb]` configurations.

9.5.3.2.4 TiKV_raft_log_lag

- Alert rule:

  `histogram_quantile(0.99, sum(rate(tikv_raftstore_log_lag_bucket[1m]))by (le, instance))> 5000`

- Description:

  If this value is relatively large, it means Follower has lagged far behind Leader, and Raft cannot be replicated normally. It is possibly because the TiKV machine where Follower is located is stuck or down.

9.5.3.2.5 TiKV_async_request_snapshot_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_duration_second
↪ {type="snapshot"}[1m]))by (le, instance, type))> 1
```

- Description:

  If this value is relatively large, it means the load pressure on Raftstore is too high, and it might be stuck already.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

9.5.3.2.6 TiKV_async_request_write_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_duration_second
↪ {type="write"}[1m]))by (le, instance, type))> 1
```

- Description:

  If this value is relatively large, it means the Raft write takes a long time.

- Solution:

  1. Check the pressure on Raftstore. See the solution in TiKV_channel_full_total.
  2. Check the pressure on the apply worker thread.

9.5.3.2.7 TiKV_coprocessor_request_wait_seconds

- Alert rule:

```
histogram_quantile(0.9999, sum(rate(tikv_coprocessor_request_wait_seconds_bucket
↪ [1m]))by (le, instance, req))> 10
```

- Description:

  If this value is relatively large, it means the pressure on the Coprocessor worker is high. There might be a slow task that makes the Coprocessor thread stuck.

- Solution:

  1. View the slow query log from the TiDB log to see whether the index or full table scan is used in a query, or see whether it is needed to analyze;
  2. Check whether there is a hot spot;

3. View the Coprocessor monitor and see whether `total` and `process` in `coprocessor table/index scan` match. If they differ a lot, it indicates too many invalid queries are performed. You can see whether there is `over seek bound`. If so, there are too many versions that GC does not handle in time. Then you need to increase the number of parallel GC threads.

9.5.3.2.8 TiKV_raftstore_thread_cpu_seconds_total

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"raftstore_.*"}[1m]))by (
↪ instance, name)> 1.6
```

- Description:

  The pressure on the Raftstore thread is too high.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

9.5.3.2.9 TiKV_raft_append_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_append_log_duration_seconds_bucket
↪ [1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of appending Raft log. If it is high, it usually means I/O is too busy.

9.5.3.2.10 TiKV_raft_apply_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_apply_log_duration_seconds_bucket
↪ [1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of applying Raft log. If it is high, it usually means I/O is too busy.

9.5.3.2.11 TiKV_scheduler_latch_wait_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_latch_wait_duration_seconds_bucket
↪ [1m]))by (le, instance, type))> 1
```

- Description:

  The waiting time for the write operations to obtain the memory lock in Scheduler. If it is high, there might be many write conflicts, or that some operations that lead to conflicts take a long time to finish and block other operations that wait for the same lock.

- Solution:

  1. View the scheduler command duration in the Scheduler-All monitor and see which command is most time-consuming;
  2. View the scheduler scan details in the Scheduler-All monitor and see whether `total` and `process` match. If they differ a lot, there are many invalid scans. You can also see whether there is `over seek bound`. If there is too much, it indicates GC does not work in time;
  3. View the storage async snapshot/write duration in the Storage monitor and see whether the Raft operation is performed in time.

9.5.3.2.12 TiKV_thread_apply_worker_cpu_seconds

- Alert rule:

```
max(rate(tikv_thread_cpu_seconds_total{name=~"apply_.*"}[1m]))by (
↪ instance)> 0.9
```

- Description:

  The apply Raft log thread is under great pressure and is approaching or has exceeded its limit. This is often caused by a burst of writes.

9.5.3.3 Warning-level alerts

9.5.3.3.1 TiKV_leader_drops

- Alert rule:

```
delta(tikv_pd_heartbeat_tick_total{type="leader"}[30s])< -10
```

- Description:

  It is often caused by a stuck Raftstore thread.

- Solution:

    1. Refer to TiKV_channel_full_total.
    2. It there is low pressure on TiKV, consider whether the PD scheduling is too frequent. You can view the Operator Create panel on the PD page, and check the types and number of the PD scheduling.

9.5.3.3.2 TiKV_raft_process_ready_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration_secs_bucket
↪ {type='ready'}[1m]))by (le, instance, type))> 2
```

- Description:

    Indicates the time cost of handling Raft ready. If this value is large, it is often caused by the stuck appending log task.

9.5.3.3.3 TiKV_raft_process_tick_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration_secs_bucket
↪ {type='tick'}[1m]))by (le, instance, type))> 2
```

- Description:

    Indicates the time cost of handling Raft tick. If this value is large, it is often caused by too many Regions.

- Solution:

    1. Consider using a higher-level log such as `warn` or `error`.
    2. Add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

9.5.3.3.4 TiKV_scheduler_context_total

- Alert rule:

```
abs(delta( tikv_scheduler_context_total[5m]))> 1000
```

- Description:

    The number of write commands that are being executed by Scheduler. If this value is large, it means the task is not finished timely.

- Solution:

    Refer to TiKV_scheduler_latch_wait_duration_seconds.

9.5.3.3.5 TiKV_scheduler_command_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_command_duration_seconds_bucket
↪ [1m]))by (le, instance, type))> 1
```

- Description:

  Indicates the time cost of executing the Scheduler command.

- Solution:

  Refer to TiKV_scheduler_latch_wait_duration_seconds.

9.5.3.3.6 TiKV_coprocessor_outdated_request_wait_seconds

- Alert rule:

```
delta(tikv_coprocessor_outdated_request_wait_seconds_count[10m])> 0
```

- Description:

  The waiting time of the expired requests by Coprocessor. If this value is large, it means there is high pressure on Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

9.5.3.3.7 TiKV_coprocessor_pending_request

- Alert rule:

```
delta(tikv_coprocessor_pending_request[10m])> 5000
```

- Description:

  The queuing requests of Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

9.5.3.3.8 TiKV_batch_request_snapshot_nums

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"cop_.*"}[1m]))by (instance
↪ )/ (count(tikv_thread_cpu_seconds_total{name=~"cop_.*"})* 0.9)/
↪ count(count(tikv_thread_cpu_seconds_total)by (instance))> 0
```

- Description:

  The Coprocessor CPU usage of a TiKV machine exceeds 90%.

9.5.3.3.9 TiKV_pending_task

- Alert rule:

  ```
  sum(tikv_worker_pending_task_total)BY (instance,name)> 1000
  ```

- Description:

  The number of pending tasks of TiKV.

- Solution:

  Check which kind of tasks has a higher value. You can normally find a solution to the Coprocessor and apply worker tasks from other metrics.

9.5.3.3.10 TiKV_low_space

- Alert rule:

  ```
  sum(tikv_store_size_bytes{type="available"})by (instance)/ sum(tikv_store_size_byte
  ↪ {type="capacity"})by (instance)< 0.2
  ```

- Description:

  The data volume of TiKV exceeds 80% of the configured node capacity or the disk capacity of the machine.

- Solution:

  - Check the balance condition of node space.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.5.3.3.11 TiKV_approximate_region_size

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_raftstore_region_size_bucket[1m
  ↪ ]))by (le))> 1073741824
  ```

- Description:

  The maximum Region approximate size that is scanned by the TiKV split checker is continually larger than 1 GB within one minute.

- Solution:

  The speed of splitting Regions is slower than the write speed. To alleviate this issue, you'd better update TiDB to a version that supports batch-split (>= 2.1.0-rc1). If it is not possible to update temporarily, you can use `pd-ctl operator add split-region <region_id> --policy=approximate` to manually split Regions.

9.5.4 TiFlash alert rules

For the detailed descriptions of TiFlash alert rules, see TiFlash Alert Rules.

9.5.5 TiDB Binlog alert rules

For the detailed descriptions of TiDB Binlog alert rules, see TiDB Binlog monitoring document.

9.5.6 TiCDC Alert rules

For the detailed descriptions of TiCDC alert rules, see TiCDC Alert Rules.

9.5.7 Node_exporter host alert rules

This section gives the alert rules for the Node_exporter host.

9.5.7.1 Emergency-level alerts

9.5.7.1.1 NODE_disk_used_more_than_80%

- Alert rule:

```
node_filesystem_avail_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/boot"}
↪  / node_filesystem_size_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/
↪ boot"} * 100 <= 20
```

- Description:

  The disk space usage of the machine exceeds 80%.

- Solution:

  - Log in to the machine, run the `df -h` command to check the disk space usage.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.5.7.1.2 NODE_disk_inode_more_than_80%

- Alert rule:

```
node_filesystem_files_free{fstype=~"(ext.|xfs)"} / node_filesystem_files
↪ {fstype=~"(ext.|xfs)"} * 100 < 20
```

- Description:

  The inode usage of the filesystem on the machine exceeds 80%.

- Solution:

  - Log in to the machine and run the `df -i` command to view the node usage of the filesystem.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.5.7.1.3 NODE_disk_readonly

- Alert rule:

  ```
  node_filesystem_readonly{fstype=~"(ext.|xfs)"} == 1
  ```

- Description:

  The filesystem is read-only and data cannot be written in it. It is often caused by disk failure or filesystem corruption.

- Solution:

  - Log in to the machine and create a file to test whether it is normal.
  - Check whether the disk LED is normal. If not, replace the disk and repair the filesystem of the machine.

9.5.7.2 Critical-level alerts

9.5.7.2.1 NODE_memory_used_more_than_80%

- Alert rule:

  ```
  (((node_memory_MemTotal_bytes-node_memory_MemFree_bytes-node_memory_Cached_bytes
  ↪ )/(node_memory_MemTotal_bytes)*100))>= 80
  ```

- Description:

  The memory usage of the machine exceeds 80%.

- Solution:

  - View the Memory panel of the host in the Grafana Node Exporter dashboard, and see whether Used memory is too high and Available memory is too low.
  - Log in to the machine and run the `free -m` command to view the memory usage. You can run `top` to check whether there is any abnormal process that has an overly high memory usage.

9.5.7.3 Warning-level alerts

9.5.7.3.1 NODE_node_overload

- Alert rule:

  ```
  (node_load5 / count without (cpu, mode)(node_cpu_seconds_total{mode="
  ↪ system"}))> 1
  ```

- Description:

  The CPU load on the machine is relatively high.

- Solution:

  - View the CPU Usage and Load Average of the host in the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the load average and the CPU usage, and see whether there is any abnormal process that has an overly high CPU usage.

9.5.7.3.2 NODE_cpu_used_more_than_80%

- Alert rule:

  ```
  avg(irate(node_cpu_seconds_total{mode="idle"}[5m]))by(instance)* 100 <=
  ↪ 20
  ```

- Description:

  The CPU usage of the machine exceeds 80%.

- Solution:

  - View the CPU Usage and Load Average of the host on the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the Load Average and the CPU Usage, and see whether there is any abnormal process that has an overly high CPU usage.

9.5.7.3.3 NODE_tcp_estab_num_more_than_50000

- Alert rule:

  ```
  node_netstat_Tcp_CurrEstab > 50000
  ```

- Description:

  There are more than 50,000 TCP links in the "establish" status on the machine.

- Solution:

  - Log in to the machine and run `ss -s` to check the number of TCP links in the "estab" status in the current system.
  - Run `netstat` to check whether there is any abnormal link.

9.5.7.3.4 NODE_disk_read_latency_more_than_32ms

- Alert rule:

```
((rate(node_disk_read_time_seconds_total{device=~".+"}[5m])/ rate(
↪ node_disk_reads_completed_total{device=~".+"}[5m]))or (irate(node_disk_read_time
↪ {device=~".+"}[5m])/ irate(node_disk_reads_completed_total{device
↪ =~".+"}[5m])))* 1000 > 32
```

- Description:

  The read latency of the disk exceeds 32 ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the read latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

9.5.7.3.5 NODE_disk_write_latency_more_than_16ms

- Alert rule:

```
((rate(node_disk_write_time_seconds_total{device=~".+"}[5m])/ rate
↪ (node_disk_writes_completed_total{device=~".+"}[5m]))or (irate(
↪ node_disk_write_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_writes_co
↪ {device=~".+"}[5m])))> 16
```

- Description:

  The write latency of the disk exceeds 16ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the write latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

9.5.8 Blackbox_exporter TCP, ICMP, and HTTP alert rules

This section gives the alert rules for the Blackbox_exporter TCP, ICMP, and HTTP.

9.5.8.1 Emergency-level alerts

9.5.8.1.1 TiDB_server_is_down

- Alert rule:

  `probe_success{group="tidb"} == 0`

- Description:

  Failure to probe the TiDB service port.

- Solution:

  - Check whether the machine that provides the TiDB service is down.
  - Check whether the TiDB process exists.
  - Check whether the network between the monitoring machine and the TiDB machine is normal.

9.5.8.1.2 TiFlash_server_is_down

- Alert rule:

  `probe_success{group="tiflash"} == 0`

- Description:

  Failure to probe the TiFlash service port.

- Solution:

  - Check whether the machine that provides the TiFlash service is down.
  - Check whether the TiFlash process exists.
  - Check whether the network between the monitoring machine and the TiFlash machine is normal.

9.5.8.1.3 Pump_server_is_down

- Alert rule:

  `probe_success{group="pump"} == 0`

- Description:

  Failure to probe the pump service port.

- Solution:

  - Check whether the machine that provides the pump service is down.
  - Check whether the pump process exists.
  - Check whether the network between the monitoring machine and the pump machine is normal.

9.5.8.1.4 Drainer_server_is_down

- Alert rule:

  ```
  probe_success{group="drainer"} == 0
  ```

- Description:

  Failure to probe the Drainer service port.

- Solution:

  - Check whether the machine that provides the Drainer service is down.
  - Check whether the Drainer process exists.
  - Check whether the network between the monitoring machine and the Drainer machine is normal.

9.5.8.1.5 TiKV_server_is_down

- Alert rule:

  ```
  probe_success{group="tikv"} == 0
  ```

- Description:

  Failure to probe the TiKV service port.

- Solution:

  - Check whether the machine that provides the TiKV service is down.
  - Check whether the TiKV process exists.
  - Check whether the network between the monitoring machine and the TiKV machine is normal.

9.5.8.1.6 PD_server_is_down

- Alert rule:

  ```
  probe_success{group="pd"} == 0
  ```

- Description:

  Failure to probe the PD service port.

- Solution:

  - Check whether the machine that provides the PD service is down.
  - Check whether the PD process exists.
  - Check whether the network between the monitoring machine and the PD machine is normal.

9.5.8.1.7 Node_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="node_exporter"} == 0
  ```

- Description:

  Failure to probe the Node_exporter service port.

- Solution:

  - Check whether the machine that provides the Node_exporter service is down.
  - Check whether the Node_exporter process exists.
  - Check whether the network between the monitoring machine and the Node_exporter machine is normal.

9.5.8.1.8 Blackbox_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="blackbox_exporter"} == 0
  ```

- Description:

  Failure to probe the Blackbox_Exporter service port.

- Solution:

  - Check whether the machine that provides the Blackbox_Exporter service is down.
  - Check whether the Blackbox_Exporter process exists.
  - Check whether the network between the monitoring machine and the Blackbox_Exporter machine is normal.

9.5.8.1.9 Grafana_server_is_down

- Alert rule:

  ```
  probe_success{group="grafana"} == 0
  ```

- Description:

  Failure to probe the Grafana service port.

- Solution:

  - Check whether the machine that provides the Grafana service is down.
  - Check whether the Grafana process exists.
  - Check whether the network between the monitoring machine and the Grafana machine is normal.

9.5.8.1.10 Pushgateway_server_is_down

- Alert rule:

  ```
  probe_success{group="pushgateway"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service port.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

9.5.8.1.11 Kafka_exporter_is_down

- Alert rule:

  ```
  probe_success{group="kafka_exporter"} == 0
  ```

- Description:

  Failure to probe the Kafka_Exporter service port.

- Solution:

  - Check whether the machine that provides the Kafka_Exporter service is down.
  - Check whether the Kafka_Exporter process exists.
  - Check whether the network between the monitoring machine and the Kafka_Exporter machine is normal.

9.5.8.1.12 Pushgateway_metrics_interface

- Alert rule:

  ```
  probe_success{job="blackbox_exporter_http"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service http interface.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

9.5.8.2 Warning-level alerts

9.5.8.2.1 BLACKER_ping_latency_more_than_1s

- Alert rule:

  ```
  max_over_time(probe_duration_seconds{job=~"blackbox_exporter.*_icmp"}[1
  ↪ m])> 1
  ```

- Description:

  The ping latency exceeds 1 second.

- Solution:

  - View the ping latency between the two nodes on the Grafana Blackbox Exporter page to check whether it is too high.
  - Check the TCP panel on the Grafana Node Exporter page to check whether there is any packet loss.

9.6 TiFlash Alert Rules

This document introduces the alert rules of the TiFlash cluster.

9.6.1 TiFlash_schema_error

- Alert rule:

  ```
  increase(tiflash_schema_apply_count{type="failed"}[15m])> 0
  ```

- Description:

  When the schema apply error occurs, an alert is triggered.

- Solution:

  The error might be caused by some wrong logic. Get support from PingCAP or the community.

9.6.2 TiFlash_schema_apply_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_schema_apply_duration_seconds_bucket
  ↪ [1m]))BY (le, instance))> 20
  ```

- Description:

  When the probability that the apply duration exceeds 20 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by the internal problems of the TiFlash storage engine. Get support from PingCAP or the community.

9.6.3 `TiFlash_raft_read_index_duration`

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_raft_read_index_duration_seconds_bucket
↪ [1m]))BY (le, instance))> 3
```

- Description:

  When the probability that the read index duration exceeds 3 seconds is over 99%, an alert is triggered.

> **Note:**
>
> `read index` is the kvproto request sent to the TiKV leader. TiKV region retries, busy store, or network problems might lead to long request time of `read index`.

- Solution:

  The frequent retries might be caused by frequent splitting or migration of the TiKV cluster. You can check the TiKV cluster status to identify the retry reason.

9.6.4 `TiFlash_raft_wait_index_duration`

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_raft_wait_index_duration_seconds_bucket
↪ [1m]))BY (le, instance))> 2
```

- Description:

  When the probability that the waiting time for Region Raft Index in TiFlash exceeds 2 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by a communication error between TiKV and the proxy. Get support from PingCAP or the community.

9.7 Customize Configurations of Monitoring Servers

When you deploy a TiDB cluster using TiUP, TiUP also deploys monitoring servers, such as Prometheus, Grafana, and Alertmanager. In the meantime, if you scale out this cluster, TiUP also adds the new nodes into monitoring scope.

To customize the configurations of the monitoring servers mentioned above, you can follow the instructions below to add related configuration items in the topology.yaml of the TiDB cluster.

Note:

- Do not modify the configurations files of the monitoring server directly. Because these modifications will be overwritten by later TiUP operations such as deployment, scaling out, scaling in, and reloading.
- If your monitoring servers are not deployed and managed by TiUP, you can directly modify the configuration files of the monitoring servers instead of referring to this document.
- This feature is supported in TiUP v1.9.0 and above. Therefore, check the TiUP version before using this feature.

9.7.1 Customize Prometheus configurations

Currently, TiUP supports customizing Prometheus rule and scrape configuration files.

9.7.1.1 Customize Prometheus rule configuration

1. Customize the rule configuration file and place it under a directory of the machine where TiUP locates.
2. In the topology.yaml file, set `rule_dir` to the directory of the customized rule configuration file.

   The following is a configuration example of monitoring_servers in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Prometheus
    ↪ Server.
monitoring_servers:
  # # The ip address of the Monitoring Server.
- host: 127.0.0.1
  rule_dir: /home/tidb/prometheus_rule # prometheus rule dir on TiUP
      ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized rule configurations from `rule_dir` (for example, `/home/tidb/prometheus_rule`) and sends them to the Prometheus Server to replace the default rule configuration.

9.7.1.2 Customize Prometheus scrape configuration

1. Open the topology.yaml file of the TiDB cluster.
2. In the `monitoring_servers` configuration, add the `additional_scrape_conf` field.

   The following is a configuration example of monitoring_servers in the topology.yaml file:

```
monitoring_servers:
- host: xxxxxxx
ssh_port: 22
port: 9090
deploy_dir: /tidb-deploy/prometheus-9090
data_dir: /tidb-data/prometheus-9090
log_dir: /tidb-deploy/prometheus-9090/log
external_alertmanagers: []
arch: amd64
os: linux
additional_scrape_conf:
  metric_relabel_configs:
    - source_labels: [__name__]
        separator: ;
        regex: tikv_thread_nonvoluntary_context_switches|
            ↪ tikv_thread_voluntary_context_switches|
            ↪ tikv_threads_io_bytes_total
        action: drop
    - source_labels: [__name__,name]
        separator: ;
        regex: tikv_thread_cpu_seconds_total;(tokio|rocksdb).+
        action: drop
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the `additional_scrape_conf` field to the corresponding parameters of the Prometheus configuration file.

9.7.2 Customize Grafana configurations

Currently, TiUP supports customizing Grafana Dashboard and other configurations.

9.7.2.1 Customize Grafana Dashboard

1. Customize the configuration file of the Grafana Dashboard and place it under a directory of the machine where TiUP locates.

2. In the topology.yaml file, set `dashboard_dir` to the directory of the customized Dashboard configuration file.

   The following is a configuration example of grafana_servers in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
   ↪ Servers.
grafana_servers:
  # # The ip address of the Grafana Server.
 - host: 127.0.0.1
 dashboard_dir: /home/tidb/dashboards # grafana dashboard dir on TiUP
    ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized Dashboard configurations from `dashboard_dir` (for example, `/home/tidb/dashboards`) and sends the configurations to the Grafana Server to replace the default Dashboard configuration.

9.7.2.2 Customize other Grafana configurations

1. Open the topology.yaml file of the TiDB cluster.

2. Add other configuration items in the `grafana_servers` configuration.

   The following is a configuration example of the `[log.file] level` and `smtp` fields in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
   ↪ Servers.
grafana_servers:
# # The ip address of the Grafana Server.
- host: 127.0.0.1
    config:
    log.file.level: warning
    smtp.enabled: true
    smtp.host: {IP}:{port}
    smtp.user: example@pingcap.com
    smtp.password: {password}
    smtp.skip_verify: true
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the `config` field to the Grafana configuration file `grafana.ini`.

9.7.3 Customize Alertmanager configurations

Currently, TiUP supports customizing the listening address of Alertmanager.

Alertmanager deployed by TiUP listens to `alertmanager_servers.host` by default. You cannot access Alertmanager if you use a proxy. To address this issue, you can specify the listening address by adding `listen_host` to the cluster configuration file topology.yaml. The recommended value is 0.0.0.0.

The following example sets the `listen_host` field to 0.0.0.0.

```
alertmanager_servers:
  # # The ip address of the Alertmanager Server.
  - host: 172.16.7.147
    listen_host: 0.0.0.0
    # # SSH port of the server.
    ssh_port: 22
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the `listen_host` field to `--web.listen-address` in Alertmanager startup parameters.

9.8 Monitoring and Alert for Backup and Restore

This document describes the monitoring and alert of the backup and restore feature, including how to deploy monitoring components, monitoring metrics, and common alerts.

9.8.1 Log backup monitoring

Log backup supports using Prometheus to collect monitoring metrics. Currently all monitoring metrics are built into TiKV.

9.8.1.1 Monitoring configuration

- For clusters deployed using TiUP, Prometheus automatically collects monitoring metrics.
- For clusters deployed manually, follow the instructions in TiDB Cluster Monitoring Deployment to add TiKV-related jobs to the `scrape_configs` section of the Prometheus configuration file.

9.8.1.2 Grafana configuration

- For clusters deployed using TiUP, the Grafana dashboard contains the point-in-time recovery (PITR) panel. The **Backup Log** panel in the TiKV-Details dashboard is the PITR panel.

- For clusters deployed manually, refer to Import a Grafana dashboard and upload the tikv_details JSON file to Grafana. Then find the **Backup Log** panel in the TiKV-Details dashboard.

9.8.1.3 Monitoring metrics

Metrics	Type	Description
tikv_log_backup_interval_actor_acting_duration_sec	Histogram	The duration of handling internal messages and events. `message :: TaskType`
tikv_log_backup_initial_scan_reason	Counter	Statistics of the reasons why initial scan is triggered. The main reason is leader transfer or Region version change. `reason :: {"leader-changed", "region-changed", "retry"}`
tikv_log_backup_event_handle_duration_sec	Histogram	The duration of handling KV events. Compared with `tikv_log_backup_on_event_duration_seconds`, this metric also includes the duration of internal conversion. `stage :: {"to_stream_event", "save_to_temp_file"}`
tikv_log_backup_handle_kv_batch	Histogram	Statistics of the sizes of KV pair batches sent by Raftstore.
tikv_log_backup_initial_scan_disk_read	Counter	The size of data read from the disk during initial scan. In Linux, this information is from procfs, which is the size of data actually read from the block device. The configuration item `initial-scan-rate-limit` applies to this metric.
tikv_log_backup_initial_scan_operations	Histogram	The size of KV bytes actually generated during initial scan. Because of compression and read amplification, this value might be different from that of `tikv_log_backup_initial_scan_disk_read`.
tikv_log_backup_skip_kv_count	Counter	The number of Raft events being skipped during the log backup because they are not helpful to the backup.
tikv_log_backup_errors	Counter	The errors that can be retried or ignored during the log backup. `type :: ErrorType`
tikv_log_backup_fatal_errors	Counter	The errors that cannot be retried or ignored during the log backup. When an error of this type occurs, the log backup is paused. `type :: ErrorType`
tikv_log_backup_heap_memory	Gauge	The memory occupied by events that are unconsumed and found by initial scan during log backup.
tikv_log_backup_on_event_duration_seconds	Histogram	The duration of storing KV events to temporary files. `stage :: {"write_to_tempfile", "syscall_write"}`
tikv_log_backup_store_checkpoint_ts	Gauge	The checkpoint ts, which is deprecated. It is close to the GC safepoint registered by the current store. `task :: string`

Metrics	Type	Description
tidb_log_backup_last_checkpoint	Gauge	The global checkpoint TS. It is a time point till which log data has been backed up. `task :: string`
tikv_log_backup_flush_duration_sec	Histogram	The duration of moving local temporary files to the external storage. `stage :: {"generate_metadata", "save_files", "clear_temp_files"}`
tikv_log_backup_flush_file_size	Histogram	The statistics of the sizes of files generated during the backup.
tikv_log_backup_initial_scan_duration_sec	Histogram	The statistics of the overall duration of initial scan.
tikv_log_backup_skip_retry_observe	Counter	Statistics of the errors that can be ignored during log backup, or the reasons why retry is skipped. `reason :: {"region-absent", "not-leader", "stale-command"}`
tikv_log_backup_initial_scan_operations	Counter	Statistics of RocksDB-related operations during initial scan. `cf :: {"default", "write", "lock"}, op :: RocksDBOP`
tikv_log_backup_enabled	Gauge	Whether to enable log backup. If the value is greater than `0`, log backup is enabled.
tikv_log_backup_observed_region	Gauge	The number of Regions being listened to.
tikv_log_backup_task_status	Gauge	The status of the log backup task. `0` means running. `1` means paused. `2` means error. `task :: string`
tikv_log_backup_pending_initial_scan	Gauge	Statistics of pending initial scans. `stage :: {"queuing", "executing"}`

9.8.1.4 Log backup alerts

9.8.1.4.1 Alert configuration

Currently, PITR does not have built-in alert items. This section introduces how to configure alert items in PITR and recommends some items.

To configure alert items in PITR, follow these steps:

1. Create a configuration file (for example, `pitr.rules.yml`) for the alert rules on the node where Prometheus is located. In the file, fill in the alert rules according to the Prometheus documentation, the following recommended alert items, and the configuration sample.
2. In the `rule_files` field of the Prometheus configuration file, add the path of the alert rule file.
3. Send `SIGHUP` signal to the Prometheus process (`kill -HUP pid`) or send an HTTP `POST` request to `http://prometheus-addr/-/reload` (before you send the HTTP request, add the `--web.enable-lifecycle` parameter when starting Prometheus).

The recommended alert items are as follows:

9.8.1.4.2 LogBackupRunningRPOMoreThan10m

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 60 > 10 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 0`
- Alert level: warning
- Description: The log data is not persisted to the storage for more than 10 minutes. This alert item is a reminder. In most cases, it does not affect log backup.

A configuration sample of this alert item is as follows:

```
groups:
- name: PiTR
  rules:
  - alert: LogBackupRunningRPOMoreThan10m
    expr: max(time() - tidb_log_backup_last_checkpoint / 262144000) by (task ) / 60 > 10 and max(tidb_log_backup_last_checkpoint) by (task) > 0  and max(tikv_log_backup_task_status) by (task) == 0
    labels:
      severity: warning
    annotations:
      summary: RPO of log backup is high
      message: RPO of the log backup task {{ $labels.task }} is more than 10 m
```

9.8.1.4.3 LogBackupRunningRPOMoreThan30m

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 60 > 30 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 0`
- Alert level: critical
- Description: The log data is not persisted to the storage for more than 30 minutes. This alert often indicates anomalies. You can check the TiKV logs to find the cause.

9.8.1.4.4 LogBackupPausingMoreThan2h

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 3600 > 2 and max(tidb_log_backup_last_checkpoint)by (task)> 0  and max(tikv_log_backup_task_status)by (task)== 1`
- Alert level: warning
- Description: The log backup task is paused for more than 2 hours. This alert item is a reminder and you are expected to run `br log resume` as soon as possible.

9.8.1.4.5 LogBackupPausingMoreThan12h

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 3600 > 12 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 1`
- Alert level: critical
- Description: The log backup task is paused for more than 12 hours. You are expected to run `br log resume` as soon as possible to resume the task. Log tasks paused for too long have the risk of data loss.

9.8.1.4.6 LogBackupFailed

- Alert item: `max(tikv_log_backup_task_status)by (task)== 2 and max(tidb_log_backup_last_checkpoint)by (task)> 0`
- Alert level: critical
- Description: The log backup task fails. You need to run `br log status` to see the failure reason. If necessary, you need to further check the TiKV logs.

9.8.1.4.7 LogBackupGCSafePointExceedsCheckpoint

- Alert item: `min(tidb_log_backup_last_checkpoint)by (instance)- max(tikv_gcworker_autogc_safe_point)by (instance)< 0`
- Alert level: critical
- Description: Some data has been garbage-collected before the backup. This means that some data has been lost and is very likely to affect your services.

10 Troubleshoot

10.1 Issue Summary

10.1.1 TiDB Troubleshooting Map

This document summarizes common issues in TiDB and other components. You can use this map to diagnose and solve issues when you encounter related problems.

10.1.1.1 1. Service Unavailable

10.1.1.1.1 1.1 The client reports `Region is Unavailable` error

- 1.1.1 The `Region is Unavailable` error is usually because a Region is not available for a period of time. You might encounter `TiKV server is busy`, or the request to TiKV fails due to `not leader` or `epoch not match`, or the request to TiKV time out. In such cases, TiDB performs a `backoff` retry mechanism. When the `backoff` exceeds a threshold (20s by default), the error will be sent to the client. Within the `backoff` threshold, this error is not visible to the client.
- 1.1.2 Multiple TiKV instances are OOM at the same time, which causes no Leader during the OOM period. See case-991 in Chinese.
- 1.1.3 TiKV reports `TiKV server is busy`, and exceeds the `backoff` time. For more details, refer to 4.3. `TiKV server is busy` is a result of the internal flow control mechanism and should not be counted in the `backoff` time. This issue will be fixed.
- 1.1.4 Multiple TiKV instances failed to start, which causes no Leader in a Region. When multiple TiKV instances are deployed in a physical machine, the failure of the physical machine can cause no Leader in a Region if the label is not properly configured. See case-228 in Chinese.
- 1.1.5 When a Follower apply is lagged in a previous epoch, after the Follower becomes a Leader, it rejects the request with `epoch not match`. See case-958 in Chinese (TiKV needs to optimize its mechanism).

10.1.1.1.2 1.2 PD errors cause service unavailable

Refer to 5 PD issues.

10.1.1.2 2. Latency increases significantly

10.1.1.2.1 2.1 Transient increase

- 2.1.1 Wrong TiDB execution plan causes latency increase. Refer to 3.3.
- 2.1.2 PD Leader election issue or OOM. Refer to 5.2 and 5.3.
- 2.1.3 A significant number of Leader drops in some TiKV instances. Refer to 4.4.
- 2.1.4 For other causes, see Troubleshoot Increased Read and Write Latency.

10.1.1.2.2 2.2 Persistent and significant increase

- 2.2.1 TiKV single thread bottleneck
  - Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana -> TiKV-details -> Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue. See case-612 in Chinese.

  - For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana -> TiKV-details -> Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.

- 2.2.2 CPU load increases.
- 2.2.3 TiKV slow write. Refer to 4.5.
- 2.2.4 TiDB wrong execution plan. Refer to 3.3.
- 2.2.5 For other causes, see Troubleshoot Increased Read and Write Latency.

10.1.1.3 3. TiDB issues

10.1.1.3.1 3.1 DDL

- 3.1.1 An error `ERROR 1105 (HY000): unsupported modify decimal column precision` is reported when you modify the length of the `decimal` field. TiDB does not support changing the length of the `decimal` field.
- 3.1.2 TiDB DDL job hangs or executes slowly (use `admin show ddl jobs` to check DDL progress)
  - Cause 1: Network issue with other components (PD/TiKV).
  - Cause 2: Early versions of TiDB (earlier than v3.0.8) have heavy internal load because of a lot of goroutine at high concurrency.
  - Cause 3: In early versions (v2.1.15 & versions < v3.0.0-rc1), PD instances fail to delete TiDB keys, which causes every DDL change to wait for two leases.
  - For other unknown causes, report a bug.
  - Solution:
    * For cause 1, check the network connection between TiDB and TiKV/PD.
    * For cause 2 and 3, the issues are already fixed in later versions. You can upgrade TiDB to a later version.
    * For other causes, you can use the following solution of migrating the DDL owner.
  - DDL owner migration:
    * If you can connect to the TiDB server, execute the owner election command again: `curl -X POST http://{TiDBIP}:10080/ddl/owner/resign`
    * If you cannot connect to the TiDB server, use `tidb-ctl` to delete the DDL owner from the etcd of the PD cluster to trigger re-election: `tidb-ctl etcd delowner [LeaseID] [flags] + ownerKey`

- 3.1.3 TiDB reports `information schema is changed` error in log
  - For the detailed causes and solution, see Why the `Information schema is changed` error is reported.
  - Background: The increased number of `schema version` is consistent with the number of `schema state` of each DDL change operation. For example, the `create table` operation has 1 version change, and the `add column` operation has 4 version changes. Therefore, too many column change operations might cause `schema version` to increase fast. For details, refer to online schema change.
- 3.1.4 TiDB reports `information schema is out of date` in log
  - Cause 1: The TiDB server that is executing the DML statement is stopped by `graceful kill` and prepares to exit. The execution time of the transaction that contains the DML statement exceeds one DDL lease. An error is reported when the transaction is committed.
  - Cause 2: The TiDB server cannot connect to PD or TiKV when it is executing the DML statement. As a result, the TiDB server did not load the new schema within one DDL lease (`45s` by default), or the TiDB server disconnects from PD with the `keep alive` setting.
  - Cause 3: TiKV has high load or network timed out. Check the node loads in **Grafana** -> **TiDB** and **TiKV**.
  - Solution:
    * For cause 1, retry the DML operation when TiDB is started.
    * For cause 2, check the network between the TiDB server and PD/TiKV.
    * For cause 3, investigate why TiKV is busy. Refer to 4 TiKV issues.

10.1.1.3.2 3.2 OOM issues

- 3.2.1 Symptom
  - Client: The client reports the error `ERROR 2013 (HY000): Lost connection to MySQL server during query`.
  - Check the log
    * Execute `dmesg -T | grep tidb-server`. The result shows the OOM-killer log around the time point when the error occurs.
    * Grep the "Welcome to TiDB" log in `tidb.log` around the time point after the error occurs (namely, the time when tidb-server restarts).
    * Grep `fatal error: runtime: out of memory` or `cannot allocate memory` in `tidb_stderr.log`.
    * In v2.1.8 or earlier versions, you can grep `fatal error: stack overflow` in the `tidb_stderr.log`.

  - Monitor: The memory usage of tidb-server instances increases sharply in a short period of time.

- 3.2.2 Locate the SQL statement that causes OOM. (Currently all versions of TiDB cannot locate SQL accurately. You still need to analyze whether OOM is caused by the SQL statement after you locate one.)

  - For versions >= v3.0.0, grep "expensive_query" in `tidb.log`. That log message records SQL queries that timed out or exceed memory quota.
  - For versions < v3.0.0, grep "memory exceeds quota" in `tidb.log` to locate SQL queries that exceed memory quota.

> **Note:**
>
> The default threshold for a single SQL memory usage is `1GB`. You can set this parameter by configuring the system variable `tidb_mem_quota_query`.

- 3.2.3 Mitigate OOM issues

  - By enabling `SWAP`, you can mitigate the OOM issue caused by overuse of memory by large queries. When the memory is insufficient, this method can have impact on the performance of large queries due to the I/O overhead. The degree to which the performance is affected depends on the remaining memory space and the disk I/O speed.

- 3.2.4 Typical reasons for OOM

  - The SQL query has `join`. If you view the SQL statement by using `explain`, you can find that the `join` operation selects the `HashJoin` algorithm and the `inner` table is large.
  - The data volume of a single `UPDATE/DELETE` query is too large. See case-882 in Chinese.
  - The SQL contains multiple sub-queries connected by `Union`. See case-1828 in Chinese.

For more information about troubleshooting OOM, see Troubleshoot TiDB OOM Issues.

10.1.1.3.3 3.3 Wrong execution plan

- 3.3.1 Symptom
  - SQL query execution time is much longer compared with that of previous executions, or the execution plan suddenly changes. If the execution plan is logged in the slow log, you can directly compare the execution plans.
  - SQL query execution time is much longer compared with that of other databases such as MySQL. Compare the execution plan with other databases to see the differences, such as `Join Order`.
  - In slow log, the number of SQL execution time `Scan Keys` is large.
- 3.3.2 Investigate the execution plan
  - `explain analyze {SQL}`. When the execution time is acceptable, compare `count` in the result of `explain analyze` and the number of `row` in `execution info`. If a large difference is found in the `TableScan/IndexScan` row, it is likely that the statistics is incorrect. If a large difference is found in other rows, the problem might not be in the statistics.
  - `select count(*)`. When the execution plan contains a `join` operation, `explain analyze` might take a long time. You can check whether the problem is in the statistics by executing `select count(*)` for the conditions on `TableScan/IndexScan` and comparing the `row count` information in the `explain` result.
- 3.3.3 Mitigation
  - For v3.0 and later versions, use the `SQL Bind` feature to bind the execution plan.
  - Update the statistics. If you are roughly sure that the problem is caused by the statistics, dump the statistics. If the cause is outdated statistics, such as the `modify count/row count` in `show stats_meta` is greater than a certain value (for example, 0.3), or the table has an index of time column, you can try recovering by using `analyze table`. If `auto analyze` is configured, check whether the `tidb_auto_analyze_ratio` system variable is too large (for example, greater than 0.3), and whether the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`.
  - For other situations, report a bug.

10.1.1.3.4 3.4 SQL execution error

- 3.4.1 The client reports the `ERROR 1265(01000)Data Truncated` error. This is because the way TiDB internally calculates the precision of `Decimal` type is incompatible with that of MySQL. This issue has been fixed in v3.0.10 (#14438).

- Cause:

  In MySQL, if two large-precision `Decimal` are divided and the result exceeds the maximum decimal precision (`30`), only `30` digits are reserved and no error is reported;

  In TiDB, the calculation result is the same as in MySQL, but inside the data structure that represents `Decimal`, a field for decimal precision still retains the actual precision.

  Take `(0.1^30)/ 10` as an example. The results in TiDB and MySQL are both `0`, because the precision is `30` at most. However, in TiDB, the field for decimal precision is still `31`.

  After multiple `Decimal` divisions, even though the result is correct, this precision field could grow larger and larger, and eventually exceeds the threshold in TiDB (`72`), and the `Data Truncated` error is reported.

  The multiplication of `Decimal` does not have this issue, because the out-of-bounds is bypassed, and the precision is set to the maximum precision limit.

- Solution: You can bypass this issue by manually adding `Cast(xx as decimal(a , b))`, in which `a` and `b` are the target precisions.

10.1.1.3.5 3.5 Slow query issues

To identify slow queries, see Identify slow queries. To analyze and handle slow queries, see Analyze slow queries.

10.1.1.3.6 3.6 Hotspot issues

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency. For detailed solutions, see Troubleshoot Hotspot Issues.

10.1.1.3.7 3.7 High disk I/O usage

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck. For how to locate and handle the issue of high I/O usage in TiDB, see Troubleshoot High Disk I/O Usage.

10.1.1.3.8 3.8 Lock conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. To learn how to troubleshoot

lock-related issues and how to handle optimistic and pessimistic lock conflicts, see Troubleshoot Lock Conflicts.

10.1.1.3.9 3.9 Inconsistency between data and indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

To learn more about the inconsistency error and how to bypass the check, see Troubleshoot Inconsistency Between Data and Indexes.

10.1.1.4 4. TiKV issues

10.1.1.4.1 4.1 TiKV panics and fails to start

- 4.1.1 `sync-log = false`. The `unexpected raft log index: last_index X < applied_index Y` error is returned after the machine is powered off.

  This issue is expected. You can restore the Region using `tikv-ctl`.

- 4.1.2 If TiKV is deployed on a virtual machine, when the virtual machine is killed or the physical machine is powered off, the `entries[X, Y] is unavailable from storage` error is reported.

  This issue is expected. The `fsync` of virtual machines is not reliable, so you need to restore the Region using `tikv-ctl`.

- 4.1.3 For other unexpected causes, report a bug.

10.1.1.4.2 4.2 TiKV OOM

- 4.2.1 If the `block-cache` configuration is too large, it might cause OOM.

  To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**.

  Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"` parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- 4.2.2 Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM.

  To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana -> TiKV-details -> coprocessor overview**.

- 4.2.3 Other components occupy too much memory.

  This issue is unexpected. You can report a bug.

10.1.1.4.3 4.3 The client reports the `server is busy` error

Check the specific cause for busy by viewing the monitor **Grafana -> TiKV -> errors**. `server is busy` is caused by the flow control mechanism of TiKV, which informs `tidb/tikv-client` that TiKV is currently under too much pressure and will retry later.

- 4.3.1 TiKV RocksDB encounters `write stall`.

  A TiKV instance has two RocksDB instances, one in `data/raft` to save the Raft log, another in `data/db` to save the real data. You can check the specific cause for stall by running `grep "Stalling" RocksDB` in the log. The RocksDB log is a file starting with `LOG`, and `LOG` is the current log.

  - Too many `level0 sst` causes stall. You can add the `[rocksdb] max-sub-compactions = 2` (or 3) parameter to speed up `level0 sst` compaction. The compaction task from level0 to level1 is divided into several subtasks (the max number of subtasks is the value of `max-sub-compactions`) to be executed concurrently. See case-815 in Chinese.
  - Too many `pending compaction bytes` causes stall. The disk I/O fails to keep up with the write operations in business peaks. You can mitigate this problem by increasing the `soft-pending-compaction-bytes-limit` and `hard-pending-compaction-bytes-limit` of the corresponding CF.
    * The default value of `[rocksdb.defaultcf] soft-pending-compaction-bytes-limit` is `64GB`. If the pending compaction bytes reaches the threshold, RocksDB slows down the write speed. You can set `[rocksdb.defaultcf] soft-pending-compaction-bytes-limit` to `128GB`.
    * The default value of `hard-pending-compaction-bytes-limit` is `256GB`. If the pending compaction bytes reaches the threshold (this is not likely to happen, because RocksDB slows down the write after the pending compaction bytes reaches `soft-pending-compaction-bytes-limit`), RocksDB stops the write operation. You can set `hard-pending-compaction-bytes-limit` to `512GB`.
    * If the disk I/O capacity fails to keep up with the write for a long time, it is recommended to scale up your disk. If the disk throughput reaches the

upper limit and causes write stall (for example, the SATA SSD is much lower than NVME SSD), while the CPU resources is sufficient, you may apply a compression algorithm of higher compression ratio. This way, the CPU resources is traded for disk resources, and the pressure on the disk is eased.

* If the default CF compaction sees a high pressure, change the `[rocksdb.defaultcf] compression-per-level` parameter from `["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

– Too many memtables causes stall. This usually occurs when the amount of instant writes is large and the memtables flush to the disk slowly. If the disk write speed cannot be improved, and this issue only occurs during business peaks, you can mitigate it by increasing the `max-write-buffer-number` of the corresponding CF.

* For example, set `[rocksdb.defaultcf] max-write-buffer-number` to `8` (`5` by default). Note that this might cause more memory usage in the peak, because more memtables might be in the memory.

- 4.3.2 `scheduler too busy`

  – Serious write conflict. `latch wait duration` is high. You can view `latch wait duration` in the monitor **Grafana -> TiKV-details -> scheduler prewrite/scheduler commit**. When the write tasks pile up in the scheduler, the pending write tasks exceed the threshold set in `[storage] scheduler-pending-write-threshold` (100MB). You can verify the cause by viewing the metric corresponding to `MVCC_CONFLICT_COUNTER`.

  – Slow write causes write tasks to pile up. The data being written to TiKV exceeds the threshold set by `[storage] scheduler-pending-write-threshold` (100MB). Refer to 4.5.

- 4.3.3 `raftstore is busy`. The processing of messages is slower than the receiving of messages. The short-term `channel full` status does not affect the service, but if the error persists for a long time, it might cause Leader switch.

  – `append log` encounters stall. Refer to 4.3.1.
  – `append log duration` is high, which causes slow processing of messages. You can refer to 4.5 to analyze why `append log duration` is high.
  – raftstore receives a large batch of messages in an instant (check in the TiKV Raft messages dashboard), and fails to process them. Usually the short-term `channel full` status does not affect the service.

- 4.3.4 TiKV coprocessor is in a queue. The number of piled up tasks exceeds `coprocessor threads * readpool.coprocessor.max-tasks-per-worker-[normal|low|high]`. Too many large queries leads to the tasks piling up in coprocessor. You need to check whether a execution plan change causes a large number of table scan operations. Refer to 3.3.

10.1.1.4.4 4.4 Some TiKV nodes drop Leader frequently

- 4.4.1 Re-election because TiKV is restarted
  - After TiKV panics, it is pulled up by systemd and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
  - TiKV is stopped or killed by a third party and then pulled up by systemd. Check the cause by viewing `dmesg` and the TiKV log.
  - TiKV is OOM, which causes restart. Refer to 4.2.
  - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage). See case case-500 in Chinese.
- 4.4.2 TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`. Refer to 4.3.1.
- 4.4.3 Re-election because of network isolation.

10.1.1.4.5 4.5 TiKV write is slow

- 4.5.1 Check whether the TiKV write is low by viewing the `prewrite/commit/raw-put` duration of TiKV gRPC (only for RawKV clusters). Generally, you can locate the slow phase according to the performance-map. Some common situations are listed as follows.
- 4.5.2 The scheduler CPU is busy (only for transaction kv).

  The `scheduler command duration` of prewrite/commit is longer than the sum of `scheduler latch wait duration` and `storage async write duration`. The scheduler worker has a high CPU demand, such as over 80% of `scheduler-worker-pool-size` * 100%, or the CPU resources of the entire machine are relatively limited. If the write workload is large, check if `[storage] scheduler-worker-pool-size` is set too small.

  For other situations, report a bug.
- 4.5.3 Append log is slow.

  The **Raft IO**/`append log duration` in TiKV Grafana is high, usually because the disk write operation is slow. You can verify the cause by checking the `WAL Sync Duration max` value of RocksDB - raft.

  For other situations, report a bug.
- 4.5.4 The raftstore thread is busy.

  The **Raft Propose**/`propose wait duration` is significantly larger than the append log duration in TiKV Grafana. Take the following methods:

  - Check whether the `[raftstore] store-pool-size` configuration value is too small. It is recommended to set the value between `1` and `5` and not too large.
  - Check whether the CPU resources on the machine are insufficient.

- 4.5.5 Apply is slow.

  The **Raft IO**/`apply log duration` in TiKV Grafana is high, which usually comes with a high **Raft Propose**/`apply wait duration`. The possible causes are as follows:

  - `[raftstore] apply-pool-size` is too small (it is recommended to set the value between `1` and `5` and not too large), and the **Thread CPU**/`apply CPU` is large.
  - The CPU resources on the machine are insufficient.
  - Region write hot spot. A single apply thread has high CPU usage. Currently, we cannot properly address the hot spot problem on a single Region, which is being improved. To view the CPU usage of each thread, modify the Grafana expression and add `by (instance, name)`.
  - RocksDB write is slow. **RocksDB kv**/`max write duration` is high. A single Raft log might contain multiple KVs. When writing into RocksDB, 128 KVs are written into RocksDB in a write batch. Therefore, an apply log might be associated with multiple writes in RocksDB.
  - For other situations, report a bug.

- 4.5.6 Raft commit log is slow.

  The **Raft IO**/`commit log duration` in TiKV Grafana is high (this metric is only supported in Grafana after v4.x). Every Region corresponds to an independent Raft group. Raft has a flow control mechanism, similar to the sliding window mechanism of TCP. You can control the size of the sliding window by configuring the `[raftstore]` ↪ `raft-max-inflight-msgs = 256` parameter. If there is a write hot spot and the `commit log duration` is high, you can adjust the parameter, such as increasing it to `1024`.

- 4.5.7 For other situations, refer to the write path on performance-map and analyze the cause.

10.1.1.5 5. PD issues

10.1.1.5.1 5.1 PD scheduling

- 5.1.1 Merge

  - Empty Regions across tables cannot be merged. You need to modify the `[` ↪ `coprocessor] split-region-on-table` parameter in TiKV, which is set to `false` in v4.x by default. See case-896 in Chinese.

  - Region merge is slow. You can check whether the merged operator is generated by accessing the monitor dashboard in **Grafana** -> **PD** -> **operator**. To accelerate the merge, increase the value of `merge-schedule-limit`.

- 5.1.2 Add replicas or take replicas online/offline

  - The TiKV disk uses 80% of the capacity, and PD does not add replicas. In this situation, the number of miss peers increases, so TiKV needs to be scaled out. See case-801 in Chinese.
  - When a TiKV node is taken offline, some Region cannot be migrated to other nodes. This issue has been fixed in v3.0.4 (#5526). See case-870 in Chinese.

- 5.1.3 Balance

  - The Leader/Region count is not evenly distributed. See case-394 and case-759 in Chinese. The major cause is that the balance performs scheduling based on the size of Region/Leader, so this might result in the uneven distribution of the count. In TiDB 4.0, the `[leader-schedule-policy]` parameter is introduced, which enables you to set the scheduling policy of Leader to be `count`-based or `size`-based.

10.1.1.5.2 5.2 PD election

- 5.2.1 PD switches Leader.

  - Cause 1: Disk. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana** -> **disk performance** -> **latency/load**. You can also use the FIO tool to run a check on the disk if necessary. See case-292 in Chinese.
  - Cause 2: Network. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana** -> **PD** -> **etcd**. See case-177 in Chinese.
  - Cause 3: High system load. The log shows `server is likely overloaded`. See case-214 in Chinese.

- 5.2.2 PD cannot elect a Leader or the election is slow.

  - PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19. See case-875 in Chinese.

  - The election is slow: The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region -storage` to `true`, which significantly reduce the Region loading duration. See case-429 in Chinese.

- 5.2.3 PD timed out when TiDB executes SQL statements.

  - PD doesn't have a Leader or switches Leader. Refer to 5.2.1 and 5.2.2.
  - Network issue. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana -> blackbox_exporter -> ping latency**.
  - PD panics. Report a bug.
  - PD is OOM. Refer to 5.3.
  - If the issue has other causes, get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

- 5.2.4 Other issues

  - PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040). For details, see case-947 in Chinese.
  - For other situations, report a bug.

10.1.1.5.3 5.3 PD OOM

- 5.3.1 When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- 5.3.2 PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that TCP InSegs is relatively large. This issue has been fixed in v3.0.6 (#1952).

10.1.1.5.4 5.4 Grafana display

- 5.4.1 The monitor in **Grafana -> PD -> cluster -> role** displays follower. The Grafana expression issue has been fixed in v3.0.8.

10.1.1.6 6. Ecosystem tools

10.1.1.6.1 6.1 TiDB Binlog

- 6.1.1 TiDB Binlog is a tool that collects changes from TiDB and provides backup and replication to downstream TiDB or MySQL platforms. For details, see TiDB Binlog on GitHub.
- 6.1.2 The `Update Time` in Pump/Drainer Status is updated normally, and no anomaly shows in the log, but no data is written to the downstream.
  - Binlog is not enabled in the TiDB configuration. Modify the `[binlog]` configuration in TiDB.
- 6.1.3 `sarama` in Drainer reports the `EOF` error.
  - The Kafka client version in Drainer is inconsistent with the version of Kafka. You need to modify the `[syncer.to] kafka-version` configuration.
- 6.1.4 Drainer fails to write to Kafka and panics, and Kafka reports the `Message was too large` error.
  - The binlog data is too large, so the single message written to Kafka is too large. You need to modify the following configuration of Kafka:

    ```
    message.max.bytes=1073741824
    replica.fetch.max.bytes=1073741824
    fetch.message.max.bytes=1073741824
    ```

    For details, see case-789 in Chinese.
- 6.1.5 Inconsistent data in upstream and downstream
  - Some TiDB nodes do not enable binlog. For v3.0.6 or later versions, you can check the binlog status of all the nodes by accessing the http://127.0.0.1:10080/info/all interface. For versions earlier than v3.0.6, you can check the binlog status by viewing the configuration file.
  - Some TiDB nodes go into the `ignore binlog` status. For v3.0.6 or later versions, you can check the binlog status of all the nodes by accessing the http://127.0.0.1:10080/info/all interface. For versions earlier than v3.0.6, check the TiDB log to see whether it contains the `ignore binlog` keyword.
  - The value of the timestamp column is inconsistent in upstream and downstream.
    * This is caused by different time zones. You need to ensure that Drainer is in the same time zone as the upstream and downstream databases. Drainer obtains its time zone from `/etc/localtime` and does not support the `TZ` environment variable. See case-826 in Chinese.

    * In TiDB, the default value of timestamp is `null`, but the same default value in MySQL 5.7 (not including MySQL 8) is the current time. Therefore, when the timestamp in upstream TiDB is `null` and the downstream is MySQL 5.7, the data in the timestamp column is inconsistent. You need to run `set @@global.explicit_defaults_for_timestamp=on;` in the upstream before enabling binlog.
  - For other situations, report a bug.

- 6.1.6 Slow replication

  - The downstream is TiDB/MySQL, and the upstream performs frequent DDL operations. See case-1023 in Chinese.
  - The downstream is TiDB/MySQL, and the table to be replicated has no primary key and no unique index, which causes reduced performance in binlog. It is recommended to add the primary key or unique index.
  - If the downstream outputs to files, check whether the output disk or network disk is slow.
  - For other situations, report a bug.

- 6.1.7 Pump cannot write binlog and reports the `no space left on device` error.

  - The local disk space is insufficient for Pump to write binlog data normally. You need to clean up the disk space and then restart Pump.

- 6.1.8 Pump reports the `fail to notify all living drainer` error when it is started.

  - Cause: When Pump is started, it notifies all Drainer nodes that are in the `online` state. If it fails to notify Drainer, this error log is printed.
  - Solution: Use the binlogctl tool to check whether each Drainer node is normal or not. This is to ensure that all Drainer nodes in the `online` state are working normally. If the state of a Drainer node is not consistent with its actual working status, use the binlogctl tool to change its state and then restart Pump. See the case fail-to-notify-all-living-drainer.

- 6.1.9 Drainer reports the `gen update sqls failed: table xxx: row data is corruption []` error.

  - Trigger: The upstream performs DML operations on this table while performing `DROP COLUMN` DDL. This issue has been fixed in v3.0.6. See case-820 in Chinese.

- 6.1.10 Drainer replication is hung. The process remains active but the checkpoint is not updated.

  - This issues has been fixed in v3.0.4. See case-741 in Chinese.

- 6.1.11 Any component panics.
  - Report a bug.

10.1.1.6.2 6.2 Data Migration

- 6.2.1 TiDB Data Migration (DM) is a migration tool that supports data migration from MySQL/MariaDB into TiDB. For details, see DM on GitHub.
- 6.2.2 `Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you run `query status` or check the log.
  - The database related passwords in all the DM configuration files should be encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt the password. Cleartext passwords can be used since v1.0.6.
  - During DM operation, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data replication task.
  - To deploy different versions of DM-worker/DM-master/dmctl in a DM cluster, see the case study on AskTUG in Chinese.
- 6.2.3 A replication task is interrupted with the `driver: bad connection` error returned.
  - The `driver: bad connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure and TiDB restart), and that the data of the current request has not yet been sent to TiDB.
    * For versions earlier than DM 1.0.0 GA, stop the task by running `stop-task` and then restart the task by running `start-task`.
    * For DM 1.0.0 GA or later versions, an automatic retry mechanism for this type of error is added. See #265.
- 6.2.4 A replication task is interrupted with the `invalid connection` error.
  - The `invalid connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy), and that a part of the data for the current request has been sent to TiDB. Because DM has the feature of concurrently replicating data to the downstream in replication tasks, several errors might occur when a task is interrupted. You can check these errors by running `query-status` or `query-error`.
    * If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.

    * If DM does not retry or fails to retry automatically because of version problems (automatic retry is introduced in v1.0.0-rc.1), use `stop-task` to stop the task and then use `start-task` to restart the task.

- 6.2.5 The relay unit reports the error `event from * in * diff from passed-in event *`, or a replication task is interrupted with an error that fails to get or parse binlog, such as `get binlog error ERROR 1236 (HY000)and binlog checksum mismatch, data may be corrupted returned`

  – During the process that DM pulls relay log or the incremental replication, this two errors might occur if the size of the upstream binlog file exceeds 4 GB.

  – Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the binlog file size, and store the replicated binlog positions as checkpoints. However, the official MySQL uses uint32 to store binlog positions, which means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

  – Solution:

    * For relay processing units, manually recover replication.
    * For binlog replication processing units, manually recover replication.

- 6.2.6 The DM replication is interrupted, and the log returns `ERROR 1236 (HY000) The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION = 1, but the master has purged binary logs containing GTIDs that the slave requires.`

  – Check whether the master binlog is purged.

  – Check the position information recorded in `relay.meta`.

    * `relay.meta` has recorded the empty GTID information. DM-worker saves the GTID information in memory to `relay.meta` when it exits or in every 30s. When DM-worker does not obtain the upstream GTID information, it saves the empty GTID information to `relay.meta`. See case-772 in Chinese.
    * The binlog event recorded in `relay.meta` triggers the incomplete recover process and records the wrong GTID information. This issue is fixed in v1.0.2, and might occur in earlier versions.

- 6.2.7 The DM replication process returns an error `Error 1366: incorrect utf8 value eda0bdedb29d(\ufffd\ufffd\ufffd\ufffd\ufffd\ufffd)`.

  – This value cannot be successfully written into MySQL 8.0 or TiDB, but can be written into MySQL 5.7. You can skip the data format check by enabling the `tidb_skip_utf8_check` parameter.

10.1.1.6.3 6.3 TiDB Lightning

- 6.3.1 TiDB Lightning is a tool for fast full import of large amounts of data into a TiDB cluster. See TiDB Lightning on GitHub.
- 6.3.2 Import speed is too slow.
  - `region-concurrency` is set too high, which causes thread contention and reduces performance. Three ways to troubleshoot:
    * The setting can be found from the start of the log by searching `region-concurrency`.
    * If TiDB Lightning shares a server with other services (for example, Importer), you must manually set `region-concurrency` to 75% of the total number of CPU cores on that server.
    * If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning might not be able to read this out. In this case, `region-concurrency` must also be manually reduced.
  - Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Mydumper output. If the indices are negligible, you may first remove them from the schema, and add them back via `CREATE INDEX` after the import is complete.
  - The version of TiDB Lightning is old. Try the latest version, which might improve the import speed.
- 6.3.3 `checksum failed: checksum mismatched remote vs local`.
  - Cause 1: The table might already have data. These old data can affect the final checksum.
  - Cause 2: If the checksum of the target database is 0, which means nothing is imported, it is possible that the cluster is too hot and fails to take in any data.
  - Cause 3: If the data source is generated by the machine and not backed up by Mydumper, ensure it respects the constrains of the table. For example:
    * `AUTO_INCREMENT` columns need to be positive, and do not contain the value "0".
    * UNIQUE and PRIMARY KEYs must not have duplicate entries.
  - Solution: See Troubleshooting Solution.
- 6.3.4 `Checkpoint for ⋯ has invalid status:(error code)`
  - Cause: Checkpoint is enabled, and Lightning/Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed. The error code is an integer less than 25, with possible

values as `0, 3, 6, 9, 12, 14, 15, 17, 18, 20 and 21`. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later the exit occurs.

- Solution: See Troubleshooting Solution.

- 6.3.5 `ResourceTemporarilyUnavailable("Too many open engines …: 8")`

  - Cause: The number of concurrent engine files exceeds the limit specified by tikv-importer. This could be caused by misconfiguration. In addition, even when the configuration is correct, if tidb-lightning has exited abnormally before, an engine file might be left at a dangling open state, which could cause this error as well.
  - Solution: See Troubleshooting Solution.

- 6.3.6 `cannot guess encoding for input file, please convert to UTF-8 manually`

  - Cause: TiDB Lightning only supports the UTF-8 and GB-18030 encodings. This error means the file is not in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical ALTER TABLE executions.
  - Solution: See Troubleshooting Solution.

- 6.3.7 `[sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 0 45 0 0}'`

  - Cause: A timestamp type entry has a time value that does not exist. This is either because of DST changes or because the time value has exceeded the supported range (from Jan 1, 1970 to Jan 19, 2038).
  - Solution: See Troubleshooting Solution.

10.1.1.7 7. Common log analysis

10.1.1.7.1 7.1 TiDB

- 7.1.1 `GC life time is shorter than transaction duration`.

  The transaction duration exceeds the GC lifetime (10 minutes by default).

  You can increase the GC lifetime by modifying the `tidb_gc_life_time` system variable. Generally, it is not recommended to modify this parameter, because changing it might cause many old versions to pile up if this transaction has a large number of `UPDATE` and `DELETE` statements.

- 7.1.2 `txn takes too much time`.

  This error is returned when you commit a transaction that has not been committed for a long time (over 590 seconds).

  If your application needs to execute a transaction of such a long time, you can increase the `[tikv-client] max-txn-time-use = 590` parameter and the GC lifetime to avoid this issue. It is recommended to check whether your application needs such a long transaction time.

- 7.1.3 `coprocessor.go` reports `request outdated`.

  This error is returned when the coprocessor request sent to TiKV waits in a queue at TiKV for over 60 seconds.

  You need to investigate why the TiKV coprocessor is in a long queue.

- 7.1.4 `region_cache.go` reports a large number of `switch region peer to next due to send request fail`, and the error message is `context deadline exceeded`.

  The request for TiKV timed out and triggers the region cache to switch the request to other nodes. You can continue to run the `grep "<addr> cancelled` command on the `addr` field in the log and take the following steps according to the `grep` results:

  - `send request is cancelled`: The request timed out during the sending phase. You can investigate the monitoring **Grafana** -> **TiDB** -> **Batch Client**/`Pending Request Count by TiKV` and see whether the Pending Request Count is greater than 128:
    * If the value is greater than 128, the sending goes beyond the processing capacity of KV, so the sending piles up.
    * If the value is not greater than 128, check the log to see if the report is caused by the operation and maintenance changes of the corresponding KV; otherwise, this error is unexpected, and you need to report a bug.
  - `wait response is cancelled`: The request timed out after it is sent to TiKV. You need to check the response time of the corresponding TiKV address and the Region logs in PD and KV at that time.

- 7.1.5 `distsql.go` reports `inconsistent index`.

  The data index seems to be inconsistent. Run the `admin check table <TableName>` command on the table where the reported index is. If the check fails, disable garbage collection by running the following command, and report a bug:

```
SET GLOBAL tidb_gc_enable = 0;
```

10.1.1.7.2 7.2 TiKV

- 7.2.1 `key is locked`.

  The read and write have conflict. The read request encounters data that has not been committed and needs to wait until the data is committed.

  A small number of this error has no impact on the business, but a large number of this error indicates that the read-write conflict is severe in your business.

- 7.2.2 `write conflict`.

  This is the write-write conflict in optimistic transactions. If multiple transactions modify the same key, only one transaction succeed and other transactions automatically obtain the timestamp again and retry the operation, with no impact on the business.

  If the conflict is severe, it might cause transaction failure after multiple retries. In this case, it is recommended to use the pessimistic lock. For more details about the error and the solution, see Troubleshoot Write Conflicts in Optimistic Transactions.

- 7.2.3 `TxnLockNotFound`.

  This transaction commit is too slow, causing it to be rolled back by other transactions after Time To Live (TTL). This transaction will automatically retry, so the business is usually not affected. For a transaction with a size of 0.25 MB or smaller, the default TTL is 3 seconds. For more details, see the `LockNotFound` error.

- 7.2.4 `PessimisticLockNotFound`.

  Similar to `TxnLockNotFound`. The pessimistic transaction commit is too slow and thus rolled back by other transactions.

- 7.2.5 `stale_epoch`.

  The request epoch is outdated, so TiDB re-sends the request after updating the routing. The business is not affected. Epoch changes when Region has a split/merge operation or a replica is migrated.

- 7.2.6 `peer is not leader`.

  The request is sent to a replica that is not Leader. If the error response indicates which replica is the latest Leader, TiDB updates the local routing according the error and sends a new request to the latest Leader. Usually, the business is not affected.

  In v3.0 and later versions, TiDB tries other peers if the request to the previous Leader fails, which might lead to frequent `peer is not leader` in TiKV log. You can check the `switch region peer to next due to send request fail` log of the corresponding Region in TiDB to determine the root cause of the sending failure. For details, refer to 7.1.4.

  This error might also be returned if a Region has no Leader due to other reasons. For details, see 4.4.

10.1.2 TiDB Cluster Troubleshooting Guide

You can use this guide to help you diagnose and solve basic problems while using TiDB. If your problem is not resolved, please collect the following information and create an issue:

- The exact error message and the operations while the error occurs
- The state of all the components
- The `error/fatal/panic` information in the log of the component that reports the error
- The configuration and deployment topology
- The TiDB component related issue in `dmesg`

For other information, see Frequently Asked Questions (FAQ).

10.1.2.1 Cannot connect to the database

1. Make sure all the services are started, including `tidb-server`, `pd-server`, and `tikv-server`.
2. Use the `ps` command to check if all the processes are running.
    - If a certain process is not running, see the following corresponding sections to diagnose and solve the issue.
    - If all the processes are running, check the `tidb-server` log to see if the following messages are displayed:
        - InformationSchema is out of date: This message is displayed if the `tikv-server` cannot be connected. Check the state and log of `pd-server` and `tikv-server`.
        - panic: This message is displayed if there is an issue with the program. Please provide the detailed panic log and create an issue.
3. If the data is cleared and the services are re-deployed, make sure that:
    - All the data in `tikv-server` and `pd-server` are cleared. The specific data is stored in `tikv-server` and the metadata is stored in `pd-server`. If only one of the two servers is cleared, the data will be inconsistent.
    - After the data in `pd-server` and `tikv-server` are cleared and the `pd-server` and `tikv-server` are restarted, the `tidb-server` must be restarted too. The cluster ID is randomly allocated when the `pd-server` is initialized. So when the cluster is re-deployed, the cluster ID changes and you need to restart the `tidb-server` to get the new cluster ID.

10.1.2.2 Cannot start `tidb-server`

See the following for the situations when the `tidb-server` cannot be started:

- Error in the startup parameters.

  See the TiDB configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tidb-server` is not occupied.

- Cannot connect to `pd-server`.

  - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
  - If there is no issue with the network, check the state and log of the `pd-server` process.

10.1.2.3 Cannot start `tikv-server`

See the following for the situations when the `tikv-server` cannot be started:

- Error in the startup parameters: See the TiKV configuration and options.
- The port is occupied: Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tikv-server` is not occupied.
- Cannot connect to `pd-server`.

  - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
  - If there is no issue with the network, check the state and log of the `pd-server` process.

- The file is occupied.

  Do not open two TiKV files on one database file directory.

10.1.2.4 Cannot start `pd-server`

See the following for the situations when the `pd-server` cannot be started:

- Error in the startup parameters.

  See the PD configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `pd-server` is not occupied.

10.1.2.5 The TiDB/TiKV/PD process aborts unexpectedly

- Is the process started on the foreground? The process might exit because the client aborts.
- Is `nohup+&` run in the command line? This might cause the process to abort because it receives the hup signal. It is recommended to write and run the startup command in a script.

10.1.2.6 TiDB panic

Please provide the panic log and create an issue.

10.1.2.7 The connection is rejected

Make sure the network parameters of the operating system are correct, including but not limited to:

- The port in the connection string is consistent with the `tidb-server` starting port.
- The firewall is configured correctly.

10.1.2.8 Open too many files

Before starting the process, make sure the result of `ulimit -n` is large enough. It is recommended to set the value to `unlimited` or larger than `1000000`.

10.1.2.9 Database access times out and the system load is too high

First, check the slow query log and see if it is because of some inappropriate SQL statement.

If you failed to solve the problem, provide the following information:

- The deployment topology
  - How many `tidb-server`/`pd-server`/`tikv-server` instances are deployed?
  - How are these instances distributed in the machines?
- The hardware configuration of the machines where these instances are deployed:
  - The number of CPU cores
  - The size of the memory
  - The type of the disk (SSD or Hard Drive Disk)
  - Are they physical machines or virtual machines?
- Are there other services besides the TiDB cluster?

- Are the `pd-servers` and `tikv-servers` deployed separately?
- What is the current operation?
- Check the CPU thread name using the `top -H` command.
- Are there any exceptions in the network or IO monitoring data recently?

10.1.3 Troubleshoot a TiFlash Cluster

This section describes some commonly encountered issues when using TiFlash, the reasons, and the solutions.

10.1.3.1 TiFlash fails to start

The issue might occur due to different reasons. It is recommended that you troubleshoot it following the steps below:

1. Check whether your system is RedHat Enterprise Linux 8.

   RedHat Enterprise Linux 8 does not have the `libnsl.so` system library. You can manually install it via the following command:

   ```
   shell dnf install libnsl
   ```

2. Check your system's `ulimit` parameter setting.

   ```
   shell ulimit -n 1000000
   ```

3. Use the PD Control tool to check whether there is any TiFlash instance that failed to go offline on the node (same IP and Port) and force the instance(s) to go offline. For detailed steps, refer to Scale in a TiFlash cluster.

If the above methods cannot resolve your issue, save the TiFlash log files and get support from PingCAP or the community.

10.1.3.2 TiFlash replica is always unavailable

This is because TiFlash is in an abnormal state caused by configuration errors or environment issues. Take the following steps to identify the faulty component:

1. Check whether PD enables the `Placement Rules` feature:

   ```
   echo 'config show replication' | /path/to/pd-ctl -u http://${pd-ip}:${
       ↪ pd-port}
   ```

   - If `true` is returned, go to the next step.
   - If `false` is returned, enable the Placement Rules feature and go to the next step.

2. Check whether the TiFlash process is working correctly by viewing `UpTime` on the TiFlash-Summary monitoring panel.

3. Check whether the TiFlash proxy status is normal through `pd-ctl`.

```
echo "store" | /path/to/pd-ctl -u http://${pd-ip}:${pd-port}
```

   The TiFlash proxy's `store.labels` includes information such as `{"key": "engine ↪ ", "value": "tiflash"}`. You can check this information to confirm a TiFlash proxy.

4. Check whether `pd buddy` can correctly print the logs (the log path is the value of `log` in the [flash.flash_cluster] configuration item; the default log path is under the `tmp` directory configured in the TiFlash configuration file).

5. Check whether the number of configured replicas is less than or equal to the number of TiKV nodes in the cluster. If not, PD cannot replicate data to TiFlash:

```
echo 'config placement-rules show' | /path/to/pd-ctl -u http://${pd-ip
    ↪ }:${pd-port}
```

   Reconfirm the value of `default: count`.

> **Note:**
> After the placement rules feature is enabled, the previously configured `max-replicas` and `location-labels` no longer take effect. To adjust the replica policy, use the interface related to placement rules.

6. Check whether the remaining disk space of the machine (where `store` of the TiFlash node is) is sufficient. By default, when the remaining disk space is less than 20% of the `store` capacity (which is controlled by the `low-space-ratio` parameter), PD cannot schedule data to this TiFlash node.

10.1.3.3 Some queries return the `Region Unavailable` error

If the load pressure on TiFlash is too heavy and it causes that TiFlash data replication falls behind, some queries might return the `Region Unavailable` error.

In this case, you can balance the load pressure by adding more TiFlash nodes.

10.1.3.4 Data file corruption

Take the following steps to handle the data file corruption:

1. Refer to Take a TiFlash node down to take the corresponding TiFlash node down.
2. Delete the related data of the TiFlash node.
3. Redeploy the TiFlash node in the cluster.

10.1.3.5 TiFlash analysis is slow

If a statement contains operators or functions not supported in the MPP mode, TiDB does not select the MPP mode. Therefore, the analysis of the statement is slow. In this case, you can execute the `EXPLAIN` statement to check for operators or functions not supported in the MPP mode.

```
create table t(a datetime);
alter table t set tiflash replica 1;
insert into t values('2022-01-13');
set @@session.tidb_enforce_mpp=1;
explain select count(*) from t where subtime(a, '12:00:00') > '2022-01-01'
    ↪ group by a;
show warnings;
```

In this example, the warning message shows that TiDB does not select the MPP mode because TiDB 5.4 and earlier versions do not support the `subtime` function.

```
+---------+------+-----------------------------------------------------------------------
    ↪
> | Level   | Code | Message
    ↪                                                                 |
+---------+------+-----------------------------------------------------------------------
    ↪
| Warning | 1105 | Scalar function 'subtime'(signature: SubDatetimeAndString
    ↪ , return type: datetime) is not supported to push down to tiflash now
    ↪ . |
+---------+------+-----------------------------------------------------------------------
    ↪
```

10.1.3.6 Data is not replicated to TiFlash

After deploying a TiFlash node and starting replication (by performing the ALTER operation), no data is replicated to it. In this case, you can identify and address the problem by following the steps below:

1. Check whether the replication is successful by running the `ALTER table <tbl_name>` ↪ `set tiflash replica <num>` command and check the output.

    - If there is output, go to the next step.
    - If there is no output, run the `SELECT * FROM information_schema.tiflash_replica` ↪ command to check whether TiFlash replicas have been created. If not, run the `ALTER table ${tbl_name} set tiflash replica ${num}` command again, check whether other statements (for example, `add index`) have been executed, or check whether DDL executions are successful.

2. Check whether TiFlash Region replication runs correctly.

   Check whether there is any change in `progress`:

   - If yes, TiFlash replication runs correctly.
   - If no, TiFlash replication is abnormal. In `tidb.log`, search the log saying `Tiflash replica is not available`. Check whether `progress` of the corresponding table is updated. If not, check the `tiflash log` for further information. For example, search `lag_region_info` in `tiflash log` to find out which Region lags behind.

3. Check whether the Placement Rules function has been enabled by using pd-ctl:

```
echo 'config show replication' | /path/to/pd-ctl -u http://<pd-ip>:<pd-port>
```

   - If `true` is returned, go to the next step.
   - If `false` is returned, enable the Placement Rules feature and go to the next step.

4. Check whether the `max-replicas` configuration is correct:

   - If the value of `max-replicas` does not exceed the number of TiKV nodes in the cluster, go to the next step.
   - If the value of `max-replicas` is greater than the number of TiKV nodes in the cluster, the PD does not replicate data to the TiFlash node. To address this issue, change `max-replicas` to an integer fewer than or equal to the number of TiKV nodes in the cluster.

> **Note:**
>
> `max-replicas` is defaulted to 3. In production environments, the value is usually fewer than the number of TiKV nodes. In test environments, the value can be 1.

```
curl -X POST -d '{
    "group_id": "pd",
    "id": "default",
    "start_key": "",
    "end_key": "",
    "role": "voter",
    "count": 3,
    "location_labels": [
    "host"
    ]
}' <http://172.16.x.xxx:2379/pd/api/v1/config/rule>
```

5. Check whether TiDB has created any placement rule for tables.

   Search the logs of TiDB DDL Owner and check whether TiDB has notified PD to add placement rules. For non-partitioned tables, search `ConfigureTiFlashPDForTable`. For partitioned tables, search `ConfigureTiFlashPDForPartitions`.

   - If the keyword is found, go to the next step.
   - If not, collect logs of the corresponding component for troubleshooting.

6. Check whether PD has configured any placement rule for tables.

   Run the `curl http://<pd-ip>:<pd-port>/pd/api/v1/config/rules/group/tiflash` command to view all TiFlash placement rules on the current PD. If a rule with the ID being `table-<table_id>-r` is found, the PD has configured a placement rule successfully.

7. Check whether the PD schedules properly.

   Search the `pd.log` file for the `table-<table_id>-r` keyword and scheduling behaviors like `add operator`.

   - If the keyword is found, the PD schedules properly.
   - If not, the PD does not schedule properly.

10.1.3.7 Data replication gets stuck

If data replication on TiFlash starts normally but then all or some data fails to be replicated after a period of time, you can confirm or resolve the issue by performing the following steps:

1. Check the disk space.

   Check whether the disk space ratio is higher than the value of `low-space-ratio` (defaulted to 0.8. When the space usage of a node exceeds 80%, the PD stops migrating data to this node to avoid exhaustion of disk space).

   - If the disk usage ratio is greater than or equal to the value of `low-space-ratio`, the disk space is insufficient. To relieve the disk space, remove unnecessary files, such as `space_placeholder_file` (if necessary, set `reserve-space` to 0MB after removing the file) under the `${data}/flash/` folder.
   - If the disk usage ratio is less than the value of `low-space-ratio`, the disk space is sufficient. Go to the next step.

2. Check whether there is any `down peer` (a `down peer` might cause the replication to get stuck).

   Run the `pd-ctl region check-down-peer` command to check whether there is any `down peer`. If any, run the `pd-ctl operator add remove-peer <region-id> <tiflash-store-id>` command to remove it.

10.1.3.8 Data replication is slow

The causes may vary. You can address the problem by performing the following steps.

1. Increase `store limit` to accelerate replication.
2. Adjust the load on TiFlash.

   Excessively high load on TiFlash can also result in slow replication. You can check the load of TiFlash indicators on the **TiFlash-Summary** panel on Grafana:

   - `Applying snapshots Count`: `TiFlash-summary` > `raft` > `Applying snapshots Count`
   - `Snapshot Predecode Duration`: `TiFlash-summary` > `raft` > `Snapshot Predecode Duration`
   - `Snapshot Flush Duration`: `TiFlash-summary` > `raft` > `Snapshot Flush Duration`
   - `Write Stall Duration`: `TiFlash-summary` > `Storage Write Stall` > `Write Stall Duration`
   - `generate snapshot CPU`: `TiFlash-Proxy-Details` > `Thread CPU` > `Region task worker pre-handle/generate snapshot CPU`

   Based on your service priorities, adjust the load accordingly to achieve optimal performance.

10.2 Issue Scenarios

10.2.1 Slow Queries

10.2.1.1 Identify Slow Queries

To help users identify slow queries, analyze and improve the performance of SQL execution, TiDB outputs the statements whose execution time exceeds `tidb_slow_log_threshold` (The default value is 300 milliseconds) to slow-query-file (The default value is "tidb-slow.log").

TiDB enables the slow query log by default. You can enable or disable the feature by modifying the system variable `tidb_enable_slow_log`.

10.2.1.1.1 Usage example

```
#### Time: 2019-08-14T09:26:59.487776265+08:00

10.2.1.1.2 Fields description

Note:

The unit of all the following time fields in the slow query log is **"second"**.

Slow query basics:

- `Time`: The print time of log.
- `Query_time`: The execution time of a statement.
- `Parse_time`: The parsing time for the statement.
- `Compile_time`: The duration of the query optimization.
- `Optimize_time`: The time consumed for optimizing the execution plan.
- `Wait_TS`: The waiting time of the statement to get transaction timestamps.
- `Query`: A SQL statement. `Query` is not printed in the slow log, but the corresponding field is called `Query` after the slow log is mapped to the memory table.
- `Digest`: The fingerprint of the SQL statement.
- `Txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `Is_internal`: Whether a SQL statement is TiDB internal. `true` indicates that a SQL statement is executed internally in TiDB and `false` indicates that a SQL statement is executed by the user.
- `Index_names`: The index names used by the statement.
- `Stats`: The health state of the involved tables. `pseudo` indicates that the state is unhealthy.
- `Succ`: Whether a statement is executed successfully.
- `Backoff_time`: The waiting time before retry when a statement encounters errors that require a retry. The common errors as such include: `lock occurs`, `Region split`, and `tikv server is busy`.
- `Plan`: The execution plan of a statement. Execute the `SELECT tidb_decode_plan('xxx...')` statement to parse the specific execution plan.
- `Binary_plan`: The execution plan of a binary-encoded statement. Execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan. The `Plan` and `Binary_plan` fields carry the same information. However, the format of execution plans parsed from the two fields are different.
- `Prepared`: Whether this statement is a `Prepare` or `Execute` request or not.
- `Plan_from_cache`: Whether this statement hits the execution plan cache.
- `Plan_from_binding`: Whether this statement uses the bound execution plans.
- `Has_more_results`: Whether this statement has more results to be fetched by users.
- `Rewrite_time`: The time consumed for rewriting the query of this statement.
- `Preproc_subqueries`: The number of subqueries (in the statement) that are executed in advance. For example, the `where id in (select if from t)` subquery might be executed in advance.

- `Preproc_subqueries_time`: The time consumed for executing the subquery of this statement in advance.
- `Exec_retry_count`: The retry times of this statement. This field is usually for pessimistic transactions in which the statement is retried when the lock is failed.
- `Exec_retry_time`: The execution retry duration of this statement. For example, if a statement has been executed three times in total (failed for the first two times), `Exec_retry_time` means the total duration of the first two executions. The duration of the last execution is `Query_time` minus `Exec_retry_time`.
- `KV_total`: The time spent on all the RPC requests on TiKV or TiFlash by this statement.
- `PD_total`: The time spent on all the RPC requests on PD by this statement.
- `Backoff_total`: The time spent on all the backoff during the execution of this statement.
- `Write_sql_response_total`: The time consumed for sending the results back to the client by this statement.
- `Result_rows`: The row count of the query results.
- `IsExplicitTxn`: Whether this statement is in an explicit transaction. If the value is `false`, the transaction is `autocommit=1` and the statement is automatically committed after execution.

The following fields are related to transaction execution:

- `Prewrite_time`: The duration of the first phase (prewrite) of the two-phase transaction commit.
- `Commit_time`: The duration of the second phase (commit) of the two-phase transaction commit.
- `Get_commit_ts_time`: The time spent on getting `commit_ts` during the second phase (commit) of the two-phase transaction commit.
- `Local_latch_wait_time`: The time that TiDB spends on waiting for the lock before the second phase (commit) of the two-phase transaction commit.
- `Write_keys`: The count of keys that the transaction writes to the Write CF in TiKV.
- `Write_size`: The total size of the keys or values to be written when the transaction commits.
- `Prewrite_region`: The number of TiKV Regions involved in the first phase (prewrite) of the two-phase transaction commit. Each Region triggers a remote procedure call.

Memory usage fields:

- `Mem_max`: The maximum memory space used during the execution period of a SQL statement (the unit is byte).

Hard disk fields:

- `Disk_max`: The maximum disk space used during the execution period of a SQL statement (the unit is byte).

User fields:

- `User`: The name of the user who executes this statement.
- `Host`: The host name of this statement.
- `Conn_ID`: The Connection ID (session ID). For example, you can use the keyword `con:3` to search for the log whose session ID is `3`.
- `DB`: The current database.

TiKV Coprocessor Task fields:

- `Request_count`: The number of Coprocessor requests that a statement sends.
- `Total_keys`: The number of keys that Coprocessor has scanned.
- `Process_time`: The total processing time of a SQL statement in TiKV. Because data is sent to TiKV concurrently, this value might exceed `Query_time`.
- `Wait_time`: The total waiting time of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `Process_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `Num_cop_tasks`: The number of Coprocessor tasks sent by this statement.
- `Cop_proc_avg`: The average execution time of cop-tasks, including some waiting time that cannot be counted, such as the mutex in RocksDB.
- `Cop_proc_p90`: The P90 execution time of cop-tasks.
- `Cop_proc_max`: The maximum execution time of cop-tasks.
- `Cop_proc_addr`: The address of the cop-task with the longest execution time.
- `Cop_wait_avg`: The average waiting time of cop-tasks, including the time of request queueing and getting snapshots.
- `Cop_wait_p90`: The P90 waiting time of cop-tasks.
- `Cop_wait_max`: The maximum waiting time of cop-tasks.
- `Cop_wait_addr`: The address of the cop-task whose waiting time is the longest.
- `Cop_backoff_{backoff-type}_total_times`: The total times of backoff caused by an error.
- `Cop_backoff_{backoff-type}_total_time`: The total time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_time`: The longest time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_addr`: The address of the cop-task that has the longest backoff time caused by an error.
- `Cop_backoff_{backoff-type}_avg_time`: The average time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_p90_time`: The P90 percentile backoff time caused by an error.

10.2.1.1.3 Related system variables

- tidb_slow_log_threshold: Sets the threshold for the slow log. The SQL statement whose execution time exceeds this threshold is recorded in the slow log. The default value is 300 (ms).
- tidb_query_log_max_len: Sets the maximum length of the SQL statement recorded in the slow log. The default value is 4096 (byte).
- tidb_redact_log: Determines whether to desensitize user data using ? in the SQL statement recorded in the slow log. The default value is 0, which means to disable the feature.
- tidb_enable_collect_execution_info: Determines whether to record the physical execution information of each operator in the execution plan. The default value is 1. This feature impacts the performance by approximately 3%. After enabling this feature, you can view the Plan information as follows:

```
> select tidb_decode_plan('
    ↪ jAOIMAk1XzE3CTAJMQlmdW5jczpjb3VudChDb2x1bW4jNyktPkMJC/

+-------------------------------------------------------------------------
    ↪
```

If you are conducting a performance test, you can disable the feature of automatically collecting the execution information of operators:

```
set @@tidb_enable_collect_execution_info=0;
```

The returned result of the `Plan` field has roughly the same format with that of `EXPLAIN` or `EXPLAIN ANALYZE`. For more details of the execution plan, see `EXPLAIN` or `EXPLAIN ANALYZE`.

For more information, see TiDB specific variables and syntax.

10.2.1.1.4 Memory mapping in slow log

You can query the content of the slow query log by querying the `INFORMATION_SCHEMA.` ↪ `SLOW_QUERY` table. Each column name in the table corresponds to one field name in the slow log. For table structure, see the introduction to the `SLOW_QUERY` table in Information Schema.

> **Note:**
>
> Every time you query the `SLOW_QUERY` table, TiDB reads and parses the current slow query log.

For TiDB 4.0, `SLOW_QUERY` supports querying the slow log of any period of time, including the rotated slow log file. You need to specify the `TIME` range to locate the slow log files that need to be parsed. If you don't specify the `TIME` range, TiDB only parses the current slow log file. For example:

- If you don't specify the time range, TiDB only parses the slow query data that TiDB is writing to the slow log file:

```
select count(*),
     min(time),
     max(time)
from slow_query;
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 122492   | 2020-03-11 23:35:20.908574 | 2020-03-25 19:16:38.229035 |
+----------+----------------------------+----------------------------+
```

- If you specify the time range, for example, from `2020-03-10 00:00:00` to `2020-03-11 00:00:00`, TiDB first locates the slow log files of the specified time range, and then parses the slow query information:

```
select count(*),
     min(time),
     max(time)
from slow_query
where time > '2020-03-10 00:00:00'
  and time < '2020-03-11 00:00:00';
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 2618049 | 2020-03-10 00:00:00.427138 | 2020-03-10 23:00:22.716728 |
+----------+----------------------------+----------------------------+
```

> **Note:**
>
> If the slow log files of the specified time range are removed, or there is no slow query, the query returns NULL.

TiDB 4.0 adds the `CLUSTER_SLOW_QUERY` system table to query the slow query information of all TiDB nodes. The table schema of the `CLUSTER_SLOW_QUERY` table differs from that of the `SLOW_QUERY` table in that an `INSTANCE` column is added to `CLUSTER_SLOW_QUERY`. The `INSTANCE` column represents the TiDB node address of the row information on the slow query. You can use `CLUSTER_SLOW_QUERY` the way you do with `SLOW_QUERY`.

When you query the `CLUSTER_SLOW_QUERY` table, TiDB pushes the computation and the judgment down to other nodes, instead of retrieving all slow query information from other nodes and executing the operations on one TiDB node.

10.2.1.1.5 `SLOW_QUERY` / `CLUSTER_SLOW_QUERY` usage examples

Top-N slow queries

Query the Top 2 slow queries of users. `Is_internal=false` means excluding slow queries inside TiDB and only querying slow queries of users.

```
select query_time, query
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 2;
```

Output example:

```
+--------------+-----------------------------------------------------------------------+
   ↪
| query_time | query                                                                  |
+--------------+-----------------------------------------------------------------------+
   ↪
| 12.77583857 | select * from t_slim, t_wide where t_slim.c0=t_wide.c0; |
|  0.734982725 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=
   ↪ t1.c0; |
+--------------+-----------------------------------------------------------------------+
   ↪
```

Query the Top-N slow queries of the `test` user

In the following example, the slow queries executed by the `test` user are queried, and the first two results are displayed in reverse order of execution time.

```
select query_time, query, user
from information_schema.slow_query
where is_internal = false
  and user = "test"
order by query_time desc
limit 2;
```

Output example:

```
+-------------+-------------------------------------------------------------------------+------
   ↪
| Query_time | query                                                                   |
   ↪ user         |
+-------------+-------------------------------------------------------------------------+------
   ↪
| 0.676408014 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=t1
   ↪ .c1; | test |
+-------------+-------------------------------------------------------------------------+------
   ↪
```

Query similar slow queries with the same SQL fingerprints

After querying the Top-N SQL statements, continue to query similar slow queries using the same fingerprints.

1. Acquire Top-N slow queries and the corresponding SQL fingerprints.

```
select query_time, query, digest
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 1;
```

Output example:

```
+-------------+-----------------------------+-----------------------------------
    ↪
| query_time | query                      | digest
    ↪                                                        |
+-------------+-----------------------------+-----------------------------------
    ↪
| 0.302558006 | select * from t1 where a=1; | 4751
    ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa |
+-------------+-----------------------------+-----------------------------------
    ↪
```

2. Query similar slow queries with the fingerprints.

```
select query, query_time
from information_schema.slow_query
where digest = "4751
    ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa";
```

Output example:

```
+-----------------------------+-------------+
| query                      | query_time |
+-----------------------------+-------------+
| select * from t1 where a=1; | 0.302558006 |
| select * from t1 where a=2; | 0.401313532 |
+-----------------------------+-------------+
```

10.2.1.1.6 Query slow queries with pseudo stats

```
select query, query_time, stats
from information_schema.slow_query
where is_internal = false
  and stats like '%pseudo%';
```

Output example:

```
+----------------------------+------------+--------------------------------+
   ↪
| query                      | query_time | stats                          |
+----------------------------+------------+--------------------------------+
   ↪
| select * from t1 where a=1; | 0.302558006 | t1:pseudo                     |
| select * from t1 where a=2; | 0.401313532 | t1:pseudo                     |
| select * from t1 where a>2; | 0.602011247 | t1:pseudo                     |
| select * from t1 where a>3; | 0.50077719 | t1:pseudo                      |
| select * from t1 join t2; | 0.931260518 | t1:407872303825682445,t2:pseudo
   ↪ |
+----------------------------+------------+--------------------------------+
   ↪
```

Query slow queries whose execution plan is changed

When the execution plan of SQL statements of the same category is changed, the execution slows down, because the statistics is outdated, or the statistics is not accurate enough to reflect the real data distribution. You can use the following SQL statement to query SQL statements with different execution plans.

```
select count(distinct plan_digest) as count,
      digest,
      min(query)
from cluster_slow_query
group by digest
having count > 1
limit 3\G
```

Output example:

```
***************************[ 1. row ]***************************
count     | 2
digest    | 17b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94
min(query) | SELECT DISTINCT c FROM sbtest25 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (291638, 291737)];
***************************[ 2. row ]***************************
count     | 2
digest    | 9337865f3e2ee71c1c2e740e773b6dd85f23ad00f8fa1f11a795e62e15fc9b23
min(query) | SELECT DISTINCT c FROM sbtest22 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (215420, 215519)];
***************************[ 3. row ]***************************
count     | 2
digest    | db705c89ca2dfc1d39d10e0f30f285cbbadec7e24da4f15af461b148d8ffb020
min(query) | SELECT DISTINCT c FROM sbtest11 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (303359, 303458)];
```

Then you can query the different plans using the SQL fingerprint in the query result above:

```
select min(plan),
      plan_digest
from cluster_slow_query
where digest='17
   ↪ b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94'
group by plan_digest\G
```

Output example:

```
*************************** 1. row ***************************
  min(plan):  Sort_6               root   100.00131380758702   sbtest.
     ↪ sbtest25.c:asc
        ─HashAgg_10          root   100.00131380758702   group by:sbtest.
          ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
          ↪ .c
          ─TableReader_15    root   100.00131380758702   data:
            ↪ TableRangeScan_14
            ─TableScan_14    cop    100.00131380758702   table:sbtest25,
              ↪ range:[502791,502890], keep order:false
plan_digest: 6
   ↪ afbbd21f60ca6c6fdf3d3cd94f7c7a49dd93c00fcf8774646da492e50e204ee
*************************** 2. row ***************************
  min(plan):  Sort_6               root   1                    sbtest.
     ↪ sbtest25.c:asc
        ─HashAgg_12          root   1                    group by:sbtest.

Query the number of slow queries for each TiDB node in a cluster

```
select instance, count(*) from information_schema.cluster_slow_query where
   ↪ time >= "2020-03-06 00:00:00" and time < now() group by instance;
```

Output example:

```
+---------------+----------+
| instance      | count(*) |
```

```
+---------------+----------+
| 0.0.0.0:10081 | 124      |
| 0.0.0.0:10080 | 119771   |
+---------------+----------+
```

Query slow logs occurring only in abnormal time period

If you find problems such as decreased QPS or increased latency for the time period from `2020-03-10 13:24:00` to `2020-03-10 13:27:00`, the reason might be that a large query crops up. Run the following SQL statement to query slow logs that occur only in abnormal time period. The time range from `2020-03-10 13:20:00` to `2020-03-10 13:23:00` refers to the normal time period.

```
SELECT * FROM
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ count(*),
        min(time),
        sum(query_time) AS sum_query_time,
        sum(Process_time) AS sum_process_time,
        sum(Wait_time) AS sum_wait_time,
        sum(Commit_time),
        sum(Request_count),
        sum(process_keys),
        sum(Write_keys),
        max(Cop_proc_max),
        min(query),min(prev_stmt),
        digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:24:00'
           AND time < '2020-03-10 13:27:00'
           AND Is_internal = false
    GROUP BY digest) AS t1
WHERE t1.digest NOT IN
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:20:00'
           AND time < '2020-03-10 13:23:00'
    GROUP BY digest)
ORDER BY t1.sum_query_time DESC limit 10\G
```

Output example:

```
***************************[ 1. row ]***************************
count(*)         | 200
min(time)        | 2020-03-10 13:24:27.216186
sum_query_time   | 50.114126194
sum_process_time | 268.351
```

```
sum_wait_time    | 8.476
sum(Commit_time) | 1.044304306
sum(Request_count) | 6077
sum(process_keys) | 202871950
sum(Write_keys)  | 319500
max(Cop_proc_max) | 0.263
min(query)       | delete from test.tcs2 limit 5000;
min(prev_stmt)   |
digest           | 24
   ↪ bd6d8a9b238086c9b8c3d240ad4ef32f79ce94cf5a468c0b8fe1eb5f8d03df
```

Parse other TiDB slow log files

TiDB uses the session variable `tidb_slow_query_file` to control the files to be read and parsed when querying `INFORMATION_SCHEMA.SLOW_QUERY`. You can query the content of other slow query log files by modifying the value of the session variable.

```
set tidb_slow_query_file = "/path-to-log/tidb-slow.log"
```

Parse TiDB slow logs with `pt-query-digest`

Use `pt-query-digest` to parse TiDB slow logs.

> **Note:**
>
> It is recommended to use `pt-query-digest` 3.0.13 or later versions.

For example:

```
pt-query-digest --report tidb-slow.log
```

Output example:

```
#### 320ms user time, 20ms system time, 27.00M rss, 221.32M vsz
#### Current date: Mon Mar 18 13:18:51 2019

```

10.2.1.1.7 Identify problematic SQL statements

Not all of the `SLOW_QUERY` statements are problematic. Only those whose `process_time` is very large increase the pressure on the entire cluster.

The statements whose `wait_time` is very large and `process_time` is very small are usually not problematic. This is because the statement is blocked by real problematic statements and it has to wait in the execution queue, which leads to a much longer response time.

`ADMIN SHOW SLOW` command

In addition to the TiDB log file, you can identify slow queries by running the `ADMIN SHOW SLOW` command:

```
ADMIN SHOW SLOW recent N
ADMIN SHOW SLOW TOP [internal | all] N
```

`recent N` shows the recent N slow query records, for example:

```
ADMIN SHOW SLOW recent 10
```

`top N` shows the slowest N query records recently (within a few days). If the `internal` option is provided, the returned results would be the inner SQL executed by the system; If the `all` option is provided, the returned results would be the user's SQL combinated with inner SQL; Otherwise, this command would only return the slow query records from the user's SQL.

```
ADMIN SHOW SLOW top 3
ADMIN SHOW SLOW top internal 3
ADMIN SHOW SLOW top all 5
```

TiDB stores only a limited number of slow query records because of the limited memory. If the value of `N` in the query command is greater than the records count, the number of returned records is smaller than `N`.

The following table shows output details:

Column name	Description
start	The starting time of the SQL execution
duration	The duration of the SQL execution
details	The details of the SQL execution
succ	Whether the SQL statement is executed successfully. `1` means success and `0` means failure.

Column name	Description
conn_id	The connection ID for the session
transaction_ts	The `commit ↪ ↪ ts` for a transaction commit
user	The user name for the execution of the statement
db	The database involved when the statement is executed

Column name	Description
table_ids	The ID of the table involved when the SQL statement is executed
index_ids	The ID of the index involved when the SQL statement is executed
internal	This is a TiDB internal SQL statement
digest	The fingerprint of the SQL statement

Column name	Description
sql	The SQL statement that is being executed or has been executed

10.2.1.2 Analyze Slow Queries

To address the issue of slow queries, you need to take the following two steps:

1. Among many queries, identify which type of queries are slow.
2. Analyze why this type of queries are slow.

You can easily perform step 1 using the slow query log and the statement summary table features. It is recommended to use TiDB Dashboard, which integrates the two features and directly displays the slow queries in your browser.

This document focuses on how to perform step 2 - analyze why this type of queries are slow.

Generally, slow queries have the following major causes:

- Optimizer issues, such as wrong index selected, wrong join type or sequence selected.
- System issues. All issues not caused by the optimizer are system issues. For example, a busy TiKV instance processes requests slowly; outdated Region information causes slow queries.

In actual situations, optimizer issues might cause system issues. For example, for a certain type of queries, the optimizer uses a full table scan instead of the index. As a result, the SQL queries consume many resources, which causes the CPU usage of some TiKV instances to soar. This seems like a system issue, but in essence, it is an optimizer issue.

To identify system issues is relatively simple. To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. Therefore, it is recommended to analyze slow queries by following these procedures:

1. Identify the performance bottleneck of the query, that is, the time-consuming part of the query process.
2. Analyze the system issues: analyze the possible causes according to the query bottleneck and the monitoring/log information of that time.
3. Analyze the optimizer issues: analyze whether there is a better execution plan.

The procedures above are explained in the following sections.

10.2.1.2.1 Identify the performance bottleneck of the query

First, you need to have a general understanding of the query process. The key stages of the query execution process in TiDB are illustrated in TiDB performance map.

You can get the duration information using the following methods:

- Slow log. It is recommended to view the slow log in TiDB Dashboard.
- `EXPLAIN ANALYZE` statement.

The methods above are different in the following aspects:

- The slow log records the duration of almost all stages of a SQL execution, from parsing to returning results, and is relatively comprehensive (you can query and analyze the slow log in TiDB Dashboard in an intuitive way).
- By executing `EXPLAIN ANALYZE`, you can learn the time consumption of each operator in an actual SQL execution. The results have more detailed statistics of the execution duration.

In summary, the slow log and `EXPLAIN ANALYZE` statements help you determine the SQL query is slow in which component (TiDB or TiKV) at which stage of the execution. Therefore, you can accurately identify the performance bottleneck of the query.

In addition, since v4.0.3, the `Plan` field in the slow log also includes the SQL execution information, which is the result of `EXPLAIN ANALYZE`. So you can find all information of SQL duration in the slow log.

10.2.1.2.2 Analyze system issues

System issues can be divided into the following types according to different execution stages of a SQL statement:

1. TiKV is slow in data processing. For example, the TiKV coprocessor processes data slowly.
2. TiDB is slow in execution. For example, a `Join` operator processes data slowly.
3. Other key stages are slow. For example, getting the timestamp takes a long time.

For each slow query, first determine to which type the query belongs, and then analyze it in detail.

TiKV is slow in data processing

If TiKV is slow in data processing, you can easily identify it in the result of `EXPLAIN ANALYZE`. In the following example, `StreamAgg_8` and `TableFullScan_15`, two `tikv-tasks` (as indicated by `cop[tikv]` in the `task` column), take `170ms` to execute. After subtracting `170ms`, the execution time of TiDB operators account for a very small proportion of the total execution time. This indicates that the bottleneck is in TiKV.

```
+--
   ↪ ------------------------+---------+---------+-----------+---------------+-----
   ↪
| id                        | estRows | actRows | task   | access object |
   ↪ execution info                                                          |
   ↪ operator info                | memory   | disk |
+--
   ↪ ------------------------+---------+---------+-----------+---------------+-----
   ↪
| StreamAgg_16              | 1.00    | 1       | root      |               | time
   ↪ :170.08572ms, loops:2                                                   |
   ↪ funcs:count(Column#5)->Column#3 | 372 Bytes | N/A |
|  ─TableReader_17          | 1.00    | 1       | root      |               | time
   ↪ :170.080369ms, loops:2, rpc num: 1, rpc time:17.023347ms, proc keys
   ↪ :28672 | data:StreamAgg_8  | 202 Bytes | N/A |
|    ─StreamAgg_8           | 1.00    | 1       | cop[tikv] |               | time
   ↪ :170ms, loops:29                                                        |
   ↪ funcs:count(1)->Column#5    | N/A       | N/A |
|      ─TableFullScan_15    | 7.00    | 28672   | cop[tikv] | table:t       | time
   ↪ :170ms, loops:29                                                        |
   ↪ keep order:false, stats:pseudo | N/A    | N/A |
+--
   ↪ ------------------------+---------+---------+-----------+---------------+-----
   ↪
```

In addition, the `Cop_process` and `Cop_wait` fields in the slow log can also help your analysis. In the following example, the total duration of the query is around `180.85ms`, and the largest `coptask` takes `171ms`. This indicates that the bottleneck of this query is on the TiKV side.

For the description of each field in the slow log, see fields description.

```
#### Query_time: 0.18085
...
#### Num_cop_tasks: 1
#### Cop_process: Avg_time: 170ms P90_time: 170ms Max_time: 170ms Max_addr:
   ↪ 10.6.131.78
```

```
#### Cop_wait: Avg_time: 1ms P90_time: 1ms Max_time: 1ms Max_Addr:
    ↪ 10.6.131.78
```

After identifying that TiKV is the bottleneck, you can find out the cause as described in the following sections.

TiKV instance is busy

During the execution of a SQL statement, TiDB might fetch data from multiple TiKV instances. If one TiKV instance responds slowly, the overall SQL execution speed is slowed down.

The `Cop_wait` field in the slow log can help you determine this cause.

```
#### Cop_wait: Avg_time: 1ms P90_time: 2ms Max_time: 110ms Max_Addr:
    ↪ 10.6.131.78
```

The log above shows that a `cop-task` sent to the `10.6.131.78` instance waits `110ms` ↪ before being executed. It indicates that this instance is busy. You can check the CPU monitoring of that time to confirm the cause.

Too many outdated keys

A TiKV instance has much outdated data, which needs to be cleaned up for data scan. This impacts the processing speed.

Check `Total_keys` and `Processed_keys`. If they are greatly different, the TiKV instance has too many keys of the older versions.

```
...
#### Total_keys: 2215187529 Processed_keys: 1108056368
...
```

Other key stages are slow

Slow in getting timestamps

You can compare `Wait_TS` and `Query_time` in the slow log. The timestamps are prefetched, so generally `Wait_TS` should be low.

```
#### Query_time: 0.0300000
...
#### Wait_TS: 0.02500000
```

Outdated Region information

Region information on the TiDB side might be outdated. In this situation, TiKV might return the `regionMiss` error. Then TiDB gets the Region information from PD again, which is reflected in the `Cop_backoff` information. Both the failed times and the total duration are recorded.

```
#### Cop_backoff_regionMiss_total_times: 200
    ↪ Cop_backoff_regionMiss_total_time: 0.2
    ↪ Cop_backoff_regionMiss_max_time: 0.2 Cop_backoff_regionMiss_max_addr:
    ↪  127.0.0.1 Cop_backoff_regionMiss_avg_time: 0.2
    ↪ Cop_backoff_regionMiss_p90_time: 0.2
#### Cop_backoff_rpcPD_total_times: 200 Cop_backoff_rpcPD_total_time: 0.2
    ↪ Cop_backoff_rpcPD_max_time: 0.2 Cop_backoff_rpcPD_max_addr: 127.0.0.1
    ↪  Cop_backoff_rpcPD_avg_time: 0.2 Cop_backoff_rpcPD_p90_time: 0.2
```

Subqueries are executed in advance

For statements with non-correlated subqueries, the subquery part might be executed in advance. For example, in `select * from t1 where a = (select max(a)from t2)`, the `select max(a)from t2` part might be executed in advance in the optimization stage. The result of `EXPLAIN ANALYZE` does not show the duration of this type of subqueries.

```
mysql> explain analyze select count(*) from t where a=(select max(t1.a)
    ↪ from t t1, t t2 where t1.a=t2.a);
+--
    ↪ ----------------------------+----------+---------+-----------+---------------+--
    ↪
| id                          | estRows | actRows | task    | access object |
    ↪ execution info      | operator info                 | memory   | disk |
+--
    ↪ ----------------------------+----------+---------+-----------+---------------+--
    ↪
| StreamAgg_59                | 1.00    | 1       | root      |               | time
    ↪ :4.69267ms, loops:2 | funcs:count(Column#10)->Column#8 | 372 Bytes |
    ↪ N/A |
|  ─TableReader_60            | 1.00    | 1       | root      |               |
    ↪ time:4.690428ms, loops:2 | data:StreamAgg_48          | 141 Bytes | N/A
    ↪  |
|    ─StreamAgg_48            | 1.00    |         | cop[tikv] |               |
    ↪ time:0ns, loops:0     | funcs:count(1)->Column#10    | N/A       | N/A
    ↪ |
|      ─Selection_58          | 16384.00 |       | cop[tikv] |               |
    ↪ time:0ns, loops:0     | eq(test.t.a, 1)              | N/A       | N/A
    ↪ |
|        ─TableFullScan_57    | 16384.00 | -1    | cop[tikv] | table:t       |
    ↪ time:0s, loops:0      | keep order:false             | N/A       | N/A
    ↪ |
+--
    ↪ ----------------------------+----------+---------+-----------+---------------+--
    ↪
5 rows in set (7.77 sec)
```

But you can identify this type of subquery execution in the slow log:

```
#### Query_time: 7.770634843
...
#### Rewrite_time: 7.765673663 Preproc_subqueries: 1 Preproc_subqueries_time
    ↪ : 7.765231874
```

From log record above, you can see that a subquery is executed in advance and takes `7.76s`.

TiDB is slow in execution

Assume that the execution plan in TiDB is correct but the execution is slow. To solve this type of issue, you can adjust parameters or use the hint according to the result of `EXPLAIN ANALYZE` for the SQL statement.

If the execution plan is incorrect, see the Analyze optimizer issues section.

Low concurrency

If the bottleneck is in the operator with concurrency, speed up the execution by adjusting the concurrency. For example:

```
mysql> explain analyze select sum(t1.a) from t t1, t t2 where t1.a=t2.a;
+--
    ↪ ------------------------------+-------------+----------+----------+--------
    ↪
| id                           | estRows     | actRows  | task     | access
    ↪ object | execution info
    ↪                                                                | operator
    ↪ info                               | memory         | disk   |
+--
    ↪ ------------------------------+-------------+----------+----------+--------
    ↪

    ↪                          | 33.6318359375 KB | N/A  |
|       └─Selection_17           | 16384.00   |          | cop[tikv] |
    ↪             | time:0ns, loops:0
    ↪                                                          | not(isnull(
    ↪ test.t.a))                       | N/A            | N/A    |
|         └─TableFullScan_16     | 16384.00   | -1       | cop[tikv] | table:
    ↪ t1   | time:0s, loops:0
    ↪                                                           | keep order:
    ↪ false                            | N/A            | N/A    |
+--
    ↪ ---------------------------------+-------------+----------+----------+-------
    ↪
9 rows in set (9.67 sec)
```

As shown above, `HashJoin_14` and `Projection_24` consume much of the execution time. Consider increasing their concurrency using SQL variables to speed up execution.

All system variables are documented in system-variables. To increase the concurrency of `HashJoin_14`, you can modify the `tidb_hash_join_concurrency` system variable.

Data is spilled to disk

Another cause of slow execution is disk spill that occurs during execution if the memory limit is reached. You can find out this cause in the execution plan and the slow log:

```
+--
    ↪ ----------------------+----------+---------+----------+---------------+------
    ↪

Join operations with Cartesian product

Join operations with Cartesian product generate data volume as large as `left child row count * right child row count`. This is inefficient and should be avoided.

This type of join operations is marked `CARTESIAN` in the execution plan. For example:

```
mysql> explain select * from t t1, t t2 where t1.a>t2.a;
+--
    ↪ ---------------------------+------------+----------+--------------+---------
    ↪
| id                          | estRows    | task     | access object | operator
    ↪  info                                  |
+--
    ↪ ---------------------------+------------+----------+--------------+---------
    ↪

```

10.2.1.2.3 Analyze optimizer issues

To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. You need to have some understanding of the optimization process and each operator.

For the following examples, assume that the table schema is `create table t (id int ↪ , a int, b int, c int, primary key(id), key(a), key(b, c))`.

1. `select * from t`: There is no filter condition and a full table scan is performed. So the `TableFullScan` operator is used to read data.
2. `select a from t where a=2`: There is a filter condition and only the index columns are read, so the `IndexReader` operator is used to read data.
3. `select * from t where a=2`: There is a filter condition for `a` but the `a` index cannot fully cover the data to be read, so the `IndexLookup` operator is used.
4. `select b from t where c=3`: Without the prefix condition, the multi-column index cannot be used. So the `IndexFullScan` is used.
5. …

The examples above are operators used for data reads. For more operators, see Understand TiDB Execution Plan.

In addition, reading SQL Tuning Overview helps you better understand the TiDB optimizer and determine whether the execution plan is reasonable or not.

Most optimizer issues are explained in SQL Tuning Overview. For the solutions, see the following documents:

1. Wrong Index Solution
2. Wrong join order
3. Expressions are not pushed down

10.2.2 Troubleshoot TiDB OOM Issues

This document describes how to troubleshoot TiDB OOM (Out of Memory) issues, including phenomena, causes, solutions, and diagnostic information.

10.2.2.1 Typical OOM phenomena

The following are some typical OOM phenomena:

- The client side reports the following error: `SQL error, errno = 2013, state = '
  ↪ HY000': Lost connection to MySQL server during query`.
- The Grafana dashboard shows:
  - **TiDB** > **Server** > **Memory Usage** shows that the `process/heapInUse` metric keeps rising, and suddenly drops to zero after reaching the threshold.
  - **TiDB** > **Server** > **Uptime** suddenly drops to zero.
  - **TiDB-Runtime** > **Memory Usage** shows that the `estimate-inuse` metric keeps rising.
- Check `tidb.log`, and you can find the following log entries:
  - An alarm about OOM: `[WARN] [memory_usage_alarm.go:139] ["tidb-
    ↪ server has the risk of OOM. Running SQLs and heap profile will
    ↪ be recorded in record path"]`. For more information, see memory-usage
    ↪ -alarm-ratio.
  - A log entry about restart: `[INFO] [printer.go:33] ["Welcome to TiDB."]`.

10.2.2.2 Overall troubleshooting process

When you troubleshoot OOM issues, follow this process:

1. Confirm whether it is an OOM issue.

   Execute the following command to check the operating system logs. If there is an `oom-killer` log near the time when the problem occurs, you can confirm that it is an OOM issue.

   ```
   dmesg -T | grep tidb-server
   ```

   The following is an example of the log that contains `oom-killer`:

   ```
   ......
   Mar 14 16:55:03 localhost kernel: tidb-server invoked oom-killer:
       ↪ gfp_mask=0x201da, order=0, oom_score_adj=0
   Mar 14 16:55:03 localhost kernel: tidb-server cpuset=/ mems_allowed=0
   Mar 14 16:55:03 localhost kernel: CPU: 14 PID: 21966 Comm: tidb-server
       ↪ Kdump: loaded Not tainted 3.10.0-1160.el7.x86_64 #1
   Mar 14 16:55:03 localhost kernel: Hardware name: QEMU Standard PC (
       ↪ i440FX + PIIX, 1996), BIOS rel-1.14.0-0-g155821a1990b-prebuilt.
       ↪ qemu.org 04/01/2014
   ......
   Mar 14 16:55:03 localhost kernel: Out of memory: Kill process 21945 (
       ↪ tidb-server) score 956 or sacrifice child
   Mar 14 16:55:03 localhost kernel: Killed process 21945 (tidb-server),
       ↪ UID 1000, total-vm:33027492kB, anon-rss:31303276kB, file-rss:0kB,
       ↪  shmem-rss:0kB
   ```

```
Mar 14 16:55:07 localhost systemd: tidb-4000.service: main process
    ↪ exited, code=killed, status=9/KILL
......
```

2. After confirming that it is an OOM issue, you can further investigate whether the OOM is caused by deployment or the database.

    - If the OOM is caused by a deployment issue, you need to investigate the resource configuration and impact of hybrid deployment.
    - If the OOM is caused by a database issue, the following are some possible causes:
        - TiDB handles large data traffic, such as large queries, large writes, and data import.
        - TiDB is in a high concurrency scenario, where multiple SQL statements consume resources concurrently or operator concurrency is high.
        - TiDB has a memory leak and resources are not released.

    Refer to the following sections for specific troubleshooting methods.

10.2.2.3 Typical causes and solutions

OOM issues are usually caused by the following:

- Deployment issues
- Database issues
- Client side issues

10.2.2.3.1 Deployment issues

The following are some causes of OOM due to improper deployment:

- The memory capacity of the operating system is too small.
- The TiUP configuration `resource_control` is not appropriate.
- In the case of hybrid deployments (meaning that TiDB and other applications are deployed on the same server), TiDB is killed accidentally by `oom-killer` due to lack of resources.

10.2.2.3.2 Database issues

This section describes the causes and solutions for OOM caused by database issues.

> **Note:**
>
> If you have configured `tidb_mem_quota_query`, an error occurs: `ERROR 1105 (HY000): Out Of Memory Quota![conn_id=54]`. It is caused by the memory usage control behavior of the database. It is a normal behavior.

Executing SQL statements consumes too much memory

You can take the following measures to reduce the memory usage of SQL statements, depending on the different causes of OOM issues.

- If the execution plan of SQL is not optimal, for example, due to lack of proper indexes, outdated statistics, or optimizer bugs, a wrong execution plan of SQL might be selected. A huge intermediate result set will then be accumulated in the memory. In this case, consider the following measures:
  - Add appropriate indexes.
  - Use the disk spill feature for execution operators.
  - Adjust the JOIN order between tables.
  - Use hints to optimize SQL statements.
- Some operators and functions are not supported to be pushed down to the storage level, resulting in a huge accumulation of intermediate result sets. In this case, you need to refine the SQL statements or use hints to optimize, and use the functions or operators that support pushing down.
- The execution plan contains the operator HashAgg. HashAgg is executed concurrently by multiple threads, which is faster but consumes more memory. Instead, you can use `STREAM_AGG()`.
- Reduce the number of Regions to be read simultaneously or reduce the concurrency of operators to avoid memory problems caused by high concurrency. The corresponding system variables include:
  - `tidb_distsql_scan_concurrency`
  - `tidb_index_serial_scan_concurrency`
  - `tidb_executor_concurrency`
- The concurrency of sessions is too high near the time point when the problem occurs. In this case, consider scaling out the TiDB cluster by adding more TiDB nodes.

Large transactions or large writes consume too much memory

You need to plan for memory capacity. When a transaction is executed, the memory usage of the TiDB process is scaled up comparing with the transaction size, up to two to three times or more of the transaction size.

You can split a single large transaction to multiple smaller transactions.

The process of collecting and loading statistical information consumes too much memory

A TiDB node needs to load statistics into memory after it starts. TiDB consumes memory when collecting statistical information. You can control memory usage in the following ways:

- Specify a sampling rate, only collect statistics for specific columns, and reduce `ANALYZE` concurrency.
- Since TiDB v6.1.0, you can use the system variable `tidb_stats_cache_mem_quota` to control the memory usage for statistical information.
- Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the maximum memory usage when TiDB updates statistics.

For more information, see Introduction to Statistics.

Prepared statements are overused

The client side keeps creating prepared statements but does not execute `deallocate prepare stmt`, which causes memory consumption to continue to rise and eventually triggers TiDB OOM. The reason is that the memory occupied by a prepared statement is not released until the session is closed. This is especially important for long-time connection sessions.

To solve the problem, consider the following measures:

- Adjust the session lifecycle.
- Adjust the `wait_timeout` and `max_execution_time` of the connection pool.
- Use the system variable `max_prepared_stmt_count` to control the maximum number of prepared statements in a session.

`tidb_enable_rate_limit_action` is not configured properly

The system variable `tidb_enable_rate_limit_action` controls memory usage effectively when an SQL statement only reads data. When this variable is enabled and computing operations (such as join or aggregation operations) are required, memory usage might not be under the control of `tidb_mem_quota_query`, which increases the risk of OOM.

It is recommended that you disable this system variable. Since TiDB v6.3.0, this system variable is disabled by default.

10.2.2.3.3 Client side issues

If OOM occurs on the client side, investigate the following:

- Check the trend and speed on **Grafana TiDB Details > Server > Client Data Traffic** to see if there is a network blockage.
- Check whether there is an application OOM caused by wrong JDBC configuration parameters. For example, if the `defaultFetchSize` parameter for streaming read is incorrectly configured, it can cause data to be heavily accumulated on the client side.

10.2.2.4 Diagnostic information to be collected to troubleshoot OOM issues

To locate the root cause of an OOM issue, you need to collect the following information:

- Collect the memory-related configurations of the operating system:
  - TiUP configuration: `resource_control.memory_limit`
  - Operating system configurations:
    * Memory information: `cat /proc/meminfo`
    * Kernel parameters: `vm.overcommit_memory`
  - NUMA information:
    * `numactl --hardware`
    * `numactl --show`
- Collect the version information and the memory-related configurations of the database:
  - TiDB version
  - `tidb_mem_quota_query`
  - `memory-usage-alarm-ratio`
  - `mem-quota-query`
  - `oom-action`
  - `tidb_enable_rate_limit_action`
  - `server-memory-quota`
  - `oom-use-tmp-storage`
  - `tmp-storage-path`
  - `tmp-storage-quota`
  - `tidb_analyze_version`
- Check the daily usage of TiDB memory on the Grafana dashboard: **TiDB** > **Server** > **Memory Usage**.
- Check the SQL statements that consume more memory.
  - View SQL statement analysis, slow queries, and memory usage on the TiDB Dashboard.
  - Check `SLOW_QUERY` and `CLUSTER_SLOW_QUERY` in `INFORMATION_SCHEMA`.
  - Check `tidb_slow_query.log` on each TiDB node.
  - Run `grep "expensive_query" tidb.log` to check the corresponding log entries.
  - Run `EXPLAIN ANALYZE` to check the memory usage of operators.
  - Run `SELECT * FROM information_schema.processlist;` to check the value of the `MEM` column.
- Run the following command to collect the TiDB Profile information when memory usage is high:

```
curl -G http://{TiDBIP}:10080/debug/zip?seconds=10" > profile.zip
```

- Run `grep "tidb-server has the risk of OOM" tidb.log` to check the path of the alert file collected by TiDB Server. The following is an example output:

```
["tidb-server has the risk of OOM. Running SQLs and heap profile will
    ↪ be recorded in record path"] ["is server-memory-quota set"=false]
    ↪  ["system memory total"=14388137984] ["system memory usage
    ↪ "=11897434112] ["tidb-server memory usage"=11223572312] [memory-
    ↪ usage-alarm-ratio=0.8] ["record path"="/tmp/0_tidb/
    ↪ MC4wLjAuMDoOMDAwLzAuMC4wLjA6MTAwODA=/tmp-storage/record"]
```

10.2.3 Troubleshoot Hotspot Issues

This document describes how to locate and resolve the problem of read and write hotspots.

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency.

10.2.3.1 Common hotspots

This section describes TiDB encoding rules, table hotspots, and index hotspots.

10.2.3.1.1 TiDB encoding rules

TiDB assigns a TableID to each table, an IndexID to each index, and a RowID to each row. By default, if the table uses an integer primary key, the value of the primary key is treated as the RowID. Among these IDs, TableID is unique in the entire cluster, while IndexID and RowID are unique in the table. The type of all these IDs is int64.

Each row of data is encoded as a key-value pair according to the following rule:

```
Key: tablePrefix{tableID}_recordPrefixSep{rowID}
Value: [col1, col2, col3, col4]
```

The `tablePrefix` and `recordPrefixSep` of the key are specific string constants, used to distinguish from other data in the KV space.

For Index data, the key-value pair is encoded according to the following rule:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: rowID
```

Index data has two types: the unique index and the non-unique index.

- For unique indexes, you can follow the coding rules above.
- For non-unique indexes, a unique key cannot be constructed through this encoding, because the `tablePrefix{tableID}_indexPrefixSep{indexID}` of the same index is the same and the `ColumnsValue` of multiple rows might be the same. The encoding rule for non-unique indexes is as follows:

  ```
  Key: tablePrefix{tableID}_indexPrefixSep{indexID}
      ↪ _indexedColumnsValue_rowID
  Value: null
  ```

10.2.3.1.2 Table hotspots

According to TiDB coding rules, the data of the same table is in a range prefixed by the beginning of the TableID, and the data is arranged in the order of RowID values. When RowID values are incremented during table inserting, the inserted line can only be appended to the end. The Region will split after it reaches a certain size, and then it still can only be appended to the end of the range. The `INSERT` operation can only be executed on one Region, forming a hotspot.

The common auto-increment primary key is sequentially increasing. When the primary key is of the integer type, the value of the primary key is used as the RowID by default. At this time, the RowID is sequentially increasing, and a write hotspot of the table forms when a large number of `INSERT` operations exist.

Meanwhile, the RowID in TiDB is also sequentially auto-incremental by default. When the primary key is not an integer type, you might also encounter the problem of write hotspots.

In addition, when hotspots occur during the process of data writes (on a newly created table or partition) or data reads (periodic read hotspots in read-only scenarios), you can control the Region merge behavior using table attributes. For details, see Control the Region merge behavior using table attributes.

10.2.3.1.3 Index hotspots

Index hotspots are similar to table hotspots. Common index hotspots appear in fields that are monotonously increasing in time order, or `INSERT` scenarios with a large number of repeated values.

10.2.3.2 Identify hotspot issues

Performance problems are not necessarily caused by hotspots and might be caused by multiple factors. Before troubleshooting issues, confirm whether it is related to hotspots.

- To judge write hotspots, open **Hot Write** in the **TiKV-Trouble-Shooting** monitoring panel to check whether the Raftstore CPU metric value of any TiKV node is significantly higher than that of other nodes.
- To judge read hotspots, open **Thread_CPU** in the **TiKV-Details** monitoring panel to check whether the coprocessor CPU metric value of any TiKV node is particularly high.

10.2.3.2.1 Use TiDB Dashboard to locate hotspot tables

The **Key Visualizer** feature in TiDB Dashboard helps users narrow down hotspot troubleshooting scope to the table level. The following is an example of the thermal diagram shown by **Key Visualizer**. The horizontal axis of the graph is time, and the vertical axis are various tables and indexes. The brighter the color, the greater the load. You can switch the read or write flow in the toolbar.

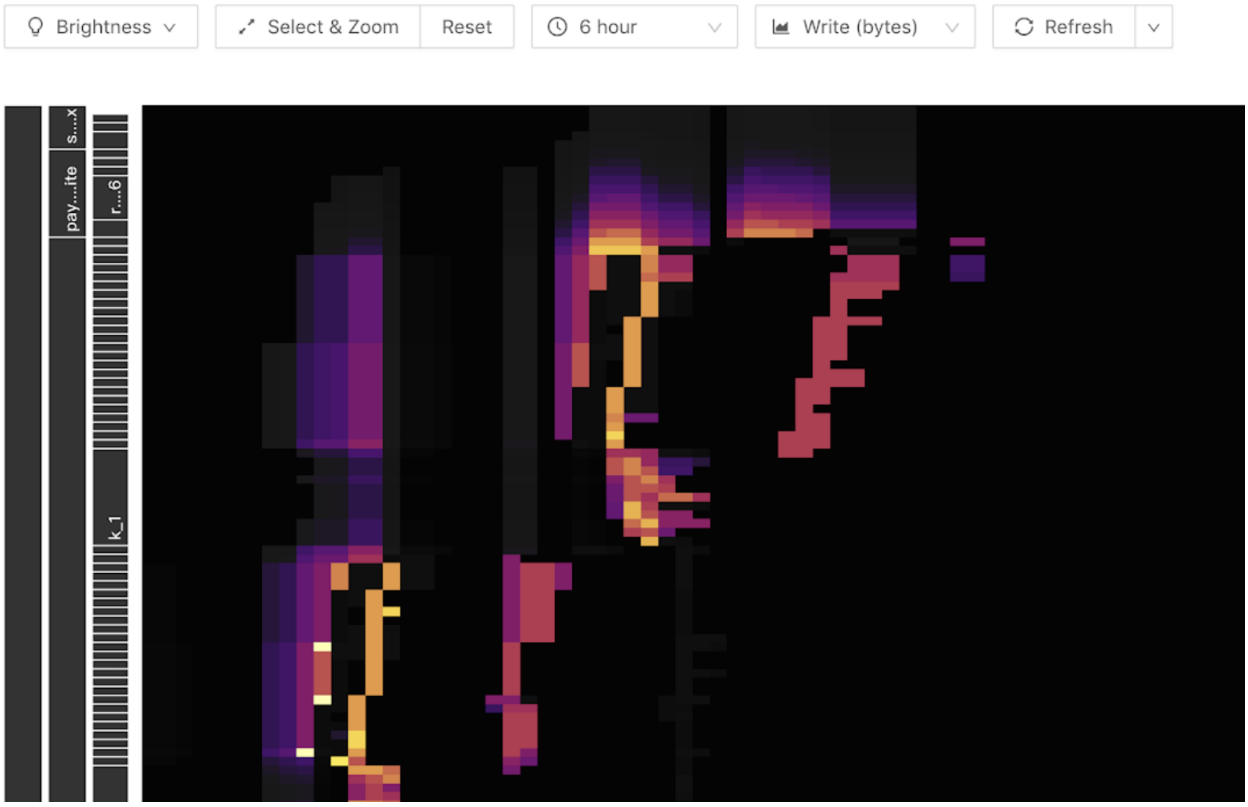

Figure 79: Dashboard Example 1

The following bright diagonal lines (oblique upward or downward) can appear in the write flow graph. Because the write only appears at the end, as the number of table Regions becomes larger, it appears as a ladder. This indicates that a write hotspot shows in this table:

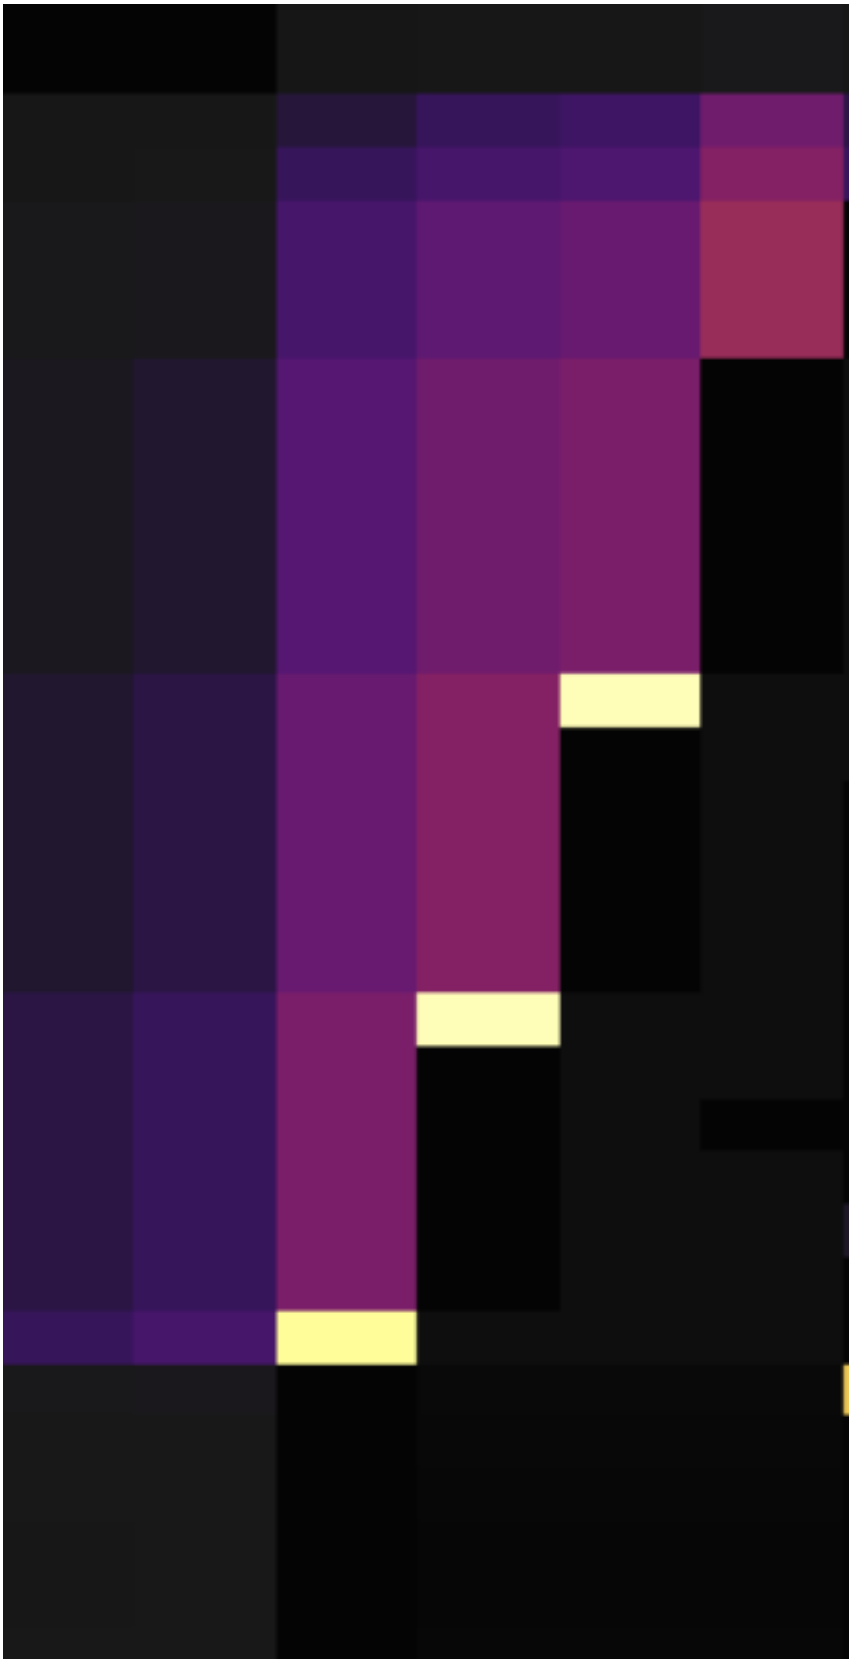

Figure 80: Dashboard Example 2

For read hotspots, a bright horizontal line is generally shown in the thermal diagram. Usually these are caused by small tables with a large number of accesses, shown as follows:

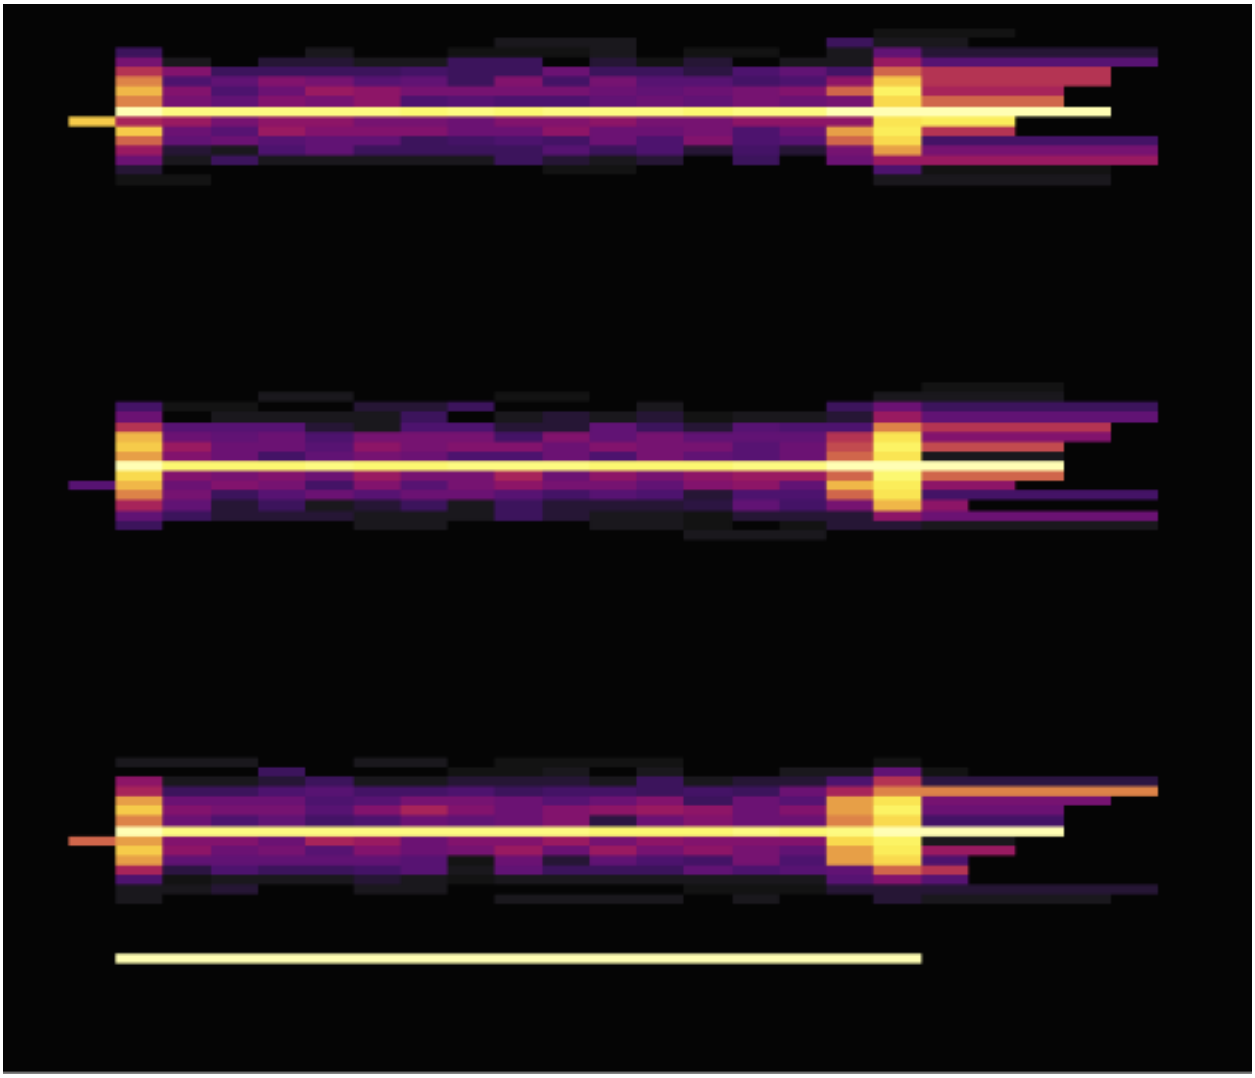

Figure 81: Dashboard Example 3

Hover over the bright block, you can see what table or index has a heavy load. For example:

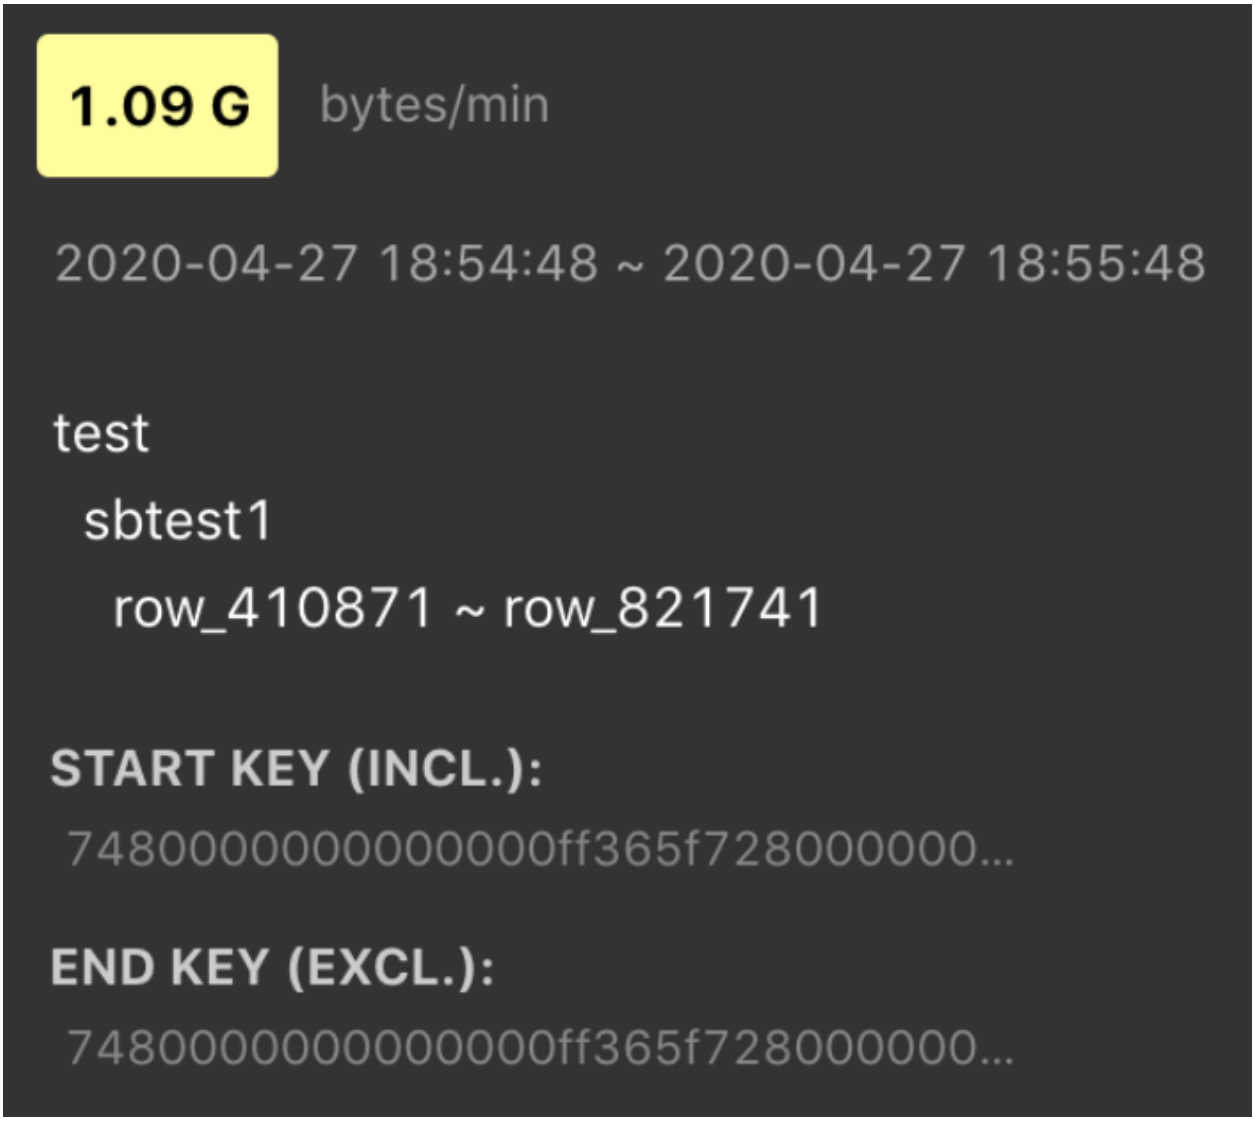

Figure 82: Dashboard Example 4

10.2.3.3 Use `SHARD_ROW_ID_BITS` to process hotspots

For a non-integer primary key or a table without a primary key or a joint primary key, TiDB uses an implicit auto-increment RowID. When a large number of `INSERT` operations exist, the data is written into a single Region, resulting in a write hotspot.

By setting `SHARD_ROW_ID_BITS`, row IDs are scattered and written into multiple Regions, which can alleviate the write hotspot issue.

```
SHARD_ROW_ID_BITS = 4 # Represents 16 shards.
SHARD_ROW_ID_BITS = 6 # Represents 64 shards.
SHARD_ROW_ID_BITS = 0 # Represents the default 1 shard.
```

Statement example:

```
CREATE TABLE: CREATE TABLE t (c int) SHARD_ROW_ID_BITS = 4;
ALTER TABLE: ALTER TABLE t SHARD_ROW_ID_BITS = 4;
```

The value of `SHARD_ROW_ID_BITS` can be dynamically modified. The modified value only takes effect for newly written data.

For the table with a primary key of the `CLUSTERED` type, TiDB uses the primary key of the table as the RowID. At this time, the `SHARD_ROW_ID_BITS` option cannot be used because it changes the RowID generation rules. For the table with the primary key of the `NONCLUSTERED` type, TiDB uses an automatically allocated 64-bit integer as the RowID. In this case, you can use the `SHARD_ROW_ID_BITS` feature. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

The following two load diagrams shows the case where two tables without primary keys use `SHARD_ROW_ID_BITS` to scatter hotspots. The first diagram shows the situation before scattering hotspots, while the second one shows the situation after scattering hotspots.

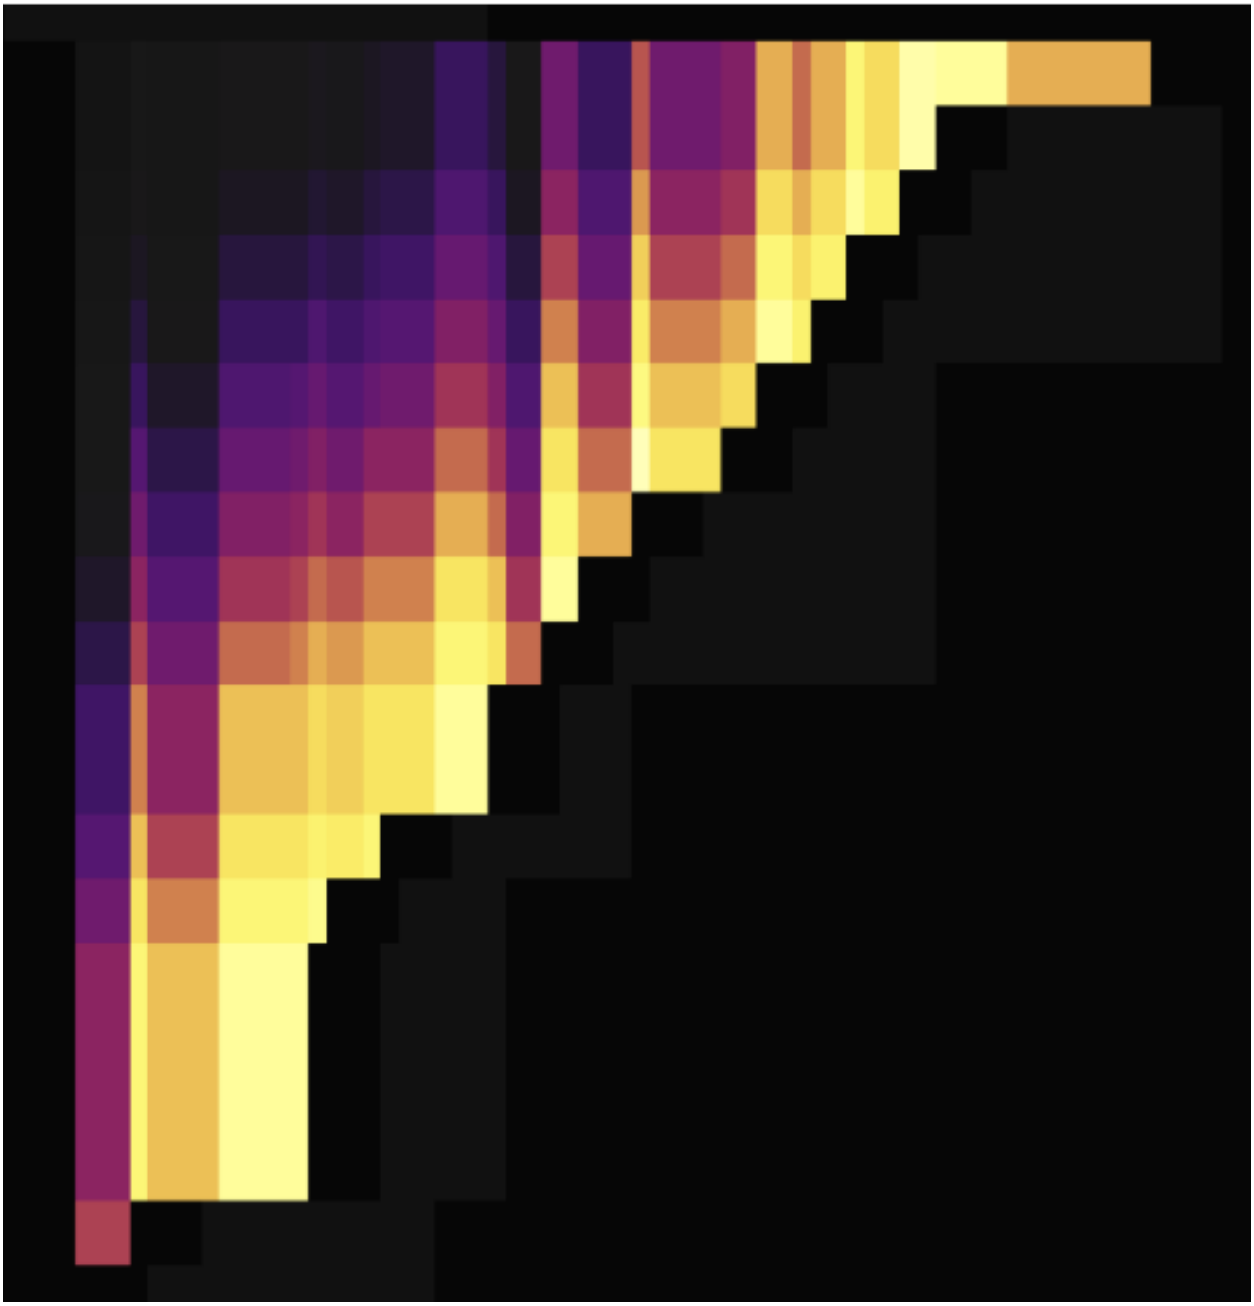

Figure 83: Dashboard Example 5

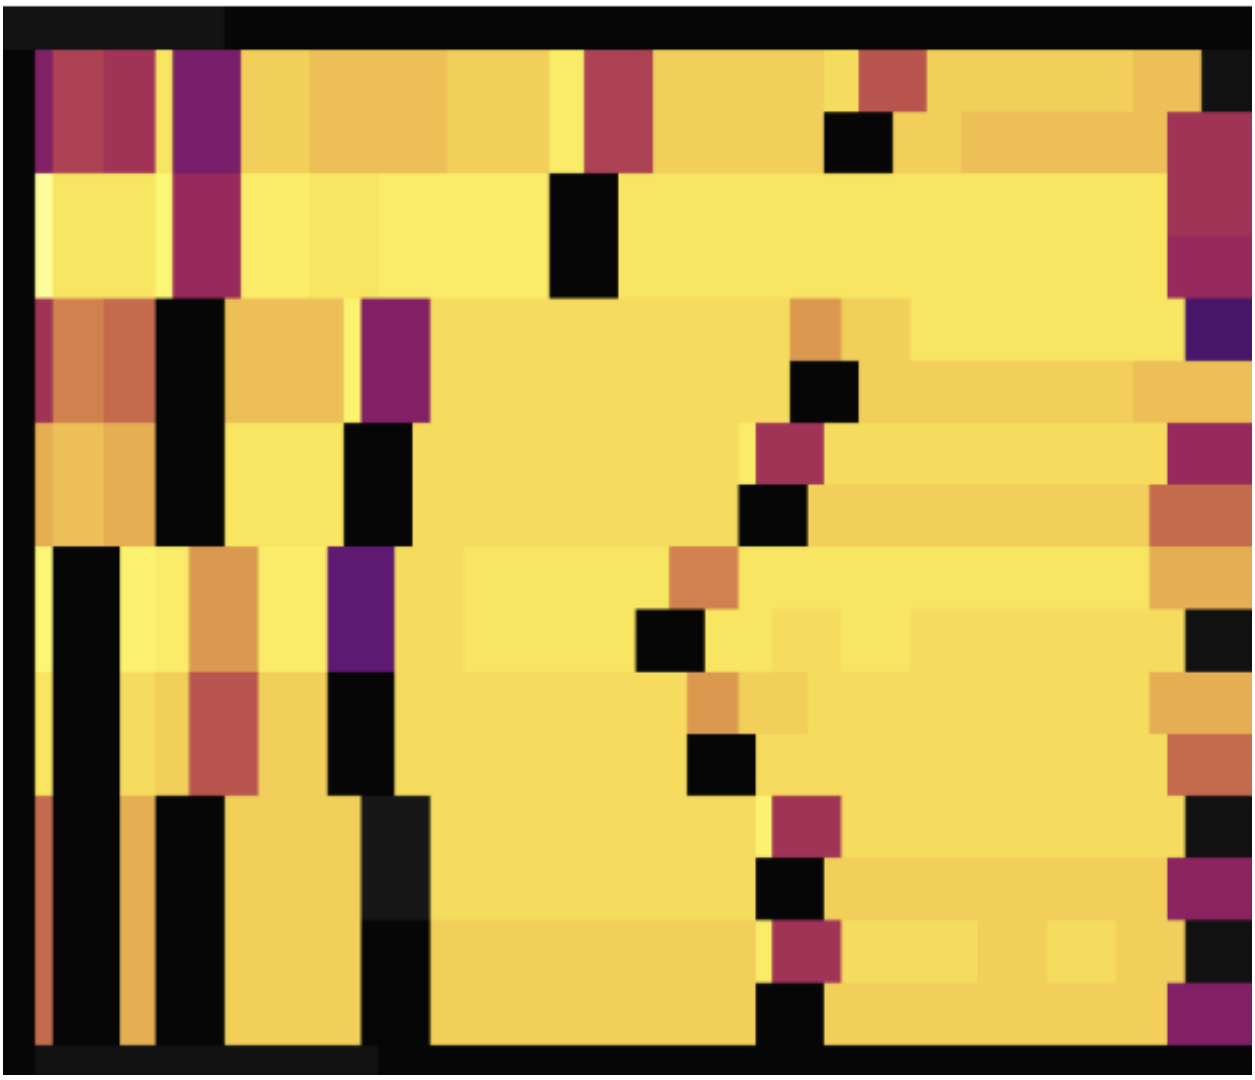

Figure 84: Dashboard Example 6

As shown in the load diagrams above, before setting `SHARD_ROW_ID_BITS`, load hotspots are concentrated on a single Region. After setting `SHARD_ROW_ID_BITS`, load hotspots become scattered.

10.2.3.4 Handle auto-increment primary key hotspot tables using `AUTO_RANDOM`

To resolve the write hotspots brought by auto-increment primary keys, use `AUTO_RANDOM` to handle hotspot tables that have auto-increment primary keys.

If this feature is enabled, TiDB generates randomly distributed and non-repeated (before the space is used up) primary keys to achieve the purpose of scattering write hotspots.

Note that the primary keys generated by TiDB are no longer auto-increment primary

keys and you can use `LAST_INSERT_ID()` to obtain the primary key value assigned last time.

To use this feature, modify `AUTO_INCREMENT` to `AUTO_RANDOM` in the `CREATE TABLE` statement. This feature is suitable for non-application scenarios where the primary keys only need to guarantee uniqueness.

For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b varchar(255));
INSERT INTO t (b) VALUES ("foo");
SELECT * FROM t;
```

```
+------------+---+
| a          | b |
+------------+---+
| 1073741825 | b |
+------------+---+
```

```
SELECT LAST_INSERT_ID();
```

```
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1073741825       |
+------------------+
```

The following two load diagrams shows the situations both before and after modifying `AUTO_INCREMENT` to `AUTO_RANDOM` to scatter hotspots. The first one uses `AUTO_INCREMENT`, while the second one uses `AUTO_RANDOM`.

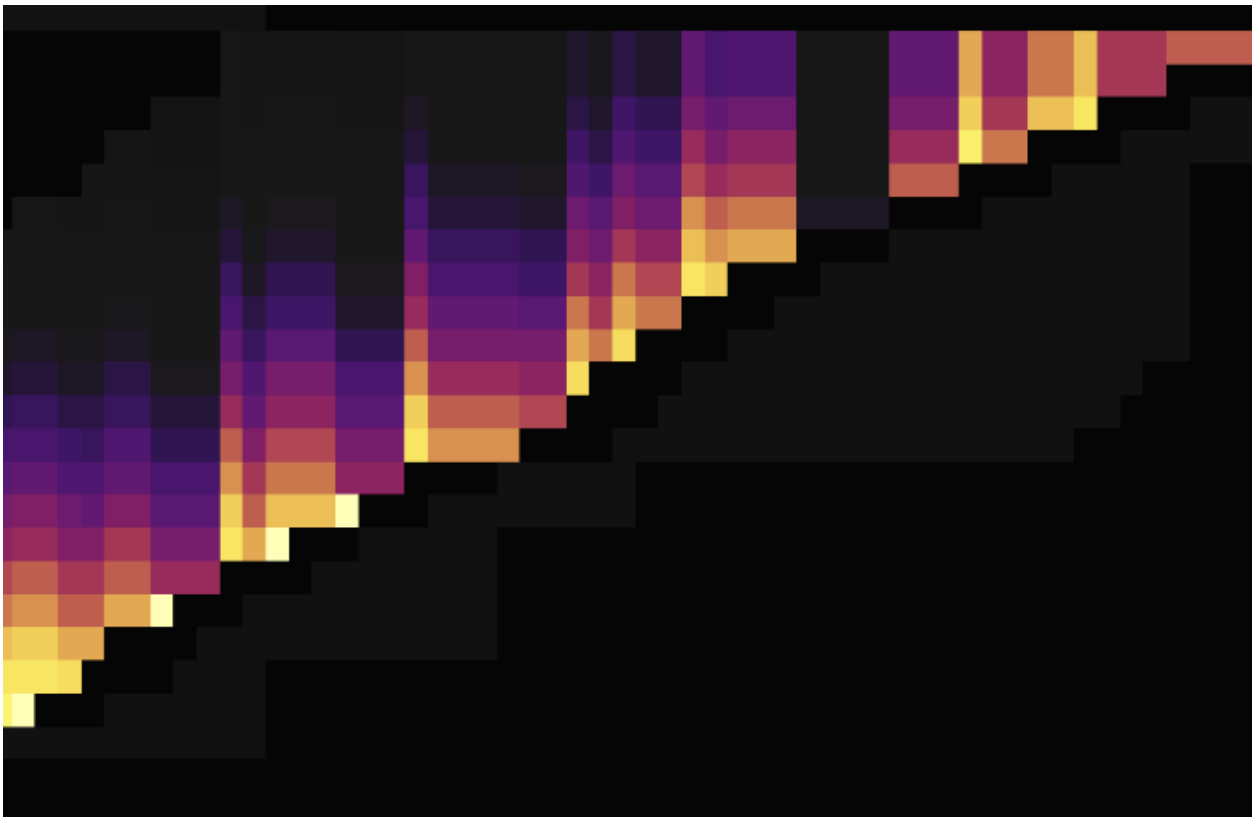

Figure 85: Dashboard Example 7

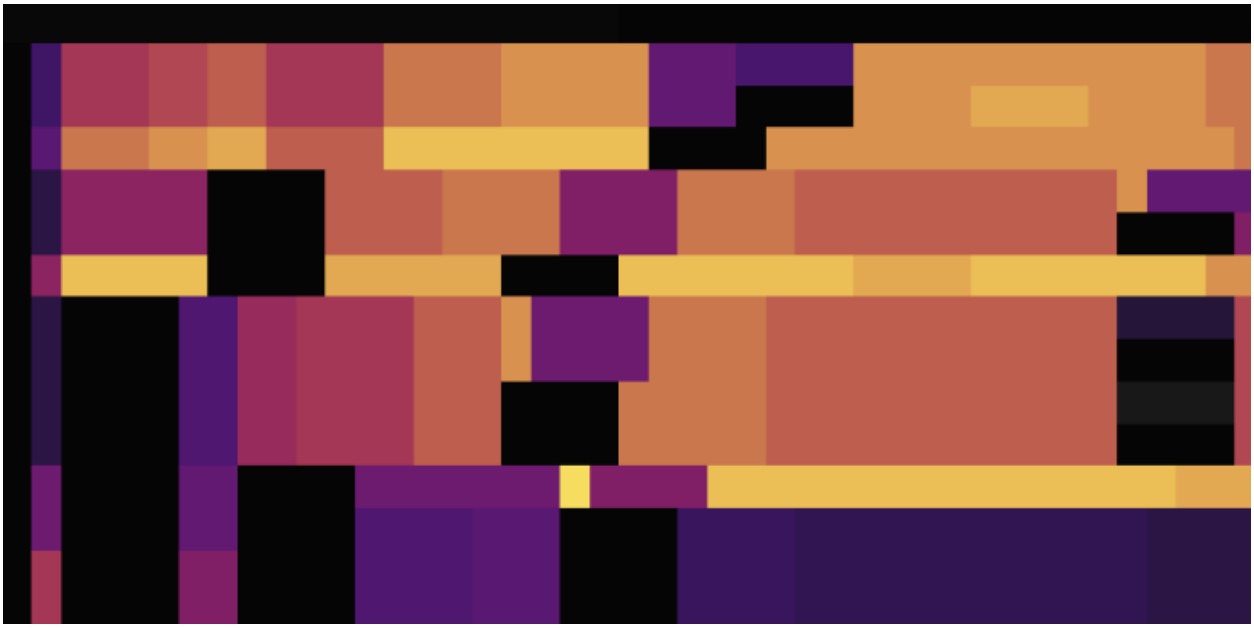

Figure 86: Dashboard Example 8

As shown in the load diagrams above, using `AUTO_RANDOM` to replace `AUTO_INCREMENT` can well scatter hotspots.

For more details, see AUTO_RANDOM.

10.2.3.5 Optimization of small table hotspots

The Coprocessor Cache feature of TiDB supports pushing down computing result caches. After this feature is enabled, TiDB caches the computing results that will be pushed down to TiKV. This feature works well for read hotspots of small tables.

For more details, see Coprocessor Cache.

10.2.4 Troubleshoot Increased Read and Write Latency

This document introduces the possible causes of read and write latency and jitters, and how to troubleshoot these issues.

10.2.4.1 Common causes

10.2.4.1.1 Incorrect TiDB execution plan

The execution plan of queries is unstable and might select the incorrect index, which causes higher latency.

Phenomenon

- If the query execution plan is output in the slow log, you can directly view the plan. Execute the `select tidb_decode_plan('xxx...')` statement to parse the detailed execution plan.
- The number of scanned keys in the monitor abnormally increases; in the slow log, the number of `Scan Keys` are large.
- The SQL execution duration in TiDB is greatly different than that in other databases such as MySQL. You can compare the execution plan of other databases (for example, whether `Join Order` is different).

Possible reason

The statistics is inaccurate.

Troubleshooting methods

- Update the statistical information

  - Execute `analyze table` manually and execute `analyze` periodically with the `crontab` command to keep the statistics accurate.
  - Execute `auto analyze` automatically. Lower the threshold value of `analyze ratio`, increase the frequency of information collection, and set the start and end time of the execution. See the following examples:
    * `set global tidb_auto_analyze_ratio=0.2;`
    * `set global tidb_auto_analyze_start_time='00:00 +0800';`
    * `set global tidb_auto_analyze_end_time='06:00 +0800';`

- Bind the execution plan
  - Modify the application SQL statements and execute `use index` to consistently use the index of the column.
  - In 3.0 versions, you do not need to modify the application SQL statements. Use `create global binding` to create the binding SQL statement of `force index`.
  - In 4.0 versions, SQL Plan Management is supported, which avoids the performance decrease caused by unstable execution plans.

10.2.4.1.2 PD anomalies

Phenomenon

There is an abnormal increase of the `wait duration` metric for the PD TSO. This metric represents the duration of waiting for PD to return requests.

Possible reasons

- Disk issue. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana** -> **disk performance** -> **latency/load**. You can also use the FIO tool to run a check on the disk if necessary.

- Network issues between PD peers. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana** -> **PD** -> **etcd**.

- High server load. The log shows `server is likely overloaded`.

- PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19.

- The leader election is slow. The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region-storage` to `true`, which significantly reduce the Region loading duration.

- The network issue between TiDB and PD. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana** -> **black-box_exporter** -> **ping latency**.
- PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040).
- When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that `TCP InSegs` is relatively large. This issue has been fixed in v3.0.6 (#1952).
- PD panics. Report a bug.
- Other causes. Get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

10.2.4.1.3 TiKV anomalies

Phenomenon

The `KV Cmd Duration` metric in the monitor increases abnormally. This metric represents the duration between the time that TiDB sends a request to TiKV and the time that TiDB receives the response.

Possible reasons

- Check the `gRPC duration` metric. This metric represents the total duration of a gRPC request in TiKV. You can find out the potential network issue by comparing `gRPC duration` of TiKV and `KV duration` of TiDB. For example, the gRPC duration is short but the KV duration of TiDB is long, which indicates that the network latency between TiDB and TiKV might be high, or that the NIC bandwidth between TiDB and TiKV is fully occupied.
- Re-election because TiKV is restarted.
  - After TiKV panics, it is pulled up by `systemd` and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
  - TiKV is stopped or killed by a third party and then pulled up by `systemd`. Check the cause by viewing `dmesg` and the TiKV log.
  - TiKV is OOM, which causes restart.
  - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage).
- Check monitor: TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`.

- Re-election because of network isolation.
- If the `block-cache` configuration is too large, it might cause TiKV OOM. To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**. Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"`parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.
- Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM. To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana** -> **TiKV-details** -> **coprocessor overview**.

10.2.4.1.4 Bottleneck of a single TiKV thread

There are some single threads in TiKV that might become the bottleneck.

- Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana** -> **TiKV-details** -> **Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue.
- For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana** -> **TiKV-details** -> **Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.

10.2.4.1.5 CPU load increases

Phenomenon

The usage of CPU resources becomes the bottleneck.

Possible reasons

- Hotspot issue
- High overall load. Check the slow queries and expensive queries of TiDB. Optimize the executing queries by adding indexes or executing queries in batches. Another solution is to scale out the cluster.

10.2.4.2 Other causes

10.2.4.2.1 Cluster maintenance

Most of each online cluster has three or five nodes. If the machine to be maintained has the PD component, you need to determine whether the node is the leader or the follower. Disabling a follower has no impact on the cluster operation. Before disabling a leader, you need to switch the leadership. During the leadership change, performance jitter of about 3 seconds will occur.

10.2.4.2.2 Minority of replicas are offline

By default, each TiDB cluster has three replicas, so each Region has three replicas in the cluster. These Regions elect the leader and replicate data through the Raft protocol. The Raft protocol ensures that TiDB can still provide services without data loss even when the nodes (that are fewer than half of replicas) fail or are isolated. For the cluster with three replicas, the failure of one node might cause performance jitter but the usability and correctness in theory are not affected.

10.2.4.2.3 New indexes

Creating indexes consumes a huge amount of resources when TiDB scans tables and backfills indexes. Index creation might even conflict with the frequently updated fields, which affects the application. Creating indexes on a large table often takes a long time, so you must try to balance the index creation time and the cluster performance (for example, creating indexes at the off-peak time).

Parameter adjustment:

Currently, you can use `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` ↪ to dynamically adjust the speed of index creation. Usually, the smaller the values, the smaller the impact on the system, with longer execution time though.

In general cases, you can first keep their default values (`4` and `256`), observe the resource usage and response speed of the cluster, and then increase the value of `tidb_ddl_reorg_worker_cnt` to increase the concurrency. If no obvious jitter is observed in the monitor, increase the value of `tidb_ddl_reorg_batch_size`. If the columns involved in the index creation are frequently updated, the many resulting conflicts will cause the index creation to fail and be retried.

In addition, you can also set the value of `tidb_ddl_reorg_priority` to `PRIORITY_HIGH` to prioritize the index creation and speed up the process. But in the general OLTP system, it is recommended to keep its default value.

10.2.4.2.4 High GC pressure

The transaction of TiDB adopts the Multi-Version Concurrency Control (MVCC) mechanism. When the newly written data overwrites the old data, the old data is not replaced, and both versions of data are stored. Timestamps are used to mark different versions. The task of GC is to clear the obsolete data.

- In the phase of Resolve Locks, a large amount of `scan_lock` requests are created in TiKV, which can be observed in the gRPC-related metrics. These `scan_lock` requests call all Regions.
- In the phase of Delete Ranges, a few (or no) `unsafe_destroy_range` requests are sent to TiKV, which can be observed in the gRPC-related metrics and the **GC tasks** panel.
- In the phase of Do GC, each TiKV by default scans the leader Regions on the machine and performs GC to each leader, which can be observed in the **GC tasks** panel.

10.2.5 Troubleshoot Write Conflicts in Optimistic Transactions

This document introduces the reason of and solutions to write conflicts in optimistic transactions.

Before TiDB v3.0.8, TiDB uses the optimistic transaction model by default. In this model, TiDB does not check conflicts during transaction execution. Instead, while the transaction is finally committed, the two-phase commit (2PC) is triggered and TiDB checks write conflicts. If a write conflict exists and the auto-retry mechanism is enabled, then TiDB retries the transaction within limited times. If the retry succeeds or has reached the upper limit on retry times, TiDB returns the result of transaction execution to the client. Therefore, if a lot of write conflicts exist in the TiDB cluster, the duration can be longer.

10.2.5.1 The reason of write conflicts

TiDB implements its transactions by using the Percolator transaction model. `percolator` is generally an implementation of 2PC. For the detailed 2PC process, see TiDB Optimistic Transaction Model.

After the client sends a `COMMIT` request to TiDB, TiDB starts the 2PC process:

1. TiDB chooses one key from all keys in the transaction as the primary key of the transaction.
2. TiDB sends the `prewrite` request to all the TiKV Regions involved in this commit. TiKV judges whether all keys can preview successfully.
3. TiDB receives the result that all `prewrite` requests are successful.
4. TiDB gets the `commit_ts` from PD.
5. TiDB sends the `commit` request to the TiKV Region that contains the primary key of the transaction. After TiKV receives the `commit` request, it checks the validity of the data and clears the locks left in the `prewrite` stage.
6. After the `commit` request returns successfully, TiDB returns success to the client.

The write conflict occurs in the `prewrite` stage. When the transaction finds that another transaction is writing the current key (`data.commit_ts` > `txn.start_ts`), a write conflict occurs.

10.2.5.2 Detect write conflicts

In the TiDB Grafana panel, check the following monitoring metrics under **KV Errors**:

- **KV Backoff OPS** indicates the count of error messages per second returned by TiKV.

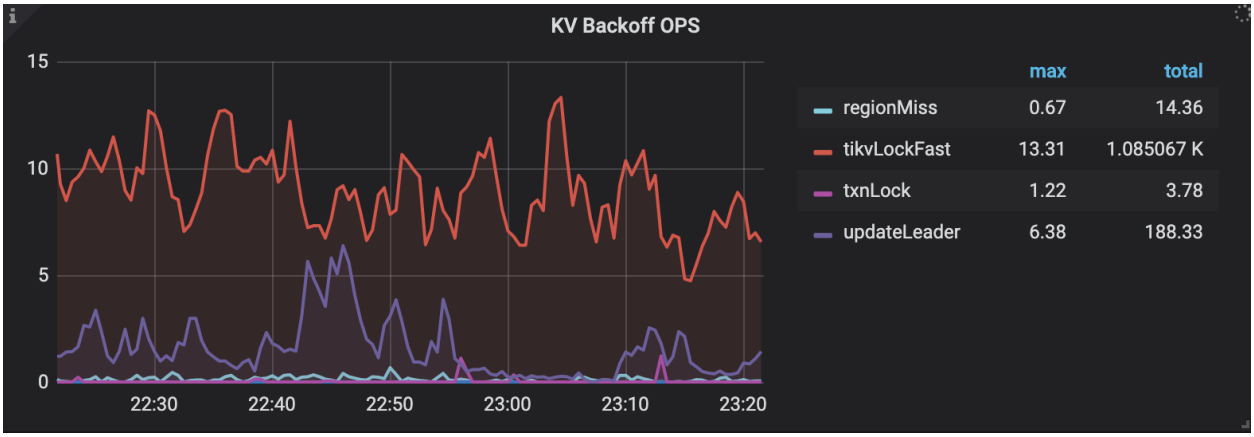

Figure 87: kv-backoff-ops

The `txnlock` metric indicates the write-write conflict. The `txnLockFast` metric indicates the read-write conflict.

- **Lock Resolve OPS** indicates the count of items related to transaction conflicts per second:

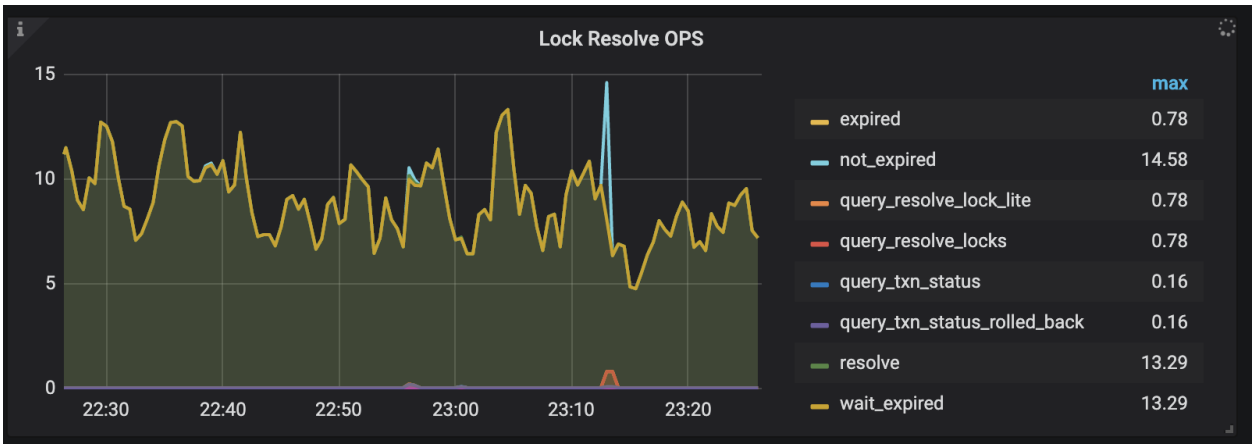

Figure 88: lock-resolve-ops

  - `not_expired` indicates the TTL of the lock was not expired. The conflict transaction cannot resolve locks until the TTL is expired.
  - `wait_expired` indicates that the transaction needs to wait the lock to expire.

  - `expired` indicates the TTL of the lock was expired. Then the conflict transaction can resolve this lock.

- **KV Retry Duration** indicates the duration of re-sends the KV request:

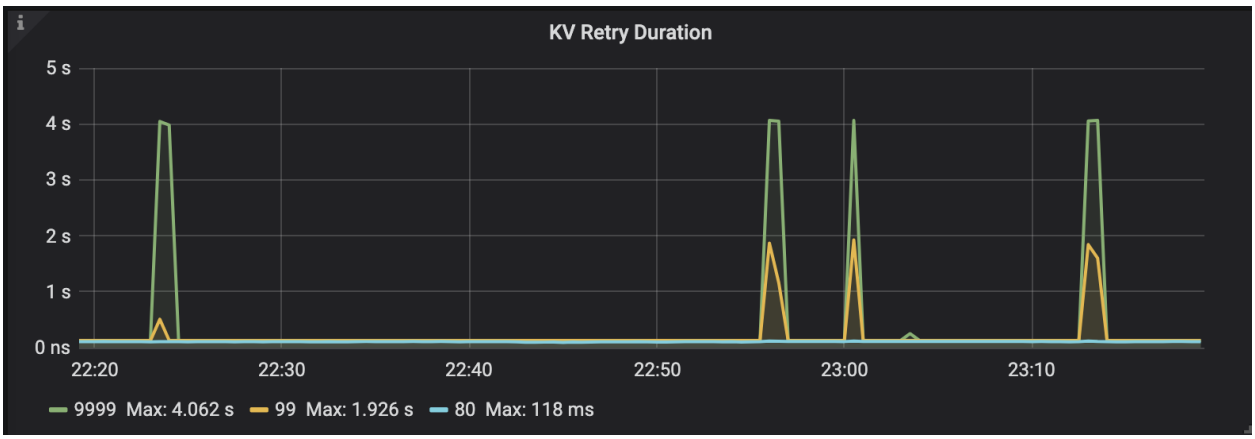

Figure 89: kv-retry-duration

You can also use `[kv:9007]Write conflict` as the keywords to search in the TiDB log. The keywords also indicate the write conflict exists in the cluster.

10.2.5.3 Resolve write conflicts

If many write conflicts exist in the cluster, it is recommended to find out the write conflict key and the reason, and then try to change the application logic to avoid write conflicts. When the write conflict exists in the cluster, you can see the log similar to the following one in the TiDB log file:

```
[2020/05/12 15:17:01.568 +08:00] [WARN] [session.go:446] ["commit failed"] [
    ↪ conn=3] ["finished txn"="Txn{state=invalid}"] [error="[kv:9007]Write
    ↪ conflict, txnStartTS=416617006551793665, conflictStartTS
    ↪ =416617018650001409, conflictCommitTS=416617023093080065, key={
    ↪ tableID=47, indexID=1, indexValues={string, }} primary={tableID=47,
    ↪ indexID=1, indexValues={string, }} [try again later]"]
```

The explanation of the log above is as follows:

- `[kv:9007]Write conflict`: indicates the write-write conflict.
- `txnStartTS=416617006551793665`: indicates the `start_ts` of the current transaction. You can use the `pd-ctl` tool to convert `start_ts` to physical time.
- `conflictStartTS=416617018650001409`: indicates the `start_ts` of the write conflict transaction.

- `conflictCommitTS=416617023093080065`: indicates the `commit_ts` of the write conflict transaction.
- `key={tableID=47, indexID=1, indexValues={string, }}`: indicates the write conflict key. `tableID` indicates the ID of the write conflict table. `indexID` indicates the ID of write conflict index. If the write conflict key is a record key, the log prints `handle=x`, indicating which record(row) has a conflict. `indexValues` indicates the value of the index that has a conflict.
- `primary={tableID=47, indexID=1, indexValues={string, }}`: indicates the primary key information of the current transaction.

You can use the `pd-ctl` tool to convert the timestamp to readable time:

```
tiup ctl:<cluster-version> pd -u https://127.0.0.1:2379 tso {TIMESTAMP}
```

You can use `tableID` to find the name of the related table:

```
curl http://{TiDBIP}:10080/db-table/{tableID}
```

You can use `indexID` and the table name to find the name of the related index:

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE TABLE_SCHEMA='{db_name}
    ↪ ' AND TABLE_NAME='{table_name}' AND INDEX_ID={indexID};
```

In addition, in TiDB v3.0.8 and later versions, the pessimistic transaction becomes the default mode. The pessimistic transaction mode can avoid write conflicts during the transaction prewrite stage, so you do not need to modify the application any more. In the pessimistic transaction mode, each DML statement writes a pessimistic lock to the related keys during execution. This pessimistic lock can prevent other transactions from modifying the same keys, thus ensuring no write conflicts exist in the `prewrite` stage of the transaction 2PC.

10.2.6 Troubleshoot High Disk I/O Usage in TiDB

This document introduces how to locate and address the issue of high disk I/O usage in TiDB.

10.2.6.1 Check the current I/O metrics

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck.

10.2.6.1.1 Locate I/O issues from monitor

The quickest way to locate I/O issues is to view the overall I/O status from the monitor, such as the Grafana dashboard which is deployed by default by TiUP. The dashboard panels related to I/O include **Overview**, **Node_exporter**, and **Disk-Performance**.

The first type of monitoring panels

In **Overview> System Info> IO Util**, you can see the I/O status of each machine in the cluster. This metric is similar to `util` in the Linux `iostat` monitor. The higher percentage represents higher disk I/O usage:

- If there is only one machine with high I/O usage in the monitor, currently there might be read and write hotspots on this machine.
- If the I/O usage of most machines in the monitor is high, the cluster now has high I/O loads.

For the first situation above (only one machine with high I/O usage), you can further observe I/O metrics from the **Disk-Performance Dashboard** such as `Disk Latency` and `Disk Load` to determine whether any anomaly exists. If necessary, use the fio tool to check the disk.

The second type of monitoring panels

The main storage component of the TiDB cluster is TiKV. One TiKV instance contains two RocksDB instances: one for storing Raft logs, located in `data/raft`, and the other for storing real data, located in `data/db`.

In **TiKV-Details > Raft IO**, you can see the metrics related to disk writes of these two instances:

- `Append log duration`: This metric indicates the response time of writes into RockDB that stores Raft logs. The `.99` response time should be within 50 ms.
- `Apply log duration`: This metric indicates the response time of writes into RockDB that stores real data. The `.99` response should be within 100 ms.

These two metrics also have the **.. per server** monitoring panel to help you view the write hotspots.

The third type of monitoring panels

In **TiKV-Details > Storage**, there are monitoring metrics related to storage:

- `Storage command total`: Indicates the number of different commands received.
- `Storage async write duration`: Includes monitoring metrics such as `disk sync` ↪ `duration`, which might be related to Raft I/O. If you encounter an abnormal situation, check the working statuses of related components by checking logs.

Other panels

In addition, some other panel metrics might help you determine whether the bottleneck is I/O, and you can try to set some parameters. By checking the prewrite/commit/raw-put (for raw key-value clusters only) of TiKV gRPC duration, you can determine that the bottleneck is indeed the slow TiKV write. The common situations of slow TiKV writes are as follows:

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which is often due to slow disk writes. You can check the value of `WAL Sync Duration max` in **RocksDB-raft** to determine the cause of slow `append log`. Otherwise, you might need to report a bug.

- The `raftstore` thread is busy. In TiKV Grafana, `Raft Propose/propose wait duration` is significantly higher than `append log duration`. Check the following aspects for troubleshooting:

  - Whether the value of `store-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1,5]` and not too large.
  - Whether the CPU resource of the machine is insufficient.

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which might usually occur along with relatively high `Raft Propose /apply wait duration`. The possible causes are as follows:

  - The value of `apply-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1, 5]` and not too large. The value of `Thread CPU /apply cpu` is also relatively high.
  - Insufficient CPU resources on the machine.
  - Write hotspot issue of a single Region (Currently, the solution to this issue is still on the way). The CPU usage of a single `apply` thread is high (which can be viewed by modifying the Grafana expression, appended with `by (instance, name)`).
  - Slow write into RocksDB, and `RocksDB kv/max write duration` is high. A single Raft log might contain multiple key-value pairs (kv). 128 kvs are written to RocksDB in a batch, so one `apply` log might involve multiple RocksDB writes.
  - For other causes, report them as bugs.

- `raft commit log` is slow. In TiKV Grafana, `Raft I/O` and `commit log duration` (only available in Grafana 4.x) metrics are relatively high. Each Region corresponds to an independent Raft group. Raft has a flow control mechanism similar to the sliding window mechanism of TCP. To control the size of a sliding window, adjust the `[raftstore] raft-max-inflight-msgs` parameter. If there is a write hotspot and `commit log duration` is high, you can properly set this parameter to a larger value, such as `1024`.

10.2.6.1.2 Locate I/O issues from log

- If the client reports errors such as `server is busy` or especially `raftstore is busy`, the errors might be related to I/O issues.

  You can check the monitoring panel (**Grafana** -> **TiKV** -> **errors**) to confirm the specific cause of the `busy` error. `server is busy` is TiKV's flow control mechanism. In this way, TiKV informs `tidb/ti-client` that the current pressure of TiKV is too high, and the client should try later.

- `Write stall` appears in TiKV RocksDB logs.

  It might be that too many level-0 SST files cause the write stall. To address the issue, you can add the `[rocksdb] max-sub-compactions = 2 (or 3)` parameter to speed up the compaction of level-0 SST files. This parameter means that the compaction tasks of level-0 to level-1 can be divided into `max-sub-compactions` subtasks for multi-threaded concurrent execution.

  If the disk's I/O capability fails to keep up with the write, it is recommended to scale up the disk. If the throughput of the disk reaches the upper limit (for example, the throughput of SATA SSD is much lower than that of NVMe SSD), which results in write stall, but the CPU resource is relatively sufficient, you can try to use a compression algorithm of higher compression ratio to relieve the pressure on the disk, that is, use CPU resources to make up for disk resources.

  For example, when the pressure of `default cf compaction` is relatively high, you can change the parameter `[rocksdb.defaultcf] compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd" , "zstd"]` to `compression-per-level = ["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

10.2.6.1.3 I/O issues found in alerts

The cluster deployment tool (TiUP) deploys the cluster with alert components by default that have built-in alert items and thresholds. The following alert items are related to I/O:

- TiKV_write_stall
- TiKV_raft_log_lag
- TiKV_async_request_snapshot_duration_seconds
- TiKV_async_request_write_duration_seconds
- TiKV_raft_append_log_duration_secs
- TiKV_raft_apply_log_duration_secs

10.2.6.2 Handle I/O issues

- When an I/O hotspot issue is confirmed to occur, you need to refer to Handle TiDB Hotspot Issues to eliminate the I/O hotspots.
- When it is confirmed that the overall I/O performance has become the bottleneck, and you can determine that the I/O performance will keep falling behind in the application side, then you can take advantage of the distributed database's capability of scaling and increase the number of TiKV nodes to have greater overall I/O throughput.
- Adjust some of the parameters as described above, and use computing/memory resources to make up for disk storage resources.

10.2.7 Troubleshoot Lock Conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. This document describes

how to use Lock View to troubleshoot lock issues and how to deal with common lock conflict issues in optimistic and pessimistic transactions.

10.2.7.1 Use Lock View to troubleshoot lock issues

Since v5.1, TiDB supports the Lock View feature. This feature has several system tables built in `information_schema` that provide more information about the lock conflicts and lock waitings.

> **Note:**
>
> Currently, the Lock View feature provides conflict and waiting information for pessimistic locks only.

For the detailed introduction of these tables, see the following documents:

- `TIDB_TRX` and `CLUSTER_TIDB_TRX`: Provides information of all running transactions on the current TiDB node or in the entire cluster, including whether the transaction is in the lock-waiting state, the lock-waiting time, and the digests of statements that have been executed in the transaction.
- `DATA_LOCK_WAITS`: Provides the pessimistic lock-waiting information in TiKV, including the `start_ts` of the blocking and blocked transaction, the digest of the blocked SQL statement, and the key on which the waiting occurs.
- `DEADLOCKS` and `CLUSTER_DEADLOCKS`: Provides the information of several deadlock events that have recently occurred on the current TiDB node or in the entire cluster, including the waiting relationship among transactions in the deadlock loops, the digest of the statement currently being executed in the transaction, and the key on which the waiting occurs.

> **Note:**
>
> The SQL statements shown in the Lock View-related system tables are normalized SQL statements (that is, SQL statements without formats and arguments), which are obtained by internal queries according to SQL digests, so the tables cannot obtain the complete statements that include the format and arguments. For the detailed description of SQL digests and normalized SQL statement, see Statement Summary Tables.

The following sections show the examples of troubleshooting some issues using these tables.

10.2.7.1.1 Deadlock errors

To get the information of the recent deadlock errors, you can query the `DEADLOCKS` or `CLUSTER_DEADLOCKS` table.

For example, to query the `DEADLOCKS` table, you can execute the following SQL statement:

```
select * from information_schema.deadlocks;
```

The following is an example output:

```
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
| DEADLOCK_ID | OCCUR_TIME                 | RETRYABLE | TRY_LOCK_TRX_ID |
    ↪ CURRENT_SQL_DIGEST                                  |
    ↪ CURRENT_SQL_DIGEST_TEXT              | KEY
    ↪                                  | KEY_INFO
    ↪
    ↪ | TRX_HOLDING_LOCK |
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
|           1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406216 |

+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
```

The query result above shows the waiting relationship among multiple transactions in the deadlock error, the normalized form of the SQL statements currently being executed in each transaction (statements without formats and arguments), the key on which the conflict occurs, and the information of the key.

For example, in the above example, the first row means that the transaction with the ID of `426812829645406216` is executing a statement like `update `t` set `v` =? Where `id ↪ ` =? ;` but is blocked by another transaction with the ID of `426812829645406217`. The

transaction with the ID of 426812829645406217 is also executing a statement that is in the form of `update `t` set `v` =? Where `id` =? ;` but is blocked by the transaction with the ID of 426812829645406216. The two transactions thus form a deadlock.

10.2.7.1.2 A few hot keys cause queueing locks

The `DATA_LOCK_WAITS` system table provides the lock-waiting status on the TiKV nodes. When you query this table, TiDB automatically obtains the real-time lock-waiting information from all TiKV nodes. If a few hot keys are frequently locked and block many transactions, you can query the `DATA_LOCK_WAITS` table and aggregate the results by key to try to find the keys on which issues frequently occur:

```
select `key`, count(*) as `count` from information_schema.data_lock_waits
    ↪ group by `key` order by `count` desc;
```

The following is an example output:

```
+----------------------------------------+-------+
| key                                    | count |
+----------------------------------------+-------+
| 748000000000000415F728000000000000001 | 2 |
| 748000000000000415F728000000000000002 | 1 |
+----------------------------------------+-------+
```

To avoid contingency, you might need to make multiple queries.

If you know the key that frequently has issues occurred, you can try to get the information of the transaction that tries to lock the key from the `TIDB_TRX` or `CLUSTER_TIDB_TRX` table.

Note that the information displayed in the `TIDB_TRX` and `CLUSTER_TIDB_TRX` tables is also the information of the transactions that are running at the time the query is performed. These tables do not display the information of the completed transactions. If there is a large number of concurrent transactions, the result set of the query might also be large. You can use the `limit` clause or the `where` clause to filter transactions with a long lock-waiting time. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

For example, to filter transactions with a long lock-waiting time using the `where` clause, you can execute the following SQL statement:

```
select trx.* from information_schema.data_lock_waits as l left join
    ↪ information_schema.tidb_trx as trx on l.trx_id = trx.id where l.key =
    ↪  "748000000000000415F728000000000000001"\G
```

The following is an example output:

```
*************************** 1. row ***************************

10.2.7.1.3 A transaction is blocked for a long time

If a transaction is known to be blocked by another transaction (or multiple transactions) and the `start_ts` (transaction ID) of the current transaction is known, you can use the following method to obtain the information of the blocking transaction. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```
select l.key, trx.*, tidb_decode_sql_digests(trx.all_sql_digests) as sqls
   ↪ from information_schema.data_lock_waits as l join information_schema.
```

```
    ↪ cluster_tidb_trx as trx on l.current_holding_trx_id = trx.id where l.
    ↪ trx_id = 426831965449355272\G
```

The following is an example output:

```
*************************** 1. row ***************************
                  key: 74800000000000004D5F728000000000000001

                    ↪ update ;","update `t` set `v` = `v` + ? where `id` =
                    ↪ ? ;"]
1 row in set (0.01 sec)
```

In the above query, the TIDB_DECODE_SQL_DIGESTS function is used on the ALL_SQL_DIGESTS column of the CLUSTER_TIDB_TRX table. This function tries to convert this column (the value is a set of SQL digests) to the normalized SQL statements, which improves readability.

If the start_ts of the current transaction is unknown, you can try to find it out from the information in the TIDB_TRX / CLUSTER_TIDB_TRX table or in the PROCESSLIST / CLUSTER_PROCESSLIST table.

10.2.7.2 Troubleshoot optimistic lock conflicts

This section provides the solutions of common lock conflict issues in the optimistic transaction mode.

10.2.7.2.1 Read-write conflicts

As the TiDB server receives a read request from a client, it gets a globally unique and increasing timestamp at the physical time as the start_ts of the current transaction. The transaction needs to read the latest data before start_ts, that is, the target key of the latest commit_ts that is smaller than start_ts. When the transaction finds that the target key is locked by another transaction, and it cannot know which phase the other transaction is in, a read-write conflict happens. The diagram is as follows:

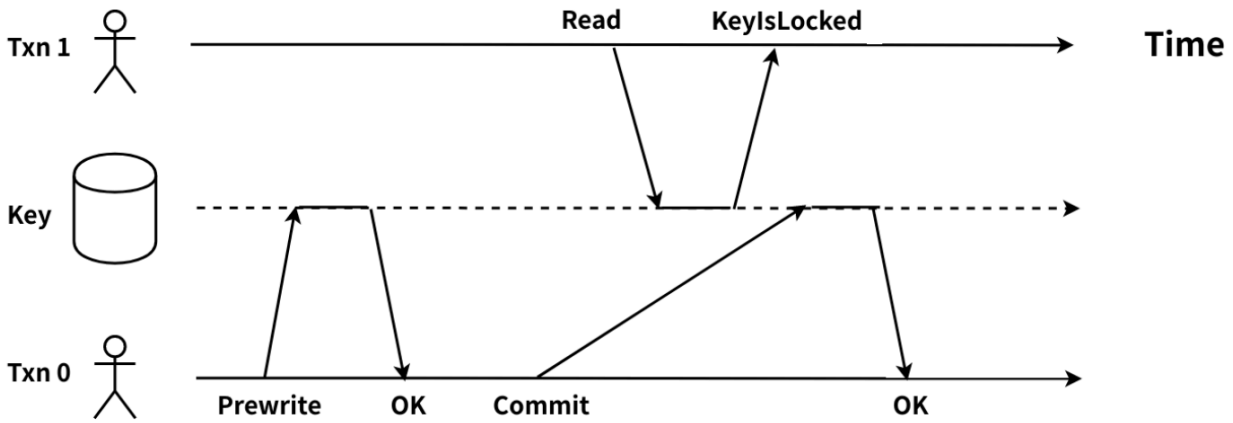

Figure 90: read-write conflict

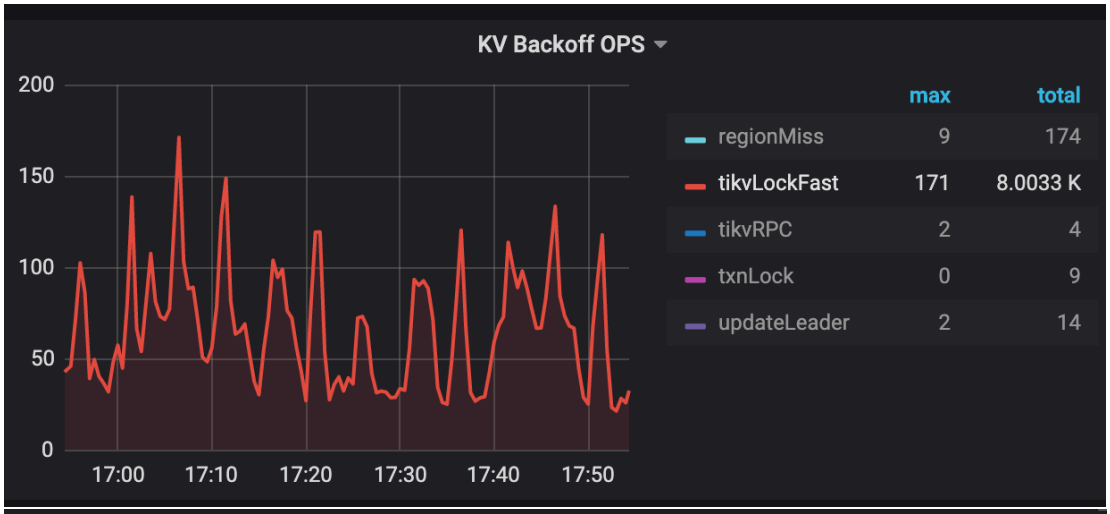
Txn0 completes the Prewrite phase and enters the Commit phase. At this time, Txn1 requests to read the same target key. Txn1 needs to read the target key of the latest commit_ts that is smaller than its start_ts. Because Txn1's start_ts is larger than Txn0's lock_ts, Txn1 must wait for the target key's lock to be cleared, but it hasn't been done. As a result, Txn1 cannot confirm whether Txn0 has been committed or not. Thus, a read-write conflict between Txn1 and Txn0 happens.

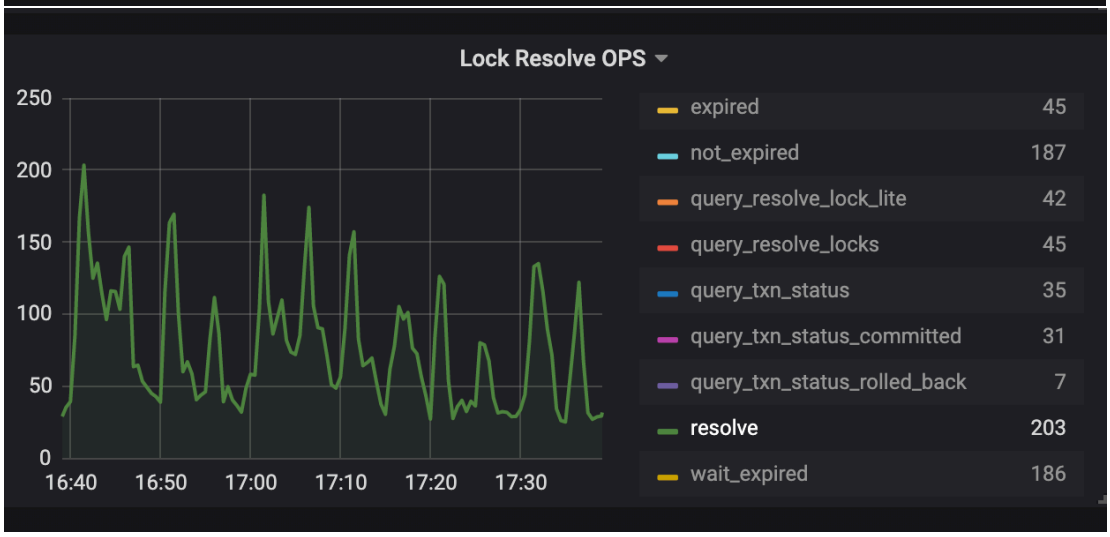
You can detect the read-write conflict in your TiDB cluster by the following ways:

1. Monitoring metrics and logs of the TiDB server

    - Monitoring data through Grafana

      In the `KV Errors` panel in the TiDB dashboard, `not_expired/resolve` in `Lock Resolve OPS` and `tikvLockFast` in `KV Backoff OPS` are monitoring metrics that can be used to check read-write conflicts in transactions. If the values of all the metrics increase, there might be many read-write conflicts. The `not_expired` item means that the transaction's lock has not timed out. The `resolve` item means that the other transaction tries to clean up the locks. The `tikvLockFast` item means that read-write conflicts occur.





- Logs of the TiDB server

  If there is any read-write conflict, you can see the following message in the TiDB log:

```
[INFO] [coprocessor.go:743] ["[TIME_COP_PROCESS] resp_time
    ↪ :406.038899ms txnStartTS:416643508703592451 region_id:8297
    ↪ store_addr:10.8.1.208:20160 backoff_ms:255 backoff_types:[
    ↪ txnLockFast,txnLockFast] kv_process_ms:333 scan_total_write
    ↪ :0 scan_processed_write:0 scan_total_data:0
    ↪ scan_processed_data:0 scan_total_lock:0 scan_processed_lock
    ↪ :0"]
```

  - txnStartTS: The start_ts of the transaction that is sending the read request. In the above log, `416643508703592451` is the start_ts.
  - backoff_types: If a read-write conflict happens, and the read request performs backoff and retry, the type of retry is `TxnLockFast`.
  - backoff_ms: The time that the read request spends in the backoff and retry, and the unit is milliseconds. In the above log, the read request spends 255

milliseconds in the backoff and retry.
  - region_id: Region ID corresponding to the target key of the read request.

2. Logs of the TiKV server

   If there is any read-write conflict, you can see the following message in the TiKV log:

```
[ERROR] [endpoint.rs:454] [error-response] [err=""locked primary_lock
    ↪ :7480000000000004
    ↪ D35F698000000000000010380000000004C788E0380000000004C0748
    ↪ lock_version: 411402933858205712 key: 7480000000000004
    ↪ D35F7280000000004C0748 lock_ttl: 3008 txn_size: 1""]
```

   This message indicates that a read-write conflict occurs in TiDB. The target key of the read request has been locked by another transaction. The locks are from the uncommitted optimistic transaction and the uncommitted pessimistic transaction after the prewrite phase.

   - primary_lock: Indicates that the target key is locked by the primary lock.
   - lock_version: The start_ts of the transaction that owns the lock.
   - key: The target key that is locked.
   - lock_ttl: The lock's TTL (Time To Live)
   - txn_size: The number of keys that are in the Region of the transaction that owns the lock.

Solutions:

- A read-write conflict triggers an automatic backoff and retry. As in the above example, Txn1 has a backoff and retry. The first time of the retry is 10 ms, the longest retry is 3000 ms, and the total time is 20000 ms at maximum.
- You can use the sub-command `decoder` of TiDB Control to view the table id and rowid of the row corresponding to the specified key:

```
./tidb-ctl decoder -f table_row -k "t\x00\x00\x00\x00\x00\x00\x00\x1c_r
    ↪ \x00\x00\x00\x00\x00\x00\x00\xfa"

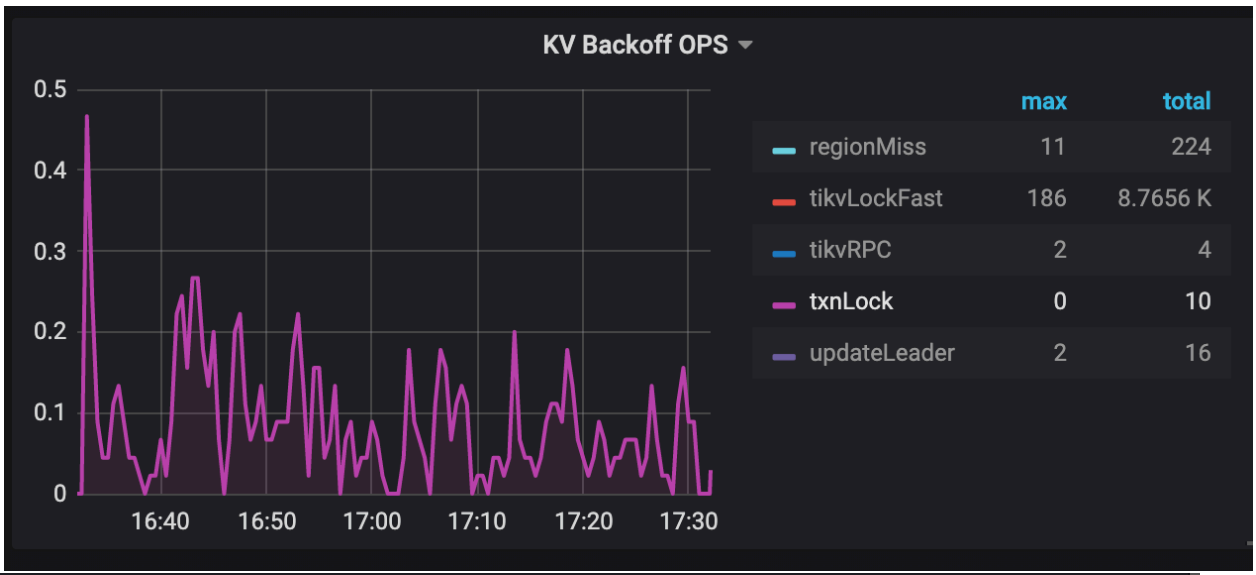
table_id: -9223372036854775780
row_id: -9223372036854775558
```

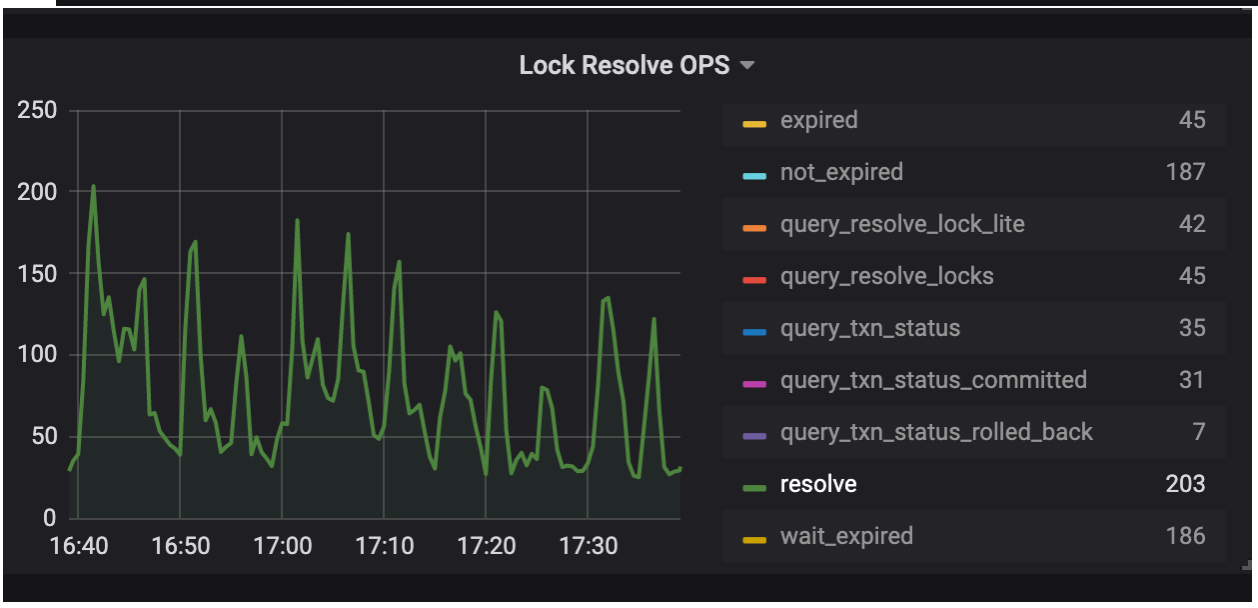
10.2.7.2.2 KeyIsLocked error

In the Prewrite phase of a transaction, TiDB checks whether there is any write-write conflict, and then checks whether the target key has been locked by another transaction. If the key is locked, the TiKV server outputs a "KeyIsLocked" error. At present, the error message is not printed in the logs of TiDB and TiKV. Same as read-write conflicts, when "KeyIsLocked" occurs, TiDB automatically performs backoff and retry for the transaction.

You can check whether there's any "KeyIsLocked" error in the TiDB monitoring on Grafana:

The `KV Errors` panel in the TiDB dashboard has two monitoring metrics `Lock Resolve OPS` and `KV Backoff OPS` which can be used to check write-write conflicts caused by a transaction. If the `resolve` item under `Lock Resolve OPS` and the `txnLock` item under `KV Backoff OPS` have a clear upward trend, a "KeyIsLocked" error occurs. `resolve` refers to the operation that attempts to clear the lock, and `txnLock` represents a write conflict.





Solutions:

- If there is a small amount of txnLock in the monitoring, no need to pay too much attention. The backoff and retry is automatically performed in the background. The first time of the retry is 100 ms and the maximum time is 3000 ms for a single retry.

- If there are too many "txnLock" operations in the `KV Backoff OPS`, it is recommended that you analyze the reasons to the write conflicts from the application side.
- If your application is a write-write conflict scenario, it is strongly recommended to use the pessimistic transaction mode.

10.2.7.2.3 LockNotFound error

The error log of "TxnLockNotFound" means that transaction commit time is longer than the the TTL time, and when the transaction is going to commit, its lock has been rolled back by other transactions. If the TiDB server enables transaction commit retry, this transaction is re-executed according to tidb_retry_limit. (Note about the difference between explicit and implicit transactions.)

You can check whether there is any "LockNotFound" error in the following ways:

1. View the logs of the TiDB server

   If a "TxnLockNotFound" error occurs, the TiDB log message is like this:

```
[WARN] [session.go:446] ["commit failed"] [conn=149370] ["finished txn
    ↪ "="Txn{state=invalid}"] [error="[kv:6]Error: KV error safe to
    ↪ retry tikv restarts txn: Txn(Mvcc(TxnLockNotFound{ start_ts:
    ↪ 412720515987275779, commit_ts: 412720519984971777, key: [116,
    ↪ 128, 0, 0, 0, 0, 1, 111, 16, 95, 114, 128, 0, 0, 0, 0, 0, 0, 2]
    ↪ })) [try again later]"]
```

   - start_ts: The start_ts of the transaction that outputs the `TxnLockNotFound` error because its lock has been rolled back by other transactions. In the above log, `412720515987275779` is the start_ts.
   - commit_ts: The commit_ts of the transaction that outputs the `TxnLockNotFound` ↪ error. In the above log, `412720519984971777` is the commit_ts.

2. View the logs of the TiKV server

   If a "TxnLockNotFound" error occurs, the TiKV log message is like this:

```
Error: KV error safe to retry restarts txn: Txn(Mvcc(TxnLockNotFound))
    ↪ [ERROR [Kv.rs:708] ["KvService::batch_raft send response fail"] [
    ↪ err=RemoteStoped]
```

   Solutions:

- By checking the time interval between start_ts and commit_ts, you can confirm whether the commit time exceeds the TTL time.

  Checking the time interval using the PD control tool:

```
tiup ctl:<cluster-version> pd tso [start_ts]
tiup ctl:<cluster-version> pd tso [commit_ts]
```

- It is recommended to check whether the write performance is slow, which might cause that the efficiency of transaction commit is poor, and thus the lock is cleared.
- In the case of disabling the TiDB transaction retry, you need to catch the exception on the application side and try again.

10.2.7.3 Troubleshoot pessimistic lock conflicts

This section provides the solutions of common lock conflict issues in the pessimistic transaction mode.

> **Note:**
>
> Even if the pessimistic transaction mode is set, autocommit transactions still try to commit using the optimistic mode first. If a conflict occurs, the transactions will switch to the pessimistic transaction mode during automatic retry.

10.2.7.3.1 Read-write conflicts

The error messages and solutions are the same as Read-write conflict for optimistic lock conflict.

10.2.7.3.2 Pessimistic lock retry limit reached

When the transaction conflict is very serious or a write conflict occurs, the optimistic transaction will be terminated directly, and the pessimistic transaction will retry the statement with the latest data from storage until there is no write conflict.

Because TiDB's locking operation is a write operation, and the process of the operation is to read first and then write, there are two RPC requests. If a write conflict occurs in the middle of a transaction, TiDB will try again to lock the target keys, and each retry will be printed to the TiDB log. The number of retries is determined by pessimistic-txn.max-retry-count.

In the pessimistic transaction mode, if a write conflict occurs and the number of retries reaches the upper limit, an error message containing the following keywords appears in the TiDB log:

```
err="pessimistic lock retry limit reached"
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust from the application side.

10.2.7.3.3 Lock wait timeout exceeded

In the pessimistic transaction mode, transactions wait for locks of each other. The timeout for waiting a lock is defined by the innodb_lock_wait_timeout parameter of TiDB. This is the maximum wait lock time at the SQL statement level, which is the expectation of a SQL statement Locking, but the lock has never been acquired. After this time, TiDB will not try to lock again and will return the corresponding error message to the client.

When a wait lock timeout occurs, the following error message will be returned to the client:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust the application logic.

10.2.7.3.4 TTL manager has timed out

The transaction execution time cannot exceed the GC time limit. In addition, the TTL time of pessimistic transactions has an upper limit, whose default value is 1 hour. Therefore, a pessimistic transaction executed for more than 1 hour will fail to commit. This timeout threshold is controlled by the TiDB parameter performance.max-txn-ttl.

When the execution time of a pessimistic transaction exceeds the TTL time, the following error message occurs in the TiDB log:

```
TTL manager has timed out, pessimistic locks may expire, please commit or
    ↪ rollback this transaction
```

Solutions:

- First, confirm whether the application logic can be optimized. For example, large transactions may trigger TiDB's transaction size limit, which can be split into multiple small transactions.
- Also, you can adjust the related parameters properly to meet the application transaction logic.

10.2.7.3.5 Deadlock found when trying to get lock

Due to resource competition between two or more transactions, a deadlock occurs. If you do not handle it manually, transactions that block each other cannot be executed successfully and will wait for each other forever. To resolve dead locks, you need to manually terminate one of the transactions to resume other transaction requests.

When a pessimistic transaction has a deadlock, one of the transactions must be terminated to unlock the deadlock. The client will return the same `Error 1213` error as in MySQL, for example:

```
[err="[executor:1213]Deadlock found when trying to get lock; try restarting
    ↪ transaction"]
```

Solutions:

- If it is difficult to confirm the cause of the deadlock, for v5.1 and later versions, you are recommended to try to query the `INFORMATION_SCHEMA.DEADLOCKS` or `INFORMATION_SCHEMA.CLUSTER_DEADLOCKS` system table to get the information of deadlock waiting chain. For details, see the Deadlock errors section and the `DEADLOCKS` table document.
- If the deadlock occurs frequently, you need to adjust the transaction query logic in your application to reduce such occurrences.

10.2.8 Troubleshoot Inconsistency Between Data and Indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

This document describes the meanings of data inconsistency errors and provides some methods to bypass the consistency check. If a data consistency error occurs, you can get support from PingCAP or the community.

10.2.8.1 Error explanation

When inconsistency between data and indexes occurs, you can check TiDB error messages to know which item is inconsistent between row data and index data, or check the related error logs for further investigation.

10.2.8.1.1 Errors reported during transaction execution

This section lists the data inconsistency errors reported when TiDB executes transactions and explains the meanings of these errors with examples.

Error 8133

```
ERROR 8133 (HY000): data inconsistency in table: t, index: k2, index-
↪ count:1 != record-count:0
```

This error indicates that for the `k2` index in table `t`, the number of indexes in the table is 1 and the number of row records is 0. The number is inconsistent.

Error 8138

```
ERROR 8138 (HY000): writing inconsistent data in table: t, expected-
↪ values:{KindString green} != record-values:{KindString GREEN}
```

This error indicates that the transaction was attempting to write an incorrect row value. For the data to be written, the encoded row data does not match the original data before encoding.

Error 8139

```
ERROR 8139 (HY000): writing inconsistent data in table: t, index: i1,
↪ index-handle:4 != record-handle:3, index: tables.mutation{key:kv.Key{0
↪ x74, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x69, 0x80, 0x0, 0
↪ x0, 0x0, 0x0, 0x0, 0x0, 0x1, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0,

↪ x6c, 0x6f}, indexID:0}
```

This error indicates that the handle (that is, the key of the row data) of the data to be written is inconsistent. For index `i1` in table `t`, the row to be written by the transaction has a handle of 4 in the index key-value pair and a handle of 3 in the row record key-value pair. The data of this row will not be written.

Error 8140

```
ERROR 8140 (HY000): writing inconsistent data in table: t, index: i2,
↪ col: c1, indexed-value:{KindString hellp} != record-value:{KindString
↪ hello}
```

This error indicates that the data in a row to be written by the transaction does not match the data in the index. For index `i2` in table `t`, a row to be written by the transaction has data `hellp` in the index key-value pair and data `hello` in the record key-value pair. The data of this row will not be written.

Error 8141

```
ERROR 8141 (HY000): assertion failed: key: 748000000000000405f7201330000000000000000f8
↪ , assertion: NotExist, start_ts: 430590532931813377, existing start ts:
↪ 430590532931551233, existing commit ts: 430590532931551234
```

This error indicates that the assertion failed when a transaction was being committed. Assuming that data and indexes are consistent, TiDB asserted that the key `748000000000000405f7201330000000000000000f8` did not exist. When the transaction was being committed, TiDB found the key did exist, written by the transaction with the `start ts` `430590532931551233`. TiDB will print the Multi-Version Concurrency Control (MVCC) history of this key to logs.

10.2.8.1.2 Errors reported in admin check

This section lists the data inconsistency errors that might occur in TiDB when you execute the `ADMIN CHECK [TABLE|INDEX]` statement, and explains the meanings of these errors with examples.

Error 8003

```
ERROR 8003 (HY000): table count 3 != index(idx)count 2
```

This error indicates that the table on which the `ADMIN CHECK` statement is executed has 3 row key-value pairs but only 2 index key-value pairs.

Error 8134

```
ERROR 8134 (HY000): data inconsistency in table: t, index: c2, col: c2
↪ , handle: "2", index-values:"KindInt64 13" != record-values:"KindInt64
↪ 12", compare err:<nil>
```

This error indicates that for index `c2` in table `t`, the value of column `c2` has the following inconsistency:

- In the index key-value pair of the row whose handle is `2`, the value of column `c2` is `13`.
- In the row record key-value pair, the value of column `c2` is `12`.

Error 8223

```
ERROR 8223 (HY000): data inconsistency in table: t2, index: i1, handle:
↪  {hello, hello}, index-values:"" != record-values:"handle: {hello, hello
↪ }, values: [KindString hello KindString hello]"
```

This error indicates that `index-values` are null and `record-values` are not null, meaning that there is no corresponding index for the row.

10.2.8.2 Solutions

If you encounter a data inconsistency error, get support from PingCAP for troubleshooting immediately instead of dealing with the error by yourself. If your application needs to skip such errors urgently, you can use the following methods to bypass the check.

10.2.8.2.1 Rewrite SQL

If the data inconsistency error occurs in a particular SQL statement only, you can bypass this error by rewriting the SQL statement to another equivalent form using different execution operators.

10.2.8.2.2 Disable error checks

For the following errors reported in transaction execution, you can bypass the corresponding checks:

- To bypass the checks of errors 8138, 8139, and 8140, configure `set @@tidb_enable_mutation_checke` `=0`.
- To bypass the checks of error 8141, configure `set @@tidb_txn_assertion_level=OFF`.

> **Note:**
>
> Disabling `tidb_enable_mutation_checker` and `tidb_txn_assertion_level` will bypass the corresponding checks of all SQL statements.

For other errors reported in transaction execution and all errors reported during the execution of the `ADMIN CHECK [TABLE|INDEX]` statement, you cannot bypass the corresponding check, because the data is already inconsistent.

10.3 Diagnostic Methods

10.3.1 SQL Diagnostics

SQL diagnostics is a feature introduced in TiDB v4.0. You can use this feature to locate problems in TiDB with higher efficiency. Before TiDB v4.0, you need to use different tools to obtain different information.

The SQL diagnostic system has the following advantages:

- It integrates information from all components of the system as a whole.
- It provides a consistent interface to the upper layer through system tables.
- It provides monitoring summaries and automatic diagnostics.
- You will find it easier to query cluster information.

10.3.1.1 Overview

The SQL diagnostic system consists of three major parts:

- **Cluster information table**: The SQL diagnostics system introduces cluster information tables that provide a unified way to get the discrete information of each instance. This system fully integrates the cluster topology, hardware information, software information, kernel parameters, monitoring, system information, slow queries, statements, and logs of the entire cluster into the table. So you can query these information using SQL statements.

- **Cluster monitoring table**: The SQL diagnostic system introduces cluster monitoring tables. All of these tables are in `metrics_schema`, and you can query monitoring information using SQL statements. Compared to the visualized monitoring before v4.0, you can use this SQL-based method to perform correlated queries on all the monitoring information of the entire cluster, and compare the results of different time periods to quickly identify performance bottlenecks. Because the TiDB cluster has many monitoring metrics, the SQL diagnostic system also provides monitoring summary tables, so you can find abnormal monitoring items more easily.

Automatic diagnostics: Although you can manually execute SQL statements to query cluster information tables, cluster monitoring tables, and summary tables to locate issues, the automatic diagnostics allows you to quickly locate common issues. The SQL diagnostic system performs automatic diagnostics based on the existing cluster information tables and monitoring tables, and provides relevant diagnostic result tables and diagnostic summary tables.

10.3.1.2 Cluster information tables

The cluster information tables bring together the information of all instances and instances in a cluster. With these tables, you can query all cluster information using only one SQL statement. The following is a list of cluster information tables:

- From the cluster topology table `information_schema.cluster_info`, you can get the current topology information of the cluster, the version of each instance, the Git Hash corresponding to the version, the starting time of each instance, and the running time of each instance.
- From the cluster configuration table `information_schema.cluster_config`, you can get the configuration of all instances in the cluster. For versions earlier than 4.0, you need to access the HTTP API of each instance one by one to get these configuration information.
- On the cluster hardware table `information_schema.cluster_hardware`, you can quickly query the cluster hardware information.
- On the cluster load table `information_schema.cluster_load`, you can query the load information of different instances and hardware types of the cluster.
- On the kernel parameter table `information_schema.cluster_systeminfo`, you can query the kernel configuration information of different instances in the cluster. Currently, TiDB supports querying the sysctl information.
- On the cluster log table `information_schema.cluster_log`, you can query cluster logs. By pushing down query conditions to each instance, the impact of the query on cluster performance is less than that of the `grep` command.

On the system tables earlier than TiDB v4.0, you can only view the current instance. TiDB v4.0 introduces the corresponding cluster tables and you can have a global view of the entire cluster on a single TiDB instance. These tables are currently in `information_schema`, and the query method is the same as other `information_schema` system tables.

10.3.1.3 Cluster monitoring tables

To dynamically observe and compare cluster conditions in different time periods, the SQL diagnostic system introduces cluster monitoring system tables. All monitoring tables are in `metrics_schema`, and you can query the monitoring information using SQL statements. Using this method, you can perform correlated queries on all monitoring information of the entire cluster and compare the results of different time periods to quickly identify performance bottlenecks.

- `information_schema.metrics_tables`: Because many system tables exist now, you can query meta-information of these monitoring tables on the `information_schema.metrics_tables` table.

Because the TiDB cluster has many monitoring metrics, TiDB provides the following monitoring summary tables in v4.0:

- The monitoring summary table `information_schema.metrics_summary` summarizes all monitoring data to for you to check each monitoring metric with higher efficiency.
- `information_schema.metrics_summary_by_label` also summarizes all monitoring data. Particularly, this table aggregates statistics using different labels of each monitoring metric.

10.3.1.4 Automatic diagnostics

On the cluster information tables and cluster monitoring tables above, you need to manually execute SQL statements to troubleshoot the cluster. TiDB v4.0 supports the automatic diagnostics. You can use diagnostic-related system tables based on the existing basic information tables, so that the diagnostics is automatically executed. The following are the system tables related to the automatic diagnostics:

- The diagnostic result table `information_schema.inspection_result` displays the diagnostic result of the system. The diagnostics is passively triggered. Executing `select * from inspection_result` triggers all diagnostic rules to diagnose the system, and the faults or risks in the system are displayed in the results.
- The diagnostic summary table `information_schema.inspection_summary` summarizes the monitoring information of a specific link or module. You can troubleshoot and locate problems based on the context of the entire module or link.

10.3.2 Statement Summary Tables

To better handle SQL performance issues, MySQL has provided statement summary tables in `performance_schema` to monitor SQL with statistics. Among these tables, `events_statements_summary_by_digest` is very useful in locating SQL problems with its abundant fields such as latency, execution times, rows scanned, and full table scans.

Therefore, starting from v4.0.0-rc.1, TiDB provides system tables in `information_schema` (*not* `performance_schema`) that are similar to `events_statements_summary_by_digest` in terms of features.

- `statements_summary`
- `statements_summary_history`
- `cluster_statements_summary`
- `cluster_statements_summary_history`
- `statements_summary_evicted`

This document details these tables and introduces how to use them to troubleshoot SQL performance issues.

10.3.2.1 `statements_summary`

`statements_summary` is a system table in `information_schema`. `statements_summary` groups the SQL statements by the SQL digest and the plan digest, and provides statistics for each SQL category.

The "SQL digest" here means the same as used in slow logs, which is a unique identifier calculated through normalized SQL statements. The normalization process ignores constant, blank characters, and is case insensitive. Therefore, statements with consistent syntaxes have the same digest. For example:

```
SELECT * FROM employee WHERE id IN (1, 2, 3) AND salary BETWEEN 1000 AND
    ↪ 2000;
select * from EMPLOYEE where ID in (4, 5) and SALARY between 3000 and 4000;
```

After normalization, they are both of the following category:

```
select * from employee where id in (...) and salary between ? and ?;
```

The "plan digest" here refers to the unique identifier calculated through normalized execution plan. The normalization process ignores constants. The same SQL statements might be grouped into different categories because the same statements might have different execution plans. SQL statements of the same category have the same execution plan.

`statements_summary` stores the aggregated results of SQL monitoring metrics. In general, each of the monitoring metrics includes the maximum value and average value. For example, the execution latency metric corresponds to two fields: `AVG_LATENCY` (average latency) and `MAX_LATENCY` (maximum latency).

To make sure that the monitoring metrics are up to date, data in the `statements_summary` table is periodically cleared, and only recent aggregated results are retained and displayed. The periodical data clearing is controlled by the `tidb_stmt_summary_refresh_interval` system variable. If you happen to make a query right after the clearing, the data displayed might be very little.

The following is a sample output of querying `statements_summary`:

```
  SUMMARY_BEGIN_TIME: 2020-01-02 11:00:00
    SUMMARY_END_TIME: 2020-01-02 11:30:00
          STMT_TYPE: Select
        SCHEMA_NAME: test
             DIGEST: 0611
                 ↪ cc2fe792f8c146cc97d39b31d9562014cf15f8d41f23a4938ca341f54182
                 ↪
        DIGEST_TEXT: select * from employee where id = ?
        TABLE_NAMES: test.employee
        INDEX_NAMES: NULL
        SAMPLE_USER: root
         EXEC_COUNT: 3
        SUM_LATENCY: 1035161
        MAX_LATENCY: 399594
        MIN_LATENCY: 301353
        AVG_LATENCY: 345053
    AVG_PARSE_LATENCY: 57000
    MAX_PARSE_LATENCY: 57000
  AVG_COMPILE_LATENCY: 175458
  MAX_COMPILE_LATENCY: 175458
  ............
             AVG_MEM: 103
             MAX_MEM: 103
             AVG_DISK: 65535
             MAX_DISK: 65535
    AVG_AFFECTED_ROWS: 0
          FIRST_SEEN: 2020-01-02 11:12:54
           LAST_SEEN: 2020-01-02 11:25:24
    QUERY_SAMPLE_TEXT: select * from employee where id=3100
     PREV_SAMPLE_TEXT:
          PLAN_DIGEST:
             ↪ f415b8d52640b535b9b12a9c148a8630d2c6d59e419aad29397842e32e8e5de3
             ↪
                PLAN: Point_Get_1   root   1      table:employee, handle:3100
```

Note:

In TiDB, the time unit of fields in statement summary tables is nanosecond (ns), whereas in MySQL the time unit is picosecond (ps).

10.3.2.2 `statements_summary_history`

The table schema of `statements_summary_history` is identical to that of `statements_summary` ↪ . `statements_summary_history` saves the historical data of a time range. By checking historical data, you can troubleshoot anomalies and compare monitoring metrics of different time ranges.

The fields `SUMMARY_BEGIN_TIME` and `SUMMARY_END_TIME` represent the start time and the end time of the historical time range.

10.3.2.3 `statements_summary_evicted`

The `tidb_stmt_summary_max_stmt_count` variable controls the maximum number of statements that the `statement_summary` table stores in memory. The `statement_summary` ↪ table uses the LRU algorithm. Once the number of SQL statements exceeds the `tidb_stmt_summary_max_stmt_count` value, the longest unused record is evicted from the table. The number of evicted SQL statements during each period is recorded in the `statements_summary_evicted` table.

The `statements_summary_evicted` table is updated only when a SQL record is evicted from the `statement_summary` table. The `statements_summary_evicted` only records the period during which the eviction occurs and the number of evicted SQL statements.

10.3.2.4 The `cluster` tables for statement summary

The `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` ↪ tables only show the statement summary of a single TiDB server. To query the data of the entire cluster, you need to query the `cluster_statements_summary` ↪ , `cluster_statements_summary_history`, or `cluster_statements_summary_evicted` tables.

`cluster_statements_summary` displays the `statements_summary` data of each TiDB server. `cluster_statements_summary_history` displays the `statements_summary_history` ↪ data of each TiDB server. `cluster_statements_summary_evicted` displays the `statements_summary_evicted` data of each TiDB server. These tables use the `INSTANCE` field to represent the address of the TiDB server. The other fields are the same as those in `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` ↪ .

10.3.2.5 Parameter configuration

The following system variables are used to control the statement summary:

- `tidb_enable_stmt_summary`: Determines whether to enable the statement summary feature. `1` represents `enable`, and `0` means `disable`. The feature is enabled by default. The statistics in the system table are cleared if this feature is disabled. The statistics are re-calculated next time this feature is enabled. Tests have shown that enabling this feature has little impact on performance.

- `tidb_stmt_summary_refresh_interval`: The interval at which the `statements_summary` ↪ table is refreshed. The time unit is second (s). The default value is `1800`.
- `tidb_stmt_summary_history_size`: The size of each SQL statement category stored in the `statements_summary_history` table, which is also the maximum number of records in the `statement_summary_evicted` table. The default value is `24`.
- `tidb_stmt_summary_max_stmt_count`: Limits the number of SQL statements that can be stored in statement summary tables. The default value is `3000`. If the limit is exceeded, those SQL statements that recently remain unused are cleared. These cleared SQL statements are recorded in the `statement_summary_evicted` table.
- `tidb_stmt_summary_max_sql_length`: Specifies the longest display length of `DIGEST_TEXT` and `QUERY_SAMPLE_TEXT`. The default value is `4096`.
- `tidb_stmt_summary_internal_query`: Determines whether to count the TiDB SQL statements. `1` means to count, and `0` means not to count. The default value is `0`.

> **Note:**
>
> When a category of SQL statement needs to be removed because the `tidb_stmt_summary_max_stmt_count` limit is exceeded, TiDB removes the data of that SQL statement category of all time ranges from the `statement_summary_history` table. Therefore, even if the number of SQL statement categories in a certain time range does not reach the limit, the number of SQL statements stored in the `statement_summary_history` table is less than the actual number of SQL statements. If this situation occurs and affects performance, you are recommended to increase the value of `tidb_stmt_summary_max_stmt_count`.

An example of the statement summary configuration is shown as follows:

```
set global tidb_enable_stmt_summary = true;
set global tidb_stmt_summary_refresh_interval = 1800;
set global tidb_stmt_summary_history_size = 24;
```

After the configuration above takes effect, every 30 minutes the `statements_summary` table is cleared. The `statements_summary_history` table stores data generated over the recent 12 hours.

The `statements_summary_evicted` table records the recent 24 periods during which SQL statements are evicted from the statement summary. The `statements_summary_evicted` ↪ table is updated every 30 minutes.

> **Note:**

> The `tidb_stmt_summary_history_size`, `tidb_stmt_summary_max_stmt_count` ↪ , and `tidb_stmt_summary_max_sql_length` configuration items affect memory usage. It is recommended that you adjust these configurations based on your needs, the SQL size, SQL count, and machine configuration. It is not recommended to set them too large values. You can calculate the memory usage using `tidb_stmt_summary_history_size` ↪ * `tidb_stmt_summary_max_stmt_count` * `tidb_stmt_summary_max_sql_length` * 3.

10.3.2.5.1 Set a proper size for statement summary

After the system has run for a period of time (depending on the system load), you can check the `statement_summary` table to see whether SQL eviction has occurred. For example:

```
select @@global.tidb_stmt_summary_max_stmt_count;
select count(*) from information_schema.statements_summary;
```

```
+-----------------------------------------+
| @@global.tidb_stmt_summary_max_stmt_count |
+-----------------------------------------+
| 3000                                    |
+-----------------------------------------+
1 row in set (0.001 sec)

+----------+
| count(*) |
+----------+
|     3001 |
+----------+
1 row in set (0.001 sec)
```

You can see that the `statements_summary` table is full of records. Then check the evicted data from the `statements_summary_evicted` table:

```
select * from information_schema.statements_summary_evicted;
```

```
+---------------------+---------------------+---------------+
| BEGIN_TIME          | END_TIME            | EVICTED_COUNT |
+---------------------+---------------------+---------------+
| 2020-01-02 16:30:00 | 2020-01-02 17:00:00 |            59 |
+---------------------+---------------------+---------------+
| 2020-01-02 16:00:00 | 2020-01-02 16:30:00 |            45 |
+---------------------+---------------------+---------------+
2 row in set (0.001 sec)
```

From the result above, you can see that a maximum of 59 SQL categories are evicted, which indicates that the proper size of the statement summary is 59 records.

10.3.2.6 Limitation

The statement summary tables have the following limitation:

All data of the statement summary tables above will be lost when the TiDB server is restarted. This is because statement summary tables are all memory tables, and the data is cached in memory instead of being persisted on storage.

10.3.2.7 Troubleshooting examples

This section provides two examples to show how to use the statement summary feature to troubleshoot SQL performance issues.

10.3.2.7.1 Could high SQL latency be caused by the server end?

In this example, the client shows slow performance with point queries on the `employee` table. You can perform a fuzzy search on SQL texts:

```
SELECT avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary
    WHERE digest_text LIKE 'select * from employee%';
```

`1ms` and `0.3ms` are considered within the normal range of `avg_latency`. Therefore, it can be concluded that the server end is not the cause. You can troubleshoot with the client or the network.

```
+-------------+-----------+-----------------------------------------+
| avg_latency | exec_count | query_sample_text                      |
+-------------+-----------+-----------------------------------------+
|     1042040 |         2 | select * from employee where name='eric' |
|      345053 |         3 | select * from employee where id=3100 |
+-------------+-----------+-----------------------------------------+
2 rows in set (0.00 sec)
```

10.3.2.7.2 Which categories of SQL statements consume the longest total time?

If the QPS decrease significantly from 10:00 to 10:30, you can find out the three categories of SQL statements with the longest time consumption from the history table:

```
SELECT sum_latency, avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary_history
    WHERE summary_begin_time='2020-01-02 10:00:00'
    ORDER BY sum_latency DESC LIMIT 3;
```

The result shows that the following three categories of SQL statements consume the longest time in total, which need to be optimized with high priority.

```
+--
    ↪ ----------+-------------+-----------+-----------------------------------
    ↪
| sum_latency | avg_latency | exec_count | query_sample_text
    ↪                                      |
+--
    ↪ ----------+-------------+-----------+-----------------------------------
    ↪
|    7855660 |    1122237 |         7 | select avg(salary) from employee
    ↪ where company_id=2013       |
|    7241960 |    1448392 |         5 | select * from employee join company
    ↪ on employee.company_id=company.id |
|    2084081 |    1042040 |         2 | select * from employee where name='
    ↪ eric'                     |
+--
    ↪ ----------+-------------+-----------+-----------------------------------
    ↪
3 rows in set (0.00 sec)
```

10.3.2.8 Fields description

10.3.2.8.1 `statements_summary` fields description

The following are descriptions of fields in the `statements_summary` table.

Basic fields:

- `STMT_TYPE`: SQL statement type.
- `SCHEMA_NAME`: The current schema in which SQL statements of this category are executed.
- `DIGEST`: The digest of SQL statements of this category.
- `DIGEST_TEXT`: The normalized SQL statement.
- `QUERY_SAMPLE_TEXT`: The original SQL statements of the SQL category. Only one original statement is taken.
- `TABLE_NAMES`: All tables involved in SQL statements. If there is more than one table, each is separated by a comma.
- `INDEX_NAMES`: All SQL indexes used in SQL statements. If there is more than one index, each is separated by a comma.
- `SAMPLE_USER`: The users who execute SQL statements of this category. Only one user is taken.
- `PLAN_DIGEST`: The digest of the execution plan.

- `PLAN`: The original execution plan. If there are multiple statements, the plan of only one statement is taken.
- `BINARY_PLAN`: The original execution plan encoded in binary format. If there are multiple statements, the plan of only one statement is taken. Execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan.
- `PLAN_CACHE_HITS`: The total number of times that SQL statements of this category hit the plan cache.
- `PLAN_IN_CACHE`: Indicates whether the previous execution of SQL statements of this category hit the plan cache.

Fields related to execution time:

- `SUMMARY_BEGIN_TIME`: The beginning time of the current summary period.
- `SUMMARY_END_TIME`: The ending time of the current summary period.
- `FIRST_SEEN`: The time when SQL statements of this category are seen for the first time.
- `LAST_SEEN`: The time when SQL statements of this category are seen for the last time.

Fields related to TiDB server:

- `EXEC_COUNT`: Total execution times of SQL statements of this category.
- `SUM_ERRORS`: The sum of errors occurred during execution.
- `SUM_WARNINGS`: The sum of warnings occurred during execution.
- `SUM_LATENCY`: The total execution latency of SQL statements of this category.
- `MAX_LATENCY`: The maximum execution latency of SQL statements of this category.
- `MIN_LATENCY`: The minimum execution latency of SQL statements of this category.
- `AVG_LATENCY`: The average execution latency of SQL statements of this category.
- `AVG_PARSE_LATENCY`: The average latency of the parser.
- `MAX_PARSE_LATENCY`: The maximum latency of the parser.
- `AVG_COMPILE_LATENCY`: The average latency of the compiler.
- `MAX_COMPILE_LATENCY`: The maximum latency of the compiler.
- `AVG_MEM`: The average memory (byte) used.
- `MAX_MEM`: The maximum memory (byte) used.
- `AVG_DISK`: The average disk space (byte) used.
- `MAX_DISK`: The maximum disk space (byte) used.

Fields related to TiKV Coprocessor task:

- `SUM_COP_TASK_NUM`: The total number of Coprocessor requests sent.
- `MAX_COP_PROCESS_TIME`: The maximum execution time of Coprocessor tasks.
- `MAX_COP_PROCESS_ADDRESS`: The address of the Coprocessor task with the maximum execution time.

- `MAX_COP_WAIT_TIME`: The maximum waiting time of Coprocessor tasks.
- `MAX_COP_WAIT_ADDRESS`: The address of the Coprocessor task with the maximum waiting time.
- `AVG_PROCESS_TIME`: The average processing time of SQL statements in TiKV.
- `MAX_PROCESS_TIME`: The maximum processing time of SQL statements in TiKV.
- `AVG_WAIT_TIME`: The average waiting time of SQL statements in TiKV.
- `MAX_WAIT_TIME`: The maximum waiting time of SQL statements in TiKV.
- `AVG_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry.
- `MAX_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry.
- `AVG_TOTAL_KEYS`: The average number of keys that Coprocessor has scanned.
- `MAX_TOTAL_KEYS`: The maximum number of keys that Coprocessor has scanned.
- `AVG_PROCESSED_KEYS`: The average number of keys that Coprocessor has processed. Compared with `avg_total_keys`, `avg_processed_keys` does not include the old versions of MVCC. A great difference between `avg_total_keys` and `avg_processed_keys` indicates that many old versions exist.
- `MAX_PROCESSED_KEYS`: The maximum number of keys that Coprocessor has processed.

Transaction-related fields:

- `AVG_PREWRITE_TIME`: The average time of the prewrite phase.
- `MAX_PREWRITE_TIME`: The longest time of the prewrite phase.
- `AVG_COMMIT_TIME`: The average time of the commit phase.
- `MAX_COMMIT_TIME`: The longest time of the commit phase.
- `AVG_GET_COMMIT_TS_TIME`: The average time of getting `commit_ts`.
- `MAX_GET_COMMIT_TS_TIME`: The longest time of getting `commit_ts`.
- `AVG_COMMIT_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `MAX_COMMIT_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `AVG_RESOLVE_LOCK_TIME`: The average time for resolving lock conflicts occurred between transactions.
- `MAX_RESOLVE_LOCK_TIME`: The longest time for resolving lock conflicts occurred between transactions.
- `AVG_LOCAL_LATCH_WAIT_TIME`: The average waiting time of the local transaction.
- `MAX_LOCAL_LATCH_WAIT_TIME`: The maximum waiting time of the local transaction.
- `AVG_WRITE_KEYS`: The average count of written keys.
- `MAX_WRITE_KEYS`: The maximum count of written keys.
- `AVG_WRITE_SIZE`: The average amount of written data (in byte).
- `MAX_WRITE_SIZE`: The maximum amount of written data (in byte).
- `AVG_PREWRITE_REGIONS`: The average number of Regions involved in the prewrite phase.
- `MAX_PREWRITE_REGIONS`: The maximum number of Regions during the prewrite phase.

- `AVG_TXN_RETRY`: The average number of transaction retries.
- `MAX_TXN_RETRY`: The maximum number of transaction retries.
- `SUM_BACKOFF_TIMES`: The sum of retries when SQL statements of this category encounter errors that require a retry.
- `BACKOFF_TYPES`: All types of errors that require retries and the number of retries for each type. The format of the field is `type:number`. If there is more than one error type, each is separated by a comma, like `txnLock:2,pdRPC:1`.
- `AVG_AFFECTED_ROWS`: The average number of rows affected.
- `PREV_SAMPLE_TEXT`: When the current SQL statement is `COMMIT`, `PREV_SAMPLE_TEXT` is the previous statement to `COMMIT`. In this case, SQL statements are grouped by the digest and `prev_sample_text`. This means that `COMMIT` statements with different `prev_sample_text` are grouped to different rows. When the current SQL statement is not `COMMIT`, the `PREV_SAMPLE_TEXT` field is an empty string.

10.3.2.8.2 `statements_summary_evicted` fields description

- `BEGIN_TIME`: Records the starting time.
- `END_TIME`: Records the ending time.
- `EVICTED_COUNT`: The number of SQL categories that are evicted during the record period.

10.3.3 TiDB Dashboard Top SQL Page

With Top SQL, you can monitor and visually explore the CPU overhead of each SQL statement in your database in real-time, which helps you optimize and resolve database performance issues. Top SQL continuously collects and stores CPU load data summarized by SQL statements at any seconds from all TiDB and TiKV instances. The collected data can be stored for up to 30 days. Top SQL presents you with visual charts and tables to quickly pinpoint which SQL statements are contributing the high CPU load of a TiDB or TiKV instance over a certain period of time.

Top SQL provides the following features:

- Visualize the top 5 types of SQL statements with the highest CPU overhead through charts and tables.
- Display detailed execution information such as queries per second, average latency, and query plan.
- Collect all SQL statements that are executed, including those that are still running.
- Allow viewing data of a specific TiDB and TiKV instance.

10.3.3.1 Recommended scenarios

Top SQL is suitable for analyzing performance issues. The following are some typical Top SQL scenarios:

- You discovered that an individual TiKV instance in the cluster has a very high CPU usage through the Grafana charts. You want to know which SQL statements cause the CPU hotspots so that you can optimize them and better leverage all of your distributed resources.
- You discovered that the cluster has a very high CPU usage overall and queries are slow. You want to quickly figure out which SQL statements are currently consuming the most CPU resources so that you can optimize them.
- The CPU usage of the cluster has drastically changed and you want to know the major cause.
- Analyze the most resource-intensive SQL statements in the cluster and optimize them to reduce hardware costs.

Top SQL cannot be used to pinpoint non-performance issues, such as incorrect data or abnormal crashes.

The Top SQL feature is still in an early stage and is being continuously enhanced. Here are some scenarios that are **not supported** at the moment:

- Analyzing the overhead of SQL statements outside of Top 5 (for example, when multiple business workloads are mixed).
- Analyzing the overhead of Top N SQL statements by various dimensions such as users and databases.
- Analyzing database performance issues that are not caused by high CPU load, such as transaction lock conflicts.

10.3.3.2 Access the page

You can access the Top SQL page using either of the following methods:

- After logging into TiDB Dashboard, click **Top SQL** on the left navigation bar.

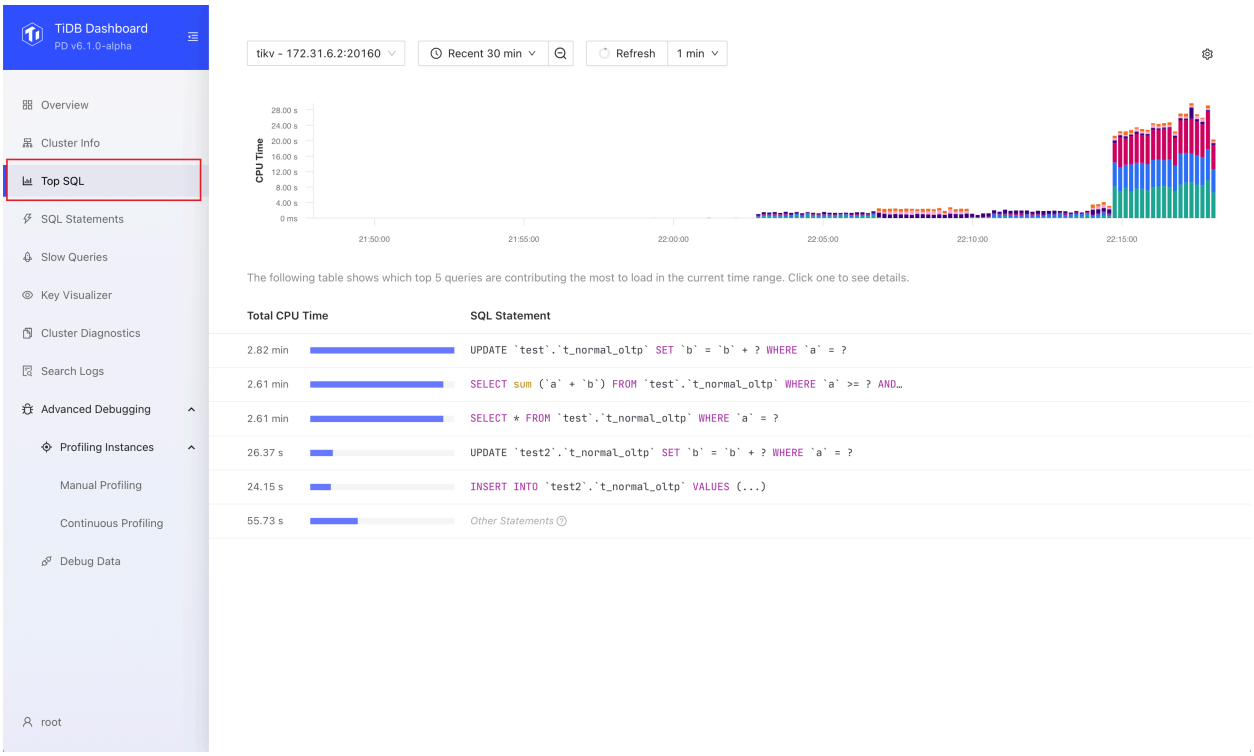

Figure 91: Top SQL

- Visit http://127.0.0.1:2379/dashboard/#/topsql in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

10.3.3.3 Enable Top SQL

> **Note:**
>
> To use Top SQL, your cluster should be deployed or upgraded with a recent version of TiUP (v1.9.0 or above) or TiDB Operator (v1.3.0 or above). If your cluster was upgraded using an earlier version of TiUP or TiDB Operator, see FAQ for instructions.

Top SQL is not enabled by default as it has a slight impact on cluster performance (within 3% on average) when enabled. You can enable Top SQL by the following steps:

1. Visit the Top SQL page.
2. Click **Open Settings**. On the right side of the **Settings** area, switch on **Enable Feature**.

3. Click **Save**.

After enabling the feature, wait up to 1 minute for Top SQL to load the data. Then you can see the CPU load details.

In addition to the UI, you can also enable the Top SQL feature by setting the TiDB system variable `tidb_enable_top_sql`:

```
SET GLOBAL tidb_enable_top_sql = 1;
```

10.3.3.4 Use Top SQL

The following are the common steps to use Top SQL.

1. Visit the Top SQL page.
2. Select a particular TiDB or TiKV instance that you want to observe the load.

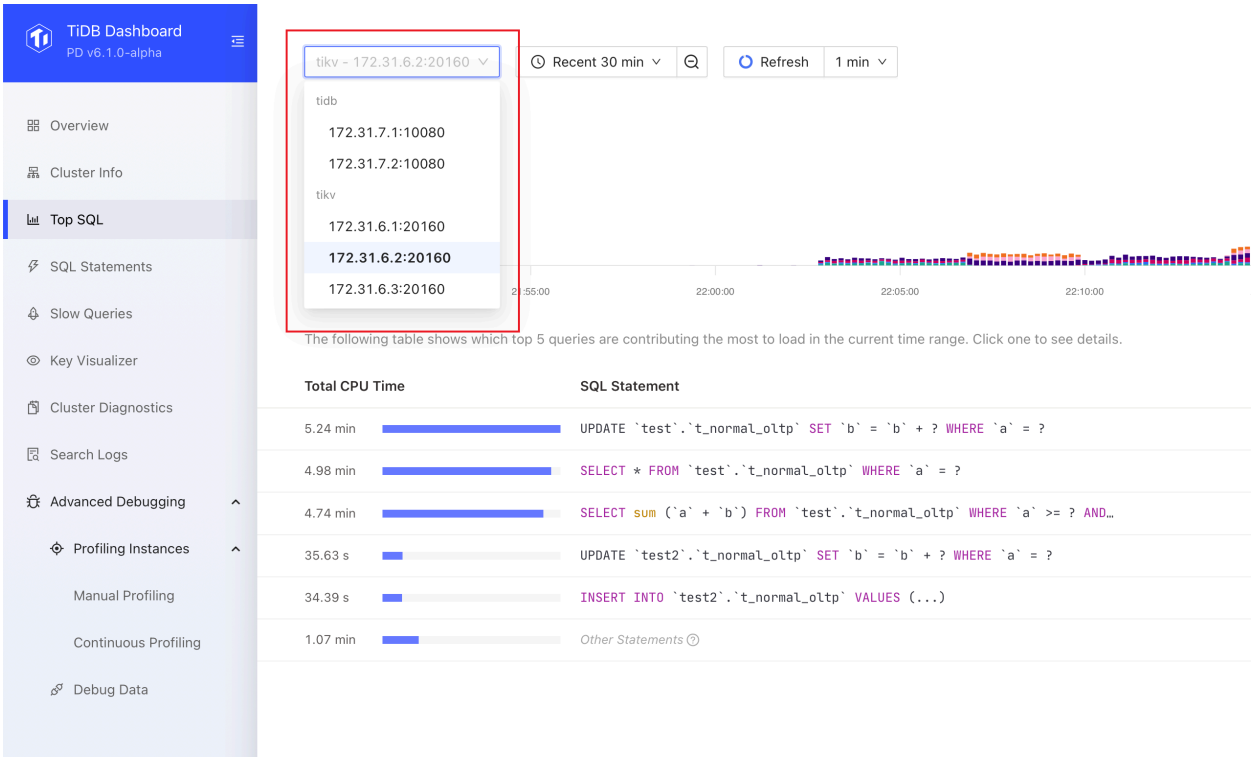

Figure 92: Select Instance

If you are unsure of which TiDB or TiKV instance to observe, you can select an arbitrary instance. Also, when the cluster CPU load is extremely unbalanced, you can first use Grafana charts to determine the specific instance you want to observe.

3. Observe the charts and tables presented by Top SQL.

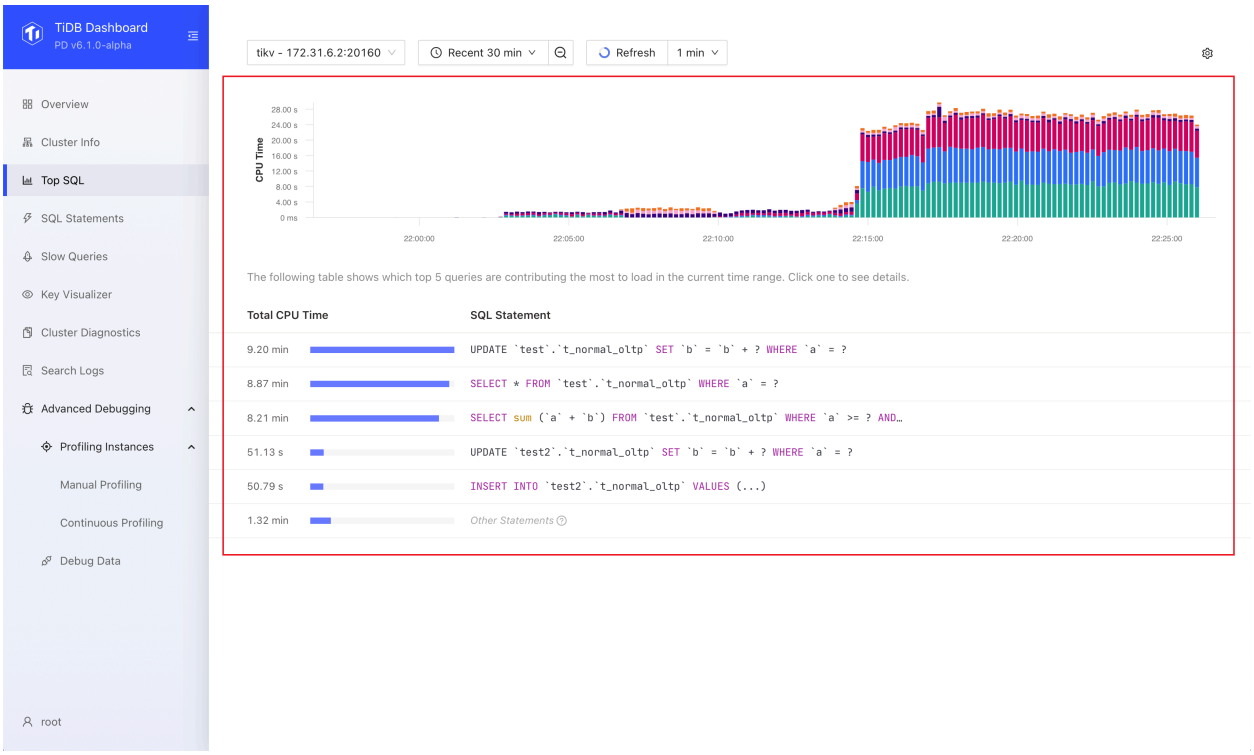

Figure 93: Chart and Table

The size of the bars in the bar chart represents the size of CPU resources consumed by the SQL statement at that moment. Different colors distinguish different types of SQL statements. In most cases, you only need to focus on the SQL statements that have a higher CPU resource overhead in the corresponding time range in the chart.

4. Click a SQL statement in the table to show more information. You can see detailed execution metrics of different plans of that statement, such as Call/sec (average queries per second) and Scan Indexes/sec (average number of index rows scanned per second).

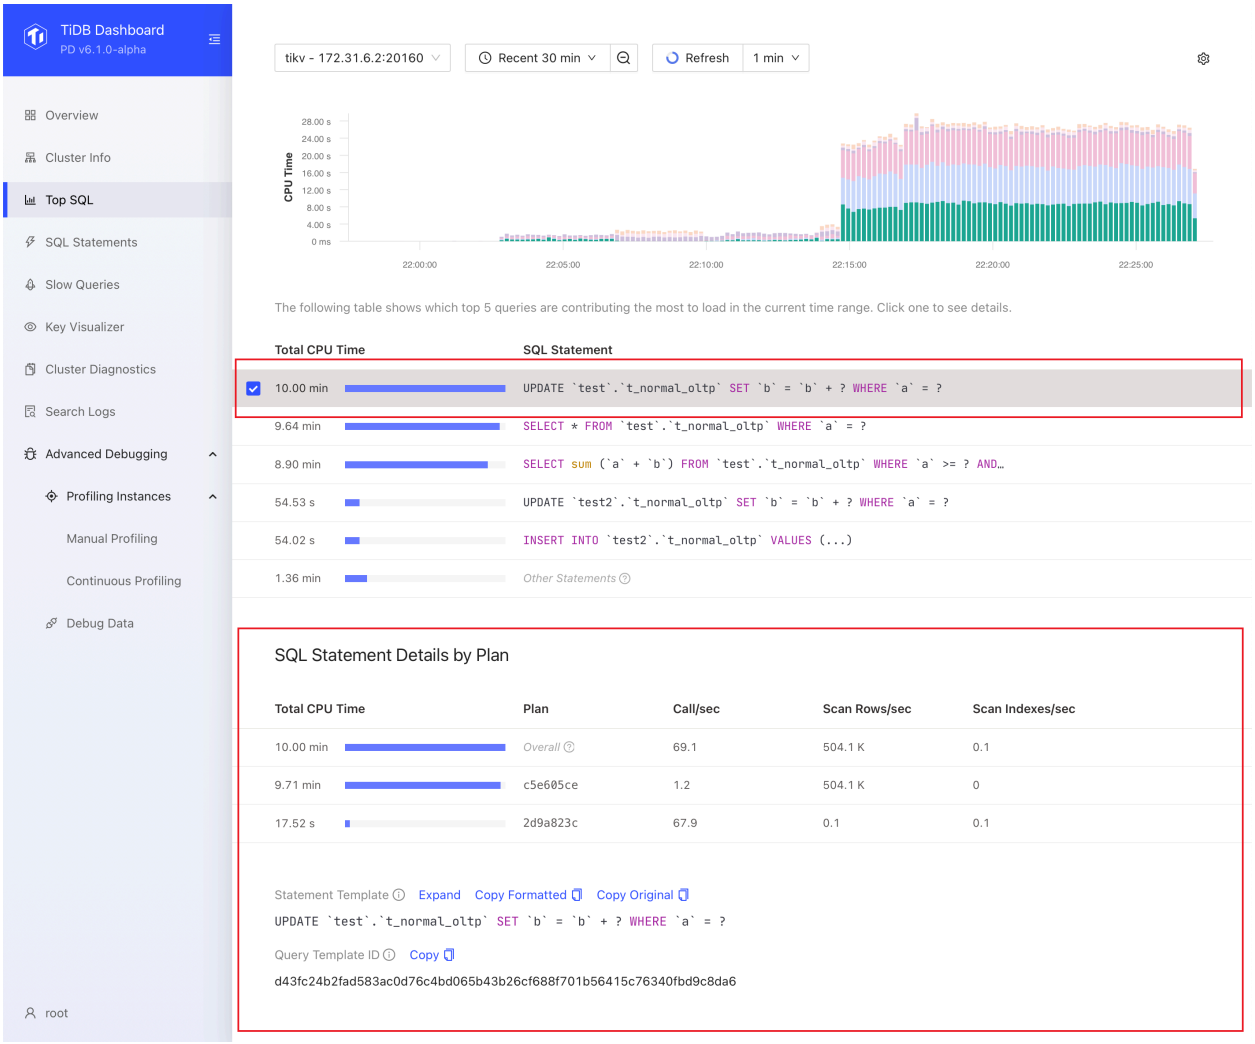

Figure 94: Details

5. Based on these initial clues, you can further explore the SQL Statement or Slow Queries page to find the root cause of high CPU consumption or large data scans of the SQL statement.

Additionally, you can configure Top SQL as follows:

- You can adjust the time range in the time picker or select a time range in the chart to get a more precise and detailed look at the problem. A smaller time range can provide more detailed data, with precision of up to 1 second.

Figure 95: Change time range

- If the chart is out of date, you can click the **Refresh** button or select Auto Refresh options from the **Refresh** drop-down list.

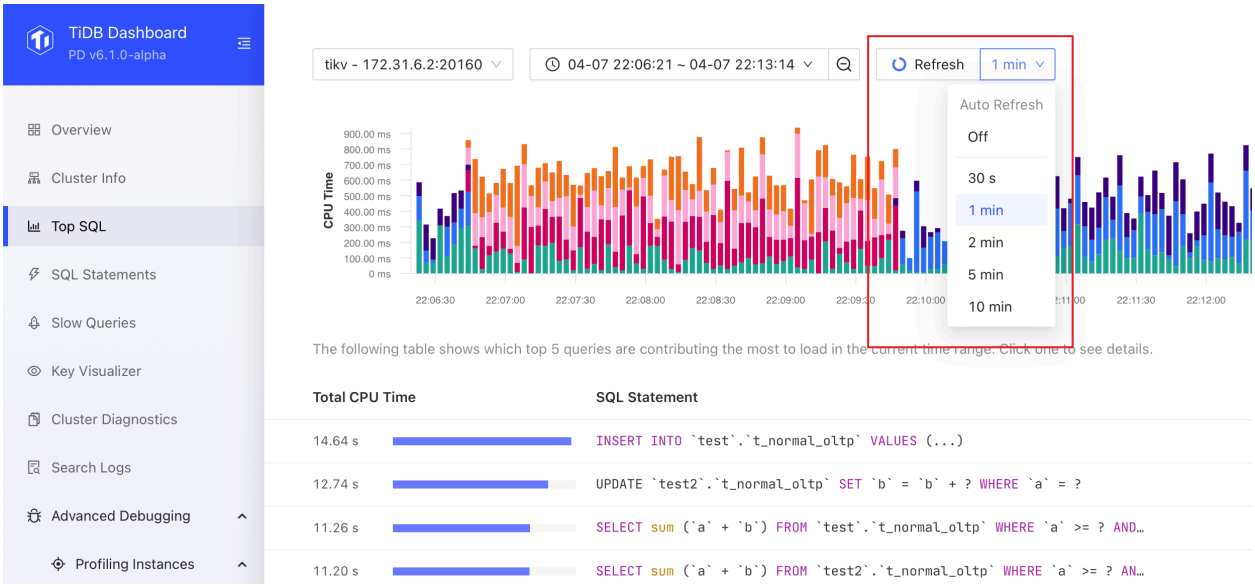

Figure 96: Refresh

10.3.3.5 Disable Top SQL

You can disable this feature by following these steps:

1. Visit Top SQL page.
2. Click the gear icon in the upper right corner to open the settings screen and switch off **Enable Feature**.
3. Click **Save**.
4. In the popped-up dialog box, click **Disable**.

In addition to the UI, you can also disable the Top SQL feature by setting the TiDB system variable `tidb_enable_top_sql`:

```
SET GLOBAL tidb_enable_top_sql = 0;
```

10.3.3.6 Frequently asked questions

1. Top SQL cannot be enabled and the UI displays "required component NgMonitoring is not started".

See TiDB Dashboard FAQ.

2. Will performance be affected after enabling Top SQL?

This feature has a slight impact on cluster performance. According to our benchmark, the average performance impact is usually less than 3% when the feature is enabled.

3. What is the status of this feature?

It is now a generally available (GA) feature and can be used in production environments.

4. What is the meaning of "Other Statements"?

"Other Statement" counts the total CPU overhead of all non-Top 5 statements. With this information, you can learn the CPU overhead contributed by the Top 5 statements compared with the overall.

5. What is the relationship between the CPU overhead displayed by Top SQL and the actual CPU usage of the process?

Their correlation is strong but they are not exactly the same thing. For example, the cost of writing multiple replicas is not counted in the TiKV CPU overhead displayed by Top SQL. In general, SQL statements with higher CPU usage result in higher CPU overhead displayed in Top SQL.

6. What is the meaning of the Y-axis of the Top SQL chart?

It represents the size of CPU resources consumed. The more resources consumed by a SQL statement, the higher the value is. In most cases, you do not need to care about the meaning or unit of the specific value.

7. Does Top SQL collect running (unfinished) SQL statements?

Yes. The bars displayed in the Top SQL chart at each moment indicate the CPU overhead of all running SQL statements at that moment.

10.3.4 Identify Expensive Queries

TiDB allows you to identify expensive queries during SQL execution, so you can diagnose and improve the performance of SQL execution. Specifically, TiDB prints the information about statements whose execution time exceeds `tidb_expensive_query_time_threshold` (60 seconds by default) or memory usage exceeds `tidb_mem_quota_query` (1 GB by default) to the tidb-server log file ("tidb.log" by default).

> **Note:**
>
> The expensive query log differs from the slow query log in this way: TiDB prints statement information to the expensive query log **as soon as** the statement exceeds the threshold of resource usage (execution time or memory usage); while TiDB prints statement information to the slow query log **after** the statement execution.

10.3.4.1 Expensive query log example

```
[2020/02/05 15:32:25.096 +08:00] [WARN] [expensivequery.go:167] [
    ↪ expensive_query] [cost_time=60.008338935s] [wait_time=0s] [
    ↪ request_count=1] [total_keys=70] [process_keys=65] [num_cop_tasks=1]
    ↪ [process_avg_time=0s] [process_p90_time=0s] [process_max_time=0s] [
    ↪ process_max_addr=10.0.1.9:20160] [wait_avg_time=0.002s] [
    ↪ wait_p90_time=0.002s] [wait_max_time=0.002s] [wait_max_addr
    ↪ =10.0.1.9:20160] [stats=t:pseudo] [conn_id=60026] [user=root] [
    ↪ database=test] [table_ids="[122]"] [txn_start_ts=414420273735139329]
    ↪ [mem_max="1035 Bytes (1.0107421875 KB)"] [sql="insert into t select
    ↪ sleep(1) from t"]
```

10.3.4.2 Fields description

Basic fields:

- `cost_time`: The execution time of a statement when the log is printed.
- `stats`: The version of statistics used by the tables or indexes involved in a statement. If the value is `pseudo`, it means that there are no available statistics. In this case, you need to analyze the tables or indexes.
- `table_ids`: The IDs of the tables involved in a statement.
- `txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `sql`: The sql statement.

Memory usage related fields:

- `mem_max`: Memory usage of a statement when the log is printed. This field has two kinds of units to measure memory usage: byte and other readable and adaptable units (such as MB and GB).

User related fields:

- `user`: The name of the user who executes the statement.
- `conn_id`: The connection ID (session ID). For example, you can use the keyword `con:60026` to search for the log whose session ID is `60026`.
- `database`: The database where the statement is executed.

TiKV Coprocessor task related fields:

- `wait_time`: The total waiting time of all Coprocessor requests of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `request_count`: The number of Coprocessor requests that a statement sends.
- `total_keys`: The number of keys that Coprocessor has scanned.
- `processed_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `num_cop_tasks`: The number of Coprocessor requests that a statement sends.
- `process_avg_time`: The average execution time of Coprocessor tasks.
- `process_p90_time`: The P90 execution time of Coprocessor tasks.
- `process_max_time`: The maximum execution time of Coprocessor tasks.
- `process_max_addr`: The address of the Coprocessor task with the longest execution time.
- `wait_avg_time`: The average waiting time of Coprocessor tasks.
- `wait_p90_time`: The P90 waiting time of Coprocessor tasks.
- `wait_max_time`: The maximum waiting time of Coprocessor tasks.
- `wait_max_addr`: The address of the Coprocessor task with the longest waiting time.

10.3.5 Use PLAN REPLAYER to Save and Restore the On-Site Information of a Cluster

When you locate and troubleshoot the issues of a TiDB cluster, you often need to provide information on the system and the execution plan. To help you get the information and troubleshoot cluster issues in a more convenient and efficient way, the `PLAN REPLAYER` ↪ command is introduced in TiDB v5.3.0. This command enables you to easily save and

restore the on-site information of a cluster, improves the efficiency of troubleshooting, and helps you more easily archive the issue for management.

The features of `PLAN REPLAYER` are as follows:

- Exports the information of a TiDB cluster at an on-site troubleshooting to a ZIP-formatted file for storage.
- Imports into a cluster the ZIP-formatted file exported from another TiDB cluster. This file contains the information of the latter TiDB cluster at an on-site troubleshooting.

10.3.5.1 Use `PLAN REPLAYER` to export cluster information

You can use `PLAN REPLAYER` to save the on-site information of a TiDB cluster. The export interface is as follows:

```
PLAN REPLAYER DUMP EXPLAIN [ANALYZE] sql-statement;
```

Based on `sql-statement`, TiDB sorts out and exports the following on-site information:

- TiDB version
- TiDB configuration
- TiDB session variables
- TiDB SQL bindings
- The table schema in `sql-statement`
- The statistics of the table in `sql-statement`
- The result of `EXPLAIN [ANALYZE] sql-statement`

> **Note:**
>
> `PLAN REPLAYER` **DOES NOT** export any table data.

10.3.5.1.1 Examples of exporting cluster information

```
use test;
create table t(a int, b int);
insert into t values(1,1), (2, 2), (3, 3);
analyze table t;

plan replayer dump explain select * from t;
```

`PLAN REPLAYER DUMP` packages the table information above into a `ZIP` file and returns the file identifier as the execution result. This file is a one-time file. After the file is downloaded, TiDB will delete it.

> **Note:**
>
> The `ZIP` file is stored in a TiDB cluster for at most one hour. After one hour, TiDB will delete it.

```
MySQL [test]> plan replayer dump explain select * from t;
```

```
+-----------------------------------------------------------------+
| Dump_link                                                       |
+-----------------------------------------------------------------+
| replayer_JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip |
+-----------------------------------------------------------------+
1 row in set (0.015 sec)
```

Alternatively, you can use the session variable `tidb_last_plan_replayer_token` to obtain the result of the last `PLAN REPLAYER DUMP` execution.

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_Fdamsm3C7ZiPJ-LQqgVjkA==_1663304195885090000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

When there are multiple SQL statements, you can obtain the result of the `PLAN REPLAYER DUMP` execution using a file. The results of multiple SQL statements are separated by `;` in this file.

```
plan replayer dump explain 'sqls.txt';
```

```
Query OK, 0 rows affected (0.03 sec)
```

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_LEDKg8sb-K0u24QesiH8ig==_1663226556509182000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Because the file cannot be downloaded on MySQL Client, you need to use the TiDB HTTP interface and the file identifier to download the file:

```
http://${tidb-server-ip}:${tidb-server-status-port}/plan_replayer/dump/${
    ↪ file_token}
```

`${tidb-server-ip}:${tidb-server-status-port}` is the address of any TiDB server in the cluster. For example:

```
curl http://127.0.0.1:10080/plan_replayer/dump/
    ↪ replayer_JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip >
    ↪ plan_replayer.zip
```

10.3.5.2 Use `PLAN REPLAYER` to import cluster information

> **Warning:**
>
> When you import the on-site information of a TiDB cluster to another cluster, the TiDB session variables, SQL bindings, table schemas and statistics of the latter cluster are modified.

With an existing `ZIP` file exported using `PLAN REPLAYER`, you can use the `PLAN REPLAYER` import interface to restore the on-site information of a cluster to any other TiDB cluster. The syntax is as follows:

```
PLAN REPLAYER LOAD 'file_name';
```

In the statement above, `file_name` is the name of the `ZIP` file to be exported.

For example:

```
PLAN REPLAYER LOAD 'plan_replayer.zip';
```

After the cluster information is imported, the TiDB cluster is loaded with the required table schema, statistics and other information that affects the construction of the execution plan. You can view the execution plan and verify statistics in the following way:

```
mysql> desc t;
+-------+---------+------+------+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+------+---------+-------+
| a     | int(11) | YES |     | NULL    |       |
| b     | int(11) | YES |     | NULL    |       |
+-------+---------+------+------+---------+-------+
```

```
2 rows in set (0.01 sec)

mysql> explain select * from t where a = 1 or b =1;
+--
   ↪ ----------------------+---------+----------+--------------+-----------------
   ↪
| id                     | estRows | task     | access object | operator info
   ↪                    |
+--
   ↪ ----------------------+---------+----------+--------------+-----------------
   ↪
| TableReader_7          | 0.01    | root     |               | data:Selection_6
   ↪                   |
| ─Selection_6           | 0.01    | cop[tikv] |              | or(eq(test.t.a,
   ↪ 1), eq(test.t.b, 1)) |
|   ─TableFullScan_5     | 6.00    | cop[tikv] | table:t      | keep order:false,
   ↪  stats:pseudo  |
+--
   ↪ ----------------------+---------+----------+--------------+-----------------
   ↪
3 rows in set (0.00 sec)

mysql> show stats_meta;
+--
   ↪ -------+-----------+---------------+-------------------+-------------+-----
   ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count |
   ↪ Row_count |
+--
   ↪ -------+-----------+---------------+-------------------+-------------+-----
   ↪
| test    | t          |               | 2022-08-26 15:52:07 |           3 |
   ↪         6 |
+--
   ↪ -------+-----------+---------------+-------------------+-------------+-----
   ↪
1 row in set (0.04 sec)
```

After the scene is loaded and restored, you can diagnose and improve the execution plan for the cluster.

10.4 Support Resources

If you encounter a problem when you use TiDB, you can reach out for support from PingCAP or the TiDB community via the following methods:

- Get support from PingCAP (requires subscription to TiDB Enterprise Edition):
  - Submit a request
- Seek help from the TiDB community:
  - The TiDB Forum
  - Slack channels: #everyone (English), #tidb-japan (Japanese)
  - Stack Overflow (questions tagged with #tidb)
- Learn TiDB's implementation and design
  - TiDB Internals forum

11 Performance Tuning

11.1 Tuning Guide

11.1.1 TiDB Performance Tuning Overview

This document introduces the basic concepts of performance tuning, such as user response time, throughput, and database time, and also provides a general process for performance tuning.

11.1.1.1 User response time and database time

11.1.1.1.1 User response time

User response time indicates how long an application takes to return the results of a request to users. As you can see from the following sequential timing diagram, the time of a typical user request contains the following:

- The network latency between the user and the application
- The processing time of the application
- The network latency during the interaction between the application and the database
- The service time of the database

The user response time is affected by various subsystems on the request chain, such as network latency and bandwidth, number and request types of concurrent users, and resource usage of server CPU and I/O. To optimize the entire system effectively, you need to first identify the bottlenecks in user response time.

To get a total user response time within a specified time range (ΔT), you can use the following formula:

Total user response time in ΔT = Average TPS (Transactions Per Second) x Average user response time x ΔT.

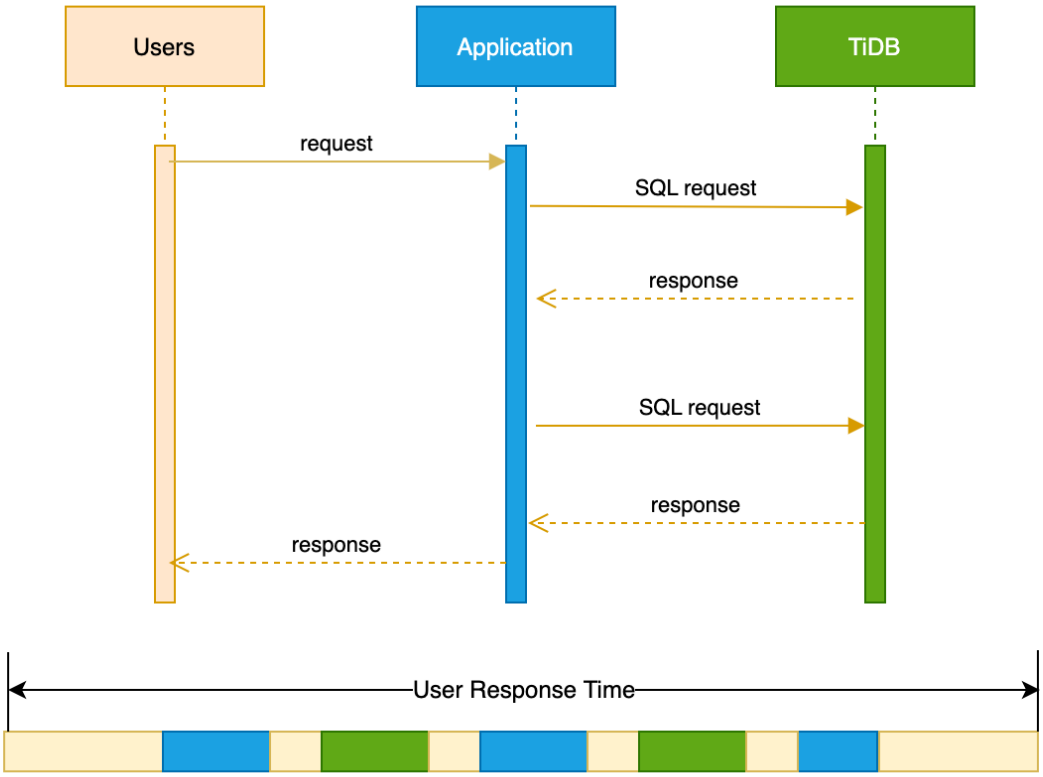

Figure 97: user_response_time

11.1.1.1.2 Database time

Database time indicates the total service time provided by a database. The database time in ΔT is the sum of the time that a database takes to process all application requests concurrently.

To get the database time, you can use any of the following methods:

- Method 1: Multiply the average query latency by QPS and by ΔT, that is, `DB Time in ΔT = QPS × avg latency × ΔT`

- Method 2: Multiply the average number of active sessions by ΔT, that is, `DB Time in ΔT = avg active connections × ΔT`
- Method 3: Calculate the time based on the TiDB internal Prometheus metric TiDB_server_handle_query_duration_seconds_sum, that is. `ΔT DB Time = rate(TiDB_server_handle_query_duration_seconds_sum)× ΔT`

11.1.1.2 Relationship between user response time and system throughput

User response time consists of service time, queuing time, and concurrent waiting time to complete a user request.

```
User Response time = Service time + Queuing delay + Coherency delay
```

- Service time: the time a system consumes on certain resources when processing a request, for example, the CPU time that a database consumes to complete a SQL request.
- Queuing delay: the time a system waits in a queue for service of certain resources when processing a request.
- Coherency delay: the time a system communicates and collaborates with other concurrent tasks, so that it can access shared resources when processing a request.

System throughput indicates the number of requests that can be completed by a system per second. User response time and throughput are usually inverse of each other. When the throughput increases, the system resource utilization and the queuing latency for a requested service increase accordingly. Once resource utilization exceeds a certain inflection point, the queuing latency will increase dramatically.

For example, for a database system running OLTP loads, after its CPU utilization exceeds 65%, the CPU queueing scheduling latency increases significantly. This is because concurrent requests of a system are not completely independent, which means that these requests can collaborate and compete for shared resources. For example, requests from different users might perform mutually exclusive locking operations on the same data. When the resource utilization increases, the queuing and scheduling latency increases too, which causes that the shared resources cannot be released in time and in turn prolongs the waiting time for shared resources by other tasks.

11.1.1.3 Performance tuning process

The performance tuning process consists of the following 6 steps:

1. Define a tuning objective.
2. Establish a performance baseline.
3. Identify bottlenecks in user response time.
4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution.
5. Implement tuning solutions.

6. Evaluate tuning results.

To achieve the tuning objective of a performance tuning project, you usually need to repeat Step 2 to Step 6 multiple times.

11.1.1.3.1 Step 1. Define a tuning objective

For different types of systems, tuning objectives are different too. For example, for a financial core OLTP system, the tuning objective might be to reduce the long-tail latency of transactions; for a financial settlement system, the tuning objective might be to make better use of hardware resources and reduce the time of batch settlement tasks.

A good tuning objective should be easily quantifiable. For example:

- Good tuning objective: The p99 latency for transfer transactions needs to be less than 200 ms during peak business hours of 9 am to 10 am.
- Poor tuning objective: The system is too slow to respond so it needs to be optimized.

Defining a clear tuning objective helps guide the subsequent performance tuning steps.

11.1.1.3.2 Step 2. Establish a performance baseline

To tune performance efficiently, you need to capture the current performance data to establish a performance baseline. The performance data to be captured typically includes the following:

- Mean and long-tail values of user response time, and throughput of your application
- Database performance data such as database time, query latency, and QPS

  TiDB measures and stores performance data thoroughly in different dimensions, such as slow query logs, Top SQL, Continuous Performance Profiling, and traffic visualizer. In addition, you can perform historical backtracking and comparison of the timing metrics data stored in Prometheus.
- Resource utilization, including resources such as CPU, IO, and network
- Configuration information, such as application configurations, database configurations, and operating system configurations

11.1.1.3.3 Step 3. Identify bottlenecks in user response time

Identify or speculate on bottlenecks in user response times based on data from the performance baseline.

Applications usually do not measure and record the full chain of user requests, so you cannot effectively break down user response time from top to bottom through the application.

In contrast, databases have a complete record of performance metrics such as query latency and throughput. Based on database time, you can determine if the bottleneck in user response time is in a database.

- If the bottleneck is not in databases, you need to rely on the resource utilization collected outside databases or profile the application to identify the bottleneck outside databases. Common scenarios include insufficient resources of an application or proxy server, and insufficient usage of hardware resources caused by serial points in an application.
- If bottlenecks are in databases, you can analyze and diagnose the database performances using comprehensive tuning tools. Common scenarios include the presence of slow SQL, unreasonable usage of a database by an application, and the presence of read and write hotspots in databases.

For more information about the analysis and diagnostic methods and tools, see Performance Analysis and Tuning.

11.1.1.3.4 Step 4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution

After identifying the bottleneck of a system through performance analysis, you can propose a tuning solution that is cost-effective, has low risks, and provides the maximum benefit based on the actual situation.

According to Amdahl's Law, the maximum gain from performance tuning depends on the percentage of the optimized part in the overall system. Therefore, you need to identify the system bottlenecks and the corresponding percentage based on the performance data, and then predict the gains after the bottleneck is resolved or optimized.

Note that even if a solution can bring the greatest potential benefits by tunning the largest bottleneck, you still need to evaluate the risks and costs of this solution. For example:

- The most straightforward tuning objective solution for a resource-overloaded system is to expand its capacity, but in practice, the expansion solution might be too costly to be adopted.
- When a slow query in a business module causes a slow response of the entire module, upgrading to a new version of the database can solve the slow query issue, but it might also affect modules that did not have this issue. Therefore, this solution might have a potentially high risk. A low-risk solution is to skip the database version upgrade and rewrite the existing slow queries for the current database version.

11.1.1.3.5 Step 5. Implement tuning solutions

Considering the benefits, risks, and costs, choose one or more tuning solutions for implementation. In the implementation process, you need to make thorough preparation for changes to the production system and record the changes in detail.

To mitigate risks and validate the benefits of a tuning solution, it is recommended that you perform validation and complete regression of changes in both test and staging environments. For example, if the selected tuning solution of a slow query is to create a new index to optimize the query access path, you need to ensure that the new index does not introduce any obvious write hotspots to the existing data insertion workload and slows down other modules.

11.1.1.3.6 Step 6. Evaluate tuning results

After applying the tuning solution, you need to evaluate the results:

- If the tuning objective is reached, the entire tuning project is completed successfully.
- If the tuning objective is not reached, you need to repeat Step 2 to Step 6 in this document until the tuning objective is reached.

After reaching your tuning objectives, you might need to further plan your system capacity to meet your business growth.

11.1.2 Performance Analysis and Tuning

This document describes a tuning approach by database time, and illustrates how to use the TiDB Performance Overview dashboard for performance analysis and tuning.

With the methods described in this document, you can analyze user response time and database time from a global and top-down perspective, to confirm whether the bottleneck in user response time is caused by database issues. If the bottleneck is in the database, you can use the database time overview and SQL latency breakdowns to identify the bottleneck and tune performance.

11.1.2.1 Performance tuning based on database time

TiDB is constantly measuring and collecting SQL processing paths and database time. Therefore, it is easy to identify database performance bottlenecks in TiDB. Based on database time metrics, you can achieve the following two goals even without data on user response time:

- Determine whether the bottleneck is in TiDB by comparing the average SQL processing latency with the idle time of a TiDB connection in a transaction.
- If the bottleneck is in TiDB, further identify the exact module in the distributed system based on database time overview, color-based performance data, key metrics, resource utilization, and top-down latency breakdowns.

11.1.2.1.1 Is TiDB the bottleneck?

- If the average idle time of TiDB connections in transactions is higher than the average SQL processing latency, the database is not to blame for the transaction latency of applications. The database time takes only a small part of the user response time, indicating that the bottleneck is outside the database.

  In this case, check the external components of the database. For example, determine whether there are sufficient hardware resources in the application server, and whether the network latency from the application to the database is excessively high.

- If the average SQL processing latency is higher than the average idle time of TiDB connections in transactions, the bottleneck in transactions is in TiDB, and the database time takes a large percentage of the user response time.

11.1.2.1.2 If the bottleneck is in TiDB, how to identify it?

The following figure shows a typical SQL process. You can see that most SQL processing paths are covered in TiDB performance metrics. The database time is broken down into different dimensions, which are colored accordingly. You can quickly understand the workload characteristics and catch the bottlenecks inside the database if any.

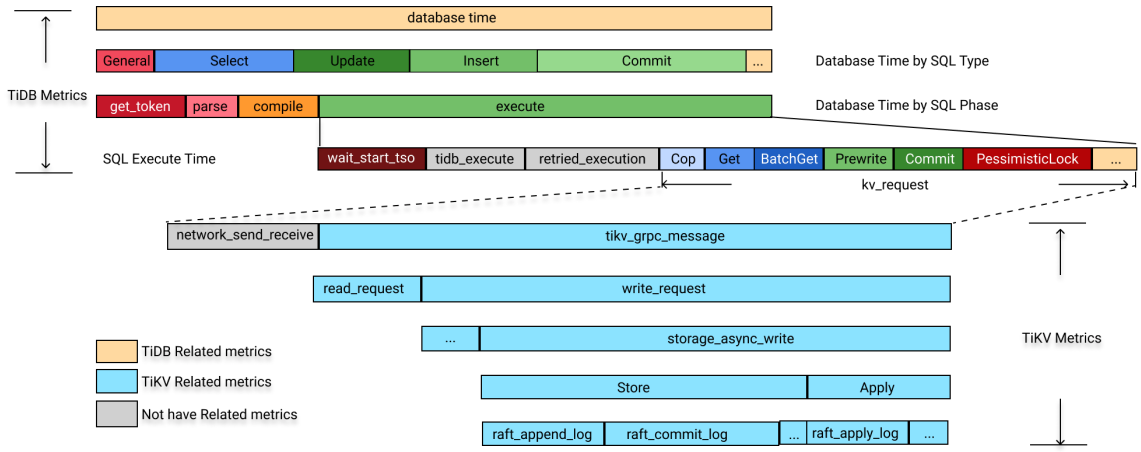

Figure 98: database time decomposition chart

Database time is the sum of all SQL processing time. A breakdown of the database time into the following three dimensions helps you quickly identify bottlenecks in TiDB:

- By SQL processing type: Determine which type of SQL statements consumes the most database time. The formula is:

```
DB Time = Select Time + Insert Time + Update Time + Delete Time +
↪ Commit Time + ...
```

- By the 4 steps of SQL processing (get_token/parse/compile/execute): Determine which step consumes the most time. The formula is:

  ```
  DB Time = Get Token Time + Parse Time + Compile Time + Execute Time
  ```

- By executor time, TSO wait time, KV request time, and execution retry time: Determine which execution step constitutes the bottleneck. The formula is:

  ```
  Execute Time ~= TiDB Executor Time + KV Request Time + PD TSO Wait Time
  ↪  + Retried execution time
  ```

11.1.2.2 Performance analysis and tuning using the Performance Overview dashboard

This section describes how to perform performance analysis and tuning based on database time using the Performance Overview dashboard in Grafana.

The Performance Overview dashboard orchestrates the metrics of TiDB, PD, and TiKV, and presents each of them in the following sections:

- Database time and SQL execution time overview: Color-coded SQL types, database time by SQL execution phase, and database time of different requests help you quickly identify database workload characteristics and performance bottlenecks.
- Key metrics and resource utilization: Contains database QPS, connection information, request command types between the applications and the database, database internal TSO and KV request OPS, and TiDB/TiKV resource usage.
- Top-down latency breakdown: Contains a comparison of query latency and connection idle time, breakdown of query latency, latency of TSO requests and KV requests in SQL execution, and breakdown of TiKV internal write latency.

11.1.2.2.1 Database time and SQL execution time overview

The database time metric is the sum of the latency that TiDB processes SQL per second, which is also the total time that TiDB concurrently processes application SQL requests per second (equal to the number of active connections).

The Performance Overview dashboard provides the following three stacked area graphs. They help you understand database workload profile and quickly identify the bottleneck causes in terms of statements, sql phase, and TiKV or PD request type during SQL execution.

- Database Time By SQL Type
- Database Time By SQL Phase
- SQL Execute Time Overview

Tune by color

The diagrams of database time breakdown and execution time overview present both expected and unexpected time consumption intuitively. Therefore, you can quickly identify performance bottleneck and learn the workload profile. Green and blue areas stand for normal time consumption and requests. If non-green or non-blue areas occupy a significant proportion in these two diagrams, the database time distribution is inappropriate.

- Database Time By SQL Type:
  - Blue: `Select` statement
  - Green: `Update`, `Insert`, `Commit` and other DML statements
  - Red: General SQL types, including `StmtPrepare`, `StmtReset`, `StmtFetch`, and `StmtClose`
- Database Time By SQL Phase: The SQL execution phase is in green and other phases are in red on general. If non-green areas are large, it means much database time is consumed in other phases than the execution phase and further cause analysis is required. A common scenario is that the compile phase shown in orange takes a large area due to unavailability of prepared plan cache.
- SQL Execute Time Overview: Green metrics stand for common KV write requests (such as `Prewrite` and `Commit`), blue metrics stand for common KV read requests (such as Cop and Get), and metrics in other colors stand for unexpected situations which you need to pay attention. For example, pessimistic lock KV requests are marked red and TSO waiting is marked dark brown. If non-blue or non-green areas are large, it means there is bottleneck during SQL execution. For example:
  - If serious lock conflicts occur, the red area will take a large proportion.
  - If excessive time is consumed in waiting TSO, the dark brown area will take a large proportion.

Example 1: TPC-C workload

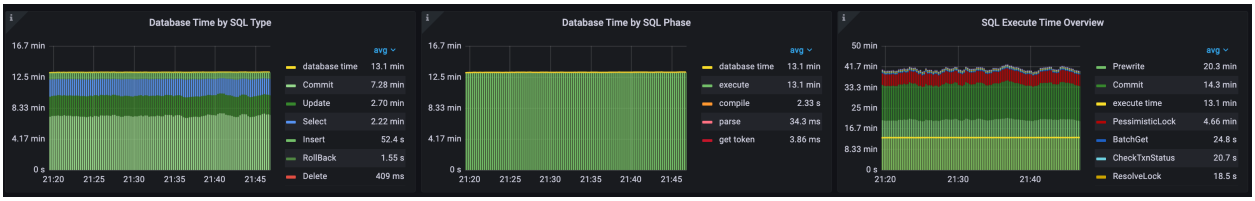

Figure 99: TPC-C

- Database Time by SQL Type: Most time-consuming statements are `commit`, `update`, `select`, and `insert` statements.

- Database Time by SQL Phase: The most time-consuming phase is SQL execution in green.
- SQL Execute Time Overview: The most time-consuming KV requests in SQL execution are `Prewrite` and `Commit` in green.

> **Note:**
>
> It is normal that the total KV request time is greater than the execute time. Because the TiDB executor may send KV requests to multiple TiKVs concurrently, causing the total KV request wait time to be greater than the execute time. In the preceding TPC-C workload, TiDB sends `Prewrite` and `Commit` requests concurrently to multiple TiKVs when a transaction is committed. Therefore, the total time for `Prewrite`, `Commit` , and `PessimisticsLock` requests in this example is obviously longer than the execute time.
>
> - The `execute` time may also be significantly greater than the total time of the KV request plus the `tso_wait` time. This means that the SQL execution time is spent mostly inside the TiDB executor. Here are two common examples:

```
> - Example 1: After TiDB executor reads a large amount of data from
    ↪ TiKV, it needs to do complex join and aggregation inside TiDB,
    ↪ which consumes a lot of time.
> - Example 2: The application experiences serious write statement lock
    ↪  conflicts. Frequent lock retries result in long `Retried
    ↪ execution time`.
```

Example 2: OLTP read-heavy workload

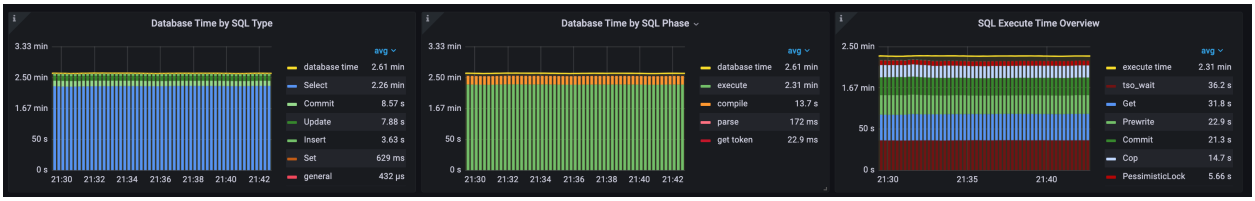

Figure 100: OLTP

- Database Time by SQL Type: Major time-consuming statements are `SELECT`, `COMMIT`, `UPDATE`, and `INSERT`, among which `SELECT` consumes most database time.
- Database Time by SQL Phase: Most time is consumed in the `execute` phase in green.

- SQL Execute Time Overview: In SQL execution phase, `pd tso_wait` in dark brown, `KV Get` in blue, and `Prewrite` and `Commit` in green are time-consuming.

Example 3: Read-only OLTP workload

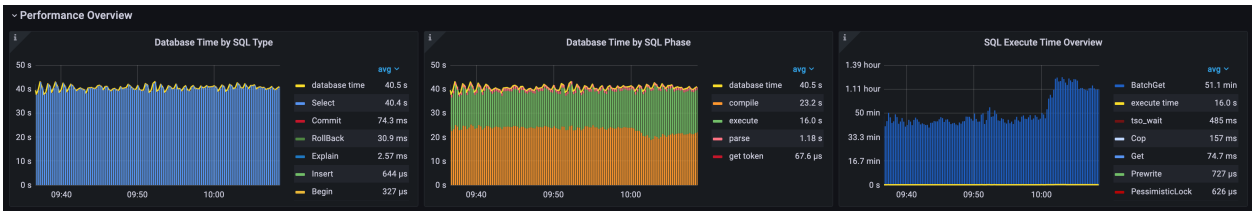

Figure 101: OLTP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Major time-consuming phases are `compile` in orange and `execute` in green. Latency in the `compile` phase is the highest, indicating that TiDB is taking too long to generate execution plans and the root cause needs to be further determined based on the subsequent performance data.
- SQL Execute Time Overview: The KV BatchGet requests in blue consume the most time during SQL execution.

> **Note:**
>
> In example 3, `SELECT` statements need to read thousands of rows concurrently from multiple TiKVs. Therefore, the total time of the `BatchGet` request is much longer than the execution time.

Example 4: Lock contention workload

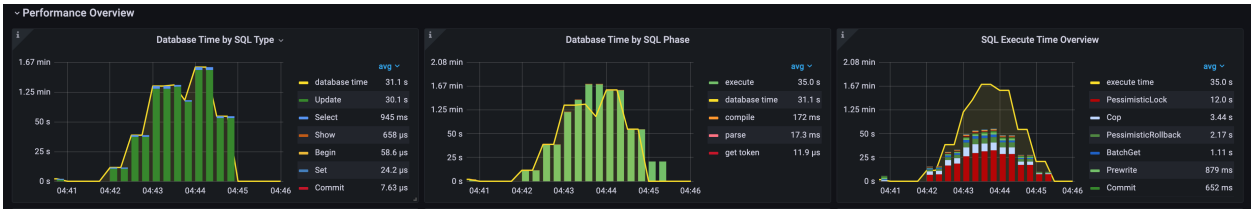

Figure 102: OLTP

- Database Time by SQL Type: Mainly are `UPDATE` statements.

- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The KV request PessimisticLock shown in red consumes the most time during SQL execution, and the execution time is obviously longer than the total time of KV requests. This is caused by serious lock conflicts in write statements and frequent lock retries prolong `Retried execution time`. Currently, TiDB does not measure `Retried execution time`.

11.1.2.2.2 TiDB key metrics and cluster resource utilization

Query Per Second, Command Per Second, and Prepared-Plan-Cache

By checking the following three panels in Performance Overview, you can learn the application workload type, how the application interacts with TiDB, and whether the application fully utilizes TiDB prepared plan cache.

- QPS: Short for Query Per Second. It shows the count of SQL statements executed by the application.
- CPS By Type: Short for Command Per Second. Command indicates MySQL protocol-specific commands. A query statement can be sent to TiDB either by a query command or a prepared statement.
- Queries Using Plan Cache OPS: The count that the TiDB cluster hits the prepared plan cache per second. prepared plan cache only supports the `prepared statement` command. When prepared plan cache is enabled in TiDB, the following three scenarios will occur:
  - No prepared plan cache is hit: The number of plan cache hit per second is 0. The application is using the query interface, or cached plans are cleaned up by calling the StmtClose command after each StmtExecute execution.
  - All prepared plan cache is hit: The number of hits per second is equal to the number of StmtExecute commands per second.
  - Some prepared plan cache is hit: The number of hits per second is fewer than the number of StmtExecute commands per second. Prepared plan cache has known limitations, for example, it does not support subqueries, SQL statements with subqueries cannot utilize prepared plan cache.

Example 1: TPC-C workload

The TPC-C workload are mainly `UPDATE`, `SELECT`, and `INSERT` statements. The total QPS is equal to the number of StmtExecute per second and the latter is almost equal to Queries Using Plan Cache OPS. Ideally, the client caches the object of the prepared statement. In this way, the cached statement is called directly when a SQL statement is executed. All SQL executions hit the prepared plan cache, and there is no need to recompile to generate execution plans.

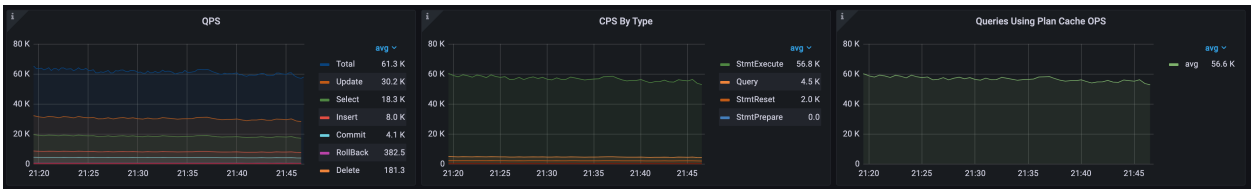

Figure 103: TPC-C

Example 2: Prepared plan cache unavailable for query commands in read-only OLTP workload

In this workload, `Commit QPS` = `Rollback QPS` = `Select QPS`. The application has enabled auto-commit concurrency, and rollback is performed every time a connection is fetched from the connection pool. As a result, these three statements are executed the same number of times.

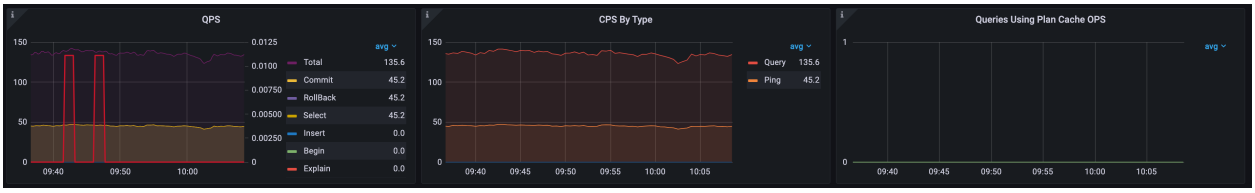

Figure 104: OLTP-Query

- The red bold line in the QPS panel stands for failed queries, and the Y-axis on the right shows the number of failed queries. A value other than 0 means the presence of failed queries.
- The total QPS is equal to the number of queries in the CPS By Type panel, the query command has been used by the application.
- The Queries Using Plan Cache OPS panel has no data, because prepared plan cache is unavailable for query command. This means that TiDB needs to parse and generate an execution plan for every query execution. As a result, the compile time is longer with increasing CPU consumption by TiDB.

Example 3: Prepared plan cache unavailable with prepared statement enabled for OLTP workload

`StmtPreare` times = `StmtExecute` times = `StmtClose` times ~= `StmtFetch` times. The application uses the prepare > execute > fetch > close loop. To prevent prepared statement object leak, many application frameworks call `close` after the `execute` phase. This creates two problems.

- A SQL execution requires four commands and four network round trips.

- Queries Using Plan Cache OPS is 0, indicating zero hit of prepared plan cache. The `StmtClose` command clears cached execution plans by default and the next `StmtPreare` command needs to generate the execution plan again.

> **Note:**
>
> Starting from TiDB v6.0.0, you can prevent the `StmtClose` command from clearing cached execution plans via the global variable (`set global tidb_ignore_prepared_cache_close_stmt=on;`). In this way, subsequent executions can hit the prepared plan cache.

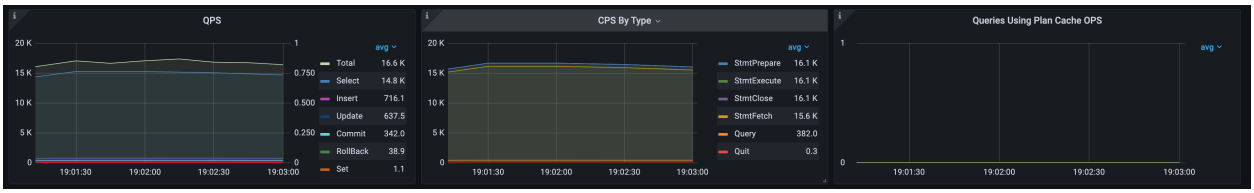

Figure 105: OLTP-Prepared

KV/TSO Request OPS and connection information

In the KV/TSO Request OPS panel, you can view the statistics of KV and TSO requests per second. Among the statistics, `kv request total` represents the sum of all requests from TiDB to TiKV. By observing the types of requests from TiDB to PD and TiKV, you can get an idea of the workload profile within the cluster.

In the Connection Count panel, you can view the total number of connections and the number of connections per TiDB. The counts help you determine whether the total number of connections is normal and the number of connections per TiDB is even. `active connections` records the number of active connections, which is equal to the database time per second.

Example 1: Busy workload

Figure 106: TPC-C

In this TPC-C workload:

- The total number of KV requests per second is 104,200. The top request types are `PessimisticsLock`, `Prewrite`, `Commit` and `BatchGet` in order of number of requests.
- The total number of connections is 810, which are evenly distributed in three TiDB instances. The number of active connections is 787.1. Therefore, 97% of the connections are active, indicating that the database is the bottleneck for this system.

Example 2: Idle workload

Figure 107: OLTP

In this workload:

- The total number of KV requests per second is 2600 and the number of TSO requests per second is 1100.
- The total number of connections is 410, which are evenly distributed in three TiDB instances. The number of active connections is only 2.5, indicating that the database system is relatively idle.

TiDB CPU, TiKV CPU, and IO usage

In the TiDB CPU and TiKV CPU/IO MBps panels, you can observe the logical CPU usage and IO throughput of TiDB and TiKV, including average, maximum, and delta (maximum CPU usage minus minimum CPU usage), based on which you can determine the overall CPU usage of TiDB and TiKV.

- Based on the `delta` value, you can determine if CPU usage in TiDB is unbalanced (usually accompanied by unbalanced application connections) and if there are read/write hot spots among the cluster.
- With an overview of TiDB and TiKV resource usage, you can quickly determine if there are resource bottlenecks in your cluster and whether TiKV or TiDB needs scale-out.

Example 1: High TiDB resource usage

In this workload, each TiDB and TiKV is configured with 8 CPUs.

Figure 108: TPC-C

- The average, maximum, and delta CPU usage of TiDB are 575%, 643%, and 136%, respectively.
- The average, maximum, and delta CPU usage of TiKV are 146%, 215%, and 118%, respectively. The average, maximum, and delta I/O throughput of TiKV are 9.06 MB/s, 19.7 MB/s, and 17.1 MB/s, respectively.

Obviously, TiDB consumes more CPU, which is near the bottleneck threshold of 8 CPUs. It is recommended that you scale out the TiDB.

Example 2: High TiKV resource usage

In the TPC-C workload below, each TiDB and TiKV is configured with 16 CPUs.

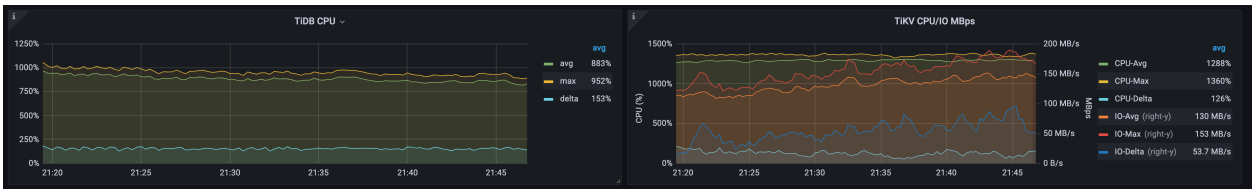

Figure 109: TPC-C

- The average, maximum, and delta CPU usage of TiDB are 883%, 962%, and 153%, respectively.
- The average, maximum, and delta CPU usage of TiKV are 1288%, 1360%, and 126%, respectively. The average, maximum, and delta I/O throughput of TiKV are 130 MB/s, 153 MB/s, and 53.7 MB/s, respectively.

Obviously, TiKV consumes more CPU, which is expected because TPC-C is a write-heavy scenario. It is recommended that you scale out the TiKV to improve performance.

11.1.2.2.3 Query latency breakdown and key latency metrics

The latency panel provides average values and 99th percentile. The average values help identify the overall bottleneck, while the 99th or 999th percentile or 999th helps determine whether there is a significant latency jitter.

Duration and Connection Idle Duration

The Duration panel contains the average and P99 latency of all statements, and the average latency of each SQL type. The Connection Idle Duration panel contains the average and the P99 connection idle duration. Connection idle duration includes the following two states:

- in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is within a transaction.
- not-in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is not within a transaction.

An applications perform transactions with the same database connction. By comparing the average query latency with the connection idle duration, you can determine if TiDB is the bottleneck for overall system, or if user response time jitter is caused by TiDB.

- If the application workload is not read-only and contains transactions, by comparing the average query latency with `avg-in-txn`, you can determine the proportion in processing transactions inside and outside the database, and identify the bottleneck in user response time.
- If the application workload is read-only or autocommit mode is on, you can compare the average query latency with `avg-not-in-txn`.

In real customer scenarios, it is not rare that the bottleneck is outside the database, for example:

- The client server configuration is too low and the CPU resources are exhausted.
- HAProxy is used as a TiDB cluster proxy, and the HAProxy CPU resource is exhausted.
- HAProxy is used as a TiDB cluster proxy, and the network bandwidth of the HAProxy server is used up under high workload.
- The network latency from the application server to the database is high. For example, the network latency is high because in public-cloud deployments the applications and the TiDB cluster are not in the same region, or the dns workload balancer and the TiDB cluster are not in the same region.
- The bottleneck is in client applications. The application server's CPU cores and Numa resources cannot be fully utilized. For example, only one JVM is used to establish thousands of JDBC connections to TiDB.

Example 1: TiDB is the bottleneck of user response time

Figure 110: TiDB is the Bottleneck

In this TPC-C workload:

- The average latency and P99 latency of all SQL statements are 477 us and 3.13 ms, respectively. The average latencies of the commit statement, insert statement, and query statement are 2.02 ms, 609 us, and 468 us, respectively.
- The average connection idle time in transactions `avg-in-txn` is 171 us.

The average query latency is significantly greater than `avg-in-txn`, which means the main bottleneck in transactions is inside the database.

Example 2: The bottleneck of user response time is not in TiDB

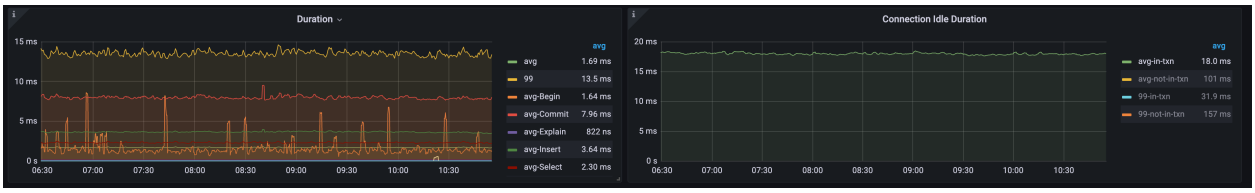

Figure 111: TiDB is the Bottleneck

In this workload, the average query latency is 1.69 ms and `avg-in-txn` is 18 ms, indicating that TiDB spends 1.69 ms on average to process a SQL statement in transactions, and then needs to wait for 18 ms to receive the next statement.

The average query latency is significantly lower than `avg-in-txn`. The bottleneck of user response time is not in TiDB. This example is in a public cloud environment, where high network latency between the application and the database results in extremely high connection idle time, because the application and the database are not in the same region.

Parse, Compile, and Execute Duration

In TiDB, there is a typical processing flow from sending query statements to returning results.

SQL processing in TiDB consists of four phases, `get token`, `parse`, `compile`, and `execute`.

- `get token`: Usually only a few microseconds and can be ignored. The token is limited only when the number of connections to a single TiDB instance reaches the token-limit limit.
- `parse`: The query statements are parsed into abstract syntax tree (AST).
- `compile`: Execution plans are compiled based on the AST from the `parse` phase and statistics. The `compile` phase contains logical optimization and physical optimization. Logical optimization optimizes query plans by rules, such as column pruning based on relational algebra. Physical optimization estimates the cost of the execution plans by statistics by a cost-based optimizer and selects a physical execution plan with the lowest cost.
- `execute`: The time consumption to execute a SQL statement. TiDB first waits for the globally unique timestamp TSO. Then the executor constructs the TiKV API request based on the Key range of the operator in the execution plan and distributes it to TiKV. `execute` time includes the TSO wait time, the KV request time, and the time spent by TiDB executor in processing data.

If an application uses the `query` or `StmtExecute` MySQL command interface only, you can use the following formula to identify the bottleneck in average latency.

```
avg Query Duration = avg Get Token + avg Parse Duration + avg Compile
    ↪ Duration + avg Execute Duration
```

Usually, the `execute` phase accounts for the most of the `query` latency. However, the `parse` and `compile` phases can also take a large part in the following cases:

- Long latency in the `parse` phase: For example, when the `query` statement is long, much CPU will be consumed to parse the SQL text.
- Long latency in the `compile` phase: If the prepared plan cache is not hit, TiDB needs to compile an execution plan for every SQL execution. The latency in the `compile` phase can be several or tens of milliseconds or even higher. If prepared plan cache is not hit, logical and physical optimization are done in the `compile` phase, which consumes a lot of CPU and memory, makes Go Runtime (TiDB is written in Go) under pressure, and affects the performance of other TiDB components. Prepared plan cache is important for efficient processing of OLTP workload in TiDB.

Example 1: Database bottleneck in the `compile` phase

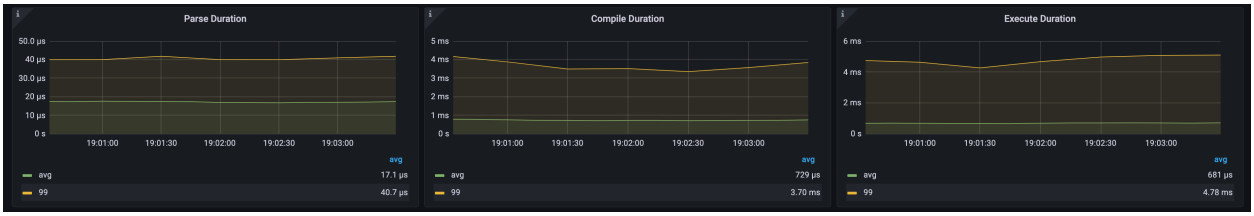

Figure 112: Compile

In the preceding figure, the average time of the `parse`, `compile`, and `execute` phases are 17.1 us, 729 us, and 681 us, respectively. The `compile` latency is high because the application uses the `query` command interface and cannot use prepared plan cache.

Example 2: Database bottleneck in the `execute` phase

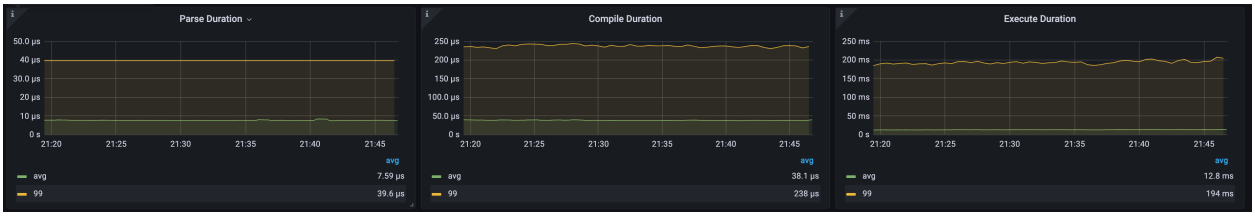

Figure 113: Execute

In this TPC-C workload, the average time of `parse`, `compile` and `execute` phases are 7.39 us, 38.1 us, and 12.8 ms, respectively. The `execute` phase is the bottleneck of the `query` latency.

KV and TSO Request Duration

TiDB interacts with PD and TiKV in the `execute` phase. As shown in the following figure, when processing SQL request, TiDB requests TSOs before entering the `parse` and `compile` phases. The PD Client does not block the caller, but returns a `TSFuture` and asynchronously sends and receives the TSO requests in the background. Once the PD client finishes handling the TSO requests, it returns `TSFuture`. The holder of the `TSFuture` needs to call the Wait method to get the final TSOs. After TiDB finishes the `parse` and `compile` phases, it enters the `execute` phase, where two situations might occur:

- If the TSO request has completed, the Wait method immediately returns an available TSO or an error
- If the TSO request has not yet completed, the Wait method is blocked until a TSO is available or an error appears (the gRPC request has been sent but no result is returned, and the network latency is high)

The TSO wait time is recorded as `TSO WAIT` and the network time of the TSO request is recorded as `TSO RPC`. After the TSO wait is complete, TiDB executor usually sends read or write requests to TiKV.

- Common KV read requests: `Get`, `BatchGet`, and `Cop`
- Common KV write requests: `PessimisticLock`, `Prewrite` and `Commit` for two-phase commits

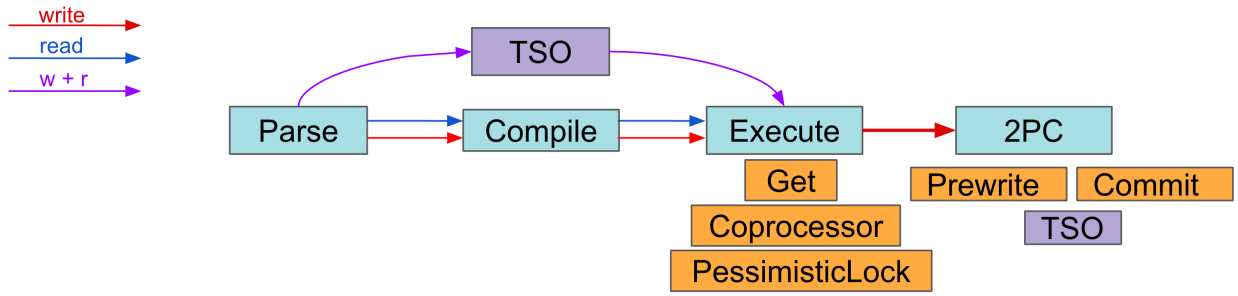

Figure 114: Execute

The indicators in this section correspond to the following three panels.

- Avg TiDB KV Request Duration: The average latency of KV requests measured by TiDB
- Avg TiKV GRPC Duration: The average latency in processing gPRC messages in TiKV
- PD TSO Wait/RPC Duration: TiDB executor TSO wait time and network latency for TSO requests (RPC)

The relationship between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is as follows:

```
Avg TiDB KV Request Duration = Avg TiKV GRPC Duration + Network latency between TiDB and TiKV + TiKV gRPC processing time + TiDB gRPC processing time and scheduling latency
```

The difference between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is closely related to the network traffic, network latency, and resource usage by TiDB and TiKV.

- In the same data center: The difference is generally less than 2 ms.
- In different availability zones in the same region: The difference is generally less than 5 ms.

Example 1: Low workload of clusters deployed on the same data center

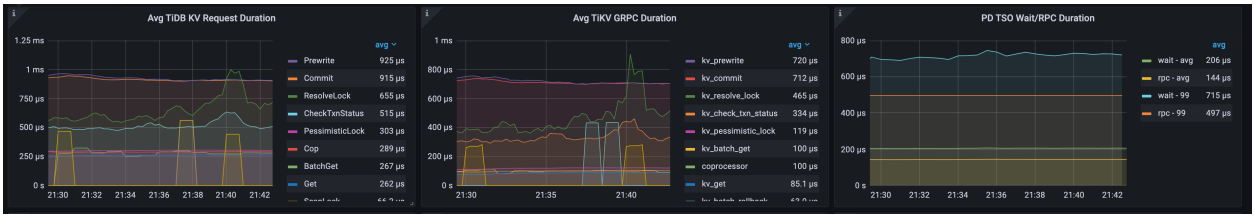

Figure 115: Same Data Center

In this workload, the average `Prewrite` latency on TiDB is 925 us, and the average `kv_prewrite` processing latency inside TiKV is 720 us. The difference is about 200 us, which is normal in the same data center. The average TSO wait latency is 206 us, and the RPC time is 144 us.

Example 2: Normal workload on public cloud clusters

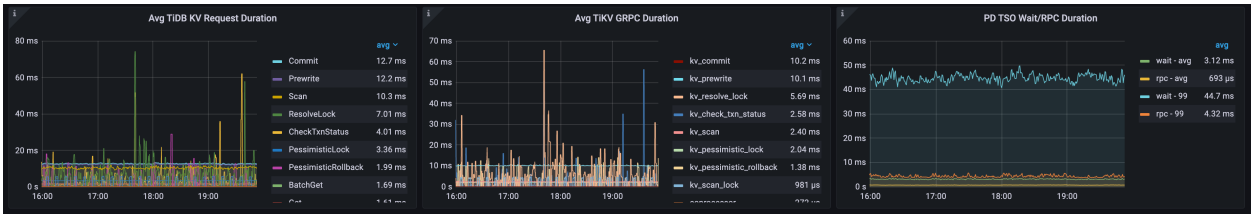

Figure 116: Cloud Env

In this example, TiDB clusters are deployed in different data centers in the same region. The average `commit` latency on TiDB is 12.7 ms, and the average `kv_commit` processing latency inside TiKV is 10.2 ms, a difference of about 2.5 ms. The average TSO wait latency is 3.12 ms, and the RPC time is 693 us.

Example 3: Resource overloaded on public cloud clusters

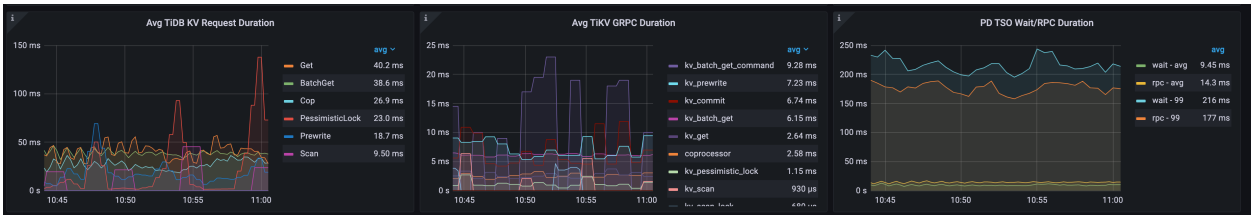

Figure 117: Cloud Env, TiDB Overloaded

In this example, the TiDB clusters are deployed in different data centers in the same region, and TiDB network and CPU resources are severely overloaded. The average `BatchGet` latency on TiDB is 38.6 ms, and the average `kv_batch_get` processing latency inside TiKV is 6.15 ms. The difference is more than 32 ms, which is much higher than the normal value. The average TSO wait latency is 9.45 ms and the RPC time is 14.3 ms.

Storage Async Write Duration, Store Duration, and Apply Duration

TiKV processes a write request in the following procedure:

- `scheduler worker` processes the write request, performs a transaction consistency check, and converts the write request into a key-value pair to be sent to the `raftstore` module.

- The TiKV consensus module `raftstore` applies the Raft consensus algorithm to make the storage layer (composed of multiple TiKVs) fault-tolerant.

  Raftstore consists of a `Store` thread and an `Apply` thread:

  - The `Store` thread processes Raft messages and new `proposals`. When a new `proposals` is received, the `Store` thread of the leader node writes to the local Raft DB and copies the message to multiple follower nodes. When this `proposals` is successfully persisted in most instances, the `proposals` is successfully committed.
  - The `Apply` thread writes the committed `proposals` to the KV DB. When the content is successfully written to the KV DB, the `Apply` thread notifies externally that the write request has completed.

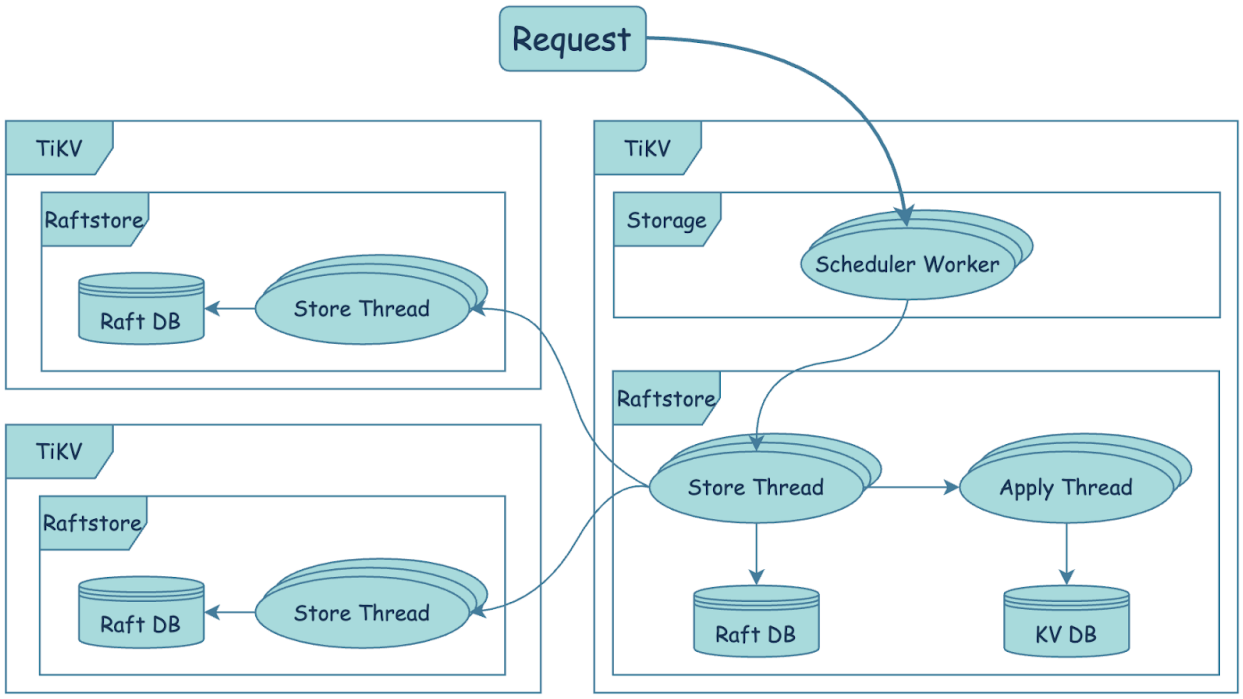

Figure 118: TiKV Write

The `Storage Async Write Duration` metric records the latency after a write request enters raftstore. The data is collected on a basis of per request.

The `Storage Async Write Duration` metric contains two parts, `Store Duration` and `Apply Duration`. You can use the following formula to determine whether the bottleneck for write requests is in the `Store` or `Apply` step.

```
avg Storage Async Write Duration = avg Store Duration + avg Apply Duration
```

Note:

`Store Duration` and `Apply Duration` are supported since v5.3.0.

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

According to the preceding formula, the QPS of a write-heavy OLTP workload in v5.4.0 is 14% higher than that in v5.3.0:

- v5.3.0: 24.4 ms ~= 17.7 ms + 6.59 ms
- v5.4.0: 21.4 ms ~= 14.0 ms + 7.33 ms

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Store Duration` compared with v5.3.0.

v5.3.0:

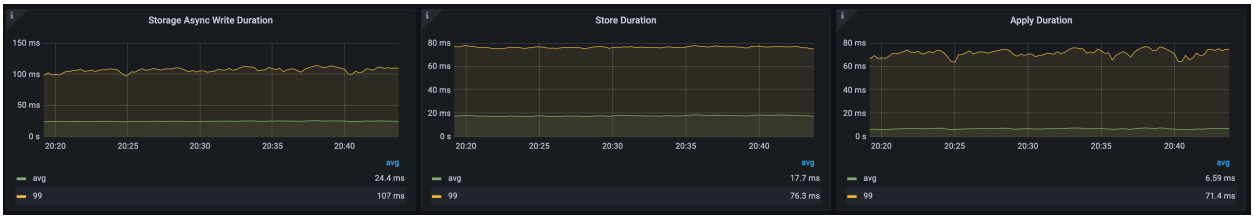

Figure 119: v5.3.0

v5.4.0:

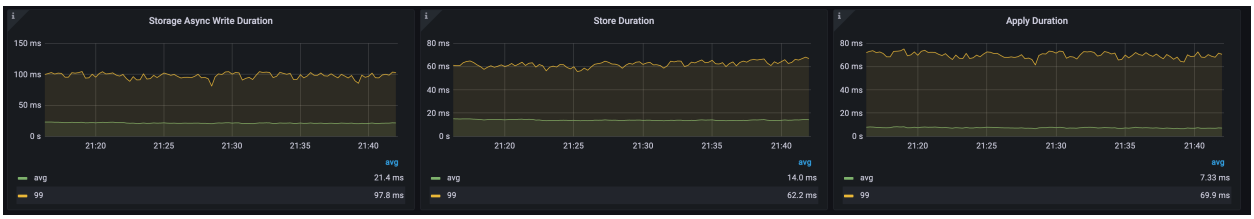

Figure 120: v5.4.0

Example 2: Store Duration is a bottleneck

Apply the preceding formula: 10.1 ms ~= 9.81 ms + 0.304 ms. The result indicates that the latency bottleneck for write requests is in `Store Duration`.

Figure 121: Store

Commit Log Duration, Append Log Duration, and Apply Log Duration

`Commit Log Duration`, `Append Log Duration`, and `Apply Log Duration` are latency metrics for key operations within raftstore. These latencies are captured at the batch operation level, with each operation combining multiple write requests. Therefore, the latencies do not directly correspond to the `Store Duration` and `Apply Duration` mentioned above.

- `Commit Log Duration` and `Append Log Duration` record time of operations performed in the `Store` thread. `Commit Log Duration` includes the time of copying Raft logs to other TiKV nodes (to ensure raft-log persistence). `Commit Log Duration` usually contains two `Append Log Duration` operations, one for the leader and the other for the follower. `Commit Log Duration` is usually significantly higher than `Append Log Duration`, because the former includes the time of copying Raft logs to other TiKV nodes through network.
- `Apply Log Duration` records the latency of `apply` Raft logs by the `Apply` thread.

Common scenarios where `Commit Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.store-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high, resulting in high `Append Log Duration` latency
- The network latency between TiKV nodes is high
- The number of the gRPC threads are too small, CPU usage is uneven among the GRPC threads.

Common scenarios where `Apply Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.apply-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

The QPS of a write-heavy OLTP workload in v5.4.0 is improved by 14% compared with that in v5.3.0. The following table compares the three key latencies.

Avg Duration	v5.3.0 (ms)	v5.4.0 (ms)
Append Log Duration	0.27	0.303
Commit Log Duration	13	8.68
Apply Log Duration	0.457	0.514

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Commit Log Duration` and `Store Duration` compared with v5.3.0.

v5.3.0:

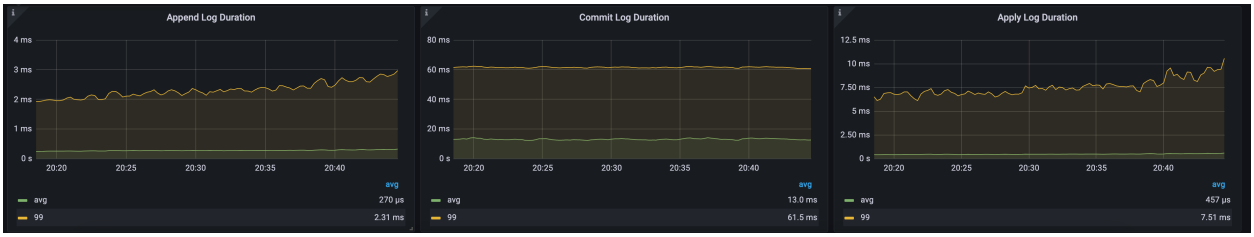

Figure 122: v5.3.0

v5.4.0:

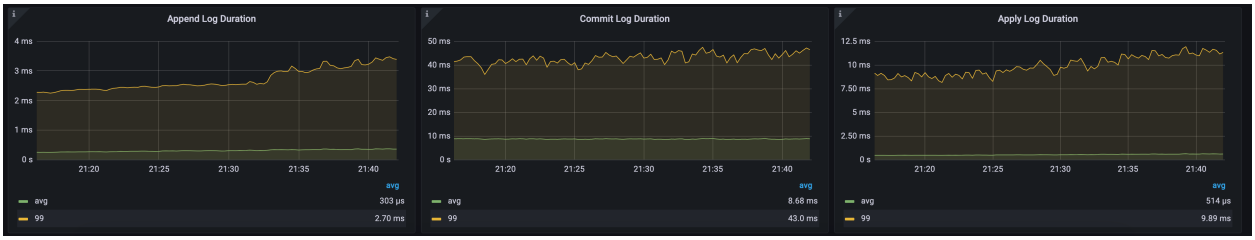

Figure 123: v5.4.0

Example 2: Commit Log Duration is a bottleneck

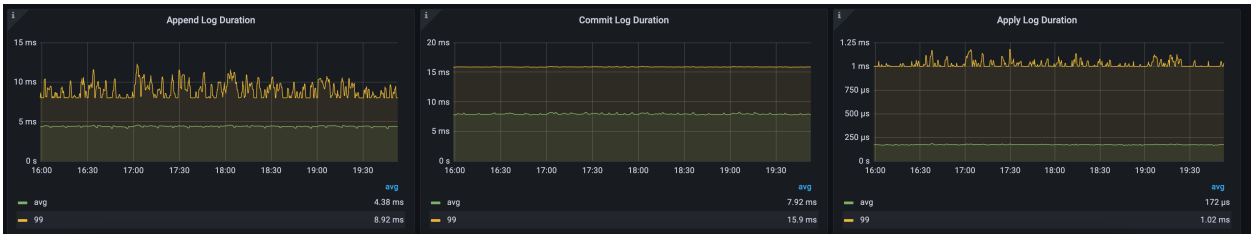

Figure 124: Store

- Average `Append Log Duration` = 4.38 ms
- Average `Commit Log Duration` = 7.92 ms
- Average `Apply Log Duration` = 172 us

For the `Store` thread, `Commit Log Duration` is obviously higher than `Apply Log Duration`. Meanwhile, `Append Log Duration` is significantly higher than `Apply Log Duration`, indicating that the `Store` thread might suffer from bottlenecks in both CPU and I/O. Possible ways to reduce `Commit Log Duration` and `Append Log Duration` are as follows:

- If TiKV CPU resources are sufficient, consider adding `Store` threads by increasing the value of `raftstore.store-pool-size`.
- If TiDB is v5.4.0 or later, consider enabling `Raft Engine` by setting `raft-engine.enable: true`. Raft Engine has a light execution path. This helps reduce I/O writes and long-tail latency of writes in some scenarios.
- If TiKV CPU resources are sufficient and TiDB is v5.3.0 or later, consider enabling `StoreWriter` by setting `raftstore.store-io-pool-size: 1`.

11.1.2.3 If my TiDB version is earlier than v6.1.0, what should I do to use the Performance Overview dashboard?

Starting from v6.1.0, Grafana has a built-in Performance Overview dashboard by default. This dashboard is compatible with TiDB v4.x and v5.x versions. If your TiDB is earlier than v6.1.0, you need to manually import `performance_overview.json`, as shown in the following figure:

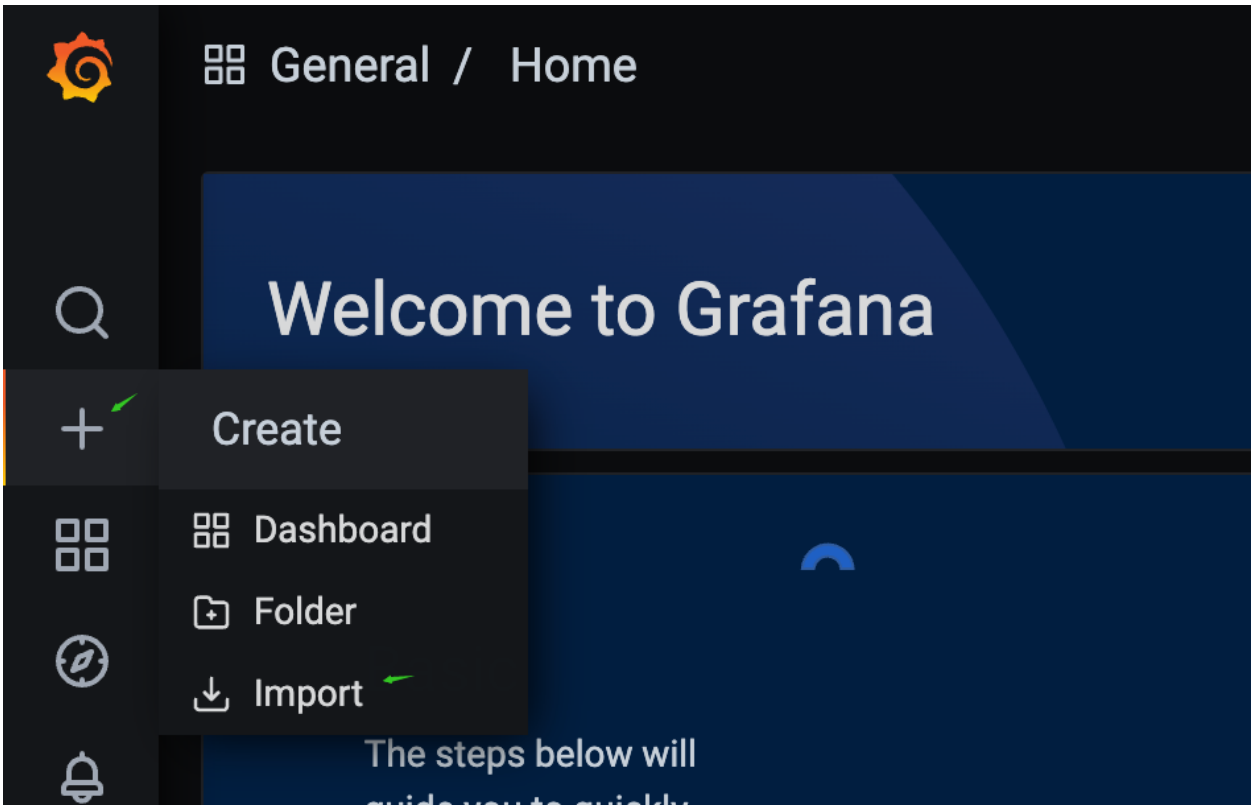

Figure 125: Store

11.1.3 Performance Tuning Practices for OLTP Scenarios

TiDB provides comprehensive performance diagnostics and analysis features, such as Top SQL and Continuous Profiling features on the TiDB Dashboard, and TiDB Performance Overview Dashboard.

This document describes how to use these features together to analyze and compare the performance of the same OLTP workload in seven different runtime scenarios, which demonstrates a performance tuning process to help you analyze and tune TiDB performance efficiently.

> **Note:**
>
> Top SQL and Continuous Profiling are not enabled by default. You need to enable them in advance.

By running the same application with different JDBC configurations in these scenarios, this document shows you how the overall system performance is affected by different

interactions between applications and databases, so that you can apply Best Practices for Developing Java Applications with TiDB for better performance.

11.1.3.1 Environment description

This document takes a core banking OLTP workload for demonstration. The configurations of the simulation environment are as follows:

- Application development language for the workload: JAVA
- SQL statements used in business: 200 statements in total, 90% of which are SELECT statements. It is a typical read-heavy OLTP workload.
- Tables used in transactions: 60 tables in total. 12 tables involve update operations, and the rest 48 tables are read-only.
- Isolation level used by the application: `read committed`.
- TiDB cluster configuration: 3 TiDB nodes and 3 TiKV nodes, with 16 CPUs allocated to each node.
- Client server configuration: 36 CPUs.

11.1.3.2 Scenario 1. Use the Query interface

11.1.3.2.1 Application configuration

The application uses the following JDBC configuration to connect to the database through the Query interface.

```
useServerPrepStmts=false
```

11.1.3.2.2 Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that the non-business SQL type `SELECT @@session.tx_isolation` consumes the most resources. Although TiDB processes these types of SQL statements quickly, these types of SQL statements have the highest number of executions that result in the highest overall CPU time consumption.

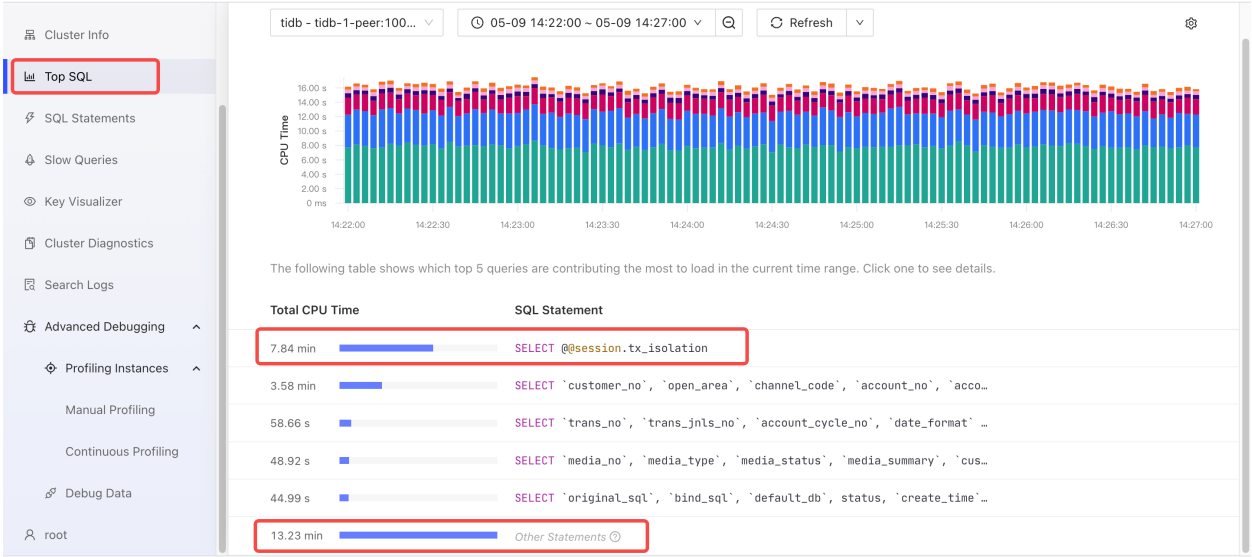

Figure 126: dashboard-for-query-interface

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is significant during the SQL execution. Because the application uses the Query interface, TiDB cannot use the execution plan cache. TiDB needs to compile and generate an execution plan for each SQL statement.

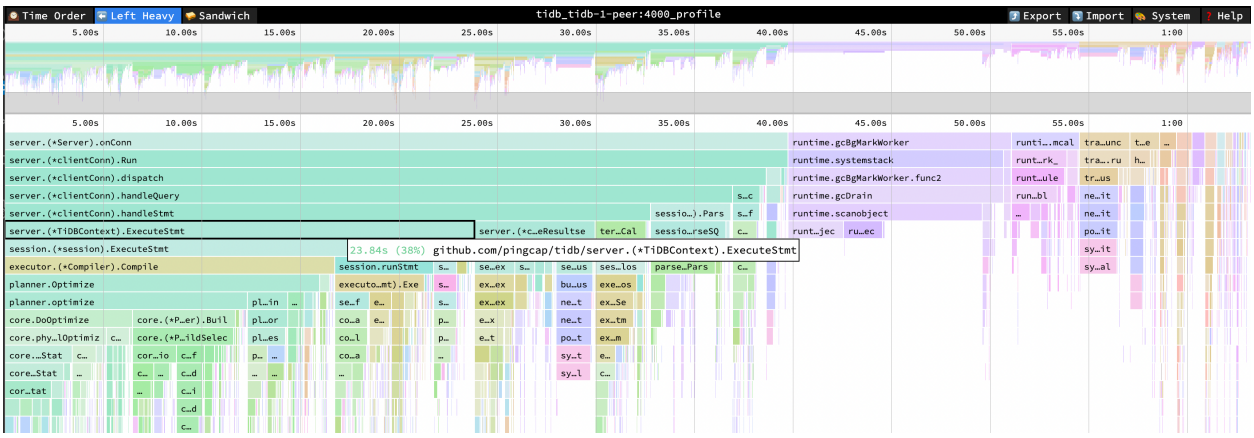

Figure 127: flame-graph-for-query-interface

- ExecuteStmt cpu = 38% cpu time = 23.84s
- Compile cpu = 27% cpu time = 17.17s
- Optimize cpu = 26% cpu time = 16.41s

Performance Overview dashboard

Check the database time overview and QPS in the following Performance Overview dashboard.

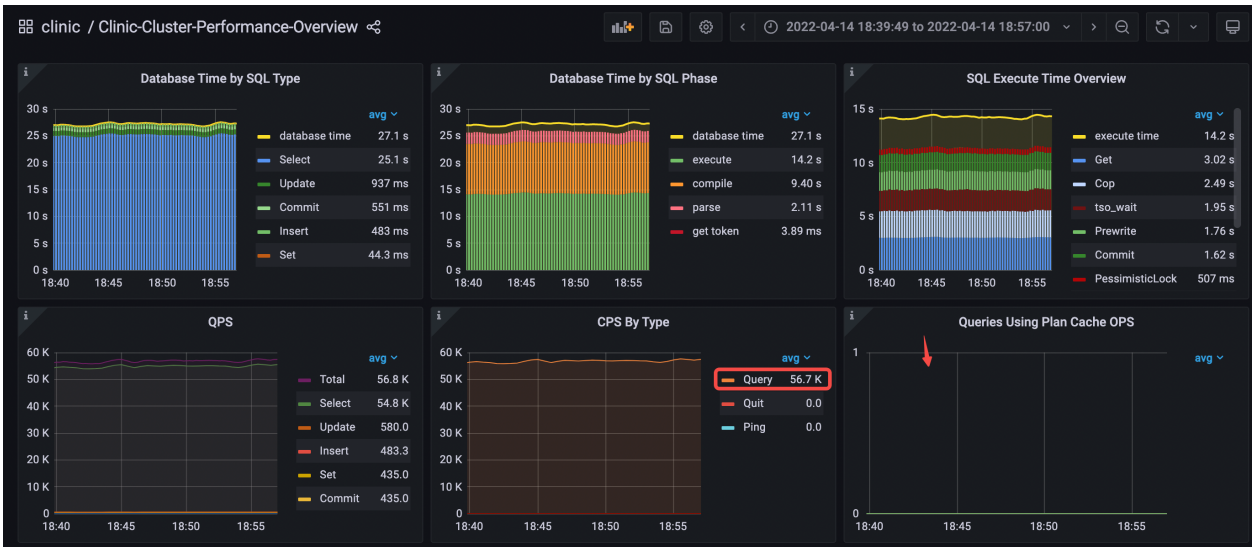

Figure 128: performance-overview-1-for-query-interface

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `tso wait` take most of the time.
- CPS By Type: only the `Query` command is used.
- Queries Using Plan Cache OPS: no data indicates that the execution plan cache is not hit.
- In the query duration, the latency of `execute` and `compile` takes the highest percentage.
- avg QPS = 56.8k

Check the resource consumption of the cluster: the average utilization of TiDB CPU is 925%, the average utilization of TiKV CPU is 201%, and the average throughput of TiKV IO is 18.7 MB/s. The resource consumption of TiDB is significantly higher.

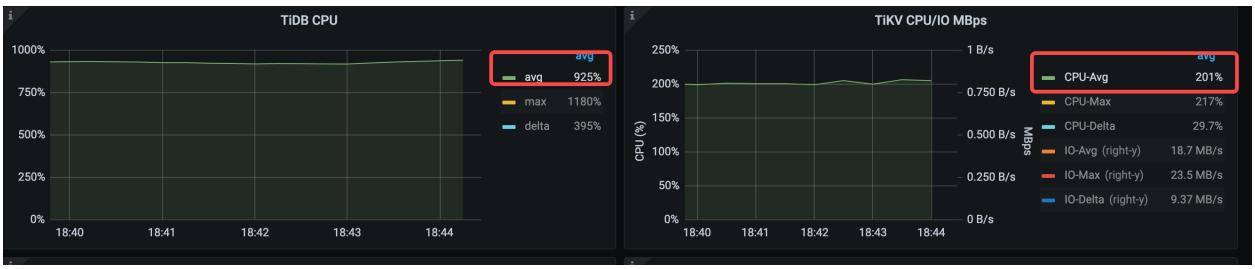

Figure 129: performance-overview-2-for-query-interface

11.1.3.2.3 Analysis conclusion

We need to eliminate these useless non-business SQL statements, which have a large number of executions and contribute to the high TiDB CPU usage.

11.1.3.3 Scenario 2. Use the maxPerformance configuration

11.1.3.3.1 Application configuration

The application adds a new parameter `useConfigs=maxPerformance` to the JDBC connection string in Scenario 1. This parameter can be used to eliminate the SQL statements sent from JDBC to the database (for example, `select @@session.transaction_read_only` ↪). The full configuration is as follows:

```
useServerPrepStmts=false&useConfigs=maxPerformance
```

11.1.3.3.2 Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that `SELECT` ↪ `@@session.tx_isolation`, which consumed the most resources, has disappeared.

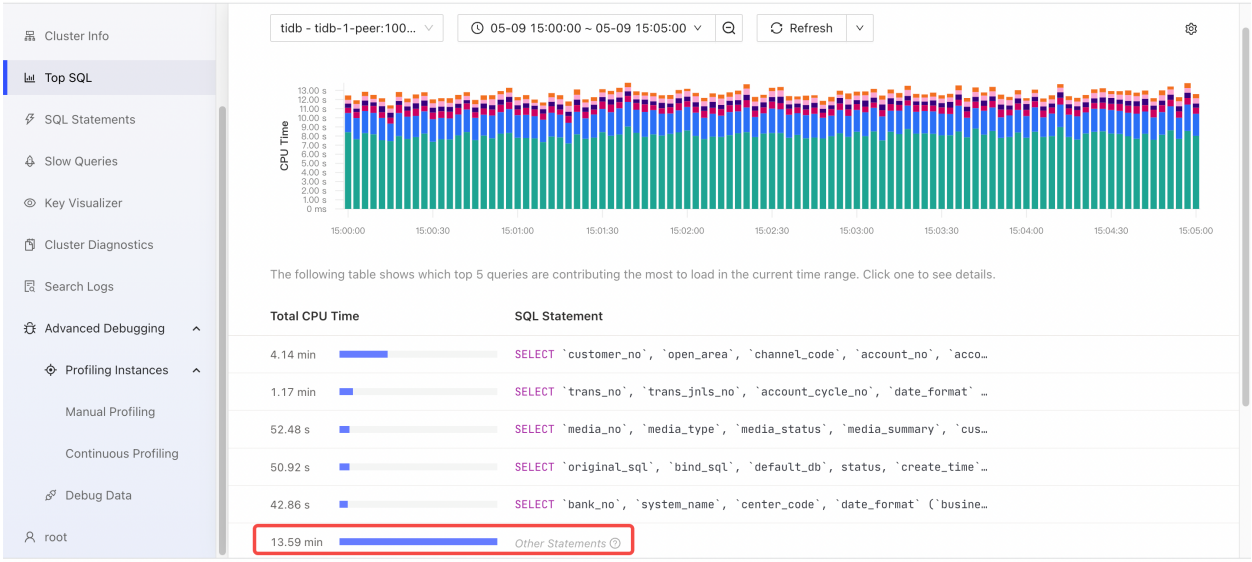

Figure 130: dashboard-for-maxPerformance

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is still significant during the SQL execution.

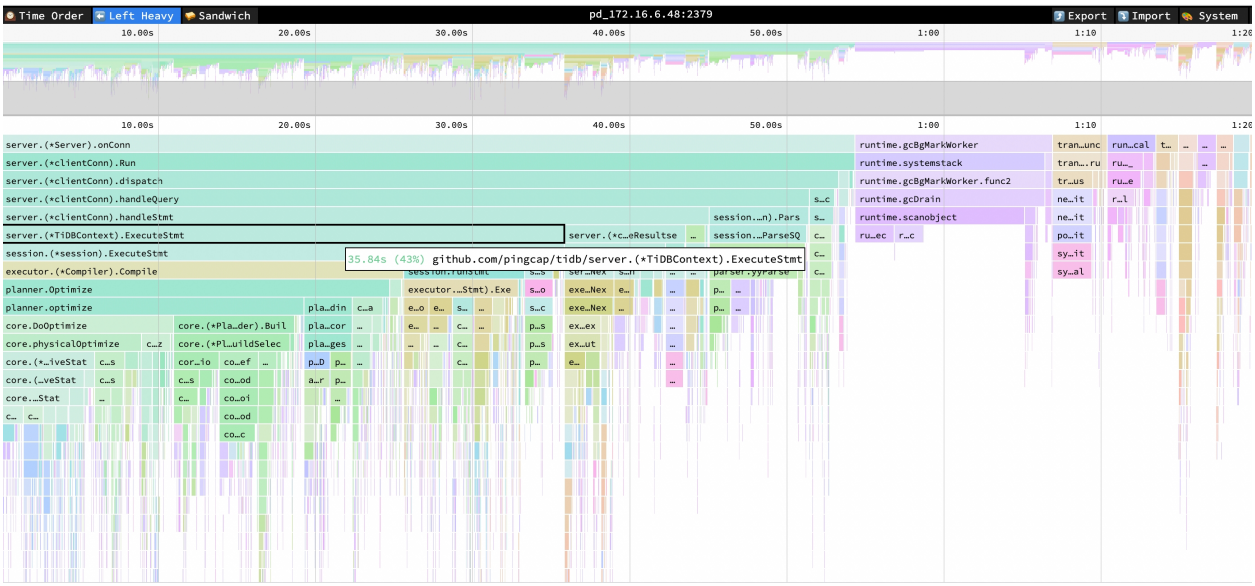

Figure 131: flame-graph-for-maxPerformance

- ExecuteStmt cpu = 43% cpu time =35.84s
- Compile cpu = 31% cpu time =25.61s
- Optimize cpu = 30% cpu time = 24.74s

Performance Overview dashboard

The data of the database time overview and QPS is as follows:

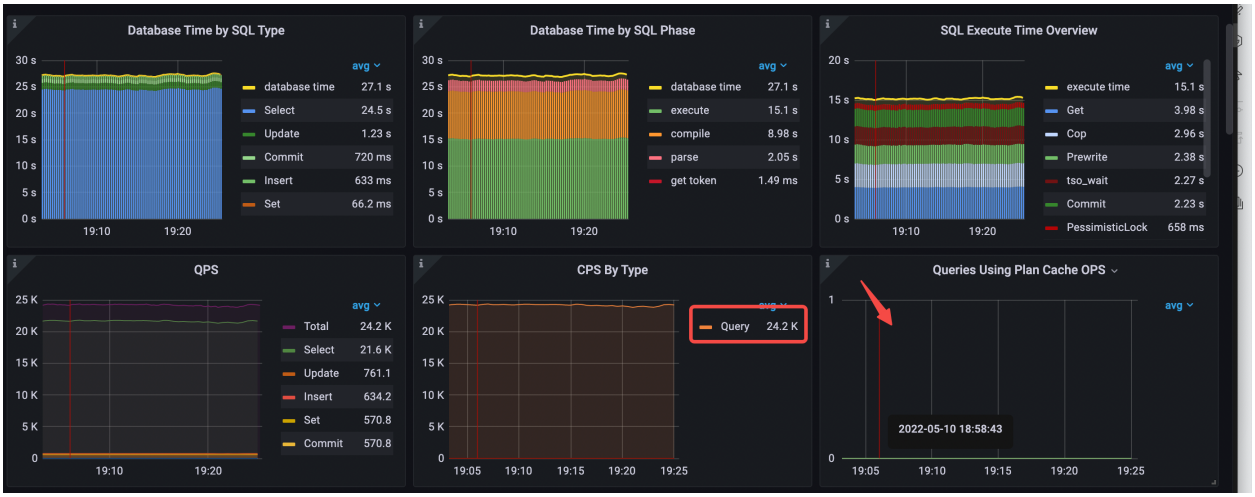

Figure 132: performance-overview-1-for-maxPerformance

- Database Time by SQL Type: the `Select` statement type takes most of the time.

- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- In the database time, the latency of `execute` and `compile` takes the highest percentage.
- CPS By Type: only the `Query` command is used.
- avg QPS = 24.2k (from 56.3k to 24.2k)
- The execution plan cache is not hit.

From Scenario 1 to Scenario 2, the average TiDB CPU utilization drops from 925% to 874%, and the average TiKV CPU utilization increases from 201% to about 250%.

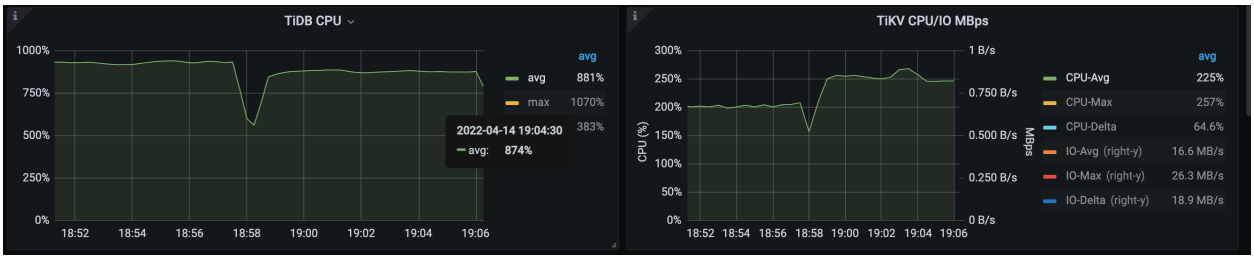

Figure 133: performance-overview-2-for-maxPerformance

The changes in key latency metrics are as follows:

Figure 134: performance-overview-3-for-maxPerformance

- avg query duration = 1.12ms (from 479 s to 1.12ms)
- avg parse duration = 84.7 s (from 37.2 s to 84.7 s)

- avg compile duration = 370 s (from 166 s to 370 s)
- avg execution duration = 626 s (from 251 s to 626 s)

11.1.3.3.3 Analysis conclusion

Compared with Scenario 1, the QPS of Scenario 2 has significantly decreased. The average query duration and average `parse`, `compile`, and `execute` durations have significantly increased. This is because SQL statements such as `select @@session.transaction_read_only` in Scenario 1, which are executed many times and have fast processing time, lower the average performance data. After Scenario 2 blocks such statements, only business-related SQL statements remain, so the average duration increases.

When the application uses the Query interface, TiDB cannot use the execution plan cache, which results in TiDB consuming high resources to compile execution plans. In this case, it is recommended that you use the Prepared Statement interface, which uses the execution plan cache of TiDB to reduce the TiDB CPU consumption caused by execution plan compiling and decrease the latency.

11.1.3.4 Scenario 3. Use the Prepared Statement interface with execution plan caching not enabled

11.1.3.4.1 Application configuration

The application uses the following connection configuration. Compared with Scenario 2, the value of the JDBC parameter `useServerPrepStmts` is modified to `true`, indicating that the Prepared Statement interface is enabled.

```
useServerPrepStmts=true&useConfigs=maxPerformance"
```

11.1.3.4.2 Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the CPU consumption of `CompileExecutePreparedStmt` and `Optimize` is still significant after the Prepared Statement interface is enabled.

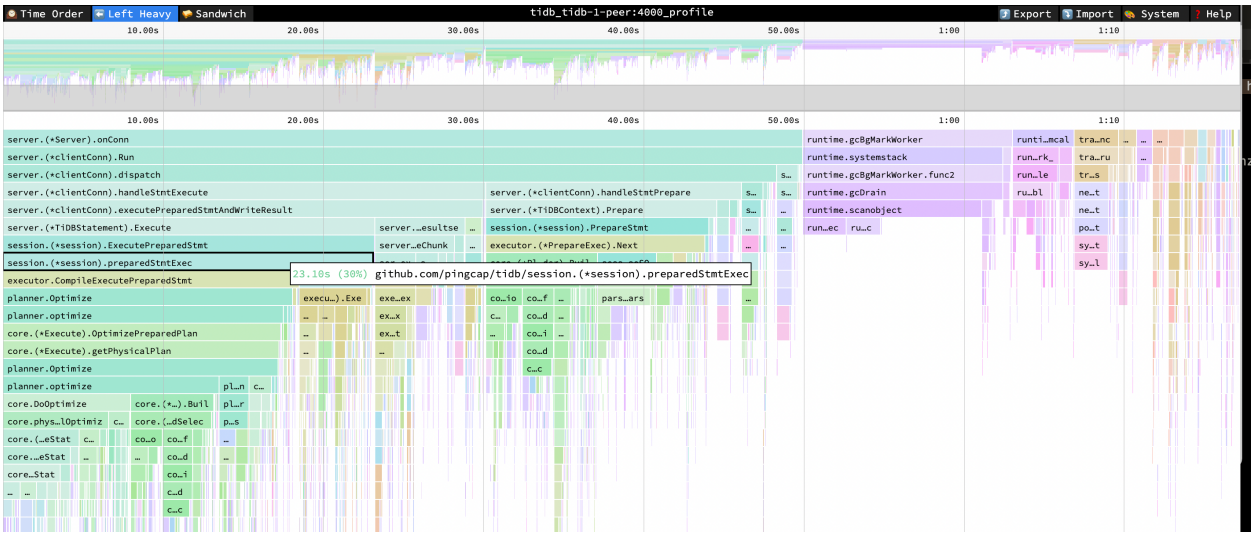

Figure 135: flame-graph-for-PrepStmts

- ExecutePreparedStmt cpu = 31% cpu time = 23.10s
- preparedStmtExec cpu = 30% cpu time = 22.92s
- CompileExecutePreparedStmt cpu = 24% cpu time = 17.83s
- Optimize cpu = 23% cpu time = 17.29s

Performance Overview dashboard

After the Prepared Statement interface is used, the data of database time overview and QPS is as follows:

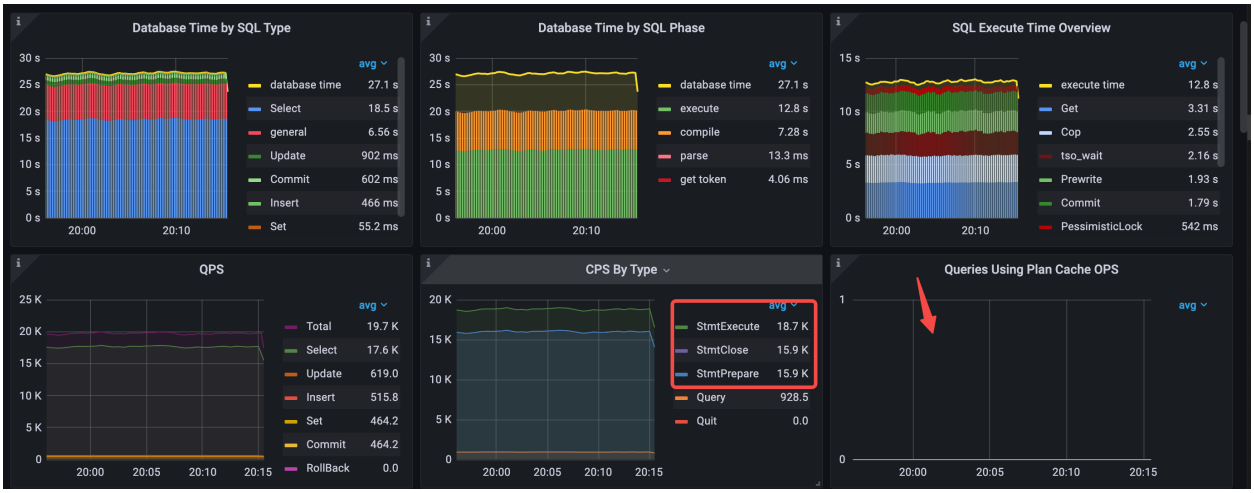

Figure 136: performance-overview-1-for-PrepStmts

The QPS drops from 24.4k to 19.7k. From the Database Time Overview, you can see that the application uses three types of Prepared commands, and the `general` statement

type (which includes the execution time of commands such as `StmtPrepare` and `StmtClose`) takes the second place in Database Time by SQL Type. This indicates that even when the Prepared Statement interface is used, the execution plan cache is not hit. The reason is that, when the `StmtClose` command is executed, TiDB clears the execution plan cache of SQL statements in the internal processing.

- Database Time by SQL Type: the `Select` statement type takes most of the time, followed by `general` statements.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- CPS By Type: 3 types of commands (`StmtPrepare`, `StmtExecute`, `StmtClose`) are used.
- avg QPS = 19.7k (from 24.4k to 19.7k)
- The execution plan cache is not hit.

The TiDB average CPU utilization increases from 874% to 936%.

Figure 137: performance-overview-1-for-PrepStmts

The key latency metrics are as follows:

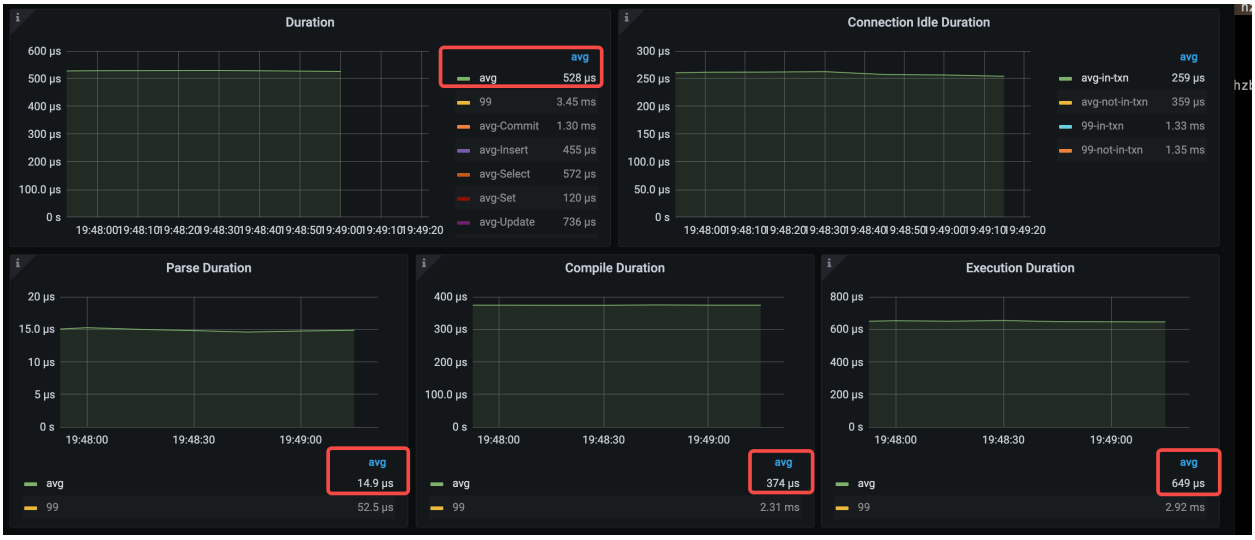

Figure 138: performance-overview-2-for-PrepStmts

- avg query duration = 528 s (from 1.12ms to 528 s)
- avg parse duration = 14.9 s (from 84.7 s to 14.9 s)
- avg compile duration = 374 s (from 370 s to 374 s)
- avg execution duration = 649 s (from 626 s to 649 s)

11.1.3.4.3 Analysis conclusion

Unlike Scenario 2, the application in Scenario 3 enables the Prepared Statement interface but still fails to hit the cache. In addition, Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). Compared with Scenario 2, Scenario 3 has two more network round-trip delays.

- Analysis for the decrease in QPS: From the **CPS By Type** pane, you can see that Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). `StmtPrepare` and `StmtClose` are non-conventional commands that are not counted by QPS, so QPS is reduced. The non-conventional commands `StmtPrepare` and `StmtClose` are counted in the `general` SQL type, so `general` time is displayed in the database overview of Scenario 3, and it accounts for more than a quarter of the database time.
- Analysis for the significant decrease in average query duration: for the `StmtPrepare` and `StmtClose` command types newly added in Scenario 3, their query duration is calculated separately in the TiDB internal processing. TiDB executes these two types of commands very quickly, so the average query duration is significantly reduced.

Although Scenario 3 uses the Prepared Statement interface, the execution plan cache is still not hit, because many application frameworks call the `StmtClose` method after

`StmtExecute` to prevent memory leaks. Starting from v6.0.0, you can set the global variable `tidb_ignore_prepared_cache_close_stmt=on;`. After that, TiDB will not clear the cached execution plans even if the application calls the `StmtClose` method, so the next SQL execution can reuse the existing execution plan and avoid compiling the execution plan repeatedly.

11.1.3.5 Scenario 4. Use the Prepared Statement interface and enable execution plan caching

11.1.3.5.1 Application configuration

The application configuration remains the same as that of Scenario 3. To resolve the issue of not hitting the cache even if the application triggers `StmtClose`, the following parameters are configured.

- Set the TiDB global variable `set global tidb_ignore_prepared_cache_close_stmt =on;` (introduced since TiDB v6.0.0, `off` by default).
- Set the TiDB configuration item `prepared-plan-cache: {enabled: true}` to enable the plan cache feature.

11.1.3.5.2 Performance analysis

TiDB Dashboard

From the flame chart of the TiDB CPU usage, you can see that `CompileExecutePreparedStmt` and `Optimize` have no significant CPU consumption. 25% of the CPU is consumed by the `Prepare` command, which contains parsing-related functions of Prepare such as `PlanBuilder` and `parseSQL`.

PreparseStmt cpu = 25% cpu time = 12.75s

Figure 139: flame-graph-for-3-commands

Performance Overview dashboard

In the Performance Overview dashboard, the most significant change is the average time of the `compile` phase, which is reduced from 8.95 seconds per second in Scenario 3 to 1.18 seconds per second. The number of queries using the execution plan cache is roughly equal to the value of `StmtExecute`. With the increase in QPS, the database time consumed by `Select` statements per second decreases, and the database time consumed by `general` statements per second type increases.

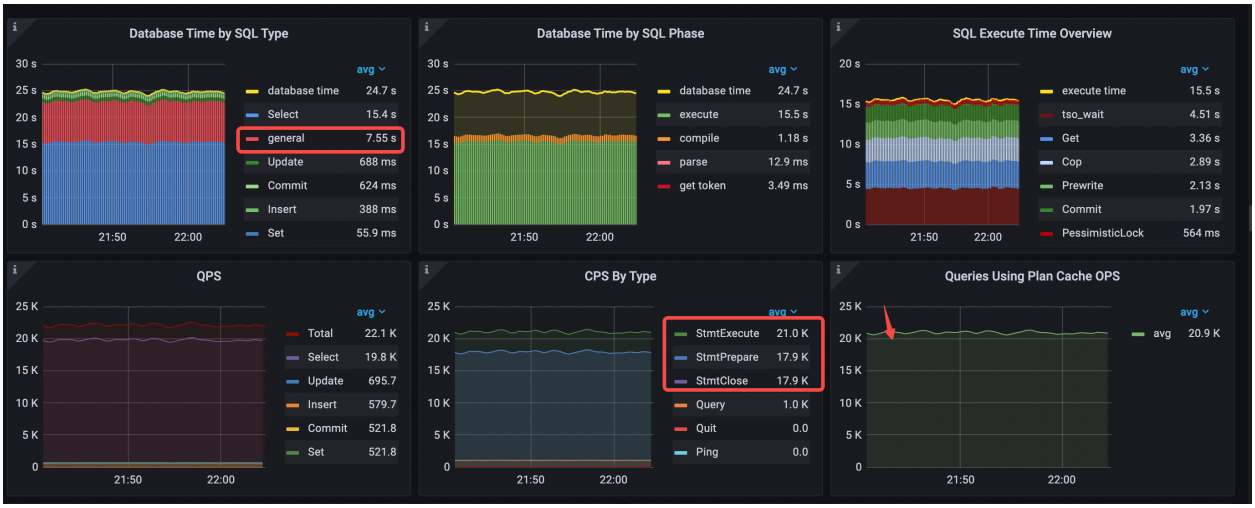

Figure 140: performance-overview-1-for-3-commands

- Database Time by SQL Type: the `Select` statement type takes the most time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: 3 types of commands (same as Scenario 3)
- Compared with scenario 3, the time consumed by `general` statements is longer because the QPS is increased.
- avg QPS = 22.1k (from 19.7k to 22.1k)

The average TiDB CPU utilization drops from 936% to 827%.

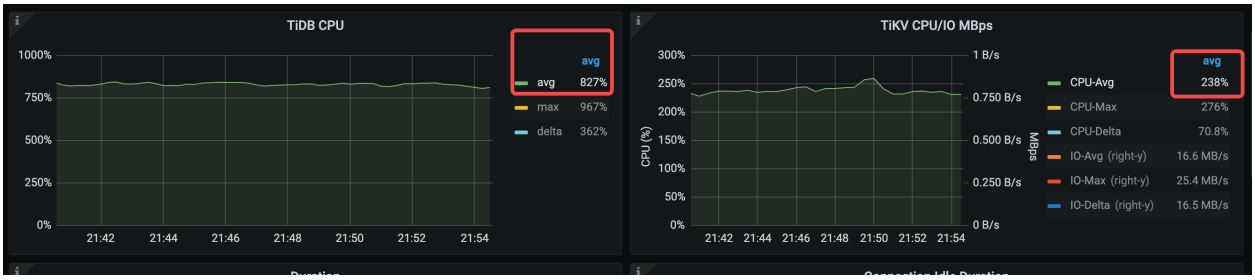

Figure 141: performance-overview-2-for-3-commands

The average `compile` time drops significantly, from 374 us to 53.3 us. Because the QPS increases, the average `execute` time increases too.

Figure 142: performance-overview-3-for-3-commands

- avg query duration = 426 s (from 528 s to 426 s)
- avg parse duration = 12.3 s (from 14.8 s to 12.3 s)
- avg compile duration = 53.3 s (from 374 s to 53.3 s)
- avg execution duration = 699 s (from 649 s to 699us)

11.1.3.5.3 Analysis conclusion

Compared with Scenario 3, Scenario 4 also uses 3 command types. The difference is that Scenario 4 hits the execution plan cache, which reduces compile duration greatly, reduces the query duration, and improves QPS.

Because the `StmtPrepare` and `StmtClose` commands consume significant database time and increase the number of interactions between the application and TiDB each time the

application executes a SQL statement. The next scenario will further tune the performance by eliminating the calls of these two commands through JDBC configurations.

11.1.3.6 Scenario 5. Cache prepared objects on the client side

11.1.3.6.1 Application configuration

Compared with Scenario 4, 3 new JDBC parameters `cachePrepStmts=true&prepStmtCacheSize=1000&prepStmtCacheSqlLimit=20480` are configured, as explained below.

- `cachePrepStmts = true`: caches Prepared Statement objects on the client side, which eliminates the calls of StmtPrepare and StmtClose.
- `prepStmtCacheSize`: the value must be greater than 0.
- `prepStmtCacheSqlLimit`: the value must be greater than the length of the SQL text.

In Scenario 5, the complete JDBC configurations are as follows.

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

11.1.3.6.2 Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the high CPU consumption of the `Prepare` command is no longer present.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

Figure 143: flame-graph-for-1-command

Performance Overview dashboard

In the Performance Overview dashboard, the most notable changes are that the three Stmt command types in the **CPS By Type** pane drop to one type, the `general` statement type in the **Database Time by SQL Type** pane is disappeared, and the QPS in the **QPS** pane increases to 30.9k.

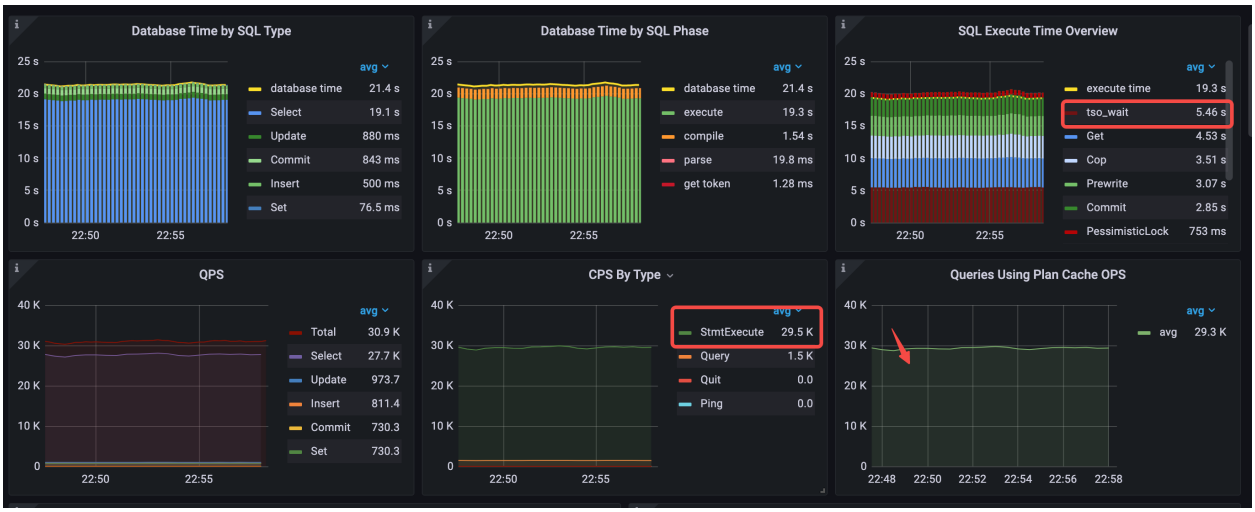

Figure 144: performance-overview-for-1-command

- Database Time by SQL Type: the `Select` statement type takes most of the time and the `general` statement type disappears.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 30.9k (from 22.1k to 30.9k)

The average TiDB CPU utilization drops from 827% to 577%. As the QPS increases, the average TiKV CPU utilization increases to 313%.

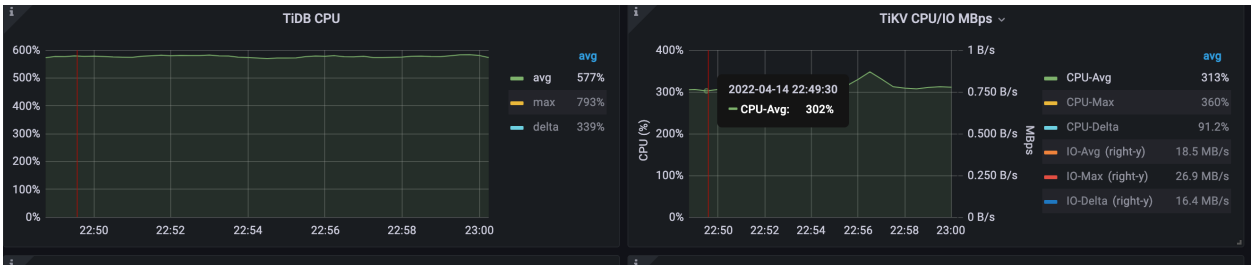

Figure 145: performance-overview-for-2-command

The key latency metrics are as follows:

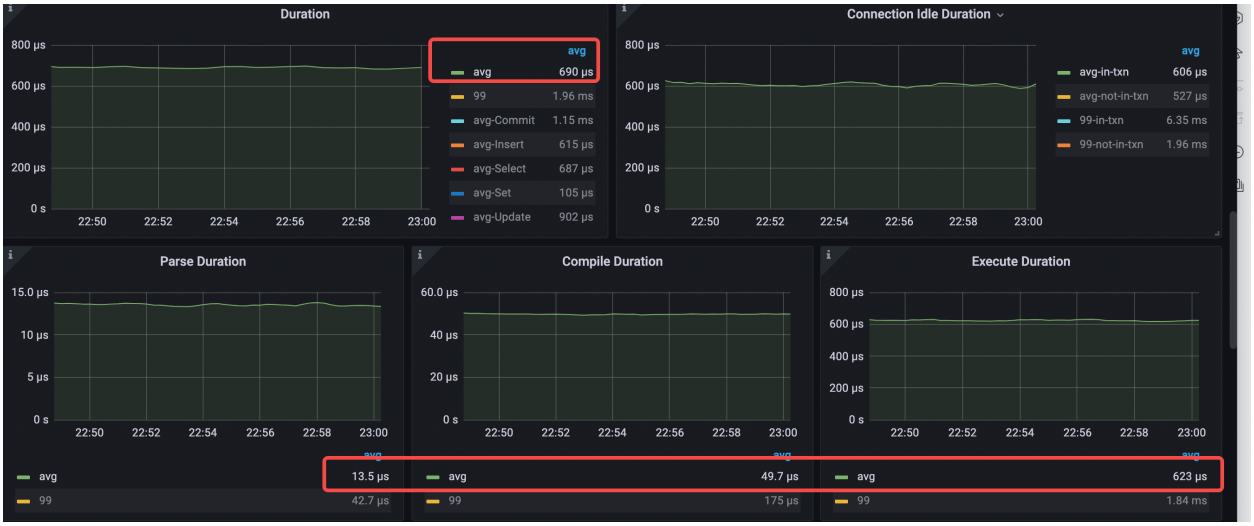

Figure 146: performance-overview-for-3-command

- avg query duration = 690 s (from 426 s to 690 s)
- avg parse duration = 13.5 s (from 12.3 s to 13.5 s)
- avg compile duration = 49.7 s (from 53.3 s to 49.7 s)
- avg execution duration = 623 s (from 699us to 623 s)
- avg pd tso wait duration = 196 s (from 224 s to 196 s)
- connection idle duration avg-in-txn = 608 s (from 250 s to 608 s)

11.1.3.6.3 Analysis conclusion

- Compared with Scenario 4, the **CPS By Type** pane in Scenario 5 has the `StmtExecute` command only, which avoids two network round trips and increases the overall system QPS.
- In the case of QPS increase, the latency decreases in terms of parse duration, compile duration, and execution duration, but the query duration increases instead. This is because TiDB processes `StmtPrepare` and `StmtClose` very quickly, and eliminating these two command types increases the average query duration.
- In Database Time by SQL Phase, `execute` takes the most time and is close to the database time. While in SQL Execute Time Overview, `tso wait` takes most of the time, and more than a quarter of `execute` time is taken to wait for TSO.
- The total `tso wait` time per second is 5.46s. The average `tso wait` time is 196 us, and the number of `tso cmd` times per second is 28k, which is very close to the QPS of 30.9k. This is because according to the implementation of the `read committed` isolation level in TiDB, every SQL statement in a transaction needs to request TSO from PD.

TiDB v6.0 provides `rc read`, which optimizes the `read committed` isolation level by reducing `tso cmd`. This feature is controlled by the global variable `set global ↪ tidb_rc_read_check_ts=on;`. When this variable is enabled, the default behavior of TiDB acts the same as the `repeatable-read` isolation level, at which only `start-ts` and `commit-ts` need to be obtained from the PD. The statements in a transaction use the `start-ts` to read data from TiKV first. If the data read from TiKV is earlier than `start-ts`, the data is returned directly. If the data read from TiKV is later than `start-ts`, the data is discarded. TiDB requests TSO from PD, and then retries the read. The `for update ts` of subsequent statements uses the latest PD TSO.

11.1.3.7 Scenario 6: Enable the `tidb_rc_read_check_ts` variable to reduce TSO requests

11.1.3.7.1 Application configuration

Compared with Scenario 5, the application configuration remains the same. The only difference is that the `set global tidb_rc_read_check_ts=on;` variable is configured to reduce TSO requests.

11.1.3.7.2 Performance analysis

Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

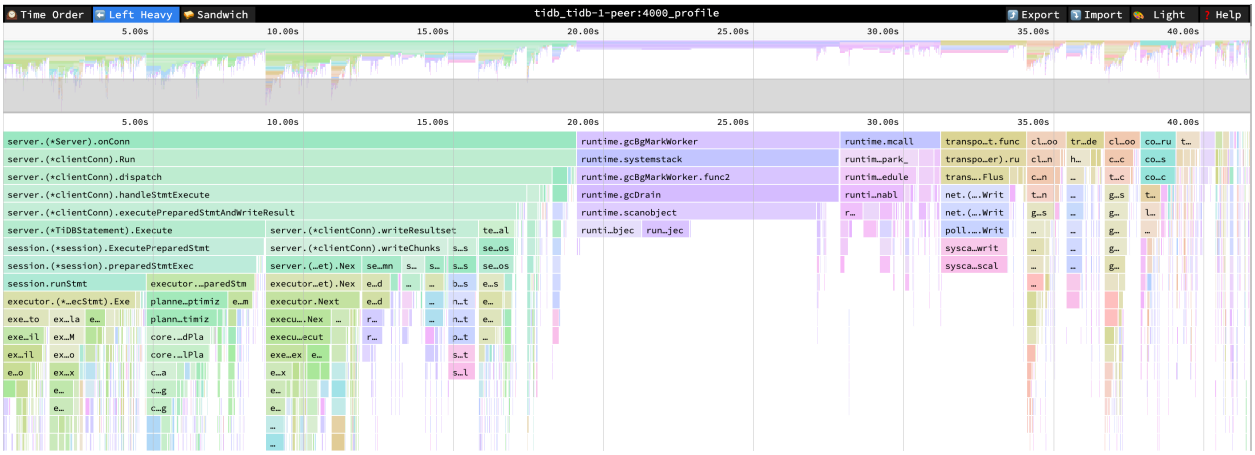

Figure 147: flame-graph-for-rc-read

Performance Overview dashboard

After using RC read, QPS increases from 30.9k to 34.9k, and the `tso wait` time consumed per second decreases from 5.46 s to 456 ms.

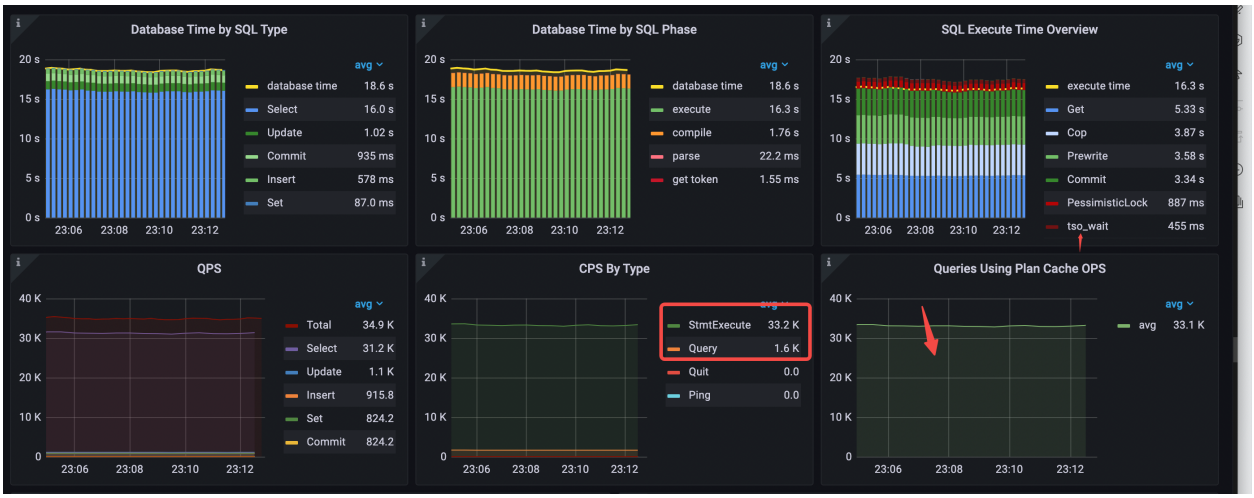

Figure 148: performance-overview-1-for-rc-read

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `Prewrite` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 34.9k (from 30.9k to 34.9k)

The `tso cmd` per second drops from 28.3k to 2.7k.

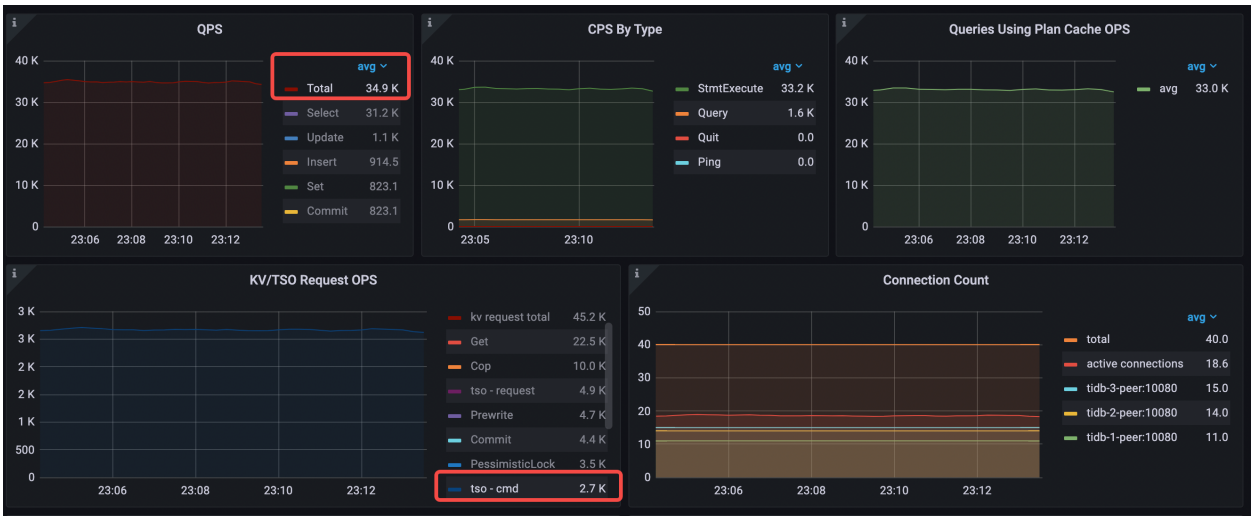

Figure 149: performance-overview-2-for-rc-read

The average TiDB CPU increases to 603% (from 577% to 603%).

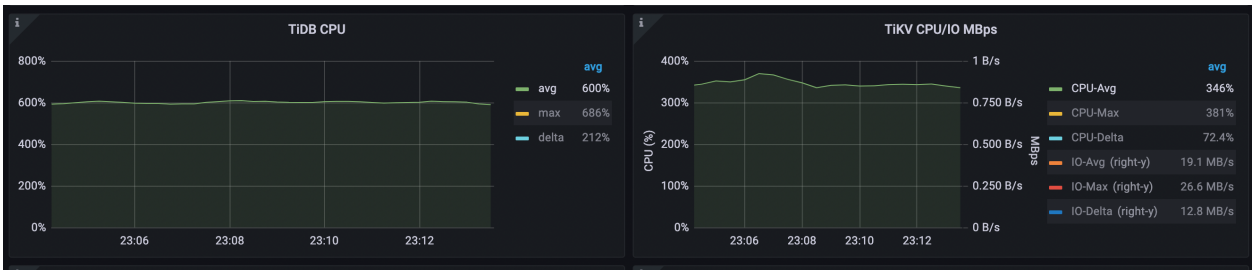

Figure 150: performance-overview-3-for-rc-read

The key latency metrics are as follows:

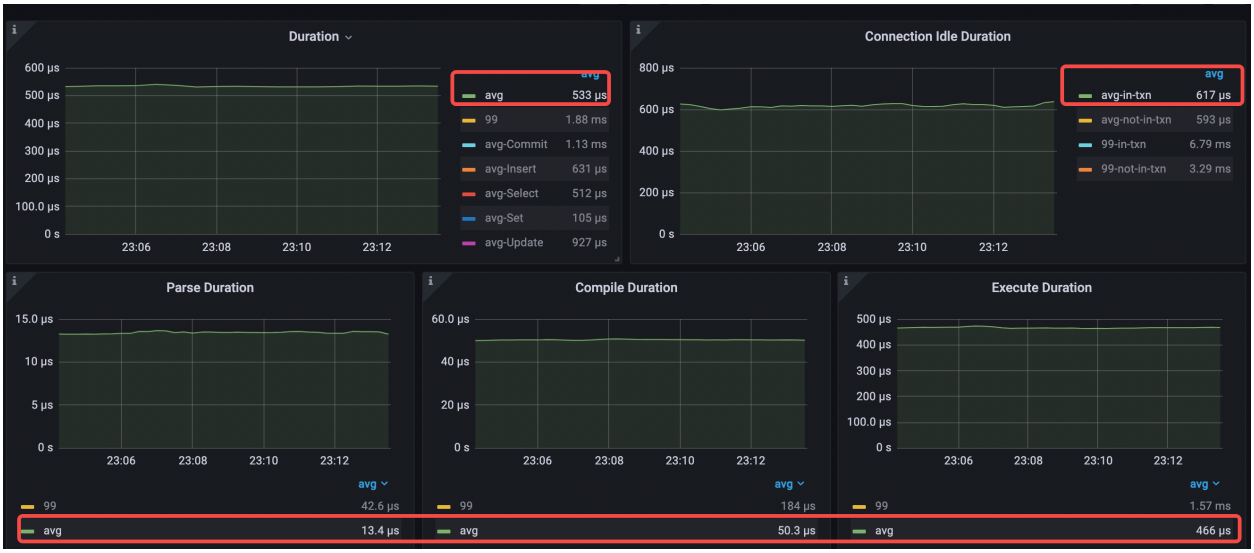

Figure 151: performance-overview-4-for-rc-read

- avg query duration = 533 s (from 690 s to 533 s)
- avg parse duration = 13.4 s (from 13.5 s to 13.4 s)
- avg compile duration = 50.3 s (from 49.7 s to 50.3 s)
- avg execution duration = 466 s (from 623 s to 466 s)
- avg pd tso wait duration = 171 s (from 196 s to 171 s)

11.1.3.7.3 Analysis conclusion

After enabling RC Read by `set global tidb_rc_read_check_ts=on;`, RC Read significantly reduces the times of `tso cmd`, thus reducing `tso wait` and average query duration, and improving QPS.

The bottlenecks of both current database time and latency are in the `execute` phase, in which the `Get` and `Cop` read requests take the highest percentage. Most of the tables in this workload are read-only or rarely modified, so you can use the small table caching feature supported since TiDB v6.0.0 to cache the data of these small tables and reduce the waiting time and resource consumption of KV read requests.

11.1.3.8 Scenario 7: Use the small table cache

11.1.3.8.1 Application configuration

Compared with Scenario 6, the application configuration remains the same. The only difference is that Scenario 7 uses SQL statements such as `alter table t1 cache;` to cache those read-only tables for the business.

11.1.3.8.2 Performance analysis

TiDB Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

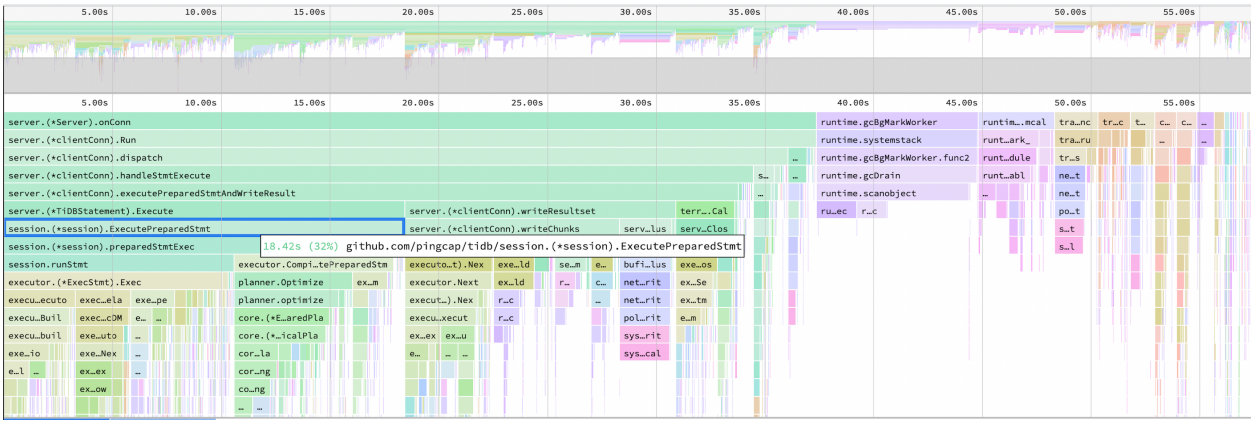

Figure 152: flame-graph-for-table-cache

Performance Overview dashboard

The QPS increases from 34.9k to 40.9k, and the KV request types take the most time in the `execute` phase change to `Prewrite` and `Commit`. The database time consumed by `Get` per second decreases from 5.33 seconds to 1.75 seconds, and the database time consumed by `Cop` per second decreases from 3.87 seconds to 1.09 seconds.

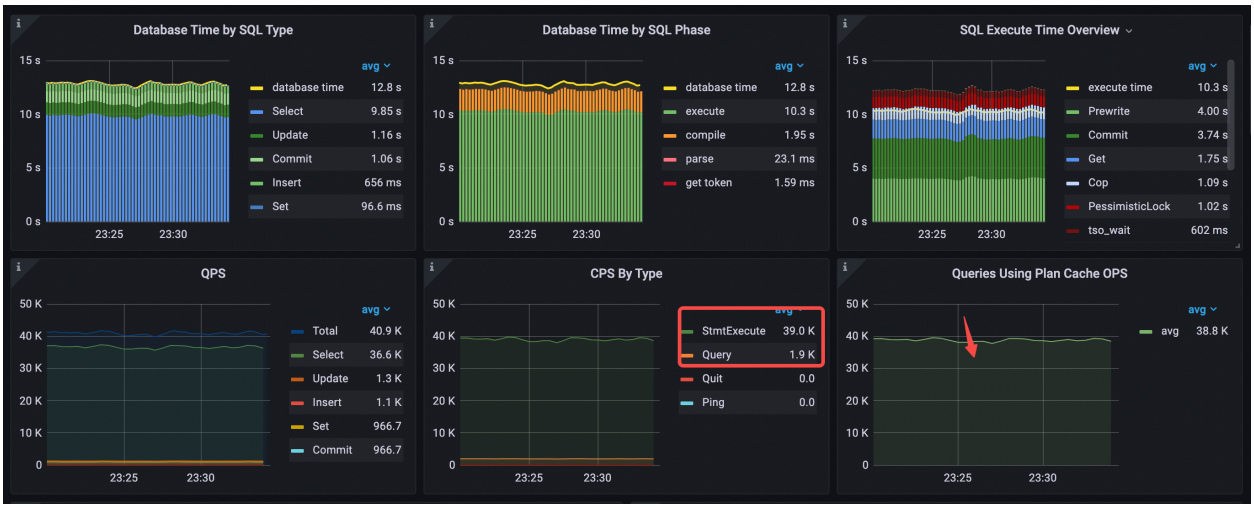

Figure 153: performance-overview-1-for-table-cache

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Prewrite`, `Commit`, and `Get` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 40.9k (from 34.9k to 40.9k)

The average TiDB CPU utilization drops from 603% to 478% and the average TiKV CPU utilization drops from 346% to 256%.

Figure 154: performance-overview-2-for-table-cache

The average query latency drops from 533 us to 313 us. The average `execute` latency drops from 466 us to 250 us.

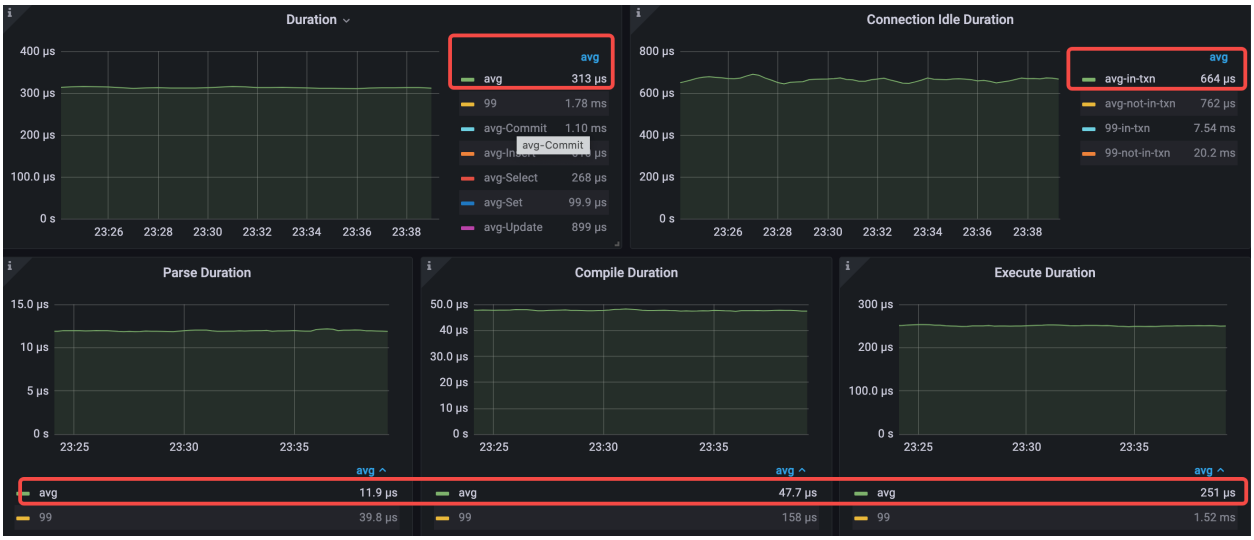

Figure 155: performance-overview-3-for-table-cache

- avg query duration = 313 s (from 533 s to 313 s)
- avg parse duration = 11.9 s (from 13.4 s to 11.9 s)
- avg compile duration = 47.7 s (from 50.3 s to 47.7 s)
- avg execution duration = 251 s (from 466 s to 251 s)

11.1.3.8.3 Analysis conclusion

After caching all read-only tables, the `Execute Duration` drops significantly because all read-only tables are cached in TiDB and there is no need to query data in TiKV for those tables, so the query duration drops and the QPS increases.

This is an optimistic result because data of read-only tables in actual business might be too large for TiDB to cache them all. Another limitation is that although the small table caching feature supports write operations, the write operation requires a default wait of 3 seconds to ensure that the cache of all TiDB nodes is invalidated first, which might not be feasible to applications with strict latency requirements.

11.1.3.9 Summary

The following table lists the performance of seven different scenarios.

Metrics	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6	Scenario 7	Comparing Scenario 5 with Scenario 2 (%)	Comparing Scenario 7 with Scenario 3 (%)
query duration	479 s	1120 s	528 s	426 s	690 s	533 s	313 s	-38%	-51%
QPS	56.3k	24.2k	19.7k	22.1k	30.9k	34.9k	40.9k	+28%	+108%

In these scenarios, Scenario 2 is a common scenario where applications use the Query interface, and Scenario 5 is an ideal scenario where applications use the Prepared Statement interface.

- Comparing Scenario 2 with Scenario 5, you can see that by using best practices for Java application development and caching Prepared Statement objects on the client side, each SQL statement requires only one command and database interaction to hit the execution plan cache, which results in a 38% drop in query latency and a 28% increase in QPS, while the average TiDB CPU utilization drops from 936% to 577%.
- Comparing Scenario 2 with Scenario 7, you can see that with the latest TiDB optimization features such as RC Read and small table cache on top of Scenario 5, latency is reduced by 51% and QPS is increased by 108%, while the average TiDB CPU utilization drops from 936% to 478%.

By comparing the performance of each scenario, we can draw the following conclusions:

- The execution plan cache of TiDB plays a critical role in the OLTP performance tuning. The RC Read and small table cache features introduced from v6.0.0 also play an important role in the further performance tuning of this workload.
- TiDB is compatible with different commands of the MySQL protocol. When using the Prepared Statement interface and setting the following JDBC connection parameters, the application can achieve its best performance:

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs= maxPerformance
```

- It is recommended that you use TiDB Dashboard (for example, the Top SQL feature and Continuous Profiling feature) and Performance Overview dashboard for performance analysis and tuning.

  - With the Top SQL feature, you can visually monitor and explore the CPU consumption of each SQL statement in your database during execution to troubleshoot database performance issues.
  - With Continuous Profiling, you can continuously collect performance data from each instance of TiDB, TiKV, and PD. When applications use different interfaces to interact with TiDB, the difference in the CPU consumption of TiDB is huge.
  - With Performance Overview Dashboard, you can get an overview of database time and SQL execution time breakdown information. You can analyze and diagnose performance based on database time to determine whether the performance bottleneck of the entire system is in TiDB or not. If the bottleneck is in TiDB, you can use the database time and latency breakdowns, along with load profile and resource usage, to identify performance bottlenecks within TiDB and tune the performance accordingly.

With a combination usage of these features, you can analyze and tune performance for real-world applications efficiently.

11.1.4 Latency Breakdown

This document breaks down the latency into metrics and then analyzes it from the user's perspective from the following aspects:

- General SQL layer
- Read queries
- Write queries
- Batch client
- TiKV snapshot
- Async write

These analyses provide you with a deep insight into time cost during TiDB SQL queries. This is a guide to TiDB's critical path diagnosis. Besides, the Diagnosis use cases section introduces how to analyze latency in real use cases.

It's better to read Performance Analysis and Tuning before this document. Note that when breaking down latency into metrics, the average value of duration or latency is calculated instead of some specific slow queries. Many metrics are shown as histogram, which is a distribution of the duration or latency. To calculate the average latency, you need to use the following sum and count counter.

```
avg = ${metric_name}_sum / ${metric_name}_count
```

Metrics described in this document can be read directly from the Prometheus dashboard of TiDB.

11.1.4.1 General SQL layer

This general SQL layer latency exists on the top level of TiDB and is shared by all SQL queries. The following is the time cost diagram of general SQL layer operation:

```
Diagram(
    NonTerminal("Token wait duration"),
    Choice(
        0,
        Comment("Prepared statement"),
        NonTerminal("Parse duration"),
    ),
    OneOrMore(
        Sequence(
        Choice(
            0,
            NonTerminal("Optimize prepared plan duration"),
            Sequence(
            Comment("Plan cache miss"),
            NonTerminal("Compile duration"),
            ),
        ),
        NonTerminal("TSO wait duration"),
        NonTerminal("Execution duration"),
        ),
        Comment("Retry"),
    ),
)
```

The general SQL layer latency can be observed as the `e2e duration` metric and is calculated as:

```
e2e duration =
    tidb_server_get_token_duration_seconds +
    tidb_session_parse_duration_seconds +
    tidb_session_compile_duration_seconds +
    tidb_session_execute_duration_seconds{type="general"}
```

- `tidb_server_get_token_duration_seconds` records the duration of Token waiting. This is usually less than 1 millisecond and is small enough to be ignored.
- `tidb_session_parse_duration_seconds` records the duration of parsing SQL queries to an Abstract Syntax Tree (AST), which can be skipped by `PREPARE/EXECUTE` statements.
- `tidb_session_compile_duration_seconds` records the duration of compiling an AST to an execution plan, which can be skipped by SQL prepare execution plan cache.

- `tidb_session_execute_duration_seconds{type="general"}` records the duration of execution, which mixes all types of user queries. This needs to be broken down into fine-grained durations for analyzing performance issues or bottlenecks.

Generally, OLTP (Online Transactional Processing) workload can be divided into read and write queries, which share some critical code. The following sections describe latency in read queries and write queries, which are executed differently.

11.1.4.2 Read queries

Read queries have only a single process form.

11.1.4.2.1 Point get

The following is the time cost diagram of point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Resolve TSO"),
        Comment("Read by clustered PK in auto-commit-txn mode or snapshot
            ↪ read"),
    ),
    Choice(
        0,
        NonTerminal("Read handle by index key"),
        Comment("Read by clustered PK, encode handle by key"),
    ),
    NonTerminal("Read value by handle"),
)
```

During point get, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handle duration +
    read value duration
```

`pd_client_cmd_handle_cmds_duration_seconds{type="wait"}` records the duration of fetching TSO (Timestamp Oracle) from PD. When reading in an auto-commit transaction mode with a clustered primary index or from a snapshot, the value will be zero.

The `read handle duration` and `read value duration` are calculated as:

```
read handle duration = read value duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="get"} =
```

```
    send request duration =
    tidb_tikvclient_request_seconds{type="Get"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

The `tidb_tikvclient_request_seconds{type="Get"}` records a duration of get requests which are sent directly to TiKV via a batched gRPC wrapper. For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration`, `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    tikv_engine_seek_micro_seconds{type="seek_average"} +
    read value duration +
    read value duration(non-short value)
```

At this time, requests are in TiKV. TiKV processes get requests by one seek and one or two read actions (short values are encoded in a write column family, and reading it once is enough). TiKV gets a snapshot before processing the read request. For more details about the TiKV snapshot duration, refer to the TiKV snapshot section.

The `read value duration(from disk)` is calculated as:

```
read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="get/
        ↪ batch_get_command"})) / sum(rate(tikv_storage_rocksdb_perf{metric
        ↪ ="block_read_count",req="get/batch_get_command"}))
```

TiKV uses RocksDB as its storage engine. When the required value is missing from the block cache, TiKV needs to load the value from the disk. For `tikv_storage_rocksdb_perf`, the get request can be either `get` or `batch_get_command`.

11.1.4.2.2 Batch point get

The following is the time cost diagram of batch point get operations:

```
Diagram(
  NonTerminal("Resolve TSO"),
  Choice(
    0,
    NonTerminal("Read all handles by index keys"),
    Comment("Read by clustered PK, encode handle by keys"),
  ),
```

```
  NonTerminal("Read values by handles"),
)
```

During batch point get, the `tidb_session_execute_duration_seconds{type="general"}` is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handles duration +
    read values duration
```

The process of batch point get is almost the same as Point get except that batch point get reads multiple values at the same time.

The `read handles duration` and `read values duration` are calculated as:

```
read handles duration = read values duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} =
    send request duration =
    tidb_tikvclient_request_seconds{type="BatchGet"} =
    tidb_tikvclient_batch_wait_duration(transaction) +
    tidb_tikvclient_batch_send_latency(transaction) +
    tikv_grpc_msg_duration_seconds{type="kv_batch_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}(transaction)
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_dur` ↪ `(transaction)`, `tidb_tikvclient_batch_send_latency(transaction)`, and `tidb_tikvclient_rpc` ↪ `{store="?"}(transaction)`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_batch_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_batch_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    n * (
        tikv_engine_seek_micro_seconds{type="seek_max"} +
        read value duration +
        read value duration(non-short value)
    )

read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ batch_get"})) / sum(rate(tikv_storage_rocksdb_perf{metric="
        ↪ block_read_count",req="batch_get"}))
```

After getting a snapshot, TiKV reads multiple values from the same snapshot. The read duration is the same as Point get. When TiKV loads data from disk, the average duration can be calculated by `tikv_storage_rocksdb_perf` with `req="batch_get"`.

11.1.4.2.3 Table scan & Index scan

The following is the time cost diagram of table scan and index scan operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related table/index ranges"),
        OneOrMore(
            NonTerminal("Wait for result"),
            Comment("Next loop: drain the result"),
        ),
    ),
)
```

During table scan and index scan, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )
    tidb_distsql_handle_query_duration_seconds{sql_type="general"} <= send
        ↪ request duration
```

Table scan and index scan are processed in the same way. `req_per_copr` is the distributed task count. Because coprocessor execution and data responding to client are in different threads, `tidb_distsql_handle_query_duration_seconds{sql_type="general"}` is the wait time and it is less than the `send request duration`.

The `send request duration` and `req_per_copr` are calculated as:

```
send request duration =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="coprocessor"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tikv_grpc_msg_duration_seconds{type="coprocessor"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} +
    tikv_coprocessor_request_wait_seconds{type="schedule"} +
    tikv_coprocessor_request_handler_build_seconds{type="index/select"} +
    tikv_coprocessor_request_handle_seconds{type="index/select"}

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    ↪ (tidb_distsql_scan_keys_partial_num_count)
```

In TiKV, the table scan type is `select` and the index scan type is `index`. The details of `select` and `index` type duration are the same.

11.1.4.2.4 Index look up

The following is the time cost diagram of index look up operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related index ranges"),
        OneOrMore(
            Sequence(
                NonTerminal("Wait for index scan result"),
                NonTerminal("Wait for table scan result"),
            ),
        Comment("Next loop: drain the result"),
        ),
    ),
)
```

During index look up, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    ) +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    (tidb_distsql_scan_keys_partial_num_count)
```

An index look up combines index scan and table scan, which are processed in a pipeline.

11.1.4.3 Write queries

Write queries are much more complex than read queries. There are some variants of write queries. The following is the time cost diagram of write queries operations:

```
Diagram(
    NonTerminal("Execute write query"),
    Choice(
        0,
```

```
        NonTerminal("Pessimistic lock keys"),
        Comment("bypass in optimistic transaction"),
    ),
    Choice(
        0,
        NonTerminal("Auto Commit Transaction"),
        Comment("bypass in non-auto-commit or explicit transaction"),
    ),
)
```

	Pessimistic transaction	Optimistic transaction
Auto-commit	execute + lock + commit	execute + commit
Non-auto-commit	execute + lock	execute

A write query is divided into the following three phases:

- execute phase: execute and write mutation into the memory of TiDB.
- lock phase: acquire pessimistic locks for the execution result.
- commit phase: commit the transaction via the two-phase commit protocol (2PC).

In the execute phase, TiDB manipulates data in memory and the main latency comes from reading the required data. For update and delete queries, TiDB reads data from TiKV first, and then updates or deletes the row in memory.

The exception is lock-time read operations (`SELECT FOR UPDATE`) with point get and batch point get, which perform read and lock in a single Remote Procedure Call (RPC).

11.1.4.3.1 Lock-time point get

The following is the time cost diagram of lock-time point get operations:

```
Diagram(
    Choice(
        0,
        Sequence(
            NonTerminal("Read handle key by index key"),
            NonTerminal("Lock index key"),
        ),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock handle key"),
    NonTerminal("Read value from pessimistic lock cache"),
)
```

During lock-time point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    2 * tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

Lock-time point get locks the key and returns its value. Compared with the lock phase after execution, this saves 1 round trip. The duration of the lock-time point get can be treated the same as Lock duration.

11.1.4.3.2 Lock-time batch point get

The following is the time cost diagram of lock-time batch point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Read handle keys by index keys"),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock index and handle keys"),
    NonTerminal("Read values from pessimistic lock cache"),
)
```

During lock-time batch point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} +
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

The execution of the lock-time batch point get is similar to the Lock-time point get except that the lock-time batch point get reads multiple values in a single RPC. For more details about the `tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"}` duration, refer to the Batch point get section.

11.1.4.3.3 Lock

This section describes the lock duration.

```
round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_pessimistic_lock
        ↪ "})) /
```

```
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2
        ↪ pc_pessimistic_lock"})) /
    committer-concurrency
)

lock = tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"} =
    round * tidb_tikvclient_request_seconds{type="PessimisticLock"}
```

Locks are acquired through the 2PC structure, which has a flow control mechanism. The flow control limits concurrent on-the-fly requests by `committer-concurrency` (default value is 128). For simplicity, the flow control can be treated as an amplification of request latency (`round`).

The `tidb_tikvclient_request_seconds{type="PessimisticLock"}` is calculated as:

```
tidb_tikvclient_request_seconds{type="PessimisticLock"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_dur` ↪ , `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds` ↪ `{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} =
    tikv_scheduler_latch_wait_duration_seconds{type="
        ↪ acquire_pessimistic_lock"} +
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    (lock in-mem key count + lock on-disk key count) * lock read duration +
    lock on-disk key count / (lock in-mem key count + lock on-disk key count
        ↪ ) *
    lock write duration
```

- Since TiDB v6.0, TiKV uses in-memory pessimistic lock by default. In-memory pessimistic lock bypass the async write process.
- `tikv_storage_engine_async_request_duration_seconds{type="snapshot"}` is a snapshot type duration. For more details, refer to the TiKV Snapshot section.
- The `lock in-mem key count` and `lock on-disk key count` are calculated as:

```
lock in-mem key count =
    sum(rate(tikv_in_memory_pessimistic_locking{result="success"})) /
```

```
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="
        ↪ kv_pessimistic_lock"}}))

lock on-disk key count =
    sum(rate(tikv_in_memory_pessimistic_locking{result="full"})) /
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="
        ↪ kv_pessimistic_lock"}}))
```

The count of in-memory and on-disk locked keys can be calculated by the in-memory lock counter. TiKV reads the keys' values before acquiring locks, and the read duration can be calculated by RocksDB performance context.

```
lock read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ acquire_pessimistic_lock"})) / sum(rate(
        ↪ tikv_storage_rocksdb_perf{metric="block_read_count",req="
        ↪ acquire_pessimistic_lock"}))
```

- `lock write duration` is the duration of writing on-disk lock. For more details, refer to the Async write section.

11.1.4.3.4 Commit

This section describes the commit duration. The following is the time cost diagram of commit operations:

```
Diagram(
    Stack(
        Sequence(
            Choice(
                0,
                Comment("use 2pc or causal consistency"),
                NonTerminal("Get min-commit-ts"),
            ),
            Optional("Async prewrite binlog"),
            NonTerminal("Prewrite mutations"),
            Optional("Wait prewrite binlog result"),
        ),
        Sequence(
            Choice(
                1,
                Comment("1pc"),
                Sequence(
                    Comment("2pc"),
                    NonTerminal("Get commit-ts"),
                    NonTerminal("Check schema, try to amend if needed"),
```

```
                NonTerminal("Commit PK mutation"),
            ),
            Sequence(
                Comment("async-commit"),
                NonTerminal("Commit mutations asynchronously"),
            ),
        ),
        Choice(
            0,
            Comment("committed"),
            NonTerminal("Async cleanup"),
        ),
        Optional("Commit binlog"),
    ),
),
)
```

The duration of the commit phase is calculated as:

```
commit =
    Get_latest_ts_time +
    Prewrite_time +
    Get_commit_ts_time +
    Commit_time

Get_latest_ts_time = Get_commit_ts_time =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"}

prewrite_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_prewrite"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_prewrite"})) /
    committer-concurrency
)

commit_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_commit"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_commit"})) /
    committer-concurrency
)

Prewrite_time =
    prewrite_round * tidb_tikvclient_request_seconds{type="Prewrite"}

Commit_time =
    commit_round * tidb_tikvclient_request_seconds{type="Commit"}
```

The commit duration can be broken down into four metrics:

- `Get_latest_ts_time` records the duration of getting latest TSO in async-commit or single-phase commit (1PC) transaction.
- `Prewrite_time` records the duration of the prewrite phase.
- `Get_commit_ts_time` records the duration of common 2PC transaction.
- `Commit_time` records the duration of the commit phase. Note that an async-commit or 1PC transaction does not have this phase.

Like pessimistic lock, flow control acts as an amplification of latency (`prewrite_round` and `commit_round` in the preceding formula).

The `tidb_tikvclient_request_seconds{type="Prewrite"}` and `tidb_tikvclient_request_secon` ↪ `{type="Commit"}` duration are calculated as:

```
tidb_tikvclient_request_seconds{type="Prewrite"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_prewrite"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tidb_tikvclient_request_seconds{type="Commit"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_commit"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_dur` ↪ , `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds` ↪ `{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_prewrite"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_prewrite"} =
    prewrite key count * prewrite read duration +
    prewrite write duration

prewrite key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="prewrite"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="prewrite"}))

prewrite read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ prewrite"})) / sum(rate(tikv_storage_rocksdb_perf{metric="
        ↪ block_read_count",req="prewrite"}))
```

Like locks in TiKV, prewrite is processed in read and write phases. The read duration can be calculated from the RocksDB performance context. For more details about the write duration, refer to the Async write section.

The `tikv_grpc_msg_duration_seconds{type="kv_commit"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_commit"} =
    commit key count * commit read duration +
    commit write duration

commit key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="commit"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="commit"}))

commit read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="commit
        ↪ "})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_read_count
        ↪ ",req="commit"})) (storage)
```

The duration of `kv_commit` is almost the same as `kv_prewrite`. For more details about the write duration, refer to the Async write section.

11.1.4.4 Batch client

The following is the time cost diagram of the batch client:

```
Diagram(
    NonTerminal("Get conn pool to the target store"),
    Choice(
        0,
        Sequence(
            Comment("Batch enabled"),
                NonTerminal("Push request to channel"),
                NonTerminal("Wait response"),
            ),
            Sequence(
            NonTerminal("Get conn from pool"),
            NonTerminal("Call RPC"),
            Choice(
                0,
                Comment("Unary call"),
                NonTerminal("Recv first"),
            ),
        ),
    ),
)
```

- The overall duration of sending a request is observed as `tidb_tikvclient_request_seconds` ↪ .
- RPC client maintains connection pools (named ConnArray) to each store, and each pool has a BatchConn with a batch request (send) channel.
- Batch is enabled when the store is TiKV and batch size is positive, which is true in most cases.
- The size of batch request channel is `tikv-client.max-batch-size` (default is `128`), the duration of enqueue is observed as `tidb_tikvclient_batch_wait_duration`.
- There are three kinds of stream requests: `CmdBatchCop`, `CmdCopStream`, and `CmdMPPConn`, which involve an additional `recv()` call to fetch the first response from the stream.

Though there is still some latency missed observed, the `tidb_tikvclient_request_seconds` ↪ can be calculated approximately as:

```
tidb_tikvclient_request_seconds{type="?"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_?"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

- `tidb_tikvclient_batch_wait_duration` records the waiting duration in the batch system.
- `tidb_tikvclient_batch_send_latency` records the encode duration in the batch system.
- `tikv_grpc_msg_duration_seconds{type="kv_?"}` is the TiKV processing duration.
- `tidb_tikvclient_rpc_net_latency_seconds` records the network latency.

11.1.4.5 TiKV snapshot

The following is the time cost diagram of TiKV snapshot operations:

```
Diagram(
    Choice(
        0,
        Comment("Local Read"),
        Sequence(
            NonTerminal("Propose Wait"),
            NonTerminal("Read index Read Wait"),
        ),
    ),
    NonTerminal("Fetch A Snapshot From KV Engine"),
)
```

The overall duration of a TiKV snapshot is observed as `tikv_storage_engine_async_request_durati` ↪ `{type="snapshot"}` and is calculated as:

```
tikv_storage_engine_async_request_duration_seconds{type="snapshot"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} =
    tikv_raftstore_request_wait_time_duration_secs +
    tikv_raftstore_commit_log_duration_seconds +
    get snapshot from rocksdb duration
```

When leader lease is expired, TiKV proposes a read index command before getting a snapshot from RocksDB. `tikv_raftstore_request_wait_time_duration_secs` and `tikv_raftstore_commit_log_duration_seconds` are the duration of committing read index command.

Since getting a snapshot from RocksDB is usually a fast operation, the `get snapshot from rocksdb duration` is ignored.

11.1.4.6 Async write

Async write is the process that TiKV writes data into the Raft-based replicated state machine asynchronously with a callback.

- The following is the time cost diagram of async write operations when the asynchronous IO is disabled:

```
Diagram(
    NonTerminal("Propose Wait"),
    NonTerminal("Process Command"),
    Choice(
        0,
        Sequence(
            NonTerminal("Wait Current Batch"),
            NonTerminal("Write to Log Engine"),
        ),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

- The following is the time cost diagram of async write operations when the asynchronous IO is enabled:

```
Diagram(
    NonTerminal("Propose Wait"),
```

```
    NonTerminal("Process Command"),
    Choice(
        0,
        NonTerminal("Wait Until Persisted by Write Worker"),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

The async write duration is calculated as:

```
async write duration(async io disabled) =
    propose +
    async io disabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds

async write duration(async io enabled) =
    propose +
    async io enabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds
```

Async write can be broken down into the following three phases:

- Propose
- Commit
- Apply: `tikv_raftstore_apply_wait_time_duration_secs + tikv_raftstore_apply_log_durat`
  ↪ in the preceding formula

The duration of the propose phase is calculated as:

```
propose =
    propose wait duration +
    propose duration

propose wait duration =
    tikv_raftstore_store_wf_batch_wait_duration_seconds

propose duration =
    tikv_raftstore_store_wf_send_to_queue_duration_seconds -
    tikv_raftstore_store_wf_batch_wait_duration_seconds
```

The Raft process is recorded in a waterfall manner. So the propose duration is calculated from the difference between the two metrics.

The duration of the commit phase is calculated as:

```
async io disabled commit = max(
    persist log locally duration,
    replicate log duration
)

async io enabled commit = max(
    wait by write worker duration,
    replicate log duration
)
```

Since v5.3.0, TiKV supports Async IO Raft (write Raft log by a StoreWriter thread pool). The Async IO Raft is only enabled when the `store-io-pool-size` is set to a positive value, which changes the process of commit. The `persist log locally duration` and `wait by write worker duration` are calculated as:

```
persist log locally duration =
    batch wait duration +
    write to raft db duration

batch wait duration =
    tikv_raftstore_store_wf_before_write_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

write to raft db duration =
    tikv_raftstore_store_wf_write_end_duration_seconds -
    tikv_raftstore_store_wf_before_write_duration_seconds

wait by write worker duration =
    tikv_raftstore_store_wf_persist_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds
```

The difference between with and without Async IO is the duration of persisting logs locally. With Async IO, the duration of persisting log locally can be calculated from the waterfall metrics directly (skip the batch wait duration).

The replicate log duration records the duration of log persisted in quorum peers, which contains an RPC duration and the duration of log persisting in the majority. The `replicate log duration` is calculated as:

```
replicate log duration =
    raftmsg send wait duration +
    commit log wait duration
```

```
raftmsg send wait duration =
    tikv_raftstore_store_wf_send_proposal_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

commit log wait duration =
    tikv_raftstore_store_wf_commit_log_duration -
    tikv_raftstore_store_wf_send_proposal_duration_seconds
```

11.1.4.6.1 Raft DB

The following is the time cost diagram of Raft DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
    NonTerminal("Write and Sync Log"),
    NonTerminal("Apply Log to Memtable"),
)
```

```
write to raft db duration = raft db write duration
commit log wait duration >= raft db write duration

raft db write duration(raft engine enabled) =
    raft_engine_write_preprocess_duration_seconds +
    raft_engine_write_leader_duration_seconds +
    raft_engine_write_apply_duration_seconds

raft db write duration(raft engine disabled) =
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_thread_wait"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_scheduling_flushes_compactions_time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_wal_time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_memtable_time"}
```

Because `commit log wait duration` is the longest duration of quorum peers, it might be larger than `raft db write duration`.

Since v6.1.0, TiKV uses Raft Engine as its default log storage engine, which changes the process of writing log.

11.1.4.6.2 KV DB

The following is the time cost diagram of KV DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
    NonTerminal("Preprocess"),
    Choice(
        0,
        Comment("No Need to Switch"),
        NonTerminal("Switch WAL or Memtable"),
    ),
    NonTerminal("Write and Sync WAL"),
    NonTerminal("Apply to Memtable"),
)
```

```
tikv_raftstore_apply_log_duration_seconds =
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_thread_wait"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_scheduling_flushes_compactions_time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_wal_time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_memtable_time"}
```

In the async write process, committed logs need to be applied to the KV DB. The applying duration can be calculated from the RocksDB performance context.

11.1.4.7 Diagnosis use cases

The preceding sections explain the details about time cost metrics during querying. This section introduces common procedures of metrics analysis when you encounter slow read or write queries. All metrics can be checked in the Database Time panel of Performance Overview Dashboard.

11.1.4.7.1 Slow read queries

If `SELECT` statements account for a significant portion of the database time, you can assume that TiDB is slow at read queries.

The execution plans of slow queries can be found in the Top SQL statements panel of TiDB Dashboard. To investigate the time costs of slow read queries, you can analyze Point get, Batch point get and some simple coprocessor queries according to the preceding descriptions.

11.1.4.7.2 Slow write queries

Before investigating slow writes, you need to troubleshoot the cause of the conflicts by checking `tikv_scheduler_latch_wait_duration_seconds_sum{type="acquire_pessimistic_lock"} by (instance)`:

- If this metric is high in some specific TiKV instances, there might be conflicts in hot Regions.
- If this metric is high across all instances, there might be conflicts in the application.

After confirming the cause of conflicts from the application, you can investigate slow write queries by analyzing the duration of Lock and Commit.

11.2 Configuration Tuning

11.2.1 Tune Operating System Performance

This document introduces how to tune each subsystem of CentOS 7.

> **Note:**
>
> - The default configuration of the CentOS 7 operating system is suitable for most services running under moderate workloads. Adjusting the performance of a particular subsystem might negatively affects other subsystems. Therefore, before tuning the system, back up all the user data and configuration information.
> - Fully test all the changes in the test environment before applying them to the production environment.

11.2.1.1 Performance analysis methods

System tuning must be based on the results of system performance analysis. This section lists common methods for performance analysis.

11.2.1.1.1 In 60 seconds

Linux Performance Analysis in 60,000 Milliseconds is published by the author Brendan Gregg and the Netflix Performance Engineering team. All tools used can be obtained from the official release of Linux. You can analyze outputs of the following list items to troubleshoot most common performance issues.

- `uptime`
- `dmesg | tail`

- `vmstat 1`
- `mpstat -P ALL 1`
- `pidstat 1`
- `iostat -xz 1`
- `free -m`
- `sar -n DEV 1`
- `sar -n TCP,ETCP 1`
- `top`

For detailed usage, see the corresponding `man` instructions.

11.2.1.1.2 perf

perf is an important performance analysis tool provided by the Linux kernel, which covers hardware level (CPU/PMU, performance monitoring unit) features and software features (software counters, trace points). For detailed usage, see perf Examples.

11.2.1.1.3 BCC/bpftrace

Starting from CentOS 7.6, the Linux kernel has supported Berkeley Packet Filter (BPF). Therefore, you can choose proper tools to conduct an in-depth analysis based on the results in In 60 seconds. Compared with perf/ftrace, BPF provides programmability and smaller performance overhead. Compared with kprobe, BPF provides higher security and is more suitable for the production environments. For detailed usage of the BCC toolkit, see BPF Compiler Collection (BCC).

11.2.1.2 Performance tuning

This section introduces performance tuning based on the classified kernel subsystems.

11.2.1.2.1 CPU—frequency scaling

cpufreq is a module that dynamically adjusts the CPU frequency. It supports five modes. To ensure service performance, select the performance mode and fix the CPU frequency at the highest supported operating frequency without dynamic adjustment. The command for this operation is `cpupower frequency-set --governor performance`.

11.2.1.2.2 CPU—interrupt affinity

- Automatic balance can be implemented through the `irqbalance` service.
- Manual balance:
  - Identify the devices that need to balance interrupts. Starting from CentOS 7.5, the system automatically configures the best interrupt affinity for certain devices and their drivers, such as devices that use the `be2iscsi` driver and NVMe settings. You can no longer manually configure interrupt affinity for such devices.

- For other devices, check the chip manual to see whether these devices support distributing interrupts.
  * If they do not, all interrupts of these devices are routed to the same CPU and cannot be modified.
  * If they do, calculate the `smp_affinity` mask and set the corresponding configuration file. For details, see the kernel document.

11.2.1.2.3 NUMA CPU binding

To avoid accessing memory across Non-Uniform Memory Access (NUMA) nodes as much as possible, you can bind a thread/process to certain CPU cores by setting the CPU affinity of the thread. For ordinary programs, you can use the `numactl` command for the CPU binding. For detailed usage, see the Linux manual pages. For network interface card (NIC) interrupts, see tune network.

11.2.1.2.4 Memory—transparent huge page (THP)

It is **NOT** recommended to use THP for database applications, because databases often have sparse rather than continuous memory access patterns. If high-level memory fragmentation is serious, a higher latency will occur when THP pages are allocated. If the direct compaction is enabled for THP, the CPU usage will surge. Therefore, it is recommended to disable THP.

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

11.2.1.2.5 Memory—virtual memory parameters

- `dirty_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to use the `pdflush` operation to write the dirty page caches to disk. The default value of `dirty_ratio` is 20% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, lowering this value helps improve the efficiency of memory reclamation.
- `dirty_background_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to write the dirty page caches to the disk in the background. The default value of `dirty_background_ratio` is 10% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, setting a lower value helps improve the efficiency of memory reclamation.

11.2.1.2.6 Storage and file system

The core I/O stack link is long, including the file system layer, the block device layer, and the driver layer.

I/O scheduler

The I/O scheduler determines when and how long I/O operations run on the storage device. It is also called I/O elevator. For SSD devices, it is recommended to set the I/O scheduling policy to `noop`.

```
echo noop > /sys/block/${SSD_DEV_NAME}/queue/scheduler
```

Formatting parameters—block size

Blocks are the working units of the file system. The block size determines how much data can be stored in a single block, and thus determines the minimum amount of data to be written or read each time.

The default block size is suitable for most scenarios. However, if the block size (or the size of multiple blocks) is the same or slightly larger than the amount of data normally read or written each time, the file system performs better and the data storage efficiency is higher. Small files still use the entire block. Files can be distributed among multiple blocks, but this will increase runtime overhead.

When using the `mkfs` command to format a device, specify the block size as a part of the file system options. The parameters that specify the block size vary with the file system. For details, see the corresponding `mkfs` manual pages, such as using `man mkfs.ext4`.

`mount` parameters

If the `noatime` option is enabled in the `mount` command, the update of metadata is disabled when files are read. If the `nodiratime` behavior is enabled, the update of metadata is disabled when the directory is read.

11.2.1.2.7 Network tuning

The network subsystem consists of many different parts with sensitive connections. The CentOS 7 network subsystem is designed to provide the best performance for most workloads and automatically optimizes the performance of these workloads. Therefore, usually you do not need to manually adjust network performance.

Network issues are usually caused by issues of hardware or related devices. So before tuning the protocol stack, rule out hardware issues.

Although the network stack is largely self-optimizing, the following aspects in the network packet processing might become the bottleneck and affect performance:

- NIC hardware cache: To correctly observe the packet loss at the hardware level, use the `ethtool -S ${NIC_DEV_NAME}` command to observe the `drops` field. When packet loss occurs, it might be that the processing speed of the hard/soft interrupts cannot catch up with the receiving speed of NIC. If the received buffer size is less than the upper limit, you can also try to increase the RX buffer to avoid packet loss. The query command is: `ethtool -g ${NIC_DEV_NAME}`, and the modification command is `ethtool -G ${NIC_DEV_NAME}`.

- Hardware interrupts: If the NIC supports the Receive-Side Scaling (RSS, also called multi-NIC receiving) feature, observe the `/proc/interrupts` NIC interrupts. If the interrupts are uneven, see CPU—frequency scaling, CPU—interrupt affinity, and NUMA CPU binding. If the NIC does not support RSS or the number of RSS is much smaller than the number of physical CPU cores, configure Receive Packet Steering (RPS, which can be regarded as the software implementation of RSS), and the RPS extension Receive Flow Steering (RFS). For detailed configuration, see the kernel document.
- Software interrupts: Observe the monitoring of `/proc/net/softnet_stat`. If the values of the other columns except the third column are increasing, properly adjust the value of `net.core.netdev_budget` or `net.core.dev_weight` for `softirq` to get more CPU time. In addition, you also need to check the CPU usage to determine which tasks are frequently using the CPU and whether they can be optimized.
- Receive queue of application sockets: Monitor the `Resv-q` column of `ss -nmp`. If the queue is full, consider increasing the size of the application socket cache or use the automatic cache adjustment method. In addition, consider whether you can optimize the architecture of the application layer and reduce the interval between reading sockets.
- Ethernet flow control: If the NIC and switch support the flow control feature, you can use this feature to leave some time for the kernel to process the data in the NIC queue, to avoid the issue of NIC buffer overflow.
- Interrupts coalescing: Too frequent hardware interrupts reduces system performance, and too late hardware interrupts causes packet loss. Newer NICs support the interrupt coalescing feature and allow the driver to automatically adjust the number of hardware interrupts. You can execute `ethtool -c ${NIC_DEV_NAME}` to check and `ethtool -C ${NIC_DEV_NAME}` to enable this feature. The adaptive mode allows the NIC to automatically adjust the interrupt coalescing. In this mode, the driver checks the traffic mode and kernel receiving mode, and evaluates the coalescing settings in real time to prevent packet loss. NICs of different brands have different features and default configurations. For details, see the NIC manuals.
- Adapter queue: Before processing the protocol stack, the kernel uses this queue to buffer the data received by the NIC, and each CPU has its own backlog queue. The maximum number of packets that can be cached in this queue is `netdev_max_backlog`. Observe the second column of `/proc/net/softnet_stat`. When the second column of a row continues to increase, it means that the CPU [row-1] queue is full and the data packet is lost. To resolve this problem, continue to double the `net.core.netdev_max_backlog` value.
- Send queue: The length value of a send queue determines the number of packets that can be queued before sending. The default value is `1000`, which is sufficient for 10 Gbps. But if you have observed the value of TX errors from the output of `ip -s link`, you can try to double it: `ip link set dev ${NIC_DEV_NAME} txqueuelen 2000`.
- Driver: NIC drivers usually provide tuning parameters. See the device hardware manual and its driver documentation.

11.2.2 TiDB Memory Control

Currently, TiDB can track the memory quota of a single SQL query and take actions to prevent OOM (out of memory) or troubleshoot OOM when the memory usage exceeds a specific threshold value. The system variable `tidb_mem_oom_action` specifies the action to take when a query reaches the memory limit:

- A value of `LOG` means that queries will continue to execute when the `tidb_mem_quota_query` limit is reached, but TiDB will print an entry to the log.
- A value of `CANCEL` means TiDB stops executing the SQL query immediately after the `tidb_mem_quota_query` limit is reached, and returns an error to the client. The error information clearly shows the memory usage of each physical execution operator that consumes memory in the SQL execution process.

11.2.2.1 Configure the memory quota of a query

The system variable `tidb_mem_quota_query` sets the limit for a query in bytes. Some usage examples:

```
-- Set the threshold value of memory quota for a single SQL query to 8GB:
SET tidb_mem_quota_query = 8 << 30;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8MB:
SET tidb_mem_quota_query = 8 << 20;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8KB:
SET tidb_mem_quota_query = 8 << 10;
```

11.2.2.2 Configure the memory usage threshold of a tidb-server instance

In the TiDB configuration file, you can set the memory usage threshold of a tidb-server instance by configuring `server-memory-quota`.

The following example sets the total memory usage of a tidb-server instance to 32 GB:

```
[performance]
server-memory-quota = 34359738368
```

In this configuration, when the memory usage of a tidb-server instance reaches 32 GB, the instance starts to kill running SQL statements randomly until the memory usage drops below 32 GB. SQL operations that are forced to terminate return an `Out Of Global Memory Limit!` error message to the client.

Warning:

- `server-memory-quota` is still an experimental feature. It is **NOT** recommended that you use it in a production environment.
- The default value of `server-memory-quota` is `0`, which means no memory limit.

Since v6.4.0, you can use the system variable `tidb_server_memory_limit` to set the threshold for the memory usage of a tidb-server instance.

For example, set the total memory usage of a tidb-server instance to 32 GB:

```
SET GLOBAL tidb_server_memory_limit = "32GB";
```

After you set this variable, when the memory usage of a tidb-server instance reaches 32 GB, TiDB will terminate the SQL operation with the largest memory usage among all running SQL operations in order, until the memory usage of the instance drops below 32 GB. The forcibly terminated SQL operation will return the `Out Of Memory Quota!` error to the client.

Currently, the memory limit set by `tidb_server_memory_limit` **DOES NOT** terminate the following SQL operations:

- DDL operations
- INSERT, UPDATE, and DELETE operations
- SQL operations that contain window functions and common table expressions

Warning:

- The global memory control of tidb-server instances is still an experimental feature. It is not recommended to use it in the production environment.
- During the startup process, TiDB does not guarantee that the `tidb_server_memory_limit` limit is enforced. If the free memory of the operating system is insufficient, TiDB might still encounter OOM. You need to ensure that the TiDB instance has enough available memory.
- In the process of memory control, the total memory usage of TiDB might slightly exceed the limit set by `tidb_server_memory_limit`.
- To ensure compatibility, when `tidb_server_memory_limit` is enabled, the system ignores the `server-memory-quota` value and uses `tidb_server_memory_limit` memory control mechanism. When `tidb_server_memory_limit` is disabled, the system uses the `server-memory-quota` value to control the memory usage of the tidb-server instance.

When the memory usage of a tidb-server instance reaches a certain proportion of the total memory (the proportion is controlled by the system variable `tidb_server_memory_limit_gc_trigger` ↪), tidb-server will try to trigger a Golang GC to relieve memory stress. To avoid frequent GCs that cause performance issues due to the instance memory fluctuating around the threshold, this GC method will trigger GC at most once every minute.

11.2.2.3 View the memory usage of the current tidb-server instance using the INFORMATION_SCHEMA system table

> **Warning:**
>
> The following system tables are introduced in v6.4.0. Currently, these tables are still experimental. The memory usage information provided is only for reference. It is not recommended to use the following system tables in a production environment to obtain memory usage information for decision-making.

To view the memory usage of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE`.

To view the memory-related operations and execution basis of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)` ↪ `MEMORY_USAGE_OPS_HISTORY`. For each instance, this table retains the latest 50 records.

11.2.2.4 Trigger the alarm of excessive memory usage

When the memory usage of a tidb-server instance exceeds its memory threshold (70% of its total memory by default) and any of the following conditions is met, TiDB records the related status files and prints an alarm log.

- It is the first time the memory usage exceeds the memory threshold.
- The memory usage exceeds the memory threshold and it has been more than 60 seconds since the last alarm.
- The memory usage exceeds the memory threshold and `(Current memory usage - ↪ Memory usage at the last alarm)/ Total memory > 10%`.

You can control the memory threshold that triggers the alarm by modifying the memory usage ratio via the system variable `tidb_memory_usage_alarm_ratio`.

When the alarm of excessive memory usage is triggered, TiDB takes the following actions:

- TiDB records the following information in the directory where the TiDB log file `filename` is located.
  - The information about the top 10 SQL statements with the highest memory usage and the top 10 SQL statements with the longest running time among all SQL statements currently being executed
  - The goroutine stack information
  - The usage status of heap memory
- TiDB prints an alarm log containing the keyword `tidb-server has the risk of OOM` and the values of the following memory-related system variables.
  - `tidb_mem_oom_action`
  - `tidb_mem_quota_query`
  - `tidb_server_memory_limit`
  - `tidb_analyze_version`
  - `tidb_enable_rate_limit_action`

To avoid accumulating too many status files for alarms, TiDB only retains the status files generated during the recent five alarms by default. You can adjust this number by configuring the system variable `tidb_memory_usage_alarm_keep_record_num`.

The following example constructs a memory-intensive SQL statement that triggers the alarm:

1. Set `tidb_memory_usage_alarm_ratio` to `0.85`:

```
SET GLOBAL tidb_memory_usage_alarm_ratio = 0.85;
```

2. Execute `CREATE TABLE t(a int);` and insert 1000 rows of data.
3. Execute `select * from t t1 join t t2 join t t3 order by t1.a`. This SQL statement outputs one billion records, which consumes a large amount of memory and therefore triggers the alarm.
4. Check the `tidb.log` file which records the total system memory, current system memory usage, memory usage of the tidb-server instance, and the directory of status files.

```
[2022/10/11 16:39:02.281 +08:00] [WARN] [memoryusagealarm.go:212] ["
    ↪ tidb-server has the risk of OOM because of memory usage exceeds
    ↪ alarm ratio. Running SQLs and heap profile will be recorded in
    ↪ record path"] ["is server-memory-quota set"=false] ["system
    ↪ memory total"=33682427904] ["system memory usage"=22120655360] ["
    ↪ tidb-server memory usage"=21468556992] [memory-usage-alarm-ratio
    ↪ =0.85] ["record path"=/tiup/deploy/tidb-4000/log/oom_record]
```

The fields of the example log file above are described as follows:

- `is server-memory-quota set` indicates whether server-memory-quota is set.
- `system memory total` indicates the total memory of the current system.
- `system memory usage` indicates the current system memory usage.
- `tidb-server memory usage` indicates the memory usage of the tidb-server instance.
- `memory-usage-alarm-ratio` indicates the value of the system variable tidb_memory_usage_alarm_ratio.
- `record path` indicates the directory of status files.

5. By checking the directory of status files (In the preceding example, the directory is `/tiup/deploy/tidb-4000/log/oom_record`), you can see a record directory with the corresponding timestamp (for example, `record2022-10-09T17:18:38+08:00`). The record directory includes three files: `goroutinue`, `heap`, and `running_sql`. These three files are suffixed with the time when status files are logged. They respectively record goroutine stack information, the usage status of heap memory, and the running SQL information when the alarm is triggered. For the content in `running_sql`, refer to expensive-queries.

11.2.2.5 Other memory control behaviors of tidb-server

11.2.2.5.1 Flow control

- TiDB supports dynamic memory control for the operator that reads data. By default, this operator uses the maximum number of threads that tidb_distsql_scan_concurrency ↪ allows to read data. When the memory usage of a single SQL execution exceeds tidb_mem_quota_query each time, the operator that reads data stops one thread.
- This flow control behavior is controlled by the system variable tidb_enable_rate_limit_action ↪ .
- When the flow control behavior is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, destroy one token now`.

11.2.2.5.2 Disk spill

TiDB supports disk spill for execution operators. When the memory usage of a SQL execution exceeds the memory quota, tidb-server can spill the intermediate data of execution operators to the disk to relieve memory pressure. Operators supporting disk spill include Sort, MergeJoin, HashJoin, and HashAgg.

- The disk spill behavior is jointly controlled by the following parameters: tidb_mem_quota_query ↪ , tidb_enable_tmp_storage_on_oom, tmp-storage-path, and tmp-storage- ↪ quota.

- When the disk spill is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, spill to disk now` or `memory exceeds quota, set aggregate mode to spill-mode`.
- Disk spill for the Sort, MergeJoin, and HashJoin operator is introduced in v4.0.0; disk spill for the HashAgg operator is introduced in v5.2.0.
- When the SQL executions containing Sort, MergeJoin, or HashJoin cause OOM, TiDB triggers disk spill by default. When SQL executions containing HashAgg cause OOM, TiDB does not trigger disk spill by default. You can configure the system variable `tidb_executor_concurrency = 1` to trigger disk spill for HashAgg.

> **Note:**
>
> The disk spill for HashAgg does not support SQL executions containing the `DISTINCT` aggregate function. When a SQL execution containing a `DISTINCT` aggregate function uses too much memory, the disk spill does not apply.

The following example uses a memory-consuming SQL statement to demonstrate the disk spill feature for HashAgg:

1. Configure the memory quota of a SQL statement to 1GB (1 GB by default):

```
SET tidb_mem_quota_query = 1 << 30;
```

2. Create a single table `CREATE TABLE t(a int);` and insert 256 rows of different data.

3. Execute the following SQL statement:

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

   Because executing this SQL statement occupies too much memory, the following "Out of Memory Quota" error message is returned:

```
ERROR 1105 (HY000): Out Of Memory Quota![conn_id=3]
```

4. Configure the system variable `tidb_executor_concurrency` to 1. With this configuration, when out of memory, HashAgg automatically tries to trigger disk spill.

```
SET tidb_executor_concurrency = 1;
```

5. Execute the same SQL statement. You can find that this time, the statement is successfully executed and no error message is returned. From the following detailed execution plan, you can see that HashAgg has used 600 MB of hard disk space.

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

```

11.2.2.6 Others

11.2.2.6.1 Mitigate OOM issues by configuring `GOMEMLIMIT`

GO 1.19 introduces an environment variable GOMEMLIMIT to set the memory limit that triggers GC.

For v6.1.3 <= TiDB < v6.5.0, you can mitigate a typical category of OOM issues by manually setting `GOMEMLIMIT`. The typical category of OOM issues is: before OOM occurs, the estimated memory in use on Grafana occupies only half of the entire memory (TiDB-Runtime > Memory Usage > estimate-inuse), as shown in the following figure:

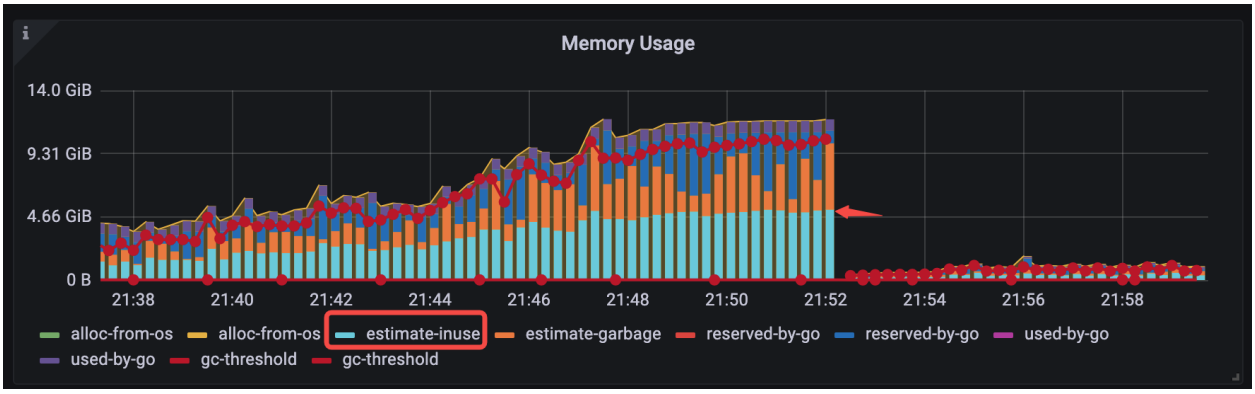

Figure 156: normal OOM case example

To verify the performance of `GOMEMLIMIT`, a test is performed to compare the specific memory usage with and without `GOMEMLIMIT` configuration.

- In TiDB v6.1.2, the TiDB server encounters OOM (system memory: about 48 GiB) after the simulated workload runs for several minutes:

Figure 157: v6.1.2 workload oom

- In TiDB v6.1.3, `GOMEMLIMIT` is set to 40000 MiB. It is found that the simulated workload runs stably for a long time, OOM does not occur in the TiDB server, and the maximum memory usage of the process is stable at around 40.8 GiB:

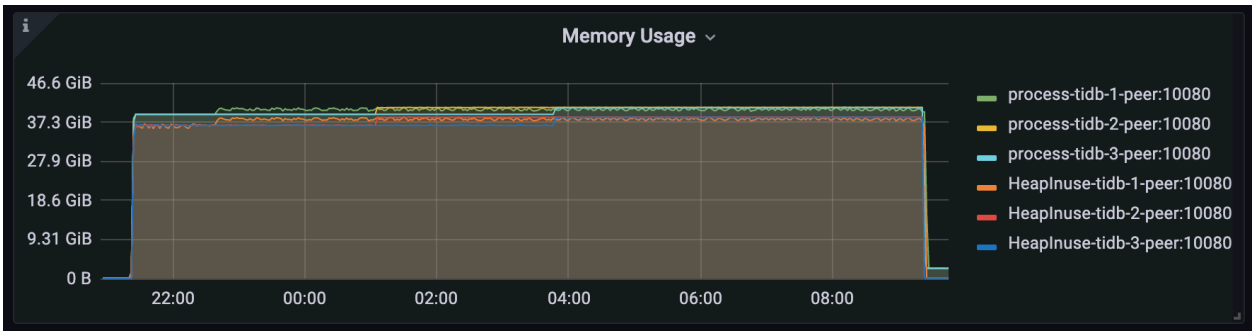

Figure 158: v6.1.3 workload no oom with GOMEMLIMIT

11.2.3 Tune TiKV Thread Pool Performance

This document introduces TiKV internal thread pools and how to tune their performance.

11.2.3.1 Thread pool introduction

The TiKV thread pool is mainly composed of gRPC, Scheduler, UnifyReadPool, Raftstore, StoreWriter, Apply, RocksDB, and some scheduled tasks and detection components that do not consume much CPU. This document mainly introduces a few CPU-intensive thread pools that affect the performance of read and write requests.

- The gRPC thread pool: it handles all network requests and forwards requests of different task types to different thread pools.
- The Scheduler thread pool: it detects write transaction conflicts, converts requests like the two-phase commit, pessimistic locking, and transaction rollbacks into key-value pair arrays, and then sends them to the Raftstore thread for Raft log replication.
- The Raftstore thread pool:
  - It processes all Raft messages and the proposal to add a new log.
  - It writes Raft logs to the disk. If the value of `store-io-pool-size` is `0`, the Raftstore thread writes the logs to the disk; if the value is not `0`, the Raftstore thread sends the logs to the StoreWriter thread.
  - When Raft logs in the majority of replicas are consistent, the Raftstore thread sends the logs to the Apply thread.
- The StoreWriter thread pool: it writes all Raft logs to the disk and returns the result to the Raftstore thread.
- The Apply thread pool: it receives the submitted log sent from the Raftstore thread pool, parses it as a key-value request, then writes it to RocksDB, calls the callback

function to notify the gRPC thread pool that the write request is complete, and returns the result to the client.

- The RocksDB thread pool: it is a thread pool for RocksDB to compact and flush tasks. For RocksDB's architecture and `Compact` operation, refer to RocksDB: A Persistent Key-Value Store for Flash and RAM Storage.
- The UnifyReadPool thread pool: it is a combination of the Coprocessor thread pool and Storage Read Pool. All read requests such as kv get, kv batch get, raw kv get, and coprocessor are executed in this thread pool.

11.2.3.2 TiKV read-only requests

TiKV's read requests are divided into the following types:

- Simple queries that specify a certain row or several rows, running in the Storage Read Pool.
- Complex aggregate calculation and range queries, running in the Coprocessor Read Pool.

Starting from TiKV v5.0, all read requests use the unified thread pool for queries by default. If your TiKV cluster is upgraded from TiKV v4.0 and the `use-unified-pool` configuration of `readpool.storage` was set to `false` before the upgrade, all read requests continue using different thread pools after the upgrade. In this scenario, to make all read requests use the unified thread pool for queries, you can set the value of `readpool.storage` ↪ `.use-unified-pool` to `true`.

11.2.3.3 Performance tuning for TiKV thread pools

- The gRPC thread pool.

  The default size (configured by `server.grpc-concurrency`) of the gRPC thread pool is `5`. This thread pool has almost no computing overhead and is mainly responsible for network I/O and deserialization requests, so generally you do not need to adjust the default configuration.

  - If the machine deployed with TiKV has a small number (less than or equal to 8) of CPU cores, consider setting the `server.grpc-concurrency` configuration item to `2`.
  - If the machine deployed with TiKV has very high configuration, TiKV undertakes a large number of read and write requests, and the value of `gRPC poll CPU` that monitors Thread CPU on Grafana exceeds 80% of `server.grpc-concurrency` ↪ , then consider increasing the value of `server.grpc-concurrency` to keep the thread pool usage rate below 80% (that is, the metric on Grafana is lower than `80% * server.grpc-concurrency`).

- The Scheduler thread pool.

  When TiKV detects that the number of machine CPU cores is larger than or equal to 16, the default size (configured by `storage.scheduler-worker-pool-size`) of the Scheduler thread pool is `8`; when TiKV detects that the number of machine CPU cores is smaller than 16, the default size is `4`.

  This thread pool is mainly used to convert complex transaction requests into simple key-value read and write requests. However, **the Scheduler thread pool itself does not perform any write operation**.

  - If it detects a transaction conflict, then this thread pool returns the conflict result to the client in advance.
  - If no conflict is detected, then this thread pool merges the key-value requests that perform write operations into a Raft log and sends it to the Raftstore thread for Raft log replication.

  Generally speaking, to avoid excessive thread switching, it is best to ensure that the utilization rate of the Scheduler thread pool is between 50% and 75%. If the thread pool size is `8`, then it is recommended to keep `TiKV-Details.Thread CPU.scheduler worker CPU` on Grafana between 400% and 600%.

- The Raftstore thread pool.

  The Raftstore thread pool is the most complex thread pool in TiKV. The default size (configured by `raftstore.store-pool-size`) of this thread pool is `2`. For the StoreWriter thread pool, the default size (configured by `raftstore.store-io-pool-size`) is `0`.

  - When the size of the StoreWriter thread pool is 0, all write requests are written into RocksDB in the way of `fsync` by the Raftstore thread. In this case, it is recommended to tune the performance as follows:
    * Keep the overall CPU usage of the Raftstore thread below 60%. When the number of Raftstore threads is 2, keep the **TiKV-Details**, **Thread CPU**, **Raft store CPU** on Grafana below 120%. Due to I/O requests, the CPU usage of Raftstore threads in theory is always lower than 100%.
    * Do not increase the size of the Raftstore thread pool to improve write performance without careful consideration, because this might increase the disk burden and degrade performance.
  - When the size of the StoreWriter thread pool is not 0, all write requests are written into RocksDB in the way of `fsync` by the StoreWriter thread. In this case, it is recommended to tune the performance as follows:
    * Enable the StoreWriter thread pool ONLY when the overall CPU resources are sufficient. When the StoreWriter thread pool is enabled, keep the CPU usage of the StoreWriter thread and the Raftstore thread below 80%.

Compared with the case that the write requests are processed by the Raftstore thread, in theory, when the write requests are processed by the StoreWriter thread, write latency and the tail latency of data read are significantly reduced. However, as the write speed grows faster, the number of Raft logs increases accordingly. This can cause the CPU overhead of the Raftstore threads, the Apply threads, and the gRPC threads to increase. In this case, insufficient CPU resources might offset the tuning effect, and as a result, the write speed might become slower than before. Therefore, if the CPU resources are not sufficient, it is not recommended to enable the StoreWriter thread. Because the Raftstore thread sends most of the I/O requests to the StoreWriter thread, you need to keep the CPU usage of the Raftstore thread below 80%.

  - In most cases, set the size of the StoreWriter thread pool to 1 or 2. This is because the size of the StoreWriter thread pool affects the number of Raft logs, so the value of the thread pool size should not be too large. If the CPU usage is higher than 80%, consider increasing the thread pool size.
  - Pay attention to the impact of increasing Raft logs on the CPU overhead of other thread pools. If necessary, you need to increase the number of Raftstore threads, Apply threads, and gRPC threads accordingly.

- The UnifyReadPool thread pool.

  The UnifyReadPool is responsible for handling all read requests. The default size (configured by `readpool.unified.max-thread-count`) is 80% of the number of the machine's CPU cores. For example, if the machine CPU has 16 cores, the default thread pool size is 12. It is recommended to adjust the CPU usage rate according to the application workloads and keep it between 60% and 90% of the thread pool size.

  If the peak value of the `TiKV-Details.Thread CPU.Unified read pool CPU` on Grafana does not exceed 800%, then it is recommended to set `readpool.unified` ↪ `.max-thread-count` to `10`. Too many threads can cause more frequent thread switching, and take up resources of other thread pools.

  Since v6.3.0, TiKV supports automatically adjusting the UnifyReadPool thread pool size based on the current CPU usage. To enable this feature, you can set the `readpool` ↪ `.unified.auto-adjust-pool-size = true`. It is recommended to automatically adjust the thread pool size for clusters that are reread and whose maximum CPU usage exceeds 80%.

- The RocksDB thread pool.

  The RocksDB thread pool is a thread pool for RocksDB to compact and flush tasks. Usually, you do not need to configure it.

  - If the machine has a small number of CPU cores, set both `rocksdb.max-` ↪ `background-jobs` and `raftdb.max-background-jobs` to `4`.
  - If you encounter write stall, go to Write Stall Reason in **RocksDB-kv** on Grafana and check on the metrics that are not `0`.

* If it is caused by reasons related to pending compaction bytes, set `rocksdb.max-sub-compactions` to `2` or `3`. This configuration item indicates the number of sub-threads allowed for a single compaction job. Its default value is `3` in TiKV 4.0 and `1` in TiKV 3.0.
* If the reason is related to memtable count, it is recommended to increase the `max-write-buffer-number` of all columns (`5` by default).
* If the reason is related to the level0 file limit, it is recommended to increase values of the following parameters to `64` or a larger number:

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

11.2.4 Tune TiKV Memory Parameter Performance

This document describes how to tune the TiKV parameters for optimal performance. You can find the default configuration file in etc/config-template.toml. To modify the configuration, you can use TiUP or modify TiKV dynamically for a limited set of configuration items. For the complete configuration, see TiKV configuration file.

TiKV uses RocksDB for persistent storage at the bottom level of the TiKV architecture. Therefore, many of the performance parameters are related to RocksDB. TiKV uses two RocksDB instances: the default RocksDB instance stores KV data, the Raft RocksDB instance (RaftDB) stores Raft logs.

TiKV implements `Column Families` (CF) from RocksDB.

- The default RocksDB instance stores KV data in the `default`, `write` and `lock` CFs.
  - The `default` CF stores the actual data. The corresponding parameters are in `[rocksdb.defaultcf]`.
  - The `write` CF stores the version information in Multi-Version Concurrency Control (MVCC) and index-related data. The corresponding parameters are in `[rocksdb.writecf]`.
  - The `lock` CF stores the lock information. The system uses the default parameters.
- The Raft RocksDB (RaftDB) instance stores Raft logs.
  - The `default` CF stores the Raft log. The corresponding parameters are in `[raftdb.defaultcf]`.

After TiKV 3.0, by default, all CFs share one block cache instance. You can configure the size of the cache by setting the `capacity` parameter under `[storage.block-cache]`. The bigger the block cache, the more hot data can be cached, and the easier to read data, in the meantime, the more system memory is occupied. To use a separate block cache instance for each CF, set `shared=false` under `[storage.block-cache]`, and configure individual block cache size for each CF. For example, you can configure the size of `write` CF by setting the `block-cache-size` parameter under `[rocksdb.writecf]`.

Before TiKV 3.0, shared block cache is not supported, and you need to configure block cache for each CF individually.

Each CF also has a separate `write buffer`. You can configure the size by setting the `write-buffer-size` parameter.

11.2.4.1 Parameter specification

```
### Log level: trace, debug, warn, error, info, off.
log-level = "info"

[server]
### Set listening address
### addr = "127.0.0.1:20160"

### Size of thread pool for gRPC
### grpc-concurrency = 4
### The number of gRPC connections between each TiKV instance
### grpc-raft-conn-num = 10

### Most read requests from TiDB are sent to the coprocessor of TiKV. This
   ↪ parameter is used to set the number of threads
### of the coprocessor. If many read requests exist, add the number of
   ↪ threads and keep the number within that of the
### system CPU cores. For example, for a 32-core machine deployed with TiKV,
   ↪  you can even set this parameter to 30 in
### repeatable read scenarios. If this parameter is not set, TiKV
   ↪ automatically sets it to CPU cores * 0.8.
### end-point-concurrency = 8

### Tag the TiKV instances to schedule replicas.
### labels = {zone = "cn-east-1", host = "118", disk = "ssd"}

[storage]
### The data directory
### data-dir = "/tmp/tikv/store"

### In most cases, you can use the default value. When importing data, it is
```

```
   ↪  recommended to set the parameter to 1024000.
### scheduler-concurrency = 102400
### This parameter controls the number of write threads. When write
   ↪ operations occur frequently, set this parameter value
### higher. Run `top -H -p tikv-pid` and if the threads named `sched-worker-
   ↪ pool` are busy, set the value of parameter
### `scheduler-worker-pool-size` higher and increase the number of write
   ↪ threads.
### scheduler-worker-pool-size = 4

[storage.block-cache]
#### Whether to create a shared block cache for all RocksDB column families.
#### ## Block cache is used by RocksDB to cache uncompressed blocks. Big
   ↪ block cache can speed up read.
#### It is recommended to turn on shared block cache. Since only the total
   ↪ cache size need to be
#### set, it is easier to configure. In most cases, it should be able to
   ↪ auto-balance cache usage
#### between column families with standard LRU algorithm.
#### ## The rest of config in the storage.block-cache session is effective
   ↪ only when shared block cache
#### is on.
### shared = true

#### Size of the shared block cache. Normally it should be tuned to 30%-50%
   ↪ of system's total memory.
#### When the config is not set, it is decided by the sum of the following
   ↪ fields or their default
#### value:
####  * rocksdb.defaultcf.block-cache-size or 25% of system's total memory
####  * rocksdb.writecf.block-cache-size or 15% of system's total memory
####  * rocksdb.lockcf.block-cache-size or 2% of system's total memory
####  * raftdb.defaultcf.block-cache-size or 2% of system's total memory
#### ## To deploy multiple TiKV nodes on a single physical machine,
   ↪ configure this parameter explicitly.
#### Otherwise, the OOM problem might occur in TiKV.

### The maximum number of threads of RocksDB background tasks. The
   ↪ background tasks include compaction and flush.
### For detailed information why RocksDB needs to implement compaction, see
   ↪ RocksDB-related materials. When write
### traffic (like the importing data size) is big, it is recommended to
   ↪ enable more threads. But set the number of the enabled
### threads smaller than that of CPU cores. For example, when importing data
   ↪ , for a machine with a 32-core CPU,
### set the value to 28.
### max-background-jobs = 8

### The maximum number of file handles RocksDB can open
### max-open-files = 40960

### The file size limit of RocksDB MANIFEST. For more details, see https://
```

```
    ↪ github.com/facebook/rocksdb/wiki/MANIFEST
max-manifest-file-size = "20MB"

### The directory of RocksDB write-ahead logs. If there are two disks on the
    ↪  machine, store the RocksDB data and WAL logs
### on different disks to improve TiKV performance.
### wal-dir = "/tmp/tikv/store"

### Use the following two parameters to deal with RocksDB archiving WAL.
### For more details, see https://github.com/facebook/rocksdb/wiki/How-to-
    ↪ persist-in-memory-RocksDB-database%3F
### wal-ttl-seconds = 0
### wal-size-limit = 0

### In most cases, set the maximum total size of RocksDB WAL logs to the
    ↪ default value.
### max-total-wal-size = "4GB"

### Use this parameter to enable or disable the statistics of RocksDB.
### enable-statistics = true

### Use this parameter to enable the readahead feature during RocksDB
    ↪ compaction. If you are using mechanical disks, it is recommended to
    ↪ set the value to 2MB at least.
### compaction-readahead-size = "2MB"

[rocksdb.defaultcf]
### The data block size. RocksDB compresses data based on the unit of block.
### Similar to page in other databases, block is the smallest unit cached in
    ↪  block-cache.
block-size = "64KB"

### The compaction mode of each layer of RocksDB data. The optional values
    ↪ include no, snappy, zlib,
### bzip2, lz4, lz4hc, and zstd.
### "no:no:lz4:lz4:lz4:zstd:zstd" indicates there is no compaction of level0
    ↪  and level1; lz4 compaction algorithm is used
### from level2 to level4; zstd compaction algorithm is used from level5 to
    ↪ level6.
### "no" means no compaction. "lz4" is a compaction algorithm with moderate
    ↪ speed and compaction ratio. The
### compaction ratio of zlib is high. It is friendly to the storage space,
    ↪ but its compaction speed is slow. This
### compaction occupies many CPU resources. Different machines deploy
    ↪ compaction modes according to CPU and I/O resources.
```

```
### For example, if you use the compaction mode of "no:no:lz4:lz4:lz4:zstd:
    ↪ zstd" and find much I/O pressure of the
### system (run the iostat command to find %util lasts 100%, or run the top
    ↪ command to find many iowaits) when writing
### (importing) a lot of data while the CPU resources are adequate, you can
    ↪ compress level0 and level1 and exchange CPU
### resources for I/O resources. If you use the compaction mode of "no:no:
    ↪ lz4:lz4:lz4:zstd:zstd" and you find the I/O
### pressure of the system is not big when writing a lot of data, but CPU
    ↪ resources are inadequate. Then run the top
### command and choose the -H option. If you find a lot of bg threads (
    ↪ namely the compaction thread of RocksDB) are
### running, you can exchange I/O resources for CPU resources and change the
    ↪  compaction mode to "no:no:no:lz4:lz4:zstd:zstd".
### In a word, it aims at making full use of the existing resources of the
    ↪ system and improving TiKV performance
### in terms of the current resources.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### The RocksDB memtable size
write-buffer-size = "128MB"

### The maximum number of the memtables. The data written into RocksDB is
    ↪ first recorded in the WAL log, and then inserted
### into memtables. When the memtable reaches the size limit of `write-
    ↪ buffer-size`, it turns into read only and generates
### a new memtable receiving new write operations. The flush threads of
    ↪ RocksDB will flush the read only memtable to the
### disks to become an sst file of level0. `max-background-flushes` controls
    ↪  the maximum number of flush threads. When the
### flush threads are busy, resulting in the number of the memtables waiting
    ↪  to be flushed to the disks reaching the limit
### of `max-write-buffer-number`, RocksDB stalls the new operation.
### "Stall" is a flow control mechanism of RocksDB. When importing data, you
    ↪  can set the `max-write-buffer-number` value
### higher, like 10.
max-write-buffer-number = 5

### When the number of sst files of level0 reaches the limit of `level0-
    ↪ slowdown-writes-trigger`, RocksDB
### tries to slow down the write operation, because too many sst files of
    ↪ level0 can cause higher read pressure of
### RocksDB. `level0-slowdown-writes-trigger` and `level0-stop-writes-
    ↪ trigger` are for the flow control of RocksDB.
### When the number of sst files of level0 reaches 4 (the default value),
```

```
   ↪ the sst files of level0 and the sst files
### of level1 which overlap those of level0 implement compaction to relieve
   ↪ the read pressure.
level0-slowdown-writes-trigger = 20

### When the number of sst files of level0 reaches the limit of `level0-stop
   ↪ -writes-trigger`, RocksDB stalls the new
### write operation.
level0-stop-writes-trigger = 36

### When the level1 data size reaches the limit value of `max-bytes-for-
   ↪ level-base`, the sst files of level1
### and their overlap sst files of level2 implement compaction. The golden
   ↪ rule: the first reference principle
### of setting `max-bytes-for-level-base` is guaranteeing that the `max-
   ↪ bytes-for-level-base` value is roughly equal to the
### data volume of level0. Thus unnecessary compaction is reduced. For
   ↪ example, if the compaction mode is
### "no:no:lz4:lz4:lz4:lz4:lz4", the `max-bytes-for-level-base` value is
   ↪ write-buffer-size * 4, because there is no
### compaction of level0 and level1 and the trigger condition of compaction
   ↪ for level0 is that the number of the
### sst files reaches 4 (the default value). When both level0 and level1
   ↪ adopt compaction, it is necessary to analyze
### RocksDB logs to know the size of an sst file compressed from an mentable
   ↪ . For example, if the file size is 32MB,
### the proposed value of `max-bytes-for-level-base` is 32MB * 4 = 128MB.
max-bytes-for-level-base = "512MB"

### The sst file size. The sst file size of level0 is influenced by the
   ↪ compaction algorithm of `write-buffer-size`
### and level0. `target-file-size-base` is used to control the size of a
   ↪ single sst file of level1-level6.
target-file-size-base = "32MB"

[rocksdb.writecf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
```

```
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"

[raftdb]
### The maximum number of the file handles RaftDB can open
### max-open-files = 40960

### Configure this parameter to enable or disable the RaftDB statistics
   ↪ information.
### enable-statistics = true

### Enable the readahead feature in RaftDB compaction. If you are using
   ↪ mechanical disks, it is recommended to set
### this value to 2MB at least.
### compaction-readahead-size = "2MB"

[raftdb.defaultcf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"
```

11.2.4.2 TiKV memory usage

Besides `block cache` and `write buffer` which occupy the system memory, the system memory is occupied in the following scenarios:

- Some of the memory is reserved as the system's page cache.
- When TiKV processes large queries such as `select * from ...`, it reads data, generates the corresponding data structure in the memory, and returns this structure to TiDB. During this process, TiKV occupies some of the memory.

11.2.4.3 Recommended configuration of TiKV

- In production environments, it is not recommended to deploy TiKV on the machine whose CPU cores are less than 8 or the memory is less than 32GB.

- If you demand a high write throughput, it is recommended to use a disk with good throughput capacity.
- If you demand a very low read-write latency, it is recommended to use SSD with high IOPS.

11.2.5 Follower Read

When a read hotspot appears in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader, and improve the throughput of the whole system by balancing the load among multiple followers. This document introduces the use and implementation mechanism of Follower Read.

11.2.5.1 Overview

The Follower Read feature refers to using any follower replica of a Region to serve a read request under the premise of strongly consistent reads. This feature improves the throughput of the TiDB cluster and reduces the load of the leader. It contains a series of load balancing mechanisms that offload TiKV read loads from the leader replica to the follower replica in a Region. TiKV's Follower Read implementation provides users with strongly consistent reads.

> **Note:**
>
> To achieve strongly consistent reads, the follower node currently needs to request the current execution progress from the leader node (that is `ReadIndex`), which causes an additional network request overhead. Therefore, the main benefits of Follower Read are to isolate read requests from write requests in the cluster and to increase overall read throughput.

11.2.5.2 Usage

To enable TiDB's Follower Read feature, modify the value of the `tidb_replica_read` variable to `follower` or `leader-and-follower`:

```
set [session | global] tidb_replica_read = '<target value>';
```

Scope: SESSION | GLOBAL

Default: leader

This variable is used to set the expected data read mode.

- When the value of `tidb_replica_read` is set to `leader` or an empty string, TiDB maintains its original behavior and sends all read operations to the leader replica to perform.
- When the value of `tidb_replica_read` is set to `follower`, TiDB selects a follower replica of the Region to perform all read operations.
- When the value of `tidb_replica_read` is set to `leader-and-follower`, TiDB can select any replicas to perform read operations. In this mode, read requests are load balanced between the leader and follower.
- When the value of `tidb_replica_read` is set to `closest-replicas`, TiDB prefers to select a replica in the same region to perform read operations, which can be a leader or a follower. If there is no replica in the same region, TiDB reads from the leader replica.
- When the value of `tidb_replica_read` is set to `closest-adaptive`, if the estimated result of a read request is greater than or equal to the value of `tidb_adaptive_closest_read_threshold`, TiDB prefers to read from a replica in the same region. Otherwise, TiDB reads from the leader replica. To prevent unbalanced read traffic distribution in various regions, TiDB dynamically detects whether the region distribution of all online TiDB and TiKV nodes is balanced. If a region contains only TiDB or TiKV nodes, TiDB forces to select the leader replica to perform read operations. For example, if all TiDB nodes in a region are down, then other online TiDB nodes are downgraded to read using leader replicas. After at least one TiDB node in this region is back online, all TiDB nodes switch back to preferring to select the replica in the same region to perform read operations.

> **Note:**
>
> When the value of `tidb_replica_read` is set to `closest-replicas` or `closest-adaptive`, you need to configure the cluster to ensure that replicas are distributed across regions according to the specified configuration. To configure `location-labels` for PD and set the correct `labels` for TiDB and TiKV, refer to Schedule replicas by topology labels. TiDB depends on the `zone` label to match TiKV nodes in the same region, so you need to make sure that the `zone` label is included in the `location-labels` of PD and `zone` is included in the configuration of each TiDB and TiKV node. If your cluster is deployed using TiDB Operator, refer to High availability of data.

11.2.5.3 Implementation mechanism

Before the Follower Read feature was introduced, TiDB applied the strong leader principle and submitted all read and write requests to the leader node of a Region to handle. Although TiKV can distribute Regions evenly on multiple physical nodes, for each Region, only the leader can provide external services. The other followers can do nothing to handle

read requests but receive the data replicated from the leader at all times and prepare for voting to elect a leader in case of a failover.

To allow data reading in the follower node without violating linearizability or affecting Snapshot Isolation in TiDB, the follower node needs to use `ReadIndex` of the Raft protocol to ensure that the read request can read the latest data that has been committed on the leader. At the TiDB level, the Follower Read feature simply needs to send the read request of a Region to a follower replica based on the load balancing policy.

11.2.5.3.1 Strongly consistent reads

When the follower node processes a read request, it first uses `ReadIndex` of the Raft protocol to interact with the leader of the Region, to obtain the latest commit index of the current Raft group. After the latest commit index of the leader is applied locally to the follower, the processing of a read request starts.

11.2.5.3.2 Follower replica selection strategy

Because the Follower Read feature does not affect TiDB's Snapshot Isolation transaction isolation level, TiDB adopts the round-robin strategy to select the follower replica. Currently, for the coprocessor requests, the granularity of the Follower Read load balancing policy is at the connection level. For a TiDB client connected to a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

However, for the non-coprocessor requests, such as a point query, the granularity of the Follower Read load balancing policy is at the transaction level. For a TiDB transaction on a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

11.2.6 Tune Region Performance

This document introduces how to tune Region performance by adjusting the Region size and how to use bucket to optimize concurrent queries when the Region size is large.

11.2.6.1 Overview

TiKV automatically shards bottom-layered data. Data is split into multiple Regions based on the key ranges. When the size of a Region exceeds a threshold, TiKV splits it into two or more Regions.

When processing a large amount of data, TiKV might split too many Regions, which causes more resource consumption and performance regression. For a certain amount of data, the larger the Region size, the fewer the Regions. Since v6.1.0, TiDB supports setting customizing Region size. The default size of a Region is 96 MiB. To reduce the number of Regions, you can adjust Regions to a larger size.

To reduce the performance overhead of many Regions, you can also enable Hibernate Region or `Region Merge`.

11.2.6.2 Use `region-split-size` to adjust Region size

> **Warning:**
>
> Currently, customized Region size is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments. The risks are as follows:
>
> - Performance jitter might be caused.
> - The query performance, especially for queries that deal with a large range of data, might decrease.
> - The Region scheduling slows down.

To adjust the Region size, you can use the `coprocessor.region-split-size` configuration item. The recommended sizes are 96 MiB, 128 MiB, or 256 MiB. The larger the `region-split-size` value, the more jittery the performance will be. It is NOT recommended to set the Region size over 1 GiB. Avoid setting the size to more than 10 GiB. When TiFlash is used, the Region size should not exceed 256 MiB.

When the Dumpling tool is used, the Region size should not exceed 1 GiB. In this case, you need to reduce the concurrency after increasing the Region size; otherwise, TiDB might run out of memory.

11.2.6.3 Use bucket to increase concurrency

> **Warning:**
>
> Currently, this is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

When Regions are set to a larger size, you need to set `coprocessor.enable-region-bucket` to `true` to increase the query concurrency. When you use this configuration, Regions are divided into buckets. Buckets are smaller ranges within a Region and are used as the unit of concurrent query to improve the scan concurrency. You can control the bucket size using `coprocessor.region-bucket-size`. The default value is `96MiB`.

11.2.7 Tune TiFlash Performance

This document introduces how to tune the performance of TiFlash, including planning machine resources and tuning TiDB parameters.

11.2.7.1 Plan resources

If you want to save machine resources and have no requirement on isolation, you can use the method that combines the deployment of both TiKV and TiFlash. It is recommended that you save enough resources for TiKV and TiFlash respectively, and do not share disks.

11.2.7.2 Tune TiDB parameters

1. For the TiDB node dedicated to OLAP/TiFlash, it is recommended that you increase the value of the `tidb_distsql_scan_concurrency` configuration item for this node to `80`:

```
set @@tidb_distsql_scan_concurrency = 80;
```

2. Enable the super batch feature:

   You can use the `tidb_allow_batch_cop` variable to set whether to merge Region requests when reading from TiFlash.

   When the number of Regions involved in the query is relatively large, try to set this variable to `1` (effective for coprocessor requests with `aggregation` operators that are pushed down to TiFlash), or set this variable to `2` (effective for all coprocessor requests that are pushed down to TiFlash).

```
set @@tidb_allow_batch_cop = 1;
```

3. Enable the optimization of pushing down aggregate functions before TiDB operators such as `JOIN` or `UNION`:

   You can use the `tidb_opt_agg_push_down` variable to control the optimizer to execute this optimization. When the aggregate operations are quite slow in the query, try to set this variable to `1`.

```
set @@tidb_opt_agg_push_down = 1;
```

4. Enable the optimization of pushing down aggregate functions with `Distinct` before TiDB operators such as `JOIN` or `UNION`:

   You can use the `tidb_opt_distinct_agg_push_down` variable to control the optimizer to execute this optimization. When the aggregate operations with `Distinct` are quite slow in the query, try to set this variable to `1`.

```
set @@tidb_opt_distinct_agg_push_down = 1;
```

11.2.8 Coprocessor Cache

Starting from v4.0, the TiDB instance supports caching the results of the calculation that is pushed down to TiKV (the Coprocessor Cache feature), which can accelerate the calculation process in some scenarios.

11.2.8.1 Configuration

You can configure Coprocessor Cache via the `tikv-client.copr-cache` configuration items in the TiDB configuration file. For details about how to enable and configure Coprocessor Cache, see TiDB Configuration File.

11.2.8.2 Feature description

- When a SQL statement is executed on a single TiDB instance for the first time, the execution result is not cached.
- Calculation results are cached in the memory of TiDB. If the TiDB instance is restarted, the cache becomes invalid.
- The cache is not shared among TiDB instances.
- Only push-down calculation result is cached. Even if cache is hit, TiDB still need to perform subsequent calculation.
- The cache is in the unit of Region. Writing data to a Region causes the Region cache to be invalid. For this reason, the Coprocessor Cache feature mainly takes effect on the data that rarely changes.
- When push-down calculation requests are the same, the cache is hit. Usually in the following scenarios, the push-down calculation requests are the same or partially the same:
  - The SQL statements are the same. For example, the same SQL statement is executed repeatedly.

    In this scenario, all the push-down calculation requests are consistent, and all requests can use the push-down calculation cache.
  - The SQL statements contain a changing condition, and the other parts are consistent. The changing condition is the primary key of the table or the partition.

    In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
  - The SQL statements contain multiple changing conditions and the other parts are consistent. The changing conditions exactly match a compound index column.

    In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
- This feature is transparent to users. Enabling or disabling this feature does not affect the calculation result and only affects the SQL execution time.

11.2.8.3 Check the cache effect

You can check the cache effect of Coprocessor by executing `EXPLAIN ANALYZE` or viewing the Grafana monitoring panel.

11.2.8.3.1 Use `EXPLAIN ANALYZE`

You can view the cache hit rate in Operators for accessing tables by using the `EXPLAIN ANALYZE` statement. See the following example:

```
EXPLAIN ANALYZE SELECT * FROM t USE INDEX(a);

```

The column `execution info` of the execution result gives the `copr_cache_hit_ratio` information, which indicates the hit rate of the Coprocessor Cache. The `0.75` in the above example means that the hit rate is about 75%.

11.2.8.3.2 View the Grafana monitoring panel

In Grafana, you can see the **copr-cache** panel in the `distsql` subsystem under the `tidb` namespace. This panel monitors the number of hits, misses, and cache discards of the Coprocessor Cache in the entire cluster.

11.2.9 Garbage Collection (GC)

11.2.9.1 GC Overview

TiDB uses MVCC to control transaction concurrency. When you update the data, the original data is not deleted immediately but is kept together with the new data, with a timestamp to distinguish the version. The goal of Garbage Collection (GC) is to clear the obsolete data.

11.2.9.1.1 GC process

Each TiDB cluster contains a TiDB instance that is selected as the GC leader, which controls the GC process.

GC runs periodically on TiDB. For each GC, TiDB firstly calculates a timestamp called "safe point". Then, TiDB clears the obsolete data under the premise that all the snapshots after the safe point retain the integrity of the data. Specifically, there are three steps involved in each GC process:

1. Resolve Locks. During this step, TiDB scans locks before the safe point on all Regions and clears these locks.
2. Delete Ranges. During this step, the obsolete data of the entire range generated from the `DROP TABLE`/`DROP INDEX` operation is quickly cleared.
3. Do GC. During this step, each TiKV node scans data on it and deletes unneeded old versions of each key.

In the default configuration, GC is triggered every 10 minutes. Each GC retains data of the recent 10 minutes, which means that the GC life time is 10 minutes by default (safe point = the current time - GC life time). If one round of GC has been running for too long, before this round of GC is completed, the next round of GC will not start even if it is time to trigger the next GC. In addition, for long-duration transactions to run properly after exceeding the GC life time, the safe point does not exceed the start time (start_ts) of the ongoing transactions.

11.2.9.1.2 Implementation details

Resolve Locks

The TiDB transaction model is implemented based on Google's Percolator. It's mainly a two-phase commit protocol with some practical optimizations. When the first phase is finished, all the related keys are locked. Among these locks, one is the primary lock and the others are secondary locks which contain a pointer to the primary lock; in the second phase, the key with the primary lock gets a write record and its lock is removed. The write record indicates the write or delete operation in the history or the transactional rollback record of this key. The type of write record that replaces the primary lock indicates whether the corresponding transaction is committed successfully. Then all the secondary locks are replaced successively. If, for some reason such as failure, these secondary locks are retained

and not replaced, you can still find the primary key based on the information in the secondary locks and determines whether the entire transaction is committed based on whether the primary key is committed. However, if the primary key information is cleared by GC and this transaction has uncommitted secondary locks, you will never learn whether these locks can be committed. As a result, data integrity cannot be guaranteed.

The Resolve Locks step clears the locks before the safe point. This means that if the primary key of a lock is committed, this lock needs to be committed; otherwise, it needs to be rolled back. If the primary key is still locked (not committed or rolled back), this transaction is seen as timing out and rolled back.

The Resolve Locks step is implemented in either of the following two ways, which can be configured using the system variable `tidb_gc_scan_lock_mode`:

> **Warning:**
>
> Currently, `PHYSICAL` (Green GC) is an experimental feature. It is not recommended that you use it in the production environment.

- `LEGACY` (default): The GC leader sends requests to all Regions to scan obsolete locks, checks the primary key statuses of scanned locks, and sends requests to commit or roll back the corresponding transaction.
- `PHYSICAL`: TiDB bypasses the Raft layer and directly scans data on each TiKV node.

Delete Ranges

A great amount of data with consecutive keys is removed during operations such as `DROP TABLE/INDEX`. Removing each key and performing GC later for them can result in low execution efficiency on storage reclaiming. In such scenarios, TiDB actually does not delete each key. Instead, it only records the range to be removed and the timestamp of the deletion. Then the Delete Ranges step performs a fast physical deletion on the ranges whose timestamp is before the safe point.

Do GC

The Do GC step clears the outdated versions for all keys. To guarantee that all timestamps after the safe point have consistent snapshots, this step deletes the data committed before the safe point, but retains the last write for each key before the safe point as long as it is not a deletion.

In this step, TiDB only needs to send the safe point to PD, and then the whole round of GC is completed. TiKV automatically detects the change of safe point and performs GC for all Region leaders on the current node. At the same time, the GC leader can continue to trigger the next round of GC.

Note:

Starting with TiDB 5.0, the Do GC step will always use the `DISTRIBUTED` gc mode. This replaces the earlier `CENTRAL` gc mode, which was implemented by TiDB servers sending GC requests to each Region.

11.2.9.2 Garbage Collection Configuration

Garbage collection is configured via the following system variables:

- `tidb_gc_enable`
- `tidb_gc_run_interval`
- `tidb_gc_life_time`
- `tidb_gc_concurrency`
- `tidb_gc_scan_lock_mode`
- `tidb_gc_max_wait_time`

11.2.9.2.1 GC I/O limit

TiKV supports the GC I/O limit. You can configure `gc.max-write-bytes-per-sec` to limit writes of a GC worker per second, and thus to reduce the impact on normal requests.

`0` indicates disabling this feature.

You can dynamically modify this configuration using tikv-ctl:

```
tikv-ctl --host=ip:port modify-tikv-config -n gc.max-write-bytes-per-sec -v
    ↪ 10MB
```

11.2.9.2.2 Changes in TiDB 5.0

In previous releases of TiDB, garbage collection was configured via the `mysql.tidb` system table. While changes to this table continue to be supported, it is recommended to use the system variables provided. This helps ensure that any changes to configuration can be validated, and prevent unexpected behavior (#20655).

The `CENTRAL` garbage collection mode is no longer supported. The `DISTRIBUTED` GC mode (which has been the default since TiDB 3.0) will automatically be used in its place. This mode is more efficient, since TiDB no longer needs to send requests to each TiKV region to trigger garbage collection.

For information on changes in previous releases, refer to earlier versions of this document using the *TIDB version selector* in the left hand menu.

11.2.9.2.3 Changes in TiDB 6.1.0

Before TiDB v6.1.0, the transaction in TiDB does not affect the GC safe point. Since v6.1.0, TiDB considers the startTS of the transaction when calculating the GC safe point, to resolve the problem that the data to be accessed has been cleared. If the transaction is too long, the safe point will be blocked for a long time, which affects the application performance.

In TiDB v6.1.0, the system variable `tidb_gc_max_wait_time` is introduced to control the maximum time that active transactions block the GC safe point. After the value is exceeded, the GC safe point is forwarded forcefully.

GC in Compaction Filter

Based on the `DISTRIBUTED` GC mode, the mechanism of GC in Compaction Filter uses the compaction process of RocksDB, instead of a separate GC worker thread, to run GC. This new GC mechanism helps to avoid extra disk read caused by GC. Also, after clearing the obsolete data, it avoids a large number of left tombstone marks which degrade the sequential scan performance.

The following example shows how to enable the mechanism in the TiKV configuration file:

```
[gc]
enable-compaction-filter = true
```

You can also enable this GC mechanism by modifying the configuration dynamically. See the following example:

```
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | false |
+------+------------------+-----------------------------+-------+
```

```
set config tikv gc.enable-compaction-filter = true;
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | true |
+------+------------------+-----------------------------+-------+
```

11.3 SQL Tuning

11.3.1 SQL Tuning Overview

SQL is a declarative language. That is, an SQL statement describes *what the final result should look like* and not a set of steps to execute in sequence. TiDB will optimize the execution, and is semantically permitted to execute parts of the query in any order provided that it correctly returns the final result as described.

A useful comparison to SQL optimization, is to describe what happens when you use GPS navigation. From your provided address, *2955 Campus Drive San Mateo CA 94403*, the GPS software plans the most time-efficient way to route you. It may make use of various statistics such as previous trips, meta data such as speed limits, and in modern cases, a live feed of traffic information. Several of these analogies translate to TiDB.

This section introduces several concepts about query execution:

- Understanding the Query Execution Plan introduces how to use the `EXPLAIN` statement to understand how TiDB has decided to execute a statement.
- SQL Optimization Process introduces what optimizations TiDB is capable of using to improve query execution performance.
- Control Execution Plans introduces ways to control the generation of the execution plan. This can be useful in cases where the execution plan decided by TiDB is suboptimal.

11.3.2 Understanding the Query Execution Plan

11.3.2.1 TiDB Query Execution Plan Overview

> **Note:**
>
> When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less -S` command. Then, after the `EXPLAIN` result is output, you can press the right arrow → button on your keyboard to horizontally scroll through the output.

SQL is a declarative language. It describes what the results of a query should look like, **not the methodology** to actually retrieve those results. TiDB considers all the possible ways in which a query could be executed, including using what order to join tables and whether any potential indexes can be used. The process of *considering query execution plans* is known as SQL optimization.

The `EXPLAIN` statement shows the selected execution plan for a given statement. That is, after considering hundreds or thousands of ways in which the query could be executed, TiDB believes that this *plan* will consume the least resources and execute in the shortest amount of time:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a INT NOT NULL,
    ↪  pad1 VARCHAR(255), INDEX(a));
INSERT INTO t VALUES (1, 1, 'aaa'),(2,2, 'bbb');
EXPLAIN SELECT * FROM t WHERE a = 1;
```

```
Query OK, 0 rows affected (0.96 sec)

Query OK, 2 rows affected (0.02 sec)
Records: 2 Duplicates: 0 Warnings: 0

+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
| id                          | estRows | task     | access object     |
    ↪ operator info                              |
+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
| IndexLookUp_10              | 10.00   | root     |                   |
    ↪                                            |
|  ─IndexRangeScan_8(Build)   | 10.00   | cop[tikv] | table:t, index:a(a) |
    ↪ range:[1,1], keep order:false, stats:pseudo |
|  ─TableRowIDScan_9(Probe)   | 10.00   | cop[tikv] | table:t          | keep
    ↪ order:false, stats:pseudo          |
+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
3 rows in set (0.00 sec)
```

`EXPLAIN` does not execute the actual query. `EXPLAIN ANALYZE` can be used to execute the query and show `EXPLAIN` information. This can be useful in diagnosing cases where the execution plan selected is suboptimal. For additional examples of using `EXPLAIN`, see the following documents:

- Indexes
- Joins
- Subqueries
- Aggregation
- Views
- Partitions

11.3.2.1.1 Understand EXPLAIN output

The following describes the output of the `EXPLAIN` statement above:

- `id` describes the name of an operator, or sub-task that is required to execute the SQL statement. See Operator overview for additional details.
- `estRows` shows an estimate of the number of rows TiDB expects to process. This number might be based on dictionary information, such as when the access method is based on a primary or unique key, or it could be based on statistics such as a CMSketch or histogram.
- `task` shows where an operator is performing the work. See Task overview for additional details.
- `access object` shows the table, partition and index that is being accessed. The parts of the index are also shown, as in the case above that the column `a` from the index was used. This can be useful in cases where you have composite indexes.
- `operator info` shows additional details about the access. See Operator info overview for additional details.

Note:

In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0.

Before v6.4.0, `estRows` means the number of estimated rows to be processed by the probe side operators for each row from the build side operators. Since v6.4.0, `estRows` means the **total number** of estimated rows to be processed by the probe side operators. The actual number of rows displayed (indicated by the `actRows` column) in the result of `EXPLAIN ANALYZE` means the total row count, so since v6.4.0 the meanings of `estRows` and `actRows` for the probe side child nodes of `IndexJoin` and `Apply` operators are consistent.

For example:

```
CREATE TABLE t1(a INT, b INT);
CREATE TABLE t2(a INT, b INT, INDEX ia(a));
EXPLAIN SELECT /*+ INL_JOIN(t2) */ * FROM t1 JOIN t2 ON t1.a =
    ↪  t2.a;
EXPLAIN SELECT (SELECT a FROM t2 WHERE t2.a = t1.b LIMIT 1)
    ↪ FROM t1;
```

```

Operator overview

An operator is a particular step that is executed as part of returning query results. The operators that perform table scans (of the disk or the TiKV Block Cache) are listed as follows:

- **TableFullScan**: Full table scan
- **TableRangeScan**: Table scans with the specified range
- **TableRowIDScan**: Scans the table data based on the RowID. Usually follows an index read operation to retrieve the matching data rows.
- **IndexFullScan**: Similar to a "full table scan", except that an index is scanned, rather than the table data.
- **IndexRangeScan**: Index scans with the specified range.

TiDB aggregates the data or calculation results scanned from TiKV/TiFlash. The data aggregation operators can be divided into the following categories:

- **TableReader**: Aggregates the data obtained by the underlying operators like `TableFullScan` or `TableRangeScan` in TiKV.
- **IndexReader**: Aggregates the data obtained by the underlying operators like `IndexFullScan` or `IndexRangeScan` in TiKV.
- **IndexLookUp**: First aggregates the RowID (in TiKV) scanned by the `Build` side. Then at the `Probe` side, accurately reads the data from TiKV based on these RowIDs. At the `Build` side, there are operators like `IndexFullScan` or `IndexRangeScan`; at the `Probe` side, there is the `TableRowIDScan` operator.
- **IndexMerge**: Similar to `IndexLookUp`. `IndexMerge` can be seen as an extension of `IndexLookupReader`. `IndexMerge` supports reading multiple indexes at the same time. There are many `Build`s and one `Probe`. The execution process of `IndexMerge` the same as that of `IndexLookUp`.

While the structure appears as a tree, executing the query does not strictly require the child nodes to be completed before the parent nodes. TiDB supports intra-query parallelism, so a more accurate way to describe the execution is that the child nodes *flow into* their parent nodes. Parent, child and sibling operators *might* potentially be executing parts of the query in parallel.

In the previous example, the `└─IndexRangeScan_8(Build)` operator finds the internal `RowID` for rows that match the `a(a)` index. The `└─TableRowIDScan_9(Probe)` operator then retrieves these rows from the table.

Range query

In the `WHERE/HAVING/ON` conditions, the TiDB optimizer analyzes the result returned by the primary key query or the index key query. For example, these conditions might include comparison operators of the numeric and date type, such as `>`, `<`, `=`, `>=`, `<=`, and the character type such as `LIKE`.

Note:

- In order to use an index, the condition must be *sargable*. For example, the condition `YEAR(date_column)< 1992` cannot use an index, but `date_column < '1992-01-01` can.
- It is recommended to compare data of the same type and character set and collation. Mixing types may require additional `cast` operations, or prevent indexes from being used.
- You can also use `AND` (intersection) and `OR` (union) to combine the range query conditions of one column. For a multi-dimensional composite index, you can use conditions in multiple columns. For example, regarding the composite index `(a, b, c)`:
  - When `a` is an equivalent query, continue to figure out the query range of `b`; when `b` is also an equivalent query, continue to figure out the query range of `c`.
  - Otherwise, if `a` is a non-equivalent query, you can only figure out the range of `a`.

Task overview

Currently, calculation tasks of TiDB can be divided into two categories: cop tasks and root tasks. A `cop[tikv]` task indicates that the operator is performed inside the TiKV coprocessor. A `root` task indicates that it will be completed inside of TiDB.

One of the goals of SQL optimization is to push the calculation down to TiKV as much as possible. The Coprocessor in TiKV supports most of the built-in SQL functions (including the aggregate functions and the scalar functions), SQL `LIMIT` operations, index scans, and table scans.

Operator info overview

The `operator info` can show useful information such as which conditions were able to be pushed down:

- `range: [1,1]` shows that the predicate from the where clause of the query (`a = 1`) was pushed right down to TiKV (the task is of `cop[tikv]`).
- `keep order:false` shows that the semantics of this query did not require TiKV to return the results in order. If the query were to be modified to require an order (such as `SELECT * FROM t WHERE a = 1 ORDER BY id`), then this condition would be `keep order:true`.
- `stats:pseudo` shows that the estimates shown in `estRows` might not be accurate. TiDB periodically updates statistics as part of a background operation. A manual update can also be performed by running `ANALYZE TABLE t`.

Different operators output different information after the `EXPLAIN` statement is executed. You can use optimizer hints to control the behavior of the optimizer, and thereby controlling the selection of the physical operators. For example, `/*+ HASH_JOIN(t1, t2)*/` means that the optimizer uses the `Hash Join` algorithm. For more details, see Optimizer Hints.

11.3.2.2 `EXPLAIN` Walkthrough

Because SQL is a declarative language, you cannot automatically tell whether a query is executed efficiently. You must first use the `EXPLAIN` statement to learn the current execution plan.

The following statement from the bikeshare example database counts how many trips were taken on July 1, 2017:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ----------------------------+----------+----------+---------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪
    ↪ |
+--
    ↪ ----------------------------+----------+----------+---------------+-----------
    ↪
| StreamAgg_20                | 1.00    | root     |               | funcs:count(
    ↪ Column#13)->Column#11
    ↪
    ↪ |
| └─TableReader_21            | 1.00    | root     |               | data:
    ↪ StreamAgg_9
    ↪
    ↪ |
|   └─StreamAgg_9             | 1.00    | cop[tikv] |              | funcs:count
    ↪ (1)->Column#13
    ↪
    ↪ |
|     └─Selection_19          | 250.00  | cop[tikv] |              | ge(
    ↪ bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(bikeshare
    ↪ .trips.start_date, 2017-07-01 23:59:59.000000) |
|       └─TableFullScan_18    | 10000.00 | cop[tikv] | table:trips | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
```

```
+--
    ↪ ----------------------------+----------+-----------+--------------+-----------
    ↪
5 rows in set (0.00 sec)
```

From the child operator `└─TableFullScan_18` back, you can see its execution process as follows, which is currently suboptimal:

1. The coprocessor (TiKV) reads the entire `trips` table as a `TableFullScan` operation. It then passes the rows that it reads to the `Selection_19` operator, which is still within TiKV.
2. The `WHERE start_date BETWEEN ..` predicate is then filtered in the `Selection_19` ↪ operator. Approximately `250` rows are estimated to meet this selection. Note that this number is estimated according to the statistics and the operator's logic. The `└─TableFullScan_18` operator shows `stats:pseudo`, which means that the table does not have the actual statistical information. After running `ANALYZE TABLE trips` to collect statistical information, the statistics are expected to be more accurate.
3. The rows that meet the selection criteria then have a `count` function applied to them. This is also completed inside the `StreamAgg_9` operator, which is still inside TiKV (`cop[tikv]`). The TiKV coprocessor can execute a number of MySQL built-in functions, `count` being one of them.
4. The results from `StreamAgg_9` are then sent to the `TableReader_21` operator which is now inside the TiDB server (the task of `root`). The `estRows` column value for this operator is `1`, which means that the operator will receive one row from each of the TiKV Regions to be accessed. For more information about these requests, see `EXPLAIN ANALYZE`.
5. The `StreamAgg_20` operator then applies a `count` function to each of the rows from the `└─TableReader_21` operator, which you can see from `SHOW TABLE REGIONS` and will be about 56 rows. Because this is the root operator, it then returns results to the client.

> **Note:**
>
> For a general view of the Regions that a table contains, execute `SHOW TABLE` ↪ `REGIONS`.

11.3.2.2.1 Assess the current performance

`EXPLAIN` only returns the query execution plan but does not execute the query. To get the actual execution time, you can either execute the query or use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
   ↪ --------------------------+---------+---------+----------+---------------+-
   ↪
| id                          | estRows | actRows | task     | access object |

   ↪
   ↪ | funcs:count(1)->Column#13
   ↪
   ↪ | N/A      | N/A |
|      ─Selection_19          | 250.00  | 11409   | cop[tikv] |               |
   ↪ proc max:640ms, min:8ms, p80:276ms, p95:476ms, iters:18695, tasks:56
   ↪
   ↪ | ge(bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(
   ↪ bikeshare.trips.start_date, 2017-07-01 23:59:59.000000) | N/A | N/A |
|        ─TableFullScan_18    | 10000.00 | 19117643 | cop[tikv] | table:trips
   ↪  | proc max:612ms, min:8ms, p80:248ms, p95:460ms, iters:18695, tasks
   ↪ :56
   ↪
   ↪ | keep order:false, stats:pseudo
   ↪
   ↪ | N/A      | N/A |
+--
```

```
    ↪ ---------------------------+---------+---------+----------+---------------+-
    ↪
5 rows in set (1.03 sec)
```

The example query above takes `1.03` seconds to execute, which is an ideal performance.

From the result of `EXPLAIN ANALYZE` above, `actRows` indicates that some of the estimates (`estRows`) are inaccurate (expecting 10 thousand rows but finding 19 million rows), which is already indicated in the `operator info` (`stats:pseudo`) of `-TableFullScan_18`. If you run `ANALYZE TABLE` first and then `EXPLAIN ANALYZE` again, you can see that the estimates are much closer:

```
ANALYZE TABLE trips;
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
Query OK, 0 rows affected (10.22 sec)

+--
    ↪ ----------------------------+-------------+---------+-----------+--------------
    ↪
5 rows in set (0.93 sec)
```

After `ANALYZE TABLE` is executed, you can see that the estimated rows for the `─TableFullScan_18` operator is accurate and the estimate for `─Selection_19` is now also much closer. In the two cases above, although the execution plan (the set of operators TiDB uses to execute this query) has not changed, quite frequently sub-optimal plans are caused by outdated statistics.

In addition to `ANALYZE TABLE`, TiDB automatically regenerates statistics as a background operation after the threshold of `tidb_auto_analyze_ratio` is reached. You can see how close TiDB is to this threshold (how healthy TiDB considers the statistics to be) by executing the `SHOW STATS_HEALTHY` statement:

```
SHOW STATS_HEALTHY;
```

```
+----------+------------+----------------+---------+
| Db_name  | Table_name | Partition_name | Healthy |
+----------+------------+----------------+---------+
| bikeshare | trips    |                |     100 |
+----------+------------+----------------+---------+
1 row in set (0.00 sec)
```

11.3.2.2.2 Identify optimizations

The current execution plan is efficient in the following aspects:

- Most of the work is handled inside the TiKV coprocessor. Only 56 rows need to be sent across the network back to TiDB for processing. Each of these rows is short and contains only the count that matches the selection.
- Aggregating the count of rows both in TiDB (`StreamAgg_20`) and in TiKV (`StreamAgg_9`) uses the stream aggregation, which is very efficient in its memory usage.

The biggest issue with the current execution plan is that the predicate `start_date BETWEEN '2017-07-01 00:00:00' AND '2017-07-01 23:59:59'` does not apply immediately. All rows are read first with a `TableFullScan` operator, and then a selection is applied afterwards. You can find out the cause from the output of `SHOW CREATE TABLE trips`:

```
SHOW CREATE TABLE trips\G
```

```
*************************** 1. row ***************************
       Table: trips
Create Table: CREATE TABLE `trips` (
  `trip_id` bigint(20) NOT NULL AUTO_INCREMENT,
  `duration` int(11) NOT NULL,
  `start_date` datetime DEFAULT NULL,
  `end_date` datetime DEFAULT NULL,
  `start_station_number` int(11) DEFAULT NULL,
  `start_station` varchar(255) DEFAULT NULL,
  `end_station_number` int(11) DEFAULT NULL,
  `end_station` varchar(255) DEFAULT NULL,
  `bike_number` varchar(255) DEFAULT NULL,
  `member_type` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`trip_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =20477318
1 row in set (0.00 sec)
```

There is **NO** index on `start_date`. You would need an index in order to push this predicate into an index reader operator. Add an index as follows:

```
ALTER TABLE trips ADD INDEX (start_date);
```

```
Query OK, 0 rows affected (2 min 10.23 sec)
```

Note:

You can monitor the progress of DDL jobs using the `ADMIN SHOW DDL JOBS` command. The defaults in TiDB are carefully chosen so that

> adding an index does not impact production workloads too much. For testing environments, consider increasing the `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` values. On a reference system, a batch size of `10240` and worker count of `32` can achieve a 10x performance improvement over the defaults.

After adding an index, you can then repeat the query in `EXPLAIN`. In the following output, you can see that a new execution plan is chosen, and the `TableFullScan` and `Selection` operators have been eliminated:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ --------------------------+---------+-----------+--------------------------
    ↪
| id                        | estRows | task    | access object
    ↪                           | operator info
    ↪                                                |
+--
    ↪ --------------------------+---------+-----------+--------------------------
    ↪
| StreamAgg_17              | 1.00    | root      |
    ↪                                               | funcs:count(Column#13)->Column
    ↪ #11                             |
|  ─IndexReader_18          | 1.00    | root      |
    ↪                                               | index:StreamAgg_9
    ↪                                                 |
|    ─StreamAgg_9           | 1.00    | cop[tikv] |
    ↪                                                   | funcs:count(1)->Column#13
    ↪                                     |
|      ─IndexRangeScan_16   | 8471.88 | cop[tikv] | table:trips, index:
    ↪ start_date(start_date) | range:[2017-07-01 00:00:00,2017-07-01
    ↪ 23:59:59], keep order:false |
+--
    ↪ --------------------------+---------+-----------+--------------------------
    ↪
4 rows in set (0.00 sec)
```

To compare the actual execution time, you can again use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```

   ↪ | range:[2017-07-01 00:00:00,2017-07-01 23:59:59], keep order:false |
   ↪  N/A | N/A |
+--
   ↪ -------------------------+---------+---------+-----------+-------------------
   ↪
4 rows in set (0.00 sec)
```

From the result above, the query time has reduced from 1.03 seconds to 0.0 seconds.

> **Note:**
>
> Another optimization that applies here is the coprocessor cache. If you are unable to add indexes, consider enabling the coprocessor cache. When it

is enabled, as long as the Region has not been modified since the operator is last executed, TiKV will return the value from the cache. This will also help reduce much of the cost of the expensive `TableFullScan` and `Selection` operators.

11.3.2.3 Explain Statements That Use Indexes

TiDB supports several operators which make use of indexes to speed up query execution:

- IndexLookup
- IndexReader
- Point_Get and Batch_Point_Get
- IndexFullScan

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 intkey INT NOT NULL,
 pad1 VARBINARY(1024),
 INDEX (intkey)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM
   ↪ dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
   ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
   ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
   ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
```

11.3.2.3.1 IndexLookup

TiDB uses the `IndexLookup` operator when retrieving data from a secondary index. In this case, the following queries will all use the `IndexLookup` operator on the `intkey` index:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT * FROM t1 WHERE intkey < 10;
EXPLAIN SELECT * FROM t1 WHERE intkey BETWEEN 300 AND 310;
EXPLAIN SELECT * FROM t1 WHERE intkey IN (123,29,98);
EXPLAIN SELECT * FROM t1 WHERE intkey >= 99 AND intkey <= 103;
```

```

+--
   ↪ ----------------------------+--------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator has two child nodes:

- The `└─IndexRangeScan_8(Build)` operator performs a range scan on the `intkey` index and retrieves the values of the internal `RowID` (for this table, the primary key).
- The `└─TableRowIDScan_9(Probe)` operator then retrieves the full row from the table data.

Because an `IndexLookup` task requires two steps, the SQL Optimizer might choose the `TableFullScan` operator based on statistics in scenarios where a large number of rows match. In the following example, a large number of rows match the condition of `intkey > 100`, and a `TableFullScan` is chosen:

```
EXPLAIN SELECT * FROM t1 WHERE intkey > 100;
```

```
+--
   ↪ ---------------------+--------+----------+--------------+-----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪      |
```

```
+--
    ↪ ----------------------+---------+-----------+--------------+-----------------
    ↪
| TableReader_7         | 898.50 | root     |              | data:Selection_6
    ↪     |
|  ─Selection_6         | 898.50 | cop[tikv] |              | gt(test.t1.intkey
    ↪ , 100) |
|    ─TableFullScan_5   | 1010.00 | cop[tikv] | table:t1 | keep order:false
    ↪     |
+--
    ↪ ----------------------+---------+-----------+--------------+-----------------
    ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator can also be used to efficiently optimize `LIMIT` on an indexed column:

```
EXPLAIN SELECT * FROM t1 ORDER BY intkey DESC LIMIT 10;
```

```
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
| id                          | estRows | task    | access object
    ↪              | operator info                   |
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
| IndexLookUp_21              | 10.00   | root      |
    ↪                               | limit embedded(offset:0, count:10) |
|  ─Limit_20(Build)           | 10.00   | cop[tikv] |
    ↪                               | offset:0, count:10             |
|    ─IndexFullScan_18        | 10.00   | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:true, desc    |
|  ─TableRowIDScan_19(Probe)  | 10.00   | cop[tikv] | table:t1
    ↪                   | keep order:false, stats:pseudo |
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
4 rows in set (0.00 sec)
```

In the above example, the last 10 rows are read from the index `intkey`. These `RowID` values are then retrieved from the table data.

11.3.2.3.2 IndexReader

TiDB supports the *covering index optimization*. If all rows can be retrieved from an index, TiDB will skip the second step that is usually required in an `IndexLookup`. Consider the following two examples:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT id FROM t1 WHERE intkey = 123;
```

```
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task    | access object
   ↪              | operator info                 |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| IndexLookUp_10              | 1.00    | root     |
   ↪                             |                                 |
|  ─IndexRangeScan_8(Build)  | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[123,123], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 1.00    | cop[tikv] | table:t1
   ↪                  | keep order:false              |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)

+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
| id                    | estRows | task    | access object               |
   ↪ operator info                |
+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
| Projection_4          | 1.00    | root     |                             |
   ↪ test.t1.id                    |
|  ─IndexReader_6       | 1.00    | root     |                              |
   ↪ index:IndexRangeScan_5        |
|    ─IndexRangeScan_5  | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[123,123], keep order:false |
+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
3 rows in set (0.00 sec)
```

Because `id` is also the internal `RowID`, it is stored in the `intkey` index. After using the `intkey` index as part of `IndexRangeScan_5`, the value of the `RowID` can be returned directly.

11.3.2.3.3 Point_Get and Batch_Point_Get

TiDB uses the `Point_Get` or `Batch_Point_Get` operator when retrieving data directly from a primary key or unique key. These operators are more efficient than `IndexLookup`. For example:

```
EXPLAIN SELECT * FROM t1 WHERE id = 1234;
EXPLAIN SELECT * FROM t1 WHERE id IN (1234,123);

ALTER TABLE t1 ADD unique_key INT;
UPDATE t1 SET unique_key = id;
ALTER TABLE t1 ADD UNIQUE KEY (unique_key);

EXPLAIN SELECT * FROM t1 WHERE unique_key = 1234;
EXPLAIN SELECT * FROM t1 WHERE unique_key IN (1234, 123);
```

```
+-------------+---------+------+---------------+---------------+
| id          | estRows | task | access object | operator info |

    ↪
1 row in set (0.00 sec)
```

11.3.2.3.4 IndexFullScan

Because indexes are ordered, the `IndexFullScan` operator can be used to optimize common queries such as the `MIN` or `MAX` values for an indexed value:

```
EXPLAIN SELECT MIN(intkey) FROM t1;
EXPLAIN SELECT MAX(intkey) FROM t1;
```

```
+--
    ↪ --------------------------+---------+----------+-----------------------------
    ↪
```

```
| id                          | estRows | task    | access object

+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
| StreamAgg_12                | 1.00    | root     |
    ↪ | funcs:min(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
    ↪                               | offset:0, count:1               |
|    ─IndexReader_29          | 1.00    | root     |
    ↪                               | index:Limit_28                  |
|      ─Limit_28              | 1.00    | cop[tikv] |
    ↪                             | offset:0, count:1               |
|        ─IndexFullScan_27    | 1.00    | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:true           |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
5 rows in set (0.00 sec)

+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
| id                          | estRows | task    | access object
    ↪ | operator info                   |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
| StreamAgg_12                | 1.00    | root     |
    ↪ | funcs:max(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
    ↪                               | offset:0, count:1               |
|    ─IndexReader_29          | 1.00    | root     |
    ↪                               | index:Limit_28                  |
|      ─Limit_28              | 1.00    | cop[tikv] |
    ↪                             | offset:0, count:1               |
|        ─IndexFullScan_27    | 1.00    | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:true, desc     |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
5 rows in set (0.00 sec)
```

In the above statements, an `IndexFullScan` task is performed on each TiKV Region. Despite the name `FullScan`, only the first row needs to be read (`─Limit_28`). Each TiKV

Region returns its `MIN` or `MAX` value to TiDB, which then performs Stream Aggregation to filter for a single row. Stream Aggregation with the aggregation function `MAX` or `MIN` also ensures that `NULL` is returned if the table is empty.

By contrast, executing the `MIN` function on an unindexed value will result in `TableFullScan`. The query will require all rows to be scanned in TiKV, but a `TopN` calculation is performed to ensure each TiKV Region only returns one row to TiDB. Although `TopN` prevents excessive rows from being transferred between TiKV and TiDB, this statement is still considered far less efficient than the above example where `MIN` is able to make use of an index.

```
EXPLAIN SELECT MIN(pad1) FROM t1;
```

```

|    ─StreamAgg_8         | 1.00    | cop[tikv] |                                |
    ↪  funcs:count(test.t1.intkey)->Column#7, funcs:sum(test.t1.intkey)->
    ↪ Column#8 |
|      ─IndexFullScan_19  | 1010.00 | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:false                                     |
+--
    ↪ ----------------------+---------+-----------+---------------------------
    ↪
4 rows in set (0.00 sec)
```

In the above examples, `IndexFullScan` is more efficient than `TableFullScan` because the width of the value in the `(intkey + RowID)` index is less than the width of the full row.

The following statement does not support using an `IndexFullScan` operator because additional columns are required from the table:

```
EXPLAIN SELECT AVG(intkey), ANY_VALUE(pad1) FROM t1;
```

```

11.3.2.4 Explain Statements That Use Joins

In TiDB, the SQL Optimizer needs to decide in which order tables should be joined and what is the most efficient join algorithm for a particular SQL statement. The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
   ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
   ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
SELECT SLEEP(1);
ANALYZE TABLE t1, t2;
```

11.3.2.4.1 Index Join

If the number of estimated rows that need to be joined is small (typically less than 10000 rows), it is preferable to use the index join method. This method of join works similar to the primary method of join used in MySQL. In the following example, the operator `└─TableReader_28(Build)` first reads the table `t1`. For each row that matches, TiDB will probe the table `t2`:

> **Note:**
>
> In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0. For more details, see TiDB Query Execution Plan Overview.

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.id =
    ↪ t2.t1_id;
```

```

    ↪ keep order:false                                  |
|   └─TableRowIDScan_9(Probe)  | 90000.00 | cop[tikv] | table:t2
    ↪                | keep order:false
    ↪
    ↪ |
+--
    ↪ ------------------------------+----------+-----------+-----------------------
    ↪
```

Index join is efficient in memory usage, but might be slower to execute than other join methods when a large number of probe operations are required. Consider also the following query:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id=t2.t1_id WHERE t1.pad1 = 'value'
    ↪ and t2.pad1='value';
```

In an inner join operation, TiDB implements join reordering and might access either `t1` or `t2` first. Assume that TiDB selects `t1` as the first table to apply the `build` step, and then TiDB is able to filter on the predicate `t1.col = 'value'` before probing the table `t2`. The filter for the predicate `t2.col='value'` will be applied on each probe of table `t2`, which might be less efficient than other join methods.

Index join is effective if the build side is small and the probe side is pre-indexed and large. Consider the following query where an index join performs worse than a hash join and is not chosen by the SQL Optimizer:

```
-- DROP previously added index
ALTER TABLE t2 DROP INDEX t1_id;

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```

In the above example, the index join operation is missing an index on `t1.int_col`. Once this index is added, the performance of the operation improves from `0.3 sec` to `0.06 sec`, as the following result shows:

```
-- Re-add index
ALTER TABLE t2 ADD INDEX (t1_id);

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
   ↪ .int_col = 1;
```

```

Note:

In the above example, the SQL Optimizer selects the hash join plan which performs worse than the index join. Query optimization is an NP-complete problem, and less-than-optimal plans might be chosen. If this is a frequent query, it is recommended to use SQL Plan Management to bind a hint to a query, which can be easier to manage than inserting hints into queries that your application sends to TiDB.

Variations of Index Join

An index join operation using the hint `INL_JOIN` creates a hash table of the intermediate results before joining on the outer table. TiDB also supports creating a hash table on

the outer table using the hint INL_HASH_JOIN. Each of these variations of index join is automatically selected by the SQL Optimizer.

Configuration

Index join performance is influenced by the following system variables:

- tidb_index_join_batch_size (default value: 25000) - the batch size of index lookup join operations.
- tidb_index_lookup_join_concurrency (default value: 4) - the number of concurrent index lookup tasks.

11.3.2.4.2 Hash Join

In a hash join operation, TiDB reads and caches the data on the Build side of the join in a hash table, and then reads the data on the Probe side of the join, probing the hash table to access required rows. Hash joins require more memory to execute than index joins but execute much faster when there are a lot of rows that need to be joined. The hash join operator is multi-threaded in TiDB and executes in parallel.

An example of hash join is as follows:

```
EXPLAIN SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--

   ↪ equal:[eq(test.t1.id, test.t2.id)] |
| ├─TableReader_29(Build)  | 142020.00 | root    |               | data:
   ↪ TableFullScan_28                    |
| │ └─TableFullScan_28     | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ false                            |
| └─TableReader_31(Probe)  | 180000.00 | root    |               | data:
   ↪ TableFullScan_30                    |
|   └─TableFullScan_30     | 180000.00 | cop[tikv] | table:t2 | keep order:
   ↪ false                            |
+--
   ↪ ---------------------------+----------+----------+---------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of `HashJoin_27`, TiDB performs the following operations in order:

1. Cache the data of the `Build` side in memory.
2. Construct a Hash Table on the `Build` side based on the cached data.
3. Read the data at the `Probe` side.
4. Use the data of the `Probe` side to probe the Hash Table.
5. Return qualified data to the user.

The `operator info` column in the `EXPLAIN` result table also records other information about `HashJoin_27`, including whether the query is Inner Join or Outer Join, and what are the conditions of Join. In the above example, the query is an Inner Join, where the Join condition `equal:[eq(test.t1.id, test.t2.id)]` partly corresponds with the query condition `WHERE t1.id = t2.id`. The operator info of the other Join operators in the following examples is similar to this one.

Runtime Statistics

If `tidb_mem_quota_query` (default value: 1 GB) is exceeded, and the `tidb_enable_tmp_storage_on_o` ↪ value is `ON` (default), TiDB will attempt to use temporary storage, and might create the `Build` operator (used as part of the hash join) on disk. Runtime statistics such as memory usage are recorded in the `execution info` of the `EXPLAIN ANALYZE` result table. The following example shows the output of `EXPLAIN ANALYZE` with a 1 GB (default) and a 500 MB quota for `tidb_mem_quota_query`. At 500 MB, disk is used for temporary storage:

```
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
    ↪  t2.id;
SET tidb_mem_quota_query=500 * 1024 * 1024;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
    ↪  t2.id;
```

```

5 rows in set (0.98 sec)
```

Configuration

Hash join performance is influenced by the following system variables:

- `tidb_mem_quota_query` (default value: 1GB) - if the memory quota for a query is exceeded, TiDB will attempt to spill the `Build` operator of a hash join to disk to save memory.
- `tidb_hash_join_concurrency` (default value: `5`) - the number of concurrent hash join tasks.

11.3.2.4.3 Merge Join

Merge join is a special sort of join that applies when both sides of the join are read in sorted order. It can be described as similar to an *efficient zipper merge*: as data is read on both the `Build` and the `Probe` sides of the join, the join operation works like a streaming operation. Merge joins require far less memory than hash join but do not execute in parallel.

The following is an example:

```
EXPLAIN SELECT /*+ MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
| id                        | estRows  | task     | access object | operator
   ↪ info                                |
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
| MergeJoin_7               | 142020.00 | root    |               | inner join,
   ↪ left key:test.t1.id, right key:test.t2.id |
|  ─TableReader_12(Build)  | 180000.00 | root    |               | data:
   ↪ TableFullScan_11                          |
|    ─TableFullScan_11     | 180000.00 | cop[tikv] | table:t2 | keep order:
   ↪ true                                      |
|  ─TableReader_10(Probe)  | 142020.00 | root    |               | data:
   ↪ TableFullScan_9                           |
|    ─TableFullScan_9      | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ true                                      |
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of the merge join operator, TiDB performs the following operations:

1. Read all the data of a Join Group from the `Build` side into the memory.
2. Read the data of the `Probe` side.
3. Compare whether each row of data on the `Probe` side matches a complete Join Group on the `Build` side. Apart from equivalent conditions, there are non-equivalent conditions. Here "match" mainly refers to checking whether non-equivalent conditions are met. Join Group refers to the data with the same value among all Join Keys.

11.3.2.5 Explain Statements in the MPP Mode

TiDB supports using the MPP mode to execute queries. In the MPP mode, the TiDB optimizer generates execution plans for MPP. Note that the MPP mode is only available for tables that have replicas on TiFlash.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id int, value int);
```

```
INSERT INTO t1 values(1,2),(2,3),(1,3);
ALTER TABLE t1 set tiflash replica 1;
ANALYZE TABLE t1;
SET tidb_allow_mpp = 1;
```

11.3.2.5.1 MPP query fragments and MPP tasks

In the MPP mode, a query is logically sliced into multiple query fragments. Take the following statement as an example:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

This query is divided into two fragments in the MPP mode. One for the first-stage aggregation and the other for the second-stage aggregation, also the final aggregation. When this query is executed, each query fragment is instantiated into one or more MPP tasks.

11.3.2.5.2 Exchange operators

`ExchangeReceiver` and `ExchangeSender`are two exchange operators specific for MPP execution plans. The `ExchangeReceiver` operator reads data from downstream query fragments and the `ExchangeSender` operator sends data from downstream query fragments to upstream query fragments. In the MPP mode, the root operator of each MPP query fragment is `ExchangeSender`, meaning that query fragments are delimited by the `ExchangeSender` operator.

The following is a simple MPP execution plan:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ---------------------------------+---------+------------------+--------------

   ↪ ExchangeType: PassThrough                         |
|    ─Projection_26                 | 2.00    | batchCop[tiflash] |              |
   ↪ Column#4                                          |
|      ─HashAgg_27                  | 2.00    | batchCop[tiflash] |              |
   ↪ group by:test.t1.id, funcs:sum(Column#7)->Column#4 |
```

```
|       └─ExchangeReceiver_29     | 2.00   | batchCop[tiflash] |           |
   ↪                                                          |
|         └─ExchangeSender_28     | 2.00   | batchCop[tiflash] |           |
   ↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
|           └─HashAgg_9           | 2.00   | batchCop[tiflash] |           |
   ↪ group by:test.t1.id, funcs:count(1)->Column#7 |
|             └─TableFullScan_25  | 3.00   | batchCop[tiflash] | table:t1  |
   ↪ keep order:false                                         |
+--
   ↪ ---------------------------------+---------+-------------------+--------------
   ↪
```

The above execution plan contains two query fragments:

- The first is `[TableFullScan_25, HashAgg_9, ExchangeSender_28]`, which is mainly responsible for the first-stage aggregation.
- The second is `[ExchangeReceiver_29, HashAgg_27, Projection_26, ExchangeSender_30 ↪ ]`, which is mainly responsible for the second-stage aggregation.

The `operator info` column of the `ExchangeSender` operator shows the exchange type information. Currently, there are three exchange types. See the following:

- HashPartition: The `ExchangeSender` operator firstly partitions data according to the Hash values and then distributes data to the `ExchangeReceiver` operator of upstream MPP tasks. This exchange type is often used for Hash Aggregation and Shuffle Hash Join algorithms.
- Broadcast: The `ExchangeSender` operator distributes data to upstream MPP tasks through broadcast. This exchange type is often used for Broadcast Join.
- PassThrough: The `ExchangeSender` operator sends data to the only upstream MPP task, which is different from the Broadcast type. This exchange type is often used when returning data to TiDB.

In the example execution plan, the exchange type of the operator `ExchangeSender_28` is HashPartition, meaning that it performs the Hash Aggregation algorithm. The exchange type of the operator `ExchangeSender_30` is PassThrough, meaning that it is used to return data to TiDB.

MPP is also often applied to join operations. The MPP mode in TiDB supports the following two join algorithms:

- Shuffle Hash Join: Shuffle the data input from the join operation using the HashPartition exchange type. Then, upstream MPP tasks join data within the same partition.
- Broadcast Join: Broadcast data of the small table in the join operation to each node, after which each node joins the data separately.

The following is a typical execution plan for Shuffle Hash Join:

```
SET tidb_broadcast_join_threshold_count=0;
SET tidb_broadcast_join_threshold_size=0;
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

+--
   ↪ ------------------------------------+--------+-------------+--------------+
   ↪
12 rows in set (0.00 sec)
```

In the above execution plan:

- The query fragment `[TableFullScan_20, Selection_21, ExchangeSender_22]`

reads data from table b and shuffles data to upstream MPP tasks.

- The query fragment `[TableFullScan_16, Selection_17, ExchangeSender_18]` reads data from table a and shuffles data to upstream MPP tasks.
- The query fragment `[ExchangeReceiver_19, ExchangeReceiver_23, HashJoin_44 ↪ , ExchangeSender_47]` joins all data and returns it to TiDB.

A typical execution plan for Broadcast Join is as follows:

```
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```
+--

   ↪ not(isnull(test.t1.id))                   |
|              ─TableFullScan_17       | 6.00    | cop[tiflash] | table:a      |
   ↪ keep order:false                          |
|        ─Selection_22(Probe)          | 6.00    | cop[tiflash] |              |
   ↪ not(isnull(test.t1.id))                   |
|          ─TableFullScan_21           | 6.00    | cop[tiflash] | table:b      |
   ↪ keep order:false                          |
+--
   ↪ ------------------------------------+--------+-------------+--------------+
   ↪
```

In the above execution plan:

- The query fragment `[TableFullScan_17, Selection_18, ExchangeSender_19]` reads data from the small table (table a) and broadcasts the data to each node that

contains data from the large table (table b).
- The query fragment `[TableFullScan_21, Selection_22, ExchangeReceiver_20, HashJoin_43, ExchangeSender_46]` joins all data and returns it to TiDB.

11.3.2.5.3 `EXPLAIN ANALYZE` statements in the MPP mode

The `EXPLAIN ANALYZE` statement is similar to `EXPLAIN`, but it also outputs some runtime information.

The following is the output of a simple `EXPLAIN ANALYZE` example:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--

    ↪                                         | N/A    | N/A |
+--
    ↪ ---------------------------------+---------+---------+-------------------+-----
    ↪
```

Compared to the output of `EXPLAIN`, the `operator info` column of the operator `ExchangeSender` also shows `tasks`, which records the id of the MPP task that the query fragment instantiates into. In addition, each MPP operator has a `threads` field in the `execution info` column, which records the concurrency of operations when TiDB executes this operator. If the cluster consists of multiple nodes, this concurrency is the result of adding up the concurrency of all nodes.

11.3.2.6 Explain Statements That Use Subqueries

TiDB performs several optimizations to improve the performance of subqueries. This document describes some of these optimizations for common subqueries and how to interpret the output of `EXPLAIN`.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
CREATE TABLE t3 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 t1_id INT NOT NULL,
 UNIQUE (t1_id)
);

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
INSERT INTO t3 SELECT NULL, id FROM t1 WHERE id < 1000;

SELECT SLEEP(1);
ANALYZE TABLE t1, t2, t3;
```

11.3.2.6.1 Inner join (non-unique subquery)

In the following example, the `IN` subquery searches for a list of IDs from the table `t2` ↪ . For semantic correctness, TiDB needs to guarantee that the column `t1_id` is unique. Using `EXPLAIN`, you can see the execution plan used to remove duplicates and perform an `INNER JOIN` operation:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2);
```

```
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪

   ↪                | range: decided by [test.t2.t1_id], keep order:false
   ↪                                                                    |
+--
   ↪ ----------------------------+---------+----------+-----------------------
```

```
    ↪
```

From the query results above, you can see that TiDB uses the index join operation `IndexJoin_14` to join and transform the subquery. In the execution plan, the execution process is as follows:

1. The index scanning operator `IndexFullScan_31` at the TiKV side reads the values of the `t2.t1_id` column.
2. Some tasks of the `StreamAgg_39` operator deduplicate the values of `t1_id` in TiKV.
3. Some tasks of the `StreamAgg_49(Build)` operator deduplicate the values of `t1_id` in TiDB. The deduplication is performed by the aggregate function `firstrow(test.t2.t1_id)`.
4. The operation results are joined with the primary key of the `t1` table. The join condition is `eq(test.t1.id, test.t2.t1_id)`.

11.3.2.6.2 Inner join (unique subquery)

In the previous example, aggregation is required to ensure that the values of `t1_id` are unique before joining against the table `t1`. But in the following example, `t3.t1_id` is already guaranteed unique because of a `UNIQUE` constraint:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t3);
```

```
+--

    ↪ t1_id) | keep order:false
    ↪
    ↪ |
```

```
|  └─TableReader_15(Probe)  | 999.00 | root     |                                  |
   ↪ data:TableRangeScan_14
   ↪
   ↪ |
|    └─TableRangeScan_14    | 999.00 | cop[tikv] | table:t1                 |
   ↪ range: decided by [test.t3.t1_id], keep order:false
   ↪                                                                  |
+--
   ↪ -------------------------+---------+-----------+--------------------------
   ↪
```

Semantically because `t3.t1_id` is guaranteed unique, it can be executed directly as an `INNER JOIN`.

11.3.2.6.3 Semi join (correlated subquery)

In the previous two examples, TiDB is able to perform an `INNER JOIN` operation after the data inside the subquery is made unique (via `StreamAgg`) or guaranteed unique. Both joins are performed using an Index Join.

In this example, TiDB chooses a different execution plan:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2 WHERE t1_id !=
   ↪ t1.int_col);
```

```
+--

From the result above, you can see that TiDB uses a `Semi Join` algorithm. Semi-join differs from inner join: semi-join only permits the first value on the right key (`t2.t1_id`), which means that the duplicates are eliminated as a part of the join operator task. The join algorithm is also Merge Join, which is like an efficient zipper-merge as the operator reads data from both the left and the right side in sorted order.

The original statement is considered a *correlated subquery*, because the subquery refers to a column (`t1.int_col`) that exists outside of the subquery. However, the output of `EXPLAIN` shows the execution plan after the subquery decorrelation optimization has been applied. The condition `t1_id != t1.int_col` is rewritten to `t1.id != t1.int_col`. TiDB can perform this in `└─Selection_21` as it is reading data from the table `t1`, so this decorrelation and rewriting make the execution a lot more efficient.

11.3.2.6.4 Anti semi join (`NOT IN` subquery)

In the following example, the query semantically returns all rows from the table `t3` *unless* `t3.t1_id` is in the subquery:

```
EXPLAIN SELECT * FROM t3 WHERE t1_id NOT IN (SELECT id FROM t1 WHERE
    ↪ int_col < 100);
```

```

   ↪ ---------------------------+---------+-----------+---------------+-------------
   ↪
```

This query starts by reading the table `t3` and then probes the table `t1` based on the `PRIMARY KEY`. The join type is an *anti semi join*; anti because this example is for the non-existence of the value (`NOT IN`) and semi-join because only the first row needs to match before the join is rejected.

11.3.2.6.5 Null-aware semi join (`IN` and `= ANY` subqueries)

The value of the `IN` or `= ANY` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `IN` and `= ANY` operators are converted to semi join and left outer semi join respectively. In the preceding example of Semi join, since columns `test.t1.id` ↪ and `test.t2.t1_id` on both sides of the join key are `not NULL`, the semi join does not need to be considered as null-aware (`NULL` is not processed specially). TiDB processes the null-aware semi join based on the Cartesian product and filter without special optimization. The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a,b) IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a,b) IN (SELECT * FROM s);
```

```

    ↪
8 rows in set (0.01 sec)
```

In the first query statement `EXPLAIN SELECT (a,b)IN (SELECT * FROM s)FROM t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by the `IN` subquery is null-aware. Specifically, the Cartesian product is calculated first, then the column connected by `IN` or `= ANY` is put into other conditions as a normal equality query for filtering.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a,b)IN (SELECT * ↪ FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the `IN` subquery should have been converted to a null-aware semi join. But TiDB optimizes it by converting semi join to inner join and aggregate. This is because `NULL` and `false` are equivalent in `IN` subqueries for non-scalar output. The `NULL` rows in the push-down filter results in the negative semantics of the `WHERE` clause. Therefore, these rows can be ignored beforehand.

> **Note:**
>
> The `Exists` operator is also converted to semi join, but it is not null-aware.

11.3.2.6.6 Null-aware anti semi join (`NOT IN` and `!= ALL` subqueries)

The value of the `NOT IN` or `!= ALL` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `NOT IN` and `! = ALL` operators are converted to anti semi join and anti left outer semi join respectively. In the preceding example of Anti semi join, since columns `test.t3.t1_id` and `test.t1.id` on both sides of the join key are `not NULL`, the anti semi join does not need to be considered as null-aware (`NULL` is not processed specially).

TiDB v6.3.0 optimizes null-aware anti join (NAAJ) as follows:

- Build hash join using the null-aware equality condition (NA-EQ)

  Set operators introduce the equality condition, which requires a special process for the `NULL` value of operators on both sides of the condition. The equality condition that requires null-aware is called NA-EQ. Different from earlier versions, TiDB v6.3.0 no longer processes NA-EQ as before, but places it in other conditions after join, and then determines the legitimacy of the result set after matching the Cartesian product.

  Since TiDB v6.3.0, NA-EQ, a weakened equality condition, is still used to build hash join. This reduces the matching amount of data that needs to be traversed and speeds up the matching process. The acceleration is more significant when the percentage of total `DISTINCT()` values of the build table is almost 100%.

- Speed up the return of matching results using the special property of `NULL`

  Since anti semi join is a conjunctive normal form (CNF), a `NULL` on either side of the join leads to a definite result. This property can be used to speed up the return of the entire matching process.

The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a, b) NOT IN (SELECT * FROM s);
```

```

+--
   ↪ -------------------------+---------+----------+--------------+-----------
   ↪
5 rows in set (0.00 sec)
```

In the first query statement `EXPLAIN SELECT (a, b)NOT IN (SELECT * FROM s)FROM t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a, b)NOT IN ( SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the anti semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

Currently, TiDB can only be null-aware of anti semi join and anti left outer semi join. Only the hash join type is supported and its build table should be fixed to the right table.

> **Note:**
>
> The `Not Exists` operator is also converted to the anti semi join, but it is not null-aware.

11.3.2.6.7 Explain statements using other types of subqueries

11.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB);
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

|        2 | t_64_r_95296 |              |        3 |             1 | 3    |
    ↪          0 |         1501 |         0 |                81 |
    ↪ 63211 |
+--
    ↪ ---------+--------------+--------------+----------+---------------+------+--
    ↪
4 rows in set (0.00 sec)
```

Using `EXPLAIN` with the following aggregation statement, you can see that `StreamAgg_8` is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in `StreamAgg_16`:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ ------------------------+----------+----------+--------------+-----------
    ↪
| id                        | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ ------------------------+----------+----------+--------------+-----------
    ↪
| StreamAgg_16              | 1.00     | root     |               | funcs:count(
    ↪ Column#7)->Column#5 |
| └─TableReader_17          | 1.00     | root     |               | data:
    ↪ StreamAgg_8             |
|   └─StreamAgg_8           | 1.00     | cop[tikv] |              | funcs:count
    ↪ (1)->Column#7    |
|     └─TableFullScan_15    | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ ------------------------+----------+----------+--------------+-----------
    ↪
4 rows in set (0.00 sec)
```

This is easiest to observe in `EXPLAIN ANALYZE`, where the `actRows` matches the number of Regions from `SHOW TABLE REGIONS` because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```
+--

   ↪
4 rows in set (0.01 sec)
```

11.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the `HashAgg` operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```
+--
   ↪ ------------------------+----------+----------+--------------+------------
   ↪
| id                        | estRows  | task     | access object | operator
   ↪ info              |
+--
   ↪ ------------------------+----------+----------+--------------+------------
   ↪
| HashAgg_9                 | 1.00     | root     |               | funcs:count(
   ↪ Column#6)->Column#5 |
|  ─TableReader_10          | 1.00     | root     |               | data:
   ↪ HashAgg_5               |
|    ─HashAgg_5             | 1.00     | cop[tikv] |              | funcs:count
   ↪ (1)->Column#6    |
|      ─TableFullScan_8     | 242020.00 | cop[tikv] | table:t1 | keep order:
   ↪ false             |
+--
   ↪ ------------------------+----------+----------+--------------+------------
   ↪
4 rows in set (0.00 sec)
```

The `operator info` shows that the hashing function used to aggregate the data is `funcs` ↪ `:count(1)->Column#6`.

11.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```
CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

+--
   ↪ ------------------------+----------+----------+--------------+------------
   ↪
```

```
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪ |
+--
    ↪ ----------------------------+---------+----------+---------------+----------
    ↪
| Projection_4                | 8000.00 | root     |               | test.t2.col1
    ↪ , Column#3                                                                    |
|  ─StreamAgg_8               | 8000.00 | root     |               | group by:
    ↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
    ↪ ->test.t2.col1 |
|    ─Sort_13                 | 10000.00 | root    |               | test.t2.
    ↪ col1
    ↪                                                                             |
|      ─TableReader_12        | 10000.00 | root    |               | data:
    ↪ TableFullScan_11
    ↪                                                                               |
|        ─TableFullScan_11    | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo
    ↪ |
+--
    ↪ ----------------------------+---------+----------+---------------+----------
    ↪
5 rows in set (0.00 sec)
```

In this example, the `─Sort_13` operator can be eliminated by adding an index on `col1` ↪ . Once the index is added, the data can be read in order and the `─Sort_13` operator is eliminated:

```
ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.28 sec)

+--
    ↪ ----------------------------+---------+----------+-------------------------+
    ↪
| id                          | estRows | task     | access object           |
    ↪ operator info
    ↪
    ↪ |
+--
    ↪ ----------------------------+---------+----------+-------------------------+
    ↪
| Projection_4                | 4.00    | root     |                         |
```

```
    ↪ test.t2.col1, Column#3
    ↪                                                                    |
|  ─StreamAgg_14            | 4.00   | root     |                        |
    ↪ group by:test.t2.col1, funcs:count(Column#4)->Column#3, funcs:
    ↪ firstrow(test.t2.col1)->test.t2.col1 |
|    ─IndexReader_15        | 4.00   | root     |                        |
    ↪ index:StreamAgg_8
    ↪                                                                      |
|      ─StreamAgg_8         | 4.00   | cop[tikv] |                        |
    ↪ group by:test.t2.col1, funcs:count(1)->Column#4
    ↪                                          |
|        ─IndexFullScan_13  | 5.00   | cop[tikv] | table:t2, index:col1(col1
    ↪ ) | keep order:true, stats:pseudo
    ↪                                                    |
+--
    ↪ ---------------------------+--------+----------+-------------------------+
    ↪
5 rows in set (0.00 sec)
```

11.3.2.8 EXPLAIN Statements Using Views

EXPLAIN displays the tables and indexes that a view references, not the name of the view itself. This is because views are only virtual tables and do not store any data themselves. The definition of the view and the rest of the statement are merged together during SQL optimization.

From the bikeshare example database, you can see that the following two queries are executed in a similar manner:

```
ALTER TABLE trips ADD INDEX (duration);
CREATE OR REPLACE VIEW long_trips AS SELECT * FROM trips WHERE duration >
    ↪ 3600;
EXPLAIN SELECT * FROM long_trips;
EXPLAIN SELECT * FROM trips WHERE duration > 3600;
```

```
Query OK, 0 rows affected (2 min 10.11 sec)

Query OK, 0 rows affected (0.13 sec)

+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
| id                           | estRows   | task     | access object
    ↪                      | operator info                    |
+--
    ↪ ----------------------------+-----------+----------+-----------------------
```

```
    ↪
| IndexLookUp_12              | 6372547.67 | root    |
    ↪                                      |                                 |
|  ─IndexRangeScan_10(Build) | 6372547.67 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_11(Probe) | 6372547.67 | cop[tikv] | table:trips
    ↪                     | keep order:false                |
+--
    ↪ ----------------------------+-----------+----------+----------------------
    ↪
3 rows in set (0.00 sec)

+--
    ↪ ----------------------------+----------+----------+----------------------
    ↪
| id                          | estRows  | task     | access object
    ↪                      | operator info                   |
+--
    ↪ ----------------------------+----------+----------+----------------------
    ↪
| IndexLookUp_10              | 833219.37 | root    |
    ↪                                      |                                 |
|  ─IndexRangeScan_8(Build)  | 833219.37 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 833219.37 | cop[tikv] | table:trips
    ↪                     | keep order:false                |
+--
    ↪ ----------------------------+-----------+----------+----------------------
    ↪
3 rows in set (0.00 sec)
```

Similarly, predicates from the view are pushed down to the base table:

```
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
+--
    ↪ ----------------------------+---------+----------+----------------------
    ↪
| id                          | estRows | task    | access object
    ↪                      | operator info                           |
+--
    ↪ ----------------------------+---------+----------+----------------------
    ↪
| IndexLookUp_14              | 3.33    | root     |
```

```
    ↪                                    |
    ↪                                                 |
|  ─IndexRangeScan_11(Build)  | 3333.33 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false, stats:
    ↪ pseudo |
|  ─Selection_13(Probe)       | 3.33    | cop[tikv] |
    ↪                                  | eq(bikeshare.trips.bike_number, "
    ↪ W00950")   |
|    ─TableRowIDScan_12       | 3333.33 | cop[tikv] | table:trips
    ↪                    | keep order:false, stats:pseudo              |
+--
    ↪ ------------------------------+---------+-----------+-------------------------
    ↪
4 rows in set (0.00 sec)

+--
    ↪ ----------------------+------------+----------+--------------+-------------
    ↪
| id                    | estRows    | task     | access object | operator
    ↪ info                         |
+--
    ↪ ----------------------+------------+----------+--------------+-------------
    ↪
| TableReader_7         | 43.00      | root     |               | data:
    ↪ Selection_6                      |
|  ─Selection_6         | 43.00      | cop[tikv] |              | eq(bikeshare.
    ↪ trips.bike_number, "W00950") |
|    ─TableFullScan_5   | 19117643.00 | cop[tikv] | table:trips | keep order
    ↪ :false                   |
+--
    ↪ ----------------------+------------+----------+--------------+-------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself. Consider the following composite index:

```
ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
Query OK, 0 rows affected (2 min 31.20 sec)

+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
| id                          | estRows | task     | access object
   ↪                                     | operator info
   ↪                                     |
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
| IndexLookUp_13              | 63725.48 | root    |
   ↪                                                  |
   ↪                                                  |
|  ─IndexRangeScan_11(Build)  | 63725.48 | cop[tikv] | table:trips, index:
   ↪ bike_number(bike_number, duration) | range:("W00950" 3600,"W00950" +
   ↪ inf], keep order:false |
|  ─TableRowIDScan_12(Probe)  | 63725.48 | cop[tikv] | table:trips
   ↪                                     | keep order:false
   ↪                                   |
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
3 rows in set (0.00 sec)

+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
| id                          | estRows | task     | access object
   ↪                                     | operator info
   ↪                             |
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
| IndexLookUp_10              | 19117.64 | root    |
   ↪                                                  |
   ↪                                               |
|  ─IndexRangeScan_8(Build)  | 19117.64 | cop[tikv] | table:trips, index:
   ↪ bike_number(bike_number, duration) | range:["W00950","W00950"], keep
   ↪ order:false |
|  ─TableRowIDScan_9(Probe)  | 19117.64 | cop[tikv] | table:trips
   ↪                                     | keep order:false
   ↪                          |
+--
```

```
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement, TiDB is able to use both parts of the composite index (`bike_number, duration`). In the second statement, only the first part which is `bike_number` of the index `(bike_number, duration)` is used.

11.3.2.9 Explain Statements Using Partitions

The `EXPLAIN` statement displays the partitions that TiDB needs to access in order to execute a query. Because of partition pruning, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of `EXPLAIN`.

The sample data used in this document:

```
CREATE TABLE t1 (
 id BIGINT NOT NULL auto_increment,
 d date NOT NULL,
 pad1 BLOB,
 pad2 BLOB,
 pad3 BLOB,
 PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
 PARTITION p2016 VALUES LESS THAN (2017),
 PARTITION p2017 VALUES LESS THAN (2018),
 PARTITION p2018 VALUES LESS THAN (2019),
 PARTITION p2019 VALUES LESS THAN (2020),
 PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES

   ↪
5 rows in set (0.01 sec)
```

Starting from the inner-most (`─TableFullScan_19`) operator and working back towards the root operator (`StreamAgg_21`):

- TiDB successfully identified that only one partition (p2017) needed to be accessed. This is noted under `access object`.
- The partition itself was scanned in the operator `─TableFullScan_19` and then `─Selection_20` was applied to filter for rows that have a start date of `2017-06-01 00:00:00.000000`.
- The rows that match `─Selection_20` are then stream aggregated in the coprocessor, which natively understands the `count` function.
- Each coprocessor request then sends back one row to `─TableReader_22` inside TiDB, which is then stream aggregated under `StreamAgg_21` and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

+--
    ↪ ---------------------------------+----------+-----------+----------------------
    ↪
27 rows in set (0.00 sec)
```

From the output above:

- TiDB believes that it needs to access all of the partitions (`p2016..pMax`). This is because the predicate `YEAR(d)= 2017` is considered non-sargable. This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.

- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `└─PartitionUnion_21` unions the results from accessing each partition.

11.3.2.10 Explain Statements Using Index Merge

`IndexMerge` is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

```
mysql> EXPLAIN SELECT * from t where a = 1 or b = 1;
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                  |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| TableReader_7         | 8000.00 | root    |               | data:Selection_6
   ↪                 |
| └─Selection_6         | 8000.00 | cop[tikv] |             | or(eq(test.t.a,
   ↪ 1), eq(test.t.b, 1)) |
| └─TableFullScan_5     | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo  |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪

mysql> explain select * from t use index(idx_a, idx_b) where a > 1 or b >
   ↪ 1;
+--
   ↪ ----------------------------+---------+-----------+-----------------------+-
   ↪
| id                          | estRows | task    | access object         |
   ↪ operator info                                |
+--
   ↪ ----------------------------+---------+-----------+-----------------------+-
   ↪
| IndexMerge_16               | 6666.67 | root    |                       |
   ↪                                             |
| ├─IndexRangeScan_13(Build)  | 3333.33 | cop[tikv] | table:t, index:idx_a(a
   ↪ ) | range:(1,+inf], keep order:false, stats:pseudo |
| ├─IndexRangeScan_14(Build)  | 3333.33 | cop[tikv] | table:t, index:idx_b(b
   ↪ ) | range:(1,+inf], keep order:false, stats:pseudo |
```

```
|  └─TableRowIDScan_15(Probe)  | 6666.67 | cop[tikv] | table:t           |
   ↪ keep order:false, stats:pseudo           |
+--
   ↪ ------------------------------+---------+-----------+----------------------+-
   ↪
```

In the above query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without `IndexMerge`, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, `IndexMerge` is introduced in TiDB to access tables.

`IndexMerge` allows the optimizer to use multiple indexes per table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the figure above. Here the `IndexMerge_16` operator has three child nodes, among which `IndexRangeScan_13` and `IndexRangeScan_14` get all the `RowID`s that meet the conditions based on the result of range scan, and then the `TableRowIDScan_15` operator accurately reads all the data that meets the conditions according to these `RowID`s.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan/TableRangeScan`, the `operator info` column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan/TableFullScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_13` operator indicates that the operator scans the data from 1 to positive infinity.

Note:

- The Index Merge feature is enabled by default from v5.4.0. That is, `tidb_enable_index_merge` is `ON`.
- You can use the SQL hint `USE_INDEX_MERGE` to force the optimizer to apply Index Merge, regardless of the setting of `tidb_enable_index_merge` ↪ . To enable Index Merge when the filtering conditions contain expressions that cannot be pushed down, you must use the SQL hint `USE_INDEX_MERGE`.
- Index Merge supports only disjunctive normal form (expressions connected by `or`) and does not support conjunctive normal form (expressions connected by `and`).
- Index Merge is not supported in tempoaray tables for now.

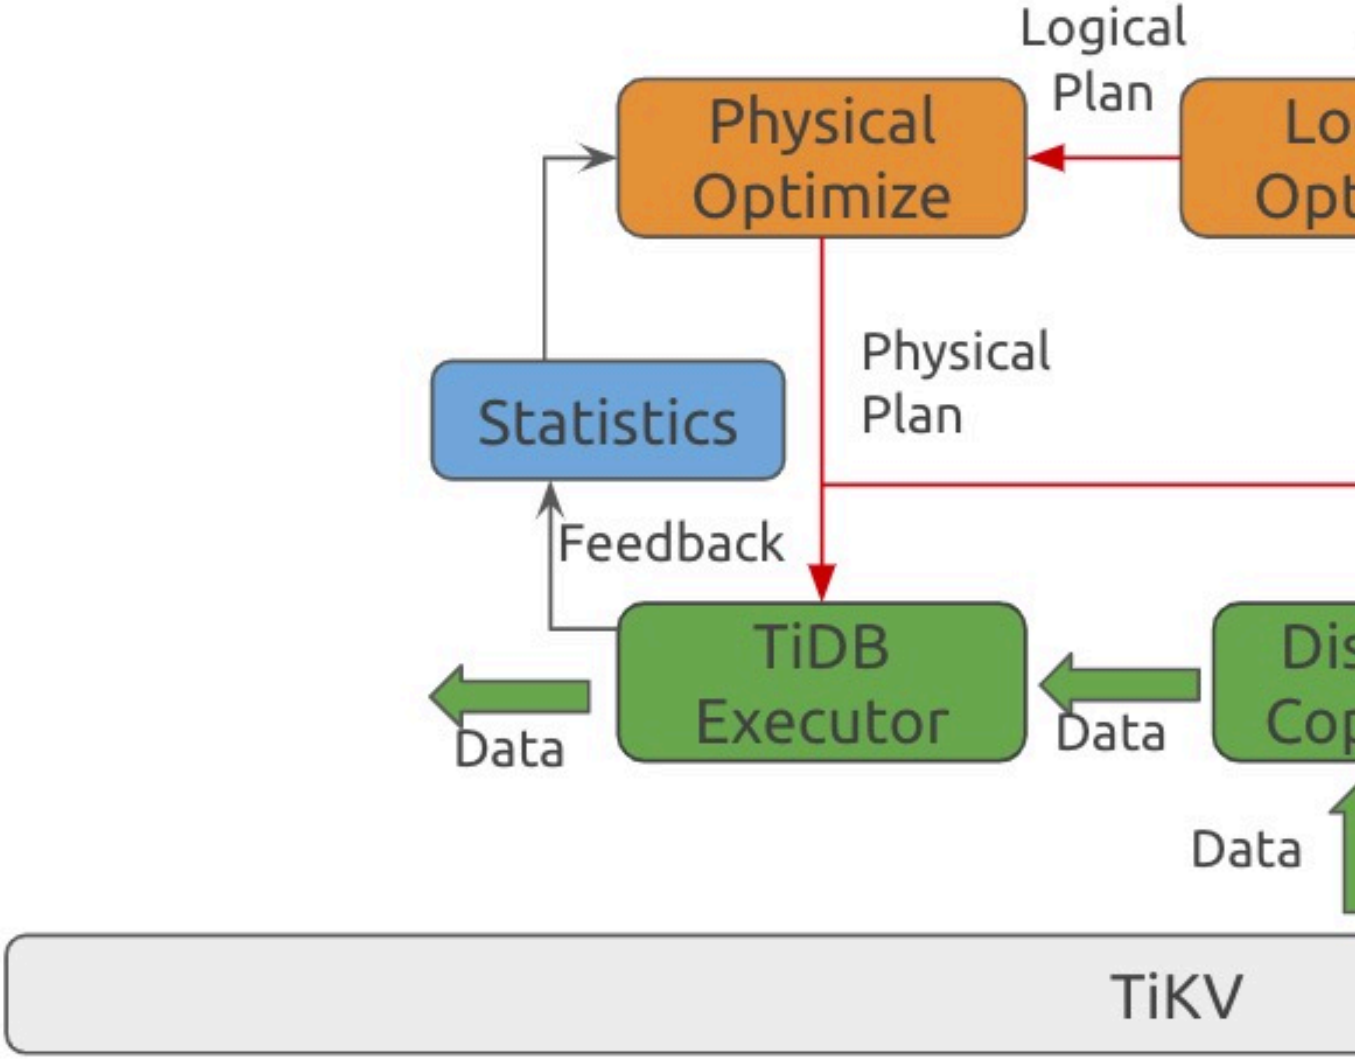

Figure 159: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see SQL Logical Optimization.

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see SQL Physical Optimization.

At the same time, when TiDB executes the `PREPARE` statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see Execution Plan Cache.

11.3.3.2 Logic Optimization

11.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the `IN` sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- Subquery Related Optimizations
- Column Pruning
- Decorrelation of Correlated Subquery
- Eliminate Max/Min
- Predicates Push Down
- Partition Pruning
- TopN and Limit Operator Push Down
- Join Reorder

11.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`
- `IN (SELECT ... FROM ..)`
- `EXISTS (SELECT ... FROM ...)`
- `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

Sometimes a subquery contains non-subquery columns, such as `select * from t where t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of subquery is usually called a "correlated subquery", and the externally introduced column is called a "correlated column". For optimizations about correlated subquery, see Decorrelation of correlated subquery. This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in Understanding TiDB Execution Plan as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

`... < ALL (SELECT ... FROM ...)` or `... > ANY (SELECT ... FROM ...)`

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is NULL. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id)and if(sum(s.id is null)!= 0, null, true)`
- `t.id < any (select s.id from s)` is rewritten as `t.id < max(s.id)or if(sum(s.id is null)!= 0, null, false)`

`... != ANY (SELECT ... FROM ...)`

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s)where (t.id != s.id or cnt_distinct > 1)`

`... = ALL (SELECT ... FROM ...)`

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s )where (t.id = s.id and cnt_distinct <= 1)`

`... IN (SELECT ... FROM ...)`

In this case, the subquery of `IN` is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of `JOIN`.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2. The form of a.` The `DISTINCT` attribute here can be eliminated automatically if `t2.a` has the `UNIQUE` attribute.

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```

   ↪
```

This rewrite gets better performance when the `IN` subquery is relatively small and the external query is relatively large, because without rewriting, using `index join` with t2 as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the `t2` table is relatively large, this rewrite affects the performance of the query. Currently, the variable tidb_opt_insubq_to_join_and_agg is used to control this optimization. When this optimization is not suitable, you can manually disable it.

`EXISTS` subquery and `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the `EXISTS` subquery is evaluated to `TRUE` in the optimization stage in advance, so it does not show in the final execution result.

```
create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);
```

```

    ↪ ---------------------+----------+-----------+--------------+-----------------
    ↪
```

In the preceding optimization, the optimizer automatically optimizes the statement execution. In addition, you can also add the SEMI_JOIN_REWRITE hint to further rewrite the statement.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

11.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b> 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the `Selection` operator uses column b. Then the `DataSource` operator uses columns a and column b. Columns c and column d can be pruned because the `DataSource` operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called "Column Pruning", corresponding to the `columnPruner` rule. If you want to disable this rule, refer to The Blocklist of Optimization Rules and Expression Pushdown.

11.3.3.2.4 Decorrelation of Correlated Subquery

Subquery related optimizations describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

Introduction

Take `select * from t1 where t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition `t2.b=t1.b`, this condition happens to be an equivalent condition, so the query can be rewritten as `select t1.* from t1, (select b, sum(a)sum_a from t2 group by b)t2 where t1.b = t2.b and t1.a < t2.sum_a;`. In this way, a correlated subquery is rewritten into `JOIN`.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, which might bring better execution performance. In this case, you can disable this optimization by using the `NO_DECORRELATE` optimizer hint or by disabling the "subquery decorrelation" optimization rule in the blocklist of optimization rules and expression pushdown. In most cases, it is recommended to use the optimizer hint along with SQL Plan Management to disable the decorrelation.

Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

|        ─Selection_22         | 9990.00 | cop[tikv] |              | not(
    ↪ isnull(test.t2.b))
    ↪                                                       |
|          ─TableFullScan_21   | 10000.00 | cop[tikv] | table:t2 | keep
    ↪ order:false, stats:pseudo
    ↪                                                     |
|  ─TableReader_15(Probe)      | 9990.00 | root     |              | data:
    ↪ Selection_14
    ↪                                                                |
|    ─Selection_14             | 9990.00 | cop[tikv] |              | not(
    ↪ isnull(test.t1.b))
    ↪                                                       |
|      ─TableFullScan_13       | 10000.00 | cop[tikv] | table:t1 | keep
    ↪ order:false, stats:pseudo
    ↪                                                     |
+--
    ↪ ------------------------------+---------+----------+--------------+--------
    ↪
```

The above is an example where the optimization takes effect. `HashJoin_11` is a normal `inner join`.

Then, you can use the `NO_DECORRELATE` optimizer hint to tell the optimizer not to perform decorrelation for the subquery:

```
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);
```

```

|        ─Projection_45                 | 100000.00 | root     |
    ↪                     | cast(test.t2.a, decimal(10,0) BINARY)->Column
    ↪ #14                                |
|          ─IndexLookUp_44              | 100000.00 | root     |
    ↪                     |
    ↪
    ↪ |
|            ─IndexRangeScan_42(Build)  | 100000.00 | cop[tikv] | table:t2,
    ↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
    ↪ order:false, stats:pseudo |
|            ─TableRowIDScan_43(Probe)  | 100000.00 | cop[tikv] | table:t2
    ↪          | keep order:false, stats:pseudo
    ↪                                                                    |
+--
    ↪ --------------------------------------+----------+-----------+--------------
    ↪
```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(` ↪ `test.t2.b, test.t1.b)]` in `operator info` of `IndexRangeScan_25(Build)`. It means

that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

11.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max`/`min` functions, the query optimizer tries to convert the `max`/`min` aggregate functions to the TopN operator by applying the `max`/`min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max`/`min` functions in the `select` statement:

- The statement with only one `max`/`min` function
- The statement with multiple `max`/`min` functions

One `max`/`min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
    ↪ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+--
    ↪ ---------------------------+---------+----------+-----------------------+---
    ↪
| id                        | estRows | task    | access object         |
    ↪ operator info                   |
+--
    ↪ ---------------------------+---------+----------+-----------------------+---
    ↪
| StreamAgg_13              | 1.00    | root     |                       |
    ↪ funcs:max(test.t.a)->Column#4   |
```

```
|  └─Limit_17                | 1.00   | root     |                          |
   ↪ offset:0, count:1                 |
|    └─IndexReader_27        | 1.00   | root     |                          |
   ↪ index:Limit_26                    |
|      └─Limit_26            | 1.00   | cop[tikv] |                          |
   ↪ offset:0, count:1                 |
|        └─IndexFullScan_25  | 1.00   | cop[tikv] | table:t, index:idx_a(a) |
   ↪  keep order:true, desc, stats:pseudo |
+--
   ↪ ---------------------------+---------+----------+-------------------------+---
   ↪
5 rows in set (0.00 sec)
```

Multiple `max`/`min` functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max`/`min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
    (select max(a) as max_a from t) t1,
    (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max` ↪ `/min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
    (select max(a) as max_a from (select a from t where a is not null order
       ↪  by a desc limit 1) t) t1,
    (select min(a) as min_a from (select a from t where a is not null order
       ↪  by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an

index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+--
   ↪ ---------------------------------+---------+----------+----------------------
   ↪
| id                                | estRows | task     | access object        |
   ↪  operator info                      |
+--

11.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```
create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
   ↪ ----------------------+---------+----------+---------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+---------------+----------------
   ↪
| TableReader_7         | 3323.33 | root     |               | data:Selection_6
   ↪           |
| └─Selection_6         | 3323.33 | cop[tikv] |              | lt(test.t.a, 1)
   ↪            |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t  | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+---------------+----------------
   ↪
3 rows in set (0.00 sec)
```

In this query, pushing down the predicate `a < 1` to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```
create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+--
   ↪ ----------------------+---------+----------+---------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
```

```
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
| TableReader_7        | 3323.33 | root     |              | data:Selection_6
   ↪           |
|  ─Selection_6         | 3323.33 | cop[tikv] |              | lt(test.t.a, 1)
   ↪            |
|    ─TableFullScan_5   | 10000.00 | cop[tikv] | table:t  | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate `a < substring('123', 1, 1)` are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate `a < 1`. After that, TiDB can push `a < 1` down to TiKV.

Case 3: push predicates below join operator

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+--
   ↪ ---------------------------+---------+----------+--------------+----------
   ↪
| id                         | estRows | task     | access object | operator
   ↪ info                         |
+--
   ↪ ---------------------------+---------+----------+--------------+----------
   ↪
| HashJoin_8                 | 4154.17 | root     |              | inner join,
   ↪ equal:[eq(test.t.a, test.s.a)] |
|  ─TableReader_15(Build)    | 3323.33 | root     |              | data:
   ↪ Selection_14                    |
|    ─Selection_14           | 3323.33 | cop[tikv] |              | lt(test.s.a
   ↪ , 1)                         |
|      ─TableFullScan_13     | 10000.00 | cop[tikv] | table:s  | keep order:
   ↪ false, stats:pseudo          |
|  ─TableReader_12(Probe)    | 3323.33 | root     |              | data:
   ↪ Selection_11                    |
|    ─Selection_11           | 3323.33 | cop[tikv] |              | lt(test.t.a
   ↪ , 1)                         |
|      ─TableFullScan_10     | 10000.00 | cop[tikv] | table:t  | keep order:
   ↪ false, stats:pseudo          |
+--
```

```
    ↪ ---------------------------+---------+----------+--------------+-----------
    ↪
7 rows in set (0.00 sec)
```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the `ON` condition is `t.a = s.a`. The predicate `s.a <1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```
create table t(id int primary key, a int not null);
desc select * from t where substring('123', a, 1) = '1';
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪                    |
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| Selection_7           | 2.00    | root     |               | eq(substring("123
    ↪ ", test.t.a, 1), "1") |
| └─TableReader_6       | 2.00    | root     |               | data:
    ↪ TableFullScan_5               |
|   └─TableFullScan_5   | 2.00    | cop[tikv] | table:t     | keep order:false,
    ↪  stats:pseudo     |
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
```

In this query, there is a predicate `substring('123', a, 1)= '1'`.

From the `explain` results, we can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `substring`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+--
    ↪ ---------------------------+---------+----------+--------------+-----------
    ↪
```

```
| id                          | estRows | task    | access object | operator
   ↪ info                           |
+--
   ↪ ----------------------------+---------+---------+---------------+----------
   ↪
| Selection_7                 | 10000.00 | root    |               | isnull(test
   ↪ .s.a)                          |
|  ─HashJoin_8                 | 12500.00 | root    |               | left outer
   ↪  join, equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_13(Build)  | 10000.00 | root    |               | data:
   ↪ TableFullScan_12                 |
|      ─TableFullScan_12     | 10000.00 | cop[tikv] | table:s     | keep order:
   ↪ false, stats:pseudo            |
|    ─TableReader_11(Probe)  | 10000.00 | root    |               | data:
   ↪ TableFullScan_10                 |
|      ─TableFullScan_10     | 10000.00 | cop[tikv] | table:t     | keep order:
   ↪ false, stats:pseudo            |
+--
   ↪ ----------------------------+---------+---------+---------------+----------
   ↪
6 rows in set (0.00 sec)
```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with `NULL` values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```
create table t(id int primary key, a char);
set @a = 1;
explain select * from t where a < @a;
+--
   ↪ ----------------------+---------+---------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+---------+---------------+----------------
   ↪
| Selection_5           | 8000.00 | root    |               | lt(test.t.a,
   ↪ getvar("a"))   |
|  ─TableReader_7       | 10000.00 | root    |               | data:
   ↪ TableFullScan_6        |
```

```
|   └─TableFullScan_6   | 10000.00 | cop[tikv] | table:t  | keep order:false
    ↪ , stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
3 rows in set (0.00 sec)
```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with `1`, and does not push down it to TiKV.

An example to help you understand is as follows:

```
create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+----+------+----------+
| id | a    | @a:=@a+1 |
+----+------+----------+
|  1 |    1 | 2        |
|  2 |    2 | 3        |
+----+------+----------+
2 rows in set (0.00 sec)
```

As you can see from this query, the value of `@a` will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

11.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
 PARTITION p0 VALUES LESS THAN (100),
```

```
 PARTITION p1 VALUES LESS THAN (200),
 PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO t1 VALUES (1, 'test1'),(101, 'test2'), (201, 'test3');
EXPLAIN SELECT * FROM t1 WHERE id BETWEEN 80 AND 120;
```

```
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
| id                        | estRows | task    | access object       |
   ↪ operator info                              |
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
| PartitionUnion_8          | 80.00   | root    |                      |
   ↪                                           |
|  ─TableReader_10          | 40.00   | root    |                      | data:
   ↪ TableRangeScan_9                        |
|    ─TableRangeScan_9      | 40.00   | cop[tikv] | table:t1, partition:p0 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
|  ─TableReader_12          | 40.00   | root    |                      | data:
   ↪ TableRangeScan_11                       |
|    ─TableRangeScan_11     | 40.00   | cop[tikv] | table:t1, partition:p1 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
5 rows in set (0.00 sec)
```

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
    ↪ ----------------------+----------+-----------+----------------------+--------
    ↪
| id                    | estRows | task     | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+----------+-----------+----------------------+--------
    ↪
| TableReader_8         | 10.00   | root     |                      | data:
    ↪ Selection_7            |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
    ↪ .x, 1)             |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+----------------------+--------
    ↪
```

In the SQL statement above, it can be known from the condition `x = 1` that all results fall in one partition. The value `1` can be confirmed to be in the `p1` partition after passing through the Hash partition. Therefore, only the `p1` partition needs to be scanned, and there is no need to access the `p2`, `p3`, and `p4` partitions that will not have matching results. From the execution plan, only one `TableFullScan` operator appears and the `p1` partition is specified in `access object`, so it can be confirmed that `partition pruning` takes effect.

Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
    ↪ --------------------------+----------+-----------+---------------------+----
    ↪
| id                          | estRows | task     | access object       |
    ↪ operator info              |
+--
    ↪ --------------------------+----------+-----------+---------------------+----
    ↪
```

```
| Union_10                  | 13333.33 | root    |                     |
   ↪                              |
|  ─TableReader_13          | 3333.33 | root     |                     | data
   ↪ :Selection_12           |
|    ─Selection_12          | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)            |
|      ─TableFullScan_11    | 10000.00 | cop[tikv] | table:t, partition:p0
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_16          | 3333.33 | root     |                     | data
   ↪ :Selection_15           |
|    ─Selection_15          | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)            |
|      ─TableFullScan_14    | 10000.00 | cop[tikv] | table:t, partition:p1
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_19          | 3333.33 | root     |                     | data
   ↪ :Selection_18           |
|    ─Selection_18          | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)            |
|      ─TableFullScan_17    | 10000.00 | cop[tikv] | table:t, partition:p2
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_22          | 3333.33 | root     |                     | data
   ↪ :Selection_21           |
|    ─Selection_21          | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)            |
|      ─TableFullScan_20    | 10000.00 | cop[tikv] | table:t, partition:p3
   ↪ | keep order:false, stats:pseudo |
+--
   ↪ ---------------------------+----------+-----------+---------------------+----
   ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the `x > 2` condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
   ↪ t2.x < 2);
```

```
+--
   ↪ ------------------------------------+----------+-----------+-----------------
   ↪
```

```
| id                                | estRows | task    | access object
   ↪       | operator info                                |
+--
   ↪ ----------------------------------+---------+----------+--------------------
   ↪

+--
   ↪ ----------------------------------+---------+----------+--------------------
   ↪
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x = 3;
```

```
+--
    ↪ ----------------------+----------+----------+----------------------+---------
    ↪
| id                    | estRows | task     | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+----------+----------+----------------------+---------
    ↪
| TableReader_8         | 10.00   | root     |                      | data:
    ↪ Selection_7            |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
    ↪ .x, 3)             |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+----------+----------+----------------------+---------
    ↪
```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x in(1,13);
```

```
+--
    ↪ -------------------------+----------+----------+---------------------+-----
    ↪
```

```
| id                        | estRows | task     | access object       |
    ↪ operator info               |
+--
    ↪ -------------------------+---------+----------+---------------------+-----
    ↪
| Union_8                   | 40.00   | root     |                     |
    ↪                             |
|  ─TableReader_11          | 20.00   | root     |                     | data:
    ↪ Selection_10           |
|    ─Selection_10          | 20.00   | cop[tikv] |                    | in(
    ↪ test.t.x, 1, 13)         |
|      ─TableFullScan_9     | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪  keep order:false, stats:pseudo |
|  ─TableReader_14          | 20.00   | root     |                     | data:
    ↪ Selection_13           |
|    ─Selection_13          | 20.00   | cop[tikv] |                    | in(
    ↪ test.t.x, 1, 13)         |
|      ─TableFullScan_12    | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ -------------------------+---------+----------+---------------------+-----
    ↪
```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x between 7 and 14;
```

```
+--

    ↪
| id                        | estRows | task     | access object       |
    ↪ operator info               |
+--
    ↪ -------------------------+---------+----------+---------------------+-----
```

```
    ↪
| Union_8                  | 500.00  | root     |                       |
    ↪                                 |
|  ─TableReader_11         | 250.00  | root     |                       | data:
    ↪ Selection_10             |
|    ─Selection_10         | 250.00  | cop[tikv] |                       | ge(
    ↪ test.t.x, 7), le(test.t.x, 14) |
|      ─TableFullScan_9    | 10000.00 | cop[tikv] | table:t, partition:p1 |
    ↪  keep order:false, stats:pseudo |
|  ─TableReader_14         | 250.00  | root     |                       | data:
    ↪ Selection_13             |
|    ─Selection_13         | 250.00  | cop[tikv] |                       | ge(
    ↪ test.t.x, 7), le(test.t.x, 14) |
|      ─TableFullScan_12   | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ -------------------------+---------+----------+-----------------------+-----
    ↪
```

Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of `fn(col)`, the query condition is one of `>`, `<`, `=`, `>=`, and `<=`, and the `fn` function is monotonous.

If the `fn` function is monotonous, for any `x` and `y`, if `x > y`, then `fn(x) > fn(y)`. Then this `fn` function can be called strictly monotonous. For any `x` and `y`, if `x > y`, then `fn` ↪ `(x) >= fn(y)`. In this case, `fn` could also be called "monotonous". Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

```
unix_timestamp
to_days
```

For example, partition pruning takes effect when the partition expression is in the form of `fn(col)`, where the `fn` is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
   partition p0 values less than (to_days('2020-04-01')),
   partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```
+--
    ↪ ----------------------+---------+----------+----------------------+---------
    ↪
| id                   | estRows | task     | access object      | operator
    ↪ info                          |
```

```
+--
   ↪ ---------------------+---------+----------+----------------------+--------
   ↪
| TableReader_8        | 3333.33 | root     |                      | data:
   ↪ Selection_7                    |
|  ─Selection_7        | 3333.33 | cop[tikv] |                      | gt(test.t
   ↪ .id, 2020-04-18 00:00:00.000000) |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ---------------------+---------+----------+----------------------+--------
   ↪
```

Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
   partition p0 values less than (5),
   partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
   ↪ t2.x < 2);
```

```
+--
   ↪ ------------------------------------+---------+----------+-----------------
   ↪
| id                                | estRows | task     | access object
   ↪       | operator info                                          |

   ↪                       | data:Selection_23
   ↪                                    |
|           └─Selection_23          | 2.00     | cop[tikv] |
   ↪                     | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|             └─TableFullScan_22    | 2.50     | cop[tikv] | table:t1,
   ↪ partition:p0 | keep order:false, stats:pseudo                |
|         └─TableReader_27          | 2.00     | root     |
   ↪                       | data:Selection_26
   ↪                                    |
|           └─Selection_26          | 2.00     | cop[tikv] |
   ↪                     | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|             └─TableFullScan_25    | 2.50     | cop[tikv] | table:t1,
   ↪ partition:p1 | keep order:false, stats:pseudo                |
+--
   ↪ ----------------------------------+----------+-----------+--------------------
   ↪
14 rows in set (0.00 sec)
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the `t1.x> val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

11.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to Optimization Rules and Blocklist for Expression Pushdown.

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```
+-------------------------+---------+----------+--------------+-------------------
   ↪
| id                      | estRows | task     | access object | operator
   ↪ info            |
+-------------------------+---------+----------+--------------+-------------------
   ↪
| TopN_7                  | 10.00   | root     |              | test.t.a,
   ↪ offset:0, count:10 |
| └─TableReader_15        | 10.00   | root     |              | data:TopN_14
   ↪                |
|   └─TopN_14             | 10.00   | cop[tikv] |             | test.t.a,
   ↪ offset:0, count:10 |
|     └─TableFullScan_13  | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo |
+-------------------------+---------+----------+--------------+-------------------
   ↪
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+---------------------------------+---------+----------+--------------+------------
   ↪
| id                              | estRows | task     | access object |
   ↪ operator info                          |
```

```

|          ─TableFullScan_24     | 10000.00 | cop[tikv] | table:t   | keep
   ↪ order:false, stats:pseudo          |
|    ─TableReader_30(Probe)      | 10000.00 | root      |               | data:
   ↪ TableFullScan_29                   |
|      ─TableFullScan_29         | 10000.00 | cop[tikv] | table:s   | keep
   ↪ order:false, stats:pseudo          |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+------------------------------+----------+-----------+---------------+---------------
   ↪
| id                           | estRows  | task      | access object | operator
   ↪ info                           |
+------------------------------+----------+-----------+---------------+---------------
   ↪
| TopN_12                     | 10.00    | root      |               | test.t.id,
   ↪ offset:0, count:10             |
|  ─HashJoin_16               | 12500.00 | root      |               | inner join,
   ↪  equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_21(Build)   | 10000.00 | root      |               | data:
   ↪ TableFullScan_20                |
```

```
|     └─TableFullScan_20     | 10000.00 | cop[tikv] | table:s  | keep order:
   ↪ false, stats:pseudo       |
|   └─TableReader_19(Probe)  | 10000.00 | root    |             | data:
   ↪ TableFullScan_18                |
|     └─TableFullScan_18     | 10000.00 | cop[tikv] | table:t  | keep order:
   ↪ false, stats:pseudo       |
+----------------------------+----------+-----------+--------------+---------------
   ↪
6 rows in set (0.00 sec)
```

TopN cannot be pushed down before `Inner Join`. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;
```

```
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| id                              | estRows | task     | access object |
   ↪ operator info                            |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| TopN_12                         | 10.00   | root     |               | test.t.id
   ↪ , offset:0, count:10                |
|  └─HashJoin_17                  | 12.50   | root     |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    └─Limit_21(Build)            | 10.00   | root     |               | offset
   ↪ :0, count:10                           |
|      └─TableReader_31           | 10.00   | root     |               | data:
   ↪ Limit_30                               |
|        └─Limit_30               | 10.00   | cop[tikv] |              | offset
   ↪ :0, count:10                           |
|          └─TableFullScan_29     | 10.00   | cop[tikv] | table:t     | keep
   ↪ order:true, stats:pseudo               |
|    └─TableReader_35(Probe)      | 10000.00 | root    |               | data:
   ↪ TableFullScan_34                       |
```

```
|     └─TableFullScan_34        | 10000.00 | cop[tikv] | table:s   | keep
    ↪ order:false, stats:pseudo            |
+-----------------------------------+----------+-----------+---------------+-------------
    ↪
8 rows in set (0.00 sec)
```

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t ↪ .id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

11.3.3.2.9 Introduction to Join Reorder

In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1

As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, the following two Join Reorder algorithms are used in TiDB:

- The greedy algorithm: among all nodes participating in the join, TiDB selects the table with the least rows to estimate its join result with each of the other tables respectively, and then selects the pair with the smallest join result. After that, TiDB continues the similar process to select and join other nodes for the next round, until all the nodes have completed the join.
- The dynamic programming algorithm: among all nodes participating in the join, TiDB enumerates all possible join orders and selects the optimal join order.

Example: the greedy algorithm of Join Reorder

Take the preceding three tables (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

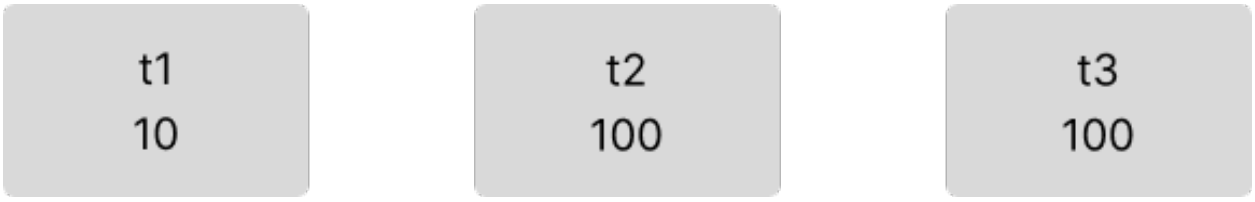

Figure 160: join-reorder-1

After that, the table with the least rows is selected and joined with other two tables respectively. By comparing the sizes of the output result sets, TiDB selects the pair with a smaller result set.

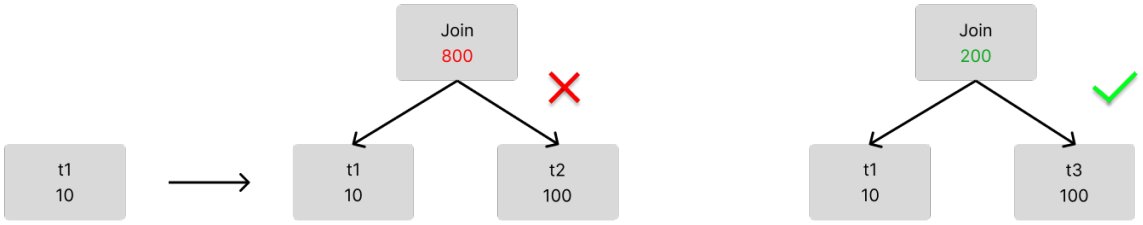

Figure 161: join-reorder-2

Then TiDB enters the next round of selection. If you try to join four tables, TiDB continues to compare the sizes of the output result sets and selects the pair with a smaller result set.

In this case only three tables are joined, so TiDB gets the final join result.

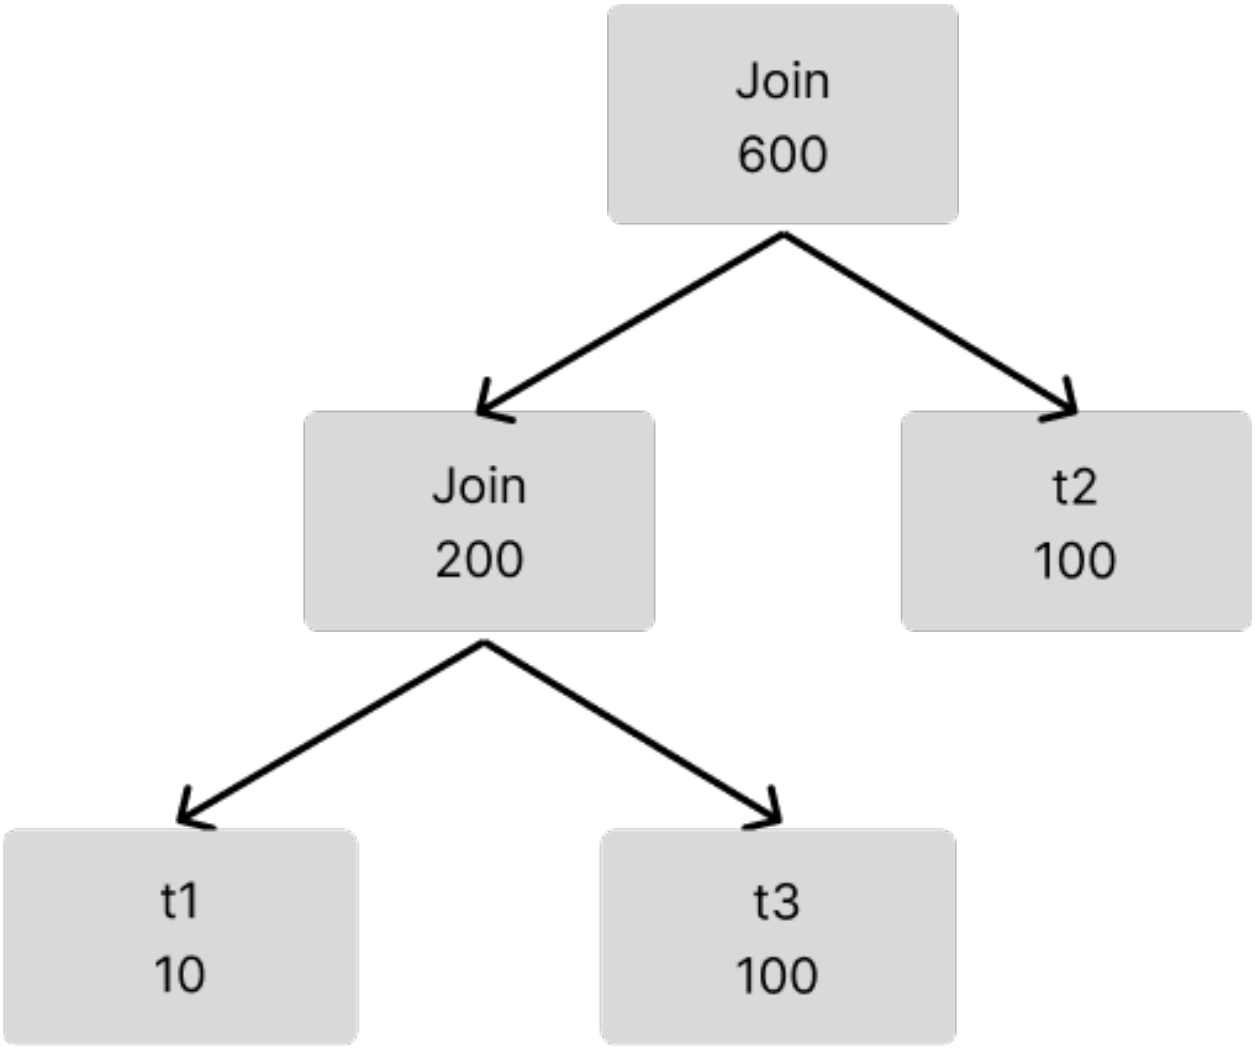

Figure 162: join-reorder-3

Example: the dynamic programming algorithm of Join Reorder

Taking the preceding three tables (t1, t2, and t3) as an example again, the dynamic programming algorithm can enumerate all possibilities. Therefore, comparing with the greedy algorithm, which must start with the `t1` table (the table with the least rows), the dynamic programming algorithm can enumerate a join order as follows:

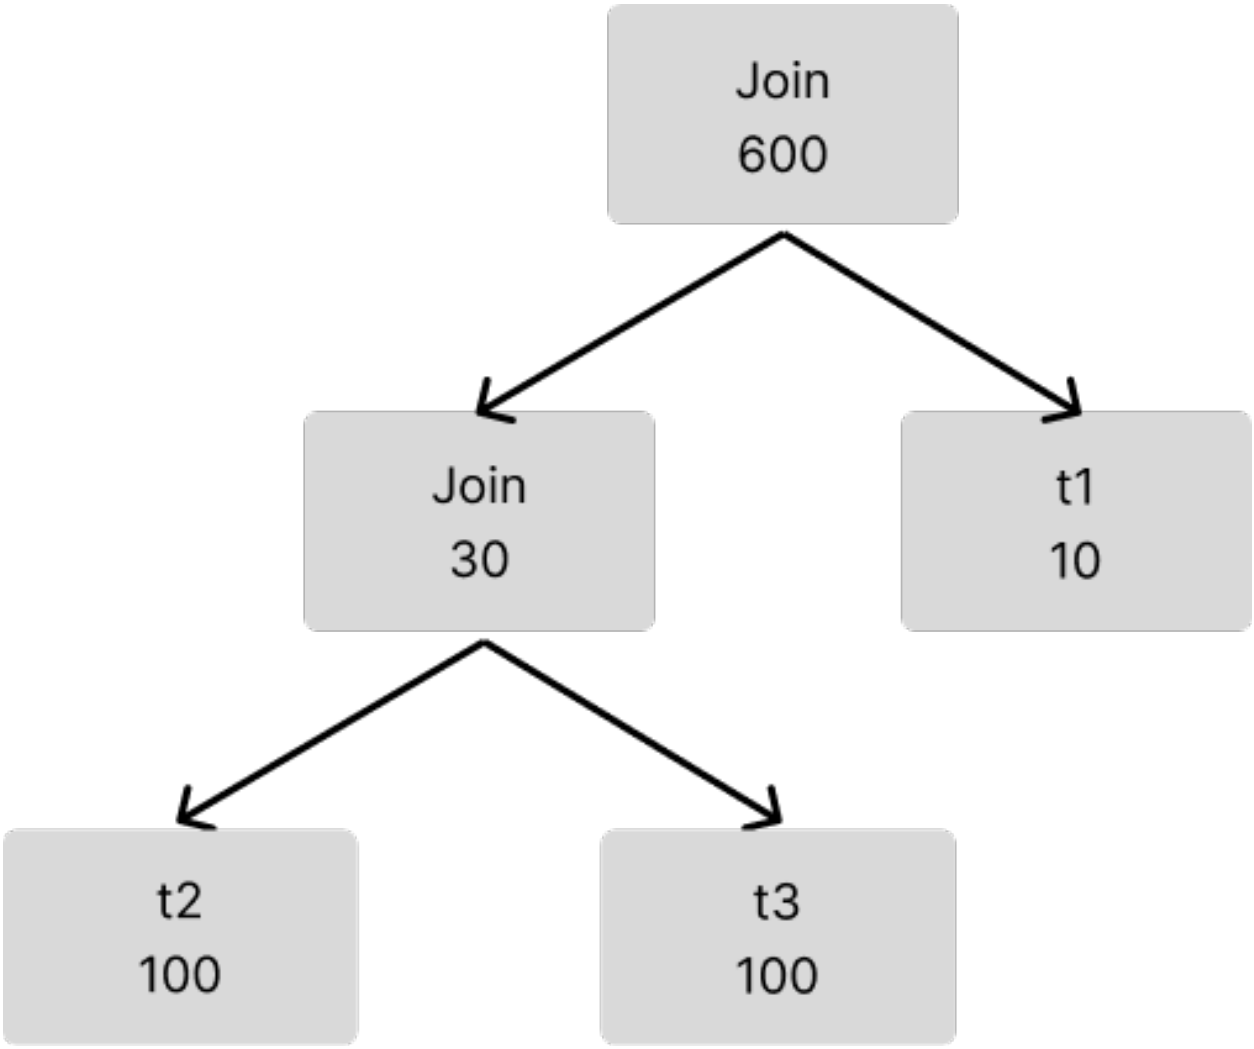

Figure 163: join-reorder-4

When this choice is better than the greedy algorithm, the dynamic programming algorithm can choose a better join order.

Because all possibilities are enumerated, the dynamic programming algorithm consumes more time and is more susceptible to statistics.

Selection of the Join Reorder algorithms

The selection of the TiDB Join Reorder algorithms is controlled by the `tidb_opt_join_reorder_thres`
↪ variable. If the number of nodes participating in Join Reorder is greater than this threshold, TiDB uses the greedy algorithm. Otherwise, TiDB uses the dynamic programming algorithm.

Limitations of Join Reorder algorithms

The current Join Reorder algorithms have the following limitations:

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.
- Currently, the Join Reorder algorithm's support for Outer Join is disabled by default. To enable it, set the value of the system variable `tidb_enable_outer_join_reorder` to `ON`.
- Currently, the dynamic programming algorithm cannot perform Join Reorder for outer join.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to Description of the syntax elements.

11.3.3.3 Physical Optimization

11.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

Understand the Query Execution Plan has introduced some physical operators. This chapter focuses on the following aspects:

- In Index Selection, you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In Introduction to Statistics, you will learn what statistics TiDB collects to obtain the data distribution of a table.
- Wrong Index Solution introduces how to use the right index when you find the index is selected wrongly.
- Distinct Optimization introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.
- Cost Model introduces how to choose a optimal execution plan based on the cost model during physical optimization.

11.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / BatchPointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the `_tidb_rowid` column, or if there are no other operators for accessing tables to

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	Tiflash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookUpReader	A table has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as IndexReader.	Since the index does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the IndexReader operator.

Note:

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection

of an operator for accessing tables.

Index selection rules

TiDB selects indexes based on rules or cost. The based rules include pre-rules and skyline-pruning. When selecting an index, TiDB tries the pre-rule first. If an index satisfies a pre-rule, TiDB directly selects this index. Otherwise, TiDB uses skyline-pruning to exclude unsuitable indexes, and then selects the index with the lowest cost based on the cost estimation of each operator that accesses tables.

Rule-based selection

Pre-rules

TiDB uses the following heuristic pre-rules to select indexes:

- Rule 1: If an index satisfies "unique index with full match + no need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)", TiDB directly selects this index.
- Rule 2: If an index satisfies "unique index with full match + the need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)", TiDB selects the index with the smallest number of rows to be retrieved from a table as a candidate index.
- Rule 3: If an index satisfies "ordinary index + no need to retrieve rows from a table + the number of rows to be read is less than the value of a certain threshold", TiDB selects the index with the smallest number of rows to be read as a candidate index.
- Rule 4: If only one candidate index is selected based on rule 2 and 3, select this candidate index. If two candidate indexes are respectively selected based on rule 2 and 3, select the index with the smaller number of rows to be read (the number of rows with index + the number of rows to be retrieved from a table).

The "index with full match" in the above rules means each indexed column has the equal condition. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if the pre-rules match an index, TiDB outputs a NOTE-level warning indicating that the index matches the pre-rule.

In the following example, because the index `idx_b` meets the condition "unique index with full match + the need to retrieve rows from a table" in rule 2, TiDB selects the index `idx_b` as the access path, and `SHOW WARNING` returns a note indicating that the index `idx_b` matches the pre-rule.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, UNIQUE INDEX idx_b(b
    ↪ ));
```

```
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT b, c FROM t WHERE b = 3 OR b = 6;
+--
    ↪ ----------------+---------+---------+------+-----------------------+---------

    ↪  point ranges with double scan |
+--
    ↪ -----+------+-------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes, which can reduce the probability of wrong index selection caused by wrong estimation. To judge an index, the following three dimensions are needed:

- How many access conditions are covered by the indexed columns. An "access condition" is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.
- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or In-

dexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do. If both indexes need TiDB to retrieve rows from the table, compare how many filtering conditions are covered by the indexed columns. Filtering conditions mean the `where` condition that can be judged based on the index. If the column set of an index covers more access conditions, the smaller the number of retrieved rows from a table, and the better the index is in this dimension.

- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.

For these three dimensions above, if the index `idx_a` performs no worse than the index `idx_b` in all three dimensions and performs better than `idx_b` in one dimension, then `idx_a` is preferred. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if skyline-pruning excludes some indexes, TiDB outputs a NOTE-level warning listing the remaining indexes after the skyline-pruning exclusion.

In the following example, the indexes `idx_b` and `idx_e` are both inferior to `idx_b_c`, so they are excluded by skyline-pruning. The returned result of `SHOW WARNING` displays the remaining indexes after skyline-pruning.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, d INT, e INT, INDEX
    ↪ idx_b(b), INDEX idx_b_c(b, c), INDEX idx_e(e));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT * FROM t WHERE b = 2 AND c > 4;
+--

Cost estimation-based selection

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

   This is usually due to stale or inaccurate statistics. You can re-execute the `analyze table` statement or modify the parameters of the `analyze table` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

   At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

3. The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

Control index selection

The index selection can be controlled by a single query through Optimizer Hints.

- `USE_INDEX` / `IGNORE_INDEX` can force the optimizer to use / not use certain indexes. `FORCE_INDEX` and `USE_INDEX` have the same effect.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

11.3.3.3.3 Introduction to Statistics

TiDB uses statistics to decide which index to choose. The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`.

In versions before v5.1.0, the default value of this variable is `1`. In v5.3.0 and later versions, the default value of this variable is `2`. If your cluster is upgraded from a version earlier than v5.3.0 to v5.3.0 or later, the default value of `tidb_analyze_version` does not change.

Note:

When `tidb_analyze_version = 2`, if memory overflow occurs after `ANALYZE` is executed, you need to set `tidb_analyze_version = 1` and perform one of the following operations:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
sql   SELECT DISTINCT(CONCAT('ANALYZE TABLE ', table_schema
↪ , '.', table_name, ';'))FROM information_schema.tables,
↪ mysql.stats_histograms WHERE stats_ver = 2 AND table_id =
↪ tidb_table_id;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
sql   SELECT DISTINCT(CONCAT('DROP STATS ', table_schema,
↪ '.', table_name, ';'))FROM information_schema.tables,
↪ mysql.stats_histograms WHERE stats_ver = 2 AND table_id =
↪  tidb_table_id;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
sql   SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt'; mysql -h
↪  XXX -u user -P 4000 ... < '/tmp/sql.txt';
```

These two versions include different information in TiDB:

Information	Version 1	Version 2
The total number of rows in the table	√	√
Column Count-Min Sketch	√	×
Index Count-Min Sketch	√	×

Information	Version 1	Version 2
Column Top-N	√	√ (Maintenance methods and precision are improved)
Index Top-N	√ (Insufficient maintenance precision might cause inaccuracy)	√ (Maintenance methods and precision are improved)
Column histogram	√	√ (The histogram does not include Top-N values.)

Information	Version 1	Version 2
Index histogram	√	√ (The histogram buckets record the number of different values in each bucket, and the histogram does not include Top-N values.)
The number of `NULL` ↪ s in the column	√	√

Information	Version 1	Version 2
The number of `NULL` ↪ s in the index	√	√
The average length of columns	√	√
The average length of indexes	√	√

Compared to Version 1, Version 2 statistics avoids the potential inaccuracy caused by hash collision when the data volume is huge. It also maintains the estimate precision in most scenarios.

This document briefly introduces the histogram, Count-Min Sketch, and Top-N, and details the collection and maintenance of statistics.

Histogram

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here "equal-depth" means that the number of values falling into each bucket is as equal as possible. For example, for a given set {1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5}, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains

four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

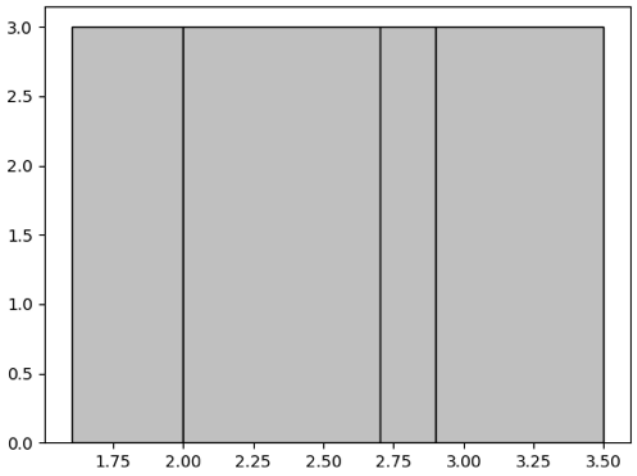

Figure 164: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to Manual Collection. When the number of buckets is larger, the accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage of memory resources. You can adjust this number appropriately according to the actual scenario.

Count-Min Sketch

Count-Min Sketch is a hash structure. When an equivalence query contains `a = 1` or `IN` query (for example, `a in (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see Full Collection.
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the

default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see Full Collection.

Top-N values

Top-N values are values with the top N occurrences in a column or index. TiDB records the values and occurrences of Top-N values.

Collect statistics

Manual collection

You can run the `ANALYZE` statement to collect statistics.

Note:

The execution time of `ANALYZE TABLE` in TiDB is longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while in TiDB a comprehensive set of statistics is completely rebuilt. Scripts that were written for MySQL may naively expect `ANALYZE TABLE` will be a short-lived operation.

For quicker analysis, you can set `tidb_enable_fast_analyze` to `1` to enable the Quick Analysis feature. The default value for this parameter is `0`.

After Quick Analysis is enabled, TiDB randomly samples approximately 10,000 rows of data to build statistics. Therefore, in the case of uneven data distribution or a relatively small amount of data, the accuracy of statistical information is relatively poor. It might lead to poor execution plans, such as choosing the wrong index. If the execution time of the normal `ANALYZE` statement is acceptable, it is recommended to disable the Quick Analysis feature.

`tidb_enable_fast_analyze` is an experimental feature, which currently **does not match exactly** with the statistical information of `tidb_analyze_version=2`. Therefore, you need to set the value of `tidb_analyze_version` to `1` when `tidb_enable_fast_analyze` is enabled.

Full collection

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|
    ↪ CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated `TOPN`s.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- `WITH FLOAT_NUM SAMPLERATE` specifies the sampling rate.

`WITH NUM SAMPLES` and `WITH FLOAT_NUM SAMPLERATE` correspond to two different algorithms of collecting samples.

- `WITH NUM SAMPLES` specifies the size of the sampling set, which is implemented in the reservoir sampling method in TiDB. When a table is large, it is not recommended to use this method to collect statistics. Because the intermediate result set of the reservoir sampling contains redundant results, it causes additional pressure on resources such as memory.
- `WITH FLOAT_NUM SAMPLERATE` is a sampling method introduced in v5.3.0. With the value range `(0, 1]`, this parameter specifies the sampling rate. It is implemented in the way of Bernoulli sampling in TiDB, which is more suitable for sampling larger tables and performs better in collection efficiency and resource usage.

Before v5.3.0, TiDB uses the reservoir sampling method to collect statistics. Since v5.3.0, the TiDB Version 2 statistics uses the Bernoulli sampling method to collect statistics by default. To re-use the reservoir sampling method, you can use the `WITH NUM SAMPLES` statement.

The current sampling rate is calculated based on an adaptive algorithm. When you can observe the number of rows in a table using `SHOW STATS_META`, you can use this number of rows to calculate the sampling rate corresponding to 100,000 rows. If you cannot observe this number, you can use the `TABLE_KEYS` column in the `TABLE_STORAGE_STATS` table as another reference to calculate the sampling rate.

> **Note:**
>
> Normally, `STATS_META` is more credible than `TABLE_KEYS`. However, after importing data through the methods like TiDB Lightning, the result of `STATS_META` is `0`. To handle this situation, you can use `TABLE_KEYS` to calculate the sampling rate when the result of `STATS_META` is much smaller than the result of `TABLE_KEYS`.

Collect statistics on some columns

In most cases, when executing SQL statements, the optimizer only uses statistics on some columns (such as columns in the `WHERE`, `JOIN`, `ORDER BY`, and `GROUP BY` statements). These columns are called `PREDICATE COLUMNS`.

If a table has many columns, collecting statistics on all the columns can cause a large overhead. To reduce the overhead, you can collect statistics on only specific columns or `PREDICATE COLUMNS` to be used by the optimizer.

> **Note:**
>
> Collecting statistics on some columns is only applicable for `tidb_analyze_version = 2`.

- To collect statistics on specific columns, use the following syntax:

```
ANALYZE TABLE TableName COLUMNS ColumnNameList [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

  In the syntax, `ColumnNameList` specifies the name list of the target columns. If you need to specify more than one column, use comma `,` to separate the column names. For example, `ANALYZE table t columns a, b`. Besides collecting statistics on the specific columns in a specific table, this syntax collects statistics on the indexed columns and all indexes in that table at the same time.

> **Note:**
>
> The syntax above is a full collection. For example, after collecting statistics on columns `a` and `b` using this syntax, if you also want to collect statistics on column `c`, you need to specify all three columns using `ANALYZE table t columns a, b, c`, rather than only specifying the additional column `c` using `ANALYZE TABLE t COLUMNS c`.

- To collect statistics on `PREDICATE COLUMNS`, do the following:

> **Warning:**
>
> Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

1. Set the value of the tidb_enable_column_tracking system variable to ON to enable TiDB to collect PREDICATE COLUMNS.

   After the setting, TiDB writes the PREDICATE COLUMNS information to the mysql.column_stats_usage system table every 100 * stats-lease.

2. After the query pattern of your business is relatively stable, collect statistics on PREDICATE COLUMNS by using the following syntax:

```
ANALYZE TABLE TableName PREDICATE COLUMNS [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

   Besides collecting statistics on PREDICATE COLUMNS in a specific table, this syntax collects statistics on indexed columns and all indexes in that table at the same time.

Note:

- If the mysql.column_stats_usage system table does not contain any PREDICATE COLUMNS record for that table, the preceding syntax collects statistics on all columns and all indexes in that table.
- After using this syntax to collect statistics, when executing a new type of SQL query, the optimizer might temporarily use the old or pseudo column statistics for this time, and TiDB will collect the statistics on the used columns from the next time.

- To collect statistics on all columns and indexes, use the following syntax:

```
ANALYZE TABLE TableName ALL COLUMNS [WITH NUM BUCKETS|TOPN|CMSKETCH
    ↪ DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE
    ↪ ];
```

If you want to persist the column configuration in the ANALYZE statement (including COLUMNS ColumnNameList, PREDICATE COLUMNS, and ALL COLUMNS), set the value of the tidb_persist_analyze_options system variable to ON to enable the ANALYZE configuration persistence feature. After enabling the ANALYZE configuration persistence feature:

- When TiDB collects statistics automatically or when you manually collect statistics by executing the ANALYZE statement without specifying the column configuration, TiDB continues using the previously persisted configuration for statistics collection.
- When you manually execute the ANALYZE statement multiple times with column configuration specified, TiDB overwrites the previously recorded persistent configuration using the new configuration specified by the latest ANALYZE statement.

To locate PREDICATE COLUMNS and columns on which statistics have been collected, use the following syntax:

```
SHOW COLUMN_STATS_USAGE [ShowLikeOrWhere];
```

The `SHOW COLUMN_STATS_USAGE` statement returns the following 6 columns:

Column name	Description
`Db_name`	The database name
`Table_name`	The table name
`Partition_name`	The partition name
`Column_name`	The column name
`Last_used_at`	The last time when the column statistics were used in the query optimization
`Last_analyzed_at`	The last time when the column statistics were collected

In the following example, after executing `ANALYZE TABLE t PREDICATE COLUMNS;`, TiDB collects statistics on columns `b`, `c`, and `d`, where column `b` is a `PREDICATE COLUMN` and columns `c` and `d` are index columns.

```
SET GLOBAL tidb_enable_column_tracking = ON;
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE t (a INT, b INT, c INT, d INT, INDEX idx_c_d(c, d));
Query OK, 0 rows affected (0.00 sec)

-- The optimizer uses the statistics on column b in this query.
SELECT * FROM t WHERE b > 1;
Empty set (0.00 sec)

-- After waiting for a period of time (100 * stats-lease), TiDB writes the
   ↪ collected `PREDICATE COLUMNS` to mysql.column_stats_usage.
```

```
-- Specify `last_used_at IS NOT NULL` to show the `PREDICATE COLUMNS`
    ↪ collected by TiDB.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
    ↪ last_used_at IS NOT NULL;
+--
    ↪ -------+-----------+---------------+------------+-------------------+------
    ↪
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
    ↪ Last_analyzed_at |
+--
    ↪ -------+-----------+---------------+------------+-------------------+------
    ↪
| test   | t          |               | b          | 2022-01-05 17:21:33 | NULL
    ↪          |
+--
    ↪ -------+-----------+---------------+------------+-------------------+------
    ↪
1 row in set (0.00 sec)

ANALYZE TABLE t PREDICATE COLUMNS;
Query OK, 0 rows affected, 1 warning (0.03 sec)

-- Specify `last_analyzed_at IS NOT NULL` to show the columns for which
    ↪ statistics have been collected.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
    ↪ last_analyzed_at IS NOT NULL;
+--
    ↪ -------+-----------+---------------+------------+-------------------+------
    ↪
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
    ↪ Last_analyzed_at |
+--
    ↪ -------+-----------+---------------+------------+-------------------+------
    ↪
| test   | t          |               | b          | 2022-01-05 17:21:33 |
    ↪ 2022-01-05 17:23:06 |
| test   | t          |               | c          | NULL                |
    ↪ 2022-01-05 17:23:06 |
| test   | t          |               | d          | NULL                |
    ↪ 2022-01-05 17:23:06 |
+--
    ↪ -------+-----------+---------------+------------+-------------------+------
    ↪
3 rows in set (0.00 sec)
```

Collect statistics on indexes

To collect statistics on all indexes in `IndexNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

When `IndexNameList` is empty, this syntax collects statistics on all indexes in `TableName` ↪ .

> **Note:**
>
> To ensure that the statistical information before and after the collection is consistent, when `tidb_analyze_version` is `2`, this syntax collects statistics on the entire table (including all columns and indexes), instead of only on indexes.

Collect statistics on partitions

- To collect statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

- To collect index statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- If you only need to collect statistics on some columns of some partitions in a table, use the following syntax:

> **Warning:**
>
> Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

```
ANALYZE TABLE TableName PARTITION PartitionNameList [COLUMNS
    ↪ ColumnNameList|PREDICATE COLUMNS|ALL COLUMNS] [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

Collect statistics of partitioned tables in dynamic pruning mode

When accessing partitioned tables in dynamic pruning mode, TiDB collects table-level statistics, which is called GlobalStats. Currently, GlobalStats is aggregated from statistics of all partitions. In dynamic pruning mode, a statistics update of any partitioned table can trigger the GlobalStats to be updated.

Note:

- When GlobalStats update is triggered:
  - If some partitions have no statistics (such as a new partition that has never been analyzed), GlobalStats generation is interrupted and a warning message is displayed saying that no statistics are available on partitions.
  - If statistics of some columns are absent in specific partitions (different columns are specified for analyzing in these partitions), GlobalStats generation is interrupted when statistics of these columns are aggregated, and a warning message is displayed saying that statistics of some columns are absent in specific partitions.
- In dynamic pruning mode, the Analyze configurations of partitions and tables should be the same. Therefore, if you specify the `COLUMNS` ↪ configuration following the `ANALYZE TABLE TableName PARTITION` ↪ `PartitionNameList` statement or the `OPTIONS` configuration following `WITH`, TiDB will ignore them and return a warning.

Incremental collection

To improve the speed of analysis after full collection, incremental collection could be used to analyze the newly added sections in monotonically non-decreasing columns such as time columns.

Note:

- Currently, the incremental collection is only provided for index.
- When using the incremental collection, you must ensure that only `INSERT` operations exist on the table, and that the newly inserted value on the index column is monotonically non-decreasing. Otherwise, the statistical information might be inaccurate, affecting the TiDB optimizer to select an appropriate execution plan.

You can perform incremental collection using the following syntax.

- To incrementally collect statistics on index columns in all `IndexNameLists` in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName INDEX [IndexNameList] [WITH NUM
    ↪ BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|
    ↪ WITH FLOATNUM SAMPLERATE];
```

- To incrementally collect statistics on index columns for partitions in all `PartitionNameLists` ↪ in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

Automatic update

For the `INSERT`, `DELETE`, or `UPDATE` statements, TiDB automatically updates the number of rows and updated rows. TiDB persists this information regularly and the update cycle is 20 * `stats-lease`. The default value of `stats-lease` is `3s`. If you specify the value as `0`, it does not update automatically.

Three system variables related to automatic update of statistics are as follows:

System Variable	Default Value	Description
tidb_auto_analyze_ratio	0.5	The threshold value of automatic update
tidb_auto_analyze_start_time	00:00 +0000	The start time in a day when TiDB can perform automatic update
tidb_auto_analyze_end_time	23:59 +0000	The end time in a day when TiDB can perform automatic update

When the ratio of the number of modified rows to the total number of rows of `tbl` ↪ in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics on this table.

To avoid the situation that modifying a small amount of data on a small table frequently triggers the automatic update, when a table has less than 1000 rows, such data modifying does not trigger the automatic update in TiDB. You can use the `SHOW STATS_META` statement to view the number of rows in a table.

> **Note:**
>
> Currently, the automatic update does not record the configuration items input at manual `ANALYZE`. Therefore, when you use the `WITH` syntax to control the collecting behavior of `ANALYZE`, you need to manually set scheduled tasks to collect statistics.

Since TiDB v6.0, TiDB supports using the `KILL` statement to terminate an `ANALYZE` task running in the background. If you find that an `ANALYZE` task running in the background consumes a lot of resources and affects your application, you can terminate the `ANALYZE` task by taking the following steps:

1. Execute the following SQL statement:

   ```
   SHOW ANALYZE STATUS
   ```

   By checking the `instance` column and the `process_id` column in the result, you can get the TiDB instance address and the task `ID` of the background `ANALYZE` task.

2. Terminate the `ANALYZE` task that is running in the background.

   - If `enable-global-kill` is `true` (`true` by default), you can execute the `KILL` ↪ `TIDB ${id};` statement directly, where `${id}` is the `ID` of the background `ANALYZE` task obtained from the previous step.
   - If `enable-global-kill` is `false`, you need to use a client to connect to the TiDB instance that is executing the backend `ANALYZE` task, and then execute the `KILL` ↪ `TIDB ${id};` statement. If you use a client to connect to another TiDB instance, or if there is a proxy between the client and the TiDB cluster, the `KILL` statement cannot terminate the background `ANALYZE` task.

   For more information on the `KILL` statement, see `KILL`.

   Control `ANALYZE` concurrency

When you run the `ANALYZE` statement, you can adjust the concurrency using the following parameters, to control its effect on the system.

`tidb_build_stats_concurrency`

Currently, when you run the `ANALYZE` statement, the task is divided into multiple small tasks. Each task only works on one column or index. You can use the `tidb_build_stats_concurrency` parameter to control the number of simultaneous tasks. The default value is `4`.

`tidb_distsql_scan_concurrency`

When you analyze regular columns, you can use the `tidb_distsql_scan_concurrency` parameter to control the number of Region to be read at one time. The default value is `15`.

`tidb_index_serial_scan_concurrency`

When you analyze index columns, you can use the `tidb_index_serial_scan_concurrency` ↪ parameter to control the number of Region to be read at one time. The default value is `1`.

Persist ANALYZE configurations

Since v5.4.0, TiDB supports persisting some `ANALYZE` configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The following are the `ANALYZE` configurations that support persistence:

Configuration	Corresponding ANALYZE syntax
The number of histogram buckets	WITH NUM BUCKETS
The number of Top-N	WITH NUM TOPN

Configuration	Corresponding ANALYZE syntax
The number of samples	WITH NUM SAMPLES
The sampling rate	WITH FLOAT_NUM SAMPLERATE
The column type	AnalyzeColumnOption ANALYZE TABLE (‘ALL COLUMNS’ | ‘PREDICATE COLUMNS’ | ‘COLUMNS’ ColumnNameList)
The column	ColumnNameList ANALYZE TABLE Identifier (‘,’ Identifier)*

Enable ANALYZE configuration persistence

The `ANALYZE` configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is `2` and `tidb_persist_analyze_options` is `ON` by default).

You can use this feature to record the persistence configurations specified in the `ANALYZE` statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configuration, TiDB will collect statistics according to the recorded configurations.

When you manually execute the `ANALYZE` statement multiple times with persistence configurations specified, TiDB overwrites the previously recorded persistent configuration using the new configurations specified by the latest `ANALYZE` statement.

Disable ANALYZE configuration persistence

To disable the `ANALYZE` configuration persistence feature, set the `tidb_persist_analyze_options` system variable to `OFF`. Because the `ANALYZE` configuration persistence feature is not applicable to `tidb_analyze_version = 1`, setting `tidb_analyze_version = 1` can also disable the feature.

After disabling the `ANALYZE` configuration persistence feature, TiDB does not clear the persisted configuration records. Therefore, if you enable this feature again, TiDB continues to collect statistics using the previously recorded persistent configurations.

> **Note:**
>
> When you enable the `ANALYZE` configuration persistence feature again, if the previously recorded persistence configurations are no longer applicable to the latest data, you need to execute the `ANALYZE` statement manually and specify the new persistence configurations.

The memory quota for collecting statistics

> **Warning:**
>
> Currently, the `ANALYZE` memory quota is an experimental feature, and the memory statistics might be inaccurate in production environments.

Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the memory quota for collecting statistics in TiDB.

To set a proper value of `tidb_mem_quota_analyze`, consider the data size of the cluster. When the default sampling rate is used, the main considerations are the number of columns, the size of column values, and the memory configuration of TiDB. Consider the following suggestions when you configure the maximum and minimum values:

Note:

The following suggestions are for reference only. You need to configure the values based on the real scenario.

- Minimum value: should be greater than the maximum memory usage when TiDB collects statistics from the table with the most columns. An approximate reference: when TiDB collects statistics from a table with 20 columns using the default configuration, the maximum memory usage is about 800 MiB; when TiDB collects statistics from a table with 160 columns using the default configuration, the maximum memory usage is about 5 GiB.
- Maximum value: should be less than the available memory when TiDB is not collecting statistics.

View `ANALYZE` state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using the following SQL statement:

```
SHOW ANALYZE STATUS [ShowLikeOrWhere]
```

This statement returns the state of `ANALYZE`. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW ANALYZE STATUS` statement returns the following 11 columns:

Column name	Description
table_schema	The database name
table_name	The table name
partition_name	The partition name

Column name	Description
job_info	The task information. If an index is analyzed, this information will include the index name. When `tidb_analyze_version` ↪ `=2`, this information will include configuration items such as sample rate.
processed_rows	The number of rows that have been analyzed
start_time	The time at which the task starts
state	The state of a task, including `pending`, `running`, `finished`, and `failed`
fail_reason	The reason why the task fails. If the execution is successful, the value is `NULL`.
instance	The TiDB instance that executes the task
process_id	The process ID that executes the task

Starting from TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the

restart using this statement. Before TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement can only show instance-level tasks, and task records are cleared after a TiDB restart.

`SHOW ANALYZE STATUS` shows the most recent task records only. Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

When `tidb_mem_quota_analyze` is set and an automatic `ANALYZE` task running in the TiDB background uses more memory than this threshold, the task will be retried. You can see failed and retried tasks in the output of the `SHOW ANALYZE STATUS` statement.

When `tidb_max_auto_analyze_time` is greater than 0 and an automatic `ANALYZE` task running in the TiDB background takes more time than this threshold, the task will be terminated.

```
mysql> SHOW ANALYZE STATUS [ShowLikeOrWhere];
+--
   ↪ ------------+------------+----------------+-----------------------------------
   ↪
| Table_schema | Table_name | Partition_name | Job_info
   ↪                                                                              |
   ↪ Processed_rows | Start_time     | End_time          | State   |
   ↪ Fail_reason                                                                  |
+--
   ↪ ------------+------------+----------------+-----------------------------------
   ↪
| test         | sbtest1   |                | retry auto analyze table all
   ↪ columns with 100 topn, 0.055 samplerate           |       2000000 |
   ↪ 2022-05-07 16:41:09 | 2022-05-07 16:41:20 | finished | NULL
   ↪                                                                  |
| test         | sbtest1   |                | auto analyze table all columns
   ↪ with 100 topn, 0.5 samplerate                     |            0 |
   ↪ 2022-05-07 16:40:50 | 2022-05-07 16:41:09 | failed | analyze panic
   ↪ due to memory quota exceeds, please try with smaller samplerate |
```

View statistics

You can view the statistics status using the following statements.

Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

```
SHOW STATS_META [ShowLikeOrWhere];
```

The syntax of `ShowLikeOrWhereOpt` is as follows:
