Subqueries containing `IN` and `= ANY` operators are converted to semi join and left outer semi join respectively. In the preceding example of `Semi join`, since columns `test.t1.id`  $\leftrightarrow$  and `test.t2.t1_id` on both sides of the join key are not `NULL`, the semi join does not need to be considered as null-aware (`NULL` is not processed specially). TiDB processes the null-aware semi join based on the Cartesian product and filter without special optimization. The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a,b) IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a,b) IN (SELECT * FROM s);
```

```
tidb> EXPLAIN SELECT (a,b) IN (SELECT * FROM s) FROM t;

↪ -----+-----+-----+-----+
↪
8 rows in set (0.01 sec)

```

In the first query statement `EXPLAIN SELECT (a,b)IN (SELECT * FROM s)FROM t;`, since columns `a` and `b` of tables `t` and `s` are `NULLABLE`, the left outer semi join converted by the `IN` subquery is null-aware. Specifically, the Cartesian product is calculated first, then the column connected by `IN` or `= ANY` is put into other conditions as a normal equality query for filtering.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a,b)IN (SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are `NULLABLE`, the `IN` subquery should have been converted to a null-aware semi join. But TiDB optimizes it by converting semi join to inner join and aggregate. This is because `NULL` and `false` are equivalent in `IN` subqueries for non-scalar output. The `NULL` rows in the push-down filter results in the negative semantics of the `WHERE` clause. Therefore, these rows can be ignored beforehand.

**Note:**

The `Exists` operator is also converted to semi join, but it is not null-aware.

### 11.3.2.6.6 Null-aware anti semi join (`NOT IN` and `!= ALL` subqueries)

The value of the `NOT IN` or `!= ALL` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `NOT IN` and `!= ALL` operators are converted to anti semi join and anti left outer semi join respectively. In the preceding example of [Anti semi join](#), since columns `test.t3.t1_id` and `test.t1.id` on both sides of the join key are `not NULL`, the anti semi join does not need to be considered as null-aware (`NULL` is not processed specially).

TiDB v6.3.0 optimizes null-aware anti join (NAAJ) as follows:

- Build hash join using the null-aware equality condition (NA-EQ)

Set operators introduce the equality condition, which requires a special process for the `NULL` value of operators on both sides of the condition. The equality condition that requires null-aware is called NA-EQ. Different from earlier versions, TiDB v6.3.0 no longer processes NA-EQ as before, but places it in other conditions after join, and then determines the legitimacy of the result set after matching the Cartesian product.

Since TiDB v6.3.0, NA-EQ, a weakened equality condition, is still used to build hash join. This reduces the matching amount of data that needs to be traversed and speeds up the matching process. The acceleration is more significant when the percentage of total `DISTINCT()` values of the build table is almost 100%.

- Speed up the return of matching results using the special property of `NULL`

Since anti semi join is a conjunctive normal form (CNF), a `NULL` on either side of the join leads to a definite result. This property can be used to speed up the return of the entire matching process.

The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a, b) NOT IN (SELECT * FROM s);
```

```
tidb> EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;
+---+
↪ -----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
```

```

↪ -----+-----+-----+-----+-----
↪
5 rows in set (0.00 sec)
```

In the first query statement `EXPLAIN SELECT (a, b)NOT IN (SELECT * FROM s)FROM ↪ t;`, since columns `a` and `b` of tables `t` and `s` are `NULLABLE`, the left outer semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the `NA-EQ` as the hash join condition, which greatly speeds up the join calculation.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a, b)NOT IN (↪ SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are `NULLABLE`, the anti semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the `NA-EQ` as the hash join condition, which greatly speeds up the join calculation.

Currently, TiDB can only be null-aware of anti semi join and anti left outer semi join. Only the hash join type is supported and its build table should be fixed to the right table.

#### Note:

The `Not Exists` operator is also converted to the anti semi join, but it is not null-aware.

### 11.3.2.6.7 Explain statements using other types of subqueries

- [Explain Statements in the MPP Mode](#)
- [Explain Statements That Use Indexes](#)
- [Explain Statements That Use Joins](#)
- [Explain Statements That Use Aggregation](#)
- [Explain Statements Using Views](#)
- [Explain Statements Using Partitions](#)
- [Explain Statements Using Index Merge](#)

### 11.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
↪ pad2 BLOB, pad3 BLOB);
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
SELECT SLEEP(1);
ANALYZE TABLE t1;
```

From the output of `SHOW TABLE REGIONS`, you can see that this table is split into multiple Regions:

```
SHOW TABLE t1 REGIONS;
```

```
+--
```

```
↪
```

```
↪
```

REGION_ID	START_KEY	END_KEY	LEADER_ID	LEADER_STORE_ID	PEERS
↪	SCATTERING	WRITTEN_BYTES	READ_BYTES	APPROXIMATE_SIZE(MB)	

```

↳ APPROXIMATE_KEYS |
+--
↳ -----+-----+-----+-----+-----+
↳
| 64 | t_64_ | t_64_r_31766 | 65 | 1 | 65 |
↳ 0 | 1325 | 102033520 | 98 |
↳ 52797 |
| 66 | t_64_r_31766 | t_64_r_63531 | 67 | 1 | 67 |
↳ 0 | 1325 | 72522521 | 104 |
↳ 78495 |
| 68 | t_64_r_63531 | t_64_r_95296 | 69 | 1 | 69 |
↳ 0 | 1325 | 0 | 104 |
↳ 95433 |
| 2 | t_64_r_95296 | | 3 | 1 | 3 |
↳ 0 | 1501 | 0 | 81 |
↳ 63211 |
+--
↳ -----+-----+-----+-----+-----+
↳
4 rows in set (0.00 sec)

```

Using EXPLAIN with the following aggregation statement, you can see that -  
↳ StreamAgg\_8 is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in StreamAgg\_16:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```

+--
↳ -----+-----+-----+-----+-----+
↳
| id | estRows | task | access object | operator
↳ info |
+--
↳ -----+-----+-----+-----+-----+
↳
| StreamAgg_16 | 1.00 | root | | funcs:count(
↳ Column#7)->Column#5 |
| -TableReader_17 | 1.00 | root | | data:
↳ StreamAgg_8 |
| -StreamAgg_8 | 1.00 | cop[tikv] | | funcs:count
↳ (1)->Column#7 |
| -TableFullScan_15 | 242020.00 | cop[tikv] | table:t1 | keep order:
↳ false |
+--

```

```

↪ -----+-----+-----+-----+
↪
4 rows in set (0.00 sec)

```

This is easiest to observe in `EXPLAIN ANALYZE`, where the `actRows` matches the number of Regions from `SHOW TABLE REGIONS` because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```

+--

↪
↪ | keep order:false | N/A | N/A |
+--
↪ -----+-----+-----+-----+
↪
4 rows in set (0.01 sec)

```

### 11.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the HashAgg operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```
+--
 ↪ -----+-----+-----+
 ↪
| id | estRows | task | access object | operator
 ↪ info |
+--
 ↪ -----+-----+-----+
 ↪
| HashAgg_9 | 1.00 | root | | funcs:count(
 ↪ Column#6)->Column#5 |
| -TableReader_10 | 1.00 | root | | data:
 ↪ HashAgg_5 |
| -HashAgg_5 | 1.00 | cop[tikv] | | funcs:count
 ↪ (1)->Column#6 |
| -TableFullScan_8 | 242020.00 | cop[tikv] | table:t1 | keep order:
 ↪ false |
+--
 ↪ -----+-----+-----+
 ↪
4 rows in set (0.00 sec)
```

The operator `info` shows that the hashing function used to aggregate the data is `funcs:count(1)->Column#6`.

### 11.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```
CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.11 sec)
```

```
Query OK, 5 rows affected (0.01 sec)
```

Records: 5 Duplicates: 0 Warnings: 0

```

+--
↪ -----+-----+-----+-----+
↪
| id | estRows | task | access object | operator
↪ info
↪ |
+--
↪ -----+-----+-----+
↪
| Projection_4 | 8000.00 | root | | test.t2.col1
↪ , Column#3
| -StreamAgg_8 | 8000.00 | root | | group by:
↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
↪ ->test.t2.col1 |
| -Sort_13 | 10000.00 | root | | test.t2.
↪ col1
↪
| -TableReader_12 | 10000.00 | root | | data:
↪ TableFullScan_11
↪
| -TableFullScan_11 | 10000.00 | cop[tikv] | table:t2 | keep order:
↪ false, stats:pseudo
↪ |
+--
↪ -----+-----+-----+
↪
5 rows in set (0.00 sec)

```

In this example, the `-Sort_13` operator can be eliminated by adding an index on `col1` `↪` . Once the index is added, the data can be read in order and the `-Sort_13` operator is eliminated:

```

ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /** STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;

```

Query OK, 0 rows affected (0.28 sec)

```

+--
↪ -----+-----+-----+
↪
| id | estRows | task | access object |
↪ operator info
↪

```

```

↪ |
+--
↪ -----+-----+-----+-----+
↪
| Projection_4 | 4.00 | root | |
↪ test.t2.col1, Column#3
↪
| -StreamAgg_14 | 4.00 | root | |
↪ group by:test.t2.col1, funcs:count(Column#4)->Column#3, funcs:
↪ firstrow(test.t2.col1)->test.t2.col1 |
| -IndexReader_15 | 4.00 | root | |
↪ index:StreamAgg_8
↪
| -StreamAgg_8 | 4.00 | cop[tikv] | |
↪ group by:test.t2.col1, funcs:count(1)->Column#4
↪
| -IndexFullScan_13 | 5.00 | cop[tikv] | table:t2, index:col1(col1
↪) | keep order:true, stats:pseudo
↪
+--
↪ -----+-----+-----+-----+
↪
5 rows in set (0.00 sec)

```

### 11.3.2.8 EXPLAIN Statements Using Views

EXPLAIN displays the tables and indexes that a **view** references, not the name of the view itself. This is because views are only virtual tables and do not store any data themselves. The definition of the view and the rest of the statement are merged together during SQL optimization.

From the **bikeshare example database**, you can see that the following two queries are executed in a similar manner:

```

ALTER TABLE trips ADD INDEX (duration);
CREATE OR REPLACE VIEW long_trips AS SELECT * FROM trips WHERE duration >
↪ 3600;
EXPLAIN SELECT * FROM long_trips;
EXPLAIN SELECT * FROM trips WHERE duration > 3600;

```

```

Query OK, 0 rows affected (2 min 10.11 sec)

```

```

Query OK, 0 rows affected (0.13 sec)

```

```

+--

```

```

↪ -----+-----+-----+-----+

```

```

↳
| id | estRows | task | access object
↳ | operator info |
+---
↳ -----+-----+-----+-----
↳
| IndexLookUp_12 | 6372547.67 | root |
↳ | | |
| -IndexRangeScan_10(Build) | 6372547.67 | cop[tikv] | table:trips, index:
↳ duration(duration) | range:(3600,+inf], keep order:false |
| -TableRowIDScan_11(Probe) | 6372547.67 | cop[tikv] | table:trips
↳ | keep order:false |
+---
↳ -----+-----+-----+-----
↳
3 rows in set (0.00 sec)

+---
↳ -----+-----+-----+-----
↳
| id | estRows | task | access object
↳ | operator info |
+---
↳ -----+-----+-----+-----
↳
| IndexLookUp_10 | 833219.37 | root |
↳ | | |
| -IndexRangeScan_8(Build) | 833219.37 | cop[tikv] | table:trips, index:
↳ duration(duration) | range:(3600,+inf], keep order:false |

| -Selection_6 | 43.00 | cop[tikv] | | eq(bikeshare.
↪ trips.bike_number, "W00950") |
| -TableFullScan_5 | 19117643.00 | cop[tikv] | table:trips | keep order
↪ :false |
+--
↪ -----+-----+-----+
↪
3 rows in set (0.00 sec)

```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself.

Consider the following composite index:

```
ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

Query OK, 0 rows affected (2 min 31.20 sec)

```
+--
↪ -----+-----+-----+
↪
| id | estRows | task | access object
↪ | | operator | info

↪ -----+-----+-----+
↪
| IndexLookUp_13 | 63725.48 | root |
↪ |
↪ |
| -IndexRangeScan_11(Build) | 63725.48 | cop[tikv] | table:trips, index:
↪ bike_number(bike_number, duration) | range:("W00950" 3600,"W00950" +
↪ inf], keep order:false |
| -TableRowIDScan_12(Probe) | 63725.48 | cop[tikv] | table:trips
↪ | keep order:false
↪ |
+--
```

```
↪ -----+-----+-----+
↪
3 rows in set (0.00 sec)
```

```
+--
↪ -----+-----+-----+
↪
| id | estRows | task | access object
↪ | | operator | info
↪ | | |
+--
↪ -----+-----+-----+
↪
| IndexLookUp_10 | 19117.64 | root |
↪ |
↪ |
| -IndexRangeScan_8(Build) | 19117.64 | cop[tikv] | table:trips, index:
↪ bike_number(bike_number, duration) | range:["W00950","W00950"], keep
```

```

↪ order:false |
| -TableRowIDScan_9(Probe) | 19117.64 | cop[tikv] | table:trips
↪ | keep order:false
↪ |
+---
↪ -----+-----+-----+
↪
3 rows in set (0.00 sec)

```

In the first statement, TiDB is able to use both parts of the composite index (↪ bike\_number, duration). In the second statement, only the first part which is bike\_number of the index (bike\_number, duration) is used.

### 11.3.2.9 Explain Statements Using Partitions

The EXPLAIN statement displays the partitions that TiDB needs to access in order to execute a query. Because of **partition pruning**, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of EXPLAIN.

The sample data used in this document:

```

CREATE TABLE t1 (
 id BIGINT NOT NULL auto_increment,
 d date NOT NULL,
 pad1 BLOB,
 pad2 BLOB,
 pad3 BLOB,
 PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
 PARTITION p2016 VALUES LESS THAN (2017),
 PARTITION p2017 VALUES LESS THAN (2018),
 PARTITION p2018 VALUES LESS THAN (2019),
 PARTITION p2019 VALUES LESS THAN (2020),
 PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES
('2016-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2016-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2016-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2017-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2017-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2017-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2018-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2018-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),

```

```

('2018-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2019-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2019-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2019-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2020-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2020-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2020-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024));

INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
 ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

SELECT SLEEP(1);
ANALYZE TABLE t1;

```

The following example shows a statement against the newly created partitioned table:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE d = '2017-06-01';
```

```

+--
 ↳ -----+-----+-----+-----+
 ↳
| id | estRows | task | access object |
 ↳ operator info |
+--
 ↳ -----+-----+-----+-----+

 ↳ funcs:count(Column#8)->Column#6 |
| -TableReader_22 | 1.00 | root | |
 ↳ data:StreamAgg_10 |
| -StreamAgg_10 | 1.00 | cop[tikv] | |
 ↳ funcs:count(1)->Column#8 |
| -Selection_20 | 8.87 | cop[tikv] | | eq
 ↳ (test.t1.d, 2017-06-01 00:00:00.000000) |
| -TableFullScan_19 | 8870.00 | cop[tikv] | table:t1, partition:
 ↳ p2017 | keep order:false |
+--
 ↳ -----+-----+-----+-----+
 ↳

```

```
5 rows in set (0.01 sec)
```

Starting from the inner-most ( `-TableFullScan_19` ) operator and working back towards the root operator ( `StreamAgg_21` ):

- TiDB successfully identified that only one partition ( `p2017` ) needed to be accessed. This is noted under `access object`.
- The partition itself was scanned in the operator `-TableFullScan_19` and then `-Selection_20` was applied to filter for rows that have a start date of `2017-06-01 00:00:00.000000`.
- The rows that match `-Selection_20` are then stream aggregated in the coprocessor, which natively understands the `count` function.
- Each coprocessor request then sends back one row to `-TableReader_22` inside TiDB, which is then stream aggregated under `StreamAgg_21` and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

27 rows in set (0.00 sec)

```

From the output above:

- TiDB believes that it needs to access all of the partitions (p2016..pMax). This is because the predicate `YEAR(d)= 2017` is considered `non-sargable`. This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.
- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `-PartitionUnion_21` unions the results from accessing each partition.

### 11.3.2.10 Explain Statements Using Index Merge

Index merge is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

Index merge in TiDB has two types: the intersection type and the union type. The former applies to the `AND` expression, while the latter applies to the `OR` expression. The union-type index merge is introduced in TiDB v4.0 as an experimental feature and has become GA in v5.4.0. The intersection type is introduced in TiDB v6.5.0, and can be used only when the `USE_INDEX_MERGE` hint is specified.

#### 11.3.2.10.1 Enable index merge

In v5.4.0 or a later TiDB version, index merge is enabled by default. In other situations, if index merge is not enabled, you need to set the variable `tidb_enable_index_merge` to `ON` to enable this feature.

```
SET session tidb_enable_index_merge = ON;
```

#### 11.3.2.10.2 Examples

```
CREATE TABLE t(a int, b int, c int, d int, INDEX idx_a(a), INDEX idx_b(b),
↪ INDEX idx_c(c), INDEX idx_d(d));
```

```
EXPLAIN SELECT /*+ NO_INDEX_MERGE() */ * FROM t WHERE a = 1 OR b = 1;
```

```
+--

 ↪ keep order:false, stats:pseudo |
+--
 ↪ -----+-----+-----+-----+
 ↪

```

In the preceding query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without index merge, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, index merge is introduced in TiDB to access tables.

For the preceding query, the optimizer chooses the union-type index merge to access the table. Index merge allows the optimizer to use multiple indexes per table, to merge the results returned by each index, and to generate the latter execution plan in the preceding output.

In the output, the `type: union` information in `operator info` of the `IndexMerge_8` `↪ operator` indicates that this operator is a union-type index merge. It has three child nodes. `IndexRangeScan_5` and `IndexRangeScan_6` scan the RowIDs that meet the condition according to the range, and then the `TableRowIDScan_7` operator accurately reads all the data that meets the condition according to these RowIDs.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan`/`TableRangeScan`, the operator info column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan`/`TableFullScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_13` operator indicates that the operator scans the data from 1 to positive infinity.

```
EXPLAIN SELECT /*+ NO_INDEX_MERGE() */ * FROM t WHERE a > 1 AND b > 1 AND c
 ↪ = 1; -- Does not use index merge

 ↳ | range:[1,1], keep order:false, stats:pseudo |
| -TableRowIDScan_8(Probe) | 1.11 | cop[tikv] | table:t |
 ↳ keep order:false, stats:pseudo |
+--
 ↳ -----+-----+-----+-----+
 ↳

```

From the preceding example, you can see that the filter condition is a **WHERE** clause that uses **AND** as the connector. Before index merge is enabled, the optimizer can only choose one of the three indexes (`idx_a`, `idx_b`, or `idx_c`).

If one of the filter conditions has a low selectivity, the optimizer directly chooses the corresponding index to achieve the ideal execution efficiency. However, if the data distribution meets all of the following three conditions, you can consider using the intersection-type index merge:

- The data size of the whole table is large, and directly reading the whole table is inefficient.
- For each one of the three filter conditions, the respective selectivity is very high, so the execution efficiency of `IndexLookup` using a single index is not ideal.
- The overall selectivity of the three filter conditions is low.

When using the intersection-type index merge to access tables, the optimizer can choose to use multiple indexes on a table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the preceding example output. The `type: intersection` information in the operator `info` of the `IndexMerge_9` operator indicates that this operator is an intersection-type index merge. The other parts of the execution plan are similar to the preceding union-type index merge example.

### Note:

- The Index Merge feature is enabled by default from v5.4.0. That is, `tidb_enable_index_merge` is ON.
- You can use the SQL hint `USE_INDEX_MERGE` to force the optimizer to apply Index Merge, regardless of the setting of `tidb_enable_index_merge` `↳ .` To enable Index Merge when the filtering conditions contain expressions that cannot be pushed down, you must use the SQL hint `USE_INDEX_MERGE`.

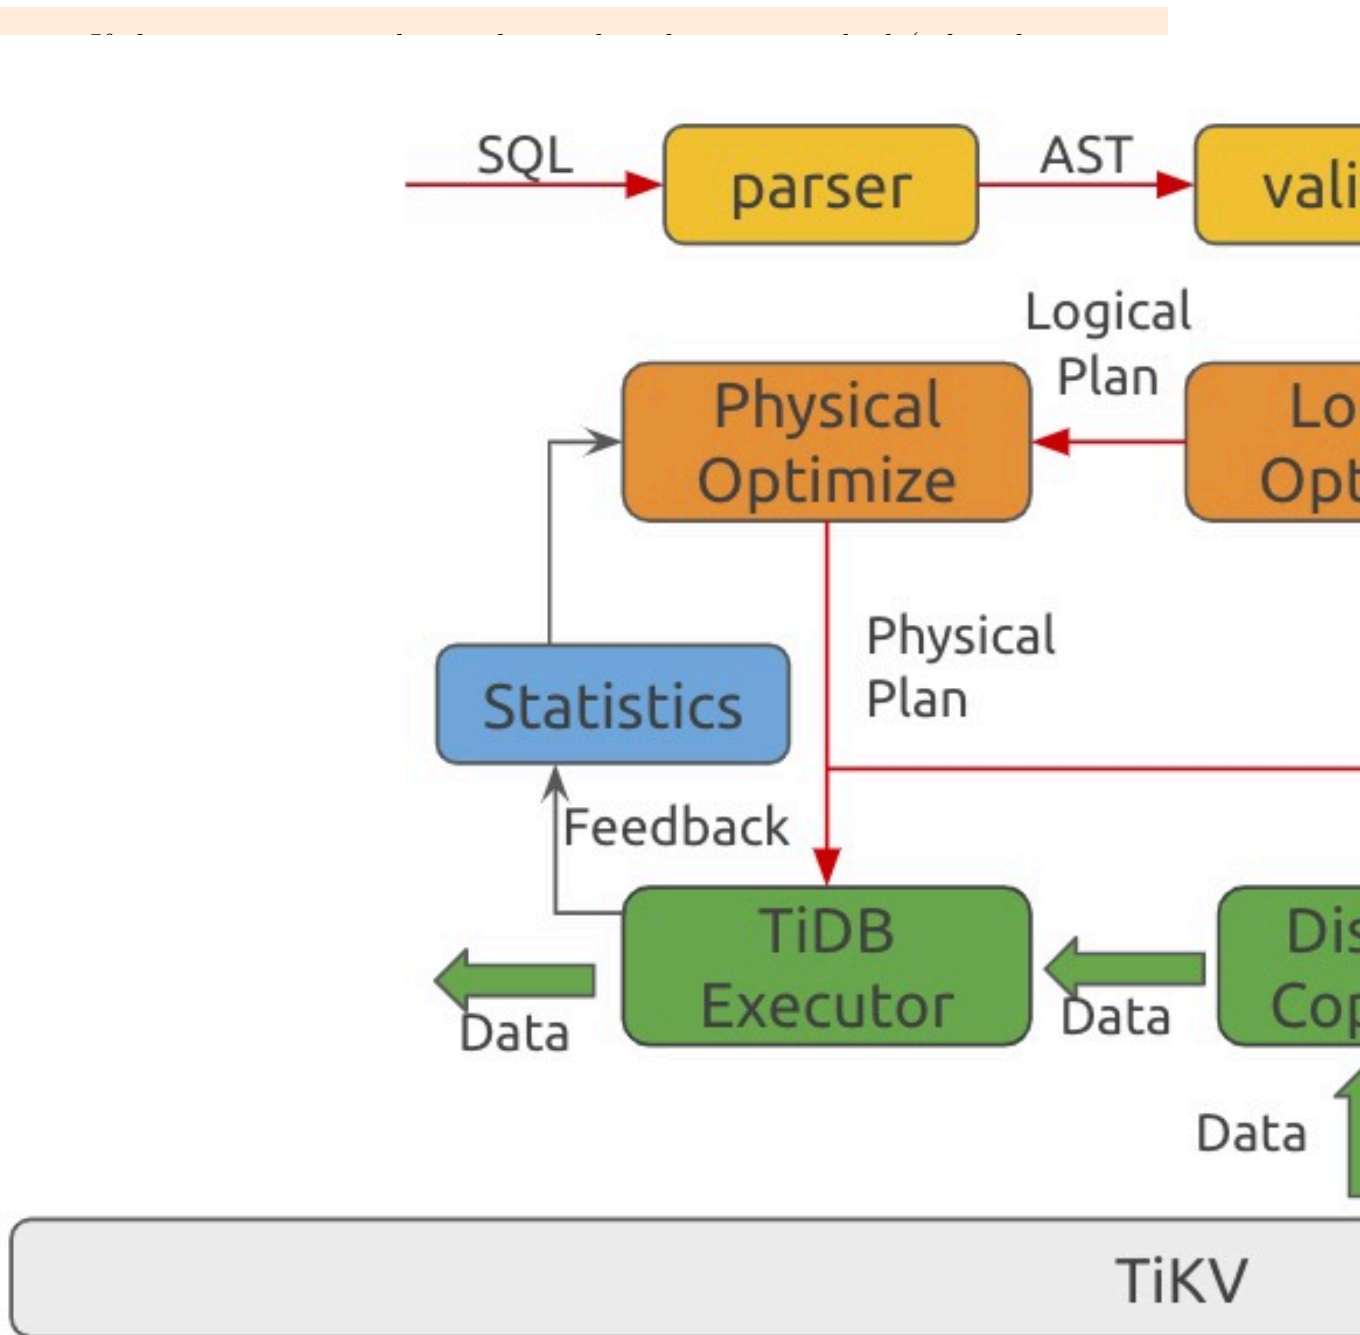

Figure 176: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see [SQL Logical Optimization](#).

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see [SQL Physical Optimization](#).

At the same time, when TiDB executes the [PREPARE](#) statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see [Execution Plan Cache](#).

### 11.3.3.2 Logic Optimization

#### 11.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the IN sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- [Subquery Related Optimizations](#)
- [Column Pruning](#)
- [Decorrelation of Correlated Subquery](#)
- [Eliminate Max/Min](#)
- [Predicates Push Down](#)
- [Partition Pruning](#)
- [TopN and Limit Operator Push Down](#)
- [Join Reorder](#)

#### 11.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- NOT IN (SELECT ... FROM ...)
- NOT EXISTS (SELECT ... FROM ...)
- IN (SELECT ... FROM ...)
- EXISTS (SELECT ... FROM ...)
- ... >/>=</<= / != (SELECT ... FROM ...)

Sometimes a subquery contains non-subquery columns, such as `select * from t where t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of

subquery is usually called a “correlated subquery”, and the externally introduced column is called a “correlated column”. For optimizations about correlated subquery, see [Decorrelation of correlated subquery](#). This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in [Understanding TiDB Execution Plan](#) as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

```
... < ALL (SELECT ... FROM ...) or ... > ANY (SELECT ... FROM ...)
```

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is `NULL`. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id) and if(sum(↔ s.id is null) != 0, null, true)`
- `t.id < any (select s.id from s)` is rewritten as `t.id < max(s.id) or if(sum(s↔ .id is null) != 0, null, false)`

```
... != ANY (SELECT ... FROM ...)
```

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id) as cnt_distinct↔ from s) where (t.id != s.id or cnt_distinct > 1)`

```
... = ALL (SELECT ... FROM ...)
```

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id) as cnt_distinct↔ from s) where (t.id = s.id and cnt_distinct <= 1)`

```
... IN (SELECT ... FROM ...)
```

In this case, the subquery of `IN` is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of `JOIN`.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2.↔ The form of a. The DISTINCT attribute here can be eliminated automatically if t2.a has the UNIQUE attribute.`

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```
+---
 ↪ -----+-----+-----+-----+

 ↪ range: decided by [test.t2.a], keep order:false, stats:pseudo
+---
 ↪ -----+-----+-----+-----+
 ↪
```

This rewrite gets better performance when the IN subquery is relatively small and the external query is relatively large, because without rewriting, using index join with t2 as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the t2 table is relatively large, this rewrite affects the performance of the query. Currently, the variable `tidb_opt_insubq_to_join_and_agg` is used to control this optimization. When this optimization is not suitable, you can manually disable it.

EXISTS subquery and ... >/>=</<=/<=/<= (SELECT ... FROM ...)

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the EXISTS subquery is evaluated to TRUE in the optimization stage in advance, so it does not show in the final execution result.

```
create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);
```

```

 ↪ stats:pseudo |
+--
 ↪ -----+-----+-----+-----+
 ↪

```

In the preceding optimization, the optimizer automatically optimizes the statement execution. In addition, you can also add the `SEMI_JOIN_REWRITE` hint to further rewrite the statement.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

### 11.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b > 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the `Selection` operator uses column

b. Then the `DataSource` operator uses columns a and column b. Columns c and column d can be pruned because the `DataSource` operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called “Column Pruning”, corresponding to the `columnPruner` rule. If you want to disable this rule, refer to [The Blocklist of Optimization Rules and Expression Pushdown](#).

#### 11.3.3.2.4 Decorrelation of Correlated Subquery

[Subquery related optimizations](#) describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

##### Introduction

Take `select * from t1 where t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition `t2.b=t1.b`, this condition happens to be an equivalent condition, so the query can be rewritten as `select t1.* from t1, (select b, sum(a)sum_a from t2 group by b)t2 where t1.b = t2.b and t1.a < t2.sum_a;`. In this way, a correlated subquery is rewritten into JOIN.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

##### Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, which might bring better execution performance. In this case, you can disable this optimization by using the `NO_DECORRELATE` optimizer hint or by disabling the “subquery decorrelation” optimization rule in the [blocklist of optimization rules and expression pushdown](#). In most cases, it is recommended to use the optimizer hint along with [SQL Plan Management](#) to disable the decorrelation.

##### Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
 ↪ = t1.b);
```

```

+--
 ↪ -----+-----+-----+-----+
 ↪
| id | estRows | task | access object |
 ↪ operator info
 ↪
+--
 ↪ -----+-----+-----+-----+
 ↪
| HashJoin_11 | 9990.00 | root | | inner
 ↪ join, equal:[eq(test.t1.b, test.t2.b)], other cond:lt(cast(test.t1.a
 ↪ , Column#7) |
| -HashAgg_23(Build) | 7992.00 | root | | group by
 ↪ :test.t2.b, funcs:sum(Column#8)->Column#7, funcs:firstrow(test.t2.b)
 ↪ ->test.t2.b |
| -TableReader_24 | 7992.00 | root | | data:
 ↪ HashAgg_16
 ↪
| -HashAgg_16 | 7992.00 | cop[tikv] | | group by
 ↪ :test.t2.b, funcs:sum(test.t2.a)->Column#8
 ↪
| -Selection_22 | 9990.00 | cop[tikv] | | not(
 ↪ isnull(test.t2.b))
 ↪
| -TableFullScan_21 | 10000.00 | cop[tikv] | table:t2 | keep
 ↪ order:false, stats:pseudo
 ↪
| -TableReader_15(Probe) | 9990.00 | root | | data:
 ↪ Selection_14
 ↪
| -Selection_14 | 9990.00 | cop[tikv] | | not(
 ↪ isnull(test.t1.b))
 ↪
| -TableFullScan_13 | 10000.00 | cop[tikv] | table:t1 | keep
 ↪ order:false, stats:pseudo
 ↪
+--
 ↪ -----+-----+-----+-----+
 ↪

```

The above is an example where the optimization takes effect. HashJoin\_11 is a normal inner join.

Then, you can use the NO\_DECORRELATE optimizer hint to tell the optimizer not to perform decorrelation for the subquery:

```
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
 ↪ t2.a) from t2 where t2.b = t1.b);
```

```
+--
 ↪ -----+-----+-----+
 ↪
| id | estRows | task | access object

 ↪ |
| -StreamAgg_20 | 10000.00 | root |
 ↪ | funcs:sum(Column#14)->Column#7
 ↪
 ↪ |
| -Projection_45 | 100000.00 | root |
 ↪ | cast(test.t2.a, decimal(10,0) BINARY)->Column
 ↪ #14
| -IndexLookUp_44 | 100000.00 | root |
 ↪
 ↪
 ↪ |
| -IndexRangeScan_42(Build) | 100000.00 | cop[tikv] | table:t2,
 ↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
 ↪ order:false, stats:pseudo |
| -TableRowIDScan_43(Probe) | 100000.00 | cop[tikv] | table:t2
 ↪ | keep order:false, stats:pseudo
 ↪
 ↪
```

```
+--
↪ -----+-----+-----+-----
↪
```

Disabling the decorrelation rule can also achieve the same effect:

```
insert into mysql.opt_rule_blacklist values("decorrelate");
admin reload opt_rule_blacklist;
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
↪ = t1.b);
```

```
+--
↪ -----+-----+-----+-----
↪
| id | estRows | task | access object
↪ | operator info
↪ |
+--
↪ -----+-----+-----+-----
↪
| Projection_10 | 10000.00 | root |
↪ | test.t1.a, test.t1.b
↪ |
| -Apply_12 | 10000.00 | root |
↪ | CARTESIAN inner join, other cond:lt(cast(test.
↪ t1.a, decimal(10,0) BINARY), Column#7) |

↪ | data:TableFullScan_13
↪ |
| -TableFullScan_13 | 10000.00 | cop[tikv] | table:t1
↪ | keep order:false, stats:pseudo
↪ |
| -MaxOneRow_15(Probe) | 10000.00 | root |
↪ |
↪ |
↪ |
| -StreamAgg_20 | 10000.00 | root |
↪ | funcs:sum(Column#14)->Column#7
↪ |
| -Projection_45 | 100000.00 | root |
↪ | cast(test.t2.a, decimal(10,0) BINARY)->Column
↪ #14
| -IndexLookUp_44 | 100000.00 | root |
↪ |
↪
```

```

↪ |
| - IndexRangeScan_42(Build) | 100000.00 | cop[tikv] | table:t2,
↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
↪ order:false, stats:pseudo |
| - TableRowIDScan_43(Probe) | 100000.00 | cop[tikv] | table:t2
↪ | keep order:false, stats:pseudo
↪
+---
↪ -----+-----+-----+-----+-----+-----+-----+-----+
↪

```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(test.t2.b, test.t1.b)]` in operator info of `IndexRangeScan_25(Build)`. It means that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

### 11.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max/min` functions, the query optimizer tries to convert the `max/min` aggregate functions to the `TopN` operator by applying the `max/min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max/min` functions in the `select` statement:

- The statement with only one `max/min` function
- The statement with multiple `max/min` functions

One `max/min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
↪ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+---+
| id | estRows | task | access object |
|---|---|---|---|
| StreamAgg_13 | 1.00 | root | |
| ↪ funcs:max(test.t.a)->Column#4 |
| -Limit_17 | 1.00 | root | |
| ↪ offset:0, count:1 |
| -IndexReader_27 | 1.00 | root | |
| ↪ index:Limit_26 |
| -Limit_26 | 1.00 | cop[tikv] |
| ↪ offset:0, count:1 |
| -IndexFullScan_25 | 1.00 | cop[tikv] | table:t, index:idx_a(a) |
| ↪ keep order:true, desc, stats:pseudo |
+---+
5 rows in set (0.00 sec)
```

### Multiple max/min functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max/min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
 (select max(a) as max_a from t) t1,
 (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max`  $\leftrightarrow$  /`min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
 (select max(a) as max_a from (select a from t where a is not null order
 \leftrightarrow by a desc limit 1) t) t1,
 (select min(a) as min_a from (select a from t where a is not null order
 \leftrightarrow by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+---+
 \leftrightarrow +-----+-----+-----+
 \leftrightarrow
| id | estRows | task | access object |
 \leftrightarrow operator info |
+---+
 \leftrightarrow +-----+-----+-----+
 \leftrightarrow
| Projection_17 | 1.00 | root | |
 \leftrightarrow minus(Column#4, Column#5)->Column#6 |
| -HashJoin_18 | 1.00 | root | |
 \leftrightarrow | CARTESIAN inner join |
| -StreamAgg_45(Build) | 1.00 | root | |
 \leftrightarrow | funcs:min(test.t.a)->Column#5 |
| -Limit_49 | 1.00 | root | |
 \leftrightarrow | offset:0, count:1 |
| -IndexReader_59 | 1.00 | root | |
 \leftrightarrow | index:Limit_58 |
| -Limit_58 | 1.00 | cop[tikv] | |
 \leftrightarrow | offset:0, count:1 |
| -IndexFullScan_57 | 1.00 | cop[tikv] | table:t, index:
 \leftrightarrow idx_a(a) | keep order:true, stats:pseudo |
| -StreamAgg_24(Probe) | 1.00 | root | |
 \leftrightarrow | funcs:max(test.t.a)->Column#4 |
| -Limit_28 | 1.00 | root | |
 \leftrightarrow | offset:0, count:1 |
```

```

| -IndexReader_38 | 1.00 | root |
↪ | index:Limit_37 | | |
| -Limit_37 | 1.00 | cop[tikv] |
↪ | offset:0, count:1 | | |
| -IndexFullScan_36 | 1.00 | cop[tikv] | table:t, index:
↪ idx_a(a) | keep order:true, desc, stats:pseudo |
+--
↪ -----+-----+-----+
↪
12 rows in set (0.01 sec)

```

### 11.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

#### Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```

create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
↪ -----+-----+-----+
↪
| id | estRows | task | access object | operator info
↪ | | | |
+--
↪ -----+-----+-----+
↪
| TableReader_7 | 3323.33 | root | | data:Selection_6
↪ | | | |
| -Selection_6 | 3323.33 | cop[tikv] | | lt(test.t.a, 1)
↪ | | | |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep order:false
↪ | | | | , stats:pseudo |
+--
↪ -----+-----+-----+
↪

```

```
3 rows in set (0.00 sec)
```

In this query, pushing down the predicate `a < 1` to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```
create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+---+
| id | estRows | task | access object | operator info |
+---+
| TableReader_7 | 3323.33 | root | | data:Selection_6 |
| -Selection_6 | 3323.33 | cop[tikv] | | lt(test.t.a, 1) |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep order:false, stats:pseudo |
+---+
| id | estRows | task | access object | operator info |
+---+
| HashJoin_8 | 4154.17 | root | | inner join, equal:[eq(test.t.a, test.s.a)] |
```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate `a < substring('123', 1, 1)` are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate `a < 1`. After that, TiDB can push `a < 1` down to TiKV.

Case 3: push predicates below join operator

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+---+
| id | estRows | task | access object | operator info |
+---+
| HashJoin_8 | 4154.17 | root | | inner join, equal:[eq(test.t.a, test.s.a)] |
```

```

| -TableReader_15(Build) | 3323.33 | root | | data:
| ↪ Selection_14 | | | |
| -Selection_14 | 3323.33 | cop[tikv] | | lt(test.s.a
| ↪ , 1) | | | |
| -TableFullScan_13 | 10000.00 | cop[tikv] | table:s | keep order:
| ↪ false, stats:pseudo | | | |
| -TableReader_12(Probe) | 3323.33 | root | | data:
| ↪ Selection_11 | | | |
| -Selection_11 | 3323.33 | cop[tikv] | | lt(test.t.a
| ↪ , 1) | | | |
| -TableFullScan_10 | 10000.00 | cop[tikv] | table:t | keep order:
| ↪ false, stats:pseudo | | | |
+--
| ↪ -----+-----+-----+-----+
| ↪
7 rows in set (0.00 sec)

```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the ON condition is `t.a = s.a`. The predicate `s.a < 1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```

create table t(id int primary key, a varchar(10) not null);
desc select * from t where truncate(a, " ") = '1';
+--
| ↪ -----+-----+-----+-----+
| ↪
| id | estRows | task | access object | operator info
| ↪ | | | |
+--
| ↪ -----+-----+-----+-----+
| ↪
| Selection_5 | 8000.00 | root | | eq(truncate(cast(
| ↪ test.t.a, double BINARY), 0), 1) |
| -TableReader_7 | 10000.00 | root | | data:
| ↪ TableFullScan_6 | |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t | keep order:false
| ↪ , stats:pseudo | |
+--
| ↪ -----+-----+-----+-----+
| ↪

```

In this query, there is a predicate `truncate(a, " ") = '1'`.

From the `explain` results, you can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `truncate`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```

create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+---
 ↪ -----+-----+-----+
 ↪
| id | estRows | task | access object | operator
 ↪ info
+---
 ↪ -----+-----+-----+
 ↪
| Selection_7 | 10000.00 | root | | isnull(test
 ↪ .s.a)
| -HashJoin_8 | 12500.00 | root | | left outer
 ↪ join, equal:[eq(test.t.a, test.s.a)] |
| -TableReader_13(Build) | 10000.00 | root | | data:
 ↪ TableFullScan_12
| -TableFullScan_12 | 10000.00 | cop[tikv] | table:s | keep order:
 ↪ false, stats:pseudo
| -TableReader_11(Probe) | 10000.00 | root | | data:
 ↪ TableFullScan_10
| -TableFullScan_10 | 10000.00 | cop[tikv] | table:t | keep order:
 ↪ false, stats:pseudo
+---
 ↪ -----+-----+-----+
 ↪
6 rows in set (0.00 sec)

```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with NULL values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```

create table t(id int primary key, a char);
set @a = 1;

```

```

explain select * from t where a < @a;
+---+
↪ -----+-----+-----+-----+
↪
| id | estRows | task | access object | operator info
↪ |
+---+
↪ -----+-----+-----+-----+
↪
| Selection_5 | 8000.00 | root | | lt(test.t.a,
↪ getvar("a")) |
| -TableReader_7 | 10000.00 | root | | data:
↪ TableFullScan_6 |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t | keep order:false
↪ , stats:pseudo |
+---+
↪ -----+-----+-----+-----+
↪
3 rows in set (0.00 sec)

```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with 1, and does not push down it to TiKV.

An example to help you understand is as follows:

```

create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+---+-----+-----+
| id | a | @a:=@a+1 |
+---+-----+-----+
| 1 | 1 | 2 |
| 2 | 2 | 3 |
+---+-----+-----+
2 rows in set (0.00 sec)

```

As you can see from this query, the value of `@a` will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

### 11.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (200),
 PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

### Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

#### Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
 ↪ -----+-----+-----+-----+
 ↪
| id | estRows | task | access object | operator
 ↪ info | | | |
+--
 ↪ -----+-----+-----+-----+
 ↪
| TableReader_8 | 10.00 | root | | data:
 ↪ Selection_7 | | | |
| -Selection_7 | 10.00 | cop[tikv] | | eq(test.t
 ↪ .x, 1) | | | |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t, partition:p1 |
 ↪ keep order:false, stats:pseudo |
+--
 ↪ -----+-----+-----+-----+
 ↪
```

In the SQL statement above, it can be known from the condition `x = 1` that all results fall in one partition. The value 1 can be confirmed to be in the `p1` partition after passing through the Hash partition. Therefore, only the `p1` partition needs to be scanned, and there is no need to access the `p2`, `p3`, and `p4` partitions that will not have matching results. From the execution plan, only one `TableFullScan` operator appears and the `p1` partition is specified in `access object`, so it can be confirmed that **partition pruning** takes effect.

#### Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

##### Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
 ↪ -----+-----+-----+-----+
 ↪
| id | estRows | task | access object |
 ↪ operator info |
+--
 ↪ -----+-----+-----+-----+
 ↪
| Union_10 | 13333.33 | root | |
 ↪ | | | |
| -TableReader_13 | 3333.33 | root | | data
 ↪ :Selection_12 | | | |
| -Selection_12 | 3333.33 | cop[tikv] | | gt(
 ↪ test.t.x, 2) | | | |
| -TableFullScan_11 | 10000.00 | cop[tikv] | table:t, partition:p0
 ↪ | keep order:false, stats:pseudo |
| -TableReader_16 | 3333.33 | root | | data
 ↪ :Selection_15 | | | |
| -Selection_15 | 3333.33 | cop[tikv] | | gt(
 ↪ test.t.x, 2) | | | |
| -TableFullScan_14 | 10000.00 | cop[tikv] | table:t, partition:p1
 ↪ | keep order:false, stats:pseudo |
| -TableReader_19 | 3333.33 | root | | data
 ↪ :Selection_18 | | | |
| -Selection_18 | 3333.33 | cop[tikv] | | gt(
 ↪ test.t.x, 2) | | | |
| -TableFullScan_17 | 10000.00 | cop[tikv] | table:t, partition:p2
 ↪ | keep order:false, stats:pseudo |
| -TableReader_22 | 3333.33 | root | | data
 ↪ :Selection_21 | | | |
| -Selection_21 | 3333.33 | cop[tikv] | | gt(
 ↪ test.t.x, 2) | | | |
| -TableFullScan_20 | 10000.00 | cop[tikv] | table:t, partition:p3
 ↪ | keep order:false, stats:pseudo |
+--
 ↪ -----+-----+-----+-----+
 ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the  $x > 2$  condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
 ↪ t2.x < 2);
```

```
+--
↪ -----+-----+-----+-----+
↪
| id | estRows | task | access object
↪ | operator info |
+--
↪ -----+-----+-----+-----+
↪
| Projection_13 | 9990.00 | root |
↪ | test.t2.x |
| -Apply_15 | 9990.00 | root |
↪ | inner join, equal:[eq(test.t2.x, test.t1.x)] |
| -TableReader_18(Build) | 9990.00 | root |
↪ | data:Selection_17 |
| -Selection_17 | 9990.00 | cop[tikv] |
↪ | not(isnull(test.t2.x)) |
| -TableFullScan_16 | 10000.00 | cop[tikv] | table:t2
↪ | keep order:false, stats:pseudo |
| -Selection_19(Probe) | 0.80 | root |
↪ | not(isnull(test.t1.x)) |
| -MaxOneRow_20 | 1.00 | root |
↪
| -Union_21 | 2.00 | root |
↪
| -TableReader_24 | 2.00 | root |
↪ | data:Selection_23 |
| -Selection_23 | 2.00 | cop[tikv] |
↪ | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
| -TableFullScan_22 | 2500.00 | cop[tikv] | table:t1,
↪ partition:p0 | keep order:false, stats:pseudo |
| -TableReader_27 | 2.00 | root |
↪ | data:Selection_26 |
| -Selection_26 | 2.00 | cop[tikv] |
↪ | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
| -TableFullScan_25 | 2500.00 | cop[tikv] | table:t1,
↪ partition:p1 | keep order:false, stats:pseudo |
+--
```

```
↪ -----+-----+-----+
↪
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```
create table t (x int) partition by range (x) (
 partition p0 values less than (5),
 partition p1 values less than (10),
 partition p2 values less than (15)
);
explain select * from t where x = 3;
```

```
+--
↪ -----+-----+-----+
↪
| id | estRows | task | access object | operator
↪ info | | | |
+--
↪ -----+-----+-----+
↪
| TableReader_8 | 10.00 | root | | data:
↪ Selection_7 | | | |
| -Selection_7 | 10.00 | cop[tikv] | | eq(test.t
↪ .x, 3) | | | |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t, partition:p0 |
↪ keep order:false, stats:pseudo |
+--
↪ -----+-----+-----+
↪
```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```

create table t (x int) partition by range (x) (
 partition p0 values less than (5),
 partition p1 values less than (10),
 partition p2 values less than (15)
);
explain select * from t where x in(1,13);

```

```

+--
 ↪ -----+-----+-----+-----+
 ↪
| id | estRows | task | access object |
 ↪ operator info | | | |
+--
 ↪ -----+-----+-----+-----+
 ↪
| Union_8 | 40.00 | root | |
 ↪ | | | |
| -TableReader_11 | 20.00 | root | | data:
 ↪ Selection_10 | | | |
| -Selection_10 | 20.00 | cop[tikv] | | in(
 ↪ test.t.x, 1, 13) | | | |
| -TableFullScan_9 | 10000.00 | cop[tikv] | table:t, partition:p0 |
 ↪ keep order:false, stats:pseudo | | | |
| -TableReader_14 | 20.00 | root | | data:
 ↪ Selection_13 | | | |
| -Selection_13 | 20.00 | cop[tikv] | | in(
 ↪ test.t.x, 1, 13) | | | |
| -TableFullScan_12 | 10000.00 | cop[tikv] | table:t, partition:p2 |
 ↪ keep order:false, stats:pseudo | | | |
+--
 ↪ -----+-----+-----+-----+
 ↪

```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

#### Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```

create table t (x int) partition by range (x) (
 partition p0 values less than (5),
 partition p1 values less than (10),

```

```

partition p2 values less than (15)
);
explain select * from t where x between 7 and 14;

```

```

+---
 ↪ -----+-----+-----+-----+
 ↪

 ↪ operator info |
+---
 ↪ -----+-----+-----+-----+
 ↪
| Union_8 | 500.00 | root | |
 ↪ |
| -TableReader_11 | 250.00 | root | | data:
 ↪ Selection_10 |
| -Selection_10 | 250.00 | cop[tikv] | | ge(
 ↪ test.t.x, 7), le(test.t.x, 14) |
| -TableFullScan_9 | 10000.00 | cop[tikv] | table:t, partition:p1 |
 ↪ keep order:false, stats:pseudo |
| -TableReader_14 | 250.00 | root | | data:
 ↪ Selection_13 |
| -Selection_13 | 250.00 | cop[tikv] | | ge(
 ↪ test.t.x, 7), le(test.t.x, 14) |
| -TableFullScan_12 | 10000.00 | cop[tikv] | table:t, partition:p2 |
 ↪ keep order:false, stats:pseudo |
+---
 ↪ -----+-----+-----+-----+
 ↪

```

### Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of  $fn(col)$ , the query condition is one of  $>$ ,  $<$ ,  $=$ ,  $>=$ , and  $<=$ , and the  $fn$  function is monotonous.

If the  $fn$  function is monotonous, for any  $x$  and  $y$ , if  $x > y$ , then  $fn(x) > fn(y)$ . Then this  $fn$  function can be called strictly monotonous. For any  $x$  and  $y$ , if  $x > y$ , then  $fn(x) >= fn(y)$ . In this case,  $fn$  could also be called “monotonous”. Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

- `UNIX_TIMESTAMP()`
- `TO_DAYS()`

For example, partition pruning takes effect when the partition expression is in the form of  $fn(col)$ , where the  $fn$  is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
 partition p0 values less than (to_days('2020-04-01')),
 partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```
+--
 ↪ -----+-----+-----+
 ↪

| -Selection_7 | 3333.33 | cop[tikv] | | gt(test.t
 ↪ .id, 2020-04-18 00:00:00.000000) |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t, partition:p1 |
 ↪ keep order:false, stats:pseudo |
+--
 ↪ -----+-----+-----+
 ↪
```

### Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
 partition p0 values less than (5),
 partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
 ↪ t2.x < 2);
```

```
+--
 ↪ -----+-----+-----+
 ↪
| id | estRows | task | access object |
 ↪ | operator info |
+--
 ↪ -----+-----+-----+
 ↪
```

```

| Projection_13 | 9990.00 | root |
| ↪ | test.t2.x
| ↪ |
| -Apply_15 | 9990.00 | root |
| ↪ | CARTESIAN inner join, other cond:lt(test.t2.x,
| ↪ test.t1.x) |
| -TableReader_18(Build) | 9990.00 | root |
| ↪ | data:Selection_17
| ↪ |
| -Selection_17 | 9990.00 | cop[tikv] |
| ↪ | not(isnull(test.t2.x))
| ↪ |
| -TableFullScan_16 | 10000.00 | cop[tikv] | table:t2
| ↪ | keep order:false, stats:pseudo
| -Selection_19(Probe) | 0.80 | root |
| ↪ | not(isnull(test.t1.x))
| ↪ |
| -MaxOneRow_20 | 1.00 | root |
| ↪ |
| ↪ |
| -Union_21 | 2.00 | root |
| ↪ |
| ↪ |
| -TableReader_24 | 2.00 | root |
| ↪ | data:Selection_23
| ↪ |
| -Selection_23 | 2.00 | cop[tikv] |
| ↪ | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
| ↪ |
| -TableFullScan_22 | 2.50 | cop[tikv] | table:t1,
| ↪ partition:p0 | keep order:false, stats:pseudo
| -TableReader_27 | 2.00 | root |
| ↪ | data:Selection_26
| ↪ |
| -Selection_26 | 2.00 | cop[tikv] |
| ↪ | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
| ↪ |
| -TableFullScan_25 | 2.50 | cop[tikv] | table:t1,
| ↪ partition:p1 | keep order:false, stats:pseudo
+--
| ↪ -----+-----+-----+
| ↪
14 rows in set (0.00 sec)

```

Each time this query reads a row from t2, it will query on the t1 partitioned table.

Theoretically, the `t1.x > val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

### 11.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to [Optimization Rules and Blocklist for Expression Pushdown](#).

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```
+-----+-----+-----+-----+
| id | estRows | task | access object | operator |
| info | | | | |
+-----+-----+-----+-----+
| TopN_7 | 10.00 | root | | test.t.a, |
| offset:0, count:10 | | | | |
| -TableReader_15 | 10.00 | root | | data:TopN_14 |
| | | | | |
| -TopN_14 | 10.00 | cop[tikv] | | test.t.a, |
| offset:0, count:10 | | | | |
| -TableFullScan_13 | 10000.00 | cop[tikv] | table:t | keep order: |
| false, stats:pseudo | | | | |
+-----+-----+-----+-----+
| | | | |
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+-----+-----+-----+-----+
 ↪
| id | estRows | task | access object |
 ↪ operator info |
+-----+-----+-----+-----+
 ↪
| TopN_12 | 10.00 | root | | test.t.a,
 ↪ offset:0, count:10 |
| -HashJoin_17 | 12.50 | root | | left
 ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
| -TopN_18(Build) | 10.00 | root | | test.t.a
 ↪ , offset:0, count:10 |
| -TableReader_26 | 10.00 | root | | data:
 ↪ TopN_25 |
| -TopN_25 | 10.00 | cop[tikv] | | test.t.a
 ↪ , offset:0, count:10 |
| -TableFullScan_24 | 10000.00 | cop[tikv] | table:t | keep
 ↪ order:false, stats:pseudo |
| -TableReader_30(Probe) | 10000.00 | root | | data:
 ↪ TableFullScan_29 |
| -TableFullScan_29 | 10000.00 | cop[tikv] | table:s | keep
 ↪ order:false, stats:pseudo |
+-----+-----+-----+-----+
 ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+-----+-----+-----+-----+
 ↪
```

```

| id | estRows | task | access object | operator
↳ info
+-----+-----+-----+-----+-----+
↳
| TopN_12 | 10.00 | root | | test.t.id,
↳ offset:0, count:10
| -HashJoin_16 | 12500.00 | root | | inner join,
↳ equal:[eq(test.t.a, test.s.a)] |
| -TableReader_21(Build) | 10000.00 | root | | data:
↳ TableFullScan_20
| -TableFullScan_20 | 10000.00 | cop[tikv] | table:s | keep order:
↳ false, stats:pseudo
| -TableReader_19(Probe) | 10000.00 | root | | data:
↳ TableFullScan_18
| -TableFullScan_18 | 10000.00 | cop[tikv] | table:t | keep order:
↳ false, stats:pseudo
+-----+-----+-----+-----+-----+
↳
6 rows in set (0.00 sec)

```

TopN cannot be pushed down before Inner Join. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```

create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;

```

```

+-----+-----+-----+-----+-----+
↳
| id | estRows | task | access object |
↳ operator info
+-----+-----+-----+-----+-----+
↳
| TopN_12 | 10.00 | root | | test.t.id
↳ , offset:0, count:10
| -HashJoin_17 | 12.50 | root | | left
↳ outer join, equal:[eq(test.t.a, test.s.a)] |

```

	-Limit_21(Build)	10.00	root		offset
	↪ :0, count:10				
	-TableReader_31	10.00	root		data:
	↪ Limit_30				
	-Limit_30	10.00	cop[tikv]		offset
	↪ :0, count:10				
	-TableFullScan_29	10.00	cop[tikv]	table:t	keep
	↪ order:true, stats:pseudo				
	-TableReader_35(Probe)	10000.00	root		data:
	↪ TableFullScan_34				
	-TableFullScan_34	10000.00	cop[tikv]	table:s	keep
	↪ order:false, stats:pseudo				
+-----+-----+-----+-----+					
	↪				
8 rows in set (0.00 sec)					

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t` ↪ `.id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

### 11.3.3.2.9 Introduction to Join Reorder

In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1

As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, the following two Join Reorder algorithms are used in TiDB:

- The greedy algorithm: among all nodes participating in the join, TiDB selects the table with the least rows to estimate its join result with each of the other tables respectively, and then selects the pair with the smallest join result. After that, TiDB continues the similar process to select and join other nodes for the next round, until all the nodes have completed the join.

- The dynamic programming algorithm: among all nodes participating in the join, TiDB enumerates all possible join orders and selects the optimal join order.

Example: the greedy algorithm of Join Reorder

Take the preceding three tables (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

Figure 177: join-reorder-1

After that, the table with the least rows is selected and joined with other two tables respectively. By comparing the sizes of the output result sets, TiDB selects the pair with a smaller result set.

Figure 178: join-reorder-2

Then TiDB enters the next round of selection. If you try to join four tables, TiDB continues to compare the sizes of the output result sets and selects the pair with a smaller result set.

In this case only three tables are joined, so TiDB gets the final join result.

Figure 179: join-reorder-3

Example: the dynamic programming algorithm of Join Reorder

Taking the preceding three tables (t1, t2, and t3) as an example again, the dynamic programming algorithm can enumerate all possibilities. Therefore, comparing with the greedy algorithm, which must start with the t1 table (the table with the least rows), the dynamic programming algorithm can enumerate a join order as follows:

Figure 180: join-reorder-4

When this choice is better than the greedy algorithm, the dynamic programming algorithm can choose a better join order.

Because all possibilities are enumerated, the dynamic programming algorithm consumes more time and is more susceptible to statistics.

#### Selection of the Join Reorder algorithms

The selection of the TiDB Join Reorder algorithms is controlled by the `tidb_opt_join_reorder_thres` variable. If the number of nodes participating in Join Reorder is greater than this threshold, TiDB uses the greedy algorithm. Otherwise, TiDB uses the dynamic programming algorithm.

#### Limitations of Join Reorder algorithms

The current Join Reorder algorithms have the following limitations:

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.
- The Join Reorder algorithm's support for Outer Join is controlled by the `tidb_enable_outer_join_reorder` system variable.
- Currently, the dynamic programming algorithm cannot perform Join Reorder for outer join.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to [Description of the syntax elements](#).

### 11.3.3.3 Physical Optimization

#### 11.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

[Understand the Query Execution Plan](#) has introduced some physical operators. This chapter focuses on the following aspects:

- In [Index Selection](#), you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In [Introduction to Statistics](#), you will learn what statistics TiDB collects to obtain the data distribution of a table.
- [Wrong Index Solution](#) introduces how to use the right index when you find the index is selected wrongly.
- [Distinct Optimization](#) introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.
- [Cost Model](#) introduces how to choose a optimal execution plan based on the cost model during physical optimization.

#### 11.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

## Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

### Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / Batch-PointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	This TableReader operator is for TiKV. It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the <code>_tidb_rowid</code> column, or if there are no other opera-

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	This TableReader operator is for TiFlash. TiFlash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookupReader	A Reader has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as In-dexReader.	Since the <code>index</code> does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the In-dexReader operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexMerge	A table has multiple indexes or a multi-valued index.	When a multi-valued index or multiple indexes are used.	To use the operator, you can specify the <a href="#">optimizer hints</a> , or let the optimizer to automatically select this operator based on cost estimation. For details, see <a href="#">Explain Statements Using Index Merge</a> .

**Note:**

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection of an operator for accessing tables.

## Index selection rules

TiDB selects indexes based on rules or cost. The based rules include pre-rules and skyline-pruning. When selecting an index, TiDB tries the pre-rule first. If an index satisfies a pre-rule, TiDB directly selects this index. Otherwise, TiDB uses skyline-pruning to exclude unsuitable indexes, and then selects the index with the lowest cost based on the cost estimation of each operator that accesses tables.

## Rule-based selection

## Pre-rules

TiDB uses the following heuristic pre-rules to select indexes:

- Rule 1: If an index satisfies “unique index with full match + no need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)”, TiDB directly selects this index.
- Rule 2: If an index satisfies “unique index with full match + the need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)”, TiDB selects the index with the smallest number of rows to be retrieved from a table as a candidate index.
- Rule 3: If an index satisfies “ordinary index + no need to retrieve rows from a table + the number of rows to be read is less than the value of a certain threshold”, TiDB selects the index with the smallest number of rows to be read as a candidate index.
- Rule 4: If only one candidate index is selected based on rule 2 and 3, select this candidate index. If two candidate indexes are respectively selected based on rule 2 and 3, select the index with the smaller number of rows to be read (the number of rows with index + the number of rows to be retrieved from a table).

The “index with full match” in the above rules means each indexed column has the equal condition. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if the pre-rules match an index, TiDB outputs a NOTE-level warning indicating that the index matches the pre-rule.

In the following example, because the index `idx_b` meets the condition “unique index with full match + the need to retrieve rows from a table” in rule 2, TiDB selects the index `idx_b` as the access path, and `SHOW WARNING` returns a note indicating that the index `idx_b` matches the pre-rule.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, UNIQUE INDEX idx_b(b
 ↪));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT b, c FROM t WHERE b = 3 OR b = 6;

1 row in set (0.00 sec)
```

### Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes, which can reduce the probability of wrong index selection caused by wrong estimation. To judge an index, the following three dimensions are needed:

- How many access conditions are covered by the indexed columns. An “access condition” is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.

- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or IndexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do. If both indexes need TiDB to retrieve rows from the table, compare how many filtering conditions are covered by the indexed columns. Filtering conditions mean the `where` condition that can be judged based on the index. If the column set of an index covers more access conditions, the smaller the number of retrieved rows from a table, and the better the index is in this dimension.
- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.

For these three dimensions above, if the index `idx_a` performs no worse than the index `idx_b` in all three dimensions and performs better than `idx_b` in one dimension, then `idx_a` is preferred. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if skyline-pruning excludes some indexes, TiDB outputs a NOTE-level warning listing the remaining indexes after the skyline-pruning exclusion.

In the following example, the indexes `idx_b` and `idx_e` are both inferior to `idx_b_c`, so they are excluded by skyline-pruning. The returned result of `SHOW WARNING` displays the remaining indexes after skyline-pruning.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, d INT, e INT, INDEX
 ↪ idx_b(b), INDEX idx_b_c(b, c), INDEX idx_e(e));
Query OK, 0 rows affected (0.01 sec)

### Cost estimation-based selection

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

### Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

This is usually due to stale or inaccurate statistics. You can re-execute the `analyze` ↪ `table` statement or modify the parameters of the `analyze table` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

- The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

#### Control index selection

The index selection can be controlled by a single query through [Optimizer Hints](#).

- `USE_INDEX` / `IGNORE_INDEX` can force the optimizer to use / not use certain indexes. `FORCE_INDEX` and `USE_INDEX` have the same effect.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

#### Use a multi-valued index

##### **Warning:**

For the current version, this feature is still experimental and it is not recommended to use it in a production environment.

[Multi-value indexes](#) are different from normal indexes. TiDB currently only uses [IndexMerge](#) to access multi-valued indexes. Therefore, to use multi-valued indexes for data access, make sure that the value of the system variable `tidb_enable_index_merge` is set to `ON`.

Currently, TiDB supports accessing multi-valued indexes using `IndexMerge` that is automatically converted from `json_member_of`, `json_contains`, and `json_overlaps` conditions. You can either rely on the optimizer to automatically select `IndexMerge` based on cost, or specify the selection of multi-valued indexes through the optimizer hint `use_index_merge` or `use_index`. See the following examples:

```
mysql> CREATE TABLE t1 (j JSON, INDEX idx((CAST(j->'$.path' AS SIGNED ARRAY
 ↳)))); -- Uses '$.path' as the path to create a multi-valued index
Query OK, 0 rows affected (0.04 sec)

mysql> EXPLAIN SELECT /*+ use_index_merge(t1, idx) */ * FROM t1 WHERE (1
 ↳ MEMBER OF (j->'$.path'));

6 rows in set, 1 warning (0.00 sec)

```

For OR conditions composed of multiple member of expressions, IndexMerge can be used to access the multi-valued index:

```

mysql> CREATE TABLE t3 (a INT, j JSON, INDEX idx(a, (CAST(j AS SIGNED ARRAY
↳))));
Query OK, 0 rows affected (0.04 sec)

mysql> EXPLAIN SELECT /* use_index_merge(t3, idx) */ * FROM t3 WHERE ((a=1
↳ AND (1 member of (j)))) OR ((a=2 AND (2 member of (j))));
+--
↳ -----+-----+-----+
↳
| id | estRows | task | access object
↳ | operator info
↳ |
+--
↳ -----+-----+-----+
↳
| Selection_5 | 0.08 | root |
↳ | or(and(eq(test.t3.a, 1),
↳ json_memberof(cast(1, json BINARY), test.t3.j)), and(eq(test.t3.a,
↳ 2), json_memberof(cast(2, json BINARY), test.t3.j))) |
| -IndexMerge_9 | 0.10 | root |
↳ | type: union
↳
↳ |
| -IndexRangeScan_6(Build) | 0.10 | cop[tikv] | table:t3, index:idx(a,
↳ cast(`j` as signed array)) | range:[1 1,1 1], keep order:false,
↳ stats:pseudo
↳
↳ |

```

```

| -IndexRangeScan_7(Build) | 0.10 | cop[tikv] | table:t3, index:idx(a,
↳ cast(`j` as signed array)) | range:[2 2,2 2], keep order:false,
↳ stats:pseudo
↳
↳ |
| -TableRowIDScan_8(Probe) | 0.10 | cop[tikv] | table:t3
↳ | keep order:false, stats:pseudo
↳
↳ |
+--
↳ -----+-----+-----+
↳

```

The following are some scenarios that are not yet supported.

```

mysql> CREATE TABLE t4 (j JSON, INDEX idx((CAST(j AS SIGNED ARRAY))));
Query OK, 0 rows affected (0.04 sec)

-- If a query contains the OR condition composed of multiple json_contains
↳ expressions, the index cannot be accessed using IndexMerge.
mysql> EXPLAIN SELECT /*+ use_index_merge(t3, idx) */ * FROM t3 WHERE (

Limited by the current implementation of multi-valued index, using `use_index` might return the `Can't find a proper physical plan for this query` error while using `use_index_merge` will not return such an error. Therefore, it is recommended to use `use_index_merge` if you want to use the multi-valued index.

```

### 11.3.3.3 Introduction to Statistics

TiDB uses statistics to decide **which index to choose**.

Versions of statistics

The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`.

- For TiDB Self-Hosted, the default value of this variable is 1 before v5.1.0. In v5.3.0 and later versions, the default value of this variable is 2. If your cluster is upgraded from a version earlier than v5.3.0 to v5.3.0 or later, the default value of `tidb_analyze_version` does not change.
- For TiDB Cloud, the default value of this variable is 1.

Compared to Version 1, Version 2 statistics avoids the potential inaccuracy caused by hash collision when the data volume is huge. It also maintains the estimate precision in most scenarios.

These two versions include different information in TiDB:

Information	Version	
	1	2
The total number of rows in the table	√	√
Column Count-Min Sketch Index	√	×
Column Count-Min Sketch	√	×
Top-N	√	(Maintenance methods and precision are improved)

	Version 1	Version 2
Index	✓	✓
Top-N	(Insufficient maintenance and precision might cause inaccuracy)	(Main methods and precision are improved)
Column histogram	✓	(The histogram does not include Top-N values.)

Information	Version 1	Version 2
Index	√	√
his-togram		(The his-togram buckets record the number of different values in each bucket, and the his-togram does not include Top-N values.)
The number of NULL $\leftrightarrow$ s in the column	√	√

	Version 1	Version 2
The number of NULL values in the index	√	√
The average length of columns	√	√
The average length of indexes	√	√

When `tidb_analyze_version = 2`, if memory overflow occurs after `ANALYZE` is executed, you need to set `tidb_analyze_version = 1` to fall back to Version 1, and perform one of the following operations:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
sql SELECT DISTINCT(CONCAT('ANALYZE TABLE ', table_schema, '.', table_name
↪ , ';'))FROM information_schema.tables, mysql.stats_histograms WHERE
↪ stats_ver = 2 AND table_id = tidb_table_id;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
sql SELECT DISTINCT(CONCAT('DROP STATS ', table_schema, '.', table_name
↪ , ';'))FROM information_schema.tables, mysql.stats_histograms WHERE
↪ stats_ver = 2 AND table_id = tidb_table_id;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
sql SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt'; mysql -h ${TiDB_IP
↪ } -u user -P ${TiDB_PORT} ... < '/tmp/sql.txt'
```

This document briefly introduces the histogram, Count-Min Sketch, and Top-N, and details the collection and maintenance of statistics.

## Histogram

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here “equal-depth” means that the number of values falling into each bucket is as equal as possible. For example, for a given set {1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5}, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

Figure 181: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to [Manual Collection](#). When the number of buckets is larger, the accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage

of memory resources. You can adjust this number appropriately according to the actual scenario.

### Count-Min Sketch

Count-Min Sketch is a hash structure. When an equivalence query contains `a = 1` or `IN` query (for example, `a in (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see [Full Collection](#).
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see [Full Collection](#).

### Top-N values

Top-N values are values with the top N occurrences in a column or index. TiDB records the values and occurrences of Top-N values.

### Collect statistics

#### Manual collection

You can run the `ANALYZE` statement to collect statistics.

#### **Note:**

The execution time of `ANALYZE TABLE` in TiDB is longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while in TiDB a comprehensive set of statistics is completely rebuilt. Scripts that were written for MySQL may naively expect `ANALYZE TABLE` will be a short-lived operation.

For quicker analysis, you can set `tidb_enable_fast_analyze` to 1 to enable the Quick Analysis feature. The default value for this parameter is 0.

After Quick Analysis is enabled, TiDB randomly samples approximately 10,000 rows of data to build statistics. Therefore, in the case of uneven data distribution or a relatively small amount of data, the accuracy of statistical information is relatively poor. It might lead to poor execution plans, such as choosing the wrong index. If the execution time of the normal `ANALYZE`  $\leftrightarrow$  statement is acceptable, it is recommended to disable the Quick Analysis feature.

`tidb_enable_fast_analyze` is an experimental feature, which currently **does not match exactly** with the statistical information of `tidb_analyze_version=2`. Therefore, you need to set the value of `tidb_analyze_version` to 1 when `tidb_enable_fast_analyze` is enabled.

## Full collection

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|
 \leftrightarrow CMSKETCH WIDTH] |[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated TOPNs.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- `WITH FLOAT_NUM SAMPLERATE` specifies the sampling rate.

`WITH NUM SAMPLES` and `WITH FLOAT_NUM SAMPLERATE` correspond to two different algorithms of collecting samples.

- `WITH NUM SAMPLES` specifies the size of the sampling set, which is implemented in the reservoir sampling method in TiDB. When a table is large, it is not recommended to use this method to collect statistics. Because the intermediate result set of the reservoir sampling contains redundant results, it causes additional pressure on resources such as memory.

- `WITH FLOAT_NUM SAMPLERATE` is a sampling method introduced in v5.3.0. With the value range `(0, 1]`, this parameter specifies the sampling rate. It is implemented in the way of Bernoulli sampling in TiDB, which is more suitable for sampling larger tables and performs better in collection efficiency and resource usage.

Before v5.3.0, TiDB uses the reservoir sampling method to collect statistics. Since v5.3.0, the TiDB Version 2 statistics uses the Bernoulli sampling method to collect statistics by default. To re-use the reservoir sampling method, you can use the `WITH NUM SAMPLES` statement.

The current sampling rate is calculated based on an adaptive algorithm. When you can observe the number of rows in a table using `SHOW STATS_META`, you can use this number of rows to calculate the sampling rate corresponding to 100,000 rows. If you cannot observe this number, you can use the `TABLE_KEYS` column in the `TABLE_STORAGE_STATS` table as another reference to calculate the sampling rate.

**Note:**

Normally, `STATS_META` is more credible than `TABLE_KEYS`. However, after importing data through the methods like [TiDB Lightning](#), the result of `STATS_META` is 0. To handle this situation, you can use `TABLE_KEYS` to calculate the sampling rate when the result of `STATS_META` is much smaller than the result of `TABLE_KEYS`.

### Collect statistics on some columns

In most cases, when executing SQL statements, the optimizer only uses statistics on some columns (such as columns in the `WHERE`, `JOIN`, `ORDER BY`, and `GROUP BY` statements). These columns are called `PREDICATE COLUMNS`.

If a table has many columns, collecting statistics on all the columns can cause a large overhead. To reduce the overhead, you can collect statistics on only specific columns or `PREDICATE COLUMNS` to be used by the optimizer.

**Note:**

Collecting statistics on some columns is only applicable for `tidb_analyze_version = 2`.

- To collect statistics on specific columns, use the following syntax:

```
ANALYZE TABLE TableName COLUMNS ColumnNameList [WITH NUM BUCKETS|TOPN|
↳ CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM
↳ SAMPLERATE] ;
```

In the syntax, `ColumnNameList` specifies the name list of the target columns. If you need to specify more than one column, use comma `,` to separate the column names. For example, `ANALYZE table t columns a, b`. Besides collecting statistics on the specific columns in a specific table, this syntax collects statistics on the indexed columns and all indexes in that table at the same time.

**Note:**

The syntax above is a full collection. For example, after collecting statistics on columns `a` and `b` using this syntax, if you also want to collect statistics on column `c`, you need to specify all three columns using `ANALYZE`  
↳ `table t columns a, b, c`, rather than only specifying the additional column `c` using `ANALYZE TABLE t COLUMNS c`.

- To collect statistics on `PREDICATE COLUMNS`, do the following:

**Warning:**

Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

1. Set the value of the `tidb_enable_column_tracking` system variable to `ON` to enable TiDB to collect `PREDICATE COLUMNS`.  
After the setting, TiDB writes the `PREDICATE COLUMNS` information to the `mysql`  
↳ `.column_stats_usage` system table every `100 * stats-lease`.
2. After the query pattern of your business is relatively stable, collect statistics on `PREDICATE COLUMNS` by using the following syntax:

```
ANALYZE TABLE TableName PREDICATE COLUMNS [WITH NUM BUCKETS|TOPN|
↳ CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH
↳ FLOATNUM SAMPLERATE] ;
```

Besides collecting statistics on `PREDICATE COLUMNS` in a specific table, this syntax collects statistics on indexed columns and all indexes in that table at the same time.

**Note:**

- If the `mysql.column_stats_usage` system table does not contain any `PREDICATE COLUMNS` record for that table, the preceding syntax collects statistics on all columns and all indexes in that table.
- After using this syntax to collect statistics, when executing a new type of SQL query, the optimizer might temporarily use the old or pseudo column statistics for this time, and TiDB will collect the statistics on the used columns from the next time.

- To collect statistics on all columns and indexes, use the following syntax:

```
ANALYZE TABLE TableName ALL COLUMNS [WITH NUM BUCKETS|TOPN|CMSKETCH
↪ DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE
↪];
```

If you want to persist the column configuration in the `ANALYZE` statement (including `COLUMNS ColumnNameList`, `PREDICATE COLUMNS`, and `ALL COLUMNS`), set the value of the `tidb_persist_analyze_options` system variable to `ON` to enable the [ANALYZE configuration persistence](#) feature. After enabling the `ANALYZE` configuration persistence feature:

- When TiDB collects statistics automatically or when you manually collect statistics by executing the `ANALYZE` statement without specifying the column configuration, TiDB continues using the previously persisted configuration for statistics collection.
- When you manually execute the `ANALYZE` statement multiple times with column configuration specified, TiDB overwrites the previously recorded persistent configuration using the new configuration specified by the latest `ANALYZE` statement.

To locate `PREDICATE COLUMNS` and columns on which statistics have been collected, use the following syntax:

```
SHOW COLUMN_STATS_USAGE [ShowLikeOrWhere];
```

The `SHOW COLUMN_STATS_USAGE` statement returns the following 6 columns:

Column name	Description
<code>Db_name</code>	The database name
<code>Table_name</code>	The table name
<code>↪ Partition_name</code>	The partition name

Column name	Description
Column_name	The column name
Last_used_at	The last time when the column statistics were used in the query optimization
Last_analyzed_at	The last time when the column statistics were collected

In the following example, after executing `ANALYZE TABLE t PREDICATE COLUMNS;`, TiDB collects statistics on columns b, c, and d, where column b is a PREDICATE COLUMN and columns c and d are index columns.

```

SET GLOBAL tidb_enable_column_tracking = ON;
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE t (a INT, b INT, c INT, d INT, INDEX idx_c_d(c, d));
Query OK, 0 rows affected (0.00 sec)

-- The optimizer uses the statistics on column b in this query.
SELECT * FROM t WHERE b > 1;
Empty set (0.00 sec)

-- After waiting for a period of time (100 * stats-lease), TiDB writes the
 ↳ collected `PREDICATE COLUMNS` to mysql.column_stats_usage.
-- Specify `last_used_at IS NOT NULL` to show the `PREDICATE COLUMNS`
 ↳ collected by TiDB.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
 ↳ last_used_at IS NOT NULL;
+--
 ↳ -----+-----+-----+-----+-----+
 ↳
 | Db_name | Table_name | Partition_name | Column_name | Last_used_at |
 ↳ Last_analyzed_at |
+--
 ↳ -----+-----+-----+-----+-----+

```

```

↪
| test | t | | b | 2022-01-05 17:21:33 | NULL
↪
+--
↪ -----+-----+-----+-----+-----+
↪
1 row in set (0.00 sec)

ANALYZE TABLE t PREDICATE COLUMNS;
Query OK, 0 rows affected, 1 warning (0.03 sec)

-- Specify `last_analyzed_at IS NOT NULL` to show the columns for which
↪ statistics have been collected.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
↪ last_analyzed_at IS NOT NULL;
+--
↪ -----+-----+-----+-----+
↪
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
↪ Last_analyzed_at |
+--
↪ -----+-----+-----+-----+
↪
| test | t | | b | 2022-01-05 17:21:33 |
↪ 2022-01-05 17:23:06 |
| test | t | | c | NULL |
↪ 2022-01-05 17:23:06 |
| test | t | | d | NULL |
↪ 2022-01-05 17:23:06 |
+--
↪ -----+-----+-----+-----+
↪
3 rows in set (0.00 sec)

```

Collect statistics on indexes

To collect statistics on all indexes in `IndexNameList` in `TableName`, use the following syntax:

```

ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
↪ CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM
↪ SAMPLERATE];

```

When `IndexNameList` is empty, this syntax collects statistics on all indexes in `TableName`  
↪ .

**Note:**

To ensure that the statistical information before and after the collection is consistent, when `tidb_analyze_version` is 2, this syntax collects statistics on the entire table (including all columns and indexes), instead of only on indexes.

## Collect statistics on partitions

- To collect statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH
↪ FLOATNUM SAMPLERATE];
```

- To collect index statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
↪ WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- If you only need to **collect statistics on some columns** of some partitions in a table, use the following syntax:

**Warning:**

Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

```
ANALYZE TABLE TableName PARTITION PartitionNameList [COLUMNS
↪ ColumnNameList|PREDICATE COLUMNS|ALL COLUMNS] [WITH NUM BUCKETS|
↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH
↪ FLOATNUM SAMPLERATE];
```

## Collect statistics of partitioned tables in dynamic pruning mode

When accessing partitioned tables in **dynamic pruning mode**, TiDB collects table-level statistics, which is called `GlobalStats`. Currently, `GlobalStats` is aggregated from statistics of all partitions. In dynamic pruning mode, a statistics update of any partitioned table can trigger the `GlobalStats` to be updated.

**Note:**

- When GlobalStats update is triggered:
  - If some partitions have no statistics (such as a new partition that has never been analyzed), GlobalStats generation is interrupted and a warning message is displayed saying that no statistics are available on partitions.
  - If statistics of some columns are absent in specific partitions (different columns are specified for analyzing in these partitions), GlobalStats generation is interrupted when statistics of these columns are aggregated, and a warning message is displayed saying that statistics of some columns are absent in specific partitions.
- In dynamic pruning mode, the Analyze configurations of partitions and tables should be the same. Therefore, if you specify the `COLUMNS`  
↪ configuration following the `ANALYZE TABLE TableName PARTITION`  
↪ `PartitionNameList` statement or the `OPTIONS` configuration following `WITH`, TiDB will ignore them and return a warning.

### Incremental collection

To improve the speed of analysis after full collection, incremental collection could be used to analyze the newly added sections in monotonically non-decreasing columns such as time columns.

**Note:**

- Currently, the incremental collection is only provided for index.
- When using the incremental collection, you must ensure that only `INSERT` operations exist on the table, and that the newly inserted value on the index column is monotonically non-decreasing. Otherwise, the statistical information might be inaccurate, affecting the TiDB optimizer to select an appropriate execution plan.

You can perform incremental collection using the following syntax.

- To incrementally collect statistics on index columns in all `IndexNameLists` in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName INDEX [IndexNameList] [WITH NUM
↳ BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH] |[WITH NUM SAMPLES|
↳ WITH FLOATNUM SAMPLERATE];
```

- To incrementally collect statistics on index columns for partitions in all PartitionNameLists  
↳ in TableName:

```
ANALYZE INCREMENTAL TABLE TableName PARTITION PartitionNameList INDEX [
↳ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
↳ WIDTH] |[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

### Automatic update

For the INSERT, DELETE, or UPDATE statements, TiDB automatically updates the number of rows and updated rows. TiDB persists this information regularly and the update cycle is  $20 * \text{stats-lease}$ . The default value of `stats-lease` is 3s. If you specify the value as 0, it does not update automatically.

Three system variables related to automatic update of statistics are as follows:

System Variable	Default Value	Description
<code>tidb_auto_analyze_ratio</code>	0.5	threshold value of automatic update

System		
Vari- able	Default Value	Description
<code>tidb_auto_analyze_start_time</code>	<code>00:00:00</code>	start
	<code>+0000</code>	end
		in a day when TiDB can perform automatic update
<code>tidb_auto_analyze_end_time</code>	<code>23:59:00</code>	end
	<code>+0000</code>	end
		in a day when TiDB can perform automatic update

When the ratio of the number of modified rows to the total number of rows of `tbl`  $\hookrightarrow$  in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics on this table.

To avoid the situation that modifying a small amount of data on a small table frequently triggers the automatic update, when a table has less than 1000 rows, such data modifying does not trigger the automatic update in TiDB. You can use the `SHOW STATS_META` statement to view the number of rows in a table.

**Note:**

Currently, the automatic update does not record the configuration items input at manual `ANALYZE`. Therefore, when you use the `WITH` syntax to control the collecting behavior of `ANALYZE`, you need to manually set scheduled tasks to collect statistics.

Since TiDB v6.0, TiDB supports using the `KILL` statement to terminate an `ANALYZE` task running in the background. If you find that an `ANALYZE` task running in the background consumes a lot of resources and affects your application, you can terminate the `ANALYZE` task by taking the following steps:

1. Execute the following SQL statement:

```
SHOW ANALYZE STATUS
```

By checking the `instance` column and the `process_id` column in the result, you can get the TiDB instance address and the task ID of the background `ANALYZE` task.

2. Terminate the `ANALYZE` task that is running in the background.
  - If `enable-global-kill` is `true` (`true` by default), you can execute the `KILL` `↪ TIDB ${id};` statement directly, where `${id}` is the ID of the background `ANALYZE` task obtained from the previous step.
  - If `enable-global-kill` is `false`, you need to use a client to connect to the TiDB instance that is executing the backend `ANALYZE` task, and then execute the `KILL` `↪ TIDB ${id};` statement. If you use a client to connect to another TiDB instance, or if there is a proxy between the client and the TiDB cluster, the `KILL` statement cannot terminate the background `ANALYZE` task.

For more information on the `KILL` statement, see [KILL](#).

#### Control `ANALYZE` concurrency

When you run the `ANALYZE` statement, you can adjust the concurrency using the following parameters, to control its effect on the system.

```
tidb_build_stats_concurrency
```

Currently, when you run the `ANALYZE` statement, the task is divided into multiple small tasks. Each task only works on one column or index. You can use the `tidb_build_stats_concurrency` parameter to control the number of simultaneous tasks. The default value is 4.

```
tidb_distsql_scan_concurrency
```

When you analyze regular columns, you can use the `tidb_distsql_scan_concurrency` parameter to control the number of Region to be read at one time. The default value is 15.

`tidb_index_serial_scan_concurrency`

When you analyze index columns, you can use the `tidb_index_serial_scan_concurrency` parameter to control the number of Region to be read at one time. The default value is 1.

Persist ANALYZE configurations

Since v5.4.0, TiDB supports persisting some ANALYZE configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The following are the ANALYZE configurations that support persistence:

	Corresponding Configurations
The number of histograms buckets	WITH NUMBUCKETS
The number of Top-N	WITH NUMTOPN
The number of samples	WITH NUMSAMPLES
The sampling rate	WITH FLOATNUMSAMPLERATE

---

### Enable ANALYZE configuration persistence

The **ANALYZE** configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is 2 and `tidb_persist_analyze_options` is ON by default).

You can use this feature to record the persistence configurations specified in the **ANALYZE** ↔ statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configuration, TiDB will collect statistics according to the recorded configurations.

When you manually execute the **ANALYZE** statement multiple times with persistence configurations specified, TiDB overwrites the previously recorded persistent configuration using the new configurations specified by the latest **ANALYZE** statement.

### Disable ANALYZE configuration persistence

To disable the `ANALYZE` configuration persistence feature, set the `tidb_persist_analyze_options` ↔ system variable to `OFF`. Because the `ANALYZE` configuration persistence feature is not applicable to `tidb_analyze_version = 1`, setting `tidb_analyze_version = 1` can also disable the feature.

After disabling the `ANALYZE` configuration persistence feature, TiDB does not clear the persisted configuration records. Therefore, if you enable this feature again, TiDB continues to collect statistics using the previously recorded persistent configurations.

**Note:**

When you enable the `ANALYZE` configuration persistence feature again, if the previously recorded persistence configurations are no longer applicable to the latest data, you need to execute the `ANALYZE` statement manually and specify the new persistence configurations.

The memory quota for collecting statistics

**Warning:**

Currently, the `ANALYZE` memory quota is an experimental feature, and the memory statistics might be inaccurate in production environments.

Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the memory quota for collecting statistics in TiDB.

To set a proper value of `tidb_mem_quota_analyze`, consider the data size of the cluster. When the default sampling rate is used, the main considerations are the number of columns, the size of column values, and the memory configuration of TiDB. Consider the following suggestions when you configure the maximum and minimum values:

**Note:**

The following suggestions are for reference only. You need to configure the values based on the real scenario.

- Minimum value: should be greater than the maximum memory usage when TiDB collects statistics from the table with the most columns. An approximate reference: when

TiDB collects statistics from a table with 20 columns using the default configuration, the maximum memory usage is about 800 MiB; when TiDB collects statistics from a table with 160 columns using the default configuration, the maximum memory usage is about 5 GiB.

- Maximum value: should be less than the available memory when TiDB is not collecting statistics.

#### View ANALYZE state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using the following SQL statement:

```
SHOW ANALYZE STATUS [ShowLikeOrWhere]
```

This statement returns the state of `ANALYZE`. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW ANALYZE STATUS` statement returns the following 11 columns:

Column name	Description
<code>table_schema</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>job_info</code>	The task information. If an index is analyzed, this information will include the index name. When
<code>tidb_analyze_version</code>	$\leftrightarrow$ =2, this information will include configuration items such as sample rate.
<code>processed_rows</code>	The number of rows that have been analyzed
<code>start_time</code>	The time at which the task starts

Column name	Description
state	The state of a task, including <b>pending</b> , <b>running</b> , <b>finished</b> , and <b>failed</b>
fail_reason	The reason why the task fails. If the execution is successful, the value is <b>NULL</b> .
instance	The TiDB instance that executes the task
process_id	The process ID that executes the task

Starting from TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the restart using this statement. Before TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement can only show instance-level tasks, and task records are cleared after a TiDB restart.

`SHOW ANALYZE STATUS` shows the most recent task records only. Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

When `tidb_mem_quota_analyze` is set and an automatic `ANALYZE` task running in the TiDB background uses more memory than this threshold, the task will be retried. You can see failed and retried tasks in the output of the `SHOW ANALYZE STATUS` statement.

When `tidb_max_auto_analyze_time` is greater than 0 and an automatic `ANALYZE` task running in the TiDB background takes more time than this threshold, the task will be terminated.

```
mysql> SHOW ANALYZE STATUS [ShowLikeOrWhere];
+--
↪ -----+-----+-----+-----
↪
| Table_schema | Table_name | Partition_name | Job_info
↪
↪ Processed_rows | Start_time | End_time | State |
↪ Fail_reason |
```

```

+--
↪ -----+-----+-----+-----
↪
| test | sbtest1 | | retry auto analyze table all
↪ columns with 100 topn, 0.055 samplerate | 2000000 |
↪ 2022-05-07 16:41:09 | 2022-05-07 16:41:20 | finished | NULL
↪
| test | sbtest1 | | auto analyze table all columns
↪ with 100 topn, 0.5 samplerate | 0 |
↪ 2022-05-07 16:40:50 | 2022-05-07 16:41:09 | failed | analyze panic
↪ due to memory quota exceeds, please try with smaller samplerate |

```

### View statistics

You can view the statistics status using the following statements.

### Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

```
SHOW STATS_META [ShowLikeOrWhere];
```

The syntax of `ShowLikeOrWhereOpt` is as follows:

Figure 182: ShowLikeOrWhereOpt

Currently, the `SHOW STATS_META` statement returns the following 6 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>update_time</code>	The time of the update
<code>modify_count</code>	The number of modified rows
<code>row_count</code>	The total number of rows

**Note:**

When TiDB automatically updates the total number of rows and the number of modified rows according to DML statements, `update_time` is also updated. Therefore, `update_time` does not necessarily indicate the last time when the `ANALYZE` statement is executed.

### Health state of tables

You can use the `SHOW STATS_HEALTHY` statement to check the health state of tables and roughly estimate the accuracy of the statistics. When `modify_count >= row_count`, the health state is 0; when `modify_count < row_count`, the health state is  $(1 - \text{modify\_count} \div \text{row\_count}) * 100$ .

The syntax is as follows:

```
SHOW STATS_HEALTHY [ShowLikeOrWhere];
```

The synopsis of `SHOW STATS_HEALTHY` is:

Figure 183: ShowStatsHealthy

Currently, the `SHOW STATS_HEALTHY` statement returns the following 4 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>healthy</code>	The health state of tables

### Metadata of columns

You can use the `SHOW STATS_HISTOGRAMS` statement to view the number of different values and the number of `NULL` in all the columns.

Syntax as follows:

```
SHOW STATS_HISTOGRAMS [ShowLikeOrWhere]
```

This statement returns the number of different values and the number of `NULL` in all the columns. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_HISTOGRAMS` statement returns the following 10 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>column_name</code>	The column name (when <code>is_index</code> is 0) or the index name (when <code>is_index</code> is 1)
<code>is_index</code>	Whether it is an index column or not
<code>update_time</code>	The time of the update
<code>distinct_count</code>	The number of different values
<code>null_count</code>	The number of NULL
<code>avg_col_size</code>	The average length of columns
<code>correlation</code>	The Pearson correlation coefficient of the column and the integer primary key, which indicates the degree of association between the two columns

Buckets of histogram

You can use the `SHOW STATS_BUCKETS` statement to view each bucket of the histogram.

The syntax is as follows:

```
SHOW STATS_BUCKETS [ShowLikeOrWhere]
```

The diagram is as follows:

Figure 184: SHOW STATS\_BUCKETS

This statement returns information about all the buckets. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_BUCKETS` statement returns the following 11 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>column_name</code>	The column name (when <code>is_index</code> is 0) or the index name (when <code>is_index</code> is 1)
<code>is_index</code>	Whether it is an index column or not
<code>bucket_id</code>	The ID of a bucket
<code>count</code>	The number of all the values that falls on the bucket and the previous buckets
<code>repeats</code>	The occurrence number of the maximum value
<code>lower_bound</code>	The minimum value
<code>upper_bound</code>	The maximum value

Column name	Description
ndv	The number of different values in the bucket. When <code>tidb_analyze_version</code> $\hookrightarrow$ = 1, ndv is always 0, which has no actual meaning.

### Top-N information

You can use the `SHOW STATS_TOPN` statement to view the Top-N information currently collected by TiDB.

The syntax is as follows:

```
SHOW STATS_TOPN [ShowLikeOrWhere];
```

Currently, the `SHOW STATS_TOPN` statement returns the following 7 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name

Column name	Description
<code>column_name</code>	The name of the column (when <code>is_index</code> is 0) or the index name (when <code>is_index</code> is 1)
<code>is_index</code>	Whether it is an index column or not
<code>value</code>	The value of this column
<code>count</code>	How many times the value appears

Delete statistics

You can run the `DROP STATS` statement to delete statistics.

```
DROP STATS TableName
```

The preceding statement deletes all statistics of `TableName`. If a partitioned table is specified, this statement will delete statistics of all partitions in this table as well as `GlobalStats` generated in dynamic pruning mode.

```
DROP STATS TableName PARTITION PartitionNameList;
```

This preceding statement only deletes statistics of the specified partitions in `PartitionNameList`.

```
DROP STATS TableName GLOBAL;
```

The preceding statement only deletes `GlobalStats` generated in dynamic pruning mode of the specified table.

Load statistics

By default, depending on the size of column statistics, TiDB loads statistics differently as follows:

- For statistics that consume small amounts of memory (such as `count`, `distinctCount`, and `nullCount`), as long as the column data is updated, TiDB automatically loads the corresponding statistics into memory for use in the SQL optimization stage.
- For statistics that consume large amounts of memory (such as histograms, `TopN`, and `Count-Min Sketch`), to ensure the performance of SQL execution, TiDB loads the statistics asynchronously on demand. Take histograms as an example. TiDB loads histogram statistics on a column into memory only when the optimizer uses the histogram statistics on that column. On-demand asynchronous statistics loading does not affect the performance of SQL execution but might provide incomplete statistics for SQL optimization.

Since v5.4.0, TiDB introduces the synchronously loading statistics feature. This feature allows TiDB to synchronously load large-sized statistics (such as histograms, `TopN`, and `Count-Min Sketch` statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

To enable this feature, set the value of the `tidb_stats_load_sync_wait` system variable to a timeout (in milliseconds) that SQL optimization can wait for at most to synchronously load complete column statistics. The default value of this variable is `100`, indicating that the feature is enabled.

After enabling the synchronously loading statistics feature, you can further configure the feature as follows:

- To control how TiDB behaves when the waiting time of SQL optimization reaches the timeout, modify the value of the `tidb_stats_load_pseudo_timeout` system variable. The default value of this variable is `ON`, indicating that after the timeout, the SQL optimization process does not use any histogram, `TopN`, or `CMSketch` statistics on any columns. If this variable is set to `OFF`, after the timeout, SQL execution fails.

- To specify the maximum number of columns that the synchronously loading statistics feature can process concurrently, modify the value of the `stats-load-concurrency` option in the TiDB configuration file. The default value is 5.
- To specify the maximum number of column requests that the synchronously loading statistics feature can cache, modify the value of the `stats-load-queue-size` option in the TiDB configuration file. The default value is 1000.

## Import and export statistics

### Export statistics

The interface to export statistics is as follows:

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_name}/${table_name}
```

For example:

```
curl -s http://127.0.0.1:10080/stats/dump/test/t1 -o /tmp/t1.json
```

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database at specific time:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_name}/${table_name}/${yyyyMMddHHmmss}
```

### Import statistics

#### Note:

When you start the MySQL client, use the `--local-infile=1` option.

Generally, the imported statistics refer to the JSON file obtained using the export interface.

Syntax:

```
LOAD STATS 'file_name'
```

`file_name` is the file name of the statistics to be imported.

### Lock statistics

### Warning:

Locking statistics is an experimental feature for the current version. It is not recommended to use it in the production environment.

Since v6.5.0, TiDB supports locking statistics. After the statistics of a table are locked, the statistics of the table cannot be modified and the `ANALYZE` statement cannot be executed on the table. For example:

Create table `t`, and insert data into it. When the statistics of table `t` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> create table t(a int, b int);
Query OK, 0 rows affected (0.03 sec)

mysql> insert into t values (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> analyze table t;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> show warnings;
+---+
| Level | Code | Message |
+---+
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
| test.t |
+---+
1 row in set (0.00 sec)
```

Lock the statistics of table `t` and execute `ANALYZE`. From the output of `SHOW` `STATS_LOCKED`, you can see that the statistics of table `t` have been locked. The warning message shows that the `ANALYZE` statement has skipped table `t`.

```
mysql> lock stats t;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> show stats_locked;
+-----+-----+-----+
| Db_name | Table_name | Partition_name | Status |
+-----+-----+-----+
| test | t | | locked |
+-----+-----+-----+
1 row in set (0.01 sec)

mysql> analyze table t;
Query OK, 0 rows affected, 2 warnings (0.00 sec)

mysql> show warnings;
+---+
 ↪ -----+
 ↪
| Level | Code | Message
+---+
 ↪ -----+
 ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
 ↪ test.t |
| Warning | 1105 | skip analyze locked table: t
+---+
 ↪ -----+
 ↪
2 rows in set (0.00 sec)
```

Unlock the statistics of table `t` and `ANALYZE` can be successfully executed again.

```
mysql> unlock stats t;
Query OK, 0 rows affected (0.01 sec)

mysql> analyze table t;
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> show warnings;
+---+
 ↪ -----+
 ↪
| Level | Code | Message
+---+
 ↪ -----+
 ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
```

```
↳ test.t |
+---
↳ -----+-----+-----+-----+-----+-----+-----+-----+
↳
1 row in set (0.00 sec)
```

#### 11.3.3.3.4 Introduction to Extended Statistics

TiDB can collect the following two types of statistics:

- Basic statistics: statistics such as histograms and Count-Min Sketch. See [Introduction to Statistics](#) for details.
- Extended statistics: statistics filtered by tables and columns.

#### Tip:

Before reading this document, it is recommended that you read [Introduction to Statistics](#) first.

When the `ANALYZE` statement is executed manually or automatically, TiDB by default only collects the basic statistics and does not collect the extended statistics. This is because the extended statistics are only used for optimizer estimates in specific scenarios, and collecting them requires additional overhead.

Extended statistics are disabled by default. To collect extended statistics, you need to first enable the extended statistics, and then register each individual extended statistics object.

After the registration, the next time the `ANALYZE` statement is executed, TiDB collects both the basic statistics and the registered extended statistics.

#### Limitations

Extended statistics are not collected in the following scenarios:

- Statistics collection on indexes only
- Statistics collection using the `ANALYZE INCREMENTAL` command
- Statistics collection when the value of the system variable `tidb_enable_fast_analyze` is set to `true`

## Common operations

### Enable extended statistics

To enable extended statistics, set the system variable `tidb_enable_extended_stats` to `ON`:

```
SET GLOBAL tidb_enable_extended_stats = ON;
```

The default value of this variable is `OFF`. The setting of this system variable applies to all extended statistics objects.

### Register extended statistics

The registration for extended statistics is not a one-time task, and you need repeat the registration for each extended statistics object.

To register extended statistics, use the SQL statement `ALTER TABLE ADD STATS_EXTENDED`  $\leftrightarrow$  . The syntax is as follows:

```
ALTER TABLE table_name ADD STATS_EXTENDED IF NOT EXISTS stats_name
 \leftrightarrow stats_type(column_name, column_name...);
```

In the syntax, you can specify the table name, statistics name, statistics type, and column name of the extended statistics to be collected.

- `table_name` specifies the name of the table from which the extended statistics are collected.
- `stats_name` specifies the name of the statistics object, which must be unique for each table.
- `stats_type` specifies the type of the statistics. Currently, only the correlation type is supported.
- `column_name` specifies the column group, which might have multiple columns. Currently, you can only specify two column names.

## How it works

To improve access performance, each TiDB node maintains a cache in the system table `mysql.stats_extended` for extended statistics. After you register the extended statistics, the next time the `ANALYZE` statement is executed, TiDB will collect the extended statistics if the system table `mysql.stats_extended` has the corresponding objects.

Each row in the `mysql.stats_extended` table has a `version` column. Once a row is updated, the value of `version` is increased. In this way, TiDB loads the table into memory incrementally, instead of fully.

TiDB loads `mysql.stats_extended` periodically to ensure that the cache is kept the same as the data in the table.

### Warning:

It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can execute the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

### Delete extended statistics

To delete an extended statistics object, use the following statement:

```
ALTER TABLE table_name DROP STATS_EXTENDED stats_name;
```

### How it works

After you execute the statement, TiDB marks the value of the corresponding object in `mysql.stats_extended`'s column `status` to 2, instead of deleting the object directly.

Other TiDB nodes will read this change and delete the object in their memory cache. The background garbage collection will delete the object eventually.

### Warning:

It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can use the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

### Export and import extended statistics

The way of exporting or importing extended statistics is the same as exporting or importing basic statistics. See [Introduction to Statistics - Import and export statistics](#) for details.

Usage examples for correlation-type extended statistics

Currently, TiDB only supports the correlation-type extended statistics. This type is used to estimate the number of rows in the range query and improve index selection. The following example shows how the correlation-type extended statistics are used to estimate the number of rows in a range query.

Step 1. Define the table

Define a table `t` as follows:

```
CREATE TABLE t(col1 INT, col2 INT, KEY(col1), KEY(col2));
```

Suppose that `col1` and `col2` of table `t` both obey monotonically increasing constraints in row order. This means that the values of `col1` and `col2` are strictly correlated in order, and the correlation factor is 1.

Step 2. Execute an example query without extended statistics

Execute the following query without using extended statistics:

```
SELECT * FROM t WHERE col1 > 1 ORDER BY col2 LIMIT 1;
```

For the execution of the preceding query, the TiDB optimizer has the following options to access table `t`:

- Uses the index on `col1` to access table `t` and then sorts the result by `col2` to calculate Top-1.
- Uses the index on `col2` to meet the first row that satisfies `col1 > 1`. The cost of this access method mainly depends on how many rows are filtered out when TiDB scans the table in `col2`'s order.

Without extended statistics, the TiDB optimizer only supposes that `col1` and `col2` are independent, which **leads to a significant estimation error**.

Step 3. Enable extended statistics

Set `tidb_enable_extended_stats` to ON, and register the extended statistics object for `col1` and `col2`:

```
ALTER TABLE t ADD STATS_EXTENDED s1 correlation(col1, col2);
```

When you execute `ANALYZE` after the registration, TiDB calculates the [Pearson correlation coefficient](#) of `col1` and `col2` of table `t`, and writes the object into the `mysql.stats_extended` table.

Step 4. See how extended statistics make a difference

After TiDB has the extended statistics for correlation, the optimizer can estimate how many rows to be scanned more precisely.

At this time, for the query in [Stage 2. Execute an example query without extended statistics](#), `col1` and `col2` are strictly correlated in order. If TiDB accesses table `t` by using the index on `col2` to meet the first row that satisfies `col1 > 1`, the TiDB optimizer will equivalently translate the row count estimation into the following query:

```
SELECT * FROM t WHERE col1 <= 1 OR col1 IS NULL;
```

The preceding query result plus one will be the final estimation for the row count. In this way, you do not need to use the independent assumption and **the significant estimation error is avoided**.

If the correlation factor (1 in this example) is less than the value of the system variable `tidb_opt_correlation_threshold`, the optimizer will use the independent assumption, but it will also increase the estimation heuristically. The larger the value of `tidb_opt_correlation_exp_factor`, the larger the estimation result. The larger the absolute value of the correlation factor, the larger the estimation result.

#### 11.3.3.3.5 Wrong Index Solution

If you find that the execution speed of some query does not reach the expectation, the optimizer might choose the wrong index to run the query.

You can first view the [health state of tables](#) in the statistics, and then solve this issue according to the different health states.

##### Low health state

The low health state means TiDB has not performed the `ANALYZE` statement for a long time. You can update the statistics by running the `ANALYZE` command. After the update, if the optimizer still uses the wrong index, refer to the next section.

##### Near 100% health state

The near 100% health state suggests that the `ANALYZE` statement is just completed or was completed a short time ago. In this case, the wrong index issue might be related to TiDB's estimation logic for the number of rows.

For equivalence queries, the cause might be [Count-Min Sketch](#). You can check whether Count-Min Sketch is the cause and take corresponding solutions.

If the cause above does not apply to your problem, you can force-select indexes by using the `USE_INDEX` or `use index` optimizer hint (see [USE\\_INDEX](#) for details). Also, you can change the query behavior by using [SQL Plan Management](#) in a non-intrusive way.

##### Other situations

Apart from the aforementioned situations, the wrong index issue might also be caused by data updates which renders all the indexes no longer applicable. In such cases, you need to perform analysis on the conditions and data distribution to see whether new indexes can speed up the query. If so, you can add new indexes by running the `ADD INDEX` command.

### 11.3.3.3.6 Distinct Optimization

This document introduces the `distinct` optimization in the TiDB query optimizer, including `SELECT DISTINCT` and `DISTINCT` in the aggregate functions.

`DISTINCT` modifier in `SELECT` statements

The `DISTINCT` modifier specifies removal of duplicate rows from the result set. `SELECT`  $\leftrightarrow$  `DISTINCT` is transformed to `GROUP BY`, for example:

```
mysql> explain SELECT DISTINCT a from t;
+---+
| id | estRows | task | access object | operator info |
+---+
| HashAgg_6 | 2.40 | root | | group by:test.t.a |
| -TableReader_11 | 3.00 | root | | data: |
| -TableFullScan_10 | 3.00 | cop[tikv] | table:t | keep order:false |
+---+
3 rows in set (0.00 sec)
```

`DISTINCT` option in aggregate functions

Usually, aggregate functions with the `DISTINCT` option is executed in the TiDB layer in a single-threaded execution model.

The `tidb_opt_distinct_agg_push_down` system variable or the `distinct-agg-push`  $\leftrightarrow$  `-down` configuration item in TiDB controls whether to rewrite the distinct aggregate queries and push them to the TiKV or TiFlash Coprocessor.

Take the following queries as an example of this optimization. `tidb_opt_distinct_agg_push_down`  $\leftrightarrow$  is disabled by default, which means the aggregate functions are executed in the TiDB layer. After enabling this optimization by setting its value to 1, the `distinct a` part of `count(distinct a)` is pushed to TiKV or TiFlash Coprocessor: there is a `HashAgg_5` to remove the duplicated values on column `a` in the TiKV Coprocessor. It might reduce the computation overhead of `HashAgg_8` in the TiDB layer.

```
mysql> desc select count(distinct a) from test.t;
+---+
| id | estRows | task | access object | operator info |
+---+
3 rows in set (0.00 sec)
```

```

| id | estRows | task | access object | operator info
|-----|-----|-----|-----|-----|
| StreamAgg_6 | 1.00 | root | | funcs:count(
| ↳ distinct test.t.a)->Column#4 |
| -TableReader_10 | 10000.00 | root | | data:
| ↳ TableFullScan_9 |
| -TableFullScan_9 | 10000.00 | cop[tikv] | table:t | keep order:false
| ↳ , stats:pseudo |
+---+
|-----|-----|-----|-----|-----|
3 rows in set (0.01 sec)

mysql> set session tidb_opt_distinct_agg_push_down = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> desc select count(distinct a) from test.t;
+---+
|-----|-----|-----|-----|-----|
| id | estRows | task | access object | operator info
|-----|-----|-----|-----|-----|
| HashAgg_8 | 1.00 | root | | funcs:count(
| ↳ distinct test.t.a)->Column#3 |
| -TableReader_9 | 1.00 | root | | data:HashAgg_5
| ↳
| -HashAgg_5 | 1.00 | cop[tikv] | | group by:test.
| ↳ t.a,
| -TableFullScan_7 | 10000.00 | cop[tikv] | table:t | keep order:
| ↳ false, stats:pseudo |
+---+
|-----|-----|-----|-----|-----|
4 rows in set (0.00 sec)

```

### 11.3.3.3.7 Cost Model

TiDB uses a cost model to choose an index and operator during **physical optimization**.

The process is illustrated in the following diagram:

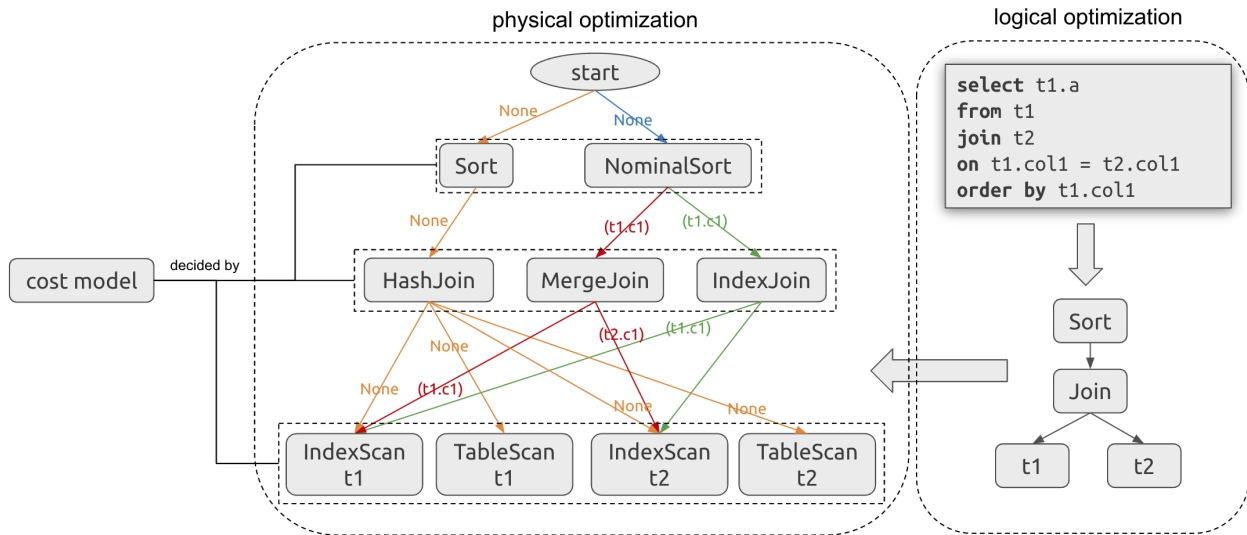

Figure 185: CostModel

TiDB calculates the access cost of each index and the execution cost of each physical operator in plans (such as HashJoin and IndexJoin) and chooses the minimum cost plan.

The following is a simplified example to explain how the cost model works. Suppose that there is a table `t`:

```
mysql> SHOW CREATE TABLE t;
+--
 ↳ -----+
 ↳
 | Table | Create Table
 ↳
 ↳ |
+--
 ↳ -----+
 ↳
 | t | CREATE TABLE `t` (
 | `a` | int(11) DEFAULT NULL,
 | `b` | int(11) DEFAULT NULL,
 | `c` | int(11) DEFAULT NULL,
 | KEY | `b` (`b`),
 | KEY | `c` (`c`)
 |) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
 ↳ -----+
 ↳
```

```
1 row in set (0.00 sec)
```

When executing the `SELECT * FROM t WHERE b < 100 and c < 100` statement, suppose that TiDB estimates 20 rows meet the `b < 100` condition and 500 rows meet `c < 100`, and the length of INT type indexes is 8. Then TiDB calculates the cost for two indexes:

- The cost of index `b` = row count of `b < 100` \* length of index `b` =  $20 * 8 = 160$
- The cost of index `c` = row count of `c < 100` \* length of index `c` =  $500 * 8 = 4000$

Because the cost of index `b` is lower, TiDB chooses `b` as the index.

The preceding example is simplified and only used to explain the basic principle. In real SQL executions, the TiDB cost model is more complex.

#### Cost Model Version 2

TiDB v6.2.0 introduces Cost Model Version 2, a new cost model.

Cost Model Version 2 provides a more accurate regression calibration of the cost formula, adjusts some of the cost formulas, and is more accurate than the previous version of the cost formula.

To switch the version of cost model, you can set the `tidb_cost_model_version` variable.

#### Note:

Switching the version of the cost model might cause changes to query plans.

### 11.3.3.4 SQL Prepare Execution Plan Cache

TiDB supports execution plan caching for `Prepare` and `Execute` queries. This includes both forms of prepared statements:

- Using the `COM_STMT_PREPARE` and `COM_STMT_EXECUTE` protocol features.
- Using the SQL statements `PREPARE` and `EXECUTE`.

The TiDB optimizer handles these two types of queries in the same way: when preparing, the parameterized query is parsed into an AST (Abstract Syntax Tree) and cached; in later execution, the execution plan is generated based on the stored AST and specific parameter values.

When the execution plan cache is enabled, in the first execution every `Prepare` statement checks whether the current query can use the execution plan cache, and if the query can use it, then put the generated execution plan into a cache implemented by LRU (Least Recently Used) linked list. In the subsequent `Execute` queries, the execution plan is obtained from the

cache and checked for availability. If the check succeeds, the step of generating an execution plan is skipped. Otherwise, the execution plan is regenerated and saved in the cache.

In the current version of TiDB, if a `Prepare` statement meets any of the following conditions, the query or the plan is not cached:

- The query contains SQL statements other than `SELECT`, `UPDATE`, `INSERT`, `DELETE`, `Union`, `Intersect`, and `Except`.
- The query accesses partitioned tables or temporary tables, or a table that contains generated columns.
- The query contains sub-queries, such as `select * from t where a > (select ...)`.
- The query contains the `ignore_plan_cache` hint, such as `select /*+ ignore_plan_cache ↪ ()*/ * from t`.
- The query contains variables other than `?` (including system variables or user-defined variables), such as `select * from t where a>? and b>@x`.
- The query contains the functions that cannot be cached: `database()`, `current_user ↪`, `current_role`, `user`, `connection_id`, `last_insert_id`, `row_count`, `version`, and `like`.
- The query uses a variable as the `LIMIT` parameter (such as `LIMIT ?` and `LIMIT 10, ?`) and the variable value is greater than 10000.
- The query contains `?` after `Order By`, such as `Order By ?`. Such queries sort data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Order By a+?`, it is cached.
- The query contains `?` after `Group By`, such as `Group By?`. Such queries group data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Group By a+?`, it is cached.
- The query contains `?` in the definition of the `Window Frame` window function, such as `(partition by year order by sale rows ? preceding)`. If `?` appears elsewhere in the window function, the query is cached.
- The query contains parameters for comparing `int` and `string`, such as `c_int >= ? ↪` or `c_int in (?, ?)`, in which `?` indicates the string type, such as `set @x='123'`. To ensure that the query result is compatible with MySQL, parameters need to be adjusted in each query, so such queries are not cached.
- The plan attempts to access `TiFlash`.
- In most cases, the plan that contains `TableDual` is not cached, unless the current `Prepare` statement does not have parameters.

The LRU linked list is designed as a session-level cache because `Prepare / Execute` cannot be executed across sessions. Each element of the LRU list is a key-value pair. The value is the execution plan, and the key is composed of the following parts:

- The name of the database where `Execute` is executed
- The identifier of the `Prepare` statement, that is, the name after the `PREPARE` keyword

- The current schema version, which is updated after every successfully executed DDL statement
- The SQL mode when executing `Execute`
- The current time zone, which is the value of the `time_zone` system variable
- The value of the `sql_select_limit` system variable

Any change in the above information (for example, switching databases, renaming `Prepare` statement, executing DDL statements, or modifying the value of SQL mode / `time_zone`), or the LRU cache elimination mechanism causes the execution plan cache miss when executing.

After the execution plan cache is obtained from the cache, TiDB first checks whether the execution plan is still valid. If the current `Execute` statement is executed in an explicit transaction, and the referenced table is modified in the transaction pre-order statement, the cached execution plan accessing this table does not contain the `UnionScan` operator, then it cannot be executed.

After the validation test is passed, the scan range of the execution plan is adjusted according to the current parameter values, and then used to perform data querying.

There are several points worth noting about execution plan caching and query performance:

- No matter an execution plan is cached or not, it is affected by SQL bindings. For execution plans that have not been cached (the first `Execute`), these plans are affected by existing SQL bindings. For execution plans that have been cached, if new SQL Bindings are created, these plans become invalid.
- Cached plans are not affected by changes in statistics, optimization rules, and blocklist pushdown by expressions.
- Considering that the parameters of `Execute` are different, the execution plan cache prohibits some aggressive query optimization methods that are closely related to specific parameter values to ensure adaptability. This causes that the query plan may not be optimal for certain parameter values. For example, the filter condition of the query is `where a > ? And a < ?`, the parameters of the first `Execute` statement are 2 and 1 respectively. Considering that these two parameters maybe be 1 and 2 in the next execution time, the optimizer does not generate the optimal `TableDual` execution plan that is specific to current parameter values;
- If cache invalidation and elimination are not considered, an execution plan cache is applied to various parameter values, which in theory also results in non-optimal execution plans for certain values. For example, if the filter condition is `where a < ?` and the parameter value used for the first execution is 1, then the optimizer generates the optimal `IndexScan` execution plan and puts it into the cache. In the subsequent executions, if the value becomes 10000, the `TableScan` plan might be the better one. But due to the execution plan cache, the previously generated `IndexScan` is used for execution. Therefore, the execution plan cache is more suitable for application scenarios where the query is simple (the ratio of compilation is high) and the execution plan is relatively fixed.

Since v6.1.0, the execution plan cache is enabled by default. You can control prepared plan cache via the system variable `tidb_enable_prepared_plan_cache`.

**Note:**

The execution plan cache feature applies only to Prepare / Execute queries and does not take effect for normal queries.

After the execution plan cache feature is enabled, you can use the session-level system variable `last_plan_from_cache` to see whether the previous Execute statement used the cached execution plan, for example:

```
MySQL [test]> create table t(a int);
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> prepare stmt from 'select * from t where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)

-- The first execution generates an execution plan and saves it in the
 ↪ cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)

-- The second execution hits the cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

If you find that a certain set of `Prepare / Execute` has unexpected behavior due to the execution plan cache, you can use the `ignore_plan_cache()` SQL hint to skip using the execution plan cache for the current statement. Still, use the above statement as an example:

```
MySQL [test]> prepare stmt from 'select /*+ ignore_plan_cache() */ * from t
↳ where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

#### 11.3.3.4.1 Diagnostics of Prepared Plan Cache

Some queries or plans cannot be cached. You can use the `SHOW WARNINGS` statement to check whether the query or plan is cached. If it is not cached, you can check the reason for the failure in the result. For example:

```
mysql> PREPARE st FROM 'SELECT * FROM t WHERE a > (SELECT MAX(a) FROM t)';
↳ -- The query contains a subquery and cannot be cached.

Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> show warnings; -- Checks the reason why the query plan cannot be
↳ cached.

+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
```

```

| Warning | 1105 | skip plan-cache: sub-queries are un-cacheable |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> prepare st from 'select * from t where a<?';

Query OK, 0 rows affected (0.00 sec)

mysql> set @a='1';

Query OK, 0 rows affected (0.00 sec)

mysql> execute st using @a; -- The optimization converts a non-INT type to
 ↪ an INT type, and the execution plan might change with the change of
 ↪ the parameter, so TiDB does not cache the plan.

Empty set, 1 warning (0.01 sec)

mysql> show warnings;

+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1105 | skip plan-cache: '1' may be converted to INT |
+-----+-----+-----+
1 row in set (0.00 sec)

```

#### 11.3.3.4.2 Memory management of Prepared Plan Cache

Using Prepared Plan Cache incurs memory overhead. To view the total memory consumption by the cached execution plans of all sessions in each TiDB instance, you can use the [Plan Cache Memory Usage monitoring panel](#) in Grafana.

#### Note:

Because of the the memory reclaim mechanism of Golang and some uncounted memory structures, the memory displayed in Grafana is not equal to the actual heap memory usage. It is tested that there is a deviation of about  $\pm 20\%$  between the memory displayed in Grafana and the actual heap memory usage.

To view the total number of execution plans cached in each TiDB instance, you can use

the **Plan Cache Plan Num** panel in Grafana.

The following is an example of the **Plan Cache Memory Usage** and **Plan Cache Plan Num** panels in Grafana:

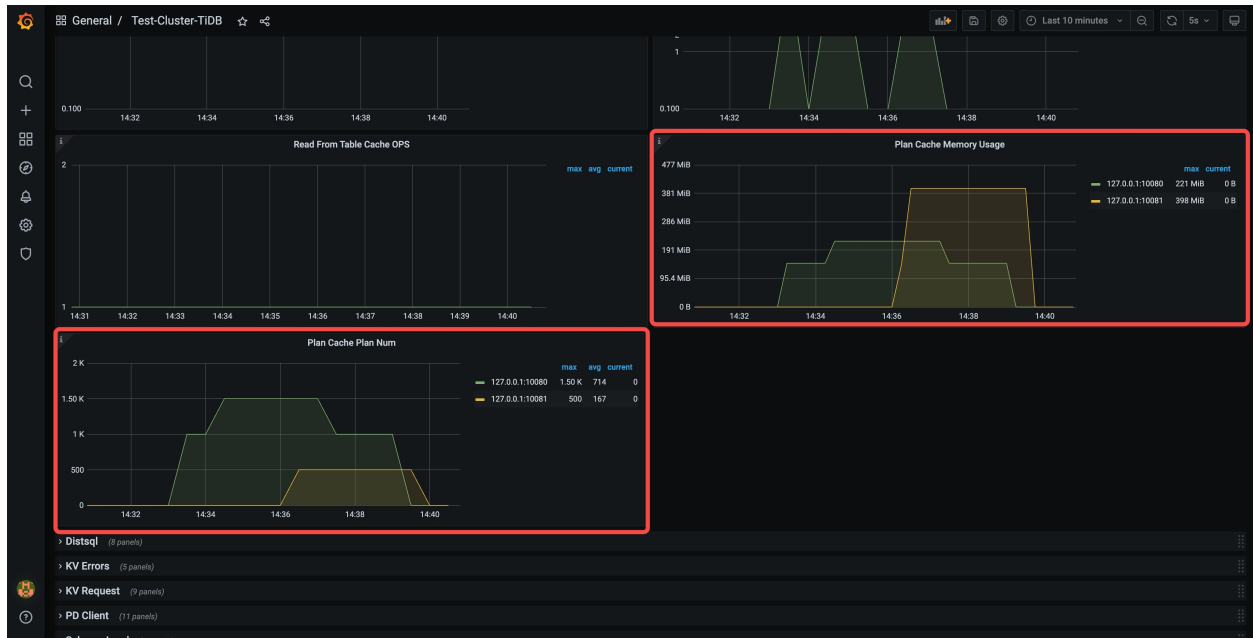

Figure 186: grafana\_panels

You can control the maximum number of plans that can be cached in each session by configuring the system variable `tidb_prepared_plan_cache_size`. For different environments, the recommended value is as follows and you can adjust it according to the monitoring panels:

- When the memory threshold of the TiDB server instance is  $\leq 64$  GiB, set `tidb_prepared_plan_cache_size` to 50.
- When the memory threshold of the TiDB server instance is  $> 64$  GiB, set `tidb_prepared_plan_cache_size` to 100.

When the unused memory of the TiDB server is less than a certain threshold, the memory protection mechanism of plan cache is triggered, through which some cached plans will be evicted.

You can control the threshold by configuring the system variable `tidb_prepared_plan_cache_memory_↔`. The threshold is 0.1 by default, which means when the unused memory of the TiDB server is less than 10% of the total memory (90% of the memory is used), the memory protection mechanism is triggered.

Due to memory limit, plan cache might be missed sometimes. You can check the status by viewing the **Plan Cache Miss OPS** metric in the Grafana dashboard.

### 11.3.3.4.3 Clear execution plan cache

You can clear execution plan cache by executing the `ADMIN FLUSH [SESSION | INSTANCE] PLAN_CACHE` statement.

In this statement, `[SESSION | INSTANCE]` specifies whether the plan cache is cleared for the current session or the whole TiDB instance. If the scope is not specified, the statement above applies to the `SESSION` cache by default.

The following is an example of clearing the `SESSION` execution plan cache:

```
MySQL [test]> create table t (a int);
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> prepare stmt from 'select * from t';
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- Select the cached plan
+-----+
| @@last_plan_from_cache |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

MySQL [test]> admin flush session plan_cache; -- Clear the cached plan of
↳ the current session
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- The cached plan cannot be
↳ selected again, because it has been cleared
+-----+
| @@last_plan_from_cache |
+-----+
| 0 |
+-----+
1 row in set (0.00 sec)
```

Currently, TiDB does not support clearing GLOBAL execution plan cache. That means you cannot clear the cached plan of the whole TiDB cluster. The following error is reported if you try to clear the GLOBAL execution plan cache:

```
MySQL [test]> admin flush global plan_cache;
ERROR 1105 (HY000): Do not support the 'admin flush global scope.'
```

#### 11.3.3.4.4 Ignore the COM\_STMT\_CLOSE command and the DEALLOCATE PREPARE statement

To reduce the syntax parsing cost of SQL statements, it is recommended that you run `prepare stmt` once, then `execute stmt` multiple times before running `deallocate`  $\leftrightarrow$  `prepare`:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...; -- Execute once
MySQL [test]> ...
MySQL [test]> execute stmt using ...; -- Execute multiple times
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In real practice, you may be used to running `deallocate prepare` each time after running `execute stmt`, as shown below:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
MySQL [test]> prepare stmt from '...'; -- Prepare twice
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In such practice, the plan obtained by the first executed statement cannot be reused by the second executed statement.

To address the problem, you can set the system variable `tidb_ignore_prepared_cache_close_stmt`  $\leftrightarrow$  to ON so TiDB ignores commands to close `prepare stmt`:

```
mysql> set @@tidb_ignore_prepared_cache_close_stmt=1; -- Enable the
 \(\rightarrow\) variable
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare once
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt; -- Execute once
Empty set (0.00 sec)

mysql> deallocate prepare stmt; -- Release after the first execute
```

```

Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare twice
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt; -- Execute twice
Empty set (0.00 sec)

mysql> select @@last_plan_from_cache; -- Reuse the last plan
+-----+
| @@last_plan_from_cache |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

```

## Monitoring

In the [Grafana dashboard](#) on the TiDB page in the **Executor** section, there are the “Queries Using Plan Cache OPS” and “Plan Cache Miss OPS” graphs. These graphs can be used to check if both TiDB and the application are configured correctly to allow the SQL Plan Cache to work correctly. The **Server** section on the same page provides the “Prepared Statement Count” graph. This graph shows a non-zero value if the application uses prepared statements, which is required for the SQL Plan Cache to function correctly.

Figure 187: sql\_plan\_cache

## 11.3.4 Control Execution Plans

### 11.3.4.1 Control Execution Plan

The first two chapters of SQL Tuning introduce how to understand TiDB’s execution plan and how TiDB generates an execution plan. This chapter introduces what methods can be used to control the generation of the execution plan when you determine the problems with the execution plan. This chapter mainly includes the following three aspects:

- In [Optimizer Hints](#), you will learn how to use hints to guide TiDB to generate an execution plan.
- But hints change the SQL statement intrusively. In some scenarios, hints cannot be simply inserted. In [SQL Plan Management](#), you will know how TiDB uses another syntax to non-intrusively control the generation of execution plans, and the methods of automatic execution plan evolution in the background to alleviate the execution plan instability caused by reasons such as version upgrades, which degrades cluster performance.
- Finally, you will learn how to use the blocklist in [Blocklist of Optimization Rules and Expression Pushdown](#).

### 11.3.4.2 Optimizer Hints

TiDB supports optimizer hints, which are based on the comment-like syntax introduced in MySQL 5.7. For example, one of the common syntaxes is `/*+ HINT_NAME([t1_name [, t2_name] ...])*/`. Use of optimizer hints is recommended in cases where the TiDB optimizer selects a less optimal query plan.

#### Note:

MySQL command-line clients earlier than 5.7.7 strip optimizer hints by default. If you want to use the `Hint` syntax in these earlier versions, add the `--comments` option when starting the client. For example: `mysql -h ↵ 127.0.0.1 -P 4000 -uroot --comments`.

#### 11.3.4.2.1 Syntax

#### Note:

If the table you want to hint is not in the database specified by `USE DATABASE`, you need to specify the database name explicitly. For example:

```
tidb> SELECT /*+ HASH_JOIN(t2, t) */ * FROM t, test2.t2;
Empty set, 1 warning (0.00 sec)

tidb> SHOW WARNINGS;
+--
↵ -----+-----+-----
↵
| Level | Code | Message
↵
↵ |
```

```

+---
 ↳ -----+-----+-----
 ↳
| Warning | 1815 | There are no matching table names for (t2)
 ↳ in optimizer hint /*+ HASH_JOIN(t2, t) */ or /*+ TIDB_HJ
 ↳ (t2, t) */. Maybe you can use the table alias name |
+---
 ↳ -----+-----+-----
 ↳
1 row in set (0.00 sec)

tidb> SELECT /*+ HASH_JOIN(test2.t2, t) */ * FROM t, test2.t2;
Empty set (0.00 sec)

tidb> SELECT /*+ READ_FROM_STORAGE(TIFLASH[test1.t1, test2.t2])
 ↳ */ t1.a FROM test1.t t1, test2.t t2 WHERE t1.a = t2.a;
Empty set (0.00 sec)

```

The examples in this document are all tables in the same database. If the tables you use are not in the same database, refer to the instructions to explicitly specify the database name.

Optimizer hints are case insensitive and specified within `/*+ ... */` comments following the `SELECT`, `UPDATE` or `DELETE` keyword in a SQL statement. Optimizer hints are not currently supported for `INSERT` statements.

Multiple hints can be specified by separating with commas. For example, the following query uses three different hints:

```

SELECT /*+ USE_INDEX(t1, idx1), HASH_AGG(), HASH_JOIN(t1) */ count(*) FROM
 ↳ t t1, t t2 WHERE t1.a = t2.b;

```

How optimizer hints affect query execution plans can be observed in the output of `EXPLAIN` and `EXPLAIN ANALYZE`.

An incorrect or incomplete hint will not result in a statement error. This is because hints are intended to have only a *hint* (suggestion) semantic to query execution. Similarly, TiDB will at most return a warning if a hint is not applicable.

**Note:**

If the comments do not follow behind the specified keywords, they will be treated as common MySQL comments. The comments do not take effect, and no warning is reported.

Currently, TiDB supports two categories of hints, which are different in scope. The first category of hints takes effect in the scope of query blocks, such as `/*+ HASH_AGG()*/`; the second category of hints takes effect in the whole query, such as `/*+ MEMORY_QUOTA(1024 MB)*/`.

Each query or sub-query in a statement corresponds to a different query block, and each query block has its own name. For example:

```
SELECT * FROM (SELECT * FROM t) t1, (SELECT * FROM t) t2;
```

The above query statement has three query blocks: the outermost `SELECT` corresponds to the first query block, whose name is `sel_1`; the two `SELECT` sub-queries correspond to the second and the third query block, whose names are `sel_2` and `sel_3`, respectively. The sequence of the numbers is based on the appearance of `SELECT` from left to right. If you replace the first `SELECT` with `DELETE` or `UPDATE`, then the corresponding query block names are `del_1` or `upd_1`.

#### 11.3.4.2.2 Hints that take effect in query blocks

This category of hints can follow behind **any** `SELECT`, `UPDATE` or `DELETE` keywords. To control the effective scope of the hint, use the name of the query block in the hint. You can make the hint parameters clear by accurately identifying each table in the query (in case of duplicated table names or aliases). If no query block is specified in the hint, the hint takes effect in the current block by default.

For example:

```
SELECT /*+ HASH_JOIN(@sel_1 t1@sel_1, t3) */ * FROM (SELECT t1.a, t1.b
↪ FROM t t1, t t2 WHERE t1.a = t2.a) t1, t t3 WHERE t1.b = t3.b;
```

This hint takes effect in the `sel_1` query block, and its parameters are the `t1` and `t3` tables in `sel_1` (`sel_2` also contains a `t1` table).

As described above, you can specify the name of the query block in the hint in the following ways:

- Set the query block name as the first parameter of the hint, and separate it from other parameters with a space. In addition to `QB_NAME`, all the hints listed in this section also have another optional hidden parameter `@QB_NAME`. By using this parameter, you can specify the effective scope of this hint.

- Append `@QB_NAME` to a table name in the parameter to explicitly specify which query block this table belongs to.

**Note:**

You must put the hint in or before the query block where the hint takes effect. If the hint is put after the query block, it cannot take effect.

### QB\_NAME

If the query statement is a complicated statement that includes multiple nested queries, the ID and name of a certain query block might be mistakenly identified. The hint `QB_NAME` can help us in this regard.

`QB_NAME` means Query Block Name. You can specify a new name to a query block. The specified `QB_NAME` and the previous default name are both valid. For example:

```
SELECT /*+ QB_NAME(QB1) */ * FROM (SELECT * FROM t) t1, (SELECT * FROM t)
↪ t2;
```

This hint specifies the outer `SELECT` query block's name to `QB1`, which makes `QB1` and the default name `sel_1` both valid for the query block.

**Note:**

In the above example, if the hint specifies the `QB_NAME` to `sel_2` and does not specify a new `QB_NAME` for the original second `SELECT` query block, then `sel_2` becomes an invalid name for the second `SELECT` query block.

### MERGE\_JOIN(t1\_name [, t1\_name ...])

The `MERGE_JOIN(t1_name [, t1_name ...])` hint tells the optimizer to use the sort-merge join algorithm for the given table(s). Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ MERGE_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

**Note:**

TIDB\_SMJ is the alias for MERGE\_JOIN in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the TIDB\_SMJ(*t1\_name*  $\hookrightarrow$  [, *t1\_name* ...]) syntax for the hint. For the later versions of TiDB, TIDB\_SMJ and MERGE\_JOIN are both valid names for the hint, but MERGE\_JOIN is recommended.

INL\_JOIN(*t1\_name* [, *t1\_name* ...])

The INL\_JOIN(*t1\_name* [, *t1\_name* ...]) hint tells the optimizer to use the index nested loop join algorithm for the given table(s). This algorithm might consume less system resources and take shorter processing time in some scenarios and might produce an opposite result in other scenarios. If the result set is less than 10,000 rows after the outer table is filtered by the WHERE condition, it is recommended to use this hint. For example:

```
select /*+ INL_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

The parameter(s) given in INL\_JOIN() is the candidate table for the inner table when you create the query plan. For example, INL\_JOIN(*t1*) means that TiDB only considers using *t1* as the inner table to create a query plan. If the candidate table has an alias, you must use the alias as the parameter in INL\_JOIN(); if it does not have an alias, use the table's original name as the parameter. For example, in the `select /*+ INL_JOIN(t1)*/  $\hookrightarrow$  * from t t1, t t2 where t1.a = t2.b;` query, you must use the *t* table's alias *t1* or *t2* rather than *t* as INL\_JOIN()'s parameter.

**Note:**

TIDB\_INLJ is the alias for INL\_JOIN in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the TIDB\_INLJ(*t1\_name*  $\hookrightarrow$  [, *t1\_name* ...]) syntax for the hint. For the later versions of TiDB, TIDB\_INLJ and INL\_JOIN are both valid names for the hint, but INL\_JOIN is recommended.

## INL\_HASH\_JOIN

The INL\_HASH\_JOIN(*t1\_name* [, *t1\_name*]) hint tells the optimizer to use the index nested loop hash join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm. The difference between the two algorithms is that INL\_JOIN creates a hash table on the joined inner table, but INL\_HASH\_JOIN creates a hash table on the joined outer table. INL\_HASH\_JOIN has a fixed limit on memory usage, while the memory used by INL\_JOIN depends on the number of rows matched in the inner table.

`HASH_JOIN(t1_name [, t1_name ...])`

The `HASH_JOIN(t1_name [, t1_name ...])` hint tells the optimizer to use the hash join algorithm for the given table(s). This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

#### Note:

`TIDB_HJ` is the alias for `HASH_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_HJ(t1_name ↪ [, t1_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_HJ` and `HASH_JOIN` are both valid names for the hint, but `HASH_JOIN` is recommended.

`HASH_JOIN_BUILD(t1_name [, t1_name ...])`

The `HASH_JOIN_BUILD(t1_name [, t1_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the build side. In this way, you can build hash tables using specific tables. For example:

```
SELECT /*+ HASH_JOIN_BUILD(t1) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

`HASH_JOIN_PROBE(t1_name [, t1_name ...])`

The `HASH_JOIN_PROBE(t1_name [, t1_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the probe side. In this way, you can execute the hash join algorithm with specific tables as the probe side. For example:

```
SELECT /*+ HASH_JOIN_PROBE(t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

`SEMI_JOIN_REWRITE()`

The `SEMI_JOIN_REWRITE()` hint tells the optimizer to rewrite the semi-join query to an ordinary join query. Currently, this hint only works for `EXISTS` subqueries.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

```
-- Does not use SEMI_JOIN_REWRITE() to rewrite the query.
EXPLAIN SELECT * FROM t WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t.a);
```

```

| ↳

```

From the preceding example, you can see that when using the `SEMI_JOIN_REWRITE()` hint, TiDB can select the execution method of IndexJoin based on the driving table `t1`.

### `NO_DECORRELATE()`

The `NO_DECORRELATE()` hint tells the optimizer not to try to perform decorrelation for the correlated subquery in the specified query block. This hint is applicable to the `EXISTS`, `IN`, `ANY`, `ALL`, `SOME` subqueries and scalar subqueries that contain correlated columns (that is, correlated subqueries).

When this hint is used in a query block, the optimizer will not try to perform decorrelation for the correlated columns between the subquery and its outer query block, but always use the Apply operator to execute the query.

By default, TiDB tries to **perform decorrelation** for correlated subqueries to achieve higher execution efficiency. However, in **some scenarios**, decorrelation might actually reduce the execution efficiency. In this case, you can use this hint to manually tell the optimizer not to perform decorrelation. For example:

```

create table t1(a int, b int);
create table t2(a int, b int, index idx(b));

```

```
-- Not using NO_DECORRELATE().
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
↳ = t1.b);
```

```

↳ order:false, stats:pseudo
```

```

↪
+--
↪
↪

```

From the preceding execution plan, you can see that the optimizer has automatically performed decorrelation. The decorrelated execution plan does not have the Apply operator. Instead, the plan has join operations between the subquery and the outer query block. The original filter condition (`t2.b = t1.b`) with the correlated column becomes a regular join condition.

```

-- Using NO_DECORRELATE().
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
↪ t2.a) from t2 where t2.b = t1.b);

```

```

↪ | funcs:sum(Column#14)->Column#7
↪
| -Projection_45 | 100000.00 | root |
↪ | cast(test.t2.a, decimal(10,0) BINARY)->Column

```

```

↪ #14 |
| - IndexLookUp_44 | 100000.00 | root |
↪ |
↪ |
↪ |
| - IndexRangeScan_42(Build) | 100000.00 | cop[tikv] | table:t2,
↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
↪ order:false, stats:pseudo |
| - TableRowIDScan_43(Probe) | 100000.00 | cop[tikv] | table:t2
↪ | keep order:false, stats:pseudo
↪ |
+---
↪ -----+-----+-----+-----
↪

```

From the preceding execution plan, you can see that the optimizer does not perform decorrelation. The execution plan still contains the Apply operator. The filter condition ( $t2.b = t1.b$ ) with the correlated column is still the filter condition when accessing the  $t2$  table.

### HASH\_AGG()

The `HASH_AGG()` hint tells the optimizer to use the hash aggregation algorithm in all the aggregate functions in the specified query block. This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```

select /*+ HASH_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.
↪ id;

```

### STREAM\_AGG()

The `STREAM_AGG()` hint tells the optimizer to use the stream aggregation algorithm in all the aggregate functions in the specified query block. Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```

select /*+ STREAM_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1
↪ .id;

```

### USE\_INDEX(t1\_name, idx1\_name [, idx2\_name ...])

The `USE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es) for a specified  $t1\_name$  table. For example, applying the following hint has the same effect as executing the `select * from t t1 use index(idx1, ↪ idx2);` statement.

```

SELECT /*+ USE_INDEX(t1, idx1, idx2) */ * FROM t1;

```

**Note:**

If you specify only the table name but not index name in this hint, the execution does not consider any index but scan the entire table.

```
FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])
```

The `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es).

The usage and effect of `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` are the same as the usage and effect of `USE_INDEX(t1_name, idx1_name [, idx2_name ...])`.

The following 4 queries have the same effect:

```
SELECT /*+ USE_INDEX(t, idx1) */ * FROM t;
SELECT /*+ FORCE_INDEX(t, idx1) */ * FROM t;
SELECT * FROM t use index(idx1);
SELECT * FROM t force index(idx1);
```

```
IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])
```

The `IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to ignore the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 ignore index(↵ idx1, idx2);` statement.

```
select /*+ IGNORE_INDEX(t1, idx1, idx2) */ * from t t1;
```

```
ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])
```

The `ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and read the specified index in order.

**Warning:**

This hint might cause SQL statements to fail. It is recommended to test it first. If an error occurs during the test, remove the hint. If the test runs normally, you can continue using it.

This hint is usually applied in the following scenario:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```

+--
 ↳ -----+-----+-----+-----+
 ↳
| id | estRows | task | access object | operator
 ↳ info |
+--
 ↳ -----+-----+-----+-----+
 ↳
| Limit_10 | 10.00 | root | | offset:0,
 ↳ count:10 |
| -IndexReader_14 | 10.00 | root | | index:
 ↳ Limit_13 |
| -Limit_13 | 10.00 | cop[tikv] | | offset:0,
 ↳ count:10 |
| -IndexFullScan_12 | 10.00 | cop[tikv] | table:t, index:a(a) | keep
 ↳ order:true, stats:pseudo |
+--
 ↳ -----+-----+-----+-----+
 ↳

```

The optimizer generates two types of plan for this query: Limit + IndexScan(keep order: true) and TopN + IndexScan(keep order: false). When the ORDER\_INDEX hint is used, the optimizer chooses the first plan that reads the index in order.

### Note:

- If the query itself does not need to read the index in order (that is, without a hint, the optimizer does not generate a plan that reads the index in order in any situation), when the ORDER\_INDEX hint is used, the error `Can't find a proper physical plan for this query` occurs. In this case, you need to remove the corresponding ORDER\_INDEX hint.
- The index on a partitioned table cannot be read in order, so do not use the ORDER\_INDEX hint on the partitioned table and its related indexes.

```
NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])
```

The NO\_ORDER\_INDEX(t1\_name, idx1\_name [, idx2\_name ...]) hint tells the optimizer to use only the given index for a specified table and not to read the specified index in order. This hint is usually applied in the following scenario.

The following example shows that the effect of the query statement is equivalent to `SELECT * FROM t t1 use index(idx1, idx2);`

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ NO_ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```
+--
 ↪ -----+-----+-----+-----+
 ↪
| id | estRows | task | access object | operator
 ↪ info | | | |
+--
 ↪ -----+-----+-----+-----+
 ↪
| TopN_7 | 10.00 | root | | test.t.a,
 ↪ offset:0, count:10 |
| -IndexReader_14 | 10.00 | root | | index:
 ↪ TopN_13 | | | |
| -TopN_13 | 10.00 | cop[tikv] | | test.t.a
 ↪ , offset:0, count:10 |
| -IndexFullScan_12 | 10000.00 | cop[tikv] | table:t, index:a(a) |
 ↪ keep order:false, stats:pseudo |
+--
 ↪ -----+-----+-----+-----+
 ↪
```

The same as the example of `ORDER_INDEX` hint, the optimizer generates two types of plans for this query: `Limit + IndexScan(keep order: true)` and `TopN + IndexScan(↪ keep order: false)`. When the `NO_ORDER_INDEX` hint is used, the optimizer will choose the latter plan to read the index out of order.

### AGG\_TO\_COP()

The `AGG_TO_COP()` hint tells the optimizer to push down the aggregate operation in the specified query block to the coprocessor. If the optimizer does not push down some aggregate function that is suitable for pushdown, then it is recommended to use this hint. For example:

```
select /*+ AGG_TO_COP() */ sum(t1.a) from t t1;
```

### LIMIT\_TO\_COP()

The `LIMIT_TO_COP()` hint tells the optimizer to push down the `Limit` and `TopN` operators in the specified query block to the coprocessor. If the optimizer does not perform such an operation, it is recommended to use this hint. For example:

```
SELECT /*+ LIMIT_TO_COP() */ * FROM t WHERE a = 1 AND b > 10 ORDER BY c
 ↪ LIMIT 1;
```

`READ_FROM_STORAGE(TIFLASH[t1_name [, t1_name ...]], TIKV[t2_name [, t1_name ...]])`

The `READ_FROM_STORAGE(TIFLASH[t1_name [, t1_name ...]], TIKV[t2_name [, t2_name ...]])` hint tells the optimizer to read specific table(s) from specific storage engine(s). Currently, this hint supports two storage engine parameters - TIKV and TIFLASH. If a table has an alias, use the alias as the parameter of `READ_FROM_STORAGE()`; if the table does not have an alias, use the table's original name as the parameter. For example:

```
select /*+ READ_FROM_STORAGE(TIFLASH[t1], TIKV[t2]) */ t1.a from t t1, t
 ↪ t2 where t1.a = t2.a;
```

`USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])`

The `USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to access a specific table with the index merge method. Index merge has two types: intersection type and union type. For details, see [Explain Statements Using Index Merge](#).

If you explicitly specify the list of indexes, TiDB selects indexes from the list to build index merge; if you do not specify the list of indexes, TiDB selects indexes from all available indexes to build index merge.

For the intersection-type index merge, the given list of indexes is a required parameter in the hint. For the union-type index merge, the given list of indexes is an optional parameter in the hint. See the following example.

```
SELECT /*+ USE_INDEX_MERGE(t1, idx_a, idx_b, idx_c) */ * FROM t1 WHERE t1.
 ↪ a > 10 OR t1.b > 10;
```

When multiple `USE_INDEX_MERGE` hints are made to the same table, the optimizer tries to select the index from the union of the index sets specified by these hints.

#### Note:

The parameters of `USE_INDEX_MERGE` refer to index names, rather than column names. The index name of the primary key is `primary`.

`LEADING(t1_name [, t1_name ...])`

The `LEADING(t1_name [, t1_name ...])` hint reminds the optimizer that, when generating the execution plan, to determine the order of multi-table joins according to the order of table names specified in the hint. For example:

```
SELECT /*+ LEADING(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id and t2.
 ↪ id = t3.id;
```

In the above query with multi-table joins, the order of joins is determined by the order of table names specified in the `LEADING()` hint. The optimizer will first join `t1` and `t2` and then join the result with `t3`. This hint is more general than `STRAIGHT_JOIN`.

The `LEADING` hint does not take effect in the following situations:

- Multiple `LEADING` hints are specified.
- The table name specified in the `LEADING` hint does not exist.
- A duplicated table name is specified in the `LEADING` hint.
- The optimizer cannot perform join operations according to the order as specified by the `LEADING` hint.
- The `straight_join()` hint already exists.
- The query contains an outer join together with the Cartesian product.
- Any of the `MERGE_JOIN`, `INL_JOIN`, `INL_HASH_JOIN`, and `HASH_JOIN` hints is used at the same time.

In the above situations, a warning is generated.

```
-- Multiple `LEADING` hints are specified.
SELECT /*+ LEADING(t1, t2) LEADING(t3) */ * FROM t1, t2, t3 WHERE t1.id =
 ↳ t2.id and t2.id = t3.id;

-- To learn why the `LEADING` hint fails to take effect, execute `show
 ↳ warnings`.
SHOW WARNINGS;
```

```
+--
 ↳ -----+-----+-----
 ↳
| Level | Code | Message
 ↳
 ↳ |
+--
 ↳ -----+-----+-----
 ↳
| Warning | 1815 | We can only use one leading hint at most, when multiple
 ↳ leading hints are used, all leading hints will be invalid |
+--
 ↳ -----+-----+-----
 ↳
```

### Note:

If the query statement includes an outer join, in the hint you can specify only the tables whose join order can be swapped. If there is a table in the hint whose join order cannot be swapped, the hint will be invalid. For example, in `SELECT * FROM t1 LEFT JOIN (t2 JOIN t3 JOIN t4) ON t1.a = t2.a;`, if you want to control the join order of `t2`, `t3`, and `t4` tables, you cannot specify `t1` in the `LEADING` hint.

## MERGE()

Using the `MERGE()` hint in queries with common table expressions (CTE) can disable the materialization of the subqueries and expand the subquery inlines into CTE. This hint is only applicable to non-recursive CTE. In some scenarios, using `MERGE()` brings higher execution efficiency than the default behavior of allocating a temporary space. For example, pushing down query conditions or in nesting CTE queries:

```
-- Uses the hint to push down the predicate of the outer query.
WITH CTE AS (SELECT /*+ MERGE() */ * FROM tc WHERE tc.a < 60) SELECT * FROM
 ↪ CTE WHERE CTE.a < 18;

-- Uses the hint in a nested CTE query to expand a CTE inline into the
 ↪ outer query.
WITH CTE1 AS (SELECT * FROM t1), CTE2 AS (WITH CTE3 AS (SELECT /*+ MERGE()
 ↪ */ * FROM t2), CTE4 AS (SELECT * FROM t3) SELECT * FROM CTE3, CTE4)
 ↪ SELECT * FROM CTE1, CTE2;
```

### Note:

`MERGE()` is only applicable to simple CTE queries. It is not applicable in the following situations:

- [Recursive CTE](#)
- Subqueries with inlines that cannot be expanded, such as aggregate operators, window functions, and `DISTINCT`.

When the number of CTE references is too high, the query performance might be lower than the default materialization behavior.

### 11.3.4.2.3 Hints that take effect globally

The global hint works in [views](#). When specified as a global hint, the hint defined in a query can take effect inside the view. To specify a global hint, first use the `QB_NAME` `↪` hint to define a query block name, and then add the target hints in the form of `ViewName@QueryBlockName`.

Step 1: Define the query block name of the view using the `QB_NAME` hint

Use the `QB_NAME` hint to define a new name for each query block of the view. The definition of the `QB_NAME` hint for views is the same as that for [query blocks](#), but the syntax is extended from `QB_NAME(QB)` to `QB_NAME(QB, ViewName@QueryBlockName [.` `↪ ViewName@QueryBlockName .ViewName@QueryBlockName ...])`.

**Note:**

There is a white space between @QueryBlockName and the immediately following .ViewName@QueryBlockName. Otherwise, the .ViewName@QueryBlockName will be treated as a part of the QueryBlockName  $\hookrightarrow$  . For example, QB\_NAME(v2\_1, v2@SEL\_1 .@SEL\_1) is valid, while QB\_NAME(v2\_1, v2@SEL\_1.@SEL\_1) cannot be parsed correctly.

- For a simple statement with a single view and no subqueries, the following example specifies the first query block name of view v:

```
SELECT /* Comment: The name of the current query block is the default
 \hookrightarrow @SEL_1 */ * FROM v;
```

For view v, the first view name in the list (ViewName@QueryBlockName [.  $\hookrightarrow$  ViewName@QueryBlockName .ViewName@QueryBlockName ...]) starting from the query statement is v@SEL\_1. The first query block of the view v can be declared as QB\_NAME(v\_1, v@SEL\_1 .@SEL\_1), or simply written as QB\_NAME(v\_1, v), omitting @SEL\_1:

```
CREATE VIEW v AS SELECT /* Comment: The name of the current query
 \hookrightarrow block is the default @SEL_1 */ * FROM t;

-- Specifies the global hint
SELECT /*+ QB_NAME(v_1, v) USE_INDEX(t@v_1, idx) */ * FROM v;
```

- For a complex statement with nested views and subqueries, the following example specifies the names for each of two query blocks of the view v1 and v2:

```
SELECT /* Comment: The name of the current query block is the default
 \hookrightarrow @SEL_1 */ * FROM v2 JOIN (
 SELECT /* Comment: The name of the current query block is the
 \hookrightarrow default @SEL_2 */ * FROM v2) vv;
```

For the first view v2, the first view name in the list starting from the first query statement is v2@SEL\_1. For the second view v2, the first view name is v2@SEL\_2. The following example only considers the first view v2.

The first query block of view v2 can be declared as QB\_NAME(v2\_1, v2@SEL\_1 .@SEL\_1  $\hookrightarrow$  ), and the second query block of the view v2 can be declared as QB\_NAME(v2\_2,  $\hookrightarrow$  v2@SEL\_1 .@SEL\_2):

```
CREATE VIEW v2 AS
```

```

SELECT * FROM t JOIN /* Comment: For view v2, the name of the
 ↪ current query block is the default @SEL_1. So, the current
 ↪ query block view list is v2@SEL_1 .@SEL_1 */
(
 SELECT COUNT(*) FROM t1 JOIN v1 /* Comment: For view v2, the
 ↪ name of the current query block is the default @SEL_2.
 ↪ So, the current query block view list is v2@SEL_1 .
 ↪ @SEL_2 */
) tt;

```

For view v1, the first view name in the list starting from the preceding statement is v2@SEL\_1 .v1@SEL\_2. The first query block in view v1 can be declared as QB\_NAME ↪ (v1\_1, v2@SEL\_1 .v1@SEL\_2 .@SEL\_1), and the second query block in view v1 can be declared as QB\_NAME(v1\_2, v2@SEL\_1 .v1@SEL\_2 .@SEL\_2):

```

CREATE VIEW v1 AS SELECT * FROM t JOIN /* Comment: For view `v1`, the
 ↪ name of the current query block is the default @SEL_1. So, the
 ↪ current query block view list is v2@SEL_1 .@SEL_2 .v1@SEL_1 */
(
 SELECT COUNT(*) FROM t1 JOIN t2 /* Comment: For view `v1`, the
 ↪ name of the current query block is the default @SEL_2.
 ↪ So, the current query block view list is v2@SEL_1 .
 ↪ @SEL_2 .v1@SEL_2 */
) tt;

```

### Note:

- To use global hints with views, you must define the corresponding QB\_NAME hints in the view. Otherwise, the global hints will not take effect.
- When using a hint to specify multiple table names in a view, you need to ensure that the table names appearing in the same hint are in the same query block of the same view.
- When you define the QB\_NAME hint in a view for the outermost query block:
  - For the first item of the view list in the QB\_NAME, if the @SEL\_ ↪ is not explicitly declared, the default is consistent with the query block position where the QB\_NAME is defined. That is, the query SELECT /\*+ QB\_NAME(qb1, v2)\*/ \* FROM v2 JOIN ↪ (SELECT /\*+ QB\_NAME(qb2, v2)\*/ \* FROM v2)vv; is equivalent to SELECT /\*+ QB\_NAME(qb1, v2@SEL\_1)\*/ \* FROM v2 JOIN ↪ (SELECT /\*+ QB\_NAME(qb2, v2@SEL\_2)\*/ \* FROM v2)vv;.

- For items other than the first item of the view list in the `QB_NAME`  $\hookrightarrow$ , only `@SEL_1` can be omitted. That is, if `@SEL_1` is declared in the first query block of the current view, `@SEL_1` can be omitted. Otherwise, `@SEL_` cannot be omitted. For the preceding example:
  - \* The first query block of the view `v2` can be declared as `QB_NAME`  $\hookrightarrow$  (`v2_1`, `v2`).
  - \* The second query block of the view `v2` can be declared as `QB_NAME(v2_2, v2.@SEL_2)`.
  - \* The first query block of the view `v1` can be declared as `QB_NAME`  $\hookrightarrow$  (`v1_1`, `v2.v1@SEL_2`).
  - \* The second query block of the view `v1` can be declared as `QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2)`.

## Step 2: Add the target hints

After defining the `QB_NAME` hint for query blocks of the view, you can add required **hints that take effect in query blocks** in the form of `ViewName@QueryBlockName` to make them effective inside the view. For example:

- Specify the `MERGE_JOIN()` hint for the first query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_1, v2) merge_join(t@v2_1) */ * FROM v2;
```

- Specify the `MERGE_JOIN()` and `STREAM_AGG()` hints for the second query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_2, v2.@SEL_2) merge_join(t1@v2_2) stream_agg(
 ↪ @v2_2) */ * FROM v2;
```

- Specify the `HASH_JOIN()` hint for the first query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_1, v2.v1@SEL_2) hash_join(t@v1_1) */ * FROM v2;
```

- Specify the `HASH_JOIN()` and `HASH_AGG()` hints for the second query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2) hash_join(t1@v1_2)
 ↪ hash_agg(@v1_2) */ * FROM v2;
```

### 11.3.4.2.4 Hints that take effect in the whole query

This category of hints can only follow behind the **first** `SELECT`, `UPDATE` or `DELETE` keyword, which is equivalent to modifying the value of the specified system variable when this query is executed. The priority of the hint is higher than that of existing system variables.

**Note:**

This category of hints also has an optional hidden variable `@QB_NAME`, but the hint takes effect in the whole query even if you specify the variable.

**NO\_INDEX\_MERGE()**

The `NO_INDEX_MERGE()` hint disables the index merge feature of the optimizer.

For example, the following query will not use index merge:

```
select /*+ NO_INDEX_MERGE() */ * from t where t.a > 0 or t.b > 0;
```

In addition to this hint, setting the `tidb_enable_index_merge` system variable also controls whether to enable this feature.

**Note:**

- `NO_INDEX_MERGE` has a higher priority over `USE_INDEX_MERGE`. When both hints are used, `USE_INDEX_MERGE` does not take effect.
- For a subquery, `NO_INDEX_MERGE` only takes effect when it is placed at the outermost level of the subquery.

**USE\_TOJA(boolean\_value)**

The `boolean_value` parameter can be `TRUE` or `FALSE`. The `USE_TOJA(TRUE)` hint enables the optimizer to convert an `in` condition (containing a sub-query) to join and aggregation operations. Comparatively, the `USE_TOJA(FALSE)` hint disables this feature.

For example, the following query will convert `in (select t2.a from t2)subq` to corresponding join and aggregation operations:

```
select /*+ USE_TOJA(TRUE) */ t1.a, t1.b from t1 where t1.a in (select t2.a
↪ from t2) subq;
```

In addition to this hint, setting the `tidb_opt_insubq_to_join_and_agg` system variable also controls whether to enable this feature.

**MAX\_EXECUTION\_TIME(N)**

The `MAX_EXECUTION_TIME(N)` hint places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it. In the following hint, `MAX_EXECUTION_TIME(1000)` means that the timeout is 1000 milliseconds (that is, 1 second):

```
select /*+ MAX_EXECUTION_TIME(1000) */ * from t1 inner join t2 where t1.id
↪ = t2.id;
```

In addition to this hint, the `global.max_execution_time` system variable can also limit the execution time of a statement.

### MEMORY\_QUOTA(N)

The `MEMORY_QUOTA(N)` hint places a limit `N` (a threshold value in MB or GB) on how much memory a statement is permitted to use. When a statement's memory usage exceeds this limit, TiDB produces a log message based on the statement's over-limit behavior or just terminates it.

In the following hint, `MEMORY_QUOTA(1024 MB)` means that the memory usage is limited to 1024 MB:

```
select /*+ MEMORY_QUOTA(1024 MB) */ * from t;
```

In addition to this hint, the `tidb_mem_quota_query` system variable can also limit the memory usage of a statement.

### READ\_CONSISTENT\_REPLICA()

The `READ_CONSISTENT_REPLICA()` hint enables the feature of reading consistent data from the TiKV follower node. For example:

```
select /*+ READ_CONSISTENT_REPLICA() */ * from t;
```

In addition to this hint, setting the `tidb_replica_read` environment variable to '`↪ follower`' or '`leader`' also controls whether to enable this feature.

### IGNORE\_PLAN\_CACHE()

The `IGNORE_PLAN_CACHE()` hint reminds the optimizer not to use the Plan Cache when handling the current `prepare` statement.

This hint is used to temporarily disable the Plan Cache for a certain type of queries when `prepare-plan-cache` is enabled.

In the following example, the Plan Cache is forcibly disabled when executing the `prepare` statement.

```
prepare stmt from 'select /*+ IGNORE_PLAN_CACHE() */ * from t where t.id =
↪ ?';
```

### STRAIGHT\_JOIN()

The `STRAIGHT_JOIN()` hint reminds the optimizer to join tables in the order of table names in the `FROM` clause when generating the join plan.

```
SELECT /*+ STRAIGHT_JOIN() */ * FROM t t1, t t2 WHERE t1.a = t2.a;
```

**Note:**

- `STRAIGHT_JOIN` has higher priority over `LEADING`. When both hints are used, `LEADING` does not take effect.
- It is recommended to use the `LEADING` hint, which is more general than the `STRAIGHT_JOIN` hint.

### `NTH_PLAN(N)`

The `NTH_PLAN(N)` hint reminds the optimizer to select the Nth physical plan found during the physical optimization. `N` must be a positive integer.

If the specified `N` is beyond the search range of the physical optimization, TiDB will return a warning and select the optimal physical plan based on the strategy that ignores this hint.

This hint does not take effect when the cascades planner is enabled.

In the following example, the optimizer is forced to select the third physical plan found during the physical optimization:

```
SELECT /*+ NTH_PLAN(3) */ count(*) from t where a > 5;
```

**Note:**

`NTH_PLAN(N)` is mainly used for testing, and its compatibility is not guaranteed in later versions. Use this hint **with caution**.

### 11.3.4.3 SQL Plan Management (SPM)

SQL Plan Management is a set of functions that execute SQL bindings to manually interfere with SQL execution plans. These functions include SQL binding, baseline capturing, and baseline evolution.

#### 11.3.4.3.1 SQL binding

An SQL binding is the basis of SPM. The [Optimizer Hints](#) document introduces how to select a specific execution plan using hints. However, sometimes you need to interfere with execution selection without modifying SQL statements. With SQL bindings, you can select a specified execution plan without modifying SQL statements.

**Note:**

To use SQL bindings, you need to have the `SUPER` privilege. If TiDB prompts that you do not have sufficient privileges, see [Privilege Management](#) to add the required privileges.

Create a binding

You can create a binding for a SQL statement according to a SQL statement or a historical execution plan.

Create a binding according to a SQL statement

```
CREATE [GLOBAL | SESSION] BINDING FOR BindableStmt USING BindableStmt
```

This statement binds SQL execution plans at the `GLOBAL` or `SESSION` level. Currently, supported bindable SQL statements (`BindableStmt`) in TiDB include `SELECT`, `DELETE`, `UPDATE`, and `INSERT / REPLACE` with `SELECT` subqueries.

**Note:**

Bindings have higher priority over manually added hints. Therefore, when you execute a statement containing a hint while a corresponding binding is present, the hint controlling the behavior of the optimizer does not take effect. However, other types of hints are still effective.

Specifically, two types of these statements cannot be bound to execution plans due to syntax conflicts. See the following examples:

```
-- Type one: Statements that get the Cartesian product by using the `JOIN`
↳ keyword and not specifying the associated columns with the `USING`
↳ keyword.
CREATE GLOBAL BINDING for
 SELECT * FROM t t1 JOIN t t2
USING
 SELECT * FROM t t1 JOIN t t2;

-- Type two: `DELETE` statements that contain the `USING` keyword.
CREATE GLOBAL BINDING for
 DELETE FROM t1 USING t1 JOIN t2 ON t1.a = t2.a
USING
 DELETE FROM t1 USING t1 JOIN t2 ON t1.a = t2.a;
```

You can bypass syntax conflicts by using equivalent statements. For example, you can rewrite the above statements in the following ways:

```
-- First rewrite of type one statements: Add a `USING` clause for the `
↳ JOIN` keyword.
CREATE GLOBAL BINDING for
 SELECT * FROM t t1 JOIN t t2 USING (a)
USING
 SELECT * FROM t t1 JOIN t t2 USING (a);

-- Second rewrite of type one statements: Delete the `JOIN` keyword.
CREATE GLOBAL BINDING for
 SELECT * FROM t t1, t t2
USING
 SELECT * FROM t t1, t t2;

-- Rewrite of type two statements: Remove the `USING` keyword from the `
↳ delete` statement.
CREATE GLOBAL BINDING for
 DELETE t1 FROM t1 JOIN t2 ON t1.a = t2.a
using
 DELETE t1 FROM t1 JOIN t2 ON t1.a = t2.a;
```

### Note:

When creating execution plan bindings for INSERT / REPLACE statements with SELECT subqueries, you need to specify the optimizer hints you want to bind in the SELECT subquery, not after the INSERT / REPLACE keyword. Otherwise, the optimizer hints do not take effect as intended.

Here are two examples:

```
-- The hint takes effect in the following statement.
CREATE GLOBAL BINDING for
 INSERT INTO t1 SELECT * FROM t2 WHERE a > 1 AND b = 1
using
 INSERT INTO t1 SELECT /*+ use_index(@sel_1 t2, a) */ * FROM t2 WHERE a
 ↳ > 1 AND b = 1;

-- The hint cannot take effect in the following statement.
CREATE GLOBAL BINDING for
 INSERT INTO t1 SELECT * FROM t2 WHERE a > 1 AND b = 1
using
```

```
INSERT /*+ use_index(@sel_1 t2, a) */ INTO t1 SELECT * FROM t2 WHERE a
↔ > 1 AND b = 1;
```

If you do not specify the scope when creating an execution plan binding, the default scope is SESSION. The TiDB optimizer normalizes bound SQL statements and stores them in the system table. When processing SQL queries, if a normalized statement matches one of the bound SQL statements in the system table and the system variable `tidb_use_plan_baselines` is set to `on` (the default value is `on`), TiDB then uses the corresponding optimizer hint for this statement. If there are multiple matchable execution plans, the optimizer chooses the least costly one to bind.

Normalization is a process that converts a constant in an SQL statement to a variable parameter and explicitly specifies the database for tables referenced in the query, with standardized processing on the spaces and line breaks in the SQL statement. See the following example:

```
SELECT * FROM t WHERE a > 1
-- After normalization, the above statement is as follows:
SELECT * FROM test . t WHERE a > ?
```

### Note:

Multiple constants joined by commas `,` are normalized as `...` instead of `?`.

For example:

```
SELECT * FROM t limit 10
SELECT * FROM t limit 10, 20
SELECT * FROM t WHERE a IN (1)
SELECT * FROM t WHERE a IN (1,2,3)
-- After normalization, the above statements are as follows:
SELECT * FROM test . t limit ?
SELECT * FROM test . t limit ...
SELECT * FROM test . t WHERE a IN (?)
SELECT * FROM test . t WHERE a IN (...)
```

When bindings are created, TiDB treats SQL statements that contain a single constant and SQL statements that contain multiple constants joined by commas differently. Therefore, you need to create bindings for the two SQL types separately.

When a SQL statement has bound execution plans in both GLOBAL and SESSION scopes, because the optimizer ignores the bound execution plan in the GLOBAL scope when

it encounters the SESSION binding, the bound execution plan of this statement in the SESSION scope shields the execution plan in the GLOBAL scope.

For example:

```
-- Creates a GLOBAL binding and specifies using `sort merge join` in this
↪ binding.
CREATE GLOBAL BINDING for
 SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
 SELECT /*+ merge_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- The execution plan of this SQL statement uses the `sort merge join`
↪ specified in the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Creates another SESSION binding and specifies using `hash join` in this
↪ binding.
CREATE BINDING for
 SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
 SELECT /*+ hash_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- In the execution plan of this statement, `hash join` specified in the
↪ SESSION binding is used, instead of `sort merge join` specified in
↪ the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;
```

When the first `SELECT` statement is being executed, the optimizer adds the `sm_join(t1, t2)` hint to the statement through the binding in the GLOBAL scope. The top node of the execution plan in the `explain` result is `MergeJoin`. When the second `SELECT` statement is being executed, the optimizer uses the binding in the SESSION scope instead of the binding in the GLOBAL scope and adds the `hash_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is `HashJoin`.

Each standardized SQL statement can have only one binding created using `CREATE BINDING` at a time. When multiple bindings are created for the same standardized SQL statement, the last created binding is retained, and all previous bindings (created and evolved) are marked as deleted. But session bindings and global bindings can coexist and are not affected by this logic.

In addition, when you create a binding, TiDB requires that the session is in a database context, which means that a database is specified when the client is connected or `use {database}` is executed.

The original SQL statement and the bound statement must have the same text after normalization and hint removal, or the binding will fail. Take the following examples:

- This binding can be created successfully because the texts before and after parameterization and hint removal are the same: `SELECT * FROM test . t WHERE a > ?`

```
sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM
↪ t use index (idx)WHERE a > 2
```

- This binding will fail because the original SQL statement is processed as `SELECT * ↪ FROM test . t WHERE a > ?`, while the bound SQL statement is processed differently as `SELECT * FROM test . t WHERE b > ?`.

```
sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM
↪ t use index(idx)WHERE b > 2
```

### Note:

For `PREPARE / EXECUTE` statements and for queries executed with binary protocols, you need to create execution plan bindings for the real query statements, not for the `PREPARE / EXECUTE` statements.

Create a binding according to a historical execution plan

To make the execution plan of a SQL statement fixed to a historical execution plan, you can use `plan_digest` to bind that historical execution plan to the SQL statement, which is more convenient than binding it according to a SQL statement.

Currently, this feature has the following limitations:

- The feature generates hints according to historical execution plans and uses the generated hints for binding. Because historical execution plans are stored in [Statement Summary Tables](#), before using this feature, you need to enable the `tidb_enable_stmt_summary` system variable first.
- Currently, this feature only supports binding historical execution plans in the `statements_summary` and `statements_summary_history` tables of the current TiDB node. If you get a `can't find any plans` error, you can connect to another TiDB node in the cluster and retry the binding.

The SQL statement of this binding method is as follows:

```
CREATE [GLOBAL | SESSION] BINDING FROM HISTORY USING PLAN DIGEST '
↪ plan_digest';
```

This statement binds an execution plan to a SQL statement using `plan_digest`. The default scope is `SESSION`. The applicable SQL statements, priorities, scopes, and effective conditions of the created bindings are the same as that of [bindings created according to SQL statements](#).

To use this binding method, you need to first get the `plan_digest` corresponding to the target historical execution plan in `statements_summary`, and then create a binding using the `plan_digest`. The detailed steps are as follows:

1. Get the `plan_digest` corresponding to the target execution plan in `statements_summary`

↪ .

For example:

```
CREATE TABLE t(id INT PRIMARY KEY , a INT, KEY(a));
SELECT /*+ IGNORE_INDEX(t, a) */ * FROM t WHERE a = 1;
SELECT * FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE
 ↪ QUERY_SAMPLE_TEXT = 'SELECT /*+ IGNORE_INDEX(t, a) */ * FROM t
 ↪ WHERE a = 1'\G;
```

The following is a part of the example query result of `statements_summary`:

```
SUMMARY_BEGIN_TIME: 2022-12-01 19:00:00
.....
DIGEST_TEXT: select * from `t` where `a` = ?
.....
PLAN_DIGEST: 4
 ↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb
 ↪
 PLAN: id task estRows operator info
 ↪ actRows execution info
 ↪
 ↪ memory disk
 TableReader_7 root 10 data:Selection_6
 ↪ 0 time:4.05ms, loops:1,
 ↪ cop_task: {num: 1, max: 598.6µs, proc_keys: 0,
 ↪ rpc_num: 2, rpc_time: 609.8µs,
 ↪ copr_cache_hit_ratio: 0.00, distsql_concurrency
 ↪ : 15} 176 Bytes N/A
 -Selection_6 cop[tikv] 10 eq(test.t.a, 1)
 ↪ 0 tikv_task:{time:560.8

↪ BIQFzCDhVQw19BAAkBX0QUg91cSgBfCAudC5hLCAxKWrmYQAYHOiOgc6hBB1hJAFAAVIQZG
↪ //////////////////////////////////8BGAE=

```

In this example, you can see that the execution plan corresponding to `plan_digest` is `4e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb`.

2. Use `plan_digest` to create a binding:

```

CREATE BINDING FROM HISTORY USING PLAN DIGEST '4
↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb';

```

To verify whether the created binding takes effect, you can [view bindings](#):

```
SHOW BINDINGS\G;
```

```

***** 1. row *****
Original_sql: select * from `test` . `t` where `a` = ?
 Bind_sql: SELECT /*+ use_index(@`sel_1` `test`.`t`) ignore_index(`t` `a`
↪ `)`*/ * FROM `test`.`t` WHERE `a` = 1

 Sql_digest: 6909
↪ a1bbce5f64ade0a532d7058dd77b6ad5d5068aee22a531304280de48349f
 Plan_digest:
1 row in set (0.01 sec)

ERROR:
No query specified

```

```

SELECT * FROM t WHERE a = 1;
SELECT @@LAST_PLAN_FROM_BINDING;

```

```

+-----+
| @@LAST_PLAN_FROM_BINDING |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

```

Remove a binding

You can remove a binding according to a SQL statement or `sql_digest`.

Remove a binding according to a SQL statement

```
DROP [GLOBAL | SESSION] BINDING FOR BindableStmt;
```

This statement removes a specified execution plan binding at the GLOBAL or SESSION level. The default scope is SESSION.

Generally, the binding in the SESSION scope is mainly used for test or in special situations. For a binding to take effect in all TiDB processes, you need to use the GLOBAL binding. A created SESSION binding shields the corresponding GLOBAL binding until the end of the SESSION, even if the SESSION binding is dropped before the session closes. In this case, no binding takes effect and the plan is selected by the optimizer.

The following example is based on the example in [create binding](#) in which the SESSION binding shields the GLOBAL binding:

```
-- Drops the binding created in the SESSION scope.
drop session binding for SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Views the SQL execution plan again.
explain SELECT * FROM t1,t2 WHERE t1.id = t2.id;
```

In the example above, the dropped binding in the SESSION scope shields the corresponding binding in the GLOBAL scope. The optimizer does not add the `sm_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is not fixed to MergeJoin by this hint. Instead, the top node is independently selected by the optimizer according to the cost estimation.

Remove a binding according to `sql_digest`

In addition to removing a binding according to a SQL statement, you can also remove a binding according to `sql_digest`.

```
DROP [GLOBAL | SESSION] BINDING FOR SQL DIGEST 'sql_digest';
```

This statement removes an execution plan binding corresponding to `sql_digest` at the GLOBAL or SESSION level. The default scope is SESSION. You can get the `sql_digest` by [viewing bindings](#).

### Note:

Executing `DROP GLOBAL BINDING` drops the binding in the current tidb-server instance cache and changes the status of the corresponding row in the system table to 'deleted'. This statement does not directly delete the records in the system table, because other tidb-server instances need to read the 'deleted' status to drop the corresponding binding in their cache. For the records in these system tables with the status of 'deleted', at every 100 `bind-info-lease` (the default value is 3s, and 300s in total) interval, the background

thread triggers an operation of reclaiming and clearing on the bindings of `update_time` before `10 bind-info-lease` (to ensure that all tidb-server instances have read the 'deleted' status and updated the cache).

### Change binding status

Change binding status according to a SQL statement

```
SET BINDING [ENABLED | DISABLED] FOR BindableStmt;
```

You can execute this statement to change the status of a binding. The default status is `ENABLED`. The effective scope is `GLOBAL` by default and cannot be modified.

When executing this statement, you can only change the status of a binding from `Disabled` to `Enabled` or from `Enabled` to `Disabled`. If no binding is available for status changes, a warning message is returned, saying `There are no bindings can be set the ↪ status. Please check the SQL text.` Note that a binding in `Disabled` status is not used by any query.

### Change binding status according to `sql_digest`

In addition to changing the binding status according to a SQL statement, you can also change the binding status according to `sql_digest`:

```
SET BINDING [ENABLED | DISABLED] FOR SQL DIGEST 'sql_digest';
```

The binding status that can be changed by `sql_digest` and the effect is the same as those changed [according to a SQL statement](#). If no binding is available for status changes, a warning message `can't find any binding for 'sql_digest'` is returned.

### View bindings

```
SHOW [GLOBAL | SESSION] BINDINGS [ShowLikeOrWhere]
```

This statement outputs the execution plan bindings at the `GLOBAL` or `SESSION` level according to the order of binding update time from the latest to earliest. The default scope is `SESSION`. Currently `SHOW BINDINGS` outputs 11 columns, as shown below:

Column Name	Note
<code>original_sql</code>	Original SQL statement after parameterization
<code>bind_sql</code>	Bound SQL statement with hints

Column Name	Note
default_db	Default database
status	Status including <b>enabled</b> (replacing the <b>using status</b> from v6.0), <b>disabled</b> , <b>deleted</b> , <b>invalid</b> , <b>rejected</b> , and <b>pending</b> ↔ <b>verify</b>
create_time	Creating time
update_time	Updating time
charset	Character set
collation	Ordering rule
source	The way in which a binding is created, including <b>manual</b> (created according to a SQL statement), <b>history</b> (created according to a historical execution plan), <b>capture</b> (captured automatically by TiDB), and <b>evolve</b> (evolved automatically by TiDB)
sql_digest	Digest of a normalized SQL statement
plan_digest	Digest of an execution plan

Troubleshoot a binding

You can use either of the following methods to troubleshoot a binding:

- Use the system variable `last_plan_from_binding` to show whether the execution plan used by the last executed statement is from the binding.

```
-- Create a global binding
CREATE GLOBAL BINDING for
 SELECT * FROM t
USING
 SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

SELECT * FROM t;
SELECT @@[SESSION.]last_plan_from_binding;
```

```
+-----+
| @@last_plan_from_binding |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)
```

- Use the `explain format = 'verbose'` statement to view the query plan of a SQL statement. If the SQL statement uses a binding, you can run `show warnings` to check which binding is used in the SQL statement.

```
-- Create a global binding
CREATE GLOBAL BINDING for
 SELECT * FROM t
USING
 SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

-- Use explain format = 'verbose' to view the execution plan of a SQL
↪ statement

explain format = 'verbose' SELECT * FROM t;

-- Run `show warnings` to view the binding used in the query.

show warnings;
```

```
+---
↪ ----+-----+-----+
↪
```

```

| Level | Code | Message
+----+
| Note | 1105 | Using the bindSQL: SELECT /*+ USE_INDEX(`t` `idx_a`)*/
 * FROM `test`.`t` |
+----+
1 row in set (0.01 sec)

```

### Cache bindings

Each TiDB instance has a least recently used (LRU) cache for bindings. The cache capacity is controlled by the system variable `tidb_mem_quota_binding_cache`. You can view bindings that are cached in the TiDB instance.

To view the cache status of bindings, run the `SHOW binding_cache status` statement. In this statement, the effective scope is GLOBAL by default and cannot be modified. This statement returns the number of available bindings in the cache, the total number of available bindings in the system, memory usage of all cached bindings, and the total memory for the cache.

```
SHOW binding_cache status;
```

```

+-----+-----+-----+-----+
| bindings_in_cache | bindings_in_table | memory_usage | memory_quota |
+-----+-----+-----+-----+
| 1 | 1 | 159 Bytes | 64 MB |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

### 11.3.4.3.2 Baseline capturing

Used for [preventing regression of execution plans during an upgrade](#), this feature captures queries that meet capturing conditions and creates bindings for these queries.

#### Enable capturing

To enable baseline capturing, set `tidb_capture_plan_baselines` to `on`. The default value is `off`.

**Note:**

Because the automatic binding creation function relies on [Statement Summary](#), make sure to enable Statement Summary before using automatic binding.

After automatic binding creation is enabled, the historical SQL statements in the Statement Summary are traversed every `bind-info-lease` (the default value is `3s`), and a binding is automatically created for SQL statements that appear at least twice. For these SQL statements, TiDB automatically binds the execution plan recorded in Statement Summary.

However, TiDB does not automatically capture bindings for the following types of SQL statements:

- `EXPLAIN` and `EXPLAIN ANALYZE` statements.
- SQL statements executed internally in TiDB, such as `SELECT` queries used for automatically loading statistical information.
- Statements that contain `Enabled` or `Disabled` bindings.
- Statements that are filtered out by capturing conditions.

**Note:**

Currently, a binding generates a group of hints to fix an execution plan generated by a query statement. In this way, for the same query, the execution plan does not change. For most OLTP queries, including queries using the same index or Join algorithm (such as `HashJoin` and `IndexJoin`), TiDB guarantees plan consistency before and after the binding. However, due to the limitations of hints, TiDB cannot guarantee plan consistency for some complex queries, such as Join of more than two tables, MPP queries, and complex OLAP queries.

For `PREPARE / EXECUTE` statements and for queries executed with binary protocols, TiDB automatically captures bindings for the real query statements, not for the `PREPARE / EXECUTE` statements.

**Note:**

Because TiDB has some embedded SQL statements to ensure the correctness of some features, baseline capturing by default automatically shields these SQL statements.

## Filter out bindings

This feature allows you to configure a blacklist to filter out queries whose bindings you do not want to capture. A blacklist has three dimensions, table name, frequency, and user name.

### Usage

Insert filtering conditions into the system table `mysql.capture_plan_baselines_blacklist`  $\hookrightarrow$  . Then the filtering conditions take effect in the entire cluster immediately.

```

-- Filter by table name
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
 \hookrightarrow filter_value) VALUES('table', 'test.t');

-- Filter by database name and table name through wildcards
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
 \hookrightarrow filter_value) VALUES('table', 'test.table_*');
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
 \hookrightarrow filter_value) VALUES('table', 'db_*.table_*');

-- Filter by frequency
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
 \hookrightarrow filter_value) VALUES('frequency', '2');

-- Filter by user name
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
 \hookrightarrow filter_value) VALUES('user', 'user1');

```

---

## Dimension

name	Description	Remarks
table	Filter by table name. Each filtering rule is in the <code>db.table</code> format. The supported filtering syntax includes <a href="#">Plain table names</a> and <a href="#">Wildcards</a> .	Case insensitive. If a table name contains illegal characters, the log returns a warning message <code>[sql-bind] failed to load mysql.capture_plan_baselines_blacklist</code> $\hookrightarrow$ .
frequency	Filter by frequency. SQL statements executed more than once are captured by default. You can set a high frequency to capture statements that are frequently executed.	Setting frequency to a value smaller than 1 is considered illegal, and the log returns a warning message <code>[sql-bind] frequency threshold <math>\hookrightarrow</math> is less than 1, ignore it</code> . If multiple frequency filter rules are inserted, the value with the highest frequency prevails.

Dimension		
name	Description	Remarks
user	Filter by user name. Statements executed by blocklisted users are not captured.	If multiple users execute the same statement and their user names are all in the blocklist, this statement is not captured.

**Note:**

- Modifying a blocklist requires the super privilege.
- If a blocklist contains illegal filters, TiDB returns the warning message `[sql-bind] unknown capture filter type, ignore it` in the log.

Prevent regression of execution plans during an upgrade

Before upgrading a TiDB cluster, you can use baseline capturing to prevent regression of execution plans by performing the following steps:

1. Enable baseline capturing and keep it working.

**Note:**

Test data shows that long-term working of baseline capturing has a slight impact on the performance of the cluster load. Therefore, it is recommended to enable baseline capturing as long as possible so that important plans (appear twice or above) are captured.

2. Upgrade the TiDB cluster. After the upgrade, TiDB uses those captured bindings to ensure execution plan consistency.
3. After the upgrade, delete bindings as required.
  - Check the binding source by running the `SHOW GLOBAL BINDINGS` statement. In the output, check the `Source` field to see whether a binding is captured (`capture`) or manually created (`manual`).
  - Determine whether to retain the captured bindings:

```
-- View the plan with the binding enabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = true;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;
```

```
-- View the plan with the binding disabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = false;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;
```

- If the execution plan is consistent, you can delete the binding safely.
- If the execution plan is inconsistent, you need to identify the cause, for example, by checking statistics. In this case, you need to retain the binding to ensure plan consistency.

### 11.3.4.3.3 Baseline evolution

Baseline evolution is an important feature of SPM introduced in TiDB v4.0.

As data updates, the previously bound execution plan might no longer be optimal. The baseline evolution feature can automatically optimize the bound execution plan.

In addition, baseline evolution, to a certain extent, can also avoid the jitter brought to the execution plan caused by the change of statistical information.

Usage

Use the following statement to enable automatic binding evolution:

```
SET GLOBAL tidb_evolve_plan_baselines = ON;
```

The default value of `tidb_evolve_plan_baselines` is `off`.

#### Warning:

- Baseline evolution is an experimental feature. Unknown risks might exist. It is **NOT** recommended that you use it in the production environment.
- This variable is forcibly set to `off` until the baseline evolution feature becomes generally available (GA). If you try to enable this feature, an error is returned. If you have already used this feature in a production environment, disable it as soon as possible. If you find that the binding status is not as expected, [get support](#) from PingCAP or the community.

After the automatic binding evolution feature is enabled, if the optimal execution plan selected by the optimizer is not among the binding execution plans, the optimizer marks the plan as an execution plan that waits for verification. At every `bind-info-lease` (the default value is 3s) interval, an execution plan to be verified is selected and compared with the binding execution plan that has the least cost in terms of the actual execution time. If

the plan to be verified has shorter execution time (the current criterion for the comparison is that the execution time of the plan to be verified is no longer than 2/3 that of the binding execution plan), this plan is marked as a usable binding. The following example describes the process above.

Assume that table `t` is defined as follows:

```
CREATE TABLE t(a INT, b INT, KEY(a), KEY(b));
```

Perform the following query on table `t`:

```
SELECT * FROM t WHERE a < 100 AND b < 100;
```

In the table defined above, few rows meet the `a < 100` condition. But for some reason, the optimizer mistakenly selects the full table scan instead of the optimal execution plan that uses index `a`. You can first use the following statement to create a binding:

```
CREATE GLOBAL BINDING for SELECT * FROM t WHERE a < 100 AND b < 100 using
↪ SELECT * FROM t use index(a) WHERE a < 100 AND b < 100;
```

When the query above is executed again, the optimizer selects index `a` (influenced by the binding created above) to reduce the query time.

Assuming that as insertions and deletions are performed on table `t`, an increasing number of rows meet the `a < 100` condition and a decreasing number of rows meet the `b < 100` condition. At this time, using index `a` under the binding might no longer be the optimal plan.

The binding evolution can address this kind of issues. When the optimizer recognizes data change in a table, it generates an execution plan for the query that uses index `b`. However, because the binding of the current plan exists, this query plan is not adopted and executed. Instead, this plan is stored in the backend evolution list. During the evolution process, if this plan is verified to have an obviously shorter execution time than that of the current execution plan that uses index `a`, index `b` is added into the available binding list. After this, when the query is executed again, the optimizer first generates the execution plan that uses index `b` and makes sure that this plan is in the binding list. Then the optimizer adopts and executes this plan to reduce the query time after data changes.

To reduce the impact that the automatic evolution has on clusters, use the following configurations:

- Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is 600s. In the actual verification process, the maximum execution time is also limited to no more than twice the time of the verified execution plan.
- Set `tidb_evolve_plan_task_start_time` (00:00 +0000 by default) and `tidb_evolve_plan_task_end_time` (23:59 +0000 by default) to limit the time window.

## Notes

Because the baseline evolution automatically creates a new binding, when the query environment changes, the automatically created binding might have multiple behavior choices. Pay attention to the following notes:

- Baseline evolution only evolves standardized SQL statements that have at least one global binding.
- Because creating a new binding deletes all previous bindings (for a standardized SQL statement), the automatically evolved binding will be deleted after manually creating a new binding.
- All hints related to the calculation process are retained during the evolution. These hints are as follows:

Hint	Description
<code>memory_quota</code> ↪	The maximum memory that can be used for a query.
<code>use_toja</code>	Whether the optimizer transforms sub-queries to Join.
<code>use_cascades</code> ↪	Whether to use the cascades optimizer.
<code>no_index_merge</code> ↪	Whether the optimizer uses Index Merge as an option for reading tables.
<code>read_consistent_replica</code> ↪	Whether to forcibly enable Follower Read when reading tables.
<code>max_execution_time</code> ↪	The longest duration for a query.

- `read_from_storage` is a special hint in that it specifies whether to read data from TiKV or from TiFlash when reading tables. Because TiDB provides isolation reads,

when the isolation condition changes, this hint has a great influence on the evolved execution plan. Therefore, when this hint exists in the initially created binding, TiDB ignores all its evolved bindings.

#### 11.3.4.3.4 Upgrade checklist

During cluster upgrade, SQL Plan Management (SPM) might cause compatibility issues and make the upgrade fail. To ensure a successful upgrade, you need to include the following list for upgrade precheck:

- When you upgrade from a version earlier than v5.2.0 (that is, v4.0, v5.0, and v5.1) to the current version, make sure that `tidb_evolve_plan_baselines` is disabled before the upgrade. To disable this variable, perform the following steps.

```
-- Check whether `tidb_evolve_plan_baselines` is disabled in the
↪ earlier version.

SELECT @@global.tidb_evolve_plan_baselines;

-- If `tidb_evolve_plan_baselines` is still enabled, disable it.

SET GLOBAL tidb_evolve_plan_baselines = OFF;
```

- Before you upgrade from v4.0 to the current version, you need to check whether the syntax of all queries corresponding to the available SQL bindings is correct in the new version. If any syntax errors exist, delete the corresponding SQL binding. To do that, perform the following steps.

```
-- Check the query corresponding to the available SQL binding in the
↪ version to be upgraded.

SELECT bind_sql FROM mysql.bind_info WHERE status = 'using';

-- Verify the result from the above SQL query in the test environment
↪ of the new version.

bind_sql_0;
bind_sql_1;
...

-- In the case of a syntax error (ERROR 1064 (42000): You have an
↪ error in your SQL syntax), delete the corresponding binding.
-- For any other errors (for example, tables are not found), it means
↪ that the syntax is compatible. No other operation is needed.
```

### 11.3.4.4 The Blocklist of Optimization Rules and Expression Pushdown

This document introduces how to use the blocklist of optimization rules and the blocklist of expression pushdown to control the behavior of TiDB.

#### 11.3.4.4.1 The blocklist of optimization rules

The blocklist of optimization rules is one way to tune optimization rules, mainly used to manually disable some optimization rules.

Important optimization rules

Optimization Rule	Name	Description
Column pruning	column_pruning	operator will prune the column if it is not needed by the upper executor.

Optimization Rule	Rule Name	Description
Decorrelate sub-query	Decorrelate	<p>Decorrelates correlated sub-queries to non-correlated joins or aggregations.</p>
Aggregation elimination	Aggregation elimination	<p>Eliminates unnecessary aggregation operators from the execution plan.</p>

Optimization Rule	Name	Description
Projection elimination	projection_eliminate	Remove unnecessary projection operators from the execution plan.
Max/Min elimination	max_min_rewrite	Eliminate some max/min functions in aggregation to the order by limit form.

Optimization	Rule	Name	Description
Predicate push-down	predicate_push_down	predicate_push_down	to push predicates down to the operator that is closer to the data source.
Outer join elimination	outer_join_elimination	outer_join_elimination	to remove the unnecessary left join or right join from the execution plan.

Optimization Rule	Rule Name	Description
Partition pruning	partition_pruning	Processor partitions which are rejected by the predicates and rewrite partitioned table query to the <b>UnionAll</b> $\hookrightarrow$ $\hookrightarrow +$ $\hookrightarrow$ $\hookrightarrow$ <b>Partition</b> $\hookrightarrow$ $\hookrightarrow$ <b>Datasource</b> $\hookrightarrow$ form.
Aggregation push-down	agg_push_down	Aggregations are pushed down to their children.

Optimization Rule	Name	Description
TopN push-down	topn_pushdown	Pushes the TopN operator to the place closer to the data source.
Join re-order	join_reorder	Decides the order of multi-table joins.

Disable optimization rules

You can use the blacklist of optimization rules to disable some of them if some rules lead to a sub-optimal execution plan for special queries.

Usage

**Note:**

All the following operations need the `super privilege` privilege of the database. Each optimization rule has a name. For example, the name of column pruning is `column_prune`. The names of all optimization rules can be found in the second column of the table [Important Optimization Rules](#).

- If you want to disable some rules, write its name to the `mysql.opt_rule_blacklist` table. For example:

```
INSERT INTO mysql.opt_rule_blacklist VALUES("join_reorder"), ("
↳ topn_push_down");
```

Executing the following SQL statement can make the above operation take effect immediately. The effective range includes all old connections of the corresponding TiDB server:

```
admin reload opt_rule_blacklist;
```

#### Note:

`admin reload opt_rule_blacklist` only takes effect on the TiDB server where the above statement has been run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

- If you want to re-enable a rule, delete the corresponding data in the table, and then run the `admin reload` statement:

```
DELETE FROM mysql.opt_rule_blacklist WHERE name IN ("join_reorder", "
↳ topn_push_down");
```

```
admin reload opt_rule_blacklist;
```

#### 11.3.4.4.2 The blacklist of expression pushdown

The blacklist of expression pushdown is one way to tune the expression pushdown, mainly used to manually disable some expressions of some specific data types.

Expressions that are supported to be pushed down

For more information about the expressions that are supported to be pushed down, see [Supported expressions for pushdown to TiKV](#).

Disable the pushdown of specific expressions

When you get wrong results due to the expression pushdown, you can use the blacklist to make a quick recovery for the application. More specifically, you can add some of the supported functions or operators to the `mysql.expr_pushdown_blacklist` table to disable the pushdown of specific expressions.

The schema of `mysql.expr_pushdown_blacklist` is shown as follows:

```
DESC mysql.expr_pushdown_blacklist;
```

```

+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| name | char(100) | NO | | NULL | |
| store_type | char(100) | NO | | tikv,tiflash,tidb | |
| reason | varchar(200) | YES | | NULL | |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)

```

Here is the description of each field above:

- **name:** The name of the function that is disabled to be pushed down.
- **store\_type:** To specify the component that you want to prevent the function from being pushed down to for computing. Available components are `tidb`, `tikv`, and `tiflash`. The `store_type` is case-insensitive. If you need to specify multiple components, use a comma to separate each component.
  - When `store_type` is `tidb`, it indicates whether the function can be executed in other TiDB servers while the TiDB memory table is being read.
  - When `store_type` is `tikv`, it indicates whether the function can be executed in TiKV server's Coprocessor component.
  - When `store_type` is `tiflash`, it indicates whether the function can be executed in TiFlash Server's Coprocessor component.
- **reason:** To record the reason why this function is added to the blacklist.

## Usage

This section describes how to use the blacklist of expression pushdown.

### Add to the blacklist

To add one or more expressions (functions or operators) to the blacklist, perform the following steps:

1. Insert the corresponding function name or operator name, and the set of components you want to disable the pushdown, to the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

### Remove from the blacklist

To remove one or more expressions from the blacklist, perform the following steps:

1. Delete the corresponding function name or operator name, and the set of components you want to disable the pushdown, from the `mysql.expr_pushdown_blacklist` table.

- Execute `admin reload expr_pushdown_blacklist`.

**Note:**

`admin reload expr_pushdown_blacklist` only takes effect on the TiDB server where this statement is run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

### 11.3.4.4.3 Expression blacklist usage example

In the following example, the `<` and `>` operators are added to the blacklist, and then the `>` operator is removed from the blacklist.

To judge whether the blacklist takes effect, observe the results of `EXPLAIN` (See [TiDB Query Execution Plan Overview](#)).

- The predicates `a < 2` and `a > 2` in the `WHERE` clause of the following SQL statement can be pushed down to TiKV.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
 ↪ -----+-----+-----+
 ↪
| id | estRows | task | access object | operator
 ↪ info | | | |
+--
 ↪ -----+-----+-----+
 ↪
| TableReader_7 | 0.00 | root | | data:
 ↪ Selection_6 | | | |
| -Selection_6 | 0.00 | cop[tikv] | | gt(ssb_1.t.
 ↪ a, 2), lt(ssb_1.t.a, 2) |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep order:
 ↪ false, stats:pseudo |
+--
 ↪ -----+-----+-----+
 ↪
3 rows in set (0.00 sec)
```

- Insert the expression to the `mysql.expr_pushdown_blacklist` table and execute `admin reload expr_pushdown_blacklist`.

```
INSERT INTO mysql.expr_pushdown_blacklist VALUES('<','tikv',''), ('>',
↪ 'tikv','');
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

- Observe the execution plan again and you will find that both the < and > operators are not pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 and a > 2;
```

```
+--
↪ -----+-----+-----+
↪
| id | estRows | task | access object | operator
↪ info | | | |
+--
↪ -----+-----+-----+
↪
| Selection_7 | 10000.00 | root | | gt(ssb_1.t.a
↪ , 2), lt(ssb_1.t.a, 2) |
| -TableReader_6 | 10000.00 | root | | data:
↪ TableFullScan_5 | | | |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep order:
↪ false, stats:pseudo |
+--
↪ -----+-----+-----+
↪
3 rows in set (0.00 sec)
```

- Remove one expression (here is >) from the blacklist and execute admin reload ↪ expr\_pushdown\_blacklist.

```
DELETE FROM mysql.expr_pushdown_blacklist WHERE name = '>';
```

```
Query OK, 1 row affected (0.01 sec)
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

- Observe the execution plan again and you will find that `<` is not pushed down while `>` is pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
 ↪ -----+-----+-----+-----+-----+
 ↪
 | id | estRows | task | access object | operator
 ↪ info | | | |
+--
 ↪ -----+-----+-----+-----+-----+
 ↪
 | Selection_8 | 0.00 | root | | lt(ssb_1.t
 ↪ .a, 2) | | | |
 | -TableReader_7 | 0.00 | root | | data:
 ↪ Selection_6 | | | |
 | -Selection_6 | 0.00 | cop[tikv] | | gt(ssb_1.
 ↪ t.a, 2) | | | |
 | -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep
 ↪ order:false, stats:pseudo | | | |
+--
 ↪ -----+-----+-----+-----+-----+
 ↪
4 rows in set (0.00 sec)
```

## 12 Tutorials

### 12.1 Multiple Availability Zones in One Region Deployment

As a distributed SQL database, TiDB combines the best features of the traditional relational database and the scalability of the NoSQL database, and is highly available across availability zones (AZs). This document introduces the deployment of multiple AZs in one region.

The term “region” in this document refers to a geographic area, while the capitalized “Region” refers to a basic unit of data storage in TiKV. “AZ” refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

#### 12.1.1 Raft protocol

Raft is a distributed consensus algorithm. Using this algorithm, both PD and TiKV, among components of the TiDB cluster, achieve disaster recovery of data, which is imple-

mented through the following mechanisms:

- The essential role of Raft members is to perform log replication and act as a state machine. Among Raft members, data replication is implemented by replicating logs. Raft members change their own states in different conditions to elect a leader to provide services.
- Raft is a voting system that follows the majority protocol. In a Raft group, if a member gets the majority of votes, its membership changes to leader. In other words, when the majority of nodes remain in the Raft group, a leader can be elected to provide services.

To take advantage of Raft's reliability, the following conditions must be met in a real deployment scenario:

- Use at least three servers in case one server fails.
- Use at least three racks in case one rack fails.
- Use at least three AZs in case one AZ fails.
- Deploy TiDB in at least three regions in case data safety issue occurs in one region.

The native Raft protocol does not have good support for an even number of replicas. Considering the impact of cross-region network latency, three AZs in the same region might be the most suitable solution to a highly available and disaster tolerant Raft deployment.

### **12.1.2 Three AZs in one region deployment**

TiDB clusters can be deployed in three AZs in the same region. In this solution, data replication across the three AZs is implemented using the Raft protocol within the cluster. These three AZs can provide read and write services at the same time. Data consistency is not affected even if one AZ fails.

#### **12.1.2.1 Simple architecture**

TiDB, TiKV, and PD are distributed among three AZs, which is the most common deployment with the highest availability.

Figure 188: 3-AZ Deployment Architecture

### Advantages:

- All replicas are distributed among three AZs, with high availability and disaster recovery capability.
- No data will be lost if one AZ is down (RPO = 0).
- Even if one AZ is down, the other two AZs will automatically start leader election and automatically resume services within a certain period (within 20 seconds in most cases). See the following diagram for more information:

Figure 189: Disaster Recovery for 3-AZ Deployment

### Disadvantages:

The performance can be affected by the network latency.

- For writes, all the data has to be replicated to at least two AZs. Because TiDB uses a two-phase commit for writes, the write latency is at least twice the latency of the network between two AZs.
- The read performance will also be affected by the network latency if the leader is not in the same AZ with the TiDB node that sends the read request.
- Each TiDB transaction needs to obtain TimeStamp Oracle (TSO) from the PD leader. So if the TiDB and PD leaders are not in the same AZ, the performance of the transactions will also be affected by the network latency because each transaction with the write request has to obtain TSO twice.

### 12.1.2.2 Optimized architecture

If not all of the three AZs need to provide services to the applications, you can dispatch all the requests to one AZ and configure the scheduling policy to migrate the TiKV Region leader and PD leader to the same AZ. In this way, neither obtaining TSO nor reading TiKV Regions will be impacted by the network latency across AZs. If this AZ is down, the PD leader and TiKV Region leader will be automatically elected in other surviving AZs, and you just need to switch the requests to the AZs that are still alive.

Figure 190: Read Performance Optimized 3-AZ Deployment

### Advantages:

The cluster's read performance and the capability to get TSO are improved. A configuration template of scheduling policy is as follows:

```
-- Evicts all leaders of other AZs to the AZ that provides services to the
↪ application.
config set label-property reject-leader LabelName labelValue

-- Migrates PD leaders and sets priority.
member leader transfer pdName1
member leader_priority pdName1 5
member leader_priority pdName2 4
member leader_priority pdName3 3
```

### Note:

Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the [placement rules](#).

## Disadvantages:

- Write scenarios are still affected by network latency across AZs. This is because Raft follows the majority protocol and all written data must be replicated to at least two AZs.
- The TiDB server that provides services is only in one AZ.
- All application traffic is processed by one AZ and the performance is limited by the network bandwidth pressure of that AZ.
- The capability to get TSO and the read performance are affected by whether the PD server and TiKV server are up in the AZ that processes application traffic. If these servers are down, the application is still affected by the cross-center network latency.

### 12.1.2.3 Deployment example

This section provides a topology example, and introduces TiKV labels and TiKV labels planning.

#### 12.1.2.3.1 Topology example

The following example assumes that three AZs (AZ1, AZ2, and AZ3) are located in one region; each AZ has two sets of racks and each rack has three servers. The example ignores the hybrid deployment or the scenario where multiple instances are deployed on one machine. The deployment of a TiDB cluster (three replicas) on three AZs in one region is as follows:

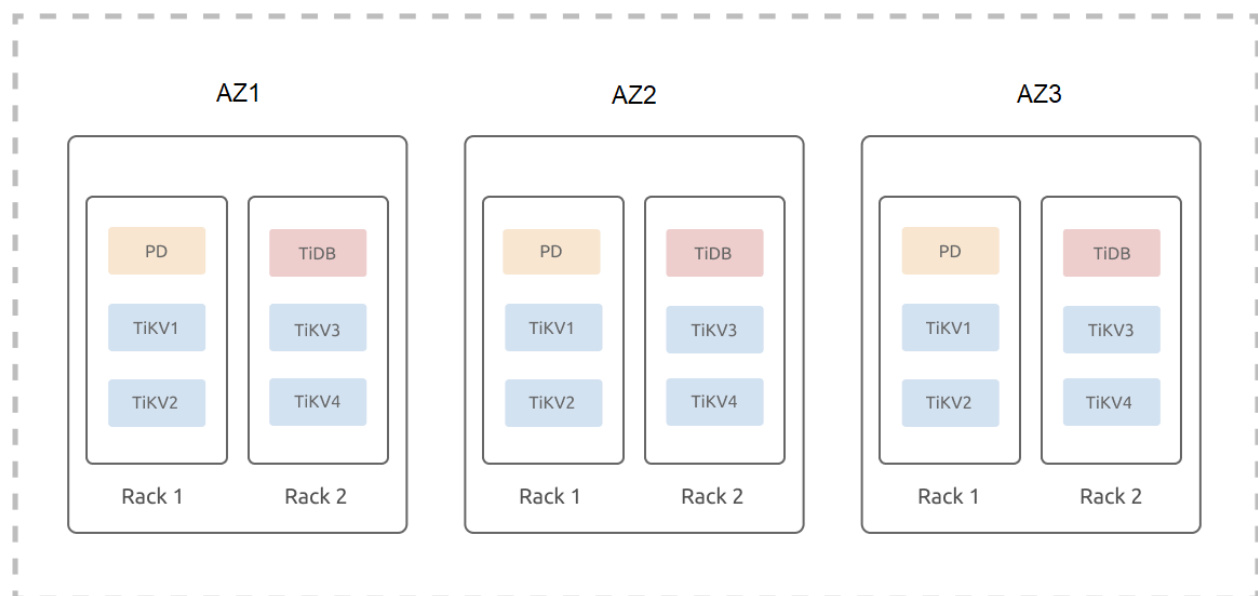

Figure 191: 3-AZ in One Region

### 12.1.2.3.2 TiKV labels

TiKV is a Multi-Raft system where data is divided into Regions and the size of each Region is 96 MB by default. Three replicas of each Region form a Raft group. For a TiDB cluster of three replicas, because the number of Region replicas is independent of the TiKV instance numbers, three replicas of a Region are only scheduled to three TiKV instances. This means that even if the cluster is scaled out to have N TiKV instances, it is still a cluster of three replicas.

Because a Raft group of three replicas tolerates only one replica failure, even if the cluster is scaled out to have N TiKV instances, this cluster still tolerates only one replica failure. Two failed TiKV instances might cause some Regions to lose replicas and the data in this cluster is no longer complete. SQL requests that access data from these Regions will fail. The probability of two simultaneous failures among N TiKV instances is much higher than the probability of two simultaneous failures among three TiKV instances. This means that the more TiKV instances the Multi-Raft system is scaled out to have, the less the availability of the system.

Because of the preceding limitation, `label` is used to describe the location information of TiKV. The label information is refreshed to the TiKV startup configuration file with deployment or rolling upgrade operations. The started TiKV reports its latest label information to PD. Based on the user-registered label name (the label metadata) and the TiKV topology, PD optimally schedules Region replicas and improves the system availability.

### 12.1.2.3.3 TiKV labels planning example

To improve the availability and disaster recovery of the system, you need to design and plan TiKV labels according to your existing physical resources and the disaster recovery capability. You also need to edit the cluster initialization configuration file according to the planned topology:

```
server_configs:
 pd:
 replication.location-labels: ["zone","az","rack","host"]

tikv_servers:
- host: 10.63.10.30
 config:
 server.labels: { zone: "z1", az: "az1", rack: "r1", host: "30" }
- host: 10.63.10.31
 config:
 server.labels: { zone: "z1", az: "az1", rack: "r1", host: "31" }
- host: 10.63.10.32
 config:
 server.labels: { zone: "z1", az: "az1", rack: "r2", host: "32" }
- host: 10.63.10.33
 config:
```

```
server.labels: { zone: "z1", az: "az1", rack: "r2", host: "33" }
- host: 10.63.10.34
 config:
 server.labels: { zone: "z2", az: "az2", rack: "r1", host: "34" }
- host: 10.63.10.35
 config:
 server.labels: { zone: "z2", az: "az2", rack: "r1", host: "35" }
- host: 10.63.10.36
 config:
 server.labels: { zone: "z2", az: "az2", rack: "r2", host: "36" }
- host: 10.63.10.37
 config:
 server.labels: { zone: "z2", az: "az2", rack: "r2", host: "37" }

- host: 10.63.10.38
 config:
 server.labels: { zone: "z3", az: "az3", rack: "r1", host: "38" }
- host: 10.63.10.39
 config:
 server.labels: { zone: "z3", az: "az3", rack: "r1", host: "39" }
- host: 10.63.10.40
 config:
 server.labels: { zone: "z3", az: "az3", rack: "r2", host: "40" }
- host: 10.63.10.41
 config:
 server.labels: { zone: "z3", az: "az3", rack: "r2", host: "41" }
```

In the preceding example, **zone** is the logical availability zone layer that controls the isolation of replicas (three replicas in the example cluster).

Considering that the AZs might be scaled out in the future, the three-layer label structure (**az**, **rack**, and **host**) is not directly adopted. Assuming that **AZ2**, **AZ3**, and **AZ4** are to be scaled out, you only need to scale out the AZs in the corresponding availability zone and scale out the racks in the corresponding AZ.

If this three-layer label structure is directly adopted, after scaling out an AZ, you might need to apply new labels and the data in TiKV needs to be rebalanced.

#### 12.1.2.4 High availability and disaster recovery analysis

The multiple AZs in one region deployment can guarantee that if one AZ fails, the cluster can automatically recover services without manual intervention. Data consistency is also guaranteed. Note that scheduling policies are used to optimize performance, but when a failure occurs, these policies prioritize availability over performance.

## 12.2 Three Availability Zones in Two Regions Deployment

This document introduces the architecture and configuration of the three availability zones (AZs) in two regions deployment.

The term “region” in this document refers to a geographic area, while the capitalized “Region” refers to a basic unit of data storage in TiKV. “AZ” refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

### 12.2.1 Overview

The architecture of three AZs in two regions is a highly available and disaster tolerant deployment solution that provides a production data AZ, a disaster recovery AZ in the same region, and a disaster recovery AZ in another region. In this mode, the three AZs in two regions are interconnected. If one AZ fails or suffers from a disaster, other AZs can still operate well and take over the key applications or all applications. Compared with the multi-AZ in one region deployment, this solution has the advantage of cross-region high availability and can survive region-level natural disasters.

The distributed database TiDB natively supports the three-AZ-in-two-region architecture by using the Raft algorithm, and guarantees the consistency and high availability of data within a database cluster. Because the network latency across AZs in the same region is relatively low, the application traffic can be dispatched to two AZs in the same region, and the traffic load can be shared by these two AZs by controlling the distribution of TiKV Region leaders and PD leaders.

### 12.2.2 Deployment architecture

This section takes the example of Seattle and San Francisco to explain the deployment mode of three AZs in two regions for the distributed database of TiDB.

In this example, two AZs (AZ1 and AZ2) are located in Seattle and another AZ (AZ3) is located in San Francisco. The network latency between AZ1 and AZ2 is lower than 3 milliseconds. The network latency between AZ3 and AZ1/AZ2 in Seattle is about 20 milliseconds (ISP dedicated network is used).

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to three AZs in two regions: AZ1 in Seattle, AZ2 in Seattle, and AZ3 in San Francisco.
- The cluster has five replicas, two in AZ1, two in AZ2, and one in AZ3. For the TiKV component, each rack has a label, which means that each rack has a replica.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

Figure 192: 3-AZ-in-2-region architecture

This architecture is highly available. The distribution of Region leaders is restricted to the two AZs (AZ1 and AZ2) that are in the same region (Seattle). Compared with the three-AZ solution in which the distribution of Region leaders is not restricted, this architecture has the following advantages and disadvantages:

- **Advantages**

- Region leaders are in AZs of the same region with low latency, so the write is faster.
- The two AZs can provide services at the same time, so the resource usage rate is higher.

- If one AZ fails, services are still available and data safety is ensured.

- **Disadvantages**

- Because the data consistency is achieved by the Raft algorithm, when two AZs in the same region fail at the same time, only one surviving replica remains in the disaster recovery AZ in another region (San Francisco). This cannot meet the requirement of the Raft algorithm that most replicas survive. As a result, the cluster can be temporarily unavailable. Maintenance staff needs to recover the cluster from the one surviving replica and a small amount of hot data that has not been replicated will be lost. But this case is a rare occurrence.
- Because the ISP dedicated network is used, the network infrastructure of this architecture has a high cost.
- Five replicas are configured in three AZs in two regions, data redundancy increases, which brings a higher storage cost.

### 12.2.2.1 Deployment details

The configuration of the three AZs in two regions (Seattle and San Francisco) deployment plan is illustrated as follows:

Figure 193: 3-AZ-2-region

From the preceding illustration, you can see that Seattle has two AZs: AZ1 and AZ2. AZ1 has three sets of racks: rac1, rac2, and rac3. AZ2 has two racks: rac4 and rac5. The AZ3 in San Francisco has the rac6 rack.

In the rac1 of AZ1, one server is deployed with TiDB and PD services, and the other two servers are deployed with TiKV services. Each TiKV server is deployed with two TiKV instances (tikv-server). This is similar to rac2, rac4, rac5, and rac6.

The TiDB server, the control machine, and the monitoring server are on rac3. The TiDB server is deployed for regular maintenance and backup. Prometheus, Grafana, and the restore tools are deployed on the control machine and monitoring machine.

Another backup server can be added to deploy Drainer. Drainer saves binlog data to a specified location by outputting files, to achieve incremental backup.

### 12.2.3 Configuration

#### 12.2.3.1 Example

See the following `tiup topology.yaml` file for example:

```
Global variables are applied to all deployments and used as the default
 ↪ value of
the deployments if a specific deployment value is missing.
global:
 user: "tidb"
 ssh_port: 22
 deploy_dir: "/data/tidb_cluster/tidb-deploy"
 data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
 tikv:
 server.grpc-compression-type: gzip
 pd:
 replication.location-labels: ["az","replication zone","rack","host"]

pd_servers:
- host: 10.63.10.10
 name: "pd-10"
- host: 10.63.10.11
 name: "pd-11"
- host: 10.63.10.12
 name: "pd-12"
- host: 10.63.10.13
 name: "pd-13"
- host: 10.63.10.14
 name: "pd-14"

tidb_servers:
- host: 10.63.10.10
- host: 10.63.10.11
```

```
- host: 10.63.10.12
- host: 10.63.10.13
- host: 10.63.10.14

tikv_servers:
- host: 10.63.10.30
 config:
 server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
 ↪ }
- host: 10.63.10.31
 config:
 server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
 ↪ }
- host: 10.63.10.32
 config:
 server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
 ↪ }
- host: 10.63.10.33
 config:
 server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
 ↪ }
- host: 10.63.10.34
 config:
 server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
 ↪ }
 raftstore.raft-min-election-timeout-ticks: 1000
 raftstore.raft-max-election-timeout-ticks: 1200

monitoring_servers:
- host: 10.63.10.60

grafana_servers:
- host: 10.63.10.60

alertmanager_servers:
- host: 10.63.10.60
```

### 12.2.3.2 Labels design

In the deployment of three AZs in two regions, the label design requires taking availability and disaster recovery into account. It is recommended that you define the four levels (`az`, `replication zone`, `rack`, and `host`) based on the physical structure of the deployment.

Figure 194: Label logical definition

In the PD configuration, add level information of TiKV labels:

```
server_configs:
 pd:
 replication.location-labels: ["az","replication zone","rack","host"]
```

The configuration of `tikv_servers` is based on the label information of the real physical deployment location of TiKV, which makes it easier for PD to perform global management and scheduling.

```
tikv_servers:
- host: 10.63.10.30
 config:
 server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
 ↪ }
- host: 10.63.10.31
 config:
 server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
 ↪ }
- host: 10.63.10.32
 config:
 server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
 ↪ }
- host: 10.63.10.33
 config:
 server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
 ↪ }
- host: 10.63.10.34
```

```
config:
 server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
 ↪ }
```

### 12.2.3.3 Optimize parameter configuration

In the deployment of three AZs in two regions, to optimize performance, you need to not only configure regular parameters, but also adjust component parameters.

- Enable gRPC message compression in TiKV. Because data of the cluster is transmitted in the network, you can enable the gRPC message compression to lower the network traffic.

```
server.grpc-compression-type: gzip
```

- Optimize the network configuration of the TiKV node in another region (San Francisco). Modify the following TiKV parameters for AZ3 in San Francisco and try to prevent the replica in this TiKV node from participating in the Raft election.

```
raftstore.raft-min-election-timeout-ticks: 1000
raftstore.raft-max-election-timeout-ticks: 1200
```

- Configure scheduling. After the cluster is enabled, use the `tiup ctl:v<CLUSTER_VERSION> ↪ > pd` tool to modify the scheduling policy. Modify the number of TiKV Raft replicas. Configure this number as planned. In this example, the number of replicas is five.

```
config set max-replicas 5
```

- Forbid scheduling the Raft leader to AZ3. Scheduling the Raft leader to another region (AZ3) causes unnecessary network overhead between AZ1/AZ2 in Seattle and AZ3 in San Francisco. The network bandwidth and latency also affect the performance of the TiDB cluster.

```
config set label-property reject-leader dc 3
```

#### Note:

Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the [placement rules](#).

- Configure the priority of PD. To avoid the situation where the PD leader is in another region (AZ3), you can increase the priority of local PD (in Seattle) and decrease the priority of PD in another region (San Francisco). The larger the number, the higher the priority.

```
member leader_priority PD-10 5
member leader_priority PD-11 5
member leader_priority PD-12 5
member leader_priority PD-13 5
member leader_priority PD-14 1
```

## 12.3 Two Availability Zones in One Region Deployment

This document introduces the deployment mode of two availability zones (AZs) in one region, including the architecture, configuration, how to enable this deployment mode, and how to use replicas in this mode.

The term “region” in this document refers to a geographic area, while the capitalized “Region” refers to a basic unit of data storage in TiKV. “AZ” refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

### 12.3.1 Introduction

TiDB usually adopts the multi-AZ deployment solution to ensure high availability and disaster recovery capability. The multi-AZ deployment solution includes multiple deployment modes, such as multiple AZs in one region and multiple AZs in two regions. This document introduces the deployment mode of two AZs in one region. Deployed in this mode, TiDB can also meet the requirements of high availability and disaster recovery, with a lower cost. This deployment solution adopts Data Replication Auto Synchronous mode, or the DR Auto-Sync mode.

Under the mode of two AZs in one region, the two AZs are less than 50 kilometers apart. They are usually located in the same region or in two adjacent regions. The network latency between the two AZs is lower than 1.5 milliseconds and the bandwidth is higher than 10 Gbps.

### 12.3.2 Deployment architecture

This section takes the example of a region where two availability zones AZ1 and AZ2 are located respectively in the east and west. AZ1 is the primary AZ and AZ2 is the disaster recovery (DR) AZ.

The architecture of the cluster deployment is as follows:

- The cluster has four replicas: two Voter replicas in AZ1, one Voter replica, and one Learner replica in AZ2. For the TiKV component, each rack has a proper label.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

### Intra-city cluster

Figure 195: 2-AZ-in-1-region architecture

This deployment solution defines three statuses to control and identify the replication status of the cluster, which restricts the replication mode of TiKV. The replication mode of the cluster can automatically and adaptively switch between the three statuses. For details, see the [Status switch](#) section.

- **sync**: Synchronous replication mode. In this mode, at least one replica in the disaster recovery AZ synchronizes with the primary AZ. The Raft algorithm ensures that each log is replicated to the DR based on the label.
- **async**: Asynchronous replication mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. The Raft algorithm follows the majority protocol to replicate logs.
- **sync-recover**: Synchronous recovery mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. Raft gradually switches to the label replication mode and then reports the label information to PD.

### 12.3.3 Configuration

#### 12.3.3.1 Example

The following tiup topology.yaml example file is a typical topology configuration for the two availability zones in one region deployment mode:

```
Global variables are applied to all deployments and used as the default
 ↪ value of
the deployments if a specific deployment value is missing.
global:
 user: "tidb"
 ssh_port: 22
 deploy_dir: "/data/tidb_cluster/tidb-deploy"
 data_dir: "/data/tidb_cluster/tidb-data"
server_configs:
 pd:
 replication.location-labels: ["az","rack","host"]
pd_servers:
- host: 10.63.10.10
 name: "pd-10"
- host: 10.63.10.11
 name: "pd-11"
- host: 10.63.10.12
 name: "pd-12"
tidb_servers:
- host: 10.63.10.10
- host: 10.63.10.11
- host: 10.63.10.12
tikv_servers:
- host: 10.63.10.30
 config:
 server.labels: { az: "east", rack: "east-1", host: "30" }
- host: 10.63.10.31
 config:
 server.labels: { az: "east", rack: "east-2", host: "31" }
- host: 10.63.10.32
 config:
 server.labels: { az: "east", rack: "east-3", host: "32" }
- host: 10.63.10.33
 config:
 server.labels: { az: "west", rack: "west-1", host: "33" }
- host: 10.63.10.34
 config:
 server.labels: { az: "west", rack: "west-2", host: "34" }
- host: 10.63.10.35
```

```
config:
 server.labels: { az: "west", rack: "west-3", host: "35" }
monitoring_servers:
- host: 10.63.10.60
grafana_servers:
- host: 10.63.10.60
alertmanager_servers:
- host: 10.63.10.60
```

### 12.3.3.2 Placement Rules

To deploy a cluster based on the planned topology, you need to use **Placement Rules** to determine the locations of the cluster replicas. Taking the deployment of four replicas (two Voter replicas are at the primary AZ, one Voter replica, and one Learner replica are at the disaster recovery AZ) as an example, you can use the Placement Rules to configure the replicas as follows:

```
cat rule.json
[
 {
 "group_id": "pd",
 "group_index": 0,
 "group_override": false,
 "rules": [
 {
 "group_id": "pd",
 "id": "az-east",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 3,
 "label_constraints": [
 {
 "key": "az",
 "op": "in",
 "values": [
 "east"
]
 }
]
 },
 {
 "location_labels": [
 "az",
 "rack",
 "host"
]
 }
]
 }
]
```

```
},
{
 "group_id": "pd",
 "id": "az-west",
 "start_key": "",
 "end_key": "",
 "role": "follower",
 "count": 2,
 "label_constraints": [
 {
 "key": "az",
 "op": "in",
 "values": [
 "west"
]
 }
],
 "location_labels": [
 "az",
 "rack",
 "host"
]
},
{
 "group_id": "pd",
 "id": "az-west",
 "start_key": "",
 "end_key": "",
 "role": "learner",
 "count": 1,
 "label_constraints": [
 {
 "key": "az",
 "op": "in",
 "values": [
 "west"
]
 }
],
 "location_labels": [
 "az",
 "rack",
 "host"
]
}
```

```
]
}
]
```

To use the configurations in `rule.json`, run the following command to back up the existing configuration to the `default.json` file and overwrite the existing configuration with `rule.json`:

```
pd-ctl config placement-rules rule-bundle load --out="default.json"
pd-ctl config placement-rules rule-bundle save --in="rule.json"
```

If you need to roll back to the previous configuration, you can restore the backup file `default.json` or write the following JSON file manually and overwrite the current configuration with this JSON file:

```
cat default.json
[
 {
 "group_id": "pd",
 "group_index": 0,
 "group_override": false,
 "rules": [
 {
 "group_id": "pd",
 "id": "default",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 5
 }
]
 }
]
```

### 12.3.3.3 Enable the DR Auto-Sync mode

The replication mode is controlled by PD. You can configure the replication mode in the PD configuration file using one of the following methods:

- Method 1: Configure the PD configuration file, and then deploy a cluster.

```
[replication-mode]
replication-mode = "dr-auto-sync"
[replication-mode.dr-auto-sync]
label-key = "az"
primary = "east"
```

```
dr = "west"
primary-replicas = 3
dr-replicas = 2
wait-store-timeout = "1m"
```

- Method 2: If you have deployed a cluster, use `pd-ctl` commands to modify the configurations of PD.

```
config set replication-mode dr-auto-sync
config set replication-mode dr-auto-sync label-key az
config set replication-mode dr-auto-sync primary east
config set replication-mode dr-auto-sync dr west
config set replication-mode dr-auto-sync primary-replicas 3
config set replication-mode dr-auto-sync dr-replicas 2
```

Descriptions of configuration items:

- `replication-mode` is the replication mode to be enabled. In the preceding example, it is set to `dr-auto-sync`. By default, the majority protocol is used.
- `label-key` is used to distinguish different AZs and needs to match Placement Rules. In this example, the primary AZ is “east” and the disaster recovery AZ is “west”.
- `primary-replicas` is the number of Voter replicas in the primary AZ.
- `dr-replicas` is the number of Voter replicas in the disaster recovery AZ.
- `wait-store-timeout` is the waiting time for switching to asynchronous replication mode when network isolation or failure occurs. If the time of network failure exceeds the waiting time, asynchronous replication mode is enabled. The default waiting time is 60 seconds.

To check the current replication status of the cluster, use the following API:

```
curl http://pd_ip:pd_port/pd/api/v1/replication_mode/status
```

```
{
 "mode": "dr-auto-sync",
 "dr-auto-sync": {
 "label-key": "az",
 "state": "sync"
 }
}
```

### 12.3.3.3.1 Status switch

The replication mode of a cluster can automatically and adaptively switch between three statuses:

- When the cluster is normal, the synchronous replication mode is enabled to maximize the data integrity of the disaster recovery AZ.
- When the network connection between the two AZs fails or the disaster recovery AZ breaks down, after a pre-set protective interval, the cluster enables the asynchronous replication mode to ensure the availability of the application.
- When the network reconnects or the disaster recovery AZ recovers, the TiKV node joins the cluster again and gradually replicates the data. Finally, the cluster switches to the synchronous replication mode.

The details for the status switch are as follows:

1. **Initialization:** At the initialization stage, the cluster is in the synchronous replication mode. PD sends the status information to TiKV, and all TiKV nodes strictly follow the synchronous replication mode to work.
2. **Switch from sync to async:** PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node fails or is disconnected. If the number of failed nodes exceeds the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can no longer serve the data replication and it is necessary to switch the status. When the failure or disconnect time exceeds the time set by `wait-store-timeout`, PD switches the status of the cluster to the async mode. Then PD sends the status of async to all TiKV nodes, and the replication mode for TiKV switches from two-availability-zone replication to the native Raft majority.
3. **Switch from async to sync:** PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node is reconnected. If the number of failed nodes is less than the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can be enabled again. PD first switches the status of the cluster to `sync-recover` and sends the status information to all TiKV nodes. All Regions of TiKV gradually switch to the two-availability-zone synchronous replication mode and then report the heartbeat information to PD. PD records the status of TiKV Regions and calculates the recovery progress. When all TiKV Regions finish the switching, PD switches the replication mode to `sync`.

#### 12.3.3.4 Disaster recovery

This section introduces the disaster recovery solution of the two AZs in one region deployment.

When a disaster occurs to a cluster in the synchronous replication mode, you can perform data recovery with `RPO = 0`:

- If the primary AZ fails and most of the Voter replicas are lost, but complete data exists in the disaster recovery AZ, the lost data can be recovered from the disaster recovery AZ. At this time, manual intervention is required with professional tools. You can [get support](#) from PingCAP or the community for a recovery solution.

- If the disaster recovery AZ fails and a few Voter replicas are lost, the cluster automatically switches to the asynchronous replication mode.

When a disaster occurs to a cluster that is not in the synchronous replication mode and you cannot perform data recovery with  $RPO = 0$ :

- If most of the Voter replicas are lost, manual intervention is required with professional tools. You can [get support](#) from PingCAP or the community for a recovery solution.

## 12.4 Read Historical Data

### 12.4.1 Use Stale Read (Recommended)

#### 12.4.1.1 Usage Scenarios of Stale Read

This document describes the usage scenarios of Stale Read. Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes.

When you are using Stale Read, TiDB will randomly select a replica for data reading, which means that all replicas are available for data reading. If your application cannot tolerate reading non-real-time data, do not use Stale Read; otherwise, the data read from the replica might not be the latest data written into TiDB.

##### 12.4.1.1.1 Scenario examples

- Scenario one: If a transaction only involves read operations and is tolerant of data staleness to some extent, you can use Stale Read to get historical data. Using Stale Read, TiDB makes the query requests sent to any replica at the expense of some real-time performance, and thus increases the throughput of query executions. Especially in some scenarios where small tables are queried, if strongly consistent reads are used, leader might be concentrated on a certain storage node, causing the query pressure to be concentrated on that node as well. Therefore, that node might become a bottleneck for the whole query. Stale Read, however, can improve the overall query throughput and significantly improve the query performance.
- Scenario two: In some scenarios of geo-distributed deployment, if strongly consistent follower reads are used, to make sure that the data read from the Followers is consistent with that stored in the Leader, TiDB requests `ReadIndex` from different data centers for verification, which increases the access latency for the whole query process. With Stale Read, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query. For more information, see [Local Read under Three Data Centers Deployment](#).

### 12.4.1.1.2 Usages

TiDB provides the methods of performing Stale Read at the statement level, the session level and the global level as follows:

- Statement level
  - Specifying an exact point in time (**recommended**): If you need TiDB to read data that is globally consistent from a specific point in time without violating the isolation level, you can specify the corresponding timestamp of that point in time in the query statement. For detailed usage, see [AS OF TIMESTAMP clause](#).
  - Specifying a time range: If you need TiDB to read the data as new as possible within a time range without violating the isolation level, you can specify the time range in the query statement. Within the specified time range, TiDB selects a suitable timestamp to read the corresponding data. “Suitable” means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. For detailed usage, refer to the introduction of the [AS OF TIMESTAMP Clause](#) and the [TIDB\\_BOUNDED\\_STALENESS function](#).
- Session level
  - Specifying a time range: In a session, if you need TiDB to read the data as new as possible within a time range in subsequent queries without violating the isolation level, you can specify the time range by setting the `tidb_read_staleness` system variable. For detailed usage, refer to [tidb\\_read\\_staleness](#).

Besides, TiDB provides a way to specify an exact point in time by setting the `tidb_external_ts` system variable on session or global level. For detailed usage, refer to [Perform Stale Read Using tidb\\_external\\_ts](#).

### 12.4.1.1.3 Restrictions

When a Stale Read query for a table is pushed down to TiFlash, the query will return an error if this table has newer DDL operations executed after the read timestamp specified by the query. This is because TiFlash only supports reading data from the tables with the latest schemas.

Take the following table as an example:

```
create table t1(id int);
alter table t1 set tiflash replica 1;
```

Execute the following DDL operation after one minute:

```
alter table t1 add column c1 int not null;
```

Then, use Stale Read to query the data from one minute ago:

```
set @@session.tidb_enforce_mpp=1;
select * from t1 as of timestamp NOW() - INTERVAL 1 minute;
```

TiFlash will report an error as follows:

```
ERROR 1105 (HY000): other error for mpp stream: From MPP<query:<query_ts
 ↪ :1673950975508472943, local_query_id:18, server_id:111947, start_ts
 ↪ :438816196526080000>,task_id:1>: Code: 0, e.displayText() = DB::
 ↪ TiFlashException: Table 323 schema version 104 newer than query
 ↪ schema version 100, e.what() = DB::TiFlashException,
```

To avoid this error, you can change the read timestamp specified by Stale Read to the time after the DDL operation.

### 12.4.1.2 Read Historical Data Using the AS OF TIMESTAMP Clause

This document describes how to perform the [Stale Read](#) feature using the AS OF ↪ TIMESTAMP clause to read historical data in TiDB, including specific usage examples and strategies for saving historical data.

TiDB supports reading historical data through a standard SQL interface, which is the AS OF TIMESTAMP SQL clause, without the need for special clients or drivers. After data is updated or deleted, you can read the historical data before the update or deletion using this SQL interface.

#### Note:

When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

#### 12.4.1.2.1 Syntax

You can use the AS OF TIMESTAMP clause in the following three ways:

- `SELECT ... FROM ... AS OF TIMESTAMP`
- `START TRANSACTION READ ONLY AS OF TIMESTAMP`
- `SET TRANSACTION READ ONLY AS OF TIMESTAMP`

If you want to specify an exact point of time, you can set a datetime value or use a time function in the AS OF TIMESTAMP clause. The format of datetime is like “2016-10-08 16:45:26.999”, with millisecond as the minimum time unit, but for most of the time, the time unit of second is enough for specifying a datetime, such as “2016-10-08 16:45:26”. You

can also get the current time to the millisecond using the `NOW(3)` function. If you want to read the data of several seconds ago, it is **recommended** to use an expression such as `NOW() - INTERVAL 10 SECOND`.

If you want to specify a time range, you can use the `TIDB_BOUNDED_STALENESS()` function in the clause. When this function is used, TiDB selects a suitable timestamp within the specified time range. “Suitable” means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. You need to use `TIDB_BOUNDED_STALENESS(t1, t2)` to call this function. `t1` and `t2` are the two ends of the time range, which can be specified using either datetime values or time functions.

Here are some examples of the `AS OF TIMESTAMP` clause:

- `AS OF TIMESTAMP '2016-10-08 16:45:26'`: Tells TiDB to read the latest data stored at 16:45:26 on October 8, 2016.
- `AS OF TIMESTAMP NOW() - INTERVAL 10 SECOND`: Tells TiDB to read the latest data stored 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 16:45:29')`: Tells TiDB to read the data as new as possible within the time range of 16:45:26 to 16:45:29 on October 8, 2016.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW() - INTERVAL 20 SECOND, NOW())`: Tells TiDB to read the data as new as possible within the time range of 20 seconds ago to the present.

#### Note:

In addition to specifying a timestamp, the most common use of the `AS OF TIMESTAMP` clause is to read data that is several seconds old. If this approach is used, it is recommended to read historical data older than 5 seconds.

You need to deploy the NTP service for your TiDB and PD nodes when you use Stale Read. This avoids the situation where the specified timestamp used by TiDB goes ahead of the latest TSO allocating progress (such as a timestamp several seconds ahead), or is later than the GC safe point timestamp. When the specified timestamp goes beyond the service scope, TiDB returns an error.

#### 12.4.1.2.2 Usage examples

This section describes different ways to use the `AS OF TIMESTAMP` clause with several examples. It first introduces how to prepare the data for recovery, and then shows how to

use `AS OF TIMESTAMP` in `SELECT`, `START TRANSACTION READ ONLY AS OF TIMESTAMP`, and `SET TRANSACTION READ ONLY AS OF TIMESTAMP` respectively.

Prepare data sample

To prepare data for recovery, create a table first and insert several rows of data:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

View the data in the table:

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

View the current time:

```
select now();
```

```
+-----+
| now() |
+-----+
| 2021-05-26 16:45:26 |
+-----+
1 row in set (0.00 sec)
```

Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

Confirm that the data of the row is updated:

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

Read historical data using the `SELECT` statement

You can use the `SELECT ... FROM ... AS OF TIMESTAMP` statement to read data from a time point in the past.

```
select * from t as of timestamp '2021-05-26 16:45:26';
```

```
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

### Note:

When reading multiple tables using one `SELECT` statement, you need to make sure that the format of `TIMESTAMP EXPRESSIONS` is consistent. For example, `select * from t as of timestamp NOW()- INTERVAL 2 SECOND, ↵ c as of timestamp NOW()- INTERVAL 2 SECOND;` In addition, you must specify the `AS OF` information for the relevant table in the `SELECT` statement; otherwise, the `SELECT` statement reads the latest data by default.

Read historical data using the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement to start a read-only transaction based on a time point in the past. The transaction reads historical data of the given time.

```
start transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

### Note:

If you start a transaction with the statement `START TRANSACTION READ ONLY`  $\leftrightarrow$  `AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

Read historical data using the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement to set the next transaction as a read-only transaction based on a specified time point in the past. The transaction reads historical data of the given time.

```
set transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
begin;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

### Note:

If you start a transaction with the statement `SET TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

### 12.4.1.3 Read Historical Data Using the `tidb_read_staleness` System Variable

To support reading the historical data, in v5.4, TiDB introduces a new system variable `tidb_read_staleness`. This document describes how to read historical data through this system variable, including detailed operating procedures.

#### 12.4.1.3.1 Feature description

The `tidb_read_staleness` system variable is used to set the time range of historical data that TiDB can read in the current session. The data type of this variable is `int` type, and the scope of it is `SESSION`. After setting the value, TiDB selects a timestamp as new as possible from the range allowed by this variable, and all subsequent read operations are performed against this timestamp. For example, if the value of this variable is set to `-5`, on the condition that TiKV has the corresponding historical version's data, TiDB selects a timestamp as new as possible within a 5-second time range.

After enabling `tidb_read_staleness`, you still can perform the following operations:

- Insert, modify, delete data or perform DML operations in the current session. These statements are not affected by `tidb_read_staleness`.
- Start an interactive transaction in the current session. Queries within this transaction still read the latest data.

After reading the historical data, you can read the latest data in the following two ways:

- Start a new session.
- Set the value of the `tidb_read_staleness` variable to `""` using the `SET` statement.

#### 12.4.1.3.2 Usage examples

This section describes how to use `tidb_read_staleness` with examples.

1. Create a table, and insert a few rows of data into the table:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. Check out the data in the table:

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

3. Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

4. Confirm that the data has been updated:

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

5. Set the `tidb_read_staleness` system variable.

The scope of this variable is `SESSION`. After setting its value, TiDB reads the latest version data before the time set by the value.

The following setting indicates that TiDB selects a timestamp as new as possible within the time range from 5 seconds ago to now and uses it as the timestamp for reading historical data:

```
set @@tidb_read_staleness="-5";
```

```
Query OK, 0 rows affected (0.00 sec)
```

**Note:**

- Use `@@` instead of `@` before `tidb_read_staleness`. `@@` means system variables, and `@` means user variables.

- You need to set the historical time range (the value of `tidb_read_staleness`) according to the total time that you spent in step 3 and step 4. Otherwise, the latest data will be displayed in the query results, not the historical data. Therefore, you need to adjust this time range according to the time you spent on operations. For example, in this example, since the set time range is 5 seconds, you need to complete step 3 and step 4 within 5 seconds.

The data read here is the data before the update, that is, the historical data:

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

6. After un-setting this variable as follows, TiDB can read the latest data:

```
set @@tidb_read_staleness="";
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

#### 12.4.1.4 Read Historical Data Using the `tidb_external_ts` Variable

To support reading the historical data, TiDB v6.4.0 introduces a system variable `tidb_external_ts`. This document describes how to read historical data through this system variable, including detailed usage examples.

#### 12.4.1.4.1 Scenarios

Read historical data from a specified point in time is very useful for data replication tools such as TiCDC. After the data replication tool completes the data replication before a certain point in time, you can set the `tidb_external_ts` system variable of the downstream TiDB to read the data before that point in time. This prevents the data inconsistency caused by data replication.

#### 12.4.1.4.2 Feature description

The system variable `tidb_external_ts` specifies the timestamp of the historical data to be read when `tidb_enable_external_ts_read` is enabled.

The system variable `tidb_enable_external_ts_read` controls whether to read historical data in the current session or globally. The default value is `OFF`, which means the feature of reading historical data is disabled, and the `tidb_external_ts` value is ignored. When `tidb_enable_external_ts_read` is set to `ON` globally, all queries read historical data before the time specified by `tidb_external_ts`. If `tidb_enable_external_ts_read` is set to `ON` only for a certain session, only queries in that session read historical data.

When the `tidb_enable_external_ts_read` is enabled, TiDB becomes read-only. All write queries will fail with an error like `ERROR 1836 (HY000): Running in read-only ↪ mode`.

#### 12.4.1.4.3 Usage examples

This section describes how to use the `tidb_external_ts` variable to read historical data with examples.

1. Create a table and insert some rows into the table:

```
CREATE TABLE t (c INT);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
INSERT INTO t VALUES (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
SELECT * FROM t;
```

```
+-----+
| c |
+-----+
| 1 |
```

```

| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)

```

- Set `tidb_external_ts` to `@@tidb_current_ts`:

```

START TRANSACTION;
SET GLOBAL tidb_external_ts=@@tidb_current_ts;
COMMIT;

```

- Insert a new row and confirm that it is inserted:

```

INSERT INTO t VALUES (4);

```

```

Query OK, 1 row affected (0.001 sec)

```

```

SELECT * FROM t;

```

```

+-----+
| id |
+-----+
| 1 |
| 2 |
| 3 |
| 4 |
+-----+
4 rows in set (0.00 sec)

```

- Set `tidb_enable_external_ts_read` to `ON` and then view data in the table:

```

SET tidb_enable_external_ts_read=ON;
SELECT * FROM t;

```

```

+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)

```

Because `tidb_external_ts` is set to the timestamp before the new row is inserted, the newly inserted row is not returned after the `tidb_enable_external_ts_read` is enabled.

## 12.4.2 Read Historical Data Using the System Variable `tidb_snapshot`

This document describes how to read data from the history versions using the system variable `tidb_snapshot`, including specific usage examples and strategies for saving historical data.

### Note:

You can also use the [Stale Read](#) feature to read historical data, which is more recommended.

### 12.4.2.1 Feature description

TiDB implements a feature to read history data using the standard SQL interface directly without special clients or drivers.

### Note:

- Even when data is updated or removed, its history versions can be read using the SQL interface.
- When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

### 12.4.2.2 How TiDB reads data from history versions

The `tidb_snapshot` system variable is introduced to support reading history data. About the `tidb_snapshot` variable:

- The variable is valid in the `SESSION` scope.
- Its value can be modified using the `SET` statement.
- The data type for the variable is text.
- The variable accepts TSO (Timestamp Oracle) and datetime. TSO is a globally unique time service, which is obtained from PD. The acceptable datetime format is “2016-10-08 16:45:26.999”. Generally, the datetime can be set using second precision, for example “2016-10-08 16:45:26”.
- When the variable is set, TiDB creates a Snapshot using its value as the timestamp, just for the data structure and there is no any overhead. After that, all the `SELECT` operations will read data from this Snapshot.

**Note:**

Because the timestamp in TiDB transactions is allocated by Placement Driver (PD), the version of the stored data is also marked based on the timestamp allocated by PD. When a Snapshot is created, the version number is based on the value of the `tidb_snapshot` variable. If there is a large difference between the local time of the TiDB server and the PD server, use the time of the PD server.

After reading data from history versions, you can read data from the latest version by ending the current Session or using the `SET` statement to set the value of the `tidb_snapshot` variable to `''` (empty string).

### 12.4.2.3 How TiDB manages the data versions

TiDB implements Multi-Version Concurrency Control (MVCC) to manage data versions. The history versions of data are kept because each update/removal creates a new version of the data object instead of updating/removing the data object in-place. But not all the versions are kept. If the versions are older than a specific time, they will be removed completely to reduce the storage occupancy and the performance overhead caused by too many history versions.

In TiDB, Garbage Collection (GC) runs periodically to remove the obsolete data versions. For GC details, see [TiDB Garbage Collection \(GC\)](#)

Pay special attention to the following:

- `tidb_gc_life_time`: This system variable is used to configure the retention time of earlier modifications (default: 10m0s).
- The output of `SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point' ↪ '`. This is the current `safePoint` where you can read historical data up to. It is updated every time the garbage collection process is run.

### 12.4.2.4 Example

1. At the initial stage, create a table and insert several rows of data:

```
mysql> create table t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into t values (1), (2), (3);
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
mysql> select * from t;
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

3. View the timestamp of the table:

```
mysql> select now();
+-----+
| now() |
+-----+
| 2016-10-08 16:45:26 |
+-----+
1 row in set (0.00 sec)
```

4. Update the data in one row:

```
mysql> update t set c=22 where c=2;
Query OK, 1 row affected (0.00 sec)
```

5. Make sure the data is updated:

```
mysql> select * from t;
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

6. Set the `tidb_snapshot` variable whose scope is Session. The variable is set so that the latest version before the value can be read.

**Note:**

In this example, the value is set to be the time before the update operation.

```
mysql> set @@tidb_snapshot="2016-10-08 16:45:26";
Query OK, 0 rows affected (0.00 sec)
```

**Note:**

You should use @@ instead of @ before `tidb_snapshot` because @@ is used to denote the system variable while @ is used to denote the user variable.

**Result:** The read from the following statement is the data before the update operation, which is the history data.

```
mysql> select * from t;
+-----+
| c |
+-----+
| 1 |
| 2 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

7. Set the `tidb_snapshot` variable to be "" (empty string) and you can read the data from the latest version:

```
mysql> set @@tidb_snapshot="";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> select * from t;
+-----+
| c |
+-----+
| 1 |
| 22 |
| 3 |
+-----+
3 rows in set (0.00 sec)
```

**Note:**

You should use @@ instead of @ before `tidb_snapshot` because @@ is used to denote the system variable while @ is used to denote the user variable.

### 12.4.2.5 How to restore historical data

Before you restore data from an older version, make sure that Garbage Collection (GC) does not clear the history data while you are working on it. This can be done by setting the `tidb_gc_life_time` variable as the following example shows. Do not forget to set the variable back to the previous value after the restore.

```
SET GLOBAL tidb_gc_life_time="60m";
```

#### Note:

Increasing the GC life time from the default 10 minutes to half an hour or more will result in additional versions of rows being retained, which might require more disk space. This might also affect the performance of certain operations such as scans when TiDB needs to skip these additional versions of the same rows during data reads.

To restore data from an older version, you can use one of the following methods:

- For simple cases, use `SELECT` after setting the `tidb_snapshot` variable and copy-paste the output, or use `SELECT ... INTO OUTFILE` and then use `LOAD DATA` to import the data later on.
- Use `Dumpling` to export a historical snapshot. `Dumpling` performs well in exporting larger sets of data.

## 12.5 Best Practices

### 12.5.1 TiDB Best Practices

This document summarizes the best practices of using TiDB, including the use of SQL and optimization tips for Online Analytical Processing (OLAP) and Online Transactional Processing (OLTP) scenarios, especially the optimization options specific for TiDB.

Before you read this document, it is recommended that you read three blog posts that introduce the technical principles of TiDB:

- [TiDB Internal \(I\) - Data Storage](#)
- [TiDB Internal \(II\) - Computing](#)
- [TiDB Internal \(III\) - Scheduling](#)

### 12.5.1.1 Preface

Database is a generic infrastructure system. It is important to consider various user scenarios during the development process and to modify the data parameters or the way to use according to actual situations in specific business scenarios.

TiDB is a distributed database compatible with the MySQL protocol and syntax. But with the internal implementation and supporting of distributed storage and transactions, the way of using TiDB is different from MySQL.

### 12.5.1.2 Basic concepts

The best practices are closely related to its implementation principles. It is recommended that you learn some of the basic mechanisms, including the Raft consensus algorithm, distributed transactions, data sharding, load balancing, the mapping solution from SQL to Key-Value (KV), the implementation method of secondary indexing, and distributed execution engines.

This section is an introduction to these concepts. For detailed information, refer to [PingCAP blog posts](#).

#### 12.5.1.2.1 Raft

Raft is a consensus algorithm that ensures data replication with strong consistency. At the bottom layer, TiDB uses Raft to replicate data. TiDB writes data to the majority of the replicas before returning the result of success. In this way, even though a few replicas might get lost, the system still has the latest data. For example, if there are three replicas, the system does not return the result of success until data has been written to two replicas. Whenever a replica is lost, at least one of the remaining two replicas have the latest data.

To store three replicas, compared with the replication of Source-Replica, Raft is more efficient. The write latency of Raft depends on the two fastest replicas, instead of the slowest one. Therefore, the implementation of geo-distributed and multiple active data centers becomes possible by using the Raft replication. In the typical scenario of three data centers distributing in two sites, to guarantee the data consistency, TiDB just needs to successfully write data into the local data center and the closer one, instead of writing to all three data centers. However, this does not mean that cross-data center deployment can be implemented in any scenario. When the amount of data to be written is large, the bandwidth and latency between data centers become the key factors. If the write speed exceeds the bandwidth or the latency is too high, the Raft replication mechanism still cannot work well.

#### 12.5.1.2.2 Distributed transactions

TiDB provides complete distributed transactions and the model has some optimizations on the basis of [Google Percolator](#). This document introduces the following features:

- Optimistic transaction model

TiDB's optimistic transaction model does not detect conflicts until the commit phase. If there are conflicts, the transaction needs retry. But this model is inefficient if the conflict is severe, because operations before retry are invalid and need to repeat.

Assume that the database is used as a counter. High access concurrency might lead to severe conflicts, resulting in multiple retries or even timeouts. Therefore, in the scenario of severe conflicts, it is recommended to use the pessimistic transaction mode or to solve problems at the system architecture level, such as placing counter in Redis. Nonetheless, the optimistic transaction model is efficient if the access conflict is not very severe.

- Pessimistic transaction mode

In TiDB, the pessimistic transaction mode has almost the same behavior as in MySQL. The transaction applies a lock during the execution phase, which avoids retries in conflict situations and ensures a higher success rate. By applying the pessimistic locking, you can also lock data in advance using `SELECT FOR UPDATE`.

However, if the application scenario has fewer conflicts, the optimistic transaction model has better performance.

- Transaction size limit

As distributed transactions need to conduct two-phase commit and the bottom layer performs Raft replication, if a transaction is very large, the commit process would be quite slow, and the following Raft replication process is thus stuck. To avoid this problem, the transaction size is limited:

- A transaction is limited to 5,000 SQL statements (by default)
- Each Key-Value entry is no more than 6 MB (by default)
- The total size of Key-Value entries is no more than 10 GB.

You can find similar limits in [Google Cloud Spanner](#).

### 12.5.1.2.3 Data sharding

TiKV automatically shards bottom-layered data according to the range of keys. Each Region is a range of keys, which is a left-closed and right-open interval,  $[\text{StartKey}, \text{EndKey} \rightarrow )$ . When the amount of Key-Value pairs in a Region exceeds a certain value, the Region automatically splits into two.

### 12.5.1.2.4 Load balancing

Placement Driver (PD) balances the load of the cluster according to the status of the entire TiKV cluster. The unit of scheduling is Region and the logic is the strategy configured by PD.

#### 12.5.1.2.5 SQL on KV

TiDB automatically maps the SQL structure into Key-Value structure. For details, see [TiDB Internal \(II\) - Computing](#).

Simply put, TiDB performs the following operations:

- A row of data is mapped to a Key-Value pair. The key is prefixed with `TableID` and suffixed with the row ID.
- An index is mapped as a Key-Value pair. The key is prefixed with `TableID+IndexID` and suffixed with the index value.

The data or indexes in the same table have the same prefix. These Key-Values are at adjacent positions in the key space of TiKV. Therefore, when the amount of data to be written is large and all is written to one table, the write hotspot is created. The situation gets worse when some index values of the continuous written data is also continuous (for example, fields that increase with time, like `update time`), which creates a few write hotspots and becomes the bottleneck of the entire system.

Similarly, if all data is read from a focused small range (for example, the continuous tens or hundreds of thousands of rows of data), an access hotspot of data is likely to occur.

#### 12.5.1.2.6 Secondary index

TiDB supports the complete secondary indexes, which are also global indexes. Many queries can be optimized by index. Thus, it is important for applications to make good use of secondary indexes.

Lots of MySQL experience is also applicable to TiDB. It is noted that TiDB has its unique features. The following are a few notes when using secondary indexes in TiDB.

- The more secondary indexes, the better?

Secondary indexes can speed up queries, but adding an index has side effects. The previous section introduces the storage model of indexes. For each additional index, there will be one more Key-Value when inserting a row. Therefore, the more indexes, the slower the writing speed and the more space it takes up.

In addition, too many indexes affects the runtime of the optimizer, and inappropriate indexes mislead the optimizer. Thus, more secondary indexes does not mean better performance.

- Which columns should create indexes?

As is mentioned above, index is important but the number of indexes should be proper. You must create appropriate indexes according to the application characteristics. In principle, you need to create an index on the columns involved in the query to improve the performance. The following are situations that need to create indexes:

- For columns with a high degree of differentiation, filtered rows are remarkably reduced through indexes.
- If there are multiple query criteria, you can choose composite indexes. Note to put the columns with the equivalent condition before composite indexes.

For example, if a commonly used query is `select * from t where c1 = 10 and c2 <= 100 and c3 > 10`, you can create a composite index `Index cidx (c1, c2, c3)`. In this way, you can use the query condition to create an index prefix and then scan.

- The difference between querying through indexes and directly scanning the table

TiDB has implemented global indexes, so indexes and data of the table are not necessarily on the same data sharding. When querying through indexes, it should firstly scan indexes to get the corresponding row ID and then use the row ID to get the data. Thus, this method involves two network requests and has a certain performance overhead.

If the query involves lots of rows, scanning index proceeds concurrently. When the first batch of results is returned, getting the data of the table can then proceed. Therefore, this is a parallel + pipeline model. Though the two accesses create overhead, the latency is not high.

The following two conditions do not have the problem of two accesses:

- Columns of the index have already met the query requirement. Assume that the `c` column on the `t` table has an index and the query is `select c from t where c > 10`; . At this time, all needed data can be obtained if you access the index. This situation is called **Covering Index**. But if you focus more on the query performance, you can put into index a portion of columns that do not need to be filtered but need to be returned in the query result, creating composite index. Take `select c1, c2 from t where c1 > 10`; as an example. You can optimize this query by creating composite index `Index c12 (c1, c2)`.
- The primary key of the table is integer. In this case, TiDB uses the value of the primary key as row ID. Thus, if the query condition is on the primary key, you can directly construct the range of the row ID, scan the table data, and get the result.

- Query concurrency

As data is distributed across many Regions, queries run in TiDB concurrently. But the concurrency by default is not high in case it consumes lots of system resources. Besides, the OLTP query usually does not involve a large amount of data and the low concurrency is enough. But for the OLAP query, the concurrency is high and TiDB modifies the query concurrency through the following system variables:

- `tidb_distsql_scan_concurrency`:

The concurrency of scanning data, including scanning the table and index data.

– `tidb_index_lookup_size`:

If it needs to access the index to get row IDs before accessing the table data, it uses a batch of row IDs as a single request to access the table data. This parameter sets the size of a batch. The larger batch increases latency, while the smaller one might lead to more queries. The proper size of this parameter is related to the amount of data that the query involves. Generally, no modification is required.

– `tidb_index_lookup_concurrency`:

If it needs to access the index to get row IDs before accessing the table data, the concurrency of getting data through row IDs every time is modified through this parameter.

- Ensure the order of results through indexes

You can use indexes to filter or sort data. Firstly, get row IDs according to the index order. Then, return the row content according to the return order of row IDs. In this way, the returned results are ordered according to the index column. It has been mentioned earlier that the model of scanning index and getting row is parallel + pipeline. If the row is returned according to the index order, a high concurrency between two queries does not reduce latency. Thus, the concurrency is low by default, but it can be modified through the `tidb_index_serial_scan_concurrency` variable.

- Reverse index scan

TiDB supports scanning an ascending index in reverse order, at a speed slower than normal scan by 20%. If the data is changed frequently and thus too many versions exist, the performance overhead might be higher. It is recommended to avoid reverse index scans as much as possible.

### 12.5.1.3 Scenarios and practices

In the last section, we discussed some basic implementation mechanisms of TiDB and their influence on usage. This section introduces specific usage scenarios and operation practices, from deployment to application usage.

#### 12.5.1.3.1 Deployment

Before deployment, read [Software and Hardware Requirements](#).

It is recommended to deploy the TiDB cluster using [TiUP](#). This tool can deploy, stop, destroy, and upgrade the whole cluster, which is quite convenient. It is not recommended to manually deploy the TiDB cluster, which might be troublesome to maintain and upgrade later.

#### 12.5.1.3.2 Data import

To improve the write performance during the import process, you can tune TiKV's parameters as stated in [Tune TiKV Memory Parameter Performance](#).

### 12.5.1.3.3 Write

As mentioned before, TiDB limits the size of a single transaction in the Key-Value layer. As for the SQL layer, a row of data is mapped to a Key-Value entry. For each additional index, one more Key-Value entry is added.

#### Note:

When you set the size limit for transactions, you need to consider the overhead of TiDB encoding and the extra transaction key. It is recommended that **the number of rows of each transaction is less than 200 and the data size of a single row is less than 100 KB**; otherwise, the performance is bad.

It is recommended to split statements into batches or add a limit to the statements, whether they are INSERT, UPDATE or DELETE statements.

When deleting a large amount of data, it is recommended to use `Delete from t where ↪ xx limit 5000;`. It deletes through the loop and use `Affected Rows == 0` as a condition to end the loop.

If the amount of data that needs to be deleted at a time is large, this loop method gets slower and slower because each deletion traverses backward. After deleting the previous data, lots of deleted flags remain for a short period (then all is cleared by Garbage Collection) and affect the following DELETE statement. If possible, it is recommended to refine the WHERE condition. Assume that you need to delete all data on 2017-05-26, you can use the following statements:

```
for i from 0 to 23:
 while affected_rows > 0:
 delete from t where insert_time >= i:00:00 and insert_time < (i+1)
 ↪ :00:00 limit 5000;
 affected_rows = select affected_rows()
```

This pseudocode means to split huge chunks of data into small ones and then delete, so that the earlier Delete statements do not affect the later ones.

### 12.5.1.3.4 Query

For query requirements and specific statements, refer to [System Variables](#).

You can control the concurrency of SQL execution through the SET statement and the selection of the Join operator through hints.

In addition, you can also use MySQL's standard index selection, the hint syntax, or control the optimizer to select indexes through `Use Index/Ignore Index hint`.

If the application scenario has both OLTP and OLAP workloads, you can send the OLTP request and OLAP request to different TiDB servers, diminishing the impact of OLAP on OLTP. It is recommended to use machines with high-performance hardware (for example, more processor cores and larger memory) for the TiDB server that processes OLAP workloads.

To completely isolate OLTP and OLAP workloads, it is recommended to run OLAP applications on TiFlash. TiFlash is a columnar storage engine with great performance on OLAP workloads. TiFlash can achieve physical isolation on the storage layer and guarantees consistent reads.

#### 12.5.1.3.5 Monitoring and log

The monitoring metrics is the best method to learn the status of the system. It is recommended that you deploy the monitoring system along with your TiDB cluster.

TiDB uses [Grafana + Prometheus](#) to monitor the system status. The monitoring system is automatically deployed and configured if you deploy TiDB using TiUP.

There are lots of items in the monitoring system, the majority of which are for TiDB developers. You do not have to understand these items without an in-depth knowledge of the source code. Some items that are related to applications or to the state of system key components are selected and put in a separate **overview** panel for users.

In addition to monitoring, you can also view the system logs. The three components of TiDB, `tidb-server`, `tikv-server`, and `pd-server`, each has a `--log-file` parameter. If this parameter has been configured when the cluster is started, logs are stored in the file configured by the parameter and log files are automatically archived on a daily basis. If the `--log-file` parameter has not been configured, the log is output to `stderr`.

Starting from TiDB 4.0, TiDB provides [TiDB Dashboard](#) UI to improve usability. You can access TiDB Dashboard by visiting [http://\\$%7BPD\\_IP%7D:\\$%7BPD\\_PORT%7D/dashboard](http://$%7BPD_IP%7D:$%7BPD_PORT%7D/dashboard) in your browser. TiDB Dashboard provides features such as viewing cluster status, performance analysis, traffic visualization, cluster diagnostics, and log searching.

#### 12.5.1.3.6 Documentation

The best way to learn about a system or solve the problem is to read its documentation and understand its implementation principles.

TiDB has a large number of official documents both in Chinese and English. If you have met an issue, you can start from [FAQ](#) and [TiDB Cluster Troubleshooting Guide](#). You can also search the issue list or create an issue in [TiDB repository on GitHub](#).

TiDB also has many useful migration tools. See [Migration Tool Overview](#) for details.

For more articles on the technical details of TiDB, see the [PingCAP official blog site](#).

#### 12.5.1.4 Best scenarios for TiDB

TiDB is suitable for the following scenarios:

- The data volume is too large for a standalone database
- You do not want to do sharding
- The access mode has no obvious hotspot
- Transactions, strong consistency, and disaster recovery are required
- You hope to have real-time Hybrid Transaction/Analytical Processing (HTAP) analytics and reduce storage links

## 12.5.2 Best Practices for Developing Java Applications with TiDB

This document introduces the best practice for developing Java applications to better use TiDB. Based on some common Java application components that interact with the backend TiDB database, this document also provides the solutions to commonly encountered issues during development.

### 12.5.2.1 Database-related components in Java applications

Common components that interact with the TiDB database in Java applications include:

- Network protocol: A client interacts with a TiDB server via the standard [MySQL protocol](#).
- JDBC API and JDBC drivers: Java applications usually use the standard [JDBC \(Java Database Connectivity\)](#) API to access a database. To connect to TiDB, you can use a JDBC driver that implements the MySQL protocol via the JDBC API. Such common JDBC drivers for MySQL include [MySQL Connector/J](#) and [MariaDB Connector/J](#).
- Database connection pool: To reduce the overhead of creating a connection each time it is requested, applications usually use a connection pool to cache and reuse connections. JDBC [DataSource](#) defines a connection pool API. You can choose from different open-source connection pool implementations as needed.
- Data access framework: Applications usually use a data access framework such as [MyBatis](#) and [Hibernate](#) to further simplify and manage the database access operations.
- Application implementation: The application logic controls when to send what commands to the database. Some applications use [Spring Transaction](#) aspects to manage transactions' start and commit logics.

Figure 196: Java application components

From the above diagram, you can see that a Java application might do the following things:

- Implement the MySQL protocol via the JDBC API to interact with TiDB.
- Get a persistent connection from the connection pool.
- Use a data access framework such as MyBatis to generate and execute SQL statements.
- Use Spring Transaction to automatically start or stop a transaction.

The rest of this document describes the issues and their solutions when you develop a Java application using the above components.

## 12.5.2.2 JDBC

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

### 12.5.2.2.1 JDBC API

For JDBC API usage, see [JDBC official tutorial](#). This section covers the usage of several important APIs.

#### Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use [Prepared Statements](#) instead of regular [execution from a text file](#) and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?`  $\rightarrow$  is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see [MySQL JDBC parameters](#).

#### Use Batch API

For batch inserts, you can use the [addBatch/executeBatch API](#). The `addBatch()`  $\rightarrow$  method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

**Note:**

In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.

If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see [Batch-related parameters](#).

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and save them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time, and waits until the client's memory is ready and it requests for the next batch.

Usually, there are two kinds of processing methods in JDBC:

- Set `FetchSize` to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise, the error `No statements may be issued when any streaming result sets are open and in use on a given connection`. Ensure that you have called `.close()` on any active streaming result sets before attempting more queries. is returned.

To avoid such an error in queries before the client finishes reading or closes `resultset` , you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- To use Cursor Fetch, first set `FetchSize` as a positive integer and configure `useCursorFetch=true` in the JDBC URL.

TiDB supports both methods, but it is preferred that you use the first method, because it is a simpler implementation and has a better execution efficiency.

#### 12.5.2.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces [MySQL Connector/J's parameter configurations](#) (If

you use MariaDB, see [MariaDB's parameter configurations](#)). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

### Prepare-related parameters

This section introduces parameters related to **Prepare**.

#### `useServerPrepStmts`

`useServerPrepStmts` is set to `false` by default, that is, even if you use the Prepare API, the “prepare” operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

#### `cachePrepStmts`

Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the “prepare” operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

#### `prepStmtCacheSqlLimit`

After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` configuration (the default value is 256). This configuration controls the maximum length of the Prepared Statements cached on the client.

The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

You need to check whether this setting is too small if you:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

#### `prepStmtCacheSize`

`prepStmtCacheSize` controls the number of cached Prepared Statements (the default value is 25). If your application requires “preparing” many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

#### Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements`  $\leftrightarrow$  `=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare("insert into t (a) values(?)");
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although Batch methods are used, the SQL statements sent to TiDB are still individual INSERT statements:

```
insert into t(a) values(10);
insert into t(a) values(11);
insert into t(a) values(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single INSERT statement:

```
insert into t(a) values(10),(11),(12);
```

Note that the rewrite of the INSERT statements is to concatenate the values after multiple “values” keywords into a whole SQL statement. If the INSERT statements have other differences, they cannot be rewritten, for example:

```
insert into t (a) values (10) on duplicate key update a = 10;
insert into t (a) values (11) on duplicate key update a = 11;
insert into t (a) values (12) on duplicate key update a = 12;
```

The above INSERT statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
insert into t (a) values (10) on duplicate key update a = values(a);
insert into t (a) values (11) on duplicate key update a = values(a);
insert into t (a) values (12) on duplicate key update a = values(a);
```

Then they meet the rewrite requirement. The above INSERT statements will be rewritten into the following one statement:

```
insert into t (a) values (10), (11), (12) on duplicate key update a =
↔ values(a);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
update t set a = 10 where id = 1; update t set a = 11 where id = 2; update
↔ t set a = 12 where id = 3;
```

In addition, because of a [client bug](#), if you want to configure `rewriteBatchedStatements`  $\leftrightarrow$  `=true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

### Integrate parameters

Through monitoring, you might notice that although the application only performs INSERT operations to the TiDB cluster, there are a lot of redundant SELECT statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` includes a group of configurations. To get the detailed configurations in MySQL Connector/J 8.0 and those in MySQL Connector/J 5.1, see [mysql-connector-j 8.0](#) and [mysql-connector-j 5.1](#) respectively.

After it is configured, you can check the monitoring to see a decreased number of SELECT statements.

### Timeout-related parameters

TiDB provides two MySQL-compatible parameters that controls the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution

in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. The default value of both parameters is 0, which by default allows the connection to be infinitely idle and infinitely busy (an infinite duration for one SQL statement to execute).

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables`  $\leftrightarrow$  `=wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

### 12.5.2.3 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least), because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

Java has many connection pool implementations such as [HikariCP](#), [tomcat-jdbc](#), [druid](#), [c3p0](#), and [dbcp](#). TiDB does not limit which connection pool you use, so you can choose whichever you like for your application.

#### 12.5.2.3.1 Configure the number of connections

It is a common practice that the connection pool size is well adjusted according to the application's own needs. Take HikariCP as an example:

- **maximumPoolSize**: The maximum number of connections in the connection pool. If this value is too large, TiDB consumes resources to maintain useless connections. If this value is too small, the application gets slow connections. So configure this value for your own good. For details, see [About Pool Sizing](#).
- **minimumIdle**: The minimum number of idle connections in the connection pool. It is mainly used to reserve some connections to respond to sudden requests when the application is idle. You can also configure it according to your application needs.

The application needs to return the connection after finishing using it. It is also recommended that the application use the corresponding connection pool monitoring (such as `metricRegistry`) to locate the connection pool issue in time.

#### 12.5.2.3.2 Probe configuration

The connection pool maintains persistent connections to TiDB. TiDB does not proactively close client connections by default (unless an error is reported), but generally there will be network proxies such as LVS or HAProxy between the client and TiDB. Usually, these proxies will proactively clean up connections that are idle for a certain period of time

(controlled by the proxy's idle configuration). In addition to paying attention to the idle configuration of the proxies, the connection pool also needs to keep alive or probe connections.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
↪ . The driver has not received any packets from the server. com.mysql.
↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
↪ failure
```

If `n in n milliseconds ago` is 0 or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as 3600000 in the above example), it is likely that this connection was idle for a long time and then closed by the intermediate proxy. The usual solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

#### 12.5.2.4 Data access framework

Applications often use some kind of data access framework to simplify database access.

##### 12.5.2.4.1 MyBatis

[MyBatis](#) is a popular Java data access framework. It is mainly used to manage SQL queries and complete the mapping between result sets and Java objects. MyBatis is highly compatible with TiDB. MyBatis rarely has problems based on its historical issues.

Here this document mainly focuses on the following configurations.

Mapper parameters

MyBatis Mapper supports two parameters:

- `select 1 from t where id = #{param1}` will be converted to `select 1 from t where id =?` as a Prepared Statement and be “prepared”, and the actual parameter will be used for reuse. You can get the best performance when using this parameter with the previously mentioned Prepare connection parameters.

- `select 1 from t where id = ${param2}` will be replaced with `select 1 from t`  
↔ `where id = 1` as a text file and be executed. If this statement is replaced with different parameters and is executed, MyBatis will send different requests for “preparing” the statements to TiDB. This might cause TiDB to cache a large number of Prepared Statements, and executing SQL operations this way has injection security risks.

## Dynamic SQL Batch

### Dynamic SQL - foreach

To support the automatic rewriting of multiple `INSERT` statements into the form of `insert ... values(...), (...), ...`, in addition to configuring `rewriteBatchedStatements` ↔ `=true` in JDBC as mentioned before, MyBatis can also use dynamic SQL to semi-automatically generate batch inserts. Take the following mapper as an example:

```
<insert id="insertTestBatch" parameterType="java.util.List" fetchSize="1">
 insert into test
 (id, v1, v2)
 values
 <foreach item="item" index="index" collection="list" separator=",">
 (
 #{item.id}, #{item.v1}, #{item.v2}
)
 </foreach>
 on duplicate key update v2 = v1 + values(v1)
</insert>
```

This mapper generates an `insert on duplicate key update` statement. The number of `(?, ?, ?)` following “values” is determined by the number of passed lists. Its final effect is similar to using `rewriteBatchedStatements=true`, which also effectively reduces communication overhead between the client and TiDB.

As mentioned before, you also need to note that the Prepared Statements will not be cached after their maximum length exceeds the value of `prepStmtCacheSqlLimit`.

## Streaming result

A [previous section](#) introduces how to stream read execution results in JDBC. In addition to the corresponding configurations of JDBC, if you want to read a super large result set in MyBatis, you also need to note that:

- You can set `fetchSize` for a single SQL statement in the mapper configuration (see the previous code block). Its effect is equivalent to calling `setFetchSize` in JDBC.
- You can use the query interface with `ResultHandler` to avoid getting the entire result set at once.
- You can use the `Cursor` class for stream reading.

If you configure mappings using XML, you can stream read results by configuring `fetchSize="-2147483648"(Integer.MIN_VALUE)` in the mapping's `<select>` section.

```
<select id="getAll" resultMap="postResultMap" fetchSize="-2147483648">
 select * from post;
</select>
```

If you configure mappings using code, you can add the `@Options(fetchSize = Integer.MIN_VALUE)` annotation and keep the type of results as `Cursor` so that the SQL results can be read in streaming.

```
@Select("select * from post")
@Options(fetchSize = Integer.MIN_VALUE)
Cursor<Post> queryAllPost();
```

#### 12.5.2.4.2 ExecutorType

You can choose `ExecutorType` during `openSession`. MyBatis supports three types of executors:

- Simple: The Prepared Statements are called to JDBC for each execution (if the JDBC configuration item `cachePrepStmts` is enabled, repeated Prepared Statements will be reused)
- Reuse: The Prepared Statements are cached in `executor`, so that you can reduce duplicate calls for Prepared Statements without using the JDBC `cachePrepStmts`
- Batch: Each update operation (`INSERT/DELETE/UPDATE`) will first be added to the batch, and will be executed until the transaction commits or a `SELECT` query is performed. If `rewriteBatchStatements` is enabled in the JDBC layer, it will try to rewrite the statements. If not, the statements will be sent one by one.

Usually, the default value of `ExecutorType` is `Simple`. You need to change `ExecutorType` when calling `openSession`. If it is the batch execution, you might find that in a transaction the `UPDATE` or `INSERT` statements are executed pretty fast, but it is slower when reading data or committing the transaction. This is actually normal, so you need to note this when troubleshooting slow SQL queries.

#### 12.5.2.5 Spring Transaction

In the real world, applications might use [Spring Transaction](#) and AOP aspects to start and stop transactions.

By adding the `@Transactional` annotation to the method definition, AOP starts the transaction before the method is called, and commits the transaction before the method returns the result. If your application has a similar need, you can find `@Transactional` in code to determine when the transaction is started and closed.

Pay attention to a special case of embedding. If it occurs, Spring will behave differently based on the [Propagation](#) configuration.

## 12.5.2.6 Misc

This section introduces some useful tools for Java to help you troubleshoot issues.

### 12.5.2.6.1 Troubleshooting tools

Using the powerful troubleshooting tools of JVM is recommended when an issue occurs in your Java application and you do not know the application logic. Here are a few common tools:

`jstack`

`jstack` is similar to `pprof/goroutine` in Go, which can easily troubleshoot the process stuck issue.

By executing `jstack pid`, you can output the IDs and stack information of all threads in the target process. By default, only the Java stack is output. If you want to output the C++ stack in the JVM at the same time, add the `-m` option.

By using `jstack` multiple times, you can easily locate the stuck issue (for example, a slow query from application's view due to using `Batch ExecutorType` in Mybatis) or the application deadlock issue (for example, the application does not send any SQL statement because it is preempting a lock before sending it).

In addition, `top -p $ PID -H` or `Java swiss knife` are common methods to view the thread ID. Also, to locate the issue of "a thread occupies a lot of CPU resources and I don't know what it is executing", do the following steps:

- Use `printf "%x\n" pid` to convert the thread ID to hexadecimal.
- Go to the `jstack` output to find the stack information of the corresponding thread.

`jmap & mat`

Unlike `pprof/heap` in Go, `jmap` dumps the memory snapshot of the entire process (in Go, it is the sampling of the distributor), and then the snapshot can be analyzed by another tool `mat`.

Through `mat`, you can see the associated information and attributes of all objects in the process, and you can also observe the running status of the thread. For example, you can use `mat` to find out how many MySQL connection objects exist in the current application, and what is the address and status information of each connection object.

Note that `mat` only handles reachable objects by default. If you want to troubleshoot young GC issues, you can adjust `mat` configuration to view unreachable objects. In addition, for investigating the memory allocation of young GC issues (or a large number of short-lived objects), using Java Flight Recorder is more convenient.

`trace`

Online applications usually do not support modifying the code, but it is often desired that dynamic instrumentation is performed in Java to locate issues. Therefore, using `btrace`

or arthas trace is a good option. They can dynamically insert trace code without restarting the application process.

Flame graph

Obtaining flame graphs in Java applications is tedious. For details, see [Java Flame Graphs Introduction: Fire For Everyone!](#).

### 12.5.2.7 Conclusion

Based on commonly used Java components that interact with databases, this document describes the common problems and solutions for developing Java applications with TiDB. TiDB is highly compatible with the MySQL protocol, so most of the best practices for MySQL-based Java applications also apply to TiDB.

Join us at [TiDB Community slack channel](#), and share with broad TiDB user group about your experience or problems when you develop Java applications with TiDB.

### 12.5.3 Best Practices for Using HAProxy in TiDB

This document describes best practices for configuration and usage of [HAProxy](#) in TiDB. HAProxy provides load balancing for TCP-based applications. From TiDB clients, you can manipulate data just by connecting to the floating virtual IP address provided by HAProxy, which helps to achieve load balance in the TiDB server layer.

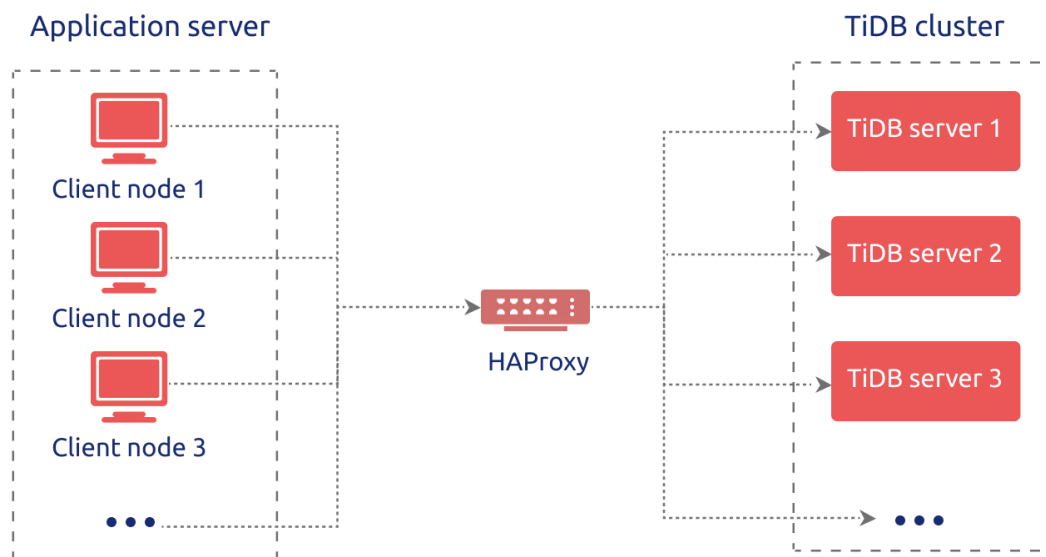

Figure 197: HAProxy Best Practices in TiDB

**Note:**

The minimum version of HAProxy that works with all versions of TiDB is v1.5. Between v1.5 and v2.1, you need to set the `post-41` option in `mysql-↔ check`. It is recommended to use HAProxy v2.2 or newer.

### 12.5.3.1 HAProxy overview

HAProxy is free, open-source software written in C language that provides a high availability load balancer and proxy server for TCP and HTTP-based applications. Because of its fast and efficient use of CPU and memory, HAProxy is now widely used by many well-known websites such as GitHub, Bitbucket, Stack Overflow, Reddit, Tumblr, Twitter, Tuenti, and AWS (Amazon Web Services).

HAProxy is written in the year 2000 by Willy Tarreau, the core contributor to the Linux kernel, who is still responsible for the maintenance of the project and provides free software updates in the open-source community. In this guide, HAProxy 2.6 is used. It is recommended to use the latest stable version. See [the released version of HAProxy](#) for details.

### 12.5.3.2 Basic features

- **High Availability:** HAProxy provides high availability with support for a graceful shutdown and a seamless switchover;
- **Load Balancing:** Two major proxy modes are supported: TCP, also known as layer 4, and HTTP, also known as layer 7. No less than 9 load balancing algorithms are supported, such as roundrobin, leastconn and random;
- **Health Check:** HAProxy periodically checks the status of HTTP or TCP mode of the server;
- **Sticky Session:** HAProxy can stick a client to a specific server for the duration when the application does not support sticky sessions;
- **SSL:** HTTPS communication and resolution are supported;
- **Monitoring and Statistics:** Through the web page, you can monitor the service state and traffic flow in real time.

### 12.5.3.3 Before you begin

Before you deploy HAProxy, make sure that you meet the hardware and software requirements.

### 12.5.3.3.1 Hardware requirements

For your server, it is recommended to meet the following hardware requirements. You can also improve server specifications according to the load balancing environment.

Hardware resource	Minimum specification
CPU	2 cores, 3.5 GHz
Memory	16 GB
Storage	50 GB (SATA)
Network Interface Card	10G Network Card

### 12.5.3.3.2 Software requirements

You can use the following operating systems and make sure the required dependencies are installed. If you use yum to install HAProxy, the dependencies are installed along with it and you do not need to separately install them again.

Operating systems

Linux distribution	Version
Red Hat Enterprise Linux	7 or 8
CentOS	7 or 8
Oracle Enterprise Linux	7 or 8
Ubuntu LTS	18.04 or later versions

#### Note:

- For more information about other supported operating systems, see [HAProxy documentation](#).

Dependencies

- epel-release
- gcc
- systemd-devel

To install the dependencies above, run the following command:

```
yum -y install epel-release gcc systemd-devel
```

### 12.5.3.4 Deploy HAProxy

You can easily use HAProxy to configure and set up a load-balanced database environment. This section shows general deployment operations. You can customize the [configuration file](#) based on your actual scenario.

#### 12.5.3.4.1 Install HAProxy

1. Download the package of the HAProxy 2.6.2 source code:

```
wget https://www.haproxy.org/download/2.6/src/haproxy-2.6.2.tar.gz
```

2. Extract the package:

```
tar xzf haproxy-2.6.2.tar.gz
```

3. Compile the application from the source code:

```
cd haproxy-2.6.2
make clean
make -j 8 TARGET=linux-glibc USE_THREAD=1
make PREFIX=${/app/haproxy} SBINDIR=${/app/haproxy/bin} install #
 ↳ Replace `${/app/haproxy}` and `${/app/haproxy/bin}` with your
 ↳ custom directories.
```

4. Reconfigure the profile:

```
echo 'export PATH=/app/haproxy/bin:$PATH' >> /etc/profile
. /etc/profile
```

5. Check whether the installation is successful:

```
which haproxy
```

HAProxy commands

Execute the following command to print a list of keywords and their basic usage:

```
haproxy --help
```

Option	Description
-v	Reports the version and build date.

Option	Description
<code>-vv</code>	Displays the version, build options, libraries versions and usable pollers.
<code>-d</code>	Enables debug mode.
<code>-db</code>	Disables background mode and multi-process mode.
<code>-dM [&lt; ↪ byte ↪ &gt;]</code>	Forces memory poisoning, which means that each and every memory region allocated with <code>malloc()</code> or <code>pool_alloc2()</code> will be filled with <code>&lt;byte&gt;</code> before being passed to the caller.
<code>-V</code>	Enables verbose mode (disables quiet mode).

Option	Description
-D	Starts as a daemon.
-C <dir>	Changes to directory <dir> before loading configuration files.
-W	Master-worker mode.
-q	Sets “quiet” mode: This disables some messages during the configuration parsing and during startup.
-c	Only performs a check of the configuration files and exits before trying to bind.
-n < ↪ limit ↪ >	Limits the per-process connection limit to <limit>.

Option	Description
<code>-m &lt;limit&gt;</code>	Limits the total allocatable memory to <code>&lt;limit&gt;</code> megabytes across all processes.
<code>-N &lt;limit&gt;</code>	Sets the default per-proxy maxconn to <code>&lt;limit&gt;</code> instead of the builtin default value (usually 2000).
<code>-L &lt;name&gt;</code>	Changes the local peer name to <code>&lt;name&gt;</code> , which defaults to the local hostname.
<code>-p &lt;file&gt;</code>	Writes all processes' PIDs into <code>&lt;file&gt;</code> during startup.

Option	Description
-de	Disables the use of epoll(7). epoll(7) is available only on Linux 2.6 and some custom Linux 2.4 systems.
-dp	Disables the use of poll(2). select(2) might be used instead.
-dS	Disables the use of splice(2), which is broken on older kernels.
-dR	Disables SO_REUSEPORT usage.
-dr	Ignores server address resolution failures.
-dV	Disables SSL verify on the server side.

Option	Description
<code>-sf &lt;</code> ↪ <code>pidlist</code> ↪ <code>&gt;</code>	Sends the “finish” signal to the PIDs in <code>pidlist</code> after startup. The processes which receive this signal wait for all sessions to finish before exiting. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGUSR1 are sent.

Option	Description
<code>-st &lt;</code> ↪ <code>pidlist</code> ↪ <code>&gt;</code>	Sends the “terminate” signal to the PIDs in <code>pidlist</code> after startup. The processes which receive this signal terminate immediately, closing all active sessions. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGTERM are sent.

Option	Description
<code>-x &lt;</code>	Connects
<code>↪ unix_socket</code>	to the
<code>↪ &gt;</code>	specified socket and retrieves all the listening sockets from the old process. Then, these sockets are used instead of binding new ones.
<code>-S &lt;bind</code>	In master-
<code>↪ &gt;[,&lt;</code>	worker
<code>↪ bind_options,</code>	
<code>↪ &gt;...]</code>	creates a master CLI. This CLI enables access to the CLI of every worker. Useful for debugging, it's a convenient way of accessing a leaving process.

For more details on HAProxy command line options, refer to [Management Guide of HAProxy](#) and [General Commands Manual of HAProxy](#).

#### 12.5.3.4.2 Configure HAProxy

A configuration template is generated when you use yum to install HAProxy. You can also customize the following configuration items according to your scenario.

```
global # Global configuration.
log 127.0.0.1 local2 # Global syslog servers (up to two).
chroot /var/lib/haproxy # Changes the current directory and
 ↪ sets superuser privileges for the startup process to improve
 ↪ security.
pidfile /var/run/haproxy.pid # Writes the PIDs of HAProxy processes
 ↪ into this file.
maxconn 4096 # The maximum number of concurrent
 ↪ connections for a single HAProxy process. It is equivalent to the
 ↪ command-line argument "-n".
nbthread 48 # The maximum number of threads. (The
 ↪ upper limit is equal to the number of CPUs)
user haproxy # Same with the UID parameter.
group haproxy # Same with the GID parameter. A
 ↪ dedicated user group is recommended.
daemon # Makes the process fork into
 ↪ background. It is equivalent to the command line "-D" argument. It
 ↪ can be disabled by the command line "-db" argument.
stats socket /var/lib/haproxy/stats # The directory where statistics
 ↪ output is saved.

defaults # Default configuration.
log global # Inherits the settings of the global
 ↪ configuration.
retries 2 # The maximum number of retries to
 ↪ connect to an upstream server. If the number of connection attempts
 ↪ exceeds the value, the backend server is considered unavailable.
timeout connect 2s # The maximum time to wait for a
 ↪ connection attempt to a backend server to succeed. It should be set
 ↪ to a shorter time if the server is located on the same LAN as
 ↪ HAProxy.
timeout client 30000s # The maximum inactivity time on the
 ↪ client side.
timeout server 30000s # The maximum inactivity time on the
 ↪ server side.

listen admin_stats # The name of the Stats page reporting
 ↪ information from frontend and backend. You can customize the name
 ↪ according to your needs.
bind 0.0.0.0:8080 # The listening port.
mode http # The monitoring mode.
option httplog # Enables HTTP logging.
maxconn 10 # The maximum number of concurrent
 ↪ connections.
```

```
stats refresh 30s # Automatically refreshes the Stats
 ↪ page every 30 seconds.
stats uri /haproxy # The URL of the Stats page.
stats realm HAProxy # The authentication realm of the
 ↪ Stats page.
stats auth admin:pingcap123 # User name and password in the Stats
 ↪ page. You can have multiple user names.
stats hide-version # Hides the version information of
 ↪ HAProxy on the Stats page.
stats admin if TRUE # Manually enables or disables the
 ↪ backend server (supported in HAProxy 1.4.9 or later versions).

listen tidb-cluster # Database load balancing.
bind 0.0.0.0:3390 # The Floating IP address and
 ↪ listening port.
mode tcp # HAProxy uses layer 4, the transport
 ↪ layer.
balance leastconn # The server with the smallest number
 ↪ of connections receives the connection. "leastconn" is recommended
 ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
 ↪ than protocols using short sessions, such as HTTP. The algorithm
 ↪ is dynamic, which means that server weights might be adjusted on
 ↪ the fly for slow starts for instance.
server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
 ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
 ↪ detected as successful twice, the server is considered available;
 ↪ if it is detected as failed three times, the server is considered
 ↪ unavailable.
server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

To check the source IP address using `SHOW PROCESSLIST`, you need to configure the [PROXY protocol](#) to connect to TiDB.

```
server tidb-1 10.9.18.229:4000 send-proxy check inter 2000 rise 2 fall 3
server tidb-2 10.9.39.208:4000 send-proxy check inter 2000 rise 2 fall 3
server tidb-3 10.9.64.166:4000 send-proxy check inter 2000 rise 2 fall 3
```

### Note:

Before using the PROXY protocol, you need to configure [proxy-protocol](#).  
↪ [networks](#) in the configuration file of the TiDB server.

#### 12.5.3.4.3 Start HAProxy

To start HAProxy, run `haproxy`. `/etc/haproxy/haproxy.cfg` is read by default (recommended).

```
haproxy -f /etc/haproxy/haproxy.cfg
```

#### 12.5.3.4.4 Stop HAProxy

To stop HAProxy, use the `kill -9` command.

1. Run the following command:

```
ps -ef | grep haproxy
```

2. Terminate the process of HAProxy:

```
kill -9 ${haproxy.pid}
```

### 12.5.4 Highly Concurrent Write Best Practices

This document describes best practices for handling highly-concurrent write-heavy workloads in TiDB, which can help to facilitate your application development.

#### 12.5.4.1 Target audience

This document assumes that you have a basic understanding of TiDB. It is recommended that you first read the following three blog articles that explain TiDB fundamentals, and [TiDB Best Practices](#):

- [Data Storage](#)
- [Computing](#)
- [Scheduling](#)

#### 12.5.4.2 Highly-concurrent write-intensive scenario

The highly concurrent write scenario often occurs when you perform batch tasks in applications, such as clearing and settlement. This scenario has the following features:

- A huge volume of data
- The need to import historical data into database in a short time
- The need to read a huge volume of data from database in a short time

These features pose these challenges to TiDB:

- The write or read capacity must be linearly scalable.
- Database performance is stable and does not decrease as a huge volume of data is written concurrently.

For a distributed database, it is important to make full use of the capacity of all nodes and to prevent a single node from becoming the bottleneck.

### 12.5.4.3 Data distribution principles in TiDB

To address the above challenges, it is necessary to start with the data segmentation and scheduling principle of TiDB. Refer to [Scheduling](#) for more details.

TiDB splits data into Regions, each representing a range of data with a size limit of 96M by default. Each Region has multiple replicas, and each group of replicas is called a Raft Group. In a Raft Group, the Region Leader executes the read and write tasks (TiDB supports [Follower-Read](#)) within the data range. The Region Leader is automatically scheduled by the Placement Driver (PD) component to different physical nodes evenly to distribute the read and write pressure.

Figure 198: TiDB Data Overview

In theory, if an application has no write hotspot, TiDB, by the virtue of its architecture, can not only linearly scale its read and write capacities, but also make full use of the distributed resources. From this point of view, TiDB is especially suitable for the high-concurrent and write-intensive scenario.

However, the actual situation often differs from the theoretical assumption.

**Note:**

No write hotspot in an application means the write scenario does not have any AUTO\_INCREMENT primary key or monotonically increasing index.

#### 12.5.4.4 Hotspot case

The following case explains how a hotspot is generated. Take the table below as an example:

```
CREATE TABLE IF NOT EXISTS TEST_HOTSPOT(
 id BIGINT PRIMARY KEY,
 age INT,
 user_name VARCHAR(32),
 email VARCHAR(128)
)
```

This table is simple in structure. In addition to `id` as the primary key, no secondary index exists. Execute the following statement to write data into this table. `id` is discretely generated as a random number.

```
SET SESSION cte_max_recursion_depth = 1000000;
INSERT INTO TEST_HOTSPOT
SELECT
 n, -- ID
 RAND()*80, -- Number between 0 and 80
 CONCAT('user-',n),
 CONCAT(
 CHAR(65 + (RAND() * 25) USING ascii), -- Number between 65 and 65+25,
 ↪ converted to a character, A-Z
 '-user-',
 n,
 '@example.com'
)
FROM
(WITH RECURSIVE nr(n) AS
 (SELECT 1 -- Start CTE at 1
 UNION ALL SELECT n + 1 -- increase n with 1 every loop
 FROM nr WHERE n < 1000000 -- stop loop at 1_000_000
) SELECT n FROM nr
) a;
```

The load comes from executing the above statement intensively in a short time.

In theory, the above operation seems to comply with the TiDB best practices, and no hotspot is caused in the application. The distributed capacity of TiDB can be fully used with adequate machines. To verify whether it is truly in line with the best practices, a test is conducted in the experimental environment, which is described as follows:

For the cluster topology, 2 TiDB nodes, 3 PD nodes and 6 TiKV nodes are deployed. Ignore the QPS performance, because this test is to clarify the principle rather than for benchmark.

Figure 199: QPS1

The client starts “intensive” write requests in a short time, which is 3K QPS received by TiDB. In theory, the load pressure should be evenly distributed to 6 TiKV nodes. However, from the CPU usage of each TiKV node, the load distribution is uneven. The `tikv-3` node is the write hotspot.

Figure 200: QPS2

Figure 201: QPS3

**Raft store CPU** is the CPU usage rate for the `raftstore` thread, usually representing the write load. In this scenario, `tikv-3` is the Leader of this Raft Group; `tikv-0` and `tikv-1` are the followers. The loads of other nodes are almost empty.

The monitoring metrics of PD also confirms that hotspot has been caused.

Figure 202: QPS4

#### 12.5.4.5 Hotspot causes

In the above test, the operation does not reach the ideal performance expected in the best practices. This is because only one Region is split by default to store the data of each newly created table in TiDB, with the following data range:

```
[CommonPrefix + TableID, CommonPrefix + TableID + 1)
```

In a short period of time, a huge volume of data is continuously written to the same Region.

Figure 203: TiKV Region Split

The above diagram illustrates the Region splitting process. As data is continuously written into TiKV, TiKV splits a Region into multiple Regions. Because the leader election is started on the original store where the Region Leader to be split is located, the leaders of the two newly split Regions might be still on the same store. This splitting process might also happen on the newly split Region 2 and Region 3. In this way, write pressure is concentrated on TiKV-Node 1.

During the continuous write process, after finding that hotspot is caused on Node 1, PD evenly distributes the concentrated Leaders to other nodes. If the number of TiKV nodes is more than the number of Region replicas, TiKV will try to migrate these Regions to idle nodes. These two operations during the write process are also reflected in the PD's monitoring metrics:

Figure 204: QPS5

After a period of continuous writes, PD automatically schedules the entire TiKV cluster to a state where pressure is evenly distributed. By that time, the capacity of the whole cluster can be fully used.

In most cases, the above process of causing a hotspot is normal, which is the Region warm-up phase of database. However, you need to avoid this phase in highly-concurrent write-intensive scenarios.

### 12.5.4.6 Hotspot solution

To achieve the ideal performance expected in theory, you can skip the warm-up phase by directly splitting a Region into the desired number of Regions and scheduling these Regions in advance to other nodes in the cluster.

In v3.0.x, v2.1.13 and later versions, TiDB supports a new feature called **Split Region**. This new feature provides the following new syntaxes:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (
 ↪ upper_value) REGIONS region_num
```

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_list)]
```

However, TiDB does not automatically perform this pre-split operation. The reason is related to the data distribution in TiDB.

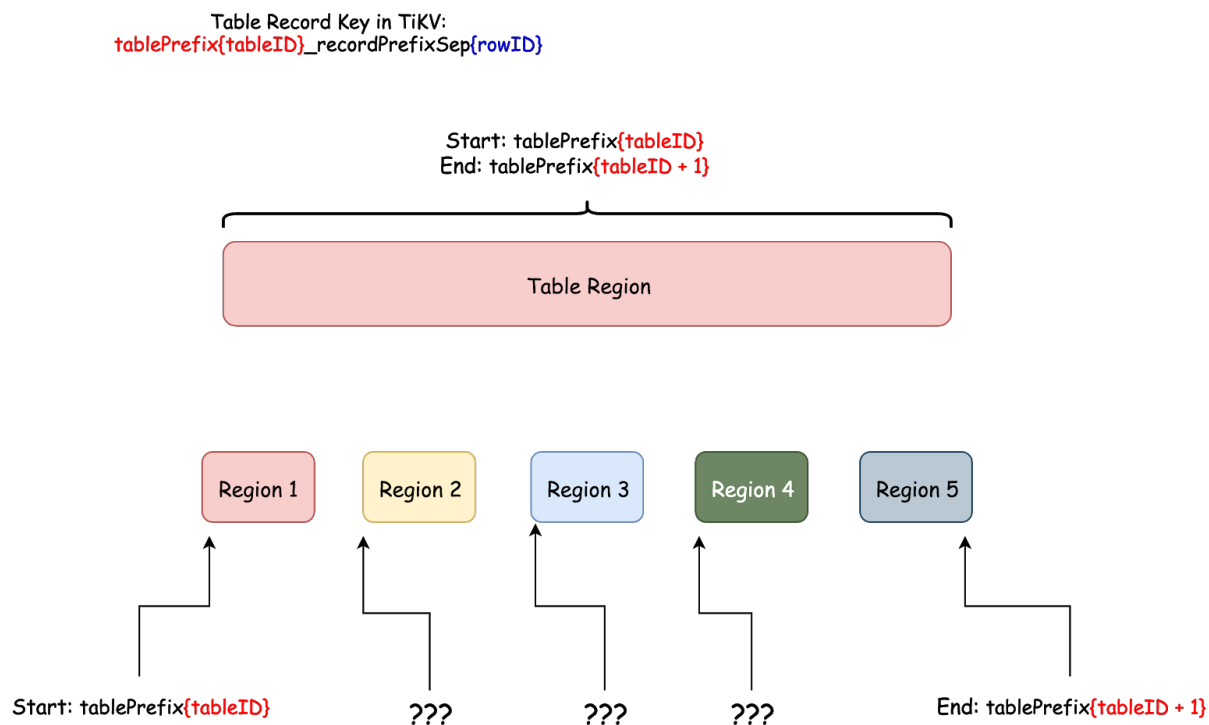

Figure 205: Table Region Range

From the diagram above, according to the encoding rule of a row's key, the `rowID` is the only variable part. In TiDB, `rowID` is an `Int64` integer. However, you might not need to evenly split the `Int64` integer range to the desired number of ranges and then to distribute these ranges to different nodes, because Region split must also be based on the actual situation.

If the write of `rowID` is completely discrete, the above method will not cause hotspots. If the row ID or index has a fixed range or prefix (for example, discretely insert data into the range of `[2000w, 5000w)`), no hotspot will be caused either. However, if you split a Region using the above method, data might still be written to the same Region at the beginning.

TiDB is a database for general usage and does not make assumptions about the data distribution. So it uses only one Region at the beginning to store the data of a table and automatically splits the Region according to the data distribution after real data is inserted.

Given this situation and the need to avoid the hotspot problem, TiDB offers the `Split`  $\leftrightarrow$  `Region` syntax to optimize performance for the highly-concurrent write-heavy scenario. Based on the above case, now scatter Regions using the `Split Region` syntax and observe the load distribution.

Because the data to be written in the test is entirely discrete within the positive range, you can use the following statement to pre-split the table into 128 Regions within the range of `minInt64` and `maxInt64`:

```
SPLIT TABLE TEST_HOTSPOT BETWEEN (0) AND (9223372036854775807) REGIONS 128;
```

After the pre-split operation, execute the `SHOW TABLE test_hotspot REGIONS;` statement to check the status of Region scattering. If the values of the `SCATTERING` column are all 0, the scheduling is successful.

You can also check the Region leader distribution using the following SQL statement. You need to replace `table_name` with the actual table name.

```
SELECT
 p.STORE_ID,
 COUNT(s.REGION_ID) PEER_COUNT
FROM
 INFORMATION_SCHEMA.TIKV_REGION_STATUS s
 JOIN INFORMATION_SCHEMA.TIKV_REGION_PEERS p ON s.REGION_ID = p.REGION_ID
WHERE
 TABLE_NAME = 'table_name'
 AND p.is_leader = 1
GROUP BY
 p.STORE_ID
ORDER BY
 PEER_COUNT DESC;
```

Then operate the write load again:

Figure 206: QPS6

Figure 207: QPS7

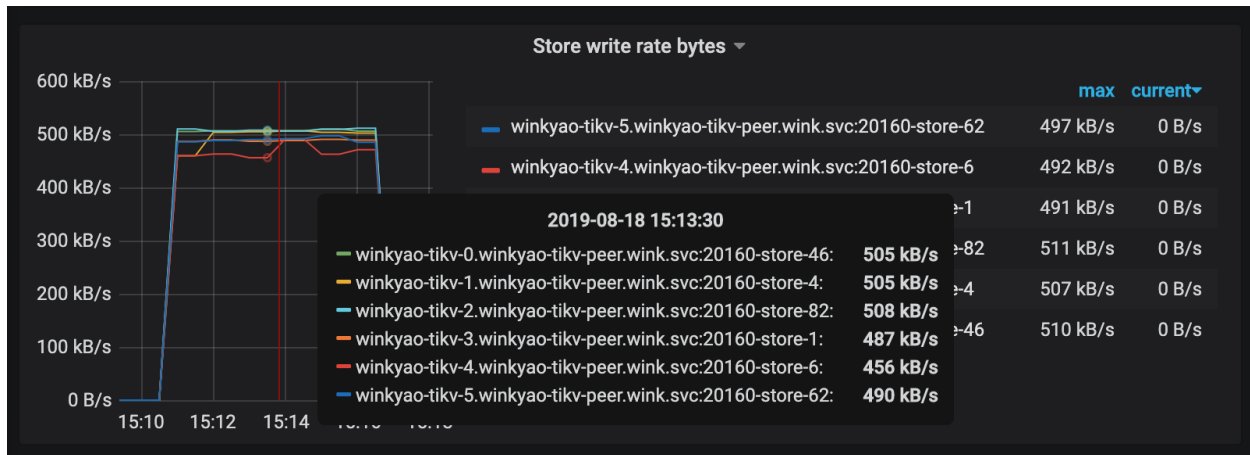

Figure 208: QPS8

You can see that the apparent hotspot problem has been resolved now.

In this case, the table is simple. In other cases, you might also need to consider the hotspot problem of index. For more details on how to pre-split the index Region, refer to [Split Region](#).

#### 12.5.4.7 Complex hotspot problems

##### Problem one:

If a table does not have a primary key, or the primary key is not the `Int` type and you do not want to generate a randomly distributed primary key ID, TiDB provides an implicit `_tidb_rowid` column as the row ID. Generally, when you do not use the `SHARD_ROW_ID_BITS` parameter, the values of the `_tidb_rowid` column are also monotonically increasing, which might causes hotspots too. Refer to [SHARD\\_ROW\\_ID\\_BITS](#) for more details.

To avoid the hotspot problem in this situation, you can use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` when creating a table. For more details about `PRE_SPLIT_REGIONS`, refer to [Pre-split Regions](#).

`SHARD_ROW_ID_BITS` is used to randomly scatter the row ID generated in the `_tidb_rowid` column. `PRE_SPLIT_REGIONS` is used to pre-split the Region after a table is created.

##### Note:

The value of `PRE_SPLIT_REGIONS` must be smaller than or equal to that of `SHARD_ROW_ID_BITS`.

Example:

```
create table t (a int, b int) SHARD_ROW_ID_BITS = 4 PRE_SPLIT_REGIONS=3;
```

- `SHARD_ROW_ID_BITS = 4` means that the values of `tidb_rowid` will be randomly distributed into 16 ( $16=2^4$ ) ranges.
- `PRE_SPLIT_REGIONS=3` means that the table will be pre-split into 8 ( $2^3$ ) Regions after it is created.

When data starts to be written into table `t`, the data is written into the pre-split 8 Regions, which avoids the hotspot problem that might be caused if only one Region exists after table creation.

#### Note:

The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`.

This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to 1, then TiDB will not return the results to the client until all the Regions are split and scattered. Otherwise, TiDB writes data before the scattering is completed, which will have a significant impact on write performance.

#### Problem two:

If a table's primary key is an integer type, and if the table uses `AUTO_INCREMENT` to ensure the uniqueness of the primary key (not necessarily continuous or incremental), you cannot use `SHARD_ROW_ID_BITS` to scatter the hotspot on this table because TiDB directly uses the row values of the primary key as `_tidb_rowid`.

To address the problem in this scenario, you can replace `AUTO_INCREMENT` with `AUTO_RANDOM` (a column attribute) when inserting data. Then TiDB automatically assigns values to the integer primary key column, which eliminates the continuity of the row ID and scatters the hotspot.

#### 12.5.4.8 Parameter configuration

In v2.1, the `latch mechanism` is introduced in TiDB to identify transaction conflicts in advance in scenarios where write conflicts frequently appear. The aim is to reduce the retry of transaction commits in TiDB and TiKV caused by write conflicts. Generally, batch tasks use the data already stored in TiDB, so the write conflicts of transaction do not exist. In this situation, you can disable the latch in TiDB to reduce memory allocation for small objects:

```
[txn-local-latches]
enabled = false
```

## 12.5.5 Best Practices for Monitoring TiDB Using Grafana

When you [deploy a TiDB cluster using TiUP](#) and have added Grafana and Prometheus in the topology configuration, a set of [Grafana + Prometheus monitoring platform](#) is deployed simultaneously to collect and display metrics for various components and machines in the TiDB cluster. This document describes best practices for monitoring TiDB using Grafana. It aims to help you use metrics to analyze the status of the TiDB cluster and diagnose problems.

### 12.5.5.1 Monitoring architecture

[Prometheus](#) is a time series database with a multi-dimensional data model and a flexible query language. [Grafana](#) is an open source monitoring system for analyzing and visualizing metrics.

Figure 209: The monitoring architecture in the TiDB cluster

For TiDB 2.1.3 or later versions, TiDB monitoring supports the pull method. It is a good adjustment with the following benefits:

- There is no need to restart the entire TiDB cluster if you need to migrate Prometheus. Before adjustment, migrating Prometheus requires restarting the entire cluster because the target address needs to be updated.

- You can deploy 2 separate sets of Grafana + Prometheus monitoring platforms (not highly available) to prevent a single point of monitoring.
- The Pushgateway which might become a single point of failure is removed.

### 12.5.5.2 Source and display of monitoring data

The three core components of TiDB (TiDB server, TiKV server and PD server) obtain metrics through the HTTP interface. These metrics are collected from the program code, and the ports are as follows:

Component	Port
TiDB server	10080
TiKV server	20181
PD server	2379

Execute the following command to check the QPS of a SQL statement through the HTTP interface. Take the TiDB server as an example:

```
curl http://__tidb_ip__:10080/metrics |grep tidb_executor_statement_total
```

```
Check the real-time QPS of different types of SQL statements. The
 ↪ numbers below are the cumulative values of counter type (scientific
 ↪ notation).
tidb_executor_statement_total{type="Delete"} 520197
tidb_executor_statement_total{type="Explain"} 1
tidb_executor_statement_total{type="Insert"} 7.20799402e+08
tidb_executor_statement_total{type="Select"} 2.64983586e+08
tidb_executor_statement_total{type="Set"} 2.399075e+06
tidb_executor_statement_total{type="Show"} 500531
tidb_executor_statement_total{type="Use"} 466016
```

The data above is stored in Prometheus and displayed on Grafana. Right-click the panel and then click the **Edit** button (or directly press the E key) shown in the following figure:

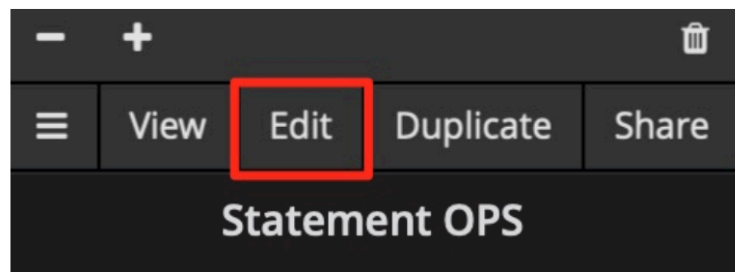

Figure 210: The Edit entry for the Metrics tab

After clicking the **Edit** button, you can see the query expression with the `tidb_executor_statement_total` metric name on the Metrics tab. The meanings of some items on the panel are as follows:

- `rate[1m]`: The growth rate in one minute. It can only be used for the data of counter type.
- `sum`: The sum of values.
- `by type`: The summed data is grouped by type in the original metric value.
- **Legend format**: The format of the metric name.
- **Resolution**: The step width defaults to 15 seconds. Resolution means whether to generate one data point for multiple pixels.

The query expression on the **Metrics** tab is as follows:

Figure 211: The query expression on the Metrics tab

Prometheus supports many query expressions and functions. For more details, refer to [Prometheus official website](#).

### 12.5.5.3 Grafana tips

This section introduces seven tips for efficiently using Grafana to monitor and analyze the metrics of TiDB.

#### 12.5.5.3.1 Tip 1: Check all dimensions and edit the query expression

In the example shown in the [source and display of monitoring data](#) section, the data is grouped by type. If you want to know whether you can group by other dimensions and quickly check which dimensions are available, you can use the following method: **Only keep**

the metric name on the query expression, no calculation, and leave the Legend  $\leftrightarrow$  format field blank. In this way, the original metrics are displayed. For example, the following figure shows that there are three dimensions (instance, job and type):

Figure 212: Edit query expression and check all dimensions

Then you can modify the query expression by adding the `instance` dimension after `type`, and adding `{{instance}}` to the Legend format field. In this way, you can check the QPS of different types of SQL statements that are executed on each TiDB server:

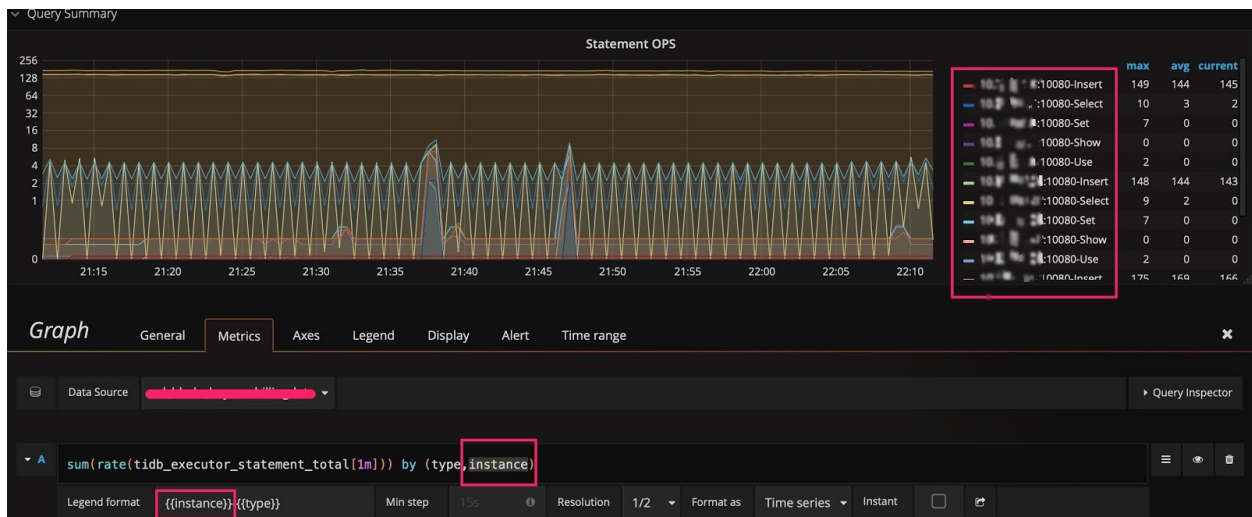

Figure 213: Add an instance dimension to the query expression

### 12.5.5.3.2 Tip 2: Switch the scale of the Y-axis

Take Query Duration as an example, the Y-axis defaults to be on a binary logarithmic scale ( $\log_2 n$ ), which narrows the gap in display. To amplify changes, you can switch it to a linear scale. Comparing the following two figures, you can easily notice the difference in display, and locate the time when an SQL statement runs slowly.

Of course, a linear scale is not suitable for all situations. For example, if you observe the performance trend for the duration of a month, there might be noises with a linear scale, making it hard to observe.

The Y-axis uses a binary logarithmic scale by default:

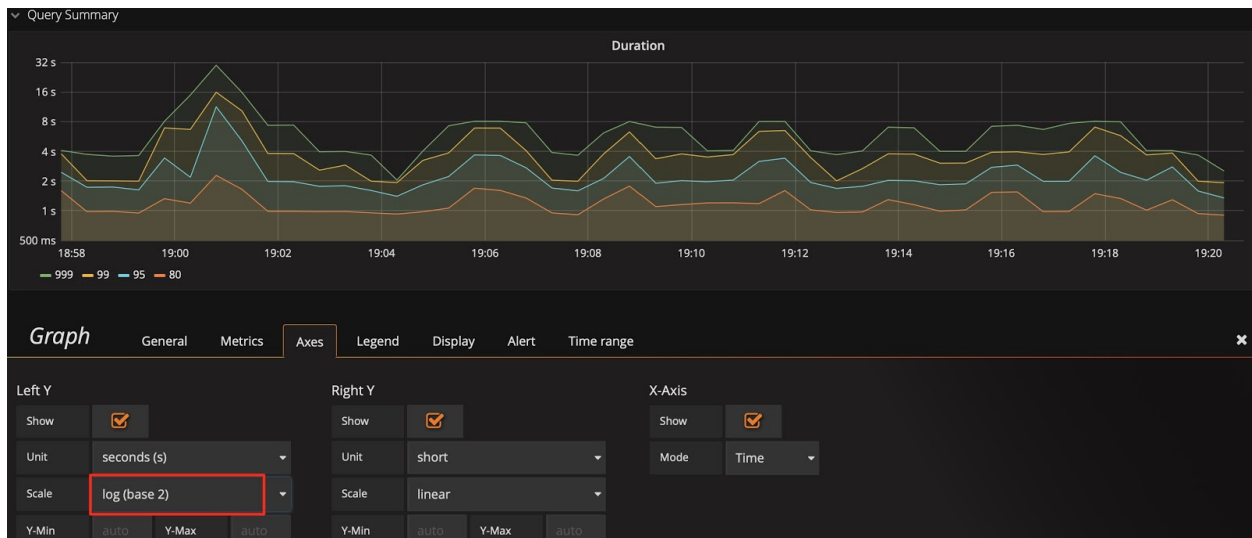

Figure 214: The Y-axis uses a binary logarithmic scale

Switch the Y-axis to a linear scale:

Figure 215: Switch to a linear scale

### Tip:

Combining tip 2 with tip 1, you can find a `sql_type` dimension to help you immediately analyze whether the `SELECT` statement or the `UPDATE` statement is slow; you can even locate the instance with slow SQL statements.

#### 12.5.5.3.3 Tip 3: Modify the baseline of the Y-axis to amplify changes

You might still cannot see the trend after switching to the linear scale. For example, in the following figure, you want to observe the real-time change of `Store size` after scaling the cluster, but due to the large baseline, small changes are not visible. In this situation, you can modify the baseline of the Y-axis from 0 to `auto` to zoom in the upper part. Check the two figures below, you can see data migration begins.

The baseline defaults to 0:

Figure 216: Baseline defaults to 0

Change the baseline to auto:

Figure 217: Change the baseline to auto

#### 12.5.5.3.4 Tip 4: Use Shared crosshair or Tooltip

In the **Settings** panel, there is a **Graph Tooltip** panel option which defaults to **Default**.

Figure 218: Graphic presentation tools

You can use **Shared crosshair** and **Shared Tooltip** respectively to test the effect as shown in the following figures. Then, the scales are displayed in linkage, which is convenient to confirm the correlation of two metrics when diagnosing problems.

Set the graphic presentation tool to **Shared crosshair**:

Figure 219: Set the graphical presentation tool to Shared crosshair

Set the graphical presentation tool to **Shared Tooltip**:

Figure 220: Set the graphic presentation tool to Shared Tooltip

### 12.5.5.3.5 Tip 5: Enter IP address:port number to check the metrics in history

PD's dashboard only shows the metrics of the current leader. If you want to check the status of a PD leader in history and it no longer exists in the drop-down list of the instance field, you can manually enter IP address:2379 to check the data of the leader.

Figure 221: Check the metrics in history

#### 12.5.5.3.6 Tip 6: Use the Avg function

Generally, only **Max** and **Current** functions are available in the legend by default. When the metrics fluctuate greatly, you can add other summary functions such as the **Avg** function to the legend to check the overall trend for the duration of time.

Add summary functions such as the **Avg** function:

Figure 222: Add summary functions such as Avg

Then check the overall trend:

Figure 223: Add Avg function to check the overall trend

### 12.5.5.3.7 Tip 7: Use the API of Prometheus to obtain the result of query expressions

Grafana obtains data through the API of Prometheus and you can use this API to obtain information as well. In addition, it also has the following usages:

- Automatically obtains information such as the cluster size and status.
- Makes minor changes to the expression to provide information for the report, such as counting the total amount of QPS per day, the peak value of QPS per day, and the response time per day.
- Performs regular health inspection on the important metrics.

The API of Prometheus is shown as follows:

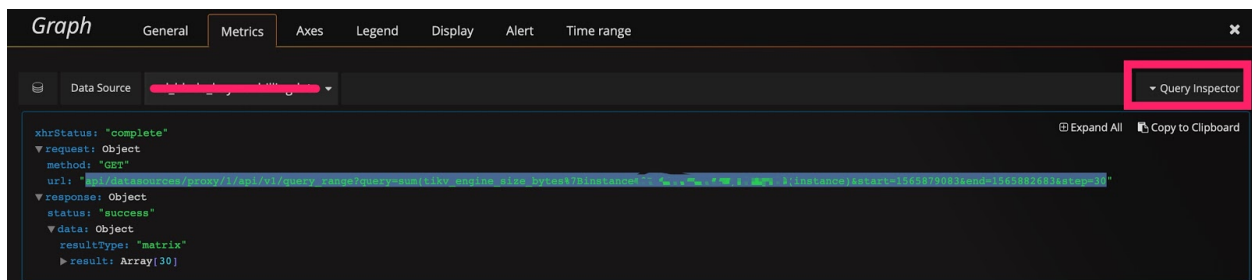

Figure 224: The API of Prometheus

```

curl -u user:pass 'http://__grafana_ip__:3000/api/datasources/proxy/1/api/v1
 ↪ /query_range?query=sum(tikv_engine_size_bytes%7
 ↪ Binstancexxxxxxxxxx20181%22%7D)%20by%20(instance)&start=1565879269&end
 ↪ =1565882869&step=30' |python -m json.tool

```

```

{

```

#### 12.5.5.4 Summary

The Grafana + Prometheus monitoring platform is a very powerful tool. Making good use of it can improve efficiency, saving you a lot of time on analyzing the status of the TiDB cluster. More importantly, it can help you diagnose problems. This tool is very useful in the operation and maintenance of TiDB clusters, especially when there is a large amount of data.

## 12.5.6 PD Scheduling Best Practices

This document details the principles and strategies of PD scheduling through common scenarios to facilitate your application. This document assumes that you have a basic understanding of TiDB, TiKV and PD with the following core concepts:

- leader/follower/learner
- operator
- operator step
- pending/down
- region/peer/Raft group
- region split
- scheduler
- store

### Note:

This document initially targets TiDB 3.0. Although some features are not supported in earlier versions (2.x), the underlying mechanisms are similar and this document can still be used as a reference.

### 12.5.6.1 PD scheduling policies

This section introduces the principles and processes involved in the scheduling system.

#### 12.5.6.1.1 Scheduling process

The scheduling process generally has three steps:

##### 1. Collect information

Each TiKV node periodically reports two types of heartbeats to PD:

- **StoreHeartbeat:** Contains the overall information of stores, including disk capacity, available storage, and read/write traffic
- **RegionHeartbeat:** Contains the overall information of regions, including the range of each region, peer distribution, peer status, data volume, and read/write traffic

PD collects and restores this information for scheduling decisions.

##### 2. Generate operators

Different schedulers generate the operators based on their own logic and requirements, with the following considerations:

- Do not add peers to a store in abnormal states (disconnected, down, busy, low space)
- Do not balance regions in abnormal states
- Do not transfer a leader to a pending peer
- Do not remove a leader directly
- Do not break the physical isolation of various region peers
- Do not violate constraints such as label property

### 3. Execute operators

To execute the operators, the general procedure is:

1. The generated operator first joins a queue managed by `OperatorController`.
2. `OperatorController` takes the operator out of the queue and executes it with a certain amount of concurrency based on the configuration. This step is to assign each operator step to the corresponding region leader.
3. The operator is marked as “finish” or “timeout” and removed from the queue.

#### 12.5.6.1.2 Load balancing

Region primarily relies on `balance-leader` and `balance-region` schedulers to achieve load balance. Both schedulers target distributing regions evenly across all stores in the cluster but with separate focuses: `balance-leader` deals with region leader to balance incoming client requests, whereas `balance-region` concerns itself with each region peer to redistribute the pressure of storage and avoid exceptions like out of storage space.

`balance-leader` and `balance-region` share a similar scheduling process:

1. Rate stores according to their resource availability.
2. `balance-leader` or `balance-region` constantly transfer leaders or peers from stores with high scores to those with low scores.

However, their rating methods are different. `balance-leader` uses the sum of all region sizes corresponding to leaders in a store, whereas the way of `balance-region` is relatively complicated. Depending on the specific storage capacity of each node, the rating method of `balance-region` might:

- based on the amount of data when there is sufficient storage (to balance data distribution among nodes).
- based on the available storage when there is insufficient storage (to balance the storage availability on different nodes).
- based on the weighted sum of the two factors above when neither of the situations applies.

Because different nodes might differ in performance, you can also set the weight of load balancing for different stores. `leader-weight` and `region-weight` are used to control the leader weight and region weight respectively (“1” by default for both). For example, when the `leader-weight` of a store is set to “2”, the number of leaders on the node is about twice as many as that of other nodes after the scheduling stabilizes. Similarly, when the `leader-weight` of a store is set to “0.5”, the number of leaders on the node is about half as many as that of other nodes.

#### 12.5.6.1.3 Hot regions scheduling

For hot regions scheduling, use `hot-region-scheduler`. Since TiDB v3.0, the process is performed as follows:

1. Count hot regions by determining read/write traffic that exceeds a certain threshold for a certain period based on the information reported by stores.
2. Redistribute these regions in a similar way to load balancing.

For hot write regions, `hot-region-scheduler` attempts to redistribute both region peers and leaders; for hot read regions, `hot-region-scheduler` only redistributes region leaders.

#### 12.5.6.1.4 Cluster topology awareness

Cluster topology awareness enables PD to distribute replicas of a region as much as possible. This is how TiKV ensures high availability and disaster recovery capability. PD continuously scans all regions in the background. When PD finds that the distribution of regions is not optimal, it generates an operator to replace peers and redistribute regions.

The component to check region distribution is `replicaChecker`, which is similar to a scheduler except that it cannot be disabled. `replicaChecker` schedules based on the configuration of `location-labels`. For example, `[zone,rack,host]` defines a three-tier topology for a cluster. PD attempts to schedule region peers to different zones first, or to different racks when zones are insufficient (for example, 2 zones for 3 replicas), or to different hosts when racks are insufficient.

#### 12.5.6.1.5 Scale-down and failure recovery

Scale-down refers to the process when you take a store offline and mark it as “offline” using a command. PD replicates the regions on the offline node to other nodes by scheduling. Failure recovery applies when stores failed and cannot be recovered. In this case, regions with peers distributed on the corresponding store might lose replicas, which requires PD to replenish on other nodes.

The processes of scale-down and failure recovery are basically the same. `replicaChecker`  $\leftrightarrow$  finds a region peer in abnormal states, and then generates an operator to replace the abnormal peer with a new one on a healthy store.

#### 12.5.6.1.6 Region merge

Region merge refers to the process of merging adjacent small regions. It serves to avoid unnecessary resource consumption by a large number of small or even empty regions after data deletion. Region merge is performed by `mergeChecker`, which processes in a similar way to `replicaChecker`: PD continuously scans all regions in the background, and generates an operator when contiguous small regions are found.

Specifically, when a newly split Region exists for more than the value of `split-merge-interval` (1h by default), if the following conditions occur at the same time, this Region triggers the Region merge scheduling:

- The size of this Region is smaller than the value of the `max-merge-region-size` (20 MiB by default)
- The number of keys in this Region is smaller than the value of `max-merge-region-keys` (200,000 by default).

#### 12.5.6.2 Query scheduling status

You can check the status of scheduling system through metrics, `pd-ctl` and logs. This section briefly introduces the methods of metrics and `pd-ctl`. Refer to [PD Monitoring Metrics](#) and [PD Control](#) for details.

##### 12.5.6.2.1 Operator status

The **Grafana PD/Operator** page shows the metrics about operators, among which:

- Schedule operator create: Operator creating information
- Operator finish duration: Execution time consumed by each operator
- Operator step duration: Execution time consumed by the operator step

You can query operators using `pd-ctl` with the following commands:

- `operator show`: Queries all operators generated in the current scheduling task
- `operator show [admin | leader | region]`: Queries operators by type

##### 12.5.6.2.2 Balance status

The **Grafana PD/Statistics - Balance** page shows the metrics about load balancing, among which:

- Store leader/region score: Score of each store
- Store leader/region count: The number of leaders/regions in each store
- Store available: Available storage on each store

You can use store commands of `pd-ctl` to query balance status of each store.

### 12.5.6.2.3 Hot Region status

The **Grafana PD/Statistics - hotspot** page shows the metrics about hot regions, among which:

- Hot write region's leader/peer distribution: the leader/peer distribution in hot write regions
- Hot read region's leader distribution: the leader distribution in hot read regions

You can also query the status of hot regions using `pd-ctl` with the following commands:

- `hot read`: Queries hot read regions
- `hot write`: Queries hot write regions
- `hot store`: Queries the distribution of hot regions by store
- `region topread [limit]`: Queries the region with top read traffic
- `region topwrite [limit]`: Queries the region with top write traffic

### 12.5.6.2.4 Region health

The **Grafana PD/Cluster/Region health** panel shows the metrics about regions in abnormal states.

You can query the list of regions in abnormal states using `pd-ctl` with region check commands:

- `region check miss-peer`: Queries regions without enough peers
- `region check extra-peer`: Queries regions with extra peers
- `region check down-peer`: Queries regions with down peers
- `region check pending-peer`: Queries regions with pending peers

## 12.5.6.3 Control scheduling strategy

You can use `pd-ctl` to adjust the scheduling strategy from the following three aspects. Refer to [PD Control](#) for more details.

### 12.5.6.3.1 Add/delete scheduler manually

PD supports dynamically adding and removing schedulers directly through `pd-ctl`. For example:

- `scheduler show`: Shows currently running schedulers in the system
- `scheduler remove balance-leader-scheduler`: Removes (disable) balance-leader-scheduler
- `scheduler add evict-leader-scheduler 1`: Adds a scheduler to remove all leaders in Store 1

### 12.5.6.3.2 Add/delete Operators manually

PD also supports adding or removing operators directly through `pd-ctl`. For example:

- `operator add add-peer 2 5`: Adds peers to Region 2 in Store 5
- `operator add transfer-leader 2 5`: Migrates the leader of Region 2 to Store 5
- `operator add split-region 2`: Splits Region 2 into two regions evenly in size
- `operator remove 2`: Removes currently pending operator in Region 2

### 12.5.6.3.3 Adjust scheduling parameter

You can check the scheduling configuration using the `config show` command in `pd-ctl`, and adjust the values using `config set {key} {value}`. Common adjustments include:

- `leader-schedule-limit`: Controls the concurrency of transferring leader scheduling
- `region-schedule-limit`: Controls the concurrency of adding/deleting peer scheduling
- `enable-replace-offline-replica`: Determines whether to enable the scheduling to take nodes offline
- `enable-location-replacement`: Determines whether to enable the scheduling that handles the isolation level of regions
- `max-snapshot-count`: Controls the maximum concurrency of sending/receiving snapshots for each store

## 12.5.6.4 PD scheduling in common scenarios

This section illustrates the best practices of PD scheduling strategies through several typical scenarios.

### 12.5.6.4.1 Leaders/regions are not evenly distributed

The rating mechanism of PD determines that leader count and region count of different stores cannot fully reflect the load balancing status. Therefore, it is necessary to confirm whether there is load imbalancing from the actual load of TiKV or storage usage.

Once you have confirmed that leaders/region are not evenly distributed, you need to check the rating of different stores.

If the scores of different stores are close, it means PD mistakenly believes that leaders/regions are evenly distributed. Possible reasons are:

- There are hot regions that cause load imbalancing. In this case, you need to analyze further based on [hot regions scheduling](#).
- There are a large number of empty regions or small regions, which leads to a great difference in the number of leaders in different stores and high pressure on Raft store. This is the time for a [region merge](#) scheduling.

- Hardware and software environment varies among stores. To control the distribution of leader/region, you can refer to **Load balancing** and adjust the values of `leader-weight` and `region-weight`.
- Other unknown reasons. Still you can adjust the values of `leader-weight` and `region-weight` to control the distribution of leader/region.

If there is a big difference in the rating of different stores, you need to examine the operator-related metrics, with special focus on the generation and execution of operators. There are two main situations:

- When operators are generated normally but the scheduling process is slow, it is possible that:
  - The scheduling speed is limited by default for load balancing purpose. You can adjust `leader-schedule-limit` or `region-schedule-limit` to larger values without significantly impacting regular services. In addition, you can also properly ease the restrictions specified by `max-pending-peer-count` and `max-snapshot-count`.
  - Other scheduling tasks are running concurrently, which slows down the balancing. In this case, if the balancing takes precedence over other scheduling tasks, you can stop other tasks or limit their speeds. For example, if you take some nodes offline when balancing is in progress, both operations consume the quota of `region-schedule-limit`. In this case, you can limit the speed of scheduler to remove nodes, or simply set `enable-replace-offline-replica = false` to temporarily disable it.
  - The scheduling process is too slow. You can check the **Operator step duration** metric to confirm the cause. Generally, steps that do not involve sending and receiving snapshots (such as `TransferLeader`, `RemovePeer`, `PromoteLearner`) should be completed in milliseconds, while steps that involve snapshots (such as `AddLearner` and `AddPeer`) are expected to be completed in tens of seconds. If the duration is obviously too long, it could be caused by high pressure on TiKV or bottleneck in network, which needs specific analysis.
- PD fails to generate the corresponding balancing scheduler. Possible reasons include:
  - The scheduler is not activated. For example, the corresponding scheduler is deleted, or its limit is set to “0”.
  - Other constraints. For example, `evict-leader-scheduler` in the system prevents leaders from being migrating to the corresponding store. Or label property is set, which makes some stores reject leaders.
  - Restrictions from the cluster topology. For example, in a cluster of 3 replicas across 3 data centers, 3 replicas of each region are distributed in different data centers due to replica isolation. If the number of stores is different among these data centers, the scheduling can only reach a balanced state within each data center, but not balanced globally.

#### 12.5.6.4.2 Taking nodes offline is slow

This scenario requires examining the generation and execution of operators through related metrics.

If operators are successfully generated but the scheduling process is slow, possible reasons are:

- The scheduling speed is limited by default. You can adjust `leader-schedule-limit` or `replica-schedule-limit` to larger values. Similarly, you can consider loosening the limits on `max-pending-peer-count` and `max-snapshot-count`.
- Other scheduling tasks are running concurrently and racing for resources in the system. You can refer to the solution in [Leaders/regions are not evenly distributed](#).
- When you take a single node offline, a number of region leaders to be processed (around 1/3 under the configuration of 3 replicas) are distributed on the node to remove. Therefore, the speed is limited by the speed at which snapshots are generated by this single node. You can speed it up by manually adding an `evict-leader-scheduler` to migrate leaders.

If the corresponding operator fails to generate, possible reasons are:

- The operator is stopped, or `replica-schedule-limit` is set to “0”.
- There is no proper node for region migration. For example, if the available capacity size of the replacing node (of the same label) is less than 20%, PD will stop scheduling to avoid running out of storage on that node. In such case, you need to add more nodes or delete some data to free the space.

#### 12.5.6.4.3 Bringing nodes online is slow

Currently, bringing nodes online is scheduled through the balance region mechanism. You can refer to [Leaders/regions are not evenly distributed](#) for troubleshooting.

#### 12.5.6.4.4 Hot regions are not evenly distributed

Hot regions scheduling issues generally fall into the following categories:

- Hot regions can be observed via PD metrics, but the scheduling speed cannot keep up to redistribute hot regions in time.

**Solution:** adjust `hot-region-schedule-limit` to a larger value, and reduce the limit quota of other schedulers to speed up hot regions scheduling. Or you can adjust `hot-region-cache-hits-threshold` to a smaller value to make PD more sensitive to traffic changes.

- Hotspot formed on a single region. For example, a small table is intensively scanned by a massive amount of requests. This can also be detected from PD metrics. Because you cannot actually distribute a single hotspot, you need to manually add a `split-region` operator to split such a region.

- The load of some nodes is significantly higher than that of other nodes from TiKV-related metrics, which becomes the bottleneck of the whole system. Currently, PD counts hotspots through traffic analysis only, so it is possible that PD fails to identify hotspots in certain scenarios. For example, when there are intensive point lookup requests for some regions, it might not be obvious to detect in traffic, but still the high QPS might lead to bottlenecks in key modules.

**Solutions:** Firstly, locate the table where hot regions are formed based on the specific business. Then add a `scatter-range-scheduler` scheduler to make all regions of this table evenly distributed. TiDB also provides an interface in its HTTP API to simplify this operation. Refer to [TiDB HTTP API](#) for more details.

#### 12.5.6.4.5 Region merge is slow

Similar to slow scheduling, the speed of region merge is most likely limited by the configurations of `merge-schedule-limit` and `region-schedule-limit`, or the region merge scheduler is competing with other schedulers. Specifically, the solutions are:

- If it is known from metrics that there are a large number of empty regions in the system, you can adjust `max-merge-region-size` and `max-merge-region-keys` to smaller values to speed up the merge. This is because the merge process involves replica migration, so the smaller the region to be merged, the faster the merge is. If the merge operators are already generated rapidly, to further speed up the process, you can set `patrol-region-interval` to 10ms (the default value of this configuration item is 10ms in v5.3.0 and later versions of TiDB). This makes region scanning faster at the cost of more CPU consumption.
- A lot of tables have been created and then emptied (including truncated tables). These empty Regions cannot be merged if the split table attribute is enabled. You can disable this attribute by adjusting the following parameters:
  - TiKV: Set `split-region-on-table` to `false`. You cannot modify the parameter dynamically.
  - PD: Use PD Control to set the parameters required by your cluster situation.
    - \* Suppose that your cluster has no TiDB instance, and the value of `key-type` is set to `raw` or `txn`. In this case, PD can merge Regions across tables, regardless of the value of `enable-cross-table-merge` setting. You can modify the `key-type` parameter dynamically.

```
config set key-type txn
```

- \* Suppose that your cluster has a TiDB instance, and the value of `key-type` is set to `table`. In this case, PD can merge Regions across tables only if the value of `enable-cross-table-merge` is set to `true`. You can modify the `key-type` parameter dynamically.

```
config set enable-cross-table-merge true
```

If the modification does not take effect, refer to [FAQ - Why the modified toml configuration for TiKV/PD does not take effect?](#).

**Note:**

After enabling Placement Rules, properly switch the value of `key-type` to avoid the failure of decoding.

For v3.0.4 and v2.1.16 or earlier, the `approximate_keys` of regions are inaccurate in specific circumstances (most of which occur after dropping tables), which makes the number of keys break the constraints of `max-merge-region-keys`. To avoid this problem, you can adjust `max-merge-region-keys` to a larger value.

#### 12.5.6.4.6 Troubleshoot TiKV node

If a TiKV node fails, PD defaults to setting the corresponding node to the **down** state after 30 minutes (customizable by configuration item `max-store-down-time`), and rebalancing replicas for regions involved.

Practically, if a node failure is considered unrecoverable, you can immediately take it offline. This makes PD replenish replicas soon in another node and reduces the risk of data loss. In contrast, if a node is considered recoverable, but the recovery cannot be done in 30 minutes, you can temporarily adjust `max-store-down-time` to a larger value to avoid unnecessary replenishment of the replicas and resources waste after the timeout.

In TiDB v5.2.0, TiKV introduces the mechanism of slow TiKV node detection. By sampling the requests in TiKV, this mechanism works out a score ranging from 1 to 100. A TiKV node with a score higher than or equal to 80 is marked as slow. You can add `evict-slow-store-scheduler` to detect and schedule slow nodes. If only one TiKV is detected as slow, and the slow score reaches the upper limit (100 by default), the leader in this node will be evicted (similar to the effect of `evict-leader-scheduler`).

#### 12.5.7 Best Practices for TiKV Performance Tuning with Massive Regions

In TiDB, data is split into Regions, each storing data for a specific key range. These Regions are distributed among multiple TiKV instances. As data is written into a cluster, millions of or even tens of millions of Regions are created. Too many Regions on a single TiKV instance can bring a heavy burden to the cluster and affect its performance.

This document introduces the workflow of Raftstore (a core module of TiKV), explains why a massive amount of Regions affect the performance, and offers methods for tuning TiKV performance.

### 12.5.7.1 Raftstore workflow

A TiKV instance has multiple Regions on it. The Raftstore module drives the Raft state machine to process Region messages. These messages include processing read or write requests on Regions, persisting or replicating Raft logs, and processing Raft heartbeats. However, an increasing number of Regions can affect performance of the whole cluster. To understand this, it is necessary to learn the workflow of Raftstore shown as follows:

Figure 225: Raftstore Workflow

**Note:**

This diagram only illustrates the workflow of Raftstore and does not represent the actual code structure.

From the above diagram, you can see that requests from the TiDB servers, after passing through the gRPC and storage modules, become read and write messages of KV (key-value), and are sent to the corresponding Regions. These messages are not immediately processed but are temporarily stored. Raftstore polls to check whether each Region has messages to process. If a Region has messages to process, Raftstore drives the Raft state machine of this Region to process these messages and perform subsequent operations according to the state changes of these messages. For example, when write requests come in, the Raft state machine stores logs into disk and sends logs to other Region replicas; when the heartbeat interval is reached, the Raft state machine sends heartbeat information to other Region replicas.

### 12.5.7.2 Performance problem

From the Raftstore workflow diagram, messages in each Region are processed one by one. When a large number of Regions exist, it takes Raftstore some time to process the heartbeats of these Regions, which can cause some delay. As a result, some read and write requests are not processed in time. If read and write pressure is high, the CPU usage of the Raftstore thread might easily become the bottleneck, which further increases the delay and affects the performance.

Generally, if the CPU usage of the loaded Raftstore reaches 85% or higher, Raftstore goes into a busy state and becomes the bottleneck. At the same time, propose wait duration can be as high as hundreds of milliseconds.

#### Note:

- For the CPU usage of Raftstore as mentioned above, Raftstore is single-threaded. If Raftstore is multi-threaded, you can increase the CPU usage threshold (85%) proportionally.
- Because I/O operations exist in the Raftstore thread, CPU usage cannot reach 100%.

#### 12.5.7.2.1 Performance monitoring

You can check the following monitoring metrics in Grafana's **TiKV Dashboard**:

- Raft store CPU in the **Thread-CPU** panel

Reference value: lower than `raftstore.store-pool-size * 85%`.

Figure 226: Check Raftstore CPU

- Propose wait duration in the **Raft Propose** panel

**Propose wait duration** is the delay between the time a request is sent to Raftstore and the time Raftstore actually starts processing the request. Long delay means that Raftstore is busy, or that processing the append log is time-consuming, making Raftstore unable to process the request in time.

Reference value: lower than 50~100 ms according to the cluster size

Figure 227: Check Propose wait duration

### 12.5.7.3 Performance tuning methods

After finding out the cause of a performance problem, try to solve it from the following two aspects:

- Reduce the number of Regions on a single TiKV instance
- Reduce the number of messages for a single Region

#### 12.5.7.3.1 Method 1: Increase Raftstore concurrency

Raftstore has been upgraded to a multi-threaded module since TiDB v3.0, which greatly reduces the possibility that a Raftstore thread becomes the bottleneck.

By default, `raftstore.store-pool-size` is configured to 2 in TiKV. If a bottleneck occurs in Raftstore, you can properly increase the value of this configuration item according to the actual situation. But to avoid introducing unnecessary thread switching overhead, it is recommended that you do not set this value too high.

#### 12.5.7.3.2 Method 2: Enable Hibernate Region

In the actual situation, read and write requests are not evenly distributed on every Region. Instead, they are concentrated on a few Regions. Then you can minimize the number of messages between the Raft leader and the followers for the temporarily idle Regions, which is the feature of Hibernate Region. In this feature, Raftstore does not send tick messages to the Raft state machines of idle Regions if not necessary. Then these Raft state machines will not be triggered to generate heartbeat messages, which can greatly reduce the workload of Raftstore.

Hibernate Region is enabled by default in [TiKV master](#). You can configure this feature according to your needs. For details, refer to [Configure Hibernate Region](#).

### 12.5.7.3.3 Method 3: Enable Region Merge

**Note:**

Region Merge is enabled by default since TiDB v3.0.

You can also reduce the number of Regions by enabling **Region Merge**. Contrary to **Region Split**, **Region Merge** is the process of merging adjacent small Regions through scheduling. After dropping data or executing the **Drop Table** or **Truncate Table** statement, you can merge small Regions or even empty Regions to reduce resource consumption.

Enable **Region Merge** by configuring the following parameters:

```
config set max-merge-region-size 20
config set max-merge-region-keys 200000
config set merge-schedule-limit 8
```

Refer to [Region Merge](#) and the following three configuration parameters in the [PD configuration file](#) for more details:

- [max-merge-region-size](#)
- [max-merge-region-keys](#)
- [merge-schedule-limit](#)

The default configuration of the **Region Merge** parameters is rather conservative. You can speed up the **Region Merge** process by referring to the method provided in [PD Scheduling Best Practices](#).

### 12.5.7.3.4 Method 4: Increase the number of TiKV instances

If I/O resources and CPU resources are sufficient, you can deploy multiple TiKV instances on a single machine to reduce the number of Regions on a single TiKV instance; or you can increase the number of machines in the TiKV cluster.

### 12.5.7.3.5 Method 5: Adjust `raft-base-tick-interval`

In addition to reducing the number of Regions, you can also reduce pressure on Raftstore by reducing the number of messages for each Region within a unit of time. For example, you can properly increase the value of the `raft-base-tick-interval` configuration item:

```
[raftstore]
raft-base-tick-interval = "2s"
```

In the above configuration, `raft-base-tick-interval` is the time interval at which Raftstore drives the Raft state machine of each Region, which means at this time interval, Raftstore sends a tick message to the Raft state machine. Increasing this interval can effectively reduce the number of messages from Raftstore.

Note that this interval between tick messages also determines the intervals between `election timeout` and `heartbeat`. See the following example:

```
raft-election-timeout = raft-base-tick-interval * raft-election-timeout-
 ↪ ticks
raft-heartbeat-interval = raft-base-tick-interval * raft-heartbeat-ticks
```

If Region followers have not received the heartbeat from the leader within the `raft ↪ -election-timeout` interval, these followers determine that the leader has failed and start a new election. `raft-heartbeat-interval` is the interval at which a leader sends a heartbeat to followers. Therefore, increasing the value of `raft-base-tick-interval` can reduce the number of network messages sent from Raft state machines but also makes it longer for Raft state machines to detect the leader failure.

#### 12.5.7.3.6 Method 6: Adjust Region size

The default size of a Region is 96 MiB, and you can reduce the number of Regions by setting Regions to a larger size. For more information, see [Tune Region Performance](#).

#### **Warning:**

Currently, customized Region size is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments. The risks are as follows:

- Performance jitter might be caused.
- The query performance, especially for queries that deal with a large range of data, might decrease.
- The Region scheduling slows down.

#### 12.5.7.4 Other problems and solutions

This section describes some other problems and solutions.

#### 12.5.7.4.1 Switching PD Leader is slow

PD needs to persist Region Meta information on etcd to ensure that PD can quickly resume to provide Region routing services after switching the PD Leader node. As the number of Regions increases, the performance problem of etcd appears, making it slower for PD to get Region Meta information from etcd when PD is switching the Leader. With millions of Regions, it might take more than ten seconds or even tens of seconds to get the meta information from etcd.

To address this problem, `use-region-storage` is enabled by default in PD since TiDB v3.0. With this feature enabled, PD stores Region Meta information on local LevelDB and synchronizes the information among PD nodes through other mechanisms.

#### 12.5.7.4.2 PD routing information is not updated in time

In TiKV, `pd-worker` regularly reports Region Meta information to PD. When TiKV is restarted or switches the Region leader, PD needs to recalculate Region's `approximate size / keys` through statistics. Therefore, with a large number of Regions, the single-threaded `pd-worker` might become the bottleneck, causing tasks to be piled up and not processed in time. In this situation, PD cannot obtain certain Region Meta information in time so that the routing information is not updated in time. This problem does not affect the actual reads and writes, but might cause inaccurate PD scheduling and require several round trips when TiDB updates Region cache.

You can check **Worker pending tasks** under **Task** in the **TiKV Grafana** panel to determine whether `pd-worker` has tasks piled up. Generally, **pending tasks** should be kept at a relatively low value.

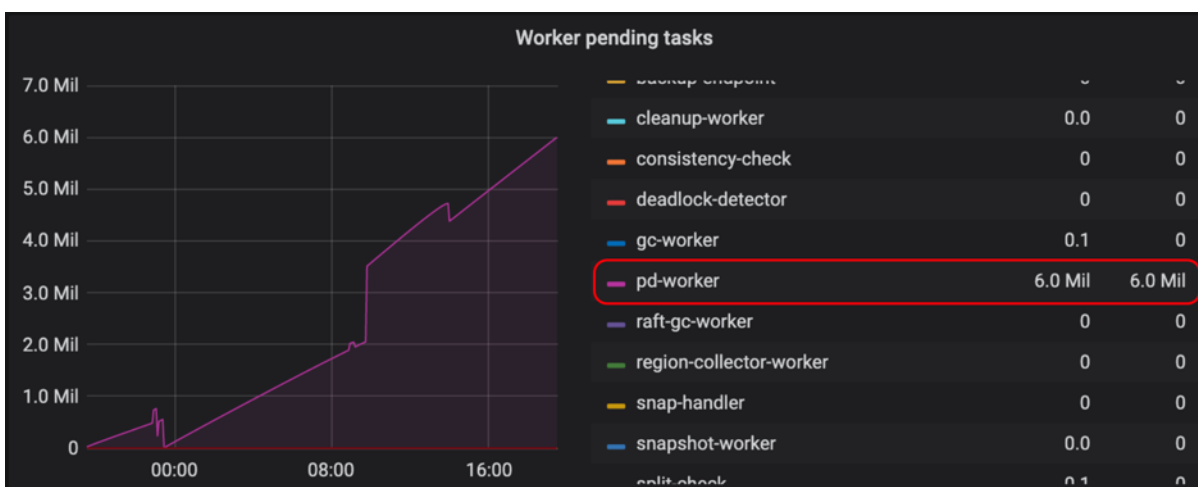

Figure 228: Check `pd-worker`

`pd-worker` has been optimized for better performance since [v3.0.5](#). If you encounter a similar problem, it is recommended to upgrade to the latest version.

### 12.5.7.4.3 Prometheus is slow to query metrics

In a large-scale cluster, as the number of TiKV instances increases, Prometheus has greater pressure to query metrics, making it slower for Grafana to display these metrics. To ease this problem, metrics pre-calculation is configured since v3.0.

## 12.5.8 Best Practices for Three-Node Hybrid Deployment

For a TiDB cluster, if you have no requirements on high performance but need to control the cost, you can deploy the TiDB, TiKV, and PD components on three machines in a hybrid way.

This document offers an example of three-node hybrid deployment and a TPC-C test against the deployed cluster. Based on this example, this document offers best practices for the deployment scenario and its parameter adjustment.

### 12.5.8.1 Prerequisites for deployment and the test method

In this example, three physical machines are used for deployment, each with 16 CPU cores and 32 GB of memory. On each machine (node), one TiDB instance, one TiKV instance, and one PD instance are deployed in a hybrid way.

Because PD and TiKV both store information on the disk, the read and write latency of disk directly affects the latency of the PD and TiKV services. To avoid the situation that PD and TiKV compete for disk resources and affect each other, it is recommended to use different disks for PD and TiKV.

In this example, the TPC-C 5000 Warehouse data is used in TiUP bench and the test lasts 12 hours with the `terminals` parameter set to 128 (concurrency). Close attention is paid to metrics related to performance stability of the cluster.

The image below shows the QPS monitor of the cluster within 12 hours with the default parameter configuration. From the image, you can see an obvious performance jitter.

Figure 229: QPS with default config

After the parameter adjustment, the performance is improved.

Figure 230: QPS with modified config

### 12.5.8.2 Parameter adjustment

Performance jitter occurs in the image above, because the default thread pool configuration and the resource allocation to background tasks are for machines with sufficient resources. In the hybrid deployment scenario, the resources are shared among multiple components, so you need to limit the resource consumption via configuration parameters.

The final cluster configuration for this test is as follows:

```

tikv:
 readpool.unified.max-thread-count: 6
 server.grpc-concurrency: 2
 storage.scheduler-worker-pool-size: 2
 gc.max-write-bytes-per-sec: 300K
 rocksdb.max-background-jobs: 3
 rocksdb.max-sub-compactions: 1
 rocksdb.rate-bytes-per-sec: "200M"

tidb:
 performance.max-procs: 8

```

The following sections introduce the meanings and the adjustment methods of these parameters.

#### 12.5.8.2.1 Configuration of TiKV thread pool size

This section offers best practices for adjusting parameters that relate to the resource allocation of thread pools for foreground applications. Reducing these thread pool sizes will compromise performance, but in the hybrid deployment scenario with limited resources, the cluster itself is hard to achieve high performance. In this scenario, the overall stability of the cluster is preferred over performance.

If you conduct an actual load test, you can first use the default configuration and observe the actual resource usage of each thread pool. Then you can adjust the corresponding configuration items and reduce the sizes of the thread pools that have lower usage.

```
readpool.unified.max-thread-count
```

The default value of this parameter is 80% of the number of machine threads. In a hybrid deployment scenario, you need to manually calculate and specify this value. You can first set it to 80% of the expected number of CPU threads used by TiKV.

```
server.grpc-concurrency
```

This parameter defaults to 4. Because in the existing deployment plan, the CPU resources are limited and the actual requests are few. You can observe the monitoring panel, lower the value of this parameter, and keep the usage rate below 80%.

In this test, the value of this parameter is set to 2. Observe the **gRPC poll CPU** panel and you can see that the usage rate is just around 80%.

Figure 231: gRPC Pool CPU

```
storage.scheduler-worker-pool-size
```

When TiKV detects that the CPU core number of the machine is greater than or equal to 16, this parameter value defaults to 8. When the CPU core number is smaller than 16, the parameter value defaults to 4. This parameter is used when TiKV converts complex transaction requests to simple key-value reads or writes, but the scheduler thread pool does not perform any writes.

Ideally, the usage rate of the scheduler thread pool is kept between 50% and 75%. Similar to the gRPC thread pool, the `storage.scheduler-worker-pool-size` parameter defaults to a larger value during the hybrid deployment, which makes resource usage insufficient. In this test, the value of this parameter is set to 2, which is in line with the best practices, a conclusion drawn by observing the corresponding metrics in the **Scheduler worker CPU** panel.

Figure 232: Scheduler Worker CPU

### 12.5.8.2.2 Resource configuration for TiKV background tasks

In addition to foreground tasks, TiKV regularly sorts data and cleans outdated data in background tasks. The default configuration allocates sufficient resources to these tasks for the scenario of high-traffic writes.

However, in the hybrid deployment scenario, this default configuration is not in line with the best practices. You need to limit the resource usage of background tasks by adjusting the following parameters.

`rocksdb.max-background-jobs` and `rocksdb.max-sub-compactions`

The RocksDB thread pool is used to perform compaction and flush jobs. The default value of `rocksdb.max-background-jobs` is 8, which obviously exceeds the resource that is in need. Therefore, the value should be adjusted to limit the resource usage.

`rocksdb.max-sub-compactions` indicates the number of concurrent sub-tasks allowed for a single compaction job, which defaults to 3. You can lower this value when the write traffic is not high.

In the test, the `rocksdb.max-background-jobs` value is set to 3 and the `rocksdb.max-sub-compactions` value is set to 1. No write stall occurs during the 12-hour test with the TPC-C load. When optimizing the two parameter values according to the actual load, you can lower the values gradually based on monitoring metrics:

- If write stall occurs, increase the value of `rocksdb.max-background-jobs`.
- If the write stall persists, set the value of `rocksdb.max-sub-compactions` to 2 or 3.

`rocksdb.rate-bytes-per-sec`

This parameter is used to limit the disk traffic for the background compaction jobs. The default configuration has no limit for this parameter. To avoid the situation that compaction jobs occupy the resources of foreground services, you can adjust this parameter value according to the sequential read and write speed of the disk, which reserves enough disk bandwidth for foreground services.

The method of optimizing the RocksDB thread pool is similar to that of optimizing the compaction thread pool. You can determine whether the value you have adjusted is suitable according to whether write stall occurs.

`gc.max_write_bytes_per_sec`

Because TiDB uses the multi-version concurrency control (MVCC) model, TiKV periodically cleans old version data in the background. When the available resources are limited, this operation causes periodical performance jitter. You can use the `gc.max_write_bytes_per_sec` parameter to limit the resource usage of such an operation.

Figure 233: GC Impact

In addition to setting this parameter value in the configuration file, you can also dynamically adjust this value in `tikv-ctl`.

```
tiup ctl:v<CLUSTER_VERSION> tikv --host=${ip:port} modify-tikv-config -n gc.
↳ max_write_bytes_per_sec -v ${limit}
```

### Note:

In application scenarios with frequent updates, limiting GC traffic might cause the MVCC versions to pile up and affect read performance. Currently, to achieve a balance between performance jitter and performance decrease, you might need to try multiple times to adjust the value of this parameter.

### 12.5.8.2.3 TiDB parameter adjustment

Generally, you can adjust the TiDB parameters of execution operators using system variables such as `tidb_hash_join_concurrency` and `tidb_index_lookup_join_concurrency`.

In this test, these parameters are not adjusted. In the load test of your actual application, if the execution operators consume an excessive amount of CPU resources, you can limit the resource usage of specific operators according to your application scenario. For more details, see [TiDB system variables](#).

#### `performance.max-procs`

This parameter is used to control how many CPU cores an entire Go process can use. By default, the value is equal to the number of CPU cores of the current machine or cgroups.

When Go is running, a proportion of threads is used for background tasks such as GC. If you do not limit the value of the `performance.max-procs` parameter, these background tasks will consume too much CPU.

## 12.5.9 Local Read under Three Data Centers Deployment

In the model of three data centers, a Region has three replicas which are isolated in each data center. However, due to the requirement of strongly consistent read, TiDB must access the Leader replica of the corresponding data for every query. If the query is generated in a data center different from that of the Leader replica, TiDB needs to read data from another data center, thus causing the access latency to increase.

This document describes how to use the [Stale Read](#) feature to avoid cross-center access and reduce the access latency at the expense of real-time data availability.

### 12.5.9.1 Deploy a TiDB cluster of three data centers

For the three-data-center deployment method, refer to [Multiple Data Centers in One City Deployment](#).

Note that if both the TiKV and TiDB nodes have the configuration item `labels` configured, the TiKV and TiDB nodes in the same data center must have the same value for the `zone` label. For example, if a TiKV node and a TiDB node are both in the data center `dc-1`, then the two nodes need to be configured with the following label:

```
[labels]
zone=dc-1
```

### 12.5.9.2 Perform local read using Stale Read

[Stale Read](#) is a mechanism that TiDB provides for the users to read historical data. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes. When using Stale Read in some scenarios of geo-distributed deployment,

TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query process.

When TiDB receives a Stale Read query, if the `zone` label of that TiDB node is configured, and `tidb_replica_read` is set to `closest-replicas`, then TiDB sends the request to the TiKV node with the same `zone` label where the corresponding data replica resides.

For how to perform Stale Read, see [Perform Stale Read using the AS OF TIMESTAMP clause](#).

## 12.5.10 UUID Best Practices

### 12.5.10.1 Overview of UUIDs

When used as a primary key, instead of an `AUTO_INCREMENT` integer value, a universally unique identifier (UUID) delivers the following benefits:

- UUIDs can be generated on multiple systems without risking conflicts. In some cases, this means that the number of network trips to TiDB can be reduced, leading to improved performance.
- UUIDs are supported by most programming languages and database systems.
- When used as a part of a URL, a UUID is not vulnerable to enumeration attacks. In comparison, with an `auto_increment` number, it is possible to guess the invoice IDs or user IDs.

### 12.5.10.2 Best practices

#### 12.5.10.2.1 Store as binary

The textual UUID format looks like this: `ab06f63e-8fe7-11ec-a514-5405db7aad56`, which is a string of 36 characters. By using `UUID_TO_BIN()`, the textual format can be converted into a binary format of 16 bytes. This allows you to store the text in a `BINARY`  $\leftrightarrow$  (16) column. When retrieving the UUID, you can use the `BIN_TO_UUID()` function to get back to the textual format.

#### 12.5.10.2.2 UUID format binary order and a clustered PK

The `UUID_TO_BIN()` function can be used with one argument, the UUID or with two arguments where the second argument is a `swap_flag`.

It is recommended to not set the `swap_flag` with TiDB to avoid [hotspots](#).

You can also explicitly set the [CLUSTERED option](#) for UUID based primary keys to avoid hotspots.

To demonstrate the effect of the `swap_flag`, here are two tables with an identical structure. The difference is that the data inserted into `uuid_demo_1` uses `UUID_TO_BIN(?, 0)` and `uuid_demo_2` uses `UUID_TO_BIN(?, 1)`.

In the screenshot of the **Key Visualizer** below, you can see that writes are concentrated in a single region of the `uuid_demo_2` table that has the order of the fields swapped in the binary format.

Figure 234: Key Visualizer

```
CREATE TABLE `uuid_demo_1` (
 `uuid` varbinary(16) NOT NULL,
 `c1` varchar(255) NOT NULL,
 PRIMARY KEY (`uuid`) CLUSTERED
)
```

```
CREATE TABLE `uuid_demo_2` (
 `uuid` varbinary(16) NOT NULL,
 `c1` varchar(255) NOT NULL,
 PRIMARY KEY (`uuid`) CLUSTERED
)
```

)

### 12.5.10.3 MySQL compatibility

UUIDs can be used in MySQL as well. The `BIN_TO_UUID()` and `UUID_TO_BIN()` functions were introduced in MySQL 8.0. The `UUID()` function is available in earlier MySQL versions as well.

## 12.5.11 Best Practices for Read-Only Storage Nodes

This document introduces how to configure read-only storage nodes and how to direct backup, analysis, testing, and other traffic to these nodes. In this way, loads with high tolerance for delay can be physically isolated from important online services.

### 12.5.11.1 Procedures

#### 12.5.11.1.1 1. Specify some TiKV nodes as read-only

To specify some TiKV nodes as read-only, you can mark these nodes with a special label (use `$` as the prefix of the label key). Unless you explicitly specify these nodes to store some data using Placement Rules, PD does not schedule any data to these nodes.

You can configure a read-only node by running the `tiup cluster edit-config` command:

```
tikv_servers:
- host: ...
 ...
 labels:
 $mode: readonly
```

#### 12.5.11.1.2 2. Use Placement Rules to store data on read-only nodes as learners

1. Run the `pd-ctl config placement-rules` command to export the default Placement Rules:

```
pd-ctl config placement-rules rule-bundle load --out="rules.json"
```

If you have not configured Placement Rules before, the output is as follows:

```
[
 {
 "group_id": "pd",
 "group_index": 0,
```

```
"group_override": false,
"rules": [
 {
 "group_id": "pd",
 "id": "default",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 3
 }
]
}
```

2. Store all data on the read-only nodes as a learner. The following example is based on the default configuration:

```
[
 {
 "group_id": "pd",
 "group_index": 0,
 "group_override": false,
 "rules": [
 {
 "group_id": "pd",
 "id": "default",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 3
 },
 {
 "group_id": "pd",
 "id": "readonly",
 "start_key": "",
 "end_key": "",
 "role": "learner",
 "count": 1,
 "label_constraints": [
 {
 "key": "$mode",
 "op": "in",
 "values": [
 "readonly"
]
 }
]
 }
]
 }
]
```

```
 }
],
 "version": 1
}
]
]
```

3. Use the `pd-ctl config placement-rules` command to write the preceding configurations to PD:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

#### Note:

- If you perform the preceding operations on a cluster with a large dataset, the entire cluster might need some time to completely replicate data to read-only nodes. During this period, the read-only nodes might not be able to provide services.
- Because of the special implementation of backup, the learner number of each label cannot exceed 1. Otherwise, it will generate duplicate data during backup.

### 12.5.11.1.3 3. Use Follower Read to read data from read-only nodes

#### 3.1 Use Follower Read in TiDB

To read data from read-only nodes when using TiDB, you can set the system variable `tidb_replica_read` to `learner`:

```
set tidb_replica_read=learner;
```

#### 3.2 Use Follower Read in TiSpark

To read data from read-only nodes when using TiSpark, you can set the configuration item `spark.tispark.replica_read` to `learner` in the Spark configuration file:

```
spark.tispark.replica_read learner
```

#### 3.3 Use Follower Read when backing up cluster data

To read data from read-only nodes when backing up cluster data, you can specify the `--replica-read-label` option in the `br` command line. Note that when running the following command in shell, you need to use single quotes to wrap the label to prevent `$` from being parsed.

```
br backup full ... --replica-read-label '$mode:readonly'
```

## 12.6 Placement Rules

### Note:

This document introduces how to manually specify placement rules in Placement Driver (PD). It is now recommended to use [Placement Rules in SQL](#). This offers a more convenient way to configure the placement of tables and partitions.

Placement Rules, introduced in v5.0, is a replica rule system that guides PD to generate corresponding schedules for different types of data. By combining different scheduling rules, you can finely control the attributes of any continuous data range, such as the number of replicas, the storage location, the host type, whether to participate in Raft election, and whether to act as the Raft leader.

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to [Disable Placement Rules](#).

### 12.6.1 Rule system

The configuration of the whole rule system consists of multiple rules. Each rule can specify attributes such as the number of replicas, the Raft role, the placement location, and the key range in which this rule takes effect. When PD is performing schedule, it first finds the rule corresponding to the Region in the rule system according to the key range of the Region, and then generates the corresponding schedule to make the distribution of the Region replica comply with the rule.

The key ranges of multiple rules can have overlapping parts, which means that a Region can match multiple rules. In this case, PD decides whether the rules overwrite each other or take effect at the same time according to the attributes of rules. If multiple rules take effect at the same time, PD will generate schedules in sequence according to the stacking order of the rules for rule matching.

In addition, to meet the requirement that rules from different sources are isolated from each other, these rules can be organized in a more flexible way. Therefore, the concept of “Group” is introduced. Generally, users can place rules in different groups according to different sources.

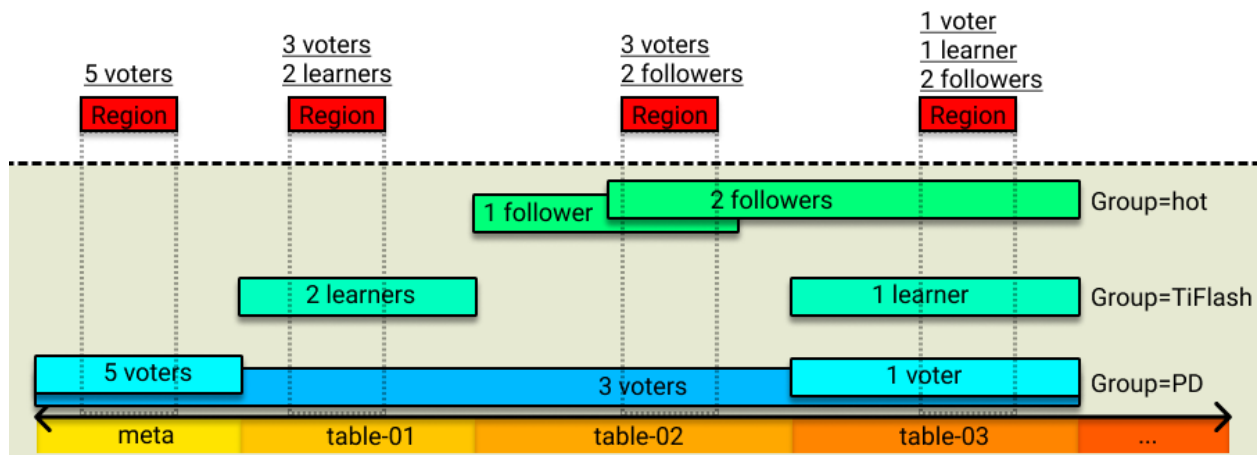

Figure 235: Placement rules overview

### 12.6.1.1 Rule fields

The following table shows the meaning of each field in a rule:

Field name	Type and restriction	Description
GroupID	string	The group ID that marks the source of the rule.
ID	string	The unique ID of a rule in a group.
Index	int	The stacking sequence of rules in a group.
Override	true/false	Whether to overwrite rules with smaller index (in a group).
StartKey	string, in hexadecimal form	Applies to the starting key of a range.
EndKey	string, in hexadecimal form	Applies to the ending key of a range.
Role	string	Replica roles, including voter/leader/follower/learner.
Count	int, positive integer	The number of replicas.
LabelConstraint	[]Constraint	Filters nodes based on the label.
LocationLabels	[]string	Used for physical isolation.
IsolationLevel	string	Used to set the minimum physical isolation level.

`LabelConstraint` is similar to the function in Kubernetes that filters labels based on these four primitives: `in`, `notIn`, `exists`, and `notExists`. The meanings of these four primitives are as follows:

- `in`: the label value of the given key is included in the given list.
- `notIn`: the label value of the given key is not included in the given list.
- `exists`: includes the given label key.
- `notExists`: does not include the given label key.

The meaning and function of `LocationLabels` are the same with those earlier than v4.0. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology:

the cluster has multiple zones (Availability Zones), each zone has multiple racks, and each rack has multiple hosts. When performing schedule, PD first tries to place the Region's peers in different zones. If this try fails (such as there are three replicas but only two zones in total), PD guarantees to place these replicas in different racks. If the number of racks is not enough to guarantee isolation, then PD tries the host-level isolation.

The meaning and function of `IsolationLevel` is elaborated in [Cluster topology configuration](#). For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology with `LocationLabels` and set `IsolationLevel` to `zone`, then PD ensures that all peers of each Region are placed in different zones during the scheduling. If the minimum isolation level restriction on `IsolationLevel` cannot be met (for example, 3 replicas are configured but there are only 2 data zones in total), PD will not try to make up to meet this restriction. The default value of `IsolationLevel` is an empty string, which means that it is disabled.

### 12.6.1.2 Fields of the rule group

The following table shows the description of each field in a rule group:

Field name	Type and restriction	Description
ID	string	The group ID that marks the source of the rule.
Index	int	The stacking sequence of different groups.
Override	true/false	Whether to override groups with smaller indexes.

## 12.6.2 Configure rules

The operations in this section are based on `pd-ctl`, and the commands involved in the operations also support calls via HTTP API.

### 12.6.2.1 Enable Placement Rules

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to [Disable Placement Rules](#). To enable this feature after it has been disabled, you can modify the PD configuration file as follows before initializing the cluster:

```
[replication]
enable-placement-rules = true
```

In this way, PD enables this feature after the cluster is successfully bootstrapped and generates corresponding rules according to the `max-replicas` and `location-labels` configurations:

```
{
 "group_id": "pd",
 "id": "default",
 "start_key": "",
```

```
"end_key": "",
"role": "voter",
"count": 3,
"location_labels": ["zone", "rack", "host"],
"isolation_level": ""
}
```

For a bootstrapped cluster, you can also enable Placement Rules dynamically through `pd-ctl`:

```
pd-ctl config placement-rules enable
```

PD also generates default rules based on the `max-replicas` and `location-labels` configurations.

#### Note:

After enabling Placement Rules, the previously configured `max-replicas` and `location-labels` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.

### 12.6.2.2 Disable Placement Rules

You can use `pd-ctl` to disable the Placement Rules feature and switch to the previous scheduling strategy.

```
pd-ctl config placement-rules disable
```

#### Note:

After disabling Placement Rules, PD uses the original `max-replicas` and `location-labels` configurations. The modification of rules (when Placement Rules is enabled) will not update these two configurations in real time. In addition, all the rules that have been configured remain in PD and will be used the next time you enable Placement Rules.

### 12.6.2.3 Set rules using `pd-ctl`

**Note:**

The change of rules affects the PD scheduling in real time. Improper rule setting might result in fewer replicas and affect the high availability of the system.

pd-ctl supports using the following methods to view rules in the system, and the output is a JSON-format rule or a rule list.

- To view the list of all rules:

```
pd-ctl config placement-rules show
```

- To view the list of all rules in a PD Group:

```
pd-ctl config placement-rules show --group=pd
```

- To view the rule of a specific ID in a Group:

```
pd-ctl config placement-rules show --group=pd --id=default
```

- To view the rule list that matches a Region:

```
pd-ctl config placement-rules show --region=2
```

In the above example, 2 is the Region ID.

Adding rules and editing rules are similar. You need to write the corresponding rules into a file and then use the **save** command to save the rules to PD:

```
cat > rules.json <<EOF
[
 {
 "group_id": "pd",
 "id": "rule1",
 "role": "voter",
 "count": 3,
 "location_labels": ["zone", "rack", "host"]
 },
 {
 "group_id": "pd",
 "id": "rule2",
 "role": "voter",
```

```
 "count": 2,
 "location_labels": ["zone", "rack", "host"]
 }
]
EOF
pd-ctl config placement save --in=rules.json
```

The above operation writes `rule1` and `rule2` to PD. If a rule with the same `GroupID + ID` already exists in the system, this rule is overwritten.

To delete a rule, you only need to set the `count` of the rule to 0, and the rule with the same `GroupID + ID` will be deleted. The following command deletes the `pd / rule2` rule:

```
cat > rules.json <<EOF
[
 {
 "group_id": "pd",
 "id": "rule2"
 }
]
EOF
pd-ctl config placement save --in=rules.json
```

#### 12.6.2.4 Use `pd-ctl` to configure rule groups

- To view the list of all rule groups:

```
pd-ctl config placement-rules rule-group show
```

- To view the rule group of a specific ID:

```
pd-ctl config placement-rules rule-group show pd
```

- To set the `index` and `override` attributes of the rule group:

```
pd-ctl config placement-rules rule-group set pd 100 true
```

- To delete the configuration of a rule group (use the default group configuration if there is any rule in the group):

```
pd-ctl config placement-rules rule-group delete pd
```

### 12.6.2.5 Use pd-ctl to batch update groups and rules in groups

To view and modify the rule groups and all rules in the groups at the same time, execute the `rule-bundle` subcommand.

In this subcommand, `get {group_id}` is used to query a group, and the output result shows the rule group and rules of the group in a nested form:

```
pd-ctl config placement-rules rule-bundle get pd
```

The output of the above command:

```
{
 "group_id": "pd",
 "group_index": 0,
 "group_override": false,
 "rules": [
 {
 "group_id": "pd",
 "id": "default",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 3
 }
]
}
```

To write the output to a file, add the `--out` argument to the `rule-bundle get` subcommand, which is convenient for subsequent modification and saving.

```
pd-ctl config placement-rules rule-bundle get pd --out="group.json"
```

After the modification is finished, you can use the `rule-bundle set` subcommand to save the configuration in the file to the PD server. Unlike the `save` command described in [Set rules using pd-ctl](#), this command replaces all the rules of this group on the server side.

```
pd-ctl config placement-rules rule-bundle set pd --in="group.json"
```

### 12.6.2.6 Use pd-ctl to view and modify all configurations

You can also view and modify all configuration using `pd-ctl`. To do that, save all configuration to a file, edit the configuration file, and then save the file to the PD server to overwrite the previous configuration. This operation also uses the `rule-bundle` subcommand.

For example, to save all configuration to the `rules.json` file, execute the following command:

```
pd-ctl config placement-rules rule-bundle load --out="rules.json"
```

After editing the file, execute the following command to save the configuration to the PD server:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

### 12.6.2.7 Use tidb-ctl to query the table-related key range

If you need special configuration for metadata or a specific table, you can execute the [keyrange command](#) in [tidb-ctl](#) to query related keys. Remember to add `--encode` at the end of the command.

```
tidb-ctl keyrange --database test --table ttt --encode
```

```
global ranges:
meta: (6d00000000000000f8, 6e00000000000000f8)
table: (7400000000000000f8, 7500000000000000f8)
table ttt ranges: (NOTE: key range might be changed after DDL)
table: (7480000000000000ff2d000000000000f8, 7480000000000000
↪ ff2e00000000000000f8)
table indexes: (7480000000000000ff2d5f698000000000fa, 7480000000000000
↪ ff2d5f720000000000fa)
index c2: (7480000000000000ff2d5f69800000000ff0000010000000000fa,
↪ 7480000000000000ff2d5f69800000000ff0000020000000000fa)
index c3: (7480000000000000ff2d5f69800000000ff0000020000000000fa,
↪ 7480000000000000ff2d5f69800000000ff0000030000000000fa)
index c4: (7480000000000000ff2d5f69800000000ff0000030000000000fa,
↪ 7480000000000000ff2d5f69800000000ff0000040000000000fa)
table rows: (7480000000000000ff2d5f720000000000fa, 7480000000000000
↪ ff2e00000000000000f8)
```

#### Note:

DDL and other operations can cause table ID changes, so you need to update the corresponding rules at the same time.

## 12.6.3 Typical usage scenarios

This section introduces the typical usage scenarios of Placement Rules.

### 12.6.3.1 Scenario 1: Use three replicas for normal tables and five replicas for the metadata to improve cluster disaster tolerance

You only need to add a rule that limits the key range to the range of metadata, and set the value of count to 5. Here is an example of this rule:

```
{
 "group_id": "pd",
 "id": "meta",
 "index": 1,
 "override": true,
 "start_key": "6d00000000000000f8",
 "end_key": "6e00000000000000f8",
 "role": "voter",
 "count": 5,
 "location_labels": ["zone", "rack", "host"]
}
```

### 12.6.3.2 Scenario 2: Place five replicas in three data centers in the proportion of 2:2:1, and the Leader should not be in the third data center

Create three rules. Set the number of replicas to 2, 2, and 1 respectively. Limit the replicas to the corresponding data centers through `label_constraints` in each rule. In addition, change role to `follower` for the data center that does not need a Leader.

```
[
 {
 "group_id": "pd",
 "id": "zone1",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 2,
 "label_constraints": [
 {"key": "zone", "op": "in", "values": ["zone1"]}
],
 "location_labels": ["rack", "host"]
 },
 {
 "group_id": "pd",
 "id": "zone2",
 "start_key": "",
 "end_key": "",
 "role": "voter",
 "count": 2,
 "label_constraints": [
 {"key": "zone", "op": "in", "values": ["zone2"]}
],
 "location_labels": ["rack", "host"]
 }
]
```

```
 },
 {
 "group_id": "pd",
 "id": "zone3",
 "start_key": "",
 "end_key": "",
 "role": "follower",
 "count": 1,
 "label_constraints": [
 {"key": "zone", "op": "in", "values": ["zone3"]}
],
 "location_labels": ["rack", "host"]
 }
]
}
```

### 12.6.3.3 Scenario 3: Add two TiFlash replicas for a table

Add a separate rule for the row key of the table and limit count to 2. Use `label_constraints` to ensure that the replicas are generated on the node of `engine`  $\leftrightarrow$  = `tiflash`. Note that a separate `group_id` is used here to ensure that this rule does not overlap or conflict with rules from other sources in the system.

```
{
 "group_id": "tiflash",
 "id": "learner-replica-table-ttt",
 "start_key": "7480000000000000ff2d5f720000000000fa",
 "end_key": "7480000000000000ff2e000000000000f8",
 "role": "learner",
 "count": 2,
 "label_constraints": [
 {"key": "engine", "op": "in", "values": ["tiflash"]}
],
 "location_labels": ["host"]
}
```

### 12.6.3.4 Scenario 4: Add two follower replicas for a table in the Beijing node with high-performance disks

The following example shows a more complicated `label_constraints` configuration. In this rule, the replicas must be placed in the `bj1` or `bj2` machine room, and the disk type must be `nvme`.

```
{
 "group_id": "follower-read",
 "id": "follower-read-table-ttt",
```

```
"start_key": "7480000000000000ff2d000000000000f8",
"end_key": "7480000000000000ff2e000000000000f8",
"role": "follower",
"count": 2,
"label_constraints": [
 {"key": "zone", "op": "in", "values": ["bj1", "bj2"]},
 {"key": "disk", "op": "in", "values": ["nvme"]}
],
"location_labels": ["host"]
}
```

### 12.6.3.5 Scenario 5: Migrate a table to the nodes with SSD disks

Different from scenario 3, this scenario is not to add new replica(s) on the basis of the existing configuration, but to forcibly override the other configuration of a data range. So you need to specify an `index` value large enough and set `override` to `true` in the rule group configuration to override the existing rule.

The rule:

```
{
 "group_id": "ssd-override",
 "id": "ssd-table-45",
 "start_key": "7480000000000000ff2d5f720000000000fa",
 "end_key": "7480000000000000ff2e000000000000f8",
 "role": "voter",
 "count": 3,
 "label_constraints": [
 {"key": "disk", "op": "in", "values": ["ssd"]}
],
 "location_labels": ["rack", "host"]
}
```

The rule group:

```
{
 "id": "ssd-override",
 "index": 1024,
 "override": true,
}
```

## 12.7 Load Base Split

Load Base Split is a new feature introduced in TiDB 4.0. It aims to solve the hotspot issue caused by unbalanced access between Regions, such as full table scans for small tables.

### 12.7.1 Scenarios

In TiDB, it is easy to generate hotspots when the load is concentrated on certain nodes. PD tries to schedule the hot Regions so that they are distributed as evenly as possible across all nodes for better performance.

However, the minimum unit for PD scheduling is Region. If the number of hotspots in a cluster is smaller than the number of nodes, or if a few hotspots have far more load than other Regions, PD can only move the hotspot from one node to another, but not make the entire cluster share the load.

This scenario is especially common with workloads that are mostly read requests, such as full table scans and index lookups for small tables, or frequent access to some fields.

Previously, the solution to this problem was to manually execute a command to split one or more hotspot Regions, but this approach has two problems:

- Evenly splitting a Region is not always the best choice, because requests might be concentrated on a few keys. In such cases, hotspots might still be on one of the Regions after evenly splitting, and it might take multiple even splits to realize the goal.
- Human intervention is not timely or simple.

### 12.7.2 Implementation principles

Load Base Split automatically splits the Region based on statistics. It identifies the Regions whose read load or CPU usage consistently exceeds the threshold for 10 seconds, and splits these Regions at a proper position. When choosing the split position, Load Base Split tries to balance the access load of both Regions after the split and avoid access across Regions.

The Region split by Load Base Split will not be merged quickly. On the one hand, PD's `MergeChecker` skips the hot Regions; on the other hand, PD also determines whether to merge two Regions according to `QPS` in the heartbeat information, to avoid the merging of two Regions with high `QPS`.

### 12.7.3 Usage

The Load Base Split feature is currently controlled by the following parameters:

- `split.qps-threshold`: The `QPS` threshold at which a Region is identified as a hotspot. The default value is 3000 per second.
- `split.byte-threshold`: The traffic threshold at which a Region is identified as a hotspot. The unit is byte and the default value is 30 MiB per second. (Introduced in v5.0)

- `split.region-cpu-overload-threshold-ratio`: The CPU usage threshold (the percentage of CPU time of the read thread pool) at which a Region is identified as a hotspot. The default value is 0.25. (Introduced in v6.2.0)

If a Region meets one of the following conditions for 10 consecutive seconds, TiKV tries to split the Region:

- the sum of its read requests exceeds `split.qps-threshold`.
- its traffic exceeds `split.byte-threshold`.
- its CPU usage in the Unified Read Pool exceeds `split.region-cpu-overload-threshold-ratio`.

Load Base Split is enabled by default, but the parameter is set to a rather high value. If you want to disable this feature, set `split.qps-threshold` and `split.byte-threshold` ↪ high enough and set `split.region-cpu-overload-threshold-ratio` to 0 at the same time.

To modify the parameter, take either of the following two methods:

- Use a SQL statement:

```
Set the QPS threshold to 1500
SET config tikv split.qps-threshold=1500;
Set the byte threshold to 15 MiB (15 * 1024 * 1024)
SET config tikv split.byte-threshold=15728640;
Set the CPU usage threshold to 50%
SET config tikv split.region-cpu-overload-threshold-ratio=0.5;
```

- Use TiKV:

```
curl -X POST "http://ip:status_port/config" -H "accept: application/
↪ json" -d '{"split.qps-threshold":"1500"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
↪ json" -d '{"split.byte-threshold":"15728640"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
↪ json" -d '{"split.region-cpu-overload-threshold-ratio":"0.5"}'
```

Accordingly, you can view the configuration by either of the following two methods:

- Use a SQL statement:

```
show config where type='tikv' and name like '%split.qps-threshold%';
```

- Use TiKV:

```
curl "http://ip:status_port/config"
```

**Note:**

Starting from v4.0.0-rc.2, you can modify and view the configuration using SQL statements.

## 12.8 Store Limit

Store Limit is a feature of PD, introduced in TiDB 3.0. It is designed to control the scheduling speed in a finer manner for better performance in different scenarios.

### 12.8.1 Implementation principles

PD performs scheduling at the unit of operator. An operator might contain several scheduling operations. For example:

```
"replace-down-replica {mv peer: store [2] to [3]} (kind:region,replica,
 ↪ region:10(4,5), createAt:2020-05-18 06:40:25.775636418 +0000 UTC m
 ↪ =+2168762.679540369, startAt:2020-05-18 06:40:25.775684648 +0000 UTC
 ↪ m=+2168762.679588599, currentStep:0, steps:[add learner peer 20 on
 ↪ store 3, promote learner peer 20 on store 3 to voter, remove peer on
 ↪ store 2])"
```

In this above example, the `replace-down-replica` operator contains the following specific operations:

1. Add a learner peer with the ID 20 to `store 3`.
2. Promote the learner peer with the ID 20 on `store 3` to a voter.
3. Delete the peer on `store 2`.

Store Limit achieves the store-level speed limit by maintaining a mapping from store IDs to token buckets in memory. The different operations here correspond to different token buckets. Currently, Store Limit only supports limiting the speed of two operations: adding learners/peers and deleting peers. That is, each store has two types of token buckets.

Every time an operator is generated, it checks whether enough tokens exist in the token buckets for its operations. If yes, the operator is added to the scheduling queue, and the corresponding token is taken from the token bucket. Otherwise, the operator is abandoned. Because the token bucket replenishes tokens at a fixed rate, the speed limit is thus achieved.

Store Limit is different from other limit-related parameters in PD (such as `region-schedule-limit` and `leader-schedule-limit`) in that it mainly limits the consuming speed of operators, while other parameters limits the generating speed of operators. Before introducing the Store Limit feature, the speed limit of scheduling is mostly at the global scope. Therefore, even if the global speed is limited, it is still possible that the scheduling operations are concentrated on some stores, affecting the performance of the cluster. By limiting the speed at a finer level, Store Limit can better control the scheduling behavior.

## 12.8.2 Usage

The parameters of Store Limit can be configured using `pd-ctl`.

### 12.8.2.1 View setting of the current store

To view the limit setting of the current store, run the following commands:

```
store limit // Shows the speed limit of adding and
↳ deleting peers in all stores.
store limit add-peer // Shows the speed limit of adding peers in
↳ all stores.
store limit remove-peer // Shows the speed limit of deleting peers
↳ in all stores.
```

### 12.8.2.2 Set limit for all stores

To set the speed limit for all stores, run the following commands:

```
store limit all 5 // All stores can at most add and delete 5
↳ peers per minute.
store limit all 5 add-peer // All stores can at most add 5 peers per
↳ minute.
store limit all 5 remove-peer // All stores can at most delete 5 peers per
↳ minute.
```

### 12.8.2.3 Set limit for a single store

To set the speed limit for a single store, run the following commands:

```
store limit 1 5 // store 1 can at most add and delete 5
↳ peers per minute.
store limit 1 5 add-peer // store 1 can at most add 5 peers per
↳ minute.
store limit 1 5 remove-peer // store 1 can at most delete 5 peers per
↳ minute.
```

## 12.9 Execution Principles and Best Practices of DDL Statements

This document provides an overview of the execution principles and best practices related to DDL statements in TiDB. The principles include the DDL Owner module and the online DDL change process.

### 12.9.1 DDL execution principles

TiDB uses an online and asynchronous approach to execute DDL statements. This means that DML statements in other sessions are not blocked while DDL statements are being executed. In other words, you can change the definitions of database objects using online and asynchronous DDL statements while your applications are running.

#### 12.9.1.1 Types of DDL statements

Based on whether DDL statements block the user application during execution, DDL statements can be divided into the following types:

- **Offline DDL statements:** When the database receives a DDL statement from the user, it first locks the database object to be modified and then changes the metadata. During the DDL execution, the database blocks the user application from modifying data.
- **Online DDL statements:** When a DDL statement is executed in the database, a specific method is used to ensure that the statement does not block the user application. This allows the user to submit modifications during the DDL execution. The method also ensures the correctness and consistency of the corresponding database object during the execution process.

Based on whether to operate the data included in the target DDL object, DDL statements can be divided into the following types:

- **Logical DDL statements:** Logical DDL statements usually only modify the metadata of the database object, without processing the data stored in the object, for example, changing the table name or changing the column name.

In TiDB, logical DDL statements are also referred to as “general DDL”. These statements typically have a short execution time, often taking only a few tens of milliseconds or seconds to complete. As a result, they do not consume much system resource and do not affect the workload on the application.

- **Physical DDL statements:** Physical DDL statements not only modify the metadata of the object to be changed, but also modify the user data stored in the object. For example, when TiDB creates an index for a table, it not only changes the definition of the table, but also performs a full table scan to build the newly added index.

In TiDB, physical DDL statements are also referred to as “reorg DDL”, which stands for reorganization. Currently, physical DDL statements only include `ADD INDEX` and lossy column type changes (such as changing from an `INT` type to a `CHAR` type). These statements take a long time to execute, and the execution time is affected by the amount of data in the table, the machine configuration, and the application workload.

Executing physical DDL statements can have an impact on the workload of the application for two reasons. On the one hand, it consumes CPU and I/O resources from TiKV to read data and write new data. On the other hand, the TiDB node where the DDL Owner is located needs to perform the corresponding computations, which consumes more CPU resources. Because TiDB does not support distributed execution of DDL statements, other TiDB nodes do not consume additional system resources during this process.

**Note:**

The execution of a physical DDL task typically causes the greatest impact on the user application. Therefore, to minimize this impact, the key point is to optimize the design of physical DDL statements during execution. This helps to reduce the impact on the user application.

### 12.9.1.2 TiDB DDL module

The TiDB DDL module introduces the role of the DDL Owner (or Owner), which serves as a proxy for executing all DDL statements within the TiDB cluster. In the current implementation, only one TiDB node in the entire cluster can be elected as the Owner at any given time. Once a TiDB node is elected as Owner, the worker started in that TiDB node can handle the DDL tasks in the cluster.

TiDB uses the election mechanism of `etcd` to elect a node to host the Owner from multiple TiDB nodes. By default, each TiDB node can potentially be elected as the Owner (you can configure `run-ddl` to manage node participation in the election). The elected Owner node has a term, and it actively maintains the term by renewing it. When the Owner node is down, another node can be elected as the new Owner through `etcd` and continue executing DDL tasks in the cluster.

A simple illustration of the DDL Owner is as follows:

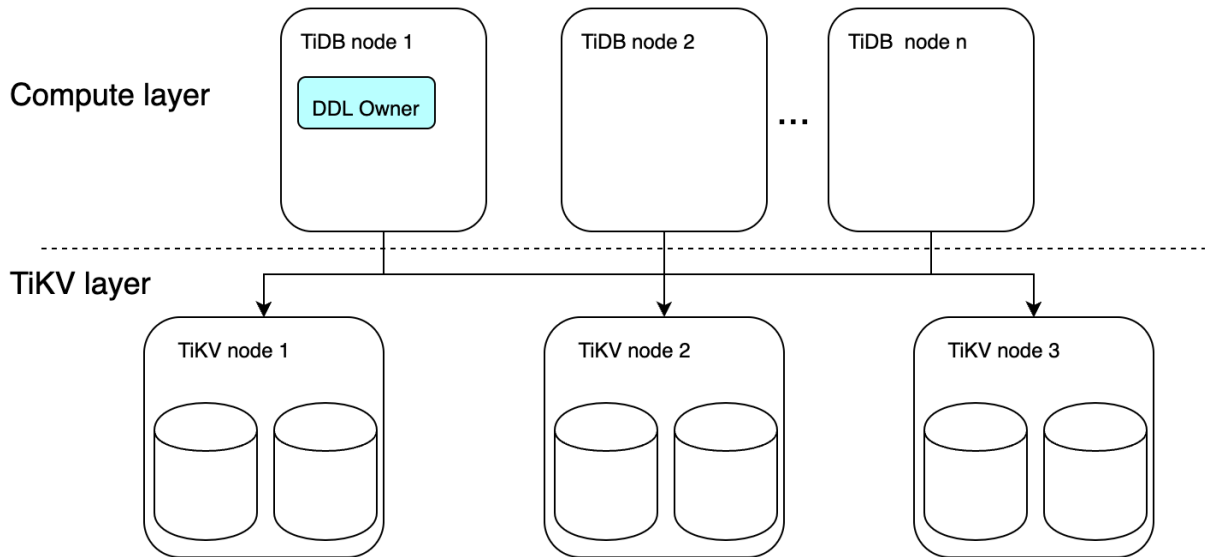

Figure 236: DDL Owner

You can use the `ADMIN SHOW DDL` statement to view the current DDL owner:

```
ADMIN SHOW DDL;
```

```
+--
| SCHEMA_VER | OWNER_ID | OWNER_ADDRESS | RUNNING_JOBS
| SELF_ID | QUERY |
+--
| 26 | 2d1982af-fa63-43ad-a3d5-73710683cc63 | 0.0.0.0:4000 | 2
| d1982af-fa63-43ad-a3d5-73710683cc63 | |
+--
1 row in set (0.00 sec)
```

### 12.9.1.3 How the online DDL asynchronous change works in TiDB

From the beginning of its design, the TiDB DDL module has opted for an online asynchronous change mode, which lets you modify your applications without experiencing any downtime.

DDL changes involve transitioning from one state to another, typically from a “before change” state to an “after change” state. With online DDL changes, this transition occurs by introducing multiple small version states that are mutually compatible. During the execution of a DDL statement, TiDB nodes in the same cluster are allowed to have different small version changes, as long as the difference between the small versions of the change objects is not more than two versions. This is possible because adjacent small versions can be mutually compatible.

In this way, evolving through multiple small versions ensures that metadata can be correctly synchronized across multiple TiDB nodes. This helps maintain the correctness and consistency of user transactions that involve changing data during the process.

Taking `ADD INDEX` as an example, the entire process of state change is as follows:

```
absent -> delete only -> write only -> write reorg -> public
```

For users, the newly created index is unavailable before the `public` state.

Before v6.2.0, the process of handling asynchronous schema changes in the TiDB SQL layer is as follows:

1. MySQL Client sends a DDL request to a TiDB server.
2. After receiving the request, a TiDB server parses and optimizes the request at the MySQL Protocol layer, and then sends it to the TiDB SQL layer for execution.

Once the SQL layer of TiDB receives the DDL request, it starts the `start job` module to encapsulate the request into a specific DDL job (that is, a DDL task), and then stores this job in the corresponding DDL job queue in the KV layer based on the statement type. The corresponding worker is notified of the job that requires processing.

3. When receiving the notification to process the job, the worker determines whether it has the role of the DDL Owner. If it does, it directly processes the job. Otherwise, it exits without any processing.

If a TiDB server is not the Owner role, then another node must be the Owner. The worker of the node in the Owner role periodically checks whether there is an available job that can be executed. If such a job is identified, the worker will process the job.

4. After the worker processes the Job, it removes the job from the job queue in the KV layer and places it in the `job history queue`. The `start job` module that encapsulated the job periodically checks the ID of the job in the `job history queue` to see whether it has been processed. If so, the entire DDL operation corresponding to the job ends.
5. TiDB server returns the DDL processing result to the MySQL Client.

Before TiDB v6.2.0, the DDL execution framework had the following limitations:

- The TiKV cluster only has two queues: `general job queue` and `add index job queue`, which handle logical DDL and physical DDL, respectively.
- The DDL Owner always processes DDL jobs in a first-in-first-out way.
- The DDL Owner can only execute one DDL task of the same type (either logical or physical) at a time, which is relatively strict, and affects the user experience.

These limitations might lead to some “unintended” DDL blocking behavior. For more details, see [SQL FAQ - DDL Execution](#).

Before TiDB v6.2.0, because the Owner can only execute one DDL task of the same type (either logical or physical) at a time, which is relatively strict, and affects the user experience.

If there is no dependency between DDL tasks, parallel execution does not affect data correctness and consistency. For example, user A adds an index to the T1 table, while user B deletes a column from the T2 table. These two DDL statements can be executed in parallel.

To improve the user experience of DDL execution, starting from v6.2.0, TiDB enables the Owner to determine the relevance of DDL tasks. The logic is as follows:

- DDL statements to be performed on the same table are mutually blocked.
- `DROP DATABASE` and DDL statements that affect all objects in the database are mutually blocked.
- Adding indexes and column type changes on different tables can be executed concurrently.
- A logical DDL statement must wait for the previous logical DDL statement to be executed before it can be executed.
- In other cases, DDL can be executed based on the level of availability for concurrent DDL execution.

In specific, TiDB has upgraded the DDL execution framework in v6.2.0 in the following aspects:

- The DDL Owner can execute DDL tasks in parallel based on the preceding logic.
- The first-in-first-out issue in the DDL Job queue has been addressed. The DDL Owner no longer selects the first job in the queue, but instead selects the job that can be executed at the current time.
- The number of workers that handle physical DDL statements has been increased, enabling multiple physical DDL statements to be executed in parallel.

Because all DDL tasks in TiDB are implemented using an online change approach, TiDB can determine the relevance of new DDL jobs through the Owner, and schedule DDL tasks based on this information. This approach enables the distributed database to achieve the same level of DDL concurrency as traditional databases.

The concurrent DDL framework enhances the execution capability of DDL statements in TiDB, making it more compatible with the usage patterns of commercial databases.

## 12.9.2 Best practices

### 12.9.2.1 Balance the physical DDL execution speed and the impact on application load through system variables

When executing physical DDL statements (including adding indexes or column type changes), you can adjust the values of the following system variables to balance the speed of DDL execution and the impact on application load:

- `tidb_ddl_reorg_worker_cnt`: This variable sets the number of reorg workers for a DDL operation, which controls the concurrency of backfilling.
- `tidb_ddl_reorg_batch_size`: This variable sets the batch size for a DDL operation in the re-organize phase, which controls the amount of data to be backfilled.

Recommended values:

- If there is no other load, you can increase the values of `tidb_ddl_reorg_worker_cnt` ↪ and `tidb_ddl_reorg_batch_size` to speed up the `ADD INDEX` operation. For example, you can set the values of the two variables to 20 and 2048, respectively.
- If there is other load, you can decrease the values of `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` to minimize the impact on other application. For example, you can set the values of these variables to 4 and 256, respectively.

#### Tip:

- The preceding two variables can be dynamically adjusted during the execution of a DDL task, and take effect in the next transaction batch.
- Choose the appropriate time to execute the DDL operation based on the type of the operation and the application load pressure. For example, it is recommended to run the `ADD INDEX` operation when the application load is low.
- Because the duration of adding an index is relatively long, TiDB will execute the task in the background after the command is sent. If the TiDB server is down, the execution will not be affected.

### 12.9.2.2 Quickly create many tables by concurrently sending DDL requests

A table creation operation takes about 50 milliseconds. The actual time taken to create a table might be longer because of the framework limitations.

To create tables faster, it is recommended to send multiple DDL requests concurrently to achieve the fastest table creation speed. If you send DDL requests serially and do not send them to the Owner node, the table creation speed will be very slow.

### 12.9.2.3 Make multiple changes in a single ALTER statement

Starting from v6.2.0, TiDB supports modifying multiple schema objects (such as columns and indexes) of a table in a single ALTER statement while ensuring the atomicity of the entire statement. Therefore, it is recommended to make multiple changes in a single ALTER statement.

### 12.9.2.4 Check the read and write performance

When TiDB is adding an index, the phase of backfilling data will cause read and write pressure on the cluster. After the ADD INDEX command is sent and the write reorg phase starts, it is recommended to check the read and write performance metrics of TiDB and TiKV on the Grafana dashboard and the application response time, to determine whether the ADD INDEX operation affects the cluster.

## 12.9.3 DDL-related commands

- **ADMIN SHOW DDL:** Used to view the status of TiDB DDL operations, including the current schema version number, the DDL ID and address of the DDL Owner, the DDL task and SQL being executed, and the DDL ID of the current TiDB instance. For details, see [ADMIN SHOW DDL](#).
- **ADMIN SHOW DDL JOBS:** Used to view the detailed status of DDL tasks running in the cluster environment. For details, see [ADMIN SHOW DDL JOBS](#).
- **ADMIN SHOW DDL JOB QUERIES job\_id [, job\_id]:** Used to view the original SQL statement of the DDL task corresponding to the job\_id. For details, see [ADMIN SHOW](#) ↪ [DDL JOB QUERIES](#).
- **ADMIN CANCEL DDL JOBS job\_id, [, job\_id]:** Used to cancel DDL tasks that have been submitted but not completed. After the cancellation is completed, the SQL statement that executes the DDL task returns the **ERROR 8214 (HY000): Cancelled** ↪ **DDL job error**.

If a completed DDL task is canceled, you can see the **DDL Job:90 not found** error in the **RESULT** column, which means that the task has been removed from the DDL waiting queue.

## 12.9.4 Common questions

For common questions about DDL execution, see [SQL FAQ - DDL execution](#).

## 13 TiDB Tools

### 13.1 TiDB Tools Overview

TiDB provides a rich set of tools to help you deploy and maintain TiDB, manage data (such as data migration, backup & restore, and data comparison), and run Spark SQL on TiKV. You can select the applicable tools according to your needs.

#### 13.1.1 Deployment and operation Tools

TiDB provides TiUP and TiDB Operator to meet your deployment and operation needs in different system environments.

##### 13.1.1.1 Deploy and operate TiDB on physical or virtual machines - TiUP

**TiUP** is a TiDB package manager on physical or virtual machines. TiUP can manage multiple TiDB components such as TiDB, PD, and TiKV. To start any component in the TiDB ecosystem, you just need to execute a single line of TiUP command.

TiUP provides [TiUP cluster](#), a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

The following are the basics of TiUP:

- [Terminology and Concepts](#)
- [Deploy a TiDB Cluster Using TiUP](#)
- [Manage TiUP Components with TiUP Commands](#)
- Applicable TiDB versions: v4.0 and later versions

##### 13.1.1.2 Deploy and operate TiDB on Kubernetes - TiDB Operator

[TiDB Operator](#) is an automatic operation system for managing TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

The following are the basics of TiDB Operator:

- [TiDB Operator Architecture](#)
- [Get Started with TiDB Operator on Kubernetes](#)
- Applicable TiDB versions: v2.1 and later versions

### 13.1.2 Data management tools

TiDB provides multiple data management tools, such as import and export, backup and restore, incremental data replication, and data validation.

#### 13.1.2.1 Data migration - TiDB Data Migration (DM)

**TiDB Data Migration** (DM) is a tool that supports full data migration and incremental data replication from MySQL/MariaDB to TiDB.

The following are the basics of DM:

- Source: MySQL/MariaDB
- Target: TiDB clusters
- Supported TiDB versions: all versions
- Kubernetes support: use [TiDB Operator](#) to deploy TiDB DM on Kubernetes.

If the data volume is less than 1 TB, it is recommended to migrate data from MySQL/-MariaDB to TiDB directly using DM. The migration process includes full data migration and incremental data replication.

If the data volume is greater than 1 TB , take the following steps:

1. Use **Dumpling** to export the full data from MySQL/MariaDB.
2. Use **TiDB Lightning** to import the data exported in Step 1 to the TiDB cluster.
3. Use TiDB DM to replicate the incremental data from MySQL/MariaDB to TiDB.

#### Note:

The Syncer tool is no longer maintained. For scenarios related to Syncer, it is recommended that you use DM to perform incremental replication.

#### 13.1.2.2 Full data export - Dumpling

**Dumpling** supports logical full data export from MySQL or TiDB.

The following are the basics of Dumpling:

- Source: MySQL/TiDB clusters
- Output: SQL/CSV files
- Supported TiDB versions: all versions
- Kubernetes support: No

**Note:**

PingCAP previously maintained a fork of the [mydumper project](#) with enhancements specific to TiDB. This fork has since been replaced by [Dumpling](#), which has been rewritten in Golang, and provides more optimizations specific to TiDB. It is strongly recommended that you use Dumpling instead of mydumper.

### 13.1.2.3 Full data import - TiDB Lightning

[TiDB Lightning](#) supports full data import of a large dataset into a TiDB cluster.

TiDB Lightning supports the following modes:

- **Physical Import Mode:** TiDB Lightning parses data into ordered key-value pairs and directly imports them into TiKV. This mode is usually for importing a large amount of data (at the TB level) to a new cluster. During the import, the cluster cannot provide services.
- **Logical Import Mode:** This mode uses TiDB/MySQL as the backend, which is slower than the **Physical Import Mode** but can be performed online. It also supports importing data to MySQL.

The following are the basics of TiDB Lightning:

- Data source:
  - The output files of Dumpling
  - Other compatible CSV files
  - Parquet files exported from Amazon Aurora or Apache Hive
- Supported TiDB versions: v2.1 and later versions
- Kubernetes support: Yes. See [Quickly restore data into a TiDB cluster on Kubernetes using TiDB Lightning](#) for details.

**Note:**

The Loader tool is no longer maintained. For scenarios related to Loader, it is recommended that you use **Logical Import Mode** instead.

#### 13.1.2.4 Backup and restore - Backup & Restore (BR)

**Backup & Restore** (BR) is a command-line tool for distributed backup and restore of the TiDB cluster data. BR can effectively back up and restore TiDB clusters of huge data volume.

The following are the basics of BR:

- Input and output data source
  - Snapshot backup and restore: [SST + backupmeta file](#)
  - Log backup and PITR: [Log backup files](#)
- Supported TiDB versions: v4.0 and later versions
- Kubernetes support: Yes. See [Back up Data to S3-Compatible Storage Using BR](#) and [Restore Data from S3-Compatible Storage Using BR](#) for details.

#### 13.1.2.5 Incremental data replication - TiCDC

**TiCDC** is a tool used for replicating incremental data of TiDB by pulling change logs from TiKV. It can restore data to a state consistent with any TSO in upstream. TiCDC also provides the TiCDC Open Protocol to support other systems to subscribe to data changes.

The following are the basics of TiCDC:

- Source: TiDB clusters
- Target: TiDB clusters, MySQL, Kafka, and Confluent
- Supported TiDB versions: v4.0.6 and later versions

#### 13.1.2.6 Incremental log replication - TiDB Binlog

**TiDB Binlog** is a tool that collects binlog for TiDB clusters and provides nearly real-time data replication and backup. You can use it for incremental data replication between TiDB clusters, such as making a TiDB cluster the secondary cluster of the primary TiDB cluster.

The following are the basics of TiDB Binlog:

- Source: TiDB clusters
- Target: TiDB clusters, MySQL, Kafka, or incremental backup files
- Supported TiDB versions: v2.1 and later versions
- Kubernetes support: Yes. See [TiDB Binlog Cluster Operations](#) and [TiDB Binlog Drainer Configurations on Kubernetes](#) for details.

### 13.1.2.7 sync-diff-inspector

**sync-diff-inspector** is a tool that compares data stored in the MySQL or TiDB databases. In addition, you can also use sync-diff-inspector to repair data in the scenario where a small amount of data is inconsistent.

The following are the basics of sync-diff-inspector:

- Source: MySQL/TiDB clusters
- Target: MySQL/TiDB clusters
- Supported TiDB versions: all versions

### 13.1.3 OLAP Query tool - TiSpark

**TiSpark** is a product developed by PingCAP to address the complexity of OLAP queries. It combines strengths of Spark, and the features of distributed TiKV clusters and TiDB to provide a one-stop Hybrid Transactional and Analytical Processing (HTAP) solution.

## 13.2 TiDB Tools Use Cases

This document introduces the common use cases of TiDB tools and how to choose the right tool for your scenario.

### 13.2.1 Deploy and operate TiDB on physical or virtual machines

If you need to deploy and operate TiDB on physical or virtual machines, you can install **TiUP**, and then use TiUP to manage TiDB components such as TiDB, PD, and TiKV.

### 13.2.2 Deploy and operate TiDB on Kubernetes

If you need to deploy and operate TiDB on Kubernetes, you can deploy a Kubernetes cluster, and then deploy **TiDB Operator**. After that, you can use TiDB Operator to deploy and operate a TiDB cluster.

### 13.2.3 Import data from CSV to TiDB

If you need to import the compatible CSV files exported by other tools to TiDB, use **TiDB Lightning**.

### 13.2.4 Import full data from MySQL/Aurora

If you need to import full data from MySQL/Aurora, use **Dumpling** first to export data as SQL dump files, and then use **TiDB Lightning** to import data into the TiDB cluster.

### 13.2.5 Migrate data from MySQL/Aurora

If you need to migrate both full data and incremental data from MySQL/Aurora, use [TiDB Data Migration \(DM\)](#) to perform the [Migrate Data from Amazon Aurora to TiDB](#).

If the full data volume is large (at the TB level), you can first use [Dumpling](#) and [TiDB Lightning](#) to perform the full data migration, and then use DM to perform the incremental data migration.

### 13.2.6 Back up and restore TiDB cluster

If you need to back up a TiDB cluster or restore backed up data to the cluster, use [BR](#) (Backup & Restore).

In addition, BR can also be used to perform [incremental backup](#) and [incremental restore](#) of TiDB cluster data.

### 13.2.7 Migrate data to TiDB

If you need to migrate data from a TiDB cluster to another TiDB cluster, use [Dumpling](#) to export full data from TiDB as SQL dump files, and then use [TiDB Lightning](#) to import data to another TiDB cluster.

If you also need to migrate incremental data, you can use [TiCDC](#).

### 13.2.8 TiDB incremental data subscription

If you need to subscribe to TiDB's incremental changes, you can use [TiCDC](#).

## 13.3 Download TiDB Tools

This document describes how to download the TiDB Toolkit.

TiDB Toolkit contains frequently used TiDB tools, such as data export tool Dumpling, data import tool TiDB Lightning, and backup and restore tool BR.

#### Tip:

- If your deployment environment has internet access, you can deploy a TiDB tool using a single [TiUP command](#), so there is no need to download the TiDB Toolkit separately.
- If you need to deploy and maintain TiDB on Kubernetes, instead of downloading the TiDB Toolkit, follow the steps in [TiDB Operator offline installation](#).

### 13.3.1 Environment requirements

- Operating system: Linux
- Architecture: amd64 or arm64

### 13.3.2 Download link

You can download TiDB Toolkit from the following link:

```
https://download.pingcap.org/tidb-community-toolkit-{version}-linux-{arch}.
↪ tar.gz
```

{version} in the link indicates the version number of TiDB and {arch} indicates the architecture of the system, which can be amd64 or arm64. For example, the download link for v6.2.0 in the amd64 architecture is <https://download.pingcap.org/tidb-community-toolkit-v6.2.0-linux-amd64.tar.gz>.

#### Note:

If you need to download the **PD Control** tool `pd-ctl`, download the TiDB installation package separately from <https://download.pingcap.org/tidb-community-server-{version}-linux-{arch}.tar.gz>.

### 13.3.3 TiDB Toolkit description

Depending on which tools you want to use, you can install the corresponding offline packages as follows:

Tool	Offline package name
TiUP	<pre>tiup-linux ↳ -{arch ↳ }.tar. ↳ gz tiup-{tiup ↳ - ↳ version ↳ }-linux ↳ -{arch ↳ }.tar. ↳ gz dm-{tiup- ↳ version ↳ }-linux ↳ -{arch ↳ }.tar. ↳ gz server-{ ↳ version ↳ }-linux ↳ -{arch ↳ }.tar. ↳ gz</pre>
Dumpling	<pre>dumpling-{ ↳ version ↳ }-linux ↳ -{arch ↳ }.tar. ↳ gz</pre>
TiDB	<pre>tidb-</pre>
Lightning	<pre>↳ lightning ↳ -ctl tidb- ↳ lightning ↳ -{ ↳ version ↳ }-linux ↳ -{arch ↳ }.tar. ↳ gz</pre>

Tool	Offline package name
TiDB Data Migration (DM)	dm-worker ↪ -{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz dm-master ↪ -{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz dmctl-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz
TiCDC	cdc-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz
TiDB Binlog	pump-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz drainer-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz binlogctl reparo

Tool	Offline package name
Backup & Restore (BR)	br-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz
sync-diff-inspector	sync_diff_inspector ↪
TiSpark	tispark-{ ↪ tispark ↪ - ↪ version ↪ }-any- ↪ any.tar ↪ .gz spark-{ ↪ spark- ↪ version ↪ }-any- ↪ any.tar ↪ .gz
PD Recover	pd-recover ↪ -{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar

#### Note:

{version} depends on the version of the tool you are installing. {arch} depends on the architecture of the system, which can be amd64 or arm64.

## 13.4 TiUP

### 13.4.1 TiUP Documentation Map

#### 13.4.1.1 User guide

- **TiUP Overview**: Gives an overall introduction to TiUP, for example, how to install and use TiUP, and the related terminologies.
- **TiUP Terminology and Concepts**: Explains the terms that you might bump into when using TiUP, and help you understand the key concepts of TiUP
- **TiUP Component Management**: Introduces all TiUP commands in detail, and how to use TiUP to download, update and delete components
- **TiUP FAQ**: Introduces common issues when you use TiUP, including FAQs of the third-party components of TiUP
- **TiUP Troubleshooting Guide**: Introduces the troubleshooting methods and solutions if you encounter issues when using TiUP
- **TiUP Reference Guide**: Introduces detailed references, including commands, components, and mirrors.

#### 13.4.1.2 TiUP resources

- **TiUP Issues**: Lists TiUP GitHub issues

### 13.4.2 TiUP Overview

Starting with TiDB 4.0, TiUP, as the package manager, makes it far easier to manage different cluster components in the TiDB ecosystem. Now you can run any component with only a single line of TiUP commands.

#### 13.4.2.1 Install TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
↳ install.sh | sh
```

This command installs TiUP in the `$HOME/.tiup` folder. The installed components and the data generated by their operation are also placed in this folder. This command also automatically adds `$HOME/.tiup/bin` to the `PATH` environment variable in the Shell `.profile` file, so you can use TiUP directly.

After installation, you can check the version of TiUP:

```
tiup --version
```

**Note:**

For TiUP versions starting from v1.11.3, the telemetry is disabled by default in newly deployed TiUP, and usage information is not collected and shared with PingCAP. For details about what is shared and how to disable the sharing, see [Telemetry](#).

### 13.4.2.2 TiUP ecosystem introduction

TiUP is not only a package manager in the TiDB ecosystem. Its ultimate mission is to enable everyone to use TiDB ecosystem tools **easier than ever before** by building its own ecosystem. This requires introducing additional packages to enrich the TiUP ecosystem.

This series of TiUP documents introduce what these packages do and how you can use them.

In the TiUP ecosystem, you can get help information by adding `--help` to any command, such as the following command to get help information for TiUP itself:

```
tiup --help
```

```
TiUP is a command-line component management tool that can help to download
↳ and install
TiDB platform components to the local system. You can run a specific version
↳ of a component via
"tiup <component>[:version]". If no version number is specified, the latest
↳ version installed
locally will be used. If the specified component does not have any version
↳ installed locally,
the latest stable version will be downloaded from the repository.
```

**Usage:**

```
tiup [flags] <command> [args...]
tiup [flags] <component> [args...]
```

**Available Commands:**

```
install Install a specific version of a component
list List the available TiDB components or versions
uninstall Uninstall components or versions of a component
update Update tiup components to the latest version
status List the status of instantiated components
clean Clean the data of instantiated components
mirror Manage a repository mirror for TiUP components
help Help about any command or component
```

#### Components Manifest:

use "tiup list" to fetch the latest components manifest

#### Flags:

```
--binary <component>[:version] Print binary path of a specific version
 ↪ of a component <component>[:version]
 and the latest version installed will be
 ↪ selected if no version specified

--binpath string Specify the binary path of component
 ↪ instance

-h, --help help for tiup
-T, --tag string Specify a tag for component instance
-v, --version version for tiup
```

Component instances with the same "tag" will share a data directory (

↪ \$TIUP\_HOME/data/\$tag):

```
$ tiup --tag mycluster playground
```

#### Examples:

```
$ tiup playground # Quick start
$ tiup playground nightly # Start a playground with the latest
 ↪ nightly version
$ tiup install <component>[:version] # Install a component of specific
 ↪ version
$ tiup update --all # Update all installed components to the
 ↪ latest version
$ tiup update --nightly # Update all installed components to the
 ↪ nightly version
$ tiup update --self # Update the "tiup" to the latest version
$ tiup list # Fetch the latest supported components
 ↪ list
$ tiup status # Display all running/terminated
 ↪ instances
$ tiup clean <name> # Clean the data of running/terminated
 ↪ instance (Kill process if it's running)
$ tiup clean --all # Clean the data of all running/
 ↪ terminated instances
```

Use "tiup [command] --help" for more information about a command.

The output is long but you can focus on only two parts:

- Available commands

- install: used to install components
  - list: used to view the list of available components
  - uninstall: used to uninstall components
  - update: used to update the component version
  - status: used to view the running history of components
  - clean: used to clear the running log of components
  - mirror: used to clone a private mirror from the official mirror
  - help: used to print out help information
- Available components
    - playground: used to start a TiDB cluster locally
    - client: used to connect to a TiDB cluster in a local machine
    - cluster: used to deploy a TiDB cluster for production environments
    - bench: used to stress test the database

#### Note:

- The number of available components will continue to grow. To check the latest supported components, execute the `tiup list` command.
- The list of available versions of components will also continue to grow. To check the latest supported component versions, execute the `tiup ↪ list <component>` command.

TiUP commands are implemented in TiUP’s internal code and used for package management operations, while TiUP components are independent component packages installed by TiUP commands.

For example, if you run the `tiup list` command, TiUP directly runs its own internal code; if you run the `tiup playground` command, TiUP first checks whether there is a local package named “playground”, and if not, TiUP downloads the package from the mirror, and then run it.

### 13.4.3 TiUP Terminology and Concepts

This document explains important terms and concepts of TiUP.

#### 13.4.3.1 TiUP components

The TiUP program contains only a few commands for downloading, updating, and uninstalling components. TiUP expands its functions with various components. A **component** is

a program or script that can be run. When running a component through `tiup <component> ↪ >`, TiUP adds a set of environment variables, creates the data directory for the program, and then runs the program.

By running the `tiup <component>` command, you can run a component supported by TiUP. The running logic is:

- If you specify a version of a component through `tiup <component>[:version]:`
  - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
  - If the component has one or more versions installed locally, but there is no version specified by you, TiUP downloads the specified version from the mirror server.
  - If the specified version of the component is installed locally, TiUP sets the environment variable to run the installed version.
- If you run a component through `tiup <component>` and specify no version:
  - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
  - If one or more versions have been installed locally, TiUP sets the environment variable to run the latest installed version.

### 13.4.3.2 TiUP mirrors

All components of TiUP are downloaded from the TiUP mirrors. TiUP mirrors contain the TAR package of each component and the corresponding meta information (version, entry startup file, checksum). TiUP uses PingCAP's official mirrors by default. You can customize the mirror source through the `TIUP_MIRRORS` environment variable.

TiUP mirrors can be a local file directory or an online HTTP server:

- `TIUP_MIRRORS=/path/to/local tiup list`
- `TIUP_MIRRORS=https://private-mirrors.example.com tiup list`

### 13.4.4 Manage TiUP Components with TiUP Commands

You can use the following TiUP commands to manage components in the TiUP ecosystem:

- `list`: Queries the component list. By using this TiUP command, you can see all the optional components to install and all the optional versions of each component.
- `install`: Installs the specific version of a component.
- `update`: Updates a component to the latest version.
- `uninstall`: Uninstalls a component.
- `status`: Checks the status of a running component.

- `clean`: Cleans up the instance on which a component is deployed.
- `help`: Prints the help information. If you append another TiUP command to this command, the usage of the appended command is printed.

This document introduces the common component management operations and the corresponding TiUP commands.

#### 13.4.4.1 Query the component list

You can use the `tiup list` command to query the component list. This usage of this command is as follows:

- `tiup list`: checks which components can be installed.
- `tiup list ${component}`: checks which versions of a specific component can be installed.

You can also use the following flags in the above commands:

- `--installed`: checks which components or which version of a specific component has been installed locally. `---all`: views all components, including the hidden ones `---↔ verbose`: views all columns (including installed versions and supported platforms)

Example 1: View all currently installed components.

```
tiup list --installed
```

Example 2: Get a list of the TiKV component of all installable versions from the server.

```
tiup list tikv
```

#### 13.4.4.2 Install components

You can use the `tiup install` command to query the component list. This usage of this command is as follows:

- `tiup install <component>`: installs the latest stable version of a specified component.
- `tiup install <component>:[version]`: installs the specified version of a specified component.

Example 1: Use TiUP to install the latest stable version of TiDB.

```
tiup install tidb
```

Example 2: Use TiUP to install the nightly version of TiDB.

```
tiup install tidb:nightly
```

Example 3: Use TiUP to install TiKV v6.6.0.

```
tiup install tikv:v6.6.0
```

### 13.4.4.3 Upgrade components

After a new version of a component is published, you can use the `tiup update` command to upgrade this component. The usage of this command is basically the same as that of `tiup install`, except for the following flags:

- `--all`: Upgrades all components.
- `--nightly`: Upgrades to the nightly version.
- `--self`: Upgrades TiUP itself to the latest version.
- `--force`: Forcibly upgrades to the latest version.

Example 1: Upgrade all components to the latest versions.

```
tiup update --all
```

Example 2: Upgrade all components to the nightly version.

```
tiup update --all --nightly
```

Example 3: Upgrade TiUP to the latest version.

```
tiup update --self
```

### 13.4.4.4 Operate components

After the installation is complete, you can use the `tiup <component>` command to start the corresponding component:

```
tiup [flags] <component>[:version] [args...]
```

Flags:

<code>-T, --tag string</code>	Specifies the tag for the component
<code>↪ instance.</code>	

To use this command, you need to specify the component name and the optional version. If no version is specified, the latest stable version (installed) of this component is used.

Before the component is started, TiUP creates a directory for it, and then puts this component into the directory for operation. The component generates all the data in this directory, and the name of this directory is the tag name specified when the component

operates. If no tag is specified, a tag name is randomly generated. This working directory will be *automatically deleted* when the instance is terminated.

If you want to start the same component multiple times and reuse the previous working directory, you can use `--tag` to specify the same name when the component is started. After the tag is specified, the working directory will *not be automatically deleted* when the instance is terminated, which makes it convenient to reuse the working directory.

Example 1: Operate TiDB v6.6.0.

```
tiup tidb:v6.6.0
```

Example 2: Specify the tag with which TiKV operates.

```
tiup --tag=experiment tikv
```

#### 13.4.4.4.1 Query the operating status of a component

You can use the `tiup status` command to check the operating status of a component:

```
tiup status
```

By executing this command, you will get a list of instances, one instance per line. The list contains the following columns:

- **Name:** The tag name of the instance.
- **Component:** The component name of the instance.
- **PID:** The process ID of the operating instance.
- **Status:** The instance status. `RUNNING` means that the instance is operating. `TERM` means that the instance is terminated.
- **Created Time:** The starting time of the instance.
- **Directory:** The working directory of the instance, which can be specified using `--tag`.
- **Binary:** The executable program of the instance, which can be specified using `--binpath`.
- **Args:** The arguments of the operating instance.

#### 13.4.4.4.2 Clean component instance

You can use the `tiup clean` command to clean up component instances and delete the working directory. If the instance is still operating before the cleaning, the related process is killed first. The command usage is as follows:

```
tiup clean [tag] [flags]
```

The following flag is supported:

- `--all`: Cleans up all instance information.

In the above command, `tag` is the instance tag to be cleaned. If `--all` is used, no tag is passed.

Example 1: Clean up the component instance with the `experiment` tag name.

```
tiup clean experiment
```

Example 2: Clean up all component instances.

```
tiup clean --all
```

#### 13.4.4.4.3 Uninstall components

The components installed using TiUP take up local disk space. If you do not want to keep too many components of old versions, you can check which versions of a component are currently installed, and then uninstall this component.

You can use the `tiup uninstall` command to uninstall all versions or specific versions of a component. This command also supports uninstalling all components. The command usage is as follows:

```
tiup uninstall [component][:version] [flags]
```

The following flags are supported in this command:

- `--all`: Uninstalls all components or versions.
- `--self`: Uninstalls TiUP itself.

`component` is the component to be uninstalled. `version` is the version to be uninstalled. Both `component` and `version` can be ignored in the `tiup uninstall` command. If you ignore either one of these two, you need to add the `--all` flag.

- If the version is ignored, adding `--all` means to uninstall all versions of this component.
- If the version and the component are both ignored, adding `--all` means to uninstall all components of all versions.

Example 1: Uninstall TiDB v6.6.0.

```
tiup uninstall tidb:v6.6.0
```

Example 2: Uninstall TiKV of all versions.

```
tiup uninstall tikv --all
```

Example 3: Uninstall all installed components.

```
tiup uninstall --all
```

## 13.4.5 TiUP FAQs

This document collects the frequently asked questions (FAQs) about TiUP.

### 13.4.5.1 Can TiUP not use the official mirror source?

TiUP supports specifying the mirror source through the `TIUP_MIRRORS` environment variable. The address of the mirror source can be a local directory or an HTTP server address. If your environment cannot access the network, you can create your own offline mirror source to use TiUP.

After using an unofficial mirror, if you want the official mirror back and use it, take one of the following measures:

- Set the `TIUP_MIRRORS` variable to the official mirror address: `https://tiup-mirrors`  
↪ `.pingcap.com`.
- Make sure that the `TIUP_MIRRORS` variable is not set, and then execute the `tiup`  
↪ `mirror set https://tiup-mirrors.pingcap.com` command.

### 13.4.5.2 How do I put my own component into the TiUP mirrors?

TiUP does not support third-party components for the time being, but the TiUP Team has developed the TiUP component development specifications and is developing the `tiup-publish` component. After everything is ready, a contributor can publish their own components to TiUP's official mirrors by using the `tiup publish <comp> <version>` command.

### 13.4.5.3 What is the difference between the TiUP playground and TiUP cluster components?

The TiUP playground component is mainly used to build a stand-alone development environment on Linux or macOS operating systems. It helps you get started quickly and run a specified version of the TiUP cluster easily. The TiUP cluster component is mainly used to deploy and maintain a production environment cluster, which is usually a large-scale cluster.

### 13.4.5.4 How do I write the topology file for the TiUP cluster component?

Refer to [these templates](#) to write the topology file. The templates include:

- Multi-DC deployment topology
- Minimal deployment topology
- Complete topology file

You can edit your topology file based on the templates and your needs.

#### 13.4.5.5 Can multiple instances be deployed on the same host?

You can use the TiUP cluster component to deploy multiple instances on the same host, but with different ports and directories configured; otherwise, directory and port conflicts might occur.

#### 13.4.5.6 Are port and directory conflicts detected within the same cluster?

Port and directory conflicts in the same cluster are detected during deployment and scaling. If there is any directory or port conflict, the deployment or scaling process is interrupted.

#### 13.4.5.7 Are port and directory conflicts detected among different clusters?

If multiple different clusters are deployed by the same TiUP control machine, the port and directory conflicts among these clusters are detected during deployment and scaling. If the clusters are deployed by different TiUP control machines, conflict detection is not supported currently.

#### 13.4.5.8 During cluster deployment, TiUP received an `ssh: handshake failed: read tcp 10.10.10.34:38980 -> 10.10.10.34:3600: read: connection reset by peer error`

The error might occur because the default number of concurrent threads of TiUP exceeds the default maximum number of SSH connections. To solve the issue, you can increase the default number of SSH connections, and then restart the `sshd` service:

```
vi /etc/ssh/sshd_config
```

```
MaxSessions 1000
MaxStartups 1000
```

### 13.4.6 TiUP Troubleshooting Guide

This document introduces some common issues when you use TiUP and the troubleshooting methods. If this document does not include the issues you bump into, [file a new issue](#) in the Github TiUP repository.

#### 13.4.6.1 Troubleshoot TiUP commands

##### 13.4.6.1.1 Can't see the latest component list using `tiup list`

TiUP does not update the latest component list from the mirror server every time. You can forcibly refresh the component list by running `tiup list`.

#### 13.4.6.1.2 Can't see the latest version information of a component using `tiup list <component>`

Same as the previous issue, the component version information is only obtained from the mirror server when there is no local cache. You can refresh the component list by running `tiup list <component>`.

#### 13.4.6.1.3 Component downloading process is interrupted

Unstable network might result in an interrupted component downloading process. You can try to download the component again. If you cannot download it after trying multiple times, it might be caused by the CDN server and you can report the issue [here](#).

#### 13.4.6.1.4 A checksum error occurs during component downloading process

Because the CDN server has a short cache time, the new checksum file might not match the component package. Try to download again after 5 minutes. If the new checksum file still does not match the component package, report the issue [here](#).

### 13.4.6.2 Troubleshoot TiUP cluster component

#### 13.4.6.2.1 unable to authenticate, attempted methods [none publickey] is prompted during deployment

During deployment, component packages are uploaded to the remote host and the initialization is performed. This process requires connecting to the remote host. This error is caused by the failure to find the SSH private key to connect to the remote host.

To solve this issue, confirm whether you have specified the private key by running `tiup`  
↪ `cluster deploy -i identity_file`:

- If the `-i` flag is not specified, it might be that TiUP does not automatically find the private key path. It is recommended to explicitly specify the private key path using `-i`.
- If the `-i` flag is specified, it might be that TiUP cannot log in to the remote host using the specified private key. You can verify it by manually executing the `ssh -i`  
↪ `identity_file user@remote` command.
- If a password is used to log in to the remote host, make sure that you have specified the `-p` flag and entered the correct login password.

#### 13.4.6.2.2 The process of upgrading the cluster using the TiUP cluster component is interrupted

To avoid misuse cases, the TiUP cluster component does not support the upgrade of specified nodes, so after the upgrade fails, you need to perform the upgrade operations again, including idempotent operations during the upgrade process.

The upgrade process can be divided into the following steps:

1. Back up the old version of components on all nodes
2. Distribute new components to remote
3. Perform a rolling restart to all components

If the upgrade is interrupted during a rolling restart, instead of repeating the `tiup cluster upgrade` operation, you can use `tiup cluster restart -N <node1> -N <node2>` to restart the nodes that have not completed the restart.

If the number of un-restarted nodes of the same component is relatively large, you can also restart a certain type of component by running `tiup cluster restart -R <component>`.

#### 13.4.6.2.3 During the upgrade, you find that `node_exporter-9100.service/blackbox_exporter` does not exist

If you previously migrated your cluster from TiDB Ansible and the exporter was not deployed in TiDB Ansible, this situation might happen. To solve it, you can manually copy the missing files from other nodes to the new node for the time being. The TiUP team will complete the missing components during the migration process.

### 13.4.7 Command Reference

#### 13.4.7.1 TiUP Reference

TiUP serves as the package manager of the TiDB ecosystem. It manages components in the TiDB ecosystem, such as TiDB, PD, and TiKV.

##### 13.4.7.1.1 Syntax

```
tiup [flags] <command> [args...] # Executes a command
or
tiup [flags] <component> [args...] # Runs a component
```

You can use the `--help` command to get the information of a specific command. The summary of each command shows its parameters and their usage. Mandatory parameters are shown in angle brackets, and optional parameters are shown in square brackets.

`<command>` represents the command name. For the list of supported commands, see the [Command list](#) below. `<component>` represents the component name. For the list of supported components, see the [Component list](#) below.

### 13.4.7.1.2 Options

`-binary`

- If you enable this option, the specified binary file path is printed.
  - Executing `tiup --binary <component>` will have the path of the latest stable installed `<component>` component printed. If `<component>` is not installed, an error is returned.
  - Executing `tiup --binary <component>:<version>` will have the path of the installed `<component>` component's `<version>` printed. If this `<version>` is not printed, an error is returned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

#### Note:

This option can only be used in commands of the `tiup [flags] <component ↵>` `<component ↵>` `[args...]` format.

`-binpath`

#### Note:

This option can only be used in commands of the `tiup [flags] <component ↵>` `<component ↵>` `[args...]` format.

- Specifies the path of the component to be executed. When a component is executed, if you do not want to use the binary file in the TiUP mirror, you can add this option to specify using the binary file in a custom path.
- Data type: `STRING`

`-T, -tag`

- Specifies a tag for the component to be started. Some components need to use disk storage during the execution, and TiUP allocates a temporary storage directory for this execution. If you want TiUP to allocate a fixed directory, you can use `-T/--tag` to specify the name of the directory, so that the same batch of files can be read and written in multiple executions with the same tag.
- Data type: `STRING`

`-v, --version`

Prints the TiUP version.

`-help`

Prints the help information.

### 13.4.7.1.3 Command list

TiUP has multiple commands, and these commands have multiple sub-commands. For the specific commands and their detailed descriptions, click the corresponding links in the list below:

- [install](#): Installs a component.
- [list](#): Shows the component list.
- [uninstall](#): Uninstalls a component.
- [update](#): Updates the installed component.
- [status](#): Shows the running status of a component.
- [clean](#): Cleans the data directory of a component.
- [mirror](#): Manages the mirror.
- [telemetry](#): Enables or disables the telemetry.
- [completion](#): Completes the TiUP command.
- [env](#): Shows the TiUP-related environment variables.
- [help](#): Shows the help information of a command or component.

### 13.4.7.1.4 Component list

- [cluster](#): Manages the TiDB cluster in a production environment.
- [dm](#): Manages the TiDB Data Migration (DM) cluster in a production environment.

## 13.4.7.2 TiUP Commands

### 13.4.7.2.1 tiup clean

The `tiup clean` command is used to clear the data generated during component operation.

Syntax

```
tiup clean [name] [flags]
```

The value of [name] is the Name field output by the `status` command. If [name] is omitted, you must add the `--all` option in the `tiup clean` command.

Option

`--all`

- Clears all operation records
- Data type: Boolean
- Default: false

Output

```
Clean instance of `%s`, directory: %s
```

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.2 tiup completion

To reduce user costs, TiUP provides the `tiup completion` command to generate a configuration file for automatic command-line completion. Currently, TiUP supports completing `bash` and `zsh` commands.

If you want to complete `bash` commands, you need to install `bash-completion` first. See the following instructions:

- On macOS: If your `bash` version is earlier than 4.1, run `brew install bash-completion`; otherwise, run `brew install bash-completion@2`.
- On Linux: Use a package manager to install `bash-completion`. For example, run `yum install bash-completion` or `apt install bash-completion`.

Syntax

```
tiup completion <shell>
```

`<shell>` is used to set the type of shell you use. Currently, `bash` and `zsh` are supported.

Usage

`bash`

Write the `tiup completion bash` command into a file and source the file in `.bash_profile`. See the following example:

```
tiup completion bash > ~/.tiup.completion.bash

printf "
tiup shell completion
source '$HOME/.tiup.completion.bash'
" >> $HOME/.bash_profile

source $HOME/.bash_profile
```

zsh

```
tiup completion zsh > "${fpath[1]}/_tiup"
```

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.3 tiup env

TiUP provides users with flexible and customized interfaces, some of which are implemented using environment variables. The `tiup env` command is used to query the user-defined environment variables that TiUP supports and their values.

Syntax

```
tiup env [name1...N]
```

[name1...N] is used to view the specified environment variables. If it is not specified, all supported environment variables are viewed by default.

Option

None

Output

- If [name1...N] is not specified, a list of “{key}”=“{value}” is output.
- If [name1...N] is specified, the “{value}” list is output in order.

In the above output, if value is empty, it means that the value of the environment variable is not set. In this case, TiUP uses the default value.

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.4 tiup help

The TiUP command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option.

Syntax

```
tiup help [command]
```

[command] is used to specify the help information of which command that users need to view. If it is not specified, the help information of TiUP is viewed.

Option

None

Output

The help information of [command] or TiUP.

[<< Back to the previous page - TiUP Reference command list](#)

#### 13.4.7.2.5 tiup install

The `tiup install` command is used for component installation. It downloads the component package of a specified version from the mirror repository and decompresses it in the local TiUP data directory for later use. In addition, when TiUP needs to run a component that does not exist in the mirror repository, it tries to download the component first and then runs it automatically. If the component does not exist in the repository, an error is reported.

Syntax

```
tiup install <component1>[:version] [component2...N] [flags]
```

<component1> and <component2> represent component names, and [version] represents an optional version number. If `version` is not added, the latest stable version of the specified component is installed. [component2...N] means that you can specify multiple components or multiple versions of the same component at the same time.

Option

None

Output

- Normally outputs the download information of the component.
- If the component does not exist, the `The component "%s" not found` error is reported.
- If the version does not exist, the `version %s not supported by component %s` error is reported.

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.6 tiup list

The command `tiup list` is used to get the list of available components of a mirror.

Syntax

```
tiup list [component] [flags]
```

[component] is an optional parameter used to specify a certain component. If [component] is set, TiUP lists all versions of the specified component; if not, TiUP lists all components.

Options

`-all`

- Displays all components. By default, TiUP does not show hidden components.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-installed`

- Only displays components and versions that have been installed.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-verbose`

- Displays installed component versions in the components list.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

Outputs

- If [component] is not set:
  - If `--verbose` is specified: TiUP outputs a component information list consisting of **Name** (component name), **Installed** (installed versions), **Owner** (component owner), and **Description** (component description).

- If `--verbose` is not specified: TiUP outputs a component information list consisting of **Name** (component name), **Owner** (component owner), and **Description** (component description).
- If `[component]` is set:
  - If the specified component exists: TiUP outputs a version information list of the specified component, consisting of **Version** (version number), **Installed** (installation status), **Release** (release date), and **Platforms** (supported platforms).
  - If the specified component does not exist: TiUP reports the error `failed to ↪ fetch component: unknown component`.

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.7 tiup mirror

tiup mirror

In TiUP, **mirror** is an important concept. TiUP currently supports two forms of mirroring:

- **Local mirror**: the TiUP client and the mirror are on the same machine, and the client accesses the mirror through the file system.
- **Remote mirror**: the TiUP client and the mirror are not on the same machine, and the client accesses the mirror through network.

The `tiup mirror` command is used to manage mirrors and provides ways to create mirrors, distribute components, and manage keys.

Syntax

```
tiup mirror <command> [flags]
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the [command list](#) below.

Option

None

Command list

- **genkey**: generates the private key file
- **sign**: signs a specific file using a private key file
- **init**: initiates an empty mirror
- **set**: sets the current mirror
- **grant**: grants a new component owner for the current mirror
- **publish**: publishes new components to the current mirror

- **modify**: modifies the attributes of the components in the current mirror
- **rotate**: updates the root certificate in the current mirror
- **clone**: clones a new mirror from an existing one
- **merge**: merges mirrors

[<< Back to the previous page - TiUP Reference command list](#)

tiup mirror clone

The command `tiup mirror clone` is used to clone an existing mirror or clone some of its components to create a new mirror. The new mirror has the same components as the old one, but uses a different signature key.

Syntax

```
tiup mirror clone <target-dir> [global version] [flags]
```

- `<target-dir>` is used to set the local path to the cloned mirror. If the path does not exist, TiUP automatically creates one.
- If `[global version]` is specified, TiUP tries to clone all components of the specified version. If some components do not have the specified version, then TiUP clones its latest version.

Options

`-f, -full`

- Whether to clone the whole mirror. If this option is set, other options becomes ignored and TiUP completely clones all components of all versions from the targeted mirror.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-a, -arch`

- Only clones components that can run on the specified platform.
- Data type: **STRING**
- Default: “amd64,arm64”

`-o, -os`

- Only clones components that can run on the specified operating system.
- Data type: **STRING**
- Default: “linux,darwin”

-prefix

- Whether to only match the prefix of versions. By default, TiUP downloads a component version when it is strictly matched. If this option is set, TiUP also downloads component versions of which prefixes are matched.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-{component}

- Specifies the version list of the component to be cloned. Fill component names in `{component}`. You can run `tiup list --all` to view available component names.
- Data type: Strings
- Default: Null

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror genkey`

TiUP `mirror`, according its definition, has three roles of users:

- Mirror administrators: They have the permission to modify `root.json`, `index.json`, `snapshot.json`, and `timestamp.json`.
- Component owners: They have the permission to modify the corresponding component.
- Normal users: They can download and use the components.

Because TiUP requires the signature of the corresponding owner/administrator to modify a file, owners/administrators must have his or her own private key. The command `tiup ↪ mirror genkey` is used to generate a private key.

### **Warning:**

**DO NOT** transmit private keys over the Internet.

Syntax

```
tiup mirror genkey [flags]
```

Options

-n, -name

- Specifies the name of the key, which also determines the name of the final generated file. The path of the generated private key file is `${TIUP_HOME}/keys/{name}.json`. `TIUP_HOME` refers to the home directory of TiUP, which is `$HOME/.tiup` by default. `name` refers to the private key name that `-n/--name` specifies.
- Data type: `STRING`
- Default: “private”

#### `-p, --public`

- Shows the corresponding public key of the private key specified in the option `-n/--name`.  
↪ `name`.
- TiUP does not create a new private key when `-p/--public` is specified. If the private key specified in `-n/--name` does not exist, TiUP returns an error.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

#### `--save`

- Saves the information of the public key as a file in the current directory. The file name is `{hash-prefix}-public.json`. `hash-prefix` is the first 16 bits of the key ID.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

#### Outputs

- If `-p/--public` is not specified:
  - If the private key specified in `-n/--name` exists: TiUP outputs `Key already`  
↪ `exists, skipped`.
  - If the private key specified in `-n/--name` does not exist: TiUP outputs `private`  
↪ `key have been write to ${TIUP_HOME}/keys/{name}.json`.
- If `-p/--public` is specified:
  - If the private key specified in `-n/--name` does not exist: TiUP reports the error `Error: open ${TIUP_HOME}/keys/{name}.json: no such file or`  
↪ `directory`.
  - If the private key specified in `-n/--name` exists: TiUP outputs the content of the corresponding public key.

[<< Back to the previous page - TiUP Mirror command list](#)

tiup mirror grant

The `tiup mirror grant` command is used to introduce a component owner to the current mirror.

Component owners can use their keys to publish new components or to modify components they previously published. Before adding a new component owner, the component owner to be added needs to send his or her own public key to the mirror administrator.

#### Note:

This command is only supported when the current mirror is a local mirror.

#### Syntax

```
tiup mirror grant <id> [flags]
```

`<id>` stands for the component owner's ID, which must be unique in the whole mirror. It is recommended to use an ID that matches the regular expression `^[a-z\d](?:[a-z\d]|\u2013|_|(?=[a-z\d])){0,38}$`.

#### Options

`-k, -key`

- Specifies the key of the introduced component owner. This key can either be public or private. If it is a private key, TiUP converts it to the corresponding public key before storing it in the mirror.
- A key can be used by only one component owner.
- Data type: `STRING`
- Default: “`${TIUP_HOME}/keys/private.json`”

`-n, -name`

- Specifies the name of the component owner. The name is displayed on the `Owner` field of the component list. If `-n/--name` is not specified, `<id>` is used as the component owner's name.
- Data type: `STRING`
- Default: `<id>`

#### Outputs

- If the command is executed successfully, there is no output.

- If the component owner's ID is duplicated, TiUP reports the error `Error: owner %s ↪ exists.`
- If the key is used by another component owner, TiUP reports the error `Error: key ↪ %s exists.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror init`

The command `tiup mirror init` is used to initialize an empty mirror. The initialized mirror does not contain any components or component owners. The command only generates the following files for the initialized mirror:

```
+ <mirror-dir> # Mirror's root directory
|-- root.json # Mirror's root certificate
|-- 1.index.json # Component/user index
|-- snapshot.json # Mirror's latest snapshot
|-- timestamp.json # Mirror's latest timestamp
|--+ keys # Mirror's private key (can be
 ↪ moved to other locations)
 |-- {hash1..hashN}-root.json # Private key of the root
 ↪ certificate
 |-- {hash}-index.json # Private key of the indexes
 |-- {hash}-snapshot.json # Private key of the snapshots
 |-- {hash}-timestamp.json # Private key of the timestamps
```

For the specific usage and content format of the above files, refer to [TiUP Mirror Reference Guide](#).

Syntax

```
tiup mirror init <path> [flags]
```

`<path>` is used to specify a local directory where TiUP generates and stores mirror files. The local directory can be a relative path. If the specified directory already exists, it must be empty; if it does not exist, TiUP creates it automatically.

Options

`-k, -key-dir`

- Specifies the directory where TiUP generates private key files. If the specified directory does not exist, TiUP automatically creates it.
- Data type: `STRING`
- If this option is not specified in the command, TiUP generates private key files in `{path}/keys` by default.

Outputs

- If the command is executed successfully, there is no output.
- If the specified <path> is not empty, TiUP reports the error `Error: the target path ↪ '%s' is not an empty directory.`
- If the specified <path> is not a directory, TiUP reports the error `Error: fdopendir: ↪ not a directory.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror merge`

The `tiup mirror merge` command is used to merge one or more mirrors to the current mirror.

To execute this command, the following conditions must be met:

- The owner IDs of all components of the target mirror exist in the current mirror.
- The `/${TIUP_HOME}/keys` directory of the user who executes this command contains all the private keys corresponding to the above owner IDs in the current mirror (you can use the command `tiup mirror set` to switch the current mirror to the mirror that is currently authorized to modify).

Syntax

```
tiup mirror merge <mirror-dir-1> [mirror-dir-N] [flags]
```

- `<mirror-dir-1>`: the first mirror to be merged into the current mirror
- `[mirror-dir-N]`: the Nth mirror to be merged into the current mirror

Option

None

Outputs

- If the command is executed successfully, there is no output.
- If the current mirror does not have a component owner of the target mirror, or if `/${TIUP_HOME}/keys` does not have the owner's private key, TiUP reports the `Error: ↪ missing owner keys for owner %s on component %s error.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror modify`

The `tiup mirror modify` command is used to modify published components. Only valid component owners can modify the components that they have published on their own. For the method to publish a component, refer to the [publish command](#).

Syntax

```
tiup mirror modify <component>[:version] [flags]
```

Each parameter is explained as follows:

- **<component>**: the component name
- **[version]**: the component version to modify. If it is not specified, the entire component is modified.

Options

**-k, -key**

- Specifies the component owner's private key used for signing the component information (`{component}.json`).
- Data type: **STRING**
- If this option is not specified in the command, "`#{TIUP_HOME}/keys/private.json`" is used by default to sign the component information.

**-yank**

Marks a specified component or version as unavailable.

- After the component is marked as unavailable, you can neither see it in the result list of `tiup list` nor install the new version of the component.
- After a component version is marked as unavailable, you can neither see it in the result list of `tiup list <component>` nor install this version.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

**-hide**

- Specifies whether to hide the component. If a component is hidden, you cannot see it in the result list of `tiup list`. To see the hidden component, you can use `tiup list ↪ --all`.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

**Note:**

This option can only be applied to the component, not to the component version.

–standalone

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

**Note:**

This option can only be applied to the component, not to the component version.

## Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
  - If the mirror is a remote mirror, TiUP reports the error `Error: The server ↪ refused, make sure you have access to this component.`
  - If the mirror is a local mirror, TiUP reports the error `Error: the signature ↪ is not correct.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror publish`

The command `tiup mirror publish` is used to publish a new component or a new version of an existing component. Only component owner that has the access to the target component can publish it. To add a new component owner, see the usage of the [grant command](#).

Syntax

```
tiup mirror publish <comp-name> <version> <tarball> <entry> [flags]
```

The meaning of each parameter is as follows:

- **<comp-name>**: The name of the components, such as `tidb`. It is recommended to use a string that matches the regular expression `^[a-z\d](?:[a-z\d]|-(?=[a-z\d])|↔){0,38}$`.
- **<version>**: The version of the component to be published. The version number needs to follow the requirements of [Semantic Versioning](#).
- **<tarball>**: The local directory of the `.tar.gz` package. You need to put dependencies and the executable file of the component in this package. TiUP uploads this package to the mirror.
- **<entry>**: The location of the component's executable file in `<tarball>`.

### Options

`-k, --key`

- Specifies the component owner's private key. The client uses the private key to sign `{component}.json` files.
- Data type: `STRING`
- Default: `"${TIUP_HOME}/keys/private.json"`

`--arch`

- Specifies the platform on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the platform from the following options:
  - `amd64`: Indicates that the files run on AMD64 machines.
  - `arm64`: Indicates that the files run on ARM64 machines.
  - `any`: Indicates that the files, such as scripts, run on both AMD64 and ARM64 machines.
- Data type: `STRING`
- Default: `"${GOARCH}"`

### Note:

If `--arch` is set to `any`, then `--os` must be set to `any` as well.

`--os`

- Specifies the operating system on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the operating system from the following options:
  - `linux`: Indicates that the files run on the Linux operating system.
  - `darwin`: Indicates that the files run on the Darwin operating system.
  - `any`: Indicates that the files, such as scripts, run on both the Linux and Darwin operating systems.
- Data type: `STRING`
- Default: “`${GOOS}`”

#### Note:

If `--os` is set to `any`, then `--arch` must be set to `any` as well.

#### `-desc`

- Specifies the description of the component.
- Data type: `String`
- Default: `NULL`

#### `-hide`

- Specifies whether the component is hidden. If it is a hidden component, it can be seen in the result list of `tiup list -all`, but not in that of `tiup list`.
- Data type: `STRING`
- Default: `NULL`

#### `-standalone`

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

#### Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
  - If the mirror is a remote mirror, TiUP reports the error `Error: The server ↪ refused, make sure you have access to this component.`
  - If the mirror is a local mirror, TiUP reports the error `Error: the signature ↪ is not correct.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror rotate`

`root.json` is an important file in a TiUP mirror. It stores the public keys needed for the entire system and is the basis of the chain of trust in TiUP. It mainly contains the following parts:

- Signatures of mirror administrators. For the official mirror, there are five signatures. For an initialized mirror, there are three signatures by default.
- The public keys used to verify the following files:
  - `root.json`
  - `index.json`
  - `snapshot.json`
  - `timestamp.json`
- Expiration date of `root.json`. For the official mirror, the expiration date is one year later than the creation date of `root.json`.

For detailed description of TiUP mirror, see [TiUP Mirror Reference](#).

You need to update `root.json` in the following cases:

- Replace the key of the mirror.
- Update the expiration date of certificate files.

After the content of `root.json` is updated, the file must be re-signed by all administrators; otherwise, the client rejects the file. The update process is as follows:

1. The user (client) updates the content of `root.json`.
2. All administrators sign the new `root.json` file.
3. `tiup-server` updates `snapshot.json` to record the version of the new `root.json` file.
4. `tiup-server` signs the new `snapshot.json` file.
5. `tiup-server` updates `timestamp.json` to record the hash value of the new `snapshot.json` file.
6. `tiup-server` signs the new `timestamp.json` file.

TiUP uses the command `tiup mirror rotate` to automate the above process.

**Note:**

- For TiUP versions earlier than v1.5.0, running this command does not return a correct new `root.json` file. See [#983](#).
- Before using this command, make sure that all TiUP clients are upgraded to v1.5.0 or a later version.

## Syntax

```
tiup mirror rotate [flags]
```

After executing this command, TiUP starts an editor for the user to modify the file content to the target value, such as changing the value of the `expires` field to a later date. Then, TiUP changes the `version` field from `N` to `N+1` and saves the file. After the file is saved, TiUP starts a temporary HTTP server and waits for all mirror administrators to sign the file.

For how mirror administrators sign files, refer to the [sign command](#).

## Options

`-addr`

- Specifies the listening address of the temporary server. You need to make sure that the address is accessible to other mirror administrators so that they can use the [sign command](#) to sign the file.
- Data type: `STRING`
- If this option is not specified in the command, TiUP listens on `0.0.0.0:8080` by default.

## Outputs

The current signature status of each mirror administrator.

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror set`

The `tiup mirror set` command is used to switch the current mirror and supports two forms of mirrors: local file system and remote network address.

The address of the official mirror is <https://tiup-mirrors.pingcap.com>.

## Syntax

```
tiup mirror set <mirror-addr> [flags]
```

<mirror-addr> is the mirror address, which has two forms:

- Network address: starts with `http` or `https`. For example, `http://172.16.5.5:8080`, `https://tiup-mirrors.pingcap.com`.
- Local file path: the absolute path of the mirror directory. For example, `/path/to/`  
↪ `local-tiup-mirror`.

Option

`-r, -root`

This option specifies the root certificate.

As the most critical part of mirror security, the root certificate of each mirror is different from one another. When you use the network mirror, it might suffer from man-in-the-middle attacks. To avoid such attacks, it is recommended to manually download the root certificate of the root network mirror to the local:

```
wget <mirror-addr>/root.json -O /path/to/local/root.json
```

Perform a manual check to ensure that the root certificate is correct, and then switch the mirror by manually specifying the root certificate:

```
tiup mirror set <mirror-addr> -r /path/to/local/root.json
```

In the steps above, if the mirror is attacked before the `wget` command, you can find that the root certificate is incorrect. If the mirror is attacked after the `wget` command, TiUP will find that the mirror does not match the root certificate.

- Data type: `String`
- Default: `{mirror-dir}/root.json`

Output

None

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror sign`

The `tiup mirror sign` command is used to sign the metadata files (\*.json) defined in TiUP `mirror`. These metadata files might be stored on the local file system or remotely stored using the HTTP protocol to provide a signature entry.

Syntax

```
tiup mirror sign <manifest-file> [flags]
```

<manifest-file> is the address of the file to be signed, which has two forms:

- Network address, which starts with HTTP or HTTPS, such as `http://172.16.5.5:8080/rotate/root.json`
- Local file path, which is a relative path or an absolute path

If it is a network address, this address must provide the following features:

- Supports the access via `http get` that returns the complete content of the signed file (including the `signatures` field).
- Supports the access via `http post`. The client adds the signature to the `signatures` field of the content that is returned by `http get` and posts to this network address.

### Options

`-k, -key`

- Specifies the location of the private key used for signing the `{component}.json` file.
- Data type: `STRING`
- - If this option is not specified in the command, `"${TIUP_HOME}/keys/private.json"` is used by default.

`-timeout`

- Specifies the access timeout time for signing through the network. The unit is in seconds.
- Data type: `INT`
- Default: 10

### Note:

This option is valid only when `<manifest-file>` is a network address.

### Output

- If the command is executed successfully, there is no output.
- If the file has been signed by the specified key, TiUP reports the error `Error: this manifest file has already been signed by specified key.`
- If the file is not a valid manifest, TiUP reports the error `Error: unmarshal manifest : %s.`

[<< Back to the previous page - TiUP Mirror command list](#)

### 13.4.7.2.8 tiup status

The `tiup status` command is used to view the operation information of the components after you run the components using the `tiup [flags] <component> [args...]` command.

#### Note:

You can only check the information of the following components:

- Components that are still in operation
- Components that run through the tag specified by `tiup -T/--tag`

#### Syntax

```
tiup status [flags]
```

#### Option

None

#### Output

A table consisting of the following fields:

- **Name:** The tag name specified by `-T/--tag`. If not specified, it is a random string.
- **Component:** The operating components.
- **PID:** The corresponding process ID of the operating components.
- **Status:** The status of the operating components.
- **Created Time:** The starting time of the components.
- **Directory:** The data directory of the components.
- **Binary:** The binary file path of the components.
- **Args:** The starting arguments of the operating components.

#### Component status

A component can run in one of the following statuses:

- **Up:** The component is running normally.
- **Down or Unreachable:** The component is not running or a network problem exists on the corresponding host.
- **Tombstone:** The data on the component has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- **Pending Offline:** The data on the component is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- **Unknown:** The running status of the component is unknown.

**Note:**

Pending `Offline` in TiUP, `Offline` returned by PD API, and `Leaving` in TiDB Dashboard indicate the same status.

Component status derives from the PD scheduling information. For more details, see [Information collection](#).

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.9 tiup telemetry

Starting from v1.11.3, the telemetry is disabled by default in newly deployed TiUP, and usage information is not collected and shared with PingCAP. In versions earlier than v1.11.3, the telemetry is enabled by default in TiUP, and usage information is collected and shared with PingCAP to improve the product.

When TiUP telemetry is enabled, usage information is shared with PingCAP when TiUP commands are executed, including (but not limited to):

- Randomly generated telemetry identifiers.
- The execution status of the TiUP command, such as whether the command execution is successful and the duration of command execution.
- Situations using TiUP for deployment, such as target machine hardware information, component version number, and modified deployment configuration name.

The information below is not shared:

- The accurate name of the cluster
- The cluster topology
- The cluster configuration file

TiUP uses the `tiup telemetry` command to control telemetry.

Syntax

```
tiup telemetry <command>
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the [commands](#) section below.

Commands

`status`

The `tiup telemetry status` command is used to view the current telemetry settings and output the following information:

- **status**: specifies enabling or disabling the telemetry (**enable|disable**).
- **uuid**: specifies the randomly generated telemetry identifiers.

reset

The `tiup telemetry reset` command is used to reset the current telemetry identifier and replaces it with a new random identifier.

enable

The `tiup telemetry enable` command is used to enable the telemetry.

disable

The `tiup telemetry disable` command is used to disable the telemetry.

[<< Back to the previous page - TiUP Reference command list](#)

#### 13.4.7.2.10 tiup uninstall

The `tiup uninstall` command is used to uninstall the installed components.

Syntax

```
tiup uninstall <component1>:<version> [component2...N] [flags]
```

- **<component1>**: the name of the component to uninstall.
- **<version>**: the version to uninstall. If this field is omitted, all installed versions of the component are uninstalled. For security reasons, the `--all` option must be added when **<version>** is omitted, indicating that all versions of a component need to be uninstalled.
- **[component2...N]**: multiple components or versions to uninstall.

Options

`-all`

- Uninstalls all installed versions of the specified component(s). You must use this option when **<version>** is omitted.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-self`

- Uninstalls TiUP itself. When this option is used, all data downloaded from the mirror is deleted, but the data generated by TiUP and its components is retained. The data is stored in the directory specified by the `TIUP_HOME` environment variable. If `TIUP_HOME` is not set, the default value is `~/.tiup/`.

- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

## Outputs

- If the command exits without any error, `Uninstalled component "%s" successfully`  
↪ `!` is output.
- If neither `<version>` nor `--all` is specified, the Use `"tiup uninstall tidbx --all`  
↪ `"` if you want to remove all versions. error is reported.

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.2.11 tiup update

The `tiup update` command is used to update the installed components or TiUP itself.

#### Syntax

```
tiup update [component1][:version] [component2..N] [flags]
```

- `[component1]`: the name of the component to update.
- `[version]`: the version to update. If this field is omitted, it means updating to the latest stable version of the component.
- `[component2..N]`: specifies updating multiple components or versions. If no component is specified, which means `[component1][:version] [component2..N]` is empty, you need to use the `--all` or the `--self` option together.

The update operation does not delete the old version. You can still specify using the old version during execution.

#### Options

`-all`

- If no component is specified, this option must be specified.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-force`

- If the specified version of the component is already installed, the update operation is skipped by default. Specifying this option will have the installed version forcibly updated.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-nightly`

- Updates the specified components to the nightly version. The `tiup update` command with this option is equivalent to the `tiup update <component>:nightly` command.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-self`

- Updates TiUP itself.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the update is successful, `Updated successfully!` is output.
- If target version does not exist, the `Error: version %s not supported by`  
↪ `component %s` error is reported.

[<< Back to the previous page - TiUP Reference command list](#)

### 13.4.7.3 TiUP Cluster Commands

#### 13.4.7.3.1 TiUP Cluster

TiUP Cluster is a cluster management component of TiUP written in Golang. You can use the TiUP Cluster component to perform daily operations and maintenance, including deploying, starting, shutting down, destroying, elastic scaling, upgrading TiDB clusters, and managing TiDB cluster parameters.

Syntax

```
tiup cluster [command] [flags]
```

[command] is the name of the command. For the supported commands, refer to the [command list](#) below.

#### Options

-ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: `STRING`
- Supported values:
  - `builtin`: uses the `easyssh` client built in `tiup-cluster` as the SSH client.
  - `system`: uses the default SSH client of the current operating system.
  - `none`: The SSH client is not used. The deployment is only for the current machine.
- If this option is not specified in the command, `builtin` is used as the default value.

-ssh-timeout

- Specifies the SSH connection timeout in seconds.
- Data type: `UINT`
- If this option is not specified in the command, the default timeout is 5 seconds.

-wait-timeout

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying `systemctl` to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each step is 120 seconds.

-y, -yes

- Skips the secondary confirmation of all risky operations. Using this option is not recommended, unless you are using a script to call TiUP.

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-v, --version`

- Prints the current version of TiUP Cluster.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h, --help`

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- `import`: imports a cluster deployed by Ansible
- `template`: outputs the topology template
- `check`: checks a cluster before and after the deployment
- `deploy`: deploys a cluster based on a specified topology
- `list`: queries the list of deployed clusters
- `display`: displays the status of a specified cluster
- `start`: starts a specified cluster
- `stop`: stops a specified cluster
- `restart`: restarts a specified cluster
- `scale-in`: scales in a specified cluster
- `scale-out`: scales out a specified cluster
- `upgrade`: upgrades a specified cluster
- `prune`: cleans up the instances in the Tombstone status for a specified cluster
- `edit-config`: modifies the configuration of a specified cluster
- `reload`: reloads the configuration of a specified cluster
- `patch`: replaces a service in a deployed cluster
- `rename`: renames a cluster
- `clean`: deletes data from the specified cluster
- `destroy`: destroys a specified cluster
- `audit`: queries the operation audit log of a specified cluster
- `replay`: retries the specified command
- `enable`: enables the auto-enabling of the cluster service after a machine is restarted
- `disable`: disables the auto-enabling of the cluster service after a machine is restarted
- `meta backup`: backs up the TiUP meta file required for the operation and maintenance of a specified cluster

- **meta restore**: restores the TiUP meta file of a specified cluster
- **help**: prints the help information

[<< Back to the previous page - TiUP Reference component list](#)

### 13.4.7.3.2 tiup cluster audit

The `tiup cluster audit` command is used to view commands executed on all clusters in the history and the execution log of each command.

Syntax

```
tiup cluster audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, it means checking the execution log of the specified `audit-id`.

Option

`-h, -help`

- Prints the help information.
- Data type: **Boolean**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

Outputs

- If `[audit-id]` is specified, the corresponding execution log is output.
- If `[audit-id]` is not specified, a table with the following fields is output:
  - ID: the `audit-id` corresponding to the record
  - Time: the execution time of the command corresponding to the record
  - Command: the command corresponding to the record

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.3 tiup cluster audit cleanup

The `tiup cluster audit cleanup` command is used to clean up the logs generated in executing the `tiup cluster` command.

Syntax

```
tiup cluster audit cleanup [flags]
```

Options

`-retain-days`

- Specifies the days for which logs are retained.
- Data type: `INT`
- Default value: `60`, in the unit of day.
- By default, logs generated within the last 60 days are retained, which means logs generated before 60 days are removed.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

```
clean audit log successfully
```

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.4 tiup cluster check

For a formal production environment, before the environment goes live, you need to perform a series of checks to ensure the clusters are in their best performance. To simplify the manual check steps, TiUP Cluster provides the `check` command to check whether the hardware and software environments of the target machines of a specified cluster meet the requirements to work normally.

List of check items

Operating system version

Check the operating system distribution and version of the deployed machines. Currently, only CentOS 7 is supported for deployment. More system versions may be supported in later releases for compatibility improvement.

## CPU EPOLLEXCLUSIVE

Check whether the CPU of the target machine supports EPOLLEXCLUSIVE.

### numactl

Check whether numactl is installed on the target machine. If tied cores are configured on the target machine, you must install numactl.

### System time

Check whether the system time of the target machine is synchronized. Compare the system time of the target machine with that of the central control machine, and report an error if the deviation exceeds a certain threshold (500 ms).

### System time zone

Check whether the system time zone of the target machines is synchronized. Compare the time zone configuration of these machines and report an error if the time zone is inconsistent.

### Time synchronization service

Check whether the time synchronization service is configured on the target machine. Namely, check whether ntpd is running.

### Swap partitioning

Check whether swap partitioning is enabled on the target machine. It is recommended to disable swap partitioning.

### Kernel parameters

Check the values of the following kernel parameters:

- `net.ipv4.tcp_tw_recycle`: 0
- `net.ipv4.tcp_syncookies`: 0
- `net.core.somaxconn`: 32768
- `vm.swappiness`: 0
- `vm.overcommit_memory`: 0 or 1
- `fs.file-max`: 1000000

### Transparent Huge Pages (THP)

Check whether THP is enabled on the target machine. It is recommended to disable THP.

### System limits

Check the limit values in the `/etc/security/limits.conf` file:

```
<deploy-user> soft nofile 1000000
<deploy-user> hard nofile 1000000
<deploy-user> soft stack 10240
```

`<deploy-user>` is the user who deploys and runs the TiDB cluster, and the last column is the minimum value required for the system.

#### SELinux

Check whether SELinux is enabled. It is recommended to disable SELinux.

#### Firewall

Check whether the Firewalld service is enabled. It is recommended to either disable the Firewalld service or add permission rules for each service in the TiDB cluster.

#### irqbalance

Check whether the irqbalance service is enabled. It is recommended to enable the irqbalance service.

#### Disk mount options

Check the mount options for ext4 partitions. Make sure the mount options include the `nodelalloc` option and the `noatime` option.

#### Port usage

Check if the ports defined in the topology (including the auto-completion default ports) are already used by the processes on the target machine.

#### **Note:**

The port usage check assumes that a cluster is not started yet. If a cluster is already deployed and started, the port usage check on the cluster fails because the ports must be in use in this case.

#### CPU core number

Check the CPU information of the target machine. For a production cluster, it is recommended that the number of the CPU logical core is greater than or equal to 16.

#### **Note:**

CPU core number is not checked by default. To enable the check, you need to add the `-enable-cpu` option to the command.

#### Memory size

Check the memory size of the target machine. For a production cluster, it is recommended that the total memory capacity is greater than or equal to 32GB.

**Note:**

Memory size is not checked by default. To enable the check, you need to add the `-enable-mem` option to the command.

### Fio disk performance test

Use flexible I/O tester (fio) to test the performance of the disk where `data_dir` is located, including the following three test items:

- `fio_randread_write_latency`
- `fio_randread_write`
- `fio_randread`

**Note:**

The fio disk performance test is not performed by default. To perform the test, you need to add the `-enable-disk` option to the command.

### Syntax

```
tiup cluster check <topology.yml | cluster-name> [flags]
```

- If a cluster is not deployed yet, you need to pass the `topology.yml` file that is used to deploy the cluster. According to the content in this file, `tiup-cluster` connects to the corresponding machine to perform the check.
- If a cluster is already deployed, you can use the `<cluster-name>` as the check object.
- If you want to check the scale-out YAML file for an existing cluster, you can use both `<scale-out.yml>` and `<cluster-name>` as the check objects.

**Note:**

If `<cluster-name>` is used for the check, you need to add the `--cluster` option in the command.

### Options

`-apply`

- Attempts to automatically repair the failed check items. Currently, tiup-cluster only attempts to repair the following check items:
  - SELinux
  - firewall
  - irqbalance
  - kernel parameters
  - System limits
  - THP (Transparent Huge Pages)
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

**Note:**

tiup cluster check also supports repairing the `scale-out.yml` file for an existing cluster with the following command format:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --
 ↪ apply --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

–cluster

- Indicates that the check is for a cluster that has been deployed.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.
- Command format:

```
tiup cluster check <topology.yml | cluster-name> --cluster [flags]
```

**Note:**

- If the `tiup cluster check <cluster-name>` command is used, you must add the `--cluster` option: `tiup cluster check <cluster-name> ↪ > --cluster`.

- `tiup cluster check` also supports checking the `scale-out.yml` file for an existing cluster with the following command format:

```
shell tiup cluster check <cluster-name> scale-out.yml --
↪ cluster --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

`-N, --node`

- Specifies the nodes to be checked. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all nodes are checked by default.

**Note:**

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

`-R, --role`

- Specifies the roles to be checked. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all roles are checked by default.

**Note:**

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

`-enable-cpu`

- Enables the check of CPU core number.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

`-enable-disk`

- Enables the fio disk performance test.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

`-enable-mem`

- Enables the memory size check.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

`-u, -user`

- Specifies the user name to connect to the target machine. The specified user needs to have the password-free sudo root privileges on the target machine.
- Data type: **STRING**
- If this option is not specified in the command, the user who executes the command is used as the default value.

**Note:**

This option is valid only if the `-cluster` option is false. Otherwise, the value of this option is fixed to the username specified in the topology file for the cluster deployment.

`-i, -identity_file`

- Specifies the key file to connect to the target machine.
- Data type: **STRING**
- The option is enabled by default with `~/.ssh/id_rsa` (the default value) passed in.

**Note:**

This option is valid only if the `--cluster` option is false. Otherwise, the value of this option is fixed to `${TIUP_HOME}/storage/cluster/clusters ↪ /<cluster-name>/ssh/id_rsa`.

`-p, --password`

- Logs in with a password when connecting to the target machine.
  - If the `--cluster` option is added for a cluster, the password is the password of the user specified in the topology file when the cluster was deployed.
  - If the `--cluster` option is not added for a cluster, the password is the password of the user specified in the `-u/--user` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h, --help`

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

### Output

A table containing the following fields:

- **Node:** the target node
- **Check:** the check item
- **Result:** the check result (Pass, Warn, or Fail)
- **Message:** the result description

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.5 tiup cluster clean

In the test environment, sometimes you might need to reset the cluster back to the state as it has been just deployed, which means deleting all data. You can do that easily using the `tiup cluster clean` command. After running it, the cluster is stopped and then cluster data is deleted. After restarting the cluster manually, you will get a clean cluster.

#### Warning:

This command will first stop the cluster even if you choose only to clean up logs. Therefore, do not use it in a production environment.

#### Syntax

```
tiup cluster clean <cluster-name> [flags]
```

`<cluster-name>` is the cluster to clean.

#### Options

`-all`

- Cleans data and the log at the same time. It is equivalent to specifying `--data` and `--log` at the same time.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.
- If it is not specified, you must specify at least one of the following options:
  - `-data`: Cleans data
  - `-log`: Cleans the log

`-data`

- Cleans data. If neither of it nor `--all` is specified, data will not be cleaned.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-log`

- Cleans the log. If neither of it nor `--all` is specified, the log will not be cleaned.

- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-ignore-node`

- Specifies the node that does not need cleaning. To specify multiple nodes, you can use this option multiple times. For example, `--ignore-node <node-A> --ignore-node ↪ <node-B>`.
- Data type: **StringArray**
- Default: empty

`-ignore-role`

- Specifies the role that does not need cleaning. To specify multiple roles, you can use this option multiple times. For example, `--ignore-role <role-A> --ignore-role ↪ <role-B>`.
- Data type: **StringArray**
- Default: empty

`-h, -help`

- Prints help information.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

Output

The execution logs of `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.6 tiup cluster deploy

The `tiup cluster deploy` command is used to deploy a new cluster.

Syntax

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

- **<cluster-name>**: the name of the new cluster, which cannot be the same as the existing cluster names.

- `<version>`: the version number of the TiDB cluster to deploy, such as `v6.6.0`.
- `<topology.yaml>`: the prepared [topology file](#).

#### Options

`-u, --user`

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

`-i, --identity_file`

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

`-p, --password`

- Specifies the password used to connect to the target machine. Do not use this option with `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`--ignore-config-check`

- This option is used to skip the configuration check. After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration.
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.
- Default: `false`

`--no-labels`

- This option is used to skip the label check.

- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD cannot learn the cluster topology, so PD might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See [Schedule Replicas by Topology Labels](#) for label configuration.
- For the test environment, this risk might matter and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`--skip-create-user`

- During the cluster deployment, `tiup-cluster` checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-h, --help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The deployment log.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.7 `tiup cluster destroy`

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup cluster destroy` command performs the following operations:

- Stops the cluster.

- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by tiup-cluster, also delete the parent directory.

### Syntax

```
tiup cluster destroy <cluster-name> [flags]
```

<cluster-name>: the name of the cluster to destroy.

### Options

-force

- In some cases, some nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to ignore these errors.
- Data type: **Boolean**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

-retain-node-data

- Specifies the nodes that need to retain data. If you need to specify more than one node, use this option multiple times: `--retain-node-data <node-A> --retain-node-data ↪ <node-B>`.
- Data type: **StringArray**
- Default: empty

-retain-role-data

- Specifies the role that needs to retain data. If you need to specify more than one role, use this option multiple times: `--retain-role-data <role-A> --retain-role ↪ -data <role-B>`.
- Data type: **StringArray**
- Default: empty

-h, -help

- Prints the help information.
- Data type: **Boolean**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

### Output

The execution log of the tiup-cluster.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.8 tiup cluster disable

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup cluster disable` command. This command executes `systemctl disable <service>` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup cluster disable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be disabled.

Options

`-N, --node`

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

**Note:**

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

`-R, --role`

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

**Note:**

If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-h, -help

- Prints the help information.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

Output

The execution log of the tiup-cluster.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.9 tiup cluster display

If you want to see the operation status of each component in the cluster, it is obviously inefficient to log in to each machine one by one. Therefore, tiup-cluster provides the **tiup**  $\rightarrow$  **cluster display** command to efficiently complete this task.

Syntax

```
tiup cluster display <cluster-name> [flags]
```

**<cluster-name>**: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

Options

-dashboard

- By default, all node information of the entire cluster is displayed. With the  $\rightarrow$  **dashboard** option, only dashboard information is displayed.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

-N, -node

- Specifies the node to display. If this option is not specified, all nodes are displayed. The value of this option is a comma-separated list of node IDs. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: **STRINGS**
- If this option is not specified in the command, all nodes are checked by default.

**Note:**

If the `-R`, `--role` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are checked.

`-R, --role`

- Specifies the role to display. If it is not specified, all roles are displayed. The value of this option is a comma-separated list of node roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: **STRINGS**
- If this option is not specified in the command, all roles are displayed by default.

**Note:**

If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are displayed.

`--process`

- Displays the CPU and memory usage information of the node when this option is enabled. This option is disabled by default.
- Data type: **BOOLEAN**
- Default value: **false**
- To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`--uptime`

- Displays the **uptime** information of the node when this option is enabled. This option is disabled by default.
- Data type: **BOOLEAN**
- Default value: **false**
- To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-status-timeout`

- Specifies the timeout period for obtaining the node status information.
- Data type: `INT`
- Default value: 10, in the unit of second.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

## Outputs

- The cluster name
- The cluster version
- SSH Client Type
- Dashboard address
- The table with the following fields:
  - ID: the node ID, composed of `IP:PORT`
  - Role: the service role deployed on this node (such as TiDB, TiKV)
  - Host: the IP of the machine corresponding to the node
  - Ports: the port number occupied by the service
  - OS/Arch: the operating system and the machine architecture of this node
  - Status: the current status of the node service
  - Data Dir: the data directory of the service. `-` means no data directory.
  - Deploy Dir: the deployment directory of the service

## Node service status

A node service can run in one of the following statuses:

- Up: The node service is running normally.
- Down or Unreachable: The node service is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the node service has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- Pending Offline: The data on the node service is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- Unknown: The running status of the node service is unknown.

**Note:**

Pending `Offline` in TiUP, `Offline` returned by PD API, and `Leaving` in TiDB Dashboard indicate the same status.

Node service status derives from the PD scheduling information. For more details, see [Information collection](#).

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.10 tiup cluster edit-config

If you need to modify the cluster configuration after the cluster is deployed, you can use the `tiup cluster edit-config` command that starts an editor for you to modify the [topology file](#) of a cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

**Note:**

- When you modify the configuration, you cannot add or delete machines. For how to add machines, see [Scale out a cluster](#). For how to delete machines, see [Scale in a cluster](#).
- After you execute the `tiup cluster edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup cluster reload` command to reload the configuration.

#### Syntax

```
tiup cluster edit-config <cluster-name> [flags]
```

`<cluster-name>` is the cluster to operate on.

#### Option

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

## Output

- If the command is successfully executed, there is no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error will be reported, reminding you to edit the file again. For the fields that cannot be modified, see the [topology file](#).

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.11 tiup cluster enable

The `tiup cluster enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

#### Note:

When all clusters are shut down and restarted, the order of service startup is determined by the node's operating system startup order. When the restart order is incorrect, in some cases, the restarted cluster still cannot provide services. For example, if TiKV is started first but PD is not started, systemd gives up if TiKV is restarted multiple times while PD is not found).

## Syntax

```
tiup cluster enable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be enabled.

## Options

`-N, -node`

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

**Note:**

If the `-R`, `--role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is enabled.

`-R`, `--role`

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

**Note:**

If the `-N`, `--node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is enabled.

`-h`, `--help`

- Prints the help information.
- Data type: **BOOLEAN**
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.12 `tiup cluster help`

`tiup-cluster` provides a wealth of help information for users in the command line interface. You can obtain it via the `help` command or the `--help` option. `tiup cluster help <command>`  $\hookrightarrow$  `command>` is basically equivalent to `tiup cluster <command> --help`.

Syntax

```
tiup cluster help [command] [flags]
```

[command] is used to specify the help information of which command that users need to view. If it is not specified, the help information of tiup-cluster is viewed.

-h, -help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The help information of the [command] or tiup-cluster.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.13 tiup cluster import

Before TiDB v4.0, TiDB clusters were mainly deployed using TiDB Ansible. For TiDB v4.0 and later releases, TiUP Cluster provides the `import` command to transfer the clusters to the tiup-cluster component for management.

#### Note:

- After importing the TiDB Ansible configuration to TiUP for management, **DO NOT** use TiDB Ansible for cluster operations anymore. Otherwise, conflicts might be caused due to inconsistent meta information.
- If the clusters deployed using TiDB Ansible are in any of the following situations, do not use the `import` command.
  - Clusters with TLS encryption enabled
  - Pure KV clusters (clusters without TiDB instances)
  - Clusters with Kafka enabled
  - Clusters with Spark enabled
  - Clusters with TiDB Lightning/TiKV Importer enabled
  - Clusters still using the old `push` mode to collect monitoring metrics (if you keep the default mode `pull` unchanged, using the `import` command is supported)
  - Clusters in which the non-default ports (the ports configured in the `group_vars` directory are compatible) are separately configured in the `inventory.ini` configuration file using `node_exporter_port` / `blackbox_exporter_port`

- If some nodes in the cluster deployed using TiDB Ansible are deployed without monitoring components, you should first use TiDB Ansible to add the corresponding node information in the `monitored_servers` section of the `inventory.ini` file, and then use the `deploy.yaml` playbook to fully deploy monitoring components. Otherwise, when you perform maintenance operations after the cluster is imported into TiUP, errors might occur due to the lack of monitoring components.

## Syntax

```
tiup cluster import [flags]
```

### Options

`-d, -dir`

- Specifies the directory where TiDB Ansible is located.
- Data type: **STRING**
- The option is enabled by default with the current directory (the default value) passed in.

`-ansible-config`

- Specifies the path of the Ansible configuration file.
- Data type: **STRING**
- The option is enabled by default with `./ansible.cfg` (the default value) passed in.

`-inventory`

- Specifies the name of the Ansible inventory file.
- Data type: **STRING**
- The option is enabled by default with `inventory.ini` (the default value) passed in.

`-no-backup`

- Controls whether to disable the backup of files in the directory where TiDB Ansible is located.
- Data type: **BOOLEAN**

- This option is disabled by default with the `false` value. After a successful import, everything in the directory specified by the `-dir` option is backed up to the ``${TIUP_HOME}/.tiup/storage/cluster/clusters/{cluster-name}/ansible-↔ backup` directory. If there are multiple inventory files (when multiple clusters are deployed) in this directory, it is recommended to enable this option. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-rename`

- Renames the imported cluster.
- Data type: `STRING`
- Default: `NULL`. If this option is not specified in the command, the `cluster_name` specified in inventory is used as the cluster name.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the import process.

[<< Back to the previous page - TiUP Cluster command list](#)

#### 13.4.7.3.14 tiup cluster list

`tiup-cluster` supports deploying multiple clusters using the same control machine. The `tiup cluster list` command outputs all clusters deployed by the currently logged-in user using this control machine.

##### Note:

The deployed cluster data is stored in the `~/.tiup/storage/cluster/↔ clusters/` directory by default, so on the same control machine, the currently logged-in user cannot view the clusters deployed by other users.

Syntax

```
tiup cluster list [flags]
```

## Options

-h, -help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

## Outputs

Outputs the table with the following fields:

- Name: the cluster name
- User: the deployment user
- Version: the cluster version
- Path: the path of the cluster deployment data on the control machine
- PrivateKey: the path of the private key that is used to connect the cluster

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.15 tiup cluster meta backup

The TiUP meta file is used for cluster operation and maintenance (OM). If this file is lost, you cannot use TiUP to manage the cluster. To avoid this situation, you can use the `tiup cluster meta backup` command to back up the TiUP meta file regularly.

#### Syntax

```
tiup cluster meta backup <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup dm list` command.

#### Options

-file (string, defaults to the current directory)

Specifies the target directory to store the TiUP meta backup file.

-h, -help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

## Output

The execution logs of `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.16 `tiup cluster meta restore`

To restore the TiUP meta file, you can use the `tiup cluster meta restore` command to restore from the backup file.

#### Syntax

```
tiup cluster meta restore <cluster-name> <backup-file> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on.
- `<backup-file>` is the path to the TiUP meta backup file.

#### Note:

The restore operation overwrites the current meta file. It is recommended to restore the meta file only when it is lost.

## Options

`-h, --help`

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

## Output

The execution logs of `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.17 `tiup cluster patch`

If you need to dynamically replace the binaries of a service while the cluster is running (namely, keep the cluster available during the replacement process), you can use the `tiup cluster patch` command. After the command is executed, TiUP does the following things:

- Uploads the binary package for replacement to the target machine.
- If the target service is a storage service such as TiKV, TiFlash, or TiDB Binlog, TiUP first takes the related nodes offline via the API.
- Stops the target service.
- Unpacks the binary package and replace the service.
- Starts the target service.

## Syntax

```
tiup cluster patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated.
- `<package-path>`: The path to the binary package used for replacement.

## Preparation

Before running the `tiup cluster patch` command, you need to pack the binary package required. Take the following steps:

### 1. Determine the following variables:

- `${component}`: the name of the component to be replaced (such as `tidb`, `tikv`, or `pd`).
- `${version}`: the version of the component (such as `v6.6.0` or `v6.5.1`).
- `${os}`: the operating system (`linux`).
- `${arch}`: the platform on which the component runs (`amd64`, `arm64`).

### 2. Download the current component package using the command:

```
wget https://tiup-mirrors.pingcap.com/${component}-${version}-${os}-${arch}.tar.gz -O /tmp/${component}-${version}-${os}-${arch}.tar.gz
```

### 3. Create a temporary directory to pack files and change to it:

```
mkdir -p /tmp/package && cd /tmp/package
```

### 4. Extract the original binary package:

```
tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz
```

### 5. Check out the file structure in the temporary directory:

```
find .
```

### 6. Copy the binary files or configuration files to their corresponding locations in the temporary directory.

7. Pack all files in the temporary directory:

```
tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *
```

After you have completed the preceding steps, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the `<package-path>` in the `tiup cluster patch` command.

Options

`--overwrite`

- After you patch a certain component (such as TiDB or TiKV), when the `tiup cluster` scales out the component, TiUP uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specify the option `--overwrite` in the command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`--transfer-timeout`

- When restarting the PD or TiKV service, TiKV/PD first transfers the leader of the node to be restarted to another node. Because the transfer process takes some time, you can use the option `--transfer-timeout` to set the maximum waiting time (in seconds). After the timeout, TiUP directly restarts the service.
- Data type: `UINT`
- If this option is not specified, TiUP directly restarts the service after waiting for 600 seconds.

**Note:**

If TiUP directly restarts the service after the timeout, the service performance might jitter.

`-N, --node`

- Specifies nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node ID from the first column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any nodes to replace by default.

**Note:**

If the option `-R`, `--role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-R, --role`

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the role deployed on a node from the second column of the [cluster status table](#) returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any roles to replace by default.

**Note:**

If the option `-N`, `--node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-offline`

- Declares that the current cluster is not running. When the option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h, --help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

## Outputs

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.18 tiup cluster prune

When [scaling in the cluster](#), for some components, TiUP does not immediately stop their services or delete their data. You need to wait for the data scheduling to complete and then manually execute the `tiup cluster prune` command to clean up.

#### Syntax

```
tiup cluster prune <cluster-name> [flags]
```

#### Option

`-h, -help`

- Prints the help information.
- Data type: BOOLEAN
- Default: false

#### Output

The log of the cleanup process.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.19 tiup cluster reload

After [modifying the cluster configuration](#), the cluster needs to be reloaded using the `tiup cluster reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running, and follows the upgrade process to restart the services in order according to the upgrade process. The cluster is still available during the restart process.

#### Syntax

```
tiup cluster reload <cluster-name> [flags]
```

`<cluster-name>`: the cluster name to operate on.

#### Options

`-force`

- Ignores errors in the reloading process and forces reload.
- Data type: BOOLEAN
- Default: false

`-transfer-timeout`

- When restarting PD or TiKV, the leader of the restarted node is migrated to other nodes first, and the migration process takes some time. You can set the maximum wait time (in seconds) by setting `-transfer-timeout`. After the timeout, the service can be restarted directly without waiting.
- Data type: UINT
- Default: 600

**Note:**

In the case of skipping the waiting and restarting directly, the service performance might jitter.

`-ignore-config-check`

- After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration. If you want to skip this check, you can use this option.
- Data type: BOOLEAN
- Default: false

`-N, --node`

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: STRINGS
- If this option is not specified in the command, all nodes are selected by default.

**Note:**

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

`-R, --role`

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. The role is the second column of the `cluster status` table.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

#### Note:

1. If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
2. If the `--skip-restart` option is specified, the `-R, --role` option is invalid.

`--skip-restart`

The `tiup cluster reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: `false`

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.20 tiup cluster rename

The cluster name is specified when [the cluster is deployed](#). If you want to change the cluster name after the cluster is deployed, you can use the command `tiup cluster rename`.

#### Note:

If the `dashboard_dir` field of `grafana_servers` is configured for the TiUP cluster, after you execute the command `tiup cluster rename` to rename the cluster, the following additional steps are required:

- For the `*.json` files in the local dashboards directory, update the `datasource` field of each file to the new cluster name, because the value of `datasource` must be the name of the cluster.
- Execute the command `tiup cluster reload -R grafana`.

#### Syntax

```
tiup cluster rename <old-cluster-name> <new-cluster-name> [flags]
```

- `<old-cluster-name>`: The old cluster name.
- `<new-cluster-name>`: The new cluster name.

#### Options

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

#### Outputs

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.21 tiup cluster replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup cluster replay` command to retry the failed commands and skip the successfully performed steps.

#### Syntax

```
tiup cluster replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-ids` using the `tiup cluster audit` command.

Option

`-h, -help`

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

[<< Back to the previous page - TiUP Cluster command list](#)

#### 13.4.7.3.22 tiup cluster restart

The command `tiup cluster restart` is used to restart all or some of the services of the specified cluster.

##### Note:

During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup cluster restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

Options

`-N, -node`

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

**Note:**

If the option `-R`, `--role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-R, --role`

- Specified the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

**Note:**

If the option `-N`, `--node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-h, --help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.23 tiup cluster scale-in

The `tiup cluster scale-in` command is used to scale in the cluster, which takes the services of the specified nodes offline, removes the specified nodes from the cluster, and deletes the remaining files from those nodes.

Particular handling of components' offline process

Because the TiKV, TiFlash, and TiDB Binlog components are taken offline asynchronously (which requires TiUP to remove the node through API first) and the stopping process takes a long time (which requires TiUP to continuously check whether the node is successfully taken offline), the TiKV, TiFlash, and TiDB Binlog components are handled particularly as follows:

- For TiKV, TiFlash, and TiDB Binlog components:
  1. TiUP Cluster takes the node offline through API and directly exits without waiting for the process to be completed.
  2. To check the status of the nodes being scaled in, you need to execute the `tiup ↪ cluster display` command and wait for the status to become `Tombstone`.
  3. To clean up the nodes in the `Tombstone` status, you need to execute the `tiup ↪ cluster prune` command. The `tiup cluster prune` command performs the following operations:
    - Stops the services of the nodes that have been taken offline.
    - Cleans up the data files of the nodes that have been taken offline.
    - Updates the cluster topology and removes the nodes that have been taken offline.

For other components:

- When taking the PD components offline, TiUP Cluster quickly deletes the specified nodes from the cluster through API, stops the service of the specified PD nodes, and then deletes the related data files from the nodes.
- When taking other components down, TiUP Cluster directly stops the node services and deletes the related data files from the specified nodes.

Syntax

```
tiup cluster scale-in <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to scale in. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

`-N, -node`

- Specifies the nodes to take down. Multiple nodes are separated by commas.
- Data type: `STRING`
- There is no default value. This option is mandatory and the value must be not null.

`-force`

- Controls whether to forcibly remove the specified nodes from the cluster. Sometimes, the host of the node to take offline might be down, which makes it impossible to connect to the node via SSH for operations, so you can forcibly remove the node from the cluster using the `--force` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

### Warning:

When you use this option to forcibly remove TiKV or TiFlash nodes that are in service or are pending offline, these nodes will be deleted immediately without waiting for data to be migrated. This imposes a very high risk of data loss. If data loss occurs in the region where the metadata is located, the entire cluster will be unavailable and unrecoverable.

### `--transfer-timeout`

- When a PD or TiKV node is to be removed, the Region leader on the node will be transferred to another node first. Because the transferring process takes some time, you can set the maximum waiting time (in seconds) by configuring `--transfer-timeout`. After the timeout, the `tiup cluster scale-in` command skips waiting and starts the scaling-in directly.
- Data type: `UINT`
- The option is enabled by default with 600 seconds (the default value) passed in.

### Note:

If a PD or TiKV node is taken offline directly without waiting for the leader transfer to be completed, the service performance might jitter.

### `-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

### Output

Shows the logs of the scaling-in process.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.24 tiup cluster scale-out

The `tiup cluster scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The `tiup-cluster` component first establishes an SSH connection to the new node, creates the necessary directories on the target node, then performs the deployment and starts the service.

When PD is scaled out, new PD nodes are added to the cluster by the join operation, and the configuration of the services associated with PD is updated; other services are directly started and added to the cluster.

#### Syntax

```
tiup cluster scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

`<topology.yaml>`: the prepared `topology file`. This topology file should only contain the new nodes that are to be added to the current cluster.

#### Options

`-u, -user`

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

`-i, -identity_file`

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

`-p, -password`

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: `false`

`-no-labels`

- This option is used to skip the label check.

- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD does not know the cluster topology, so it might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point of failure. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See [Schedule Replicas by Topology Labels](#) for label configuration.
- For the test environment, this risk might not matter, and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- Default: `false`

`--skip-create-user`

- During the cluster deployment, `tiup-cluster` checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`
- Default: `false`

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of scaling out.

[<< Back to the previous page - TiUP Cluster command list](#)

#### 13.4.7.3.25 tiup cluster start

The `tiup cluster start` command is used to start all services or some services of the specified cluster.

Syntax

```
tiup cluster start <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

`--init`

Starts the cluster in a safe way. It is recommended to use this option when the cluster is started for the first time. This method generates the password of the TiDB root user at startup and returns the password in the command line interface.

**Note:**

- After safe start of a TiDB cluster, you cannot log in to the database using the root user without a password. Therefore, you need to record the password returned by the command line for future logins.
- The password is generated only once. If you do not record or forget the password, refer to [Forget the root password](#) to change the password.

**-N, --node**

- Specifies the nodes to be started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the [cluster status table](#) returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started by default.

**Note:**

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

**-R, --role**

- Specifies the roles of nodes to be started. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the [cluster status table](#) returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started by default.

**Note:**

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-h, -help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of starting the service.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.26 tiup cluster stop

The `tiup cluster stop` command is used to stop all services or some services of the specified cluster.

#### Note:

If the core services of a cluster are stopped, the cluster cannot provide services anymore.

Syntax

```
tiup cluster stop <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

-N, -node

- Specifies the nodes to be stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the command stops all the nodes by default.

**Note:**

If the `-R`, `--role` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are stopped.

`-R`, `--role`

- Specifies the roles of nodes to be stopped. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the [cluster status table](#) returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the command stops all the roles by default.

**Note:**

If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are stopped.

`-h`, `--help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

### Output

The log of stopping the service.

[<< Back to the previous page - TiUP Cluster command list](#)

#### 13.4.7.3.27 tiup cluster template

Before deploying the cluster, you need to prepare a [topology file](#) of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup cluster ↪ template` command.

Syntax

```
tiup cluster template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 PD instances
- 3 TiKV instances
- 1 TiDB instance
- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

-full

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

-multi-dc

- Outputs the topology template of multiple data centers. To enable this option, add it to the command.
- If this option is not specified, the topology template of a single data center is output by default.

-h, -help

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

[<< Back to the previous page - TiUP Cluster command list](#)

### 13.4.7.3.28 tiup cluster upgrade

The `tiup cluster upgrade` command is used to upgrade the specified cluster to a specific version.

Syntax

```
tiup cluster upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>`: the cluster name to operate on. If you forget the cluster name, you can check it with the `cluster list` command.
- `<version>`: the target version to upgrade to, such as `v6.5.0`. Currently, it is only allowed to upgrade to a version higher than the current cluster, that is, no downgrade is allowed. It is also not allowed to upgrade to the nightly version.

## Options

`-force`

- To upgrade the cluster, you need to ensure that the cluster is currently started. In some cases, you might want to upgrade when the cluster is not started. At this time, you can use `--force` to ignore the error during the upgrade, forcibly replace the binary file and start the cluster.
- Data type: `BOOLEAN`
- Default: `false`

### Note:

Forcing an upgrade of the cluster that is providing services might result in service unavailability. Unstarted clusters are started automatically after a successful upgrade.

`-transfer-timeout`

- When upgrading PD or TiKV, the leader of the upgraded node is migrated to other nodes first. The migration process takes some time, and you can set the maximum wait time (in seconds) by the `-transfer-timeout` option. After the timeout, the wait is skipped and the service is upgraded directly.
- Data type: `uint`
- Default: `600`

### Note:

If the wait is skipped and the service is upgraded directly, the service performance might jitter.

`-ignore-config-check`

- After the binary is updated, a configuration check is performed on the TiDB, TiKV and PD components using `<binary> --config-check <config-file>`. `<binary>` is the path to the newly deployed binary and `<config-file>` is the configuration file generated based on the user configuration. To skip this check, you can use the `--ignore-config-check` option.
- Data type: `BOOLEAN`
- Default: `false`

`-offline`

- Declares that the current cluster is not running. When this option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of the cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of the upgrading progress.

[<< Back to the previous page - TiUP Cluster command list](#)

## 13.4.7.4 TiUP DM Commands

### 13.4.7.4.1 TiUP DM

Similar to [TiUP Cluster](#) which is used to manage TiDB clusters, TiUP DM is used to manage DM clusters. You can use the TiUP DM component to perform daily operations and maintenance tasks of DM clusters, including deploying, starting, stopping, destroying, elastic scaling, upgrading DM clusters, and managing the configuration parameters of DM clusters.

Syntax

```
tiup dm [command] [flags]
```

`[command]` is used to pass the name of the command. See the [Command list](#) for supported commands.

Options

`-ssh`

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: `STRING`
- Support values:
  - `builtin`: Uses the built-in `easyssh` client of `tiup-cluster` as the SSH client.
  - `system`: Uses the default SSH client of the current operating system.
  - `none`: No SSH client is used. The deployment is only for the current machine.
- If this option is not specified in the command, `builtin` is used as the default value.

`-ssh-timeout`

- Specifies the SSH connection timeout in seconds.
- Data type: `UINT`
- If this option is not specified in the command, the default timeout is 5 seconds.

`-wait-timeout`

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying `systemctl` to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each steps is 120 seconds.

`-y, -yes`

- Skips the secondary confirmation of all risky operations. It is not recommended to use this option unless you use a script to call TiUP.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-v, -version`

- Prints the current version of TiUP DM.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, -help

- Prints help information about the specified command.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

Command list

- **import**: Imports a DM v1.0 cluster deployed by DM-Ansible.
- **template**: Outputs the topology template.
- **deploy**: Deploys a cluster based on a specified topology.
- **list**: Queries the list of deployed clusters.
- **display**: Displays the status of a specified cluster.
- **start**: Starts a specified cluster.
- **stop**: Stops a specified cluster.
- **restart**: Restarts a specified cluster.
- **scale-in**: Scales in a specified cluster.
- **scale-out**: Scales out a specified cluster.
- **upgrade**: Upgrades a specified cluster.
- **prune**: Cleans up instances in the Tombstone status for a specified cluster.
- **edit-config**: Modifies the configuration of a specified cluster.
- **reload**: Reloads the configuration of a specified cluster.
- **patch**: Replaces a specified service in a deployed cluster.
- **destroy**: Destroys a specified cluster.
- **audit**: Queries the operation audit log of a specified cluster.
- **replay**: Replays the specified commands
- **enable**: Enables the auto-enabling of the cluster service after a machine is restarted.
- **disable**: Disables the auto-enabling of the cluster service after a machine is restarted.
- **help**: Prints help information.

[<< Back to the previous page - TiUP Reference component list](#)

#### 13.4.7.4.2 tiup dm audit

The `tiup dm audit` command is used to view historical commands executed on all clusters and the execution log of each command.

Syntax

```
tiup dm audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.

- If you fill in the [audit-id], the execution log of the specified audit-id is checked.

#### Option

-h, -help

- Prints the help information.
- Data type: BOOLEAN
- Default: false

#### Output

- If [audit-id] is specified, the corresponding execution log is output.
- If [audit-id] is not specified, a table with the following fields is output:
  - ID: the audit-id corresponding to this record
  - Time: the execution time of the command corresponding to the record
  - Command: the command corresponding to the record

[<< Back to the previous page - TiUP DM command list](#)

### 13.4.7.4.3 tiup dm deploy

The tiup dm deploy command is used to deploy a new cluster.

#### Syntax

```
tiup dm deploy <cluster-name> <version> <topology.yaml> [flags]
```

- <cluster-name>: the name of the new cluster, which cannot be the same as the existing cluster names.
- <version>: the version number of the DM cluster to be deployed, such as v2.0.0.
- <topology.yaml>: the prepared [topology file](#).

#### Options

-u, -user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: STRING
- Default: the current user who executes the command.

-i, -identity\_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- Default: `~/.ssh/id_rsa`

`-p, --password`

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: `false`

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The deployment log.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.4 `tiup dm destroy`

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup dm destroy` command performs the following operations:

- Stops the cluster.
- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by `tiup-dm`, also delete the parent directory.

Syntax

```
tiup dm destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to be destroyed.

Option

`-h, --help`

- Prints the help information.

- Data type: Boolean
- Default: false

## Output

The execution log of the tiup-dm.

[<< Back to the previous page - TiUP DM command list](#)

### 13.4.7.4.5 tiup dm disable

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup dm disable` command. This command executes `systemctl disable <service>` on the specified node to disable the auto-enabling of the service.

## Syntax

```
tiup dm disable <cluster-name> [flags]
```

`<cluster-name>` is the cluster whose service auto-enabling is to be disabled.

## Options

`-N, --node`

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

## Note:

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

`-R, --role`

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**

- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

**Note:**

If the `-N`, `--node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is disabled.

`-h`, `-help`

Prints the help information.

Output

The execution log of the `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.6 tiup dm display

If you want to check the operational status of each component in a DM cluster, it is inefficient to log in to each machine one by one. Therefore, `tiup-dm` provides the `tiup dm`  $\hookrightarrow$  `display` command to do this job efficiently.

Syntax

```
tiup dm display <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated. If you forget the cluster name, you can check it using the `tiup dm list` command.

Options

`-N`, `-node`

- Specifies the IDs of the nodes to query, splitting by commas for multiple nodes. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: `STRING`
- This option is enabled by default with `[]` (which means all nodes) passed in.

**Note:**

If `-R`, `--role` is also specified, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are queried.

`-R, --role`

- Specifies the roles to query, splitting by commas for multiple roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: `STRING`
- This option is enabled by default with `[]` (which means all roles) passed in.

#### Note:

If `-N, --node` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

#### Output

- Cluster name
- Cluster version
- SSH client type
- A table containing the following fields:
  - `ID`: the node ID, consisting of `IP:PORT`.
  - `Role`: the service role deployed on the node (for example, `TiDB` or `TiKV`).
  - `Host`: the IP address of the machine corresponding to the node.
  - `Ports`: the port number used by the service.
  - `OS/Arch`: the operating system and machine architecture of the node.
  - `Status`: the current status of the services on the node.
  - `Data Dir`: the data directory of the service. `-` means that there is no data directory.
  - `Deploy Dir`: the deployment directory of the service.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.7 tiup dm edit-config

If you need to modify the cluster service configuration after the cluster is deployed, you can use the `tiup dm edit-config` command that starts an editor for you to modify the [topology file](#). of the specified cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

##### Note:

- When you modify the configuration, you cannot add or delete machines. For how to add machines, see [Scale out a cluster](#). For how to delete machines, see [Scale in a cluster](#).
- After you execute the `tiup dm edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup dm reload` command to reload the configuration.

##### Syntax

```
tiup dm edit-config <cluster-name> [flags]
```

`<cluster-name>`: the cluster to operate on.

##### Option

`-h, --help`

- Prints the help information.
- Data type: BOOLEAN
- Default: false

##### Output

- Normally, no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error is reported, reminding you to edit the file again. For the fields that cannot be modified, see [the topology file](#).

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.8 tiup dm enable

The `tiup dm enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

Syntax

```
tiup dm enable <cluster-name> [flags]
```

`<cluster-name>` is the cluster whose service auto-enabling is to be enabled.

Options

`-N, --node`

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

**Note:**

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

`-R, --role`

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

**Note:**

If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-h, --help

Prints the help information.

Output

the execution log of tiup-dm.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.9 tiup dm help

tiup-dm command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option. Basically, `tiup dm help <command>`  $\leftrightarrow$  `>` is equivalent to `tiup dm <command> --help`.

Syntax

```
tiup dm help [command] [flags]
```

[command] is used to specify the help information of which command that users need to view. If it is not specified, the help information of `tiup-dm` is viewed.

-h, --help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The help information of [command] or `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.10 tiup dm import Only for upgrading DM v1.0

This command is used only for upgrading DM clusters from v1.0 to v2.0 or later versions.

In DM v1.0, the cluster is basically deployed using TiDB Ansible. TiUP DM provides the `import` command to import v1.0 clusters and redeploy the clusters in DM v2.0.

#### Note:

- The command does not support importing DM Portal components from DM v1.0 clusters.
- Before importing the cluster, stop running the original cluster first.
- For data migration tasks that need to be upgraded to v2.0, do not execute `stop-task` on these tasks.

- The command only supports importing to DM v2.0.0-rc.2 and later versions.
- The `import` command is used to import a DM v1.0 cluster to a new DM v2.0 cluster. If you need to import data migration tasks to an existing v2.0 cluster, refer to [Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+](#)
- The deployment directories of some components might be different from those in the original cluster. You can check it with the `display` command.
- Before importing the cluster, run `tiup update --self && tiup ↪ update dm` to upgrade TiUP DM components to the latest version.
- After the cluster is imported, there is only one DM-master node in the cluster. You can refer to [the scale out command](#) to scale out the DM-master node.

## Syntax

```
tiup dm import [flags]
```

### Options

`-v, --cluster-version`

- Specifies the version number for redeploying. You must use a version later than v2.0.0-rc.2 (including v2.0.0-rc.2).
- Data type: `STRING`
- This option is **required** to execute the command.

`-d, --dir`

- Specifies the directory of TiDB Ansible.
- Data type: `STRING`
- If this option is not specified in the command, the current directory is the default directory.

`-inventory`

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- If this option is not specified in the command, the default file name is `"inventory. ↪ ini"`.

`-rename`

- Renames the imported cluster.
- Data type: **STRING**
- If this option is not specified in the command, the default cluster name is the `cluster_name` specified in the inventory file.

`-h, --help`

- Prints help information.
- Data type: **BOOLEAN**
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the importing process.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.11 `tiup dm list`

`tiup-dm` supports deploying multiple clusters using the same control machine. You can use the `tiup dm list` command to check which clusters are deployed using the control machine by the currently logged-in user.

##### Note:

By default, the data of the deployed clusters is stored in the `~/.tiup/storage` ↪ `/dm/clusters/` directory. The currently logged-in user cannot view the clusters deployed by other users on the same control machine.

Syntax

```
tiup dm list [flags]
```

Options

`-h, --help`

- Prints the help information.
- Data type: **BOOLEAN**
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

## Output

A table consisting of the following fields:

- **Name:** the cluster name.
- **User:** the user who deployed the cluster.
- **Version:** the cluster version.
- **Path:** the path of the cluster deployment data on the control machine.
- **PrivateKey:** the path of the private key to the cluster.

[<< Back to the previous page - TiUP DM command list](#)

### 13.4.7.4.12 Apply Hotfix to DM Clusters Online

If you need to dynamically replace the binaries of a service while the cluster is running (that is, to keep the cluster available during the replacement), you can use the `tiup dm ↪ patch` command. The command does the following:

- Uploads the binary package for replacement to the target machine.
- Takes the related nodes offline using the API.
- Stops the target service.
- Unpacks the binary package and replaces the service.
- Starts the target service.

## Syntax

```
tiup dm patch <cluster-name> <package-path> [flags]
```

- **<cluster-name>:** The name of the cluster to be operated
- **<package-path>:** The path to the binary package used for replacement

## Preparation

You need to pack the binary package required for this command in advance according to the following steps:

- Determine the name `#{component}` of the component to be replaced (dm-master, dm-worker ...), the `#{version}` of the component (v2.0.0, v2.0.1 ...), and the operating system `#{os}` and platform `#{arch}` on which the component runs.
- Download the current component package using the command `wget https://tiup- ↪ mirrors.pingcap.com/#{component}-#{version}-#{os}-#{arch}.tar.gz -O ↪ /tmp/#{component}-#{version}-#{os}-#{arch}.tar.gz`.
- Run `mkdir -p /tmp/package && cd /tmp/package` to create a temporary directory to pack files.

- Run `tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz` to unpack the original binary package.
- Run `find .` to view the file structure in the temporary package directory.
- Copy the binary files or configuration files to the corresponding locations in the temporary directory.
- Run `tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *` to pack the files in the temporary directory.
- Finally, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the value of `<package-path>` in the `tiup dm patch` command.

## Options

`--overwrite`

- After you patch a certain component (such as `dm-worker`), when the `tiup-dm` scales out the component, `tiup-dm` uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specify the option `--overwrite` in the command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-N, --node`

- Specifies the nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all nodes to replace by default.

### Note:

If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

`-R, --role`

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.

- Data type: `STRING`
- If this option is not specified, TiUP selects all roles to replace by default.

**Note:**

If the option `-N`, `--node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N`, `--node` and `-R`, `--`  $\rightarrow$  `role`.

`-offline`

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

`-h`, `-help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

### Example

The following example shows how to apply `v5.3.0-hotfix` to the `v5.3.0` cluster deployed using TiUP. The operations might vary if you deploy the cluster using other methods.

**Note:**

Hotfix is used only for emergency fixes. Its daily maintenance is complicated. It is recommend that you upgrade the DM cluster to an official version as soon as it is released.

### Preparations

Before applying a hotfix, prepare the hotfix package `dm-linux-amd64.tar.gz` and confirm the current DM software version:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0

Git Commit Hash: 20626babf21fc381d4364646c40dd84598533d66
Git Branch: heads/refs/tags/v5.3.0
UTC Build Time: 2021-11-29 08:29:49
Go Version: go version go1.16.4 linux/amd64
```

Prepare the patch package and apply it to the DM cluster

1. Prepare the DM software package that matches the current version:

```
mkdir -p /tmp/package
tar -zxvf /root/.tiup/storage/dm/packages/dm-master-v5.3.0-linux-amd64.
 ↪ tar.gz -C /tmp/package/
tar -zxvf /root/.tiup/storage/dm/packages/dm-worker-v5.3.0-linux-amd64.
 ↪ tar.gz -C /tmp/package/
```

2. Replace the binary file with the hotfix package:

```
Decompress the hotfix package and use it to replace the binary file.
cd /root; tar -zxvf dm-linux-amd64.tar.gz
cp /root/dm-linux-amd64/bin/dm-master /tmp/package/dm-master/dm-master
cp /root/dm-linux-amd64/bin/dm-worker /tmp/package/dm-worker/dm-worker
Re-package the modified files.
Note that the packaging method might be different for other
 ↪ deployment methods.
cd /tmp/package/ && tar -czvf dm-master-hotfix-linux-amd64.tar.gz dm-
 ↪ master/
cd /tmp/package/ && tar -czvf dm-worker-hotfix-linux-amd64.tar.gz dm-
 ↪ worker/
```

3. Apply the hotfix:

Query the cluster status. The following uses the cluster named `dm-test` as an example:

```
tiup dm display dm-test
```

Output:

```
Cluster type: dm
Cluster name: dm-test
Cluster version: v5.3.0
Deploy user: tidb
SSH type: builtin
ID Role Host Ports OS/Arch
 ↪ Status Data Dir Deploy Dir
```

```

```

Apply the hotfix to the specified node or specified role. If both `-R` and `-N` are specified, the intersection will be taken.

```

Apply hotfix to a specified node.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -N
 ↪ 172.16.100.21:8261
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -N
 ↪ 172.16.100.21:8262
Apply hotfix to a specified role.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -R dm-master
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -R dm-worker

```

#### 4. Query the hotfix application result:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```

Release Version: v5.3.0-20211230
Git Commit Hash: ca7070c45013c24d34bd9c1e936071253451d707
Git Branch: heads/refs/tags/v5.3.0-20211230
UTC Build Time: 2022-01-05 14:19:02
Go Version: go version go1.16.4 linux/amd64

```

The cluster information changes accordingly:

```
tiup dm display dm-test
```

Output:

```
Starting component `dm`: /root/.tiup/components/dm/v1.8.1/tiup-dm
 ↳ display dm-test
Cluster type: dm
Cluster name: dm-test
Cluster version: v5.3.0
Deploy user: tidb
SSH type: builtin
ID Role Host Ports OS/Arch

#### 13.4.7.4.13 tiup dm prune

When you scale in the cluster(/tiup/tiup-component-dm-scale-in.md), a small amount of metadata in etcd is not cleaned up, which usually causes no problem. If you need to clean up the metadata, you can manually execute the `tiup dm prune` command.

Syntax

```
tiup dm prune <cluster-name> [flags]
```

Option

-h, -help

- Prints the help information.

- Data type: `BOOLEAN`
- Default: `false`

## Output

The log of the cleanup process.

[<< Back to the previous page - TiUP DM command list](#)

### 13.4.7.4.14 `tiup dm reload`

After [modifying the cluster configuration](#), the cluster needs to be reloaded using the `tiup dm reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running and restarts the service in order according to the upgrade process. The cluster remains available during the restart process.

#### Syntax

```
tiup dm reload <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on.

#### Options

`-N, --node`

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

#### Note:

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

`-R, --role`

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all roles are selected by default.

### Note:

- If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are restarted.
- If the `--skip-restart` option is specified, the `-R`, `--role` option is invalid.

`--skip-restart`

The `tiup dm reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: **BOOLEAN**
- Default: `false`

`-h`, `-help`

- Prints the help information.
- Data type: **BOOLEAN**
- Default: `false`

Output

The execution log of the `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.15 tiup dm replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup dm replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup dm replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-ids` using the `tiup dm audit` command.

Option

`-h, -help`

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.16 tiup dm restart

The command `tiup dm restart` is used to restart all or some of the services of the specified cluster.

**Note:**

During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup dm restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

Options

`-N, -node`

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

**Note:**

If the option `-R`, `--role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-R, --role`

- Specifies the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup ↪ -dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

**Note:**

If the option `-N`, `--node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-h, --help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.17 tiup dm scale-in

The `tiup dm scale-in` command is used to scale in the cluster. Scaling in the cluster means taking the service offline, which eventually removes the specified node from the cluster and deletes the remaining related files.

##### Syntax

```
tiup dm scale-in <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

##### Options

`-N, -node`

- Specifies the nodes to be scaled in. If you need to scale in multiple nodes, split them by commas.
- Data type: **STRINGS**
- Default: no. This option is mandatory and the value must be not null.

`-force`

- In some cases, some scale-in nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to remove these nodes from the cluster.
- Data type: **BOOLEAN**
- Default: false. If this option is not specified in the command, the specified nodes are not forcibly removed.

`-h, -help`

- Prints the help information.
- Data type: **BOOLEAN**
- Default: false

##### Output

The log of scaling in.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.18 tiup dm scale-out

The `tiup dm scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The `tiup-dm` components first establish an SSH connection to the new node, create the necessary directories on the target node, then perform the deployment and start the service.

##### Syntax

```
tiup dm scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

`<topology.yaml>`: the prepared [topology file](#). This topology file should only contain the new nodes that are to be added to the current cluster.

##### Options

`-u, -user`

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: **STRING**
- Default: the current user who executes the command.

`-i, -identity_file`

- Specifies the key file used to connect to the target machine.
- Data type: **STRING**
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

`-p, -password`

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: **BOOLEAN**
- Default: `false`

`-h, -help`

- Prints the help information.
- Data type: **BOOLEAN**
- Default: `false`

##### Output

The log of scaling out.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.19 tiup dm start

The `tiup dm start` command is used to start all or part of the services of the specified cluster.

Syntax

```
tiup dm start <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

Options

`-N, --node`

- Specifies the nodes to be started. If not specified, all nodes are started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started.

**Note:**

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

`-R, --role`

- Specifies the roles to be started. If not specified, all roles are started. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started.

**Note:**

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-h, --help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

#### Output

The log of starting the service.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.20 tiup dm stop

The `tiup dm stop` command is used to stop all or part of the services of the specified cluster.

##### Note:

The cluster cannot provide services after the core service is stopped.

#### Syntax

```
tiup dm stop <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

#### Options

-N, --node

- Specifies the nodes to be stopped. If not specified, all nodes are stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

##### Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-R, --role

- Specifies the roles to be stopped. If not specified, all roles are stopped. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

**Note:**

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-h, --help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of stopping the service.

[<< Back to the previous page - TiUP DM command list](#)

#### 13.4.7.4.21 tiup dm template

Before deploying the cluster, you need to prepare a `topology file` of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup dm template` command.

Syntax

```
tiup dm template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 DM-master instances
- 3 DM-worker instances

- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

#### Options

-full

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

-h, -help

Prints the help information.

#### Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

[<< Back to the previous page - TiUP DM command list](#)

### 13.4.7.4.22 tiup dm upgrade

The `tiup dm upgrade` command is used to upgrade a specified cluster to a specific version.

#### Syntax

```
tiup dm upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup dm list` command.
- `<version>` is the target version to be upgraded to, such as `v6.5.0`. Currently, only upgrading to a later version is allowed, and upgrading to an earlier version is not allowed, which means the downgrade is not allowed. Upgrading to a nightly version is not allowed either.

#### Options

-offline

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

-h, -help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

## Output

Log of the service upgrade process.

[<< Back to the previous page - TiUP DM command list](#)

### 13.4.8 Topology Configuration File for TiDB Deployment Using TiUP

To deploy or scale TiDB using TiUP, you need to provide a topology file ([sample](#)) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

#### 13.4.8.1 File structure

A topology configuration file for TiDB deployment using TiUP might contain the following sections:

- **global**: The cluster's global configuration. Some of the configuration items use the default values and you can configure them separately in each instance.
- **monitored**: Configuration for monitoring services, namely, the `blackbox_exporter` and the `node_exporter`. On each machine, a `node_exporter` and a `blackbox_exporter` are deployed.
- **server\_configs**: Components' global configuration. You can configure each component separately. If an instance has a configuration item with the same name, the instance's configuration item will take effect.
- **pd\_servers**: The configuration of the PD instance. This configuration specifies the machines to which the PD component is deployed.
- **tidb\_servers**: The configuration of the TiDB instance. This configuration specifies the machines to which the TiDB component is deployed.
- **tikv\_servers**: The configuration of the TiKV instance. This configuration specifies the machines to which the TiKV component is deployed.
- **tiflash\_servers**: The configuration of the TiFlash instance. This configuration specifies the machines to which the TiFlash component is deployed.
- **pump\_servers**: The configuration of the Pump instance. This configuration specifies the machines to which the Pump component is deployed.
- **drainer\_servers**: The configuration of the Drainer instance. This configuration specifies the machines to which the Drainer component is deployed.

- **cdc\_servers**: The configuration of the TiCDC instance. This configuration specifies the machines to which the TiCDC component is deployed.
- **tispark\_masters**: The configuration of the TiSpark master instance. This configuration specifies the machines to which the TiSpark master component is deployed. Only one node of TiSpark master can be deployed.
- **tispark\_workers**: The configuration of the TiSpark worker instance. This configuration specifies the machines to which the TiSpark worker component is deployed.
- **monitoring\_servers**: Specifies the machines to which Prometheus and NGMonitoring are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- **grafana\_servers**: The configuration of the Grafana instance. This configuration specifies the machines to which Grafana is deployed.
- **alertmanager\_servers**: The configuration of the Alertmanager instance. This configuration specifies the machines to which Alertmanager is deployed.

#### 13.4.8.1.1 global

The `global` section corresponds to the cluster's global configuration and has the following fields:

- **user**: The user used to start the deployed cluster. The default value is `"tidb"`. If the user specified in the `<user>` field does not exist on the target machine, this user is automatically created.
- **group**: The user group to which a user belongs. It is specified when the user is created. The value defaults to that of the `<user>` field. If the specified group does not exist, it is automatically created.
- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. The default value is `22`.
- **enable\_tls**: Specifies whether to enable TLS for the cluster. After TLS is enabled, the generated TLS certificate must be used for connections between components or between the client and the component. The default value is `false`.
- **deploy\_dir**: The deployment directory of each component. The default value is `"↔ deployed"`. Its application rules are as follows:
  - If the absolute path of `deploy_dir` is configured at the instance level, the actual deployment directory is `deploy_dir` configured for the instance.
  - For each instance, if you do not configure `deploy_dir`, its default value is the relative path `<component-name>-<component-port>`.
  - If `global.deploy_dir` is an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.

- If `global.deploy_dir` is a relative path, the component is deployed to the /  
↔ `home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>`  
directory.
- **data\_dir**: The data directory. Default value: "data". Its application rules are as follows:
  - If the absolute path of `data_dir` is configured at the instance level, the actual deployment directory is `data_dir` configured for the instance.
  - For each instance, if you do not configure `data_dir`, its default value is `<global  
↔ .data_dir>`.
  - If `data_dir` is a relative path, the component data is placed in `<deploy_dir>/<  
↔ data_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.
- **log\_dir**: The log directory. Default value: "log". Its application rules are as follows:
  - If the absolute path `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
  - For each instance, if you not configure `log_dir`, its default value is `<global.  
↔ log_dir>`.
  - If `log_dir` is a relative path, the component log is placed in `<deploy_dir>/<  
↔ log_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.
- **os**: The operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is "linux".
- **arch**: The CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are "amd64" and "arm64". The default value is "amd64".
- **resource\_control**: Runtime resource control. All configurations in this field are written into the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
  - **memory\_limit**: Limits the maximum runtime memory. For example, "2G" means that the maximum memory of 2 GB can be used.
  - **cpu\_quota**: Limits the maximum CPU usage at runtime. For example, "200%".
  - **io\_read\_bandwidth\_max**: Limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M"`.
  - **io\_write\_bandwidth\_max**: Limits maximum I/O bandwidth for disk writes. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M"`.

- `limit_core`: Controls the size of core dump.

A `global` configuration example is as follows:

```
global:
 user: "tidb"
 resource_control:
 memory_limit: "2G"
```

In the above configuration, the `tidb` user is used to start the cluster. At the same time, each component is restricted to a maximum of 2 GB of memory when it is running.

#### 13.4.8.1.2 `monitored`

`monitored` is used to configure the monitoring service on the target machine: `node_exporter` and `blackbox_exporter`. The following fields are included:

- `node_exporter_port`: The service port of `node_exporter`. The default value is 9100.
- `blackbox_exporter_port`: The service port of `blackbox_exporter`. The default value is 9115.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

A `monitored` configuration example is as follows:

```
monitored:
 node_exporter_port: 9100
 blackbox_exporter_port: 9115
```

The above configuration specifies that `node_exporter` uses the 9100 port and `blackbox_exporter` uses the 9115 port.

### 13.4.8.1.3 server\_configs

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configuration of this section can be overwritten by the configurations with the same names in an instance. `server_configs` mainly includes the following fields:

- `tidb`: TiDB service-related configuration. For the complete configuration, see [TiDB configuration file](#).
- `tikv`: TiKV service-related configuration. For the complete configuration, see [TiKV configuration file](#).
- `pd`: PD service-related configuration. For the complete configuration, see [PD configuration file](#).
- `tiflash`: TiFlash service-related configuration. For the complete configuration, see [TiFlash configuration file](#).
- `tiflash_learner`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- `pump`: Pump service-related configuration. For the complete configuration, see [TiDB Binlog configuration file](#).
- `drainer`: Drainer service-related configuration. For the complete configuration, see [TiDB Binlog configuration file](#).
- `cdc`: TiCDC service-related configuration. For the complete configuration, see [Deploy TiCDC](#).

A `server_configs` configuration example is as follows:

```
server_configs:
 tidb:
 lease: "45s"
 split-table: true
 token-limit: 1000
 instance.tidb_enable_ddl: true
 tikv:
 log-level: "info"
 readpool.unified.min-thread-count: 1
```

The above configuration specifies the global configuration of TiDB and TiKV.

#### 13.4.8.1.4 `pd_servers`

`pd_servers` specifies the machines to which PD services are deployed. It also specifies the service configuration on each machine. `pd_servers` is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the PD services are deployed. The field value is an IP address and is mandatory.
- **listen\_host**: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **name**: Specifies the name of the PD instance. Different instances must have unique names; otherwise, instances cannot be deployed.
- **client\_port**: Specifies the port that PD uses to connect to the client. The default value is 2379.
- **peer\_port**: Specifies the port for communication between PDs. The default value is 2380.
- **deploy\_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data\_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- **log\_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **numa\_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: The configuration rule of this field is the same as the `pd` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pd` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.

- **arch**: The architecture of the machine specified in **host**. If this field is not specified, the default value is the **arch** value in **global**.
- **resource\_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource\_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource\_control** are the same as the **resource\_control** content in **global**.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **listen\_host**
- **name**
- **client\_port**
- **peer\_port**
- **deploy\_dir**
- **data\_dir**
- **log\_dir**
- **arch**
- **os**

A **pd\_servers** configuration example is as follows:

```
pd_servers:
- host: 10.0.1.11
 config:
 schedule.max-merge-region-size: 20
 schedule.max-merge-region-keys: 200000
- host: 10.0.1.12
```

The above configuration specifies that PD will be deployed on 10.0.1.11 and 10.0.1.12, and makes specific configurations for the PD of 10.0.1.11.

#### 13.4.8.1.5 **tidb\_servers**

**tidb\_servers** specifies the machines to which TiDB services are deployed. It also specifies the service configuration on each machine. **tidb\_servers** is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the TiDB services are deployed. The field value is an IP address and is mandatory.
- **listen\_host**: When the machine has multiple IP addresses, **listen\_host** specifies the listening IP address of the service. The default value is 0.0.0.0.

- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the **ssh\_port** of the **global** section is used.
- **port**: The listening port of TiDB services, which is used to provide connection to the MySQL client. The default value is 4000.
- **status\_port**: The listening port of the TiDB status service, which is used to view the status of the TiDB services from the external via HTTP requests. The default value is 10080.
- **deploy\_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the **deploy\_dir** directory configured in **global**.
- **log\_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the **log\_dir** directory configured in **global**.
- **numa\_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has **numactl** installed. If this field is specified, **cpubind** and **membind** policies are allocated using **numactl**. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: The configuration rule of this field is the same as the **tidb** configuration rule in **server\_configs**. If this field is configured, the field content is merged with the **tidb** content in **server\_configs** (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in **host**.
- **os**: The operating system of the machine specified in **host**. If this field is not specified, the default value is the **os** value in **global**.
- **arch**: The architecture of the machine specified in **host**. If this field is not specified, the default value is the **arch** value in **global**.
- **resource\_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource\_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource\_control** are the same as the **resource\_control** content in **global**.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **listen\_host**
- **port**
- **status\_port**
- **deploy\_dir**

- `log_dir`
- `arch`
- `os`

A `tidb_servers` configuration example is as follows:

```
tidb_servers:
- host: 10.0.1.14
 config:
 log.level: warn
 log.slow-query-file: tidb-slow-overwrited.log
- host: 10.0.1.15
```

#### 13.4.8.1.6 `tikv_servers`

`tikv_servers` specifies the machines to which TiKV services are deployed. It also specifies the service configuration on each machine. `tikv_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiKV services are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the TiKV services. The default value is `20160`.
- `status_port`: The listening port of the TiKV status service. The default value is `20180`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as `"0,1"`.

- **config**: The configuration rule of this field is the same as the **tikv** configuration rule in **server\_configs**. If this field is configured, the field content is merged with the **tikv** content in **server\_configs** (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in **host**.
- **os**: The operating system of the machine specified in **host**. If this field is not specified, the default value is the **os** value in **global**.
- **arch**: The architecture of the machine specified in **host**. If this field is not specified, the default value is the **arch** value in **global**.
- **resource\_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource\_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource\_control** are the same as the **resource\_control** content in **global**.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **listen\_host**
- **port**
- **status\_port**
- **deploy\_dir**
- **data\_dir**
- **log\_dir**
- **arch**
- **os**

A **tikv\_servers** configuration example is as follows:

```
tikv_servers:
- host: 10.0.1.14
 config:
 server.labels: { zone: "zone1", host: "host1" }
- host: 10.0.1.15
 config:
 server.labels: { zone: "zone1", host: "host2" }
```

#### 13.4.8.1.7 **tiflash\_servers**

**tiflash\_servers** specifies the machines to which TiFlash services are deployed. It also specifies the service configuration on each machine. This section is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the TiFlash services are deployed. The field value is an IP address and is mandatory.
- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **tcp\_port**: The port of the TiFlash TCP service. The default value is 9000.
- **http\_port**: The port of the TiFlash HTTP service. The default value is 8123.
- **flash\_service\_port**: The port via which TiFlash provides services. TiDB reads data from TiFlash via this port. The default value is 3930.
- **metrics\_port**: TiFlash's status port, which is used to output metric data. The default value is 8234.
- **flash\_proxy\_port**: The port of the built-in TiKV. The default value is 20170.
- **flash\_proxy\_status\_port**: The status port of the built-in TiKV. The default value is 20292.
- **deploy\_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data\_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`. TiFlash supports multiple `data_dir` directories separated by commas.
- **log\_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **tmp\_path**: The storage path of TiFlash temporary files. The default value is `[path or the first directory of storage.latest.dir] + "/tmp"`.
- **numa\_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- **config**: The configuration rule of this field is the same as the `tiflash` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tiflash` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **learner\_config**: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.

- **os**: The operating system of the machine specified in **host**. If this field is not specified, the default value is the **os** value in **global**.
- **arch**: The architecture of the machine specified in **host**. If this field is not specified, the default value is the **arch** value in **global**.
- **resource\_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource\_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource\_control** are the same as the **resource\_control** content in **global**.

After the deployment, for the fields above, you can only add directories to **data\_dir**; for the fields below, you cannot modified these fields:

- **host**
- **tcp\_port**
- **http\_port**
- **flash\_service\_port**
- **flash\_proxy\_port**
- **flash\_proxy\_status\_port**
- **metrics\_port**
- **deploy\_dir**
- **log\_dir**
- **tmp\_path**
- **arch**
- **os**

A **tiflash\_servers** configuration example is as follows:

```
tiflash_servers:
- host: 10.0.1.21
- host: 10.0.1.22
```

#### 13.4.8.1.8 **pump\_servers**

**pump\_servers** specifies the machines to which the Pump services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. **pump\_servers** is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the Pump services are deployed. The field value is an IP address and is mandatory.
- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the **ssh\_port** of the **global** section is used.

- `port`: The listening port of the Pump services. The default value is 8250.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config`: The configuration rule of this field is the same as the `pump` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pump` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `pump_servers` configuration example is as follows:

```
pump_servers:
- host: 10.0.1.21
 config:
 gc: 7
- host: 10.0.1.22
```

#### 13.4.8.1.9 drainer\_servers

`drainer_servers` specifies the machines to which the Drainer services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. `drainer_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Drainer services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of Drainer services. The default value is 8249.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `commit_ts` (deprecated): When Drainer starts, it reads the checkpoint. If Drainer gets no checkpoint, it uses this field as the replication time point for the initial startup. This field defaults to `-1` (Drainer always gets the latest timestamp from the PD as the `commit_ts`).
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as `"0,1"`.
- `config`: The configuration rule of this field is the same as the `drainer` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `drainer` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.

- **os**: The operating system of the machine specified in **host**. If this field is not specified, the default value is the **os** value in **global**.
- **arch**: The architecture of the machine specified in **host**. If this field is not specified, the default value is the **arch** value in **global**.
- **resource\_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource\_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a **systemd** configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource\_control** are the same as the **resource\_control** content in **global**.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **port**
- **deploy\_dir**
- **data\_dir**
- **log\_dir**
- **arch**
- **os**

The **commit\_ts** field is deprecated since TiUP v1.9.2 and is not recorded in the starting script of Drainer. If you still need to use this field, refer to the following example to configure the **initial-commit-ts** field in **config**.

A **drainer\_servers** configuration example is as follows:

```
drainer_servers:
- host: 10.0.1.21
 config:
 initial-commit-ts: -1
 syncer.db-type: "mysql"
 syncer.to.host: "127.0.0.1"
 syncer.to.user: "root"
 syncer.to.password: ""
 syncer.to.port: 3306
 syncer.ignore-table:
 - db-name: test
 tbl-name: log
 - db-name: test
 tbl-name: audit
```

#### 13.4.8.1.10 `cdc_servers`

`cdc_servers` specifies the machines to which the TiCDC services are deployed. It also specifies the service configuration on each machine. `cdc_servers` is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the TiCDC services are deployed. The field value is an IP address and is mandatory.
- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **port**: The listening port of the TiCDC services. The default value is 8300.
- **deploy\_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data\_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- **log\_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **gc-ttl**: The Time To Live (TTL) duration of the service level GC safepoint set by TiCDC in PD, in seconds. The default value is 86400, which is 24 hours.
- **tz**: The time zone that the TiCDC services use. TiCDC uses this time zone when internally converting time data types such as timestamp and when replicating data to the downstream. The default value is the local time zone where the process runs.
- **numa\_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: The field content is merged with the `cdc` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- **arch**: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- **resource\_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource\_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource\_control** are the same as the **resource\_control** content in **global**.
- **ticdc\_cluster\_id**: Specifies the TiCDC cluster ID corresponding to the service. If this field is not specified, the service joins the default TiCDC cluster. This field only takes effect in TiDB v6.3.0 or later versions.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **port**
- **deploy\_dir**
- **data\_dir**
- **log\_dir**
- **arch**
- **os**
- **ticdc\_cluster\_id**

A **cdc\_servers** configuration example is as follows:

```
cdc_servers:
- host: 10.0.1.20
 gc-ttl: 86400
 data_dir: "/cdc-data"
- host: 10.0.1.21
 gc-ttl: 86400
 data_dir: "/cdc-data"
```

#### 13.4.8.1.11 **tispark\_masters**

**tispark\_masters** specifies the machines to which the master node of TiSpark is deployed. It also specifies the service configuration on each machine. **tispark\_masters** is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the TiSpark master is deployed. The field value is an IP address and is mandatory.
- **listen\_host**: When the machine has multiple IP addresses, **listen\_host** specifies the listening IP address of the service. The default value is 0.0.0.0.
- **ssh\_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the **ssh\_port** of the **global** section is used.

- `port`: Spark's listening port, used for communication before the node. The default value is 7077.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is 8080.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path of the JRE environment to be used. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `spark_config`: Configures to configure the TiSpark services. Then, a configuration file is generated and sent to the machine specified in `host`.
- `spark_env`: Configures the environment variables when Spark starts.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`
- `deploy_dir`
- `arch`
- `os`

A `tispark_masters` configuration example is as follows:

```
tispark_masters:
- host: 10.0.1.21
 spark_config:
 spark.driver.memory: "2g"
 spark.eventLog.enabled: "False"
 spark.tispark.grpc.framesize: 2147483647
 spark.tispark.grpc.timeout_in_sec: 100
 spark.tispark.meta.reload_period_in_sec: 60
 spark.tispark.request.command.priority: "Low"
 spark.tispark.table.scan_concurrency: 256
 spark_env:
```

```
SPARK_EXECUTOR_CORES: 5
SPARK_EXECUTOR_MEMORY: "10g"
SPARK_WORKER_CORES: 5
SPARK_WORKER_MEMORY: "10g"
- host: 10.0.1.22
```

#### 13.4.8.1.12 `tispark_workers`

`tispark_workers` specifies the machines to which the worker nodes of TiSpark are deployed. It also specifies the service configuration on each machine. `tispark_workers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiSpark workers are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path in which the JRE environment to be used is located. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`

- `deploy_dir`
- `arch`
- `os`

A `tispark_workers` configuration example is as follows:

```
tispark_workers:
- host: 10.0.1.22
- host: 10.0.1.23
```

#### 13.4.8.1.13 `monitoring_servers`

`monitoring_servers` specifies the machines to which the Prometheus services are deployed. It also specifies the service configuration on each machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the monitoring services are deployed. The field value is an IP address and is mandatory.
- `ng_port`: Specifies the port that NgMonitoring listens to. Introduced in TiUP v1.7.0, this field supports [Continuous Profiling](#) and [Top SQL](#). The default value is 12020.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Prometheus services. The default value is 9090.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has [numactl](#) installed. If this field is specified, `cpubind` and `membind` policies are allocated using [numactl](#). This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `storage_retention`: The retention time of the Prometheus monitoring data. The default value is "30d".

- `rule_dir`: Specifies a local directory that should contain complete `*.rules.yml` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the rules for Prometheus.
- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
  - `remote_write`: See the Prometheus document [<remote\\_write>](#).
  - `remote_read`: See the Prometheus document [<remote\\_read>](#).
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:
- host: 10.0.1.11
 rule_dir: /local/rule/dir
 remote_config:
 remote_write:
 - queue_config:
 batch_send_deadline: 5m
```

```
 capacity: 100000
 max_samples_per_send: 10000
 max_shards: 300
 url: http://127.0.0.1:8003/write
remote_read:
- url: http://127.0.0.1:8003/read
external_alertmanagers:
- host: 10.1.1.1
 web_port: 9093
- host: 10.1.1.2
 web_port: 9094
```

#### 13.4.8.1.14 grafana\_servers

`grafana_servers` specifies the machines to which the Grafana services are deployed. It also specifies the service configuration on each machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Grafana services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Grafana services. The default value is 3000.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `username`: The user name on the Grafana login interface.
- `password`: The password corresponding to Grafana.
- `dashboard_dir`: Specifies a local directory that should contain complete `dashboard`  $\hookrightarrow$  (`*.json`) files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the dashboards for Grafana.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration

file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

#### Note:

If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. For the `*.json` files in the local dashboards directory, update the value of the `datasource` field to the new cluster name (because `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:
- host: 10.0.1.11
 dashboard_dir: /local/dashboard/dir
```

#### 13.4.8.1.15 alertmanager\_servers

`alertmanager_servers` specifies the machines to which the Alertmanager services are deployed. It also specifies the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Alertmanager services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `web_port`: Specifies the port used that Alertmanager uses to provide web services. The default value is 9093.

- `cluster_port`: Specifies the communication port between one Alertmanager and other Alertmanager. The default value is 9094.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config_file`: Specifies a local file that is transferred to the target machine during the initialization phase of the cluster configuration as the configuration of Alertmanager.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
- host: 10.0.1.11
 config_file: /local/config/file
- host: 10.0.1.12
 config_file: /local/config/file
```

## 13.4.9 Topology Configuration File for DM Cluster Deployment Using TiUP

To deploy or scale a TiDB Data Migration (DM) cluster, you need to provide a topology file ([sample](#)) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

### 13.4.9.1 File structure

A topology configuration file for DM cluster deployment using TiUP might contain the following sections:

- **global**: the cluster's global configuration. Some of the configuration items use the default values of the cluster, and you can configure them separately in each instance.
- **server\_configs**: the components' global configuration. You can configure each component separately. If an instance has a configuration item with the same key, the instance's configuration item will take effect.
- **master\_servers**: the configuration of the DM-master instance. The configuration specifies the machines to which the master service of the DM component is deployed.
- **worker\_servers**: the configuration of the DM-worker instance. The configuration specifies the machines to which the worker service of the DM component is deployed.
- **monitoring\_servers**: specifies the machines to which the Prometheus instances are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- **grafana\_servers**: the configuration of the Grafana instances. The configuration specifies the machines to which the Grafana instances are deployed.
- **alertmanager\_servers**: the configuration of the Alertmanager instances. The configuration specifies the machines to which the Alertmanager instances are deployed.

#### 13.4.9.1.1 global

The **global** section corresponds to the cluster's global configuration and has the following fields:

- **user**: the user to start the deployed cluster. The default value is “tidb”. If the user specified in the `<user>` field does not exist on the target machine, TiUP will automatically try to create the user.
- **group**: the user group to which a user belongs when the user is automatically created. The default value is the same as the `<user>` field. If the specified group does not exist, it will be created automatically.
- **ssh\_port**: the SSH port to connect to the target machine for operations. The default value is “22”.
- **deploy\_dir**: the deployment directory for each component. The default value is “deploy”. The construction rules are as follows:
  - If the absolute path `deploy_dir` is configured at the instance level, the actual deployment directory is the `deploy_dir` configured for the instance.
  - For each instance, if you do not configure `deploy_dir`, the default value is the relative path `<component-name>-<component-port>`.
  - If `global.deploy_dir` is set to an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.
  - If `global.deploy_dir` is set to a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.
- **data\_dir**: the data directory. The default value is “data”. The construction rules are as follows.
  - If the absolute path `data_dir` is configured at the instance level, the actual data directory is the `data_dir` configured for the instance.
  - For each instance, if `data_dir` is not configured, the default value is `<global.data_dir>`.
  - If `data_dir` is set to a relative path, the component data is stored in `<deploy_dir>/<data_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- **log\_dir**: the data directory. The default value is “log”. The construction rules are as follows.
  - If the absolute path of `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
  - For each instance, if `log_dir` is not configured by the user, the default value is `<global.log_dir>`.
  - If `log_dir` is a relative path, the component logs will be stored in `<deploy_dir>/<log_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- **os**: the operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is “linux”.

- **arch**: the CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are “amd64” and “arm64”. The default value is “amd64”.
- **resource\_control**: runtime resource control. All configurations in this field are written to the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
  - **memory\_limit**: limits the maximum memory at runtime. For example, “2G” means that the maximum memory of 2 GB can be used.
  - **cpu\_quota**: limits the maximum CPU usage at runtime. For example, “200%”.
  - **io\_read\_bandwidth\_max**: limits the maximum I/O bandwidth for disk reads. For example, “/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M”.
  - **io\_write\_bandwidth\_max**: limits the maximum I/O bandwidth for disk writes. For example, “/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M”  
↪ .
  - **limit\_core**: controls the size of core dump.

A global configuration example:

```
global:
 user: "tidb"
 resource_control:
 memory_limit: "2G"
```

In the example, the configuration specifies that the `tidb` user is used to start the cluster, and that each component is limited to a maximum of 2 GB of memory when it is running.

#### 13.4.9.1.2 server\_configs

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configurations in the `server_configs` section can be overwritten by the configurations with the same keys in an instance. `server_configs` mainly contains the following fields:

- **master**: the configuration related to the DM-master service. For all the supported configuration items, see [DM-master Configuration File](#).
- **worker**: the configuration related to the DM-worker service, For all the supported configuration items, see [DM-worker Configuration File](#).

A `server_configs` configuration example is as follows:

```
server_configs:
 master:
 log-level: info
 rpc-timeout: "30s"
 rpc-rate-limit: 10.0
```

```
rpc-rate-burst: 40
worker:
 log-level: info
```

### 13.4.9.2 master\_servers

`master_servers` specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. `master_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `name`: specifies the name of the DM-master instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- `port`: specifies the port on which DM-master provides services. The default value is “8261”.
- `peer_port`: specifies the port for communication between DM-masters. The default value is “8291”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config`: the configuration rules of this field are the same as that of `master` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `master` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control`

in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

- `v1_source_path`: when upgrading from `v1.0.x`, you can specify the directory where the configuration file of the V1 source is located in this field.

In the `master_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `name`
- `port`
- `peer_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`
- `v1_source_path`

A `master_servers` configuration example is as follows:

```
master_servers:
- host: 10.0.1.11
 name: master1
 ssh_port: 22
 port: 8261
 peer_port: 8291
 deploy_dir: "/dm-deploy/dm-master-8261"
 data_dir: "/dm-data/dm-master-8261"
 log_dir: "/dm-deploy/dm-master-8261/log"
 numa_node: "0,1"
 # The following configs are used to overwrite the `server_configs.master
 ↪ ` values.
 config:
 log-level: info
 rpc-timeout: "30s"
 rpc-rate-limit: 10.0
 rpc-rate-burst: 40
- host: 10.0.1.18
 name: master2
- host: 10.0.1.19
 name: master3
```

### 13.4.9.3 worker\_servers

`worker_servers` specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. `worker_servers` is an array. Each array element contains the following fields:

- **host**: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- **ssh\_port**: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- **name**: specifies the name of the DM-worker instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- **port**: specifies the port on which DM-worker provides services. The default value is “8262”.
- **deploy\_dir**: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- **data\_dir**: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- **log\_dir**: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- **numa\_node**: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: the configuration rules of this field are the same as that of `worker` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `worker` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.
- **os**: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- **arch**: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- **resource\_control**: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `worker_servers` section, the following fields cannot be modified after the deployment is completed:

- host
- name
- port
- deploy\_dir
- data\_dir
- log\_dir
- arch
- os

A `worker_servers` configuration example is as follows:

```
worker_servers:
- host: 10.0.1.12
 ssh_port: 22
 port: 8262
 deploy_dir: "/dm-deploy/dm-worker-8262"
 log_dir: "/dm-deploy/dm-worker-8262/log"
 numa_node: "0,1"
 # config is used to overwrite the `server_configs.worker` values
 config:
 log-level: info
- host: 10.0.1.19
```

#### 13.4.9.3.1 monitoring\_servers

`monitoring_servers` specifies the machines to which the Prometheus service is deployed. You can also specify the service configuration on the machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Prometheus provides services. The default value is “9090”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.

- **numa\_node**: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”
- **storage\_retention**: specifies the retention time of the Prometheus monitoring data. The default value is “15d”.
- **rule\_dir**: specifies a local directory where the complete `*.rules.yml` files are located. The files in the specified directory will be sent to the target machine as the Prometheus rules during the initialization phase of the cluster configuration.
- **remote\_config**: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
  - **remote\_write**: See the Prometheus document [<remote\\_write>](#).
  - **remote\_read**: See the Prometheus document [<remote\\_read>](#).
- **external\_alertmanagers**: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- **os**: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- **arch**: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- **resource\_control**: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `monitoring_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:
- host: 10.0.1.11
 rule_dir: /local/rule/dir
```

```
remote_config:
 remote_write:
 - queue_config:
 batch_send_deadline: 5m
 capacity: 100000
 max_samples_per_send: 10000
 max_shards: 300
 url: http://127.0.0.1:8003/write
 remote_read:
 - url: http://127.0.0.1:8003/read\
external_alertmanagers:
- host: 10.1.1.1
web_port: 9093
- host: 10.1.1.2
web_port: 9094
```

### 13.4.9.3.2 grafana\_servers

`grafana_servers` specifies the machines to which the Grafana service is deployed. You can also specify the service configuration on the machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Grafana provides services. The default value is “3000”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `username`: specifies the username of the Grafana login screen.
- `password`: specifies the corresponding password of Grafana.
- `dashboard_dir`: specifies a local directory where the complete `dashboard(*.json)` files are located. The files in the specified directory will be sent to the target machine as Grafana dashboards during the initialization phase of the cluster configuration.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the

machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

**Note:**

If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. In the local `dashboards` directory, update the value of the `datasource` field to the new cluster name (the `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

In `grafana_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:
- host: 10.0.1.11
 dashboard_dir: /local/dashboard/dir
```

### 13.4.9.3.3 alertmanager\_servers

`alertmanager_servers` specifies the machines to which the Alertmanager service is deployed. You can also specify the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `web_port`: specify the port on which Alertmanager provides web services. The default value is “9093”.

- `cluster_port`: Specify the communication port between one Alertmanager and other Alertmanager. The default value is “9094”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”
- `config_file`: specifies a local file. The specified file will be sent to the target machine as the configuration for Alertmanager during the initialization phase of the cluster configuration.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In `alertmanager_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

An `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
- host: 10.0.1.11
```

```
config_file: /local/config/file
- host: 10.0.1.12
config_file: /local/config/file
```

### 13.4.10 TiUP Mirror Reference Guide

TiUP mirrors are TiUP's component warehouse, which stores components and their metadata. TiUP mirrors take the following two forms:

- Directory on the local disk: serves the local TiUP client, which is called a local mirror in this document.
- HTTP mirror started based on the remote disk directory: serves the remote TiUP client, which is called a remote mirror in this document.

#### 13.4.10.1 Create and update mirror

You can create a TiUP mirror using one of the following two methods:

- Execute `tiup mirror init` to create a mirror from scratch.
- Execute `tiup mirror clone` to clone from an existing mirror.

After the mirror is created, you can add components to or delete components from the mirror using the `tiup mirror` commands. TiUP updates a mirror by adding files and assigning a new version number to it, rather than deleting any files from the mirror.

#### 13.4.10.2 Mirror structure

A typical mirror structure is as follows:

```
+ <mirror-dir> # Mirror's root directory
|-- root.json # Mirror's root certificate
|-- {2..N}.root.json # Mirror's root certificate
|-- {1..N}.index.json # Component/user index
|-- {1..N}.{component}.json # Component metadata
|-- {component}-{version}-{os}-{arch}.tar.gz # Component binary package
|-- snapshot.json # Mirror's latest snapshot
|-- timestamp.json # Mirror's latest timestamp
|--+ commits # Mirror's update log (deletable)
 |--+ commit-{ts1..tsN}
 |-- {N}.root.json
 |-- {N}.{component}.json
 |-- {N}.index.json
 |-- {component}-{version}-{os}-{arch}.tar.gz
 |-- snapshot.json
```

```

|-- timestamp.json
|---+ keys # Mirror's private key (can be
 ↳ moved to other locations)
|-- {hash1..hashN}-root.json # Private key of the root
 ↳ certificate
|-- {hash}-index.json # Private key of the indexes
|-- {hash}-snapshot.json # Private key of the snapshots
|-- {hash}-timestamp.json # Private key of the timestamps

```

### Note:

- The `commits` directory stores the logs generated in the process of mirror update and is used to roll back the mirror. You can delete the old log directories regularly when the disk space is insufficient.
- The private key stored in the `keys` directory is sensitive. It is recommended to keep it separately.

#### 13.4.10.2.1 Root directory

In a TiUP mirror, the root certificate is used to store the public key of other metadata files. Each time any metadata file (\*.json) is obtained, TiUP client needs to find the corresponding public key in the installed `root.json` based on the metadata file type (root, index, snapshot, timestamp). Then TiUP client uses the public key to verify whether the signature is valid.

The root certificate's format is as follows:

```

{
 "signatures": [# Each metadata file
 ↳ has some signatures which are signed by several private keys
 ↳ corresponding to the file.
 {
 "keyid": "{id-of-root-key-1}", # The ID of the
 ↳ first private key that participates in the signature. This
 ↳ ID is obtained by hashing the content of the public key
 ↳ that corresponds to the private key.
 "sig": "{signature-by-root-key-1}" # The signed part of
 ↳ this file by this private key.
 },
 ...
 {
 "keyid": "{id-of-root-key-N}", # The ID of the Nth
 ↳ private key that participates in the signature.
 }
]
}

```

```

 "sig": "{signature-by-root-key-N}" # The signed part of
 ↪ this file by this private key.
 }
],
"signed": { # The signed part.
 "_type": "root", # The type of this
 ↪ file. root.json's type is root.
 "expires": "{expiration-date-of-this-file}", # The expiration
 ↪ time of the file. If the file expires, the client rejects the
 ↪ file.
 "roles": { # Records the keys
 ↪ used to sign each metadata file.
 "{role:index,root,snapshot,timestamp}": { # Each involved
 ↪ metadata file includes index, root, snapshot, and timestamp
 ↪ .
 "keys": { # Only the key's
 ↪ signature recorded in `keys` is valid.
 "{id-of-the-key-1}": { # The ID of the
 ↪ first key used to sign {role}.
 "keytype": "rsa", # The key's type.
 ↪ Currently, the key type is fixed as rsa.
 "keyval": { # The key's payload.
 "public": "{public-key-content}" # The public key's
 ↪ content.
 },
 "scheme": "rsassa-pss-sha256" # Currently, the
 ↪ scheme is fixed as rsassa-pss-sha256.
 },
 "{id-of-the-key-N}": { # The ID of the Nth
 ↪ key used to sign {role}.
 "keytype": "rsa",
 "keyval": {
 "public": "{public-key-content}"
 },
 "scheme": "rsassa-pss-sha256"
 }
 },
 "threshold": {N}, # Indicates that the
 ↪ metadata file needs at least N key signatures.
 "url": "{role}.json" # The address from
 ↪ which the file can be obtained. For index files, prefix
 ↪ it with the version number (for example, /{N}.index.
 ↪ json).
 }
 },
}

```

```

"spec_version": "0.1.0", # The specified
 ↪ version followed by this file. If the file structure is
 ↪ changed in the future, the version number needs to be upgraded
 ↪ . The current version number is 0.1.0.
"version": {N} # The version number
 ↪ of this file. You need to create a new {N+1}.root.json every
 ↪ time you update the file, and set its version to N + 1.
}
}

```

### 13.4.10.2.2 Index

The index file records all the components in the mirror and the owner information of the components.

The index file's format is as follows:

```

{
 "signatures": [# The file's
 ↪ signature.
 {
 "keyid": "{id-of-index-key-1}", # The ID of the
 ↪ first private key that participates in the signature.
 "sig": "{signature-by-index-key-1}", # The signed part of
 ↪ this file by this private key.
 },
 ...
 {
 "keyid": "{id-of-root-key-N}", # The ID of the Nth
 ↪ private key that participates in the signature.
 "sig": "{signature-by-root-key-N}" # The signed part of
 ↪ this file by this private key.
 }
],
 "signed": {
 "_type": "index", # The file type.
 "components": { # The component list
 ↪ .
 "{component1}": { # The name of the
 ↪ first component.
 "hidden": {bool}, # Whether it is a
 ↪ hidden component.
 "owner": "{owner-id}", # The component
 ↪ owner's ID.
 "standalone": {bool}, # Whether it is a
 ↪ standalone component.
 }
 }
 }
}

```

```
"url": "{component}.json", # The address from
 ↪ which the component can be obtained. You need to prefix
 ↪ it with the version number (for example, /{N}.{
 ↪ component}.json).
"yanked": {bool} # Indicates whether
 ↪ the component is marked as deleted.
},
...
"{componentN}": { # The name of the
 ↪ Nth component.
 ...
},
},
"default_components": [{"component1"}.."{componentN}"], # The default
 ↪ component that a mirror must contain. Currently, this field
 ↪ defaults to empty (disabled).
"expires": "{expiration-date-of-this-file}", # The expiration
 ↪ time of the file. If the file expires, the client rejects the
 ↪ file.
"owners": {
 "{owner1}": { # The ID of the
 ↪ first owner.
 "keys": { # Only the key's
 ↪ signature recorded in `keys` is valid.
 "{id-of-the-key-1}": { # The first key of
 ↪ the owner.
 "keytype": "rsa", # The key's type.
 ↪ Currently, the key type is fixed as rsa.
 "keyval": { # The key's payload.
 "public": "{public-key-content}" # The public key's
 ↪ content.
 },
 "scheme": "rsassa-pss-sha256" # Currently, the
 ↪ scheme is fixed as rsassa-pss-sha256.
 },
 ...
 "{id-of-the-key-N}": { # The Nth key of the
 ↪ owner.
 ...
 }
 },
 "name": "{owner-name}", # The name of the
 ↪ owner.
 "threshod": {N} # Indicates that the
 ↪ components owned by the owner must have at least N
```

```

 ↪ valid signatures.
 },
 ...
 "{ownerN}": { # The ID of the Nth
 ↪ owner.
 ...
 }
}
"spec_version": "0.1.0", # The specified
 ↪ version followed by this file. If the file structure is
 ↪ changed in the future, the version number needs to be upgraded
 ↪ . The current version number is 0.1.0.
"version": {N} # The version number
 ↪ of this file. You need to create a new {N+1}.index.json every
 ↪ time you update the file, and set its version to N + 1.
}
}

```

### 13.4.10.2.3 Component

The component's metadata file records information of the component-specific platform and the version.

The component metadata file's format is as follows:

```

{
 "signatures": [# The file's
 ↪ signature.
 {
 "keyid": "{id-of-index-key-1}", # The ID of the
 ↪ first private key that participates in the signature.
 "sig": "{signature-by-index-key-1}", # The signed part of
 ↪ this file by this private key.
 },
 ...
 {
 "keyid": "{id-of-root-key-N}", # The ID of the Nth
 ↪ private key that participates in the signature.
 "sig": "{signature-by-root-key-N}" # The signed part of
 ↪ this file by this private key.
 }
],
 "signed": {
 "_type": "component", # The file type.
 "description": "{description-of-the-component}", # The description of
 ↪ the component.
 }
}

```

```
"expires": "{expiration-date-of-this-file}", # The expiration
 ↪ time of the file. If the file expires, the client rejects the
 ↪ file.
"id": "{component-id}", # The globally
 ↪ unique ID of the component.
"nightly": "{nightly-cursor}", # The nightly cursor
 ↪ , and the value is the latest nightly version number (for
 ↪ example, v5.0.0-nightly-20201209).
"platforms": { # The component's
 ↪ supported platforms (such as darwin/amd64, linux/arm64).
 "{platform-pair-1}": {
 "{version-1}": { # The semantic
 ↪ version number (for example, v1.0.0).
 "dependencies": null, # Specifies the
 ↪ dependency relationship between components. The
 ↪ field is not used yet and is fixed as null.
 "entry": "{entry}", # The relative path
 ↪ of the entry binary file in the tar package.
 "hashs": { # The checksum of
 ↪ the tar package. sha256 and sha512 are used.
 "sha256": "{sum-of-sha256}",
 "sha512": "{sum-of-sha512}",
 },
 "length": {length-of-tar}, # The length of the
 ↪ tar package.
 "released": "{release-time}", # The release date
 ↪ of the version.
 "url": "{url-of-tar}", # The download
 ↪ address of the tar package.
 "yanked": {bool} # Indicates whether
 ↪ this version is disabled.
 }
 },
 ...
 "{platform-pair-N}": {
 ...
 }
},
"spec_version": "0.1.0", # The specified
 ↪ version followed by this file. If the file structure is
 ↪ changed in the future, the version number needs to be upgraded
 ↪ . The current version number is 0.1.0.
"version": {N} # The version number
 ↪ of this file. You need to create a new {N+1}.{component}.json
 ↪ every time you update the file, and set its version to N + 1.
```

```
}

```

#### 13.4.10.2.4 Snapshot

The snapshot file records the version number of each metadata file:

The snapshot file's structure is as follows:

```
{
 "signatures": [# The file's
 ↪ signature.
 {
 "keyid": "{id-of-index-key-1}", # The ID of the
 ↪ first private key that participates in the signature.
 "sig": "{signature-by-index-key-1}", # The signed part of
 ↪ this file by this private key.
 },
 ...
 {
 "keyid": "{id-of-root-key-N}", # The ID of the Nth
 ↪ private key that participates in the signature.
 "sig": "{signature-by-root-key-N}" # The signed part of
 ↪ this file by this private key.
 }
],
 "signed": {
 "_type": "snapshot", # The file type.
 "expires": "{expiration-date-of-this-file}", # The expiration
 ↪ time of the file. If the file expires, the client rejects the
 ↪ file.
 "meta": { # Other metadata
 ↪ files' information.
 "/root.json": {
 "length": {length-of-json-file}, # The length of root
 ↪ .json
 "version": {version-of-json-file} # The version of
 ↪ root.json
 },
 "/index.json": {
 "length": {length-of-json-file},
 "version": {version-of-json-file}
 },
 "/{component-1}.json": {
 "length": {length-of-json-file},
 "version": {version-of-json-file}
 },
 },
 },
}
```

```

 ...
 "/{component-N}.json": {
 ...
 }
},
"spec_version": "0.1.0", # The specified
 ↪ version followed by this file. If the file structure is
 ↪ changed in the future, the version number needs to be upgraded
 ↪ . The current version number is 0.1.0.
"version": 0 # The version number
 ↪ of this file, which is fixed as 0.
}

```

### 13.4.10.2.5 Timestamp

The timestamp file records the checksum of the current snapshot.

The timestamp file's format is as follows:

```

{
 "signatures": [# The file's
 ↪ signature.
 {
 "keyid": "{id-of-index-key-1}", # The ID of the
 ↪ first private key that participates in the signature.
 "sig": "{signature-by-index-key-1}", # The signed part of
 ↪ this file by this private key.
 },
 ...
 {
 "keyid": "{id-of-root-key-N}", # The ID of the Nth
 ↪ private key that participates in the signature.
 "sig": "{signature-by-root-key-N}" # The signed part of
 ↪ this file by this private key.
 }
],
 "signed": {
 "_type": "timestamp", # The file type.
 "expires": "{expiration-date-of-this-file}", # The expiration
 ↪ time of the file. If the file expires, the client rejects the
 ↪ file.
 "meta": { # The information of
 ↪ snapshot.json.
 "/snapshot.json": {
 "hashes": {

```

```
 "sha256": "{sum-of-sha256}" # snapshot.json's
 ↪ sha256.
 },
 "length": {length-of-json-file} # The length of
 ↪ snapshot.json.
 }
},
"spec_version": "0.1.0", # The specified
 ↪ version followed by this file. If the file structure is
 ↪ changed in the future, the version number needs to be upgraded
 ↪ . The current version number is 0.1.0.
"version": {N} # The version number
 ↪ of this file. You need to overwrite timestamp.json every time
 ↪ you update the file, and set its version to N + 1.
```

### 13.4.10.3 Client workflow

The client uses the following logic to ensure that the files downloaded from the mirror are safe:

- A `root.json` file is included with the binary when the client is installed.
- The running client performs the following tasks based on the existing `root.json`:
  1. Obtain the version from `root.json` and mark it as `N`.
  2. Request `{N+1}.root.json` from the mirror. If the request is successful, use the public key recorded in `root.json` to verify whether the file is valid.
  3. Request `timestamp.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
  4. Check whether the checksum of `snapshot.json` recorded in `timestamp.json` matches the checksum of the local `snapshot.json`. If the two do not match, request the latest `snapshot.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
  5. Obtain the version number `N` of the `index.json` file from `snapshot.json` and request `{N}.index.json` from the mirror. Then use the public key recorded in `root.json` to verify whether the file is valid.
  6. For components such as `tidb.json` and `tikv.json`, the client obtains the version numbers `N` of the components from `snapshot.json` and requests `{N}.component ↪ .json` from the mirror. Then the client uses the public key recorded in `index.json` to verify whether the file is valid.
  7. For component's tar files, the client obtains the URLs and checksums of the files from `{component}.json` and request the URLs for the tar packages. Then the client verifies whether the checksum is correct.

## 13.4.11 TiUP Components

### 13.4.11.1 Quickly Deploy a Local TiDB Cluster

The TiDB cluster is a distributed system that consists of multiple components. A typical TiDB cluster consists of at least three PD nodes, three TiKV nodes, and two TiDB nodes. If you want to have a quick experience on TiDB, you might find it time-consuming and complicated to manually deploy so many components. This document introduces the playground component of TiUP and how to use it to quickly build a local TiDB test environment.

#### 13.4.11.1.1 TiUP playground overview

The basic usage of the playground component is shown as follows:

```
tiup playground ${version} [flags]
```

If you directly execute the `tiup playground` command, TiUP uses the locally installed TiDB, TiKV, and PD components or installs the stable version of these components to start a TiDB cluster that consists of one TiKV instance, one TiDB instance, one PD instance, and one TiFlash instance.

This command actually performs the following operations:

- Because this command does not specify the version of the playground component, TiUP first checks the latest version of the installed playground component. Assume that the latest version is v1.11.3, then this command works the same as `tiup playground:v1.11.3`  $\leftrightarrow$  `.11.3`.
- If you have not used TiUP playground to install the TiDB, TiKV, and PD components, the playground component installs the latest stable version of these components, and then start these instances.
- Because this command does not specify the version of the TiDB, PD, and TiKV component, TiUP playground uses the latest version of each component by default. Assume that the latest version is v6.6.0, then this command works the same as `tiup playground:v1.11.3 v6.6.0`  $\leftrightarrow$  `playground:v1.11.3 v6.6.0`.
- Because this command does not specify the number of each component, TiUP playground, by default, starts a smallest cluster that consists of one TiDB instance, one TiKV instance, one PD instance, and one TiFlash instance.
- After starting each TiDB component, TiUP playground reminds you that the cluster is successfully started and provides you some useful information, such as how to connect to the TiDB cluster through the MySQL client and how to access the [TiDB Dashboard](#).

The command-line flags of the playground component are described as follows:

```
Flags:
 --db int Specify the number of TiDB instances (default:
 \leftrightarrow 1)
 --db.host host Specify the listening address of TiDB
```

```
--db.port int Specify the port of TiDB
--db.binpath string Specify the TiDB instance binary path (optional
 ↪ , for debugging)
--db.config string Specify the TiDB instance configuration file (
 ↪ optional, for debugging)
--db.timeout int Specify TiDB maximum wait time in seconds for
 ↪ starting. 0 means no limit
--drainer int Specify Drainer data of the cluster
--drainer.binpath string Specify the location of the Drainer binary
 ↪ files (optional, for debugging)
--drainer.config string Specify the Drainer configuration file
-h, --help help for tiup
--host string Specify the listening address of each component
 ↪ (default: `127.0.0.1`). Set it to `0.0.0.0` if provided for
 ↪ access of other machines
--kv int Specify the number of TiKV instances (default:
 ↪ 1)
--kv.binpath string Specify the TiKV instance binary path (optional
 ↪ , for debugging)
--kv.config string Specify the TiKV instance configuration file (
 ↪ optional, for debugging)
--mode string Specify the playground mode: 'tidb' (default)
 ↪ and 'tikv-slim'
--pd int Specify the number of PD instances (default: 1)
--pd.host host Specify the listening address of PD
--pd.binpath string Specify the PD instance binary path (optional,
 ↪ for debugging)
--pd.config string Specify the PD instance configuration file (
 ↪ optional, for debugging)
--pump int Specify the number of Pump instances. If the
 ↪ value is not `0`, TiDB Binlog is enabled.
--pump.binpath string Specify the location of the Pump binary files (
 ↪ optional, for debugging)
--pump.config string Specify the Pump configuration file (optional,
 ↪ for debugging)
-T, --tag string Specify a tag for playground
--ticdc int Specify the number of TiCDC instances (default:
 ↪ 0)
--ticdc.binpath string Specify the TiCDC instance binary path (
 ↪ optional, for debugging)
--ticdc.config string Specify the TiCDC instance configuration file (
 ↪ optional, for debugging)
--tiflash int Specify the number of TiFlash instances (
 ↪ default: 1)
--tiflash.binpath string Specify the TiFlash instance binary path (
```

```
 ↪ optional, for debugging)
--tiflash.config string Specify the TiFlash instance configuration
 ↪ file (optional, for debugging)
--tiflash.timeout int Specify TiFlash maximum wait time in seconds
 ↪ for starting. 0 means no limit
-v, --version Specify the version of playground
--without-monitor Disable the monitoring function of Prometheus
 ↪ and Grafana. If you do not add this flag, the monitoring
 ↪ function is enabled by default.
```

### 13.4.11.1.2 Examples

Check available TiDB versions

```
tiup list tidb
```

Start a TiDB cluster of a specific version

```
tiup playground ${version}
```

Replace `${version}` with the target version number.

Start a TiDB cluster of the nightly version

```
tiup playground nightly
```

In the command above, `nightly` indicates the latest development version of TiDB.

Override PD's default configuration

First, you need to copy the [PD configuration template](#). Assume you place the copied file to `~/config/pd.toml` and make some changes according to your need, then you can execute the following command to override PD's default configuration:

```
tiup playground --pd.config ~/config/pd.toml
```

Replace the default binary files

By default, when playground is started, each component is started using the binary files from the official mirror. If you want to put a temporarily compiled local binary file into the cluster for testing, you can use the `--{comp}.binpath` flag for replacement. For example, execute the following command to replace the binary file of TiDB:

```
tiup playground --db.binpath /xx/tidb-server
```

Start multiple component instances

By default, only one instance is started for each TiDB, TiKV, and PD component. To start multiple instances for each component, add the following flag:

```
tiup playground --db 3 --pd 3 --kv 3
```

Specify a tag when starting the TiDB cluster

After you stop a TiDB cluster started using TiUP playground, all cluster data is cleaned up as well. To start a TiDB cluster using TiUP playground and ensure that the cluster data is not cleaned up automatically, you can specify a tag when starting the cluster. After specifying the tag, you can find the cluster data in the `~/.tiup/data` directory. Run the following command to specify a tag:

```
tiup playground --tag <tagname>
```

For a cluster started in this way, the data files are retained after the cluster is stopped. You can use this tag to start the cluster next time so that you can use the data kept since the cluster was stopped.

### 13.4.11.1.3 Quickly connect to the TiDB cluster started by playground

TiUP provides the `client` component, which is used to automatically find and connect to a local TiDB cluster started by playground. The usage is as follows:

```
tiup client
```

This command provides a list of TiDB clusters that are started by playground on the current machine on the console. Select the TiDB cluster to be connected. After clicking Enter, a built-in MySQL client is opened to connect to TiDB.

### 13.4.11.1.4 View information of the started cluster

```
tiup playground display
```

The command above returns the following results:

Pid	Role	Uptime
---	----	-----
84518	pd	35m22.929404512s
84519	tikv	35m22.927757153s
84520	pump	35m22.92618275s
86189	tidb	exited
86526	tidb	34m28.293148663s
86190	drainer	35m19.91349249s

### 13.4.11.1.5 Scale out a cluster

The command-line parameter for scaling out a cluster is similar to that for starting a cluster. You can scale out two TiDB instances by executing the following command:

```
tiup playground scale-out --db 2
```

#### 13.4.11.1.6 Scale in a cluster

You can specify a pid in the `tiup playground scale-in` command to scale in the corresponding instance. To view the pid, execute `tiup playground display`.

```
tiup playground scale-in --pid 86526
```

### 13.4.11.2 Deploy and Maintain an Online TiDB Cluster Using TiUP

This document focuses on how to use the TiUP cluster component. For the complete steps of online deployment, refer to [Deploy a TiDB Cluster Using TiUP](#).

Similar to [the TiUP playground component](#) used for a local test deployment, the TiUP cluster component quickly deploys TiDB for production environment. Compared with playground, the cluster component provides more powerful production cluster management features, including upgrading, scaling, and even operation and auditing.

For the help information of the cluster component, run the following command:

```
tiup cluster
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.11.3/
```

```
↳ cluster
```

```
Deploy a TiDB cluster for production
```

```
Usage:
```

```
tiup cluster [command]
```

```
Available Commands:
```

```
check Precheck a cluster
deploy Deploy a cluster for production
start Start a TiDB cluster
stop Stop a TiDB cluster
restart Restart a TiDB cluster
scale-in Scale in a TiDB cluster
scale-out Scale out a TiDB cluster
destroy Destroy a specified cluster
clean (Experimental) Clean up a specified cluster
upgrade Upgrade a specified TiDB cluster
display Display information of a TiDB cluster
list List all clusters
audit Show audit log of cluster operation
import Import an existing TiDB cluster from TiDB-Ansible
edit-config Edit TiDB cluster config
reload Reload a TiDB cluster's config and restart if needed
patch Replace the remote package with a specified package and restart
↳ the service
```

```
help Help about any command

Flags:
-c, --concurrency int Maximum number of concurrent tasks allowed (
 ↪ defaults to `5`)
 --format string (EXPERIMENTAL) The format of output, available
 ↪ values are [default, json] (default "default")
-h, --help help for tiup
 --ssh string (Experimental) The executor type. Optional values
 ↪ are 'builtin', 'system', and 'none'.
 --ssh-timeout uint Timeout in seconds to connect a host via SSH.
 ↪ Operations that don't need an SSH connection are ignored. (
 ↪ default 5)
-v, --version TiUP version
 --wait-timeout uint Timeout in seconds to wait for an operation to
 ↪ complete. Inapplicable operations are ignored. (defaults to
 ↪ `120`)
-y, --yes Skip all confirmations and assumes 'yes'
```

#### 13.4.11.2.1 Deploy the cluster

To deploy the cluster, run the `tiup cluster deploy` command. The usage of the command is as follows:

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

This command requires you to provide the cluster name, the TiDB cluster version (such as `v6.5.0`), and a topology file of the cluster.

To write a topology file, refer to [the example](#). The following file is an example of the simplest topology:

#### Note:

The topology file used by the TiUP cluster component for deployment and scaling is written using [yaml](#) syntax, so make sure that the indentation is correct.

```

pd_servers:
- host: 172.16.5.134
 name: pd-134
```

```
- host: 172.16.5.139
 name: pd-139
- host: 172.16.5.140
 name: pd-140

tidb_servers:
- host: 172.16.5.134
- host: 172.16.5.139
- host: 172.16.5.140

tikv_servers:
- host: 172.16.5.134
- host: 172.16.5.139
- host: 172.16.5.140

tiflash_servers:
- host: 172.16.5.141
- host: 172.16.5.142
- host: 172.16.5.143

grafana_servers:
- host: 172.16.5.134

monitoring_servers:
- host: 172.16.5.134
```

By default, TiUP is deployed as the binary files running on the amd64 architecture. If the target machine is the arm64 architecture, you can configure it in the topology file:

```
global:
 arch: "arm64" # Configures all machines to use the binary files of
 ↪ the arm64 architecture by default

tidb_servers:
- host: 172.16.5.134
 arch: "amd64" # Configures this machine to use the binary files of
 ↪ the amd64 architecture
- host: 172.16.5.139
 arch: "arm64" # Configures this machine to use the binary files of
 ↪ the arm64 architecture
- host: 172.16.5.140 # Machines that are not configured with the arch
 ↪ field use the default value in the global field, which is arm64 in
 ↪ this case.

...
```

Save the file as `/tmp/topology.yaml`. If you want to use TiDB v6.6.0 and your cluster name is `prod-cluster`, run the following command:

```
tiup cluster deploy -p prod-cluster v6.6.0 /tmp/topology.yaml
```

During the execution, TiUP asks you to confirm your topology again and requires the root password of the target machine (the `-p` flag means inputting password):

```
Please confirm your topology:
TiDB Cluster: prod-cluster
TiDB Version: v6.6.0
Type Host Ports OS/Arch Directories

Attention:
 1. If the topology is not what you expected, check your yaml file.
 2. Please confirm there is no port/directory conflicts in same host.
Do you want to continue? [y/N]:
```

After you enter the password, TiUP cluster downloads the required components and

deploy them on the corresponding machines. When you see the following message, the deployment is successful:

```
Deployed cluster `prod-cluster` successfully
```

#### 13.4.11.2.2 View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup cluster list
```

```
Starting /root/.tiup/components/cluster/v1.11.3/cluster list
Name User Version Path
 ↪ PrivateKey

 ↪ -----
prod-cluster tidb v6.6.0 /root/.tiup/storage/cluster/clusters/prod-cluster
 ↪ /root/.tiup/storage/cluster/clusters/prod-cluster/ssh/id_rsa
```

#### 13.4.11.2.3 Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup cluster start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup cluster ↪ list`.

TiUP uses `systemd` to start a daemon process. If the process terminates unexpectedly, it will be pulled up after 15 seconds.

#### 13.4.11.2.4 Check the cluster status

TiUP provides the `tiup cluster display` command to view the status of each component in the cluster. With this command, you don't have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.11.3/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v6.6.0
ID Role Host Ports OS/
 ↪ Arch Status Data Dir Deploy Dir
```

```

```

The **Status** column uses **Up** or **Down** to indicate whether the service is running normally.

For the PD component, **|L** or **|UI** might be appended to **Up** or **Down**. **|L** indicates that the PD node is a Leader, and **|UI** indicates that **TiDB Dashboard** is running on the PD node.

### 13.4.11.2.5 Scale in a cluster

#### Note:

This section describes only the syntax of the scale-in command. For detailed steps of online scaling, refer to [Scale a TiDB Cluster Using TiUP](#).

Scaling in a cluster means making some node(s) offline. This operation removes the specific node(s) from the cluster and deletes the remaining files.

Because the offline process of the TiKV, TiFlash, and TiDB Binlog components is asynchronous (which requires removing the node through API), and the process takes a long time (which requires continuous observation on whether the node is successfully taken offline), special treatment is given to the TiKV, TiFlash, and TiDB Binlog components.

- For TiKV, TiFlash, and Binlog:
  - TiUP cluster takes the node offline through API and directly exits without waiting for the process to be completed.
  - Afterwards, when a command related to the cluster operation is executed, TiUP cluster examines whether there is a TiKV, TiFlash, or Binlog node that has been taken offline. If not, TiUP cluster continues with the specified operation; If there is, TiUP cluster takes the following steps:
    1. Stop the service of the node that has been taken offline.
    2. Clean up the data files related to the node.
    3. Remove the node from the cluster topology.
- For other components:
  - When taking the PD component down, TiUP cluster quickly deletes the specified node from the cluster through API, stops the service of the specified PD node, and deletes the related data files.
  - When taking other components down, TiUP cluster directly stops the node service and deletes the related data files.

The basic usage of the scale-in command:

```
tiup cluster scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two flags: the cluster name and the node ID. The node ID can be obtained by using the `tiup cluster display` command in the previous section.

For example, to make the TiKV node on 172.16.5.140 offline, run the following command:

```
tiup cluster scale-in prod-cluster -N 172.16.5.140:20160
```

By running `tiup cluster display`, you can see that the TiKV node is marked **Offline**:

```
tiup cluster display prod-cluster
```

```

Starting /root/.tiup/components/cluster/v1.11.3/cluster display prod-cluster

 ↪ x86_64 Offline data/tikv-20160 deploy/tikv-20160

```

After PD schedules the data on the node to other TiKV nodes, this node will be deleted automatically.

### 13.4.11.2.6 Scale out a cluster

**Note:**

This section describes only the syntax of the scale-out command. For detailed steps of online scaling, refer to [Scale a TiDB Cluster Using TiUP](#).

The scale-out operation has an inner logic similar to that of deployment: the TiUP cluster component firstly ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

When you scale out PD, the node is added to the cluster by `join`, and the configurations of services associated with PD are updated. When you scale out other services, the service is started directly and added to the cluster.

All services conduct correctness validation when they are scaled out. The validation results show whether the scaling-out is successful.

To add a TiKV node and a PD node in the `tidb-test` cluster, take the following steps:

1. Create a `scale.yaml` file, and add IPs of the new TiKV and PD nodes:

**Note:**

You need to create a topology file, which includes only the description of the new nodes, not the existing nodes.

```

pd_servers:
 - host: 172.16.5.140

tikv_servers:
 - host: 172.16.5.140
```

2. Perform the scale-out operation. TiUP cluster adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup cluster scale-out tidb-test scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup cluster display tidb-test`.

### 13.4.11.2.7 Rolling upgrade

**Note:**

This section describes only the syntax of the upgrade command. For detailed steps of online upgrade, refer to [Upgrade TiDB Using TiUP](#).

The rolling upgrade feature leverages the distributed capabilities of TiDB. The upgrade process is made as transparent as possible to the application, and does not affect the business.

Before the upgrade, TiUP cluster checks whether the configuration file of each component is rational. If so, the components are upgraded node by node; if not, TiUP reports an error and exits. The operations vary with different nodes.

#### Operations for different nodes

- Upgrade the PD node
  - First, upgrade non-Leader nodes.
  - After all the non-Leader nodes are upgraded, upgrade the Leader node.
    - \* The upgrade tool sends a command to PD that migrates Leader to an already upgraded node.
    - \* After the Leader role is switched to another node, upgrade the previous Leader node.
  - During the upgrade, if any unhealthy node is detected, the tool stops this upgrade operation and exits. You need to manually analyze the cause, fix the issue and run the upgrade again.
- Upgrade the TiKV node
  - First, add a scheduling operation in PD that migrates the Region Leader of this TiKV node. This ensures that the upgrade process does not affect the business.
  - After the Leader is migrated, upgrade this TiKV node.
  - After the upgraded TiKV is started normally, remove the scheduling of the Leader.
- Upgrade other services
  - Stop the service normally and update the node.

#### Upgrade command

The flags for the upgrade command is as follows:

```
Usage:
 cluster upgrade <cluster-name> <version> [flags]

Flags:
 --force Force upgrade won't transfer leader
 -h, --help help for upgrade
 --transfer-timeout int Timeout in seconds when transferring PD and
 ↪ TiKV store leaders (default 600)

Global Flags:
 --ssh string (Experimental) The executor type. Optional values
 ↪ are 'builtin', 'system', and 'none'.
 --wait-timeout int Timeout of waiting the operation
 --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
 ↪ for operations that don't need an SSH connection. (default 5)
 -y, --yes Skip all confirmations and assumes 'yes'
```

For example, the following command upgrades the cluster to v6.6.0:

```
tiup cluster upgrade tidb-test v6.6.0
```

#### 13.4.11.2.8 Update configuration

If you want to dynamically update the component configurations, the TiUP cluster component saves a current configuration for each cluster. To edit this configuration, execute the `tiup cluster edit-config <cluster-name>` command. For example:

```
tiup cluster edit-config prod-cluster
```

TiUP cluster opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano`.

After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup cluster reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

#### Note:

For monitoring components, customize the configuration by executing the `tiup cluster edit-config` command to add a custom configuration path on the corresponding instance. For example:

```

grafana_servers:
 - host: 172.16.5.134
 dashboard_dir: /path/to/local/dashboards/dir

monitoring_servers:
 - host: 172.16.5.134
 rule_dir: /path/to/local/rules/dir

alertmanager_servers:
 - host: 172.16.5.134
 config_file: /path/to/local/alertmanager.yml
```

The content and format requirements for files under the specified path are as follows:

- The folder specified in the `dashboard_dir` field of `grafana_servers` must contain full `*.json` files.
- The folder specified in the `rule_dir` field of `monitoring_servers` must contain full `*.rules.yml` files.
- For the format of files specified in the `config_file` field of `alertmanager_servers`, refer to [the Alertmanager configuration template](#).

When you execute `tiup reload`, TiUP first deletes all old configuration files in the target machine and then uploads the corresponding configuration from the control machine to the corresponding configuration directory of the target machine. Therefore, if you want to modify a particular configuration file, make sure that all configuration files (including the unmodified ones) are in the same directory. For example, to modify Grafana's `tidb.json` file, you need to first copy all the `*.json` files from Grafana's `dashboards` directory to your local directory. Otherwise, other JSON files will be missing from the target machine.

### Note:

If you have configured the `dashboard_dir` field of `grafana_servers`, after executing the `tiup cluster rename` command to rename the cluster, you need to complete the following operations:

1. In the local `dashboards` directory, change the cluster name to the new cluster name.
2. In the local `dashboards` directory, change `datasource` to the new cluster name, because `datasource` is named after the cluster name.
3. Execute the `tiup cluster reload -R grafana` command.

### 13.4.11.2.9 Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

Replace the remote package with a specified package and restart the service

Usage:

```
cluster patch <cluster-name> <package-path> [flags]
```

Flags:

```
-h, --help help for patch
-N, --node strings Specify the nodes
 --offline Patch a stopped cluster
 --overwrite Use this package in the future scale-out
 ↪ operations
-R, --role strings Specify the roles
 --transfer-timeout uint Timeout in seconds when transferring PD and
 ↪ TiKV store leaders, also for TiCDC drain one capture (default
 ↪ 600)
```

Global Flags:

```
-c, --concurrency int max number of parallel tasks allowed (default 5)
--format string (EXPERIMENTAL) The format of output, available
 ↪ values are [default, json] (default "default")
--ssh string (EXPERIMENTAL) The executor type: 'builtin', '
 ↪ system', 'none'.
--ssh-timeout uint Timeout in seconds to connect host via SSH, ignored
 ↪ for operations that don't need an SSH connection. (default 5)
--wait-timeout uint Timeout in seconds to wait for an operation to
 ↪ complete, ignored for operations that don't fit. (default 120)
-y, --yes Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

### 13.4.11.2.10 Import TiDB Ansible cluster

**Note:**

Currently, TiUP cluster's support for TiSpark is still **experimental**. It is not supported to import a TiDB cluster with TiSpark enabled.

Before TiUP is released, TiDB Ansible is often used to deploy TiDB clusters. To enable TiUP to take over the cluster deployed by TiDB Ansible, use the `import` command.

The usage of the `import` command is as follows:

```
tiup cluster import --help
```

```
Import an exist TiDB cluster from TiDB-Ansible
```

Usage:

```
cluster import [flags]
```

Flags:

```
-d, --dir string The path to TiDB-Ansible directory
-h, --help help for import
--inventory string The name of inventory file (default "inventory.ini
 ↪ ")
--no-backup Don't backup ansible dir, useful when there're
 ↪ multiple inventory files
-r, --rename NAME Rename the imported cluster to NAME
```

Global Flags:

```
--ssh string (Experimental) The executor type. Optional values are
 ↪ 'builtin', 'system', and 'none'.
--wait-timeout int Timeout of waiting the operation
--ssh-timeout int Timeout in seconds to connect host via SSH, ignored
 ↪ for operations that don't need an SSH connection. (default 5)
-y, --yes Skip all confirmations and assumes 'yes'
```

You can use either of the following commands to import a TiDB Ansible cluster:

```
cd tidb-ansible
tiup cluster import
```

```
tiup cluster import --dir=/path/to/tidb-ansible
```

### 13.4.11.2.11 View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
 tiup cluster audit [audit-id] [flags]

Flags:
 -h, --help help for audit
```

If the `[audit-id]` flag is not specified, the command shows a list of commands that have been executed. For example:

```
tiup cluster audit
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.11.3/
↳ cluster audit
ID Time Command
-- ---- -
4BLhr0 2022-02-09T23:55:09+08:00 /home/tidb/.tiup/components/cluster/v1
↳ .11.3/cluster deploy test v6.6.0 /tmp/topology.yaml
4BKWjF 2022-02-09T23:36:57+08:00 /home/tidb/.tiup/components/cluster/v1
↳ .11.3/cluster deploy test v6.6.0 /tmp/topology.yaml
4BKVvH 2022-02-09T23:02:08+08:00 /home/tidb/.tiup/components/cluster/v1
↳ .11.3/cluster deploy test v6.6.0 /tmp/topology.yaml
4BKkH1 2022-02-09T16:39:04+08:00 /home/tidb/.tiup/components/cluster/v1
↳ .11.3/cluster destroy test
4BKkDx 2022-02-09T16:36:57+08:00 /home/tidb/.tiup/components/cluster/v1
↳ .11.3/cluster deploy test v6.6.0 /tmp/topology.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` of a command as the flag as follows:

```
tiup cluster audit 4BLhr0
```

### 13.4.11.2.12 Run commands on a host in the TiDB cluster

To run command on a host in the TiDB cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
 cluster exec <cluster-name> [flags]

Flags:
 --command string the command run on cluster host (default "ls")
 -h, --help help for exec
```

```
-N, --node strings Only exec on host with specified nodes
-R, --role strings Only exec on host with specified roles
--sudo use root permissions (default false)
```

#### Global Flags:

```
--ssh-timeout int Timeout in seconds to connect host via SSH, ignored
 ↪ for operations that don't need an SSH connection. (default 5)
-y, --yes Skip all confirmations and assumes 'yes'
```

For example, to execute `ls /tmp` on all TiDB nodes, run the following command:

```
tiup cluster exec test-cluster --command='ls /tmp'
```

#### 13.4.11.2.13 Cluster controllers

Before TiUP is released, you can control the cluster using `tidb-ctl`, `tikv-ctl`, `pd-ctl`, and other tools. To make the tools easier to download and use, TiUP integrates them into an all-in-one component, `ctl`.

#### Usage:

```
tiup ctl:v<CLUSTER_VERSION> {tidb/pd/tikv/binlog/etcd} [flags]
```

#### Flags:

```
-h, --help help for tiup
```

This command has a corresponding relationship with those of the previous tools:

```
tidb-ctl [args] = tiup ctl tidb [args]
pd-ctl [args] = tiup ctl pd [args]
tikv-ctl [args] = tiup ctl tikv [args]
binlogctl [args] = tiup ctl binlog [args]
etcdctl [args] = tiup ctl etcd [args]
```

For example, if you previously view the store by running `pd-ctl -u http://127.0.0.1:2379 ↪ store`, now you can run the following command in TiUP:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://127.0.0.1:2379 store
```

#### 13.4.11.2.14 Environment checks for target machines

You can use the `check` command to perform a series of checks on the environment of the target machine and output the check results. By executing the `check` command, you can find common unreasonable configurations or unsupported situations. The command flag list is as follows:

```
Usage:
 tiup cluster check <topology.yml | cluster-name> [flags]
Flags:
 --apply Try to fix failed checks
 --cluster Check existing cluster, the input is a cluster
 ↪ name.
 --enable-cpu Enable CPU thread count check
 --enable-disk Enable disk IO (fio) check
 --enable-mem Enable memory size check
 -h, --help help for check
 -i, --identity_file string The path of the SSH identity file. If specified
 ↪ , public key authentication will be used.
 -p, --password Use password of target hosts. If specified,
 ↪ password authentication will be used.
 --user string The user name to login via SSH. The user must
 ↪ has root (or sudo) privilege.
```

By default, this command is used to check the environment before deployment. By specifying the `--cluster` flag to switch the mode, you can also check the target machines of an existing cluster, for example:

```
check deployed servers before deployment
tiup cluster check topology.yml --user tidb -p
check deployed servers of an existing cluster
tiup cluster check <cluster-name> --cluster
```

The CPU thread count check, memory size check, and disk performance check are disabled by default. For the production environment, it is recommended that you enable the three checks and make sure they pass to obtain the best performance.

- CPU: If the number of threads is greater than or equal to 16, the check is passed.
- Memory: If the total size of physical memory is greater than or equal to 32 GB, the check is passed.
- Disk: Execute `fio` test on the partitions of `data_dir` and record the results.

When running the checks, if the `--apply` flag is specified, the program automatically repairs the failed items. Automatic repair is limited to some items that can be adjusted by modifying the configuration or system parameters. Other unrepaired items need to be handled manually according to the actual situation.

Environment checks are not necessary for deploying a cluster. For the production environment, it is recommended to perform environment checks and pass all check items before deployment. If not all the check items are passed, the cluster might be deployed and run normally, but the best performance might not be obtained.

### 13.4.11.2.15 Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--ssh=system` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup cluster deploy <cluster-name> <version> <topo> --ssh=system`. Fill in the name of your cluster for `<cluster-name>`, the TiDB version to be deployed (such as `v6.5.0`) for `<version>`, and the topology file for `<topo>`.
- Start a cluster: `tiup cluster start <cluster-name> --ssh=system`
- Upgrade a cluster: `tiup cluster upgrade ... --ssh=system`

You can add `--ssh=system` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
or
export TIUP_NATIVE_SSH=1
or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--ssh` at the same time, `--ssh` has higher priority.

#### Note:

During the process of cluster deployment, if you need to use a password for connection (`-p`) or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

### 13.4.11.2.16 Migrate control machine and back up TiUP data

The TiUP data is stored in the `.tiup` directory in the user's home directory. To migrate the control machine, you can take the following steps to copy the `.tiup` directory to the corresponding target machine:

1. Execute `tar czvf tiup.tar.gz .tiup` in the home directory of the original machine.
2. Copy `tiup.tar.gz` to the home directory of the target machine.
3. Execute `tar xzvf tiup.tar.gz` in the home directory of the target machine.
4. Add the `.tiup` directory to the `PATH` environment variable.

If you use `bash` and you are a `tidb` user, you can add `export PATH=/home/tidb ↪ /.tiup/bin:$PATH` in `~/.bashrc` and execute `source ~/.bashrc`. Then make corresponding adjustments according to the shell and the user you use.

#### Note:

It is recommended that you back up the `.tiup` directory regularly to avoid the loss of TiUP data caused by abnormal conditions, such as disk damage of the control machine.

### 13.4.11.2.17 Back up and restore meta files for cluster deployment and O&M

If the meta files used for operation and maintenance (O&M) are lost, managing the cluster using TiUP will fail. It is recommended that you back up the meta files regularly by running the following command:

```
tiup cluster meta backup ${cluster_name}
```

If the meta files are lost, you can restore them by running the following command:

```
tiup cluster meta restore ${cluster_name} ${backup_file}
```

#### Note:

The restore operation overwrites the current meta files. Therefore, it is recommended to restore the meta files only when they are lost.

### 13.4.11.3 Create a Private Mirror

When creating a private cloud, usually, you need to use an isolated network environment, where the official mirror of TiUP is not accessible. Therefore, you can create a private mirror, which is mainly implemented by the `mirror` command. You can also use the `mirror` command for offline deployment. A private mirror also allows you to use components that you build and package by yourself.

#### 13.4.11.3.1 TiUP mirror overview

Execute the following command to get the help information of the `mirror` command:

```
tiup mirror --help
```

The `mirror` command is used to manage a component repository for TiUP, you  
↪ can use

it to create a private repository, or to add new component to an existing  
↪ repository.

The repository can be used either online or offline.

It also provides some useful utilities to `help` manage keys, users, and  
↪ versions

of components or the repository itself.

Usage:

```
tiup mirror <command> [flags]
```

Available Commands:

<code>init</code>	Initialize an empty repository
<code>sign</code>	Add signatures to a manifest file
<code>genkey</code>	Generate a new key pair
<code>clone</code>	Clone a <code>local</code> mirror from a remote mirror and download all ↪ selected components
<code>merge</code>	Merge two or more offline mirrors
<code>publish</code>	Publish a component
<code>show</code>	Show the mirror address
<code>set</code>	Set mirror address
<code>modify</code>	Modify published component
<code>renew</code>	Renew the manifest of a published component.
<code>grant</code>	grant a new owner
<code>rotate</code>	Rotate root.json

Global Flags:

```
--help Help for this command
```

Use `"tiup mirror [command] --help"` for more information about a `command`.

### 13.4.11.3.2 Clone a mirror

You can run the `tiup mirror clone` command to build a local mirror:

```
tiup mirror clone <target-dir> [global-version] [flags]
```

- `target-dir`: used to specify the directory in which cloned data is stored.
- `global-version`: used to quickly set a global version for all components.

The `tiup mirror clone` command provides many optional flags (might provide more in the future). These flags can be divided into the following categories according to their intended usages:

- Determines whether to use prefix matching to match the version when cloning  
If the `--prefix` flag is specified, the version number is matched by prefix for the clone. For example, if you specify `--prefix` as “v5.0.0”, then “v5.0.0-rc”, and “v5.0.0” are matched.
- Determines whether to use the full clone  
If you specify the `--full` flag, you can clone the official mirror fully.

**Note:**

If `--full`, `global-version` flags, and the component versions are not specified, only some meta information is cloned.

- Determines whether to clone packages from the specific platform  
If you want to clone packages only for a specific platform, use `-os` and `-arch` to specify the platform. For example:
  - Execute the `tiup mirror clone <target-dir> [global-version] --os= ↪ linux` command to clone for linux.
  - Execute the `tiup mirror clone <target-dir> [global-version] --arch= ↪ amd64` command to clone for amd64.
  - Execute the `tiup mirror clone <target-dir> [global-version] --os= ↪ linux --arch=amd64` command to clone for linux/amd64.
- Determines whether to clone a specific version of a package  
If you want to clone only one version (not all versions) of a component, use `--< ↪ component>=<version>` to specify this version. For example:
  - Execute the `tiup mirror clone <target-dir> --tidb v6.6.0` command to clone the v6.6.0 version of the TiDB component.

- Run the `tiup mirror clone <target-dir> --tidb v6.6.0 --tikv all` command to clone the v6.6.0 version of the TiDB component and all versions of the TiKV component.
- Run the `tiup mirror clone <target-dir> v6.6.0` command to clone the v6.6.0 version of all components in a cluster.

After cloning, signing keys are set up automatically.

Manage the private repository

You can share the repository cloned using `tiup mirror clone` among hosts either by sharing files via SCP, NFS, or by making the repository available over the HTTP or HTTPS protocol. Use `tiup mirror set <location>` to specify the location of the repository.

```
tiup mirror set /shared_data/tiup
```

```
tiup mirror set https://tiup-mirror.example.com/
```

#### Note:

If you run `tiup mirror set...` on the machine where you run `tiup mirror`  $\leftrightarrow$  `clone`, the next time you run `tiup mirror clone...`, the machine clones from the local mirror, not the remote one. Therefore, you need to reset the mirror by running `tiup mirror set --reset` before updating the private mirror.

Another way of using a mirror is to use the `TIUP_MIRRORS` environment variable. Here is an example for running `tiup list` with a private repository.

```
export TIUP_MIRRORS=/shared_data/tiup
tiup list
```

`TIUP_MIRRORS` setting can permanently change the mirror configuration, for example, `tiup mirror set`. For details, see [tiup issue #651](#).

Update the private repository

If you run the `tiup mirror clone` command again with the same `target-dir`, the machine will create new manifests and download the latest versions of components available.

#### Note:

Before recreating the manifest, ensure that all components and versions (including earlier ones downloaded previously) are included.

### 13.4.11.3.3 Custom repository

You can create a custom repository to work with TiDB components like TiDB, TiKV, or PD that you build by yourself. It is also possible to create your own tiup components.

To create your own components, run the `tiup package` command and perform as instructed in [Component packaging](#).

Create a custom repository

To create an empty repository in `/data/mirror`:

```
tiup mirror init /data/mirror
```

As part of creating the repository, keys will be written to `/data/mirror/keys`.

To create a new private key in `~/.tiup/keys/private.json`:

```
tiup mirror genkey
```

Grant `jdoue` with private key `~/.tiup/keys/private.json` ownership of `/data/mirror`:

```
tiup mirror set /data/mirror
tiup mirror grant jdoue
```

Work with custom components

1. Create a custom component called `hello`.

```
$ cat > hello.c << END
> #include <stdio.h>
int main() {
 printf("hello\n");
 return (0);
}
END
$ gcc hello.c -o hello
$ tiup package hello --entry hello --name hello --release v0.0.1
```

`package/hello-v0.0.1-linux-amd64.tar.gz` is created.

2. Create a repository and a private key, and grant ownership to the repository.

```
$ tiup mirror init /tmp/m
$ tiup mirror genkey
$ tiup mirror set /tmp/m
$ tiup mirror grant $USER
```

```
tiup mirror publish hello v0.0.1 package/hello-v0.0.1-linux-amd64.tar.
↪ gz hello
```

3. Run the component. If it is not installed yet, it will be downloaded first.

```
$ tiup hello
```

```
The component `hello` version is not installed; downloading from
↳ repository.
Starting component `hello`: /home/dvaneeden/.tiup/components/hello/v0
↳ .0.1/hello
hello
```

With `tiup mirror merge`, you can merge a repository with custom components into another one. This assumes that all components in `/data/my_custom_components` are signed by the current `$USER`.

```
$ tiup mirror set /data/my_mirror
$ tiup mirror grant $USER
$ tiup mirror merge /data/my_custom_components
```

#### 13.4.11.4 Stress Test TiDB Using TiUP Bench Component

When you test the performance of a database, it is often required to stress test the database. To facilitate this, TiUP has integrated the `bench` component, which provides multiple workloads for stress testing. You can access these workloads by the following commands:

```
tiup bench tpcc # Benchmark a database using TPC-C
tiup bench tpch # Benchmark a database using TPC-H
tiup bench ch # Benchmark a database using CH-benCHmark
tiup bench ycsb # Benchmark a database using YCSB
tiup bench rawsql # Benchmark a database using arbitrary SQL files
```

`tpcc`, `tpch`, `ch`, and `rawsql` share the following common command flags. However, `ycsb` is mainly configured by a `.properties` file, which is described in its [usage guide](#).

```
-t, --acThreads int OLAP client concurrency, only for CH-benCHmark (
↳ default to 1)
--conn-params string Session variables, such as setting `--conn-params
↳ tidb_isolation_read_engines='tiflash'` for TiDB queries and
↳ setting `--conn-params sslmode=disable` for PostgreSQL
↳ connections
--count int Total execution count (0 means infinite count)
-D, --db string Database name (default to "test")
-d, --driver string Database driver: mysql, postgres (default to "
↳ mysql")
--dropdata Clean up historical data before preparing
-H, --host strings Database host (default to [127.0.0.1])
```

```

--ignore-error Ignore errors when running workload
--interval duration Output interval time (default to 10s)
--isolation int Isolation Level (0: Default; 1: ReadUncommitted;
 2: ReadCommitted; 3: WriteCommitted; 4:
 ↪ RepeatableRead;
 5: Snapshot; 6: Serializable; 7: Linerizable)
--max-procs int runtime.GOMAXPROCS of go lang, the limits of how
 ↪ many cores can be used
--output string Output style. Valid values can be { plain | table
 ↪ | json } (default to "plain")
-p, --password string Database password
-P, --port ints Database port (default to [4000])
--pprof string Address of pprof endpoint
--silence Don't print errors when running workload
-S, --statusPort int Database status port (default to 10080)
-T, --threads int Thread concurrency (default to 1)
--time duration Total execution time (default to 2562047h47m16
 ↪ .854775807s)
-U, --user string Database user (default to "root")

```

- You can pass comma-separated values to `--host` and `--port` to enable client-side load balancing. For example, when you specify `--host 172.16.4.1,172.16.4.2` ↪ `--port 4000,4001`, the program will connect to `172.16.4.1:4000`, `172.16.4.1:4001`, `172.16.4.2:4000`, and `172.16.4.2:4001`, chosen in round-robin fashion.
- `--conn-params` must follow the format of [query string](#). Different databases might have different parameters. For example:

- `--conn-params tidb_isolation_read_engines='tiflash'` forces TiDB to read from TiFlash.
- `--conn-params sslmode=disable` disables SSL when you connect to PostgreSQL.

- When running CH-benCHmark, you can use `--ap-host`, `--ap-port`, and `--ap-conn-params` to specify a standalone TiDB server for OLAP queries.

The following sections describe how to run TPC-C, TPC-H, YCSB tests using TiUP.

#### 13.4.11.4.1 Run TPC-C test using TiUP

The TiUP bench component supports the following commands and flags to run the TPC-C test:

```

Available Commands:
check Check data consistency for the workload
cleanup Cleanup data for the workload

```

```
prepare Prepare data for the workload
run Run workload
```

Flags:

```
--check-all Run all consistency checks
-h, --help Help for TPC-C
--partition-type int Partition type: 1 - HASH, 2 - RANGE, 3 - LIST (
 ↪ HASH-like), 4 - LIST (RANGE-like) (default to 1)
--parts int Number of partitions (default to 1)
--warehouses int Number of warehouses (default to 10)
```

### Test procedures

The following provides simplified steps for running a TPC-C test. For detailed steps, see [How to Run TPC-C Test on TiDB](#).

1. Create 4 warehouses using 4 partitions via hash:

```
tiup bench tpcc --warehouses 4 --parts 4 prepare
```

2. Run the TPC-C test:

```
tiup bench tpcc --warehouses 4 --time 10m run
```

3. Check the consistency:

```
tiup bench tpcc --warehouses 4 check
```

4. Clean up data:

```
tiup bench tpcc --warehouses 4 cleanup
```

Preparing data via SQL might be slow when you want to run a benchmark with a large data set. In that case, you can generate data in the CSV format by the following commands and then import it to TiDB via [TiDB Lightning](#).

- Generate the CSV file:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
 ↪ csv
```

- Generate the CSV file for the specified table:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
 ↪ csv --tables history,orders
```

### 13.4.11.4.2 Run TPC-H test using TiUP

The TiUP bench component supports the following commands and parameters to run the TPC-H test:

Available Commands:

```
cleanup Cleanup data for the workload
prepare Prepare data for the workload
run Run workload
```

Flags:

```
--check Check output data, only when the scale factor equals 1
-h, --help help for tpch
--queries string All queries (default "q1,q2,q3,q4,q5,q6,q7,q8,q9,q10,
 ↪ q11,q12,q13,q14,q15,q16,q17,q18,q19,q20,q21,q22")
--sf int scale factor
```

#### Test procedures

1. Prepare data:

```
tiup bench tpch --sf=1 prepare
```

2. Run the TPC-H test by executing one of the following commands:

- If you check the result, run this command:

```
tiup bench tpch --count=22 --sf=1 --check=true run
```

- If you do not check the result, run this command:

```
tiup bench tpch --count=22 --sf=1 run
```

3. Clean up data:

```
tiup bench tpch cleanup
```

### 13.4.11.4.3 Run YCSB test using TiUP

You can stress test both TiDB and TiKV via YCSB.

#### Stress test TiDB

1. Prepare data:

```
tiup bench ycsb load tidb -p tidb.instances="127.0.0.1:4000" -p
 ↪ recordcount=10000
```

2. Run the YCSB workload:

```
The read-write percent is 95% by default
tiup bench ycsb run tidb -p tidb.instances="127.0.0.1:4000" -p
 ↪ operationcount=10000
```

Stress test TiKV

1. Prepare data:

```
tiup bench ycsb load tikv -p tikv.pd="127.0.0.1:2379" -p recordcount
 ↪ =10000
```

2. Run the YCSB workload:

```
The read-write percent is 95% by default
tiup bench ycsb run tikv -p tikv.pd="127.0.0.1:2379" -p operationcount
 ↪ =10000
```

#### 13.4.11.4.4 Run RawSQL test using TiUP

You can write an arbitrary query in a SQL file, and then use it for the test by executing `tiup bench rawsql` as follows:

1. Prepare data and the query:

```
-- Prepare data
CREATE TABLE t (a int);
INSERT INTO t VALUES (1), (2), (3);

-- Save your query in a SQL file. For example, you can save the
 ↪ following query in `demo.sql`.
SELECT a, sleep(rand()) FROM t WHERE a < 4*rand();
```

2. Run the RawSQL test:

```
shell tiup bench rawsql run --count 60 --query-files demo.sql
```

## 13.5 TiDB Operator

[TiDB Operator](#) is an automatic operation system for TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB Operator documentation (also named as TiDB on Kubernetes documentation) is independent of the TiDB documentation. To access the documentation, click the following link:

- [TiDB on Kubernetes documentation](#)

## 13.6 TiDB Data Migration

### 13.6.1 TiDB Data Migration Overview

[TiDB Data Migration](#) (DM) is an integrated data migration task management platform, which supports the full data migration and the incremental data replication from MySQL-compatible databases (such as MySQL, MariaDB, and Aurora MySQL) into TiDB. It can help to reduce the operation cost of data migration and simplify the troubleshooting process.

#### 13.6.1.1 Basic features

- **Compatibility with MySQL.** DM is compatible with MySQL 5.7 protocols and most of the features and syntax of MySQL 5.7.
- **Replicating DML and DDL events.** It supports parsing and replicating DML and DDL events in MySQL binlog.
- **Migrating and merging MySQL shards.** DM supports migrating and merging multiple MySQL database instances upstream to one TiDB database downstream. It supports customizing replication rules for different migration scenarios. It can automatically detect and handle DDL changes of upstream MySQL shards, which greatly reduces the operational cost.
- **Various types of filters.** You can predefine event types, regular expressions, and SQL expressions to filter out MySQL binlog events during the data migration process.
- **Centralized management.** DM supports thousands of nodes in a cluster. It can run and manage a large number of data migration tasks concurrently.
- **Optimization of the third-party Online Schema Change process.** In the MySQL ecosystem, tools such as gh-ost and pt-osc are widely used. DM optimizes its change process to avoid unnecessary migration of intermediate data. For details, see [online-ddl](#).
- **High availability.** DM supports data migration tasks to be scheduled freely on different nodes. The running tasks are not affected when a small number of nodes crash.

#### 13.6.1.2 Quick installation

Run the following command to install DM:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
 ↪ install.sh | sh
tiup install dm dmctl
```

### 13.6.1.3 Usage restrictions

Before using the DM tool, note the following restrictions:

- Database version requirements
  - MySQL version 5.5 ~ 5.7
  - MySQL version 8.0 (experimental features)
  - MariaDB version  $\geq 10.1.2$  (experimental features)

#### Note:

If there is a primary-secondary migration structure between the upstream MySQL/MariaDB servers, then choose the following version.

- MySQL version  $> 5.7.1$
- MariaDB version  $\geq 10.1.3$

- DDL syntax compatibility
  - Currently, TiDB is not compatible with all the DDL statements that MySQL supports. Because DM uses the TiDB parser to process DDL statements, it only supports the DDL syntax supported by the TiDB parser. For details, see [MySQL Compatibility](#).
  - DM reports an error when it encounters an incompatible DDL statement. To solve this error, you need to manually handle it using `dmctl`, either skipping this DDL statement or replacing it with specified DDL statements. For details, see [Skip or replace abnormal SQL statements](#).
  - DM does not replicate view-related DDL statements and DML statements to the downstream TiDB cluster. It is recommended that you create the view in the downstream TiDB cluster manually.
- GBK character set compatibility
  - DM does not support migrating `charset=GBK` tables to TiDB clusters earlier than v5.4.0.

### 13.6.1.4 Contributing

You are welcome to participate in the DM open sourcing project. Your contribution would be highly appreciated. For more details, see [CONTRIBUTING.md](#).

### 13.6.1.5 Community support

You can learn about DM through the online documentation. If you have any questions, contact us on [GitHub](#).

### 13.6.1.6 License

DM complies with the Apache 2.0 license. For more details, see [LICENSE](#).

### 13.6.1.7 DM versions

Before v5.4, the DM documentation is independent of the TiDB documentation. To access these earlier versions of the DM documentation, click one of the following links:

- [DM v5.3 documentation](#)
- [DM v2.0 documentation](#)
- [DM v1.0 documentation](#)

#### Note:

- Since October 2021, DM's GitHub repository has been moved to [pingcap/tiflow](#). If you see any issues with DM, submit your issue to the [pingcap/tiflow](#) repository for feedback.
- In earlier versions (v1.0 and v2.0), DM uses version numbers that are independent of TiDB. Since v5.3, DM uses the same version number as TiDB. The next version of DM v2.0 is DM v5.3. There are no compatibility changes from DM v2.0 to v5.3, and the upgrade process is the same as a normal upgrade, only an increase in version number.

## 13.6.2 Data Migration Architecture

This document introduces the architecture of Data Migration (DM).

DM consists of three components: DM-master, DM-worker, and dmctl.

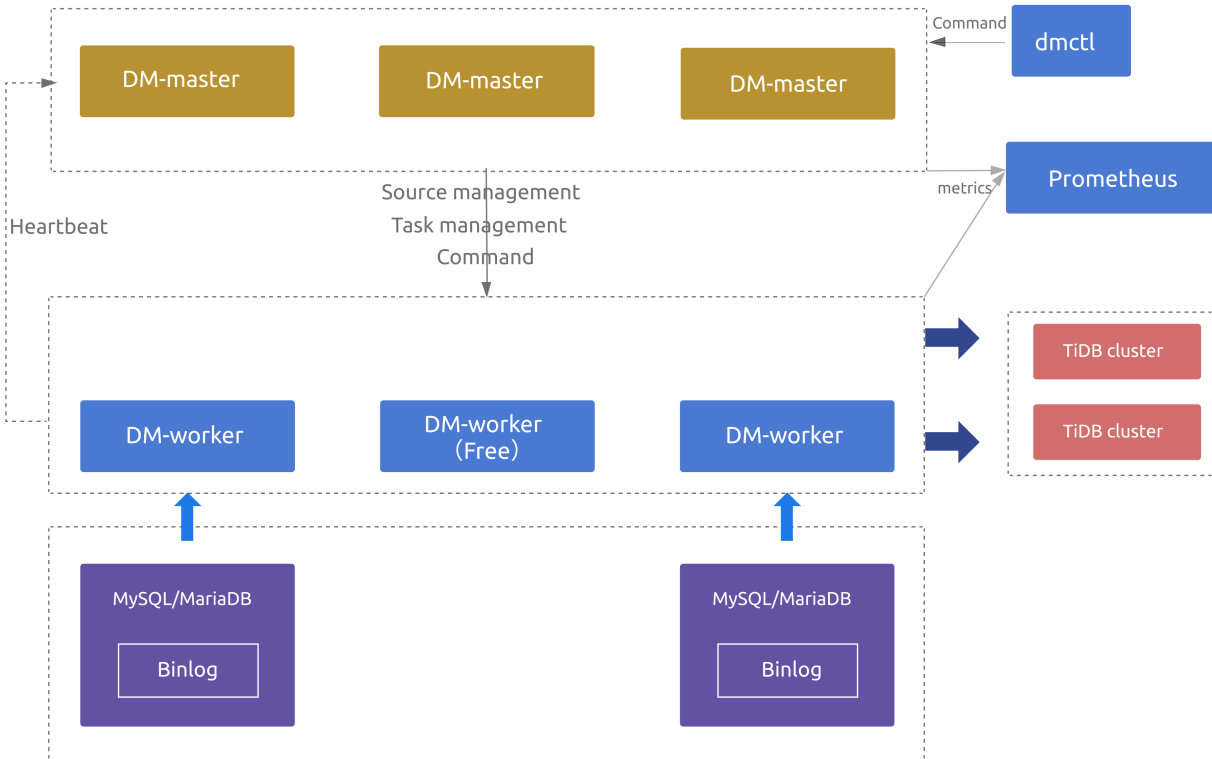

Figure 237: Data Migration architecture

### 13.6.2.1 Architecture components

#### 13.6.2.1.1 DM-master

DM-master manages and schedules the operations of data migration tasks.

- Storing the topology information of the DM cluster
- Monitoring the running state of DM-worker processes
- Monitoring the running state of data migration tasks
- Providing a unified portal for the management of data migration tasks
- Coordinating the DDL migration of sharded tables in each instance under the sharding scenario

#### 13.6.2.1.2 DM-worker

DM-worker executes specific data migration tasks.

- Persisting the binlog data to the local storage
- Storing the configuration information of the data migration subtasks
- Orchestrating the operation of the data migration subtasks

- Monitoring the running state of the data migration subtasks

For more details of DM-worker, see [DM-worker Introduction](#).

### 13.6.2.1.3 dmctl

dmctl is a command line tool used to control the DM cluster.

- Creating, updating, or dropping data migration tasks
- Checking the state of data migration tasks
- Handling errors of data migration tasks
- Verifying the configuration correctness of data migration tasks

## 13.6.2.2 Architecture features

### 13.6.2.2.1 High availability

When you deploy multiple DM-master nodes, all DM-master nodes use the embedded etcd to form a cluster. The DM-master cluster is used to store metadata such as cluster node information and task configuration. The leader node elected through etcd is used to provide services such as cluster management and data migration task management. Therefore, if the number of available DM-master nodes exceeds half of the deployed nodes, the DM cluster can normally provide services.

When the number of deployed DM-worker nodes exceeds the number of upstream MySQL/MariaDB nodes, the extra DM-worker nodes are idle by default. If a DM-worker node goes offline or is isolated from the DM-master leader, DM-master automatically schedules data migration tasks of the original DM-worker node to other idle DM-worker nodes. (If a DM-worker node is isolated, it automatically stops the data migration tasks on it); if there are no available idle DM-worker nodes, the data migration tasks of the original DM-worker are temporarily hung until one DM-worker node becomes idle, and then the tasks are automatically resumed.

#### **Note:**

When the data migration task is in the process of full export or import, the migration task does not support high availability. Here are the main reasons:

- For the full export, MySQL does not support exporting from a specific snapshot point yet. This means that after the data migration task is rescheduled or restarted, the export cannot resume from the previous interruption point.

- For the full import, DM-worker does not support reading exported full data across the nodes yet. This means that after the data migration task is scheduled to a new DM-worker node, you cannot read the exported full data on the original DM-worker node before the scheduling happens.

### 13.6.3 Quick Start Guide for TiDB Data Migration

This document describes how to migrate data from MySQL to TiDB using [TiDB Data Migration](#) (DM). This guide is a quick demo of DM features and is not recommended for any production environment.

#### 13.6.3.1 Step 1: Deploy a DM cluster

1. Install TiUP, and install `dmctl` using TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
 ↪ install.sh | sh
tiup install dm dmctl
```

2. Generate the minimal deployment topology file of a DM cluster:

```
tiup dm template
```

3. Copy the configuration information in the output, and save it as the `topology.yaml` file with the modified IP address. Deploy the DM cluster with the `topology.yaml` file using TiUP:

```
tiup dm deploy dm-test 6.0.0 topology.yaml -p
```

#### 13.6.3.2 Step 2: Prepare the data source

You can use one or multiple MySQL instances as an upstream data source.

1. Create a configuration file for each data source as follows:

```
source-id: "mysql-01"
from:
 host: "127.0.0.1"
 user: "root"
 password: "fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg=" # encrypt with `tiup
 ↪ dmctl --encrypt "123456"`
 port: 3306
```

2. Add the source to the DM cluster by running the following command. `mysql-01.yaml` is the configuration file created in the previous step.

```
tiup dmctl --master-addr=127.0.0.1:8261 operate-source create mysql-01.
 ↪ yaml # use one of master_servers as the argument of --master-
 ↪ addr
```

If you do not have a MySQL instance for testing, you can create a MySQL instance in Docker by taking the following steps:

1. Create a MySQL configuration file:

```
mkdir -p /tmp/mysqltest && cd /tmp/mysqltest

cat > my.cnf <<EOF
[mysqld]
bind-address = 0.0.0.0
character-set-server=utf8
collation-server=utf8_bin
default-storage-engine=INNODB
transaction-isolation=READ-COMMITTED
server-id = 100
binlog_format = row
log_bin = /var/lib/mysql/mysql-bin.log
show_compatibility_56 = ON
EOF
```

2. Start the MySQL instance using Docker:

```
docker run --name mysql-01 -v /tmp/mysqltest:/etc/mysql/conf.d -e
 ↪ MYSQL_ROOT_PASSWORD=my-secret-pw -d -p 3306:3306 mysql:5.7
```

3. After the MySQL instance is started, access the instance:

**Note:**

This command is only suitable for trying out data migration, and cannot be used in production environments or stress tests.

```
mysql -uroot -p -h 127.0.0.1 -P 3306
```

### 13.6.3.3 Step 3: Prepare a downstream database

You can choose an existing TiDB cluster as a target for data migration.

If you do not have a TiDB cluster for testing, you can quickly build a demonstration environment by running the following command:

```
tiup playground
```

### 13.6.3.4 Step 4: Prepare test data

Create a test table and data in one or multiple data sources. If you use an existing MySQL database, and the database contains available data, you can skip this step.

```
drop database if exists `testdm`;
create database `testdm`;
use `testdm`;
create table t1 (id bigint, uid int, name varchar(80), info varchar(100),
 ↳ primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=utf8mb4
 ↳ COLLATE=utf8mb4_bin;
create table t2 (id bigint, uid int, name varchar(80), info varchar(100),
 ↳ primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=utf8mb4
 ↳ COLLATE=utf8mb4_bin;
insert into t1 (id, uid, name) values (1, 10001, 'Gabriel García Márquez'),
 ↳ (2, 10002, 'Cien años de soledad');
insert into t2 (id, uid, name) values (3, 20001, 'José Arcadio Buendía'),
 ↳ (4, 20002, 'Úrsula Iguarán'), (5, 20003, 'José Arcadio');
```

### 13.6.3.5 Step 5: Create a data migration task

1. Create a task configuration file `testdm-task.yaml`:

```
name: testdm
task-mode: all

target-database:
 host: "127.0.0.1"
 port: 4000
 user: "root"
 password: "" # If the password is not empty, it is recommended to use
 ↳ a password encrypted with dmctl.

Configure the information of one or multiple data sources
mysql-instances:
 - source-id: "mysql-01"
 block-allow-list: "ba-rule1"
```

```
block-allow-list:
 ba-rule1:
 do-dbs: ["testdm"]
```

2. Create the task using dmctl:

```
tiup dmctl --master-addr 127.0.0.1:8261 start-task testdm-task.yaml
```

You have successfully created a task that migrates data from a `mysql-01` database to TiDB.

### 13.6.3.6 Step 6: Check the status of the task

After the task is created, you can use the `dmctl query-status` command to check the status of the task:

```
tiup dmctl --master-addr 127.0.0.1:8261 query-status testdm
```

## 13.6.4 TiDB Data Migration (DM) Best Practices

[TiDB Data Migration \(DM\)](#) is a data migration tool developed by PingCAP. It supports full and incremental data migration from MySQL-compatible databases such as MySQL, Percona MySQL, MariaDB, Amazon RDS for MySQL, and Amazon Aurora into TiDB.

You can use DM in the following scenarios:

- Perform full and incremental data migration from a single MySQL-compatible database instance to TiDB
- Migrate and merge MySQL shards of small datasets (less than 1 TiB) to TiDB
- In the data hub scenario, such as the middle platform of business data, and real-time aggregation of business data, use DM as the middleware for data migration

This document introduces how to use DM in an elegant and efficient way, and how to avoid common mistakes when using DM.

### 13.6.4.1 Performance limitations

Performance item	Limitation
Max work nodes	1000
Max task number	600
Max QPS	30k QPS/worker
Max Binlog throughput	20 MB/s/worker
Table number limit per task	Unlimited

- DM supports managing 1000 work nodes simultaneously, and the maximum number of tasks is 600. To ensure the high availability of work nodes, you should reserve some work nodes as standby nodes. The recommended number of standby nodes is 20% to 50% of the number of the work nodes that have running migration tasks.
- A single work node can theoretically support replication QPS of up to 30K QPS/worker. It varies for different schemas and workloads. The ability to handle upstream binlogs is up to 20 MB/s/worker.
- If you want to use DM as a data replication middleware for long-term use, you need to carefully design the deployment architecture of DM components. For more information, see [Deploy DM-master and DM-worker](#)

#### 13.6.4.2 Before data migration

Before data migration, the design of the overall solution is critical. The following sections describe best practices and scenarios from the business perspective and the implementation perspective.

##### 13.6.4.2.1 Best practices for the business side

To distribute the workload evenly on multiple nodes, the design for the distributed database is different from traditional databases. The solution needs to ensure both low migration cost and logic correctness after migration. The following sections describe best practices before data migration.

Business impact of `AUTO_INCREMENT` in schema design

`AUTO_INCREMENT` in TiDB is compatible with `AUTO_INCREMENT` in MySQL. However, as a distributed database, TiDB usually has multiple computing nodes (entries for the client end). When the application data is written, the workload is evenly distributed. This leads to the result that when there is an `AUTO_INCREMENT` column in the table, the auto-increment IDs of the column might be inconsecutive. For more details, see [AUTO\\_INCREMENT](#).

If your business has a strong dependence on auto-increment IDs, consider using the [SEQUENCE function](#).

Usage of clustered indexes

When you create a table, you can declare that the primary key is either a clustered index or a non-clustered index. The following sections describe the pros and cons of each choice.

- Clustered indexes

[Clustered indexes](#) use the primary key as the handle ID (row ID) for data storage. Querying using the primary key can avoid table lookup, which effectively improves the query performance. However, if the table is write-intensive and the primary key uses `AUTO_INCREMENT`, it is very likely to cause [write hotspot problems](#), resulting in a mediocre performance of the cluster and the performance bottleneck of a single storage node.

- Non-clustered indexes + `shard row id bit`

Using non-clustered indexes and `shard row id bit`, you can avoid the write hotspot problem when using `AUTO_INCREMENT`. However, table lookup in this scenario can affect the query performance when querying using the primary key.

- Clustered indexes + external distributed ID generators

If you want to use clustered indexes and keep the IDs consecutive, consider using external distributed ID generators, such as the Snowflake algorithm and Leaf. The application program generates sequence IDs, which can guarantee that the IDs are consecutive to a certain extent. It also retains the benefits of using clustered indexes. But you need to customize the applications.

- Clustered indexes + `AUTO_RANDOM`

This solution can retain the benefits of using clustered indexes and avoid the write hotspot problem. It requires less effort for customization. You can modify the schema attribute when you switch to use TiDB as the write database. In subsequent queries, if you have to use the ID column to sort data, you can use the `AUTO_RANDOM` ID column and left shift 5 bits to ensure the order of the query data. For example:

```
CREATE TABLE t (a bigint PRIMARY KEY AUTO_RANDOM, b varchar(255));
Select a, a<<5 ,b from t order by a <<5 desc
```

The following table summarizes the pros and cons of each solution.

Scenario	Recommended solution	Pros	Cons
----------	----------------------	------	------

|

TiDB will act as the primary and write-intensive database.

The business logic strongly relies on the continuity of the primary key IDs.

| Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Use `SEQUENCE` as the primary key column. | It can avoid data write hotspots and ensure the continuity and monotonic increment of business data. |

The throughput capacity of data write is decreased to ensure data write continuity.

The performance of primary key queries is decreased.

||

TiDB will act as the primary and write-intensive database.

The business logic strongly relies on the increment of the primary key IDs.

| Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Use an application ID generator to generate the primary key IDs. | It can avoid data write hotspots,

guarantee the performance of data write, and guarantee the increment of business data, but cannot guarantee continuity. |

You need to customize the application.

External ID generators strongly rely on the clock accuracy and might introduce failures.

||

TiDB will act as the primary and write-intensive database.

The business logic does not rely on the continuity of the primary key IDs.

| Create tables with clustered indexes and set `AUTO_RANDOM` for the primary key column.

It can avoid data write hotspots and has excellent query performance of primary keys.

You can smoothly switch from `AUTO_INCREMENT` to `AUTO_RANDOM`.

|

The primary key IDs are random.

The write throughput ability is limited.

It is recommended to sort the business data by using the insert time column.

If you have to use the primary key ID to sort data, you can left shift 5 bits to query, which can guarantee the increment of the data.

|| TiDB will act as a read-only database. | Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Keep the primary key column consistent with the data source. |

It can avoid data write hotspots.

It requires less customization cost.

The query performance of primary keys is impacted. |

#### 13.6.4.2.2 Key points for MySQL shards

Splitting and merging

It is recommended that you use DM to **migrate and merge MySQL shards of small datasets to TiDB**.

Besides data merging, another typical scenario is data archiving. Data is constantly being written. As time goes by, large amounts of data gradually change from hot data to warm or even cold data. Fortunately, in TiDB, you can set different **placement rules** for data. The minimum granularity of the rules is **a partition**.

Therefore, it is recommended that for write-intensive scenarios, you need to evaluate from the beginning whether you need to archive data and store hot and cold data on different media separately. If you need to archive data, you can set the partitioning rules before migration (TiDB does not support Table Rebuild operations yet). It saves you from the need to recreate tables and import data in future.

## The pessimistic mode and the optimistic mode

DM uses the pessimistic mode by default. In scenarios of migrating and merging MySQL shards, changes in upstream shard schemas can block DML writing to downstream databases. You need to wait until all the schemas are changed and have the same structure, and then continue the migration from the breakpoint.

- If the upstream schema changes take a long time, it might cause the upstream Binlog to be cleaned up. You can enable the relay log to avoid this problem. For more information, see [Use the relay log](#).
- If you do not want to block data write due to upstream schema changes, consider using the optimistic mode. In this case, DM will not block the data migration even when it spots changes in the upstream shard schemas, but will continue to migrate the data. However, if DM spots incompatible formats in upstream and downstream, the migration task will stop. You need to resolve this issue manually.

The following table summarizes the pros and cons of optimistic mode and pessimistic modes.

---

Scenario	Pros	Cons
----------	------	------

---

Scenario	Pros	Cons
----------	------	------

---

Pessimistic mode (Default)	<p>can ensure that the data migrated to the downstream will not go wrong.</p>	<p>If there are a large number of shards, the migration task will be blocked for a long time, or even stop if the upstream binlogs have been cleaned up. You can enable the relay log to avoid this problem.</p>
----------------------------	-------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Scenario	Pros	Cons
Optimistic mode	<p>Upstream schema changes will not cause data migration latency.</p>	<p>In this mode, the schema changes will ensure that schema changes are compatible. (check whether the incremental column has a default value). It is possible that the inconsistent data can be overlooked. For more information, see <a href="#">Merge and Migrate Data</a>.</p>

### 13.6.4.2.3 Other restrictions and impact

Data types in upstream and downstream

TiDB supports most MySQL data types. However, some special types are not supported yet (such as `SPATIAL`). For the compatibility of data types, see [Data Types](#).

Character sets and collations

Since TiDB v6.0.0, the new framework for collations is used by default. In earlier versions, if you want TiDB to support `utf8_general_ci`, `utf8mb4_general_ci`, `utf8_unicode_ci`, `utf8mb4_unicode_ci`, `gbk_chinese_ci` and `gbk_bin`, you need to explicitly declare it when creating the cluster by setting the value of `new_collations_enabled_on_first_bootstrap` to `true`. For more information, see [New framework for collations](#).

The default character set in TiDB is `utf8mb4`. It is recommended that you use `utf8mb4` for the upstream and downstream databases and applications. If the upstream database has explicitly specified a character set or collation, you need to check whether TiDB supports it.

Since TiDB v6.0.0, GBK is supported. For more information, see the following documents:

- [Character Set and Collation](#)
- [GBK compatibility](#)

### 13.6.4.2.4 Best practices for deployment

Deploy DM-master and DM-worker

DM consists of DM-master and DM-worker nodes.

- DM-master manages the metadata of migration tasks and schedules DM-worker nodes. It is the core of the whole DM platform. Therefore, you can deploy DM-master as clusters to ensure high availability of the DM platform.
- DM-worker executes upstream and downstream migration tasks. A DM-worker node is stateless. You can deploy at most 1000 DM-worker nodes. When using DM, it is recommended that you reserve some idle DM-workers to ensure high availability.

Plan the migration tasks

When migrating and merging MySQL shards, you can split a migration task according to the types of shards in the upstream. For example, if `usertable_1~50` and `Logtable_1~50` are two types of shards, you can create two migration tasks. It can simplify the migration task template and effectively control the impact of interruption in data migration.

For migration of large datasets, you can refer to the following suggestions to split the migration task:

- If you need to migrate multiple databases in the upstream, you can split the migration task according to the number of databases.
- Split the task according to the write pressure in the upstream, that is, split the tables with frequent DML operations in the upstream to a separate migration task. Use another migration task to migrate the tables without frequent DML operations. This method can speed up the migration progress, especially when there are a large number of logs written to a table in the upstream. But if this table that contains a large number of logs does not affect the whole business, this method still works well.

Note that splitting the migration task can only guarantee the final consistency of data. Real-time consistency may deviate significantly due to various reasons.

The following table describes the recommended deployment plans for DM-master and DM-worker in different scenarios.

Scenario	DM-master deployment	DM-worker deployment
----------	----------------------	----------------------

|

Small dataset (less than 1 TiB)

One-time data migration

| Deploy 1 DM-master node | Deploy 1~N DM-worker nodes according to the number of upstream data sources. Generally, 1 DM-worker node is recommended. | |

Large dataset (more than 1 TiB) and migrating and merging MySQL shards

One-time data migration

| It is recommended to deploy 3 DM-master nodes to ensure the availability of the DM cluster during long-time data migration. | Deploy DM-worker nodes according to the number of data sources or migration tasks. Besides working DM-worker nodes, it is recommended to deploy 1~3 idle DM-worker nodes. | | Long-term data replication | It is necessary to deploy 3 DM-master nodes. If you deploy DM-master nodes on the cloud, try to deploy them in different availability zones (AZ). | Deploy DM-worker nodes according to the number of data sources or migration tasks. It is necessary to deploy 1.5~2 times the number of DM-worker nodes that are actually needed. |

Choose and configure the upstream data source

DM backs up the full data of the entire database when performing full data migration, and uses the parallel logical backup method. During backing up MySQL, it adds a global read lock `FLUSH TABLES WITH READ LOCK`. DML and DDL operations of the upstream database will be blocked for a short time. Therefore, it is strongly recommended to use a backup database in upstream to perform the full data backup, and enable the GTID function of the data source (`enable-gtid: true`). In this way, you can avoid the impact from the upstream, and switch to the master node in the upstream to reduce the latency during the

incremental migration. For the instructions of switching the upstream MySQL data source, see [Switch DM-worker Connection between Upstream MySQL Instances](#).

Note the following:

- You can only perform full data backup on the master node of the upstream database. In this scenario, you can set the `consistency` parameter to `none` in the configuration file, `mydumpers.global.extra-args: "--consistency none"`, to avoid adding a global read lock to the master node. But this might affect the data consistency of the full backup, which may lead to inconsistent data between the upstream and downstream.
- Use backup snapshots to perform full data migration (only applicable to the migration of MySQL RDS and Aurora RDS on AWS)  
If the database to be migrated is AWS MySQL RDS or Aurora RDS, you can use RDS snapshots to directly migrate the backup data in Amazon S3 to TiDB to ensure data consistency. For more information, see [Migrate Data from Amazon Aurora to TiDB](#).

#### 13.6.4.2.5 Details of configurations

##### Capitalization

TiDB schema names are case-insensitive by default, that is, `lower_case_table_names` ↪ :2. But most upstream MySQL databases use Linux systems that are case-sensitive by default. In this case, you need to set `case-sensitive` to `true` in the DM task configuration file to ensure that the schema can be correctly migrated from the upstream.

In a special case, for example, if there is a database in the upstream that has both uppercase tables such as `Table` and lowercase tables such as `table`, then an error occurs when creating the schema:

```
ERROR 1050 (42S01): Table '{tablename}' already exists
```

##### Filter rules

You can configure the filter rules as soon as you start configuring the data source. For more information, see [Data Migration Task Configuration Guide](#). The benefits of configuring the filter rules are:

- Reduce the number of Binlog events that the downstream needs to process, thereby improving migration efficiency.
- Reduce unnecessary relay log storage, thereby saving disk space.

**Note:**

When you migrate and merge MySQL shards, if you have configured filter rules in the data source, you must make sure that the rules match between the data source and the migration task. If they do not match, it may cause the issue that the migration task cannot receive incremental data for a long time.

#### Use the relay log

In the MySQL master/standby mechanism, the standby node saves a copy of relay logs to ensure the reliability and efficiency of asynchronous replication. DM also supports saving a copy of relay logs on DM-worker. You can configure information such as the storage location and expiration time. This feature applies to the following scenarios:

- During full and incremental data migration, if the amount of full data is large, the entire process takes more time than the time for the upstream binlogs to be archived. It causes the incremental replication task to fail to start normally. If you enable the relay log, DM-worker will start receiving relay logs when the full migration is started. This avoids the failure of the incremental task.
- When you use DM to perform long-time data replication, sometimes the migration task is blocked for a long time due to various reasons. If you enable the relay log, you can effectively deal with the problem of upstream binlogs being recycled due to the blocking of the migration task.

There are some restrictions on using the relay log. DM supports high availability. When a DM-worker fails, it will try to promote an idle DM-worker instance to a working instance. If the upstream binlogs do not contain the necessary migration logs, it may cause interruption. You need to intervene manually to copy the relay log to the new DM-worker node as soon as possible, and modify the corresponding relay meta file. For details, see [Troubleshooting](#).

#### Use PT-osc/GH-ost in upstream

In daily MySQL operation and maintenance, usually you use tools such as PT-osc/GH-ost to change the schema online to minimize impact on the business. However, the whole process will be logged to MySQL Binlog. Migrating such data to TiDB downstream will result in a lot of unnecessary write operations, which is neither efficient nor economical.

To resolve this issue, DM supports third-party data tools such as PT-osc and GH-ost when you configure the migration task. When you use such tools, DM does not migrate redundant data and ensure data consistency. For details, see [Migrate from Databases that Use GH-ost/PT-osc](#).

### 13.6.4.3 Best practices during migration

This section introduces how to troubleshoot problems you might encounter during migration.

### 13.6.4.3.1 Inconsistent schemas in upstream and downstream

Common errors include:

- `messages: Column count doesn't match value count: 3 (columns)vs 2 (↔ values)`
- `Schema/Column doesn't match`

Usually such issues are caused by changed or added indexes in the downstream TiDB, or there are more columns in the downstream. When such errors occur, check whether the upstream and downstream schemas are inconsistent.

To resolve such issues, update the schema information cached in DM to be consistent with the downstream TiDB schema. For details, see [Manage Table Schemas of Tables to be Migrated](#).

If the downstream has more columns, see [Migrate Data to a Downstream TiDB Table with More Columns](#).

### 13.6.4.3.2 Interrupted migration task due to failed DDL

DM supports skipping or replacing DDL statements that cause a migration task to interrupt. For details, see [Handle Failed DDL Statements](#).

### 13.6.4.4 Data validation after data migration

It is recommended that you validate the consistency of data after data migration. TiDB provides [sync-diff-inspector](#) to help you complete the data validation.

Now [sync-diff-inspector](#) can automatically manage the table list to be checked for data consistency through DM tasks. Compared with the previous manual configuration, it is more efficient. For details, see [Data Check in the DM Replication Scenario](#).

Since DM v6.2.0, DM supports continuous data validation for incremental replication. For details, see [Continuous Data Validation in DM](#).

### 13.6.4.5 Long-term data replication

If you use DM to perform a long-term data replication task, it is necessary to back up the metadata. On the one hand, it ensures the ability to rebuild the migration cluster. On the other hand, it can implement the version control of the migration task. For details, see [Export and Import Data Sources and Task Configuration of Clusters](#).

## 13.6.5 Deploy a DM cluster

### 13.6.5.1 Software and Hardware Requirements for TiDB Data Migration

TiDB Data Migration (DM) supports mainstream Linux operating systems. See the following table for specific version requirements:

Linux OS	Version
Red Hat Enterprise Linux	7.3 or later
CentOS	7.3 or later
Oracle Enterprise Linux	7.3 or later
Ubuntu LTS	16.04 or later

DM can be deployed and run on Intel architecture servers and mainstream virtualization environments.

### 13.6.5.1.1 Recommended server requirements

DM can be deployed and run on a 64-bit generic hardware server platform (Intel x86-64 architecture). For servers used in the development, testing, and production environments, this section illustrates recommended hardware configurations (these do not include the resources used by the operating system).

Development and test environments

Component	CPU	Memory	Local Storage	Network	Number of Instances (Minimum Requirement)
DM-master	4	8 GB+	SAS, 200 GB+	Gigabit network card	1
DM-worker	8	16 GB+	SAS, 200 GB+ (Greater than the size of the migrated data)	Gigabit network card	The number of upstream MySQL instances

**Note:**

- In the test environment, DM-master and DM-worker used for functional verification can be deployed on the same server.
- To prevent interference with the accuracy of the performance test results, it is **not recommended** to use low-performance storage and network hardware configurations.
- If you need to verify the function only, you can deploy a DM-master on a single machine. The number of DM-worker deployed must be greater than or equal to the number of upstream MySQL instances. To ensure high availability, it is recommended to deploy more DM-workers.
- DM-worker stores full data in the `dump` and `load` phases. Therefore, the disk space for DM-worker needs to be greater than the total amount of data to be migrated. If the relay log is enabled for the migration task, DM-worker needs additional disk space to store upstream binlog data.

Production environment

Component	CPU	Memory	Hard Disk Type	Network	Number of Instances (Minimum Requirement)
DM-master	4	8GB+	SAS, 200GB+	Gigabit network card	1
DM-worker	4	8GB+	SAS, 200GB+	Gigabit network card	≥ 1

Component	CPU	Memory	Hard Disk Type	Network	Number of Instances (Minimum Requirement)
DM-worker	16 core+	32 GB+	SSD, 200 GB+ (Greater than the size of the mirrored data)	10 Gbit network card	Greater than the number of upstream MySQL instances
Monitor	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	

**Note:**

- In the production environment, it is not recommended to deploy and run DM-master and DM-worker on the same server, because when DM-worker writes data to disks, it might interfere with the use of disks by DM-master's high availability component.
- If a performance issue occurs, you are recommended to modify the task configuration file according to the [Optimize Configuration of DM](#) document. If the performance is not effectively optimized by tuning the configuration file, you can try to upgrade the hardware of your server.

### 13.6.5.1.2 Downstream storage space requirements

The target TiKV cluster must have enough disk space to store the imported data. In

addition to the [standard hardware requirements](#), the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has x 2 because:

- Indexes might take extra space.
- RocksDB has a space amplification effect.

You can estimate the data volume by using the following SQL statements to summarize the `data-length` field:

- Calculate the size of all schemas, in MiB. Replace `${schema_name}` with your schema name.

```
select table_schema, sum(data_length)/1024/1024 as data_length, sum(
 ↪ index_length)/1024/1024 as index_length, sum(data_length+
 ↪ index_length)/1024/1024 as sum from information_schema.tables
 ↪ where table_schema = "${schema_name}" group by table_schema;
```

- Calculate the size of the largest table, in MiB. Replace `${schema_name}` with your schema name.

```
select table_name, table_schema, sum(data_length)/1024/1024 as
 ↪ data_length, sum(index_length)/1024/1024 as index_length, sum(
 ↪ data_length+index_length)/1024/1024 as sum from
 ↪ information_schema.tables where table_schema = "${schema_name}"
 ↪ group by table_name, table_schema order by sum desc limit 5;
```

### 13.6.5.2 Deploy a DM Cluster Using TiUP

[TiUP](#) is a cluster operation and maintenance tool introduced in TiDB 4.0. TiUP provides [TiUP DM](#), a cluster management component written in Golang. By using TiUP DM, you can easily perform daily TiDB Data Migration (DM) operations, including deploying, starting, stopping, destroying, scaling, and upgrading a DM cluster, and manage DM cluster parameters.

TiUP supports deploying DM v2.0 or later DM versions. This document introduces how to deploy DM clusters of different topologies.

#### Note:

If your target machine's operating system supports SELinux, make sure that SELinux is **disabled**.

### 13.6.5.2.1 Prerequisites

When DM performs a full data replication task, the DM-worker is bound with only one upstream database. The DM-worker first exports the full amount of data locally, and then imports the data into the downstream database. Therefore, the worker's host space must be large enough to store all upstream tables to be exported. The storage path is specified later when you create the task.

In addition, you need to meet the [hardware and software requirements](#) when deploying a DM cluster.

### 13.6.5.2.2 Step 1: Install TiUP on the control machine

Log in to the control machine using a regular user account (take the `tidb` user as an example). All the following TiUP installation and cluster management operations can be performed by the `tidb` user.

1. Install TiUP by executing the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
 ↪ install.sh | sh
```

After the installing, `~/.bashrc` has been modified to add TiUP to PATH, so you need to open a new terminal or redeclare the global environment variables `source ~/.bashrc` to use it.

2. Install the TiUP DM component:

```
tiup install dm dmctl
```

### 13.6.5.2.3 Step 2: Edit the initialization configuration file

According to the intended cluster topology, you need to manually create and edit the cluster initialization configuration file.

You need to create a YAML configuration file (named `topology.yaml` for example) according to the [configuration file template](#). For other scenarios, edit the configuration accordingly.

You can use the command `tiup dm template > topology.yaml` to generate a configuration file template quickly.

The configuration of deploying three DM-masters, three DM-workers, and one monitoring component instance is as follows:

```
The global variables apply to all other components in the configuration
 ↪ . If one specific value is missing in the component instance, the
 ↪ corresponding global variable serves as the default value.
global:
```

```
user: "tidb"
ssh_port: 22
deploy_dir: "/dm-deploy"
data_dir: "/dm-data"

server_configs:
 master:
 log-level: info
 # rpc-timeout: "30s"
 # rpc-rate-limit: 10.0
 # rpc-rate-burst: 40
 worker:
 log-level: info

master_servers:
- host: 10.0.1.11
 name: master1
 ssh_port: 22
 port: 8261
 # peer_port: 8291
 # deploy_dir: "/dm-deploy/dm-master-8261"
 # data_dir: "/dm-data/dm-master-8261"
 # log_dir: "/dm-deploy/dm-master-8261/log"
 # numa_node: "0,1"
 # The following configs are used to overwrite the `server_configs.master
 ↪ ` values.
 config:
 log-level: info
 # rpc-timeout: "30s"
 # rpc-rate-limit: 10.0
 # rpc-rate-burst: 40
- host: 10.0.1.18
 name: master2
 ssh_port: 22
 port: 8261
- host: 10.0.1.19
 name: master3
 ssh_port: 22
 port: 8261
If you do not need to ensure high availability of the DM cluster,
↪ deploy only one DM-master node, and the number of deployed DM-worker
↪ nodes must be no less than the number of upstream MySQL/MariaDB
↪ instances to be migrated.
To ensure high availability of the DM cluster, it is recommended to
↪ deploy three DM-master nodes, and the number of deployed DM-worker
```

↔ nodes must exceed the number of upstream MySQL/MariaDB instances to  
↔ be migrated (for example, the number of DM-worker nodes is two more  
↔ than the number of upstream instances).

#### worker\_servers:

```
- host: 10.0.1.12
 ssh_port: 22
 port: 8262
 # deploy_dir: "/dm-deploy/dm-worker-8262"
 # log_dir: "/dm-deploy/dm-worker-8262/log"
 # numa_node: "0,1"
 # The following configs are used to overwrite the `server_configs.worker
 ↔ ` values.
 config:
 log-level: info
- host: 10.0.1.19
 ssh_port: 22
 port: 8262
```

#### monitoring\_servers:

```
- host: 10.0.1.13
 ssh_port: 22
 port: 9090
 # deploy_dir: "/tidb-deploy/prometheus-8249"
 # data_dir: "/tidb-data/prometheus-8249"
 # log_dir: "/tidb-deploy/prometheus-8249/log"
```

#### grafana\_servers:

```
- host: 10.0.1.14
 port: 3000
 # deploy_dir: /tidb-deploy/grafana-3000
```

#### alertmanager\_servers:

```
- host: 10.0.1.15
 ssh_port: 22
 web_port: 9093
 # cluster_port: 9094
 # deploy_dir: "/tidb-deploy/alertmanager-9093"
 # data_dir: "/tidb-data/alertmanager-9093"
 # log_dir: "/tidb-deploy/alertmanager-9093/log"
```

**Note:**

- It is not recommended to run too many DM-workers on one host. Each DM-worker should be allocated at least 2 core CPU and 4 GiB memory.
- Make sure that the ports among the following components are interconnected:
  - The `peer_port` (8291 by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the port of all DM-worker nodes (8262 by default).
  - Each DM-worker node can connect to the port of all DM-master nodes (8261 by default).
  - The TiUP nodes can connect to the port of all DM-master nodes (8261 by default).
  - The TiUP nodes can connect to the port of all DM-worker nodes (8262 by default).

For more `master_servers.host.config` parameter description, refer to [master parameter](#). For more `worker_servers.host.config` parameter description, refer to [worker parameter](#).

#### 13.6.5.2.4 Step 3: Execute the deployment command

##### Note:

You can use secret keys or interactive passwords for security authentication when you deploy TiDB using TiUP:

- If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;
- If you use passwords, add the `-p` flag to enter the password interaction window;
- If password-free login to the target machine has been configured, no authentication is required.

```
tiup dm deploy ${name} ${version} ./topology.yaml -u ${ssh_user} [-p] [-i /
↪ home/root/.ssh/gcp_rsa]
```

The parameters used in this step are as follows.

Parameter	Description
\$	The
↪	name
↪	name
↪	the
↪	DM
	cluster,
	eg:
	dm-
	test
\$	The
↪	ver-
↪	version
↪	of
↪	the
	DM
	cluster.
	You
	can
	see
	other
	supported
	versions
	by
	running
	tiup
↪	
↪	list
↪	
↪	dm
↪	-
↪	master
↪	.

<u>Parameter</u>	<u>Description</u>
<code>./</code>	The
<code>topology</code>	topology
<code>of</code>	of
<code>yaml</code>	the
<code>topology</code>	topology
<code>configuration</code>	configuration
<code>file</code>	file.

Parameter	Description
-	Log
↪	in
↪	to
or	the
--	tar-
↪	user
↪	ma-
	chine
	as
	the
	root
	user
	or
	other
	user
	ac-
	count
	with
	ssh
	and
	sudo
	priv-
	i-
	leges
	to
	com-
	plete
	the
	clus-
	ter
	de-
	ploy-
	ment.

Parameter	Description
-	The
↪	pass-
↪	word
or	of
--	tar-
↪	password
↪	hosts.
	If
	spec-
	i-
	fied,
	pass-
	word
	au-
	then-
	ti-
	ca-
	tion
	is
	used.

Parameter	Description
- path	The path of the SSH identity file.
-- identity_file	SSH identity file. If specified, public key authentication is used (default "/root/.ssh/id_rsa").

At the end of the output log, you will see `Deployed cluster `dm-test` successfully`. This indicates that the deployment is successful.

#### 13.6.5.2.5 Step 4: Check the clusters managed by TiUP

```
tiup dm list
```

TiUP supports managing multiple DM clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

Name	User	Version	Path	PrivateKey
dm-test	tidb	\${version}	/root/.tiup/storage/dm/clusters/dm-test	/root/.tiup ↪ /storage/dm/clusters/dm-test/ssh/id_rsa

### 13.6.5.2.6 Step 5: Check the status of the deployed DM cluster

To check the status of the `dm-test` cluster, execute the following command:

```
tiup dm display dm-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down/inactive`), and directory information.

### 13.6.5.2.7 Step 6: Start the DM cluster

```
tiup dm start dm-test
```

If the output log includes `Started cluster `dm-test` successfully`, the start is successful.

### 13.6.5.2.8 Step 7: Verify the running status of the DM cluster

Check the DM cluster status using TiUP:

```
tiup dm display dm-test
```

If the `Status` is `Up` in the output, the cluster status is normal.

### 13.6.5.2.9 Step 8: Managing migration tasks using `dmctl`

`dmctl` is a command-line tool used to control DM clusters. You are recommended to [use `dmctl` via TiUP](#).

`dmctl` supports both the command mode and the interactive mode. For details, see [Maintain DM Clusters Using `dmctl`](#).

## 13.6.5.3 Deploy a DM Cluster Offline Using TiUP

This document describes how to deploy a DM cluster offline using TiUP.

### 13.6.5.3.1 Step 1: Prepare the TiUP offline component package

- Install the TiUP package manager online.

1. Install the TiUP tool:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/install.sh | sh
```

2. Redeclare the global environment variables:

```
source .bash_profile
```

3. Confirm whether TiUP is installed:

```
which tiup
```

- Pull the mirror using TiUP

1. Pull the needed components on a machine that has access to the Internet:

```
You can modify ${version} to the needed version.
tiup mirror clone tidb-dm-${version}-linux-amd64 --os=linux --arch=
↳ amd64 \
 --dm-master=${version} --dm-worker=${version} --dmctl=${version}
↳ } \
 --alertmanager=v0.17.0 --grafana=v4.0.3 --prometheus=v4.0.3 \
 --tiup=v$(tiup --version|grep 'tiup'|awk -F ' ' '{print $1}')
↳ --dm=v$(tiup --version|grep 'tiup'|awk -F ' ' '{print $1}
↳ }')
```

The command above creates a directory named `tidb-dm-${version}-linux-amd64` in the current directory, which contains the component package managed by TiUP.

2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

```
tar czvf tidb-dm-${version}-linux-amd64.tar.gz tidb-dm-${version}-
↳ linux-amd64
```

`tidb-dm-${version}-linux-amd64.tar.gz` is an independent offline environment package.

### 13.6.5.3.2 Step 2: Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following command:

```
You can modify ${version} to the needed version.
tar xzvf tidb-dm-${version}-linux-amd64.tar.gz
sh tidb-dm-${version}-linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically executes the `tiup mirror set tidb-dm-${version}-linux-amd64` command to set the current mirror address to `tidb-dm-${version}-linux-amd64`.

To switch the mirror to another directory, manually execute the `tiup mirror set <mirror-dir>` command. If you want to switch back to the official mirror, execute `tiup mirror set https://tiup-mirrors.pingcap.com`.

### 13.6.5.3.3 Step 3: Edit the initialization configuration file

You need to edit the cluster initialization configuration file according to different cluster topologies.

For the full configuration template, refer to the [TiUP configuration parameter template](#). Create a configuration file `topology.yaml`. In other combined scenarios, edit the configuration file as needed according to the templates.

The configuration of deploying three DM-masters, three DM-workers, and one monitoring component instance is as follows:

```

global:
 user: "tidb"
 ssh_port: 22
 deploy_dir: "/home/tidb/dm/deploy"
 data_dir: "/home/tidb/dm/data"
 # arch: "amd64"

master_servers:
- host: 172.19.0.101
- host: 172.19.0.102
- host: 172.19.0.103

worker_servers:
- host: 172.19.0.101
- host: 172.19.0.102
- host: 172.19.0.103

monitoring_servers:
- host: 172.19.0.101

grafana_servers:
- host: 172.19.0.101

alertmanager_servers:
- host: 172.19.0.101
```

#### Note:

- If you do not need to ensure high availability of the DM cluster, deploy only one DM-master node, and the number of deployed DM-worker nodes must be no less than the number of upstream MySQL/MariaDB instances to be migrated.

- To ensure high availability of the DM cluster, it is recommended to deploy three DM-master nodes, and the number of deployed DM-worker nodes must be greater than the number of upstream MySQL/MariaDB instances to be migrated (for example, the number of DM-worker nodes is two more than the number of upstream instances).
- For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
- For parameters that should be effective on a specific node, configure these parameters in `config` of this node.
- Use `.` to indicate the subcategory of the configuration, such as `log.slow`  $\leftrightarrow$  `-threshold`. For more formats, see [TiUP configuration template](#).
- For more parameter description, see [master config.toml.example](#) and [worker config.toml.example](#).
- Make sure that the ports among the following components are interconnected:
  - The `peer_port` (8291 by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `port` of all DM-worker nodes (8262 by default).
  - Each DM-worker node can connect to the `port` of all DM-master nodes (8261 by default).
  - The TiUP nodes can connect to the `port` of all DM-master nodes (8261 by default).
  - The TiUP nodes can connect to the `port` of all DM-worker nodes (8262 by default).

#### 13.6.5.3.4 Step 4: Execute the deployment command

##### Note:

You can use secret keys or interactive passwords for security authentication when you deploy DM using TiUP:

- If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;
- If you use passwords, add the `-p` flag to enter the password interaction window;

- If password-free login to the target machine has been configured, no authentication is required.

```
tiup dm deploy dm-test ${version} ./topology.yaml --user root [-p] [-i /home
↪ /root/.ssh/gcp_rsa]
```

In the above command:

- The name of the deployed DM cluster is `dm-test`.
- The version of the DM cluster is `${version}`. You can view the latest versions supported by TiUP by running `tiup list dm-master`.
- The initialization configuration file is `topology.yaml`.
- `--user root`: Log in to the target machine through the `root` key to complete the cluster deployment, or you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]`: optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the `root` user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.
- TiUP DM uses the embedded SSH client. If you want to use the SSH client native to the control machine system, edit the configuration according to [using the system's native SSH client to connect to the cluster](#).

At the end of the output log, you will see `Deployed cluster `dm-test` successfully`. This indicates that the deployment is successful.

#### 13.6.5.3.5 Step 5: Check the clusters managed by TiUP

```
tiup dm list
```

TiUP supports managing multiple DM clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

```
Name User Version Path PrivateKey
---- - - - - -
dm-test tidb ${version} /root/.tiup/storage/dm/clusters/dm-test /root/.tiup
↪ /storage/dm/clusters/dm-test/ssh/id_rsa
```

#### 13.6.5.3.6 Step 6: Check the status of the deployed DM cluster

To check the status of the `dm-test` cluster, execute the following command:

```
tiup dm display dm-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down/inactive`), and directory information of the `dm-test` cluster.

#### 13.6.5.3.7 Step 7: Start the cluster

```
tiup dm start dm-test
```

If the output log includes `Started cluster `dm-test` successfully`, the start is successful.

#### 13.6.5.3.8 Step 8: Verify the running status of the cluster

Check the DM cluster status using TiUP:

```
tiup dm display dm-test
```

If the `Status` is `Up` in the output, the cluster status is normal.

### 13.6.5.4 Deploy Data Migration Using DM Binary

This document introduces how to quickly deploy the Data Migration (DM) cluster using DM binary.

#### Note:

In the production environment, it is recommended to [use TiUP to deploy a DM cluster](#).

#### 13.6.5.4.1 Download DM binary

The DM binary is included in the TiDB Toolkit. To download the TiDB Toolkit, see [Download TiDB Tools](#).

#### 13.6.5.4.2 Sample scenario

Suppose that you deploy a DM cluster based on this sample scenario:

Two DM-worker nodes and three DM-master nodes are deployed on five servers.

Here is the address of each node:

Instance	Server address	Port
DM-master1	192.168.0.4	8261
DM-master2	192.168.0.5	8261
DM-master3	192.168.0.6	8261
DM-worker1	192.168.0.7	8262
DM-worker2	192.168.0.8	8262

Based on this scenario, the following sections describe how to deploy the DM cluster.

### Note:

- If you deploy multiple DM-master or DM-worker instances in a single server, the port and working directory of each instance must be unique.
- If you do not need to ensure high availability of the DM cluster, deploy only one DM-master node, and the number of deployed DM-worker nodes must be no less than the number of upstream MySQL/MariaDB instances to be migrated.
- To ensure high availability of the DM cluster, it is recommended to deploy three DM-master nodes, and the number of deployed DM-worker nodes must be greater than the number of upstream MySQL/MariaDB instances to be migrated (for example, the number of DM-worker nodes is two more than the number of upstream instances).
- Make sure that the ports among the following components are interconnected:
  - The 8291 ports among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the 8262 ports of all DM-worker nodes.
  - Each DM-worker node can connect to the 8261 port of all DM-master nodes.

### Deploy DM-master

You can configure DM-master by using [command-line parameters](#) or [the configuration file](#).

#### DM-master command-line parameters

The following is the description of DM-master command-line parameters:

```
./dm-master --help
```

```
Usage of dm-master:
-L string
 log level: debug, info, warn, error, fatal (default "info")
-V prints version and exit
-advertise-addr string
 advertise address for client traffic (default "${master-addr}")
-advertise-peer-urls string
 advertise URLs for peer traffic (default "${peer-urls}")
-config string
 path to config file
-data-dir string
 path to the data directory (default "default.${name}")
-initial-cluster string
 initial cluster configuration for bootstrapping, e.g. dm-master=http
 ↪ ://127.0.0.1:8291
-join string
 join to an existing cluster (usage: cluster's "${master-addr}" list,
 ↪ e.g. "127.0.0.1:8261,127.0.0.1:18261")
-log-file string
 log file path
-master-addr string
 master API server and status addr
-name string
 human-readable name for this DM-master member
-peer-urls string
 URLs for peer traffic (default "http://127.0.0.1:8291")
-print-sample-config
 print sample config file of dm-worker
```

**Note:**

In some situations, you cannot use the above method to configure DM-master because some configurations are not exposed to the command line. In such cases, use the configuration file instead.

### DM-master configuration file

The following is the configuration file of DM-master. It is recommended that you configure DM-master by using this method.

1. Write the following configuration to `conf/dm-master1.toml`:

```
““toml # Master Configuration. name = “master1”
Log configurations. log-level = “info” log-file = “dm-master.log”
The listening address of DM-master. master-addr = “192.168.0.4:8261”
The peer URLs of DM-master. peer-urls = “192.168.0.4:8291”
The value of initial-cluster is the combination of the advertise-peer-
↔ urls value of all DM-master nodes in the initial cluster. initial-cluster = “mas-
ter1=http://192.168.0.4:8291,master2=http://192.168.0.5:8291,master3=http://192.168.0.6:8291”
““
```

2. Execute the following command in the terminal to run DM-master:

```
bash ./dm-master -config conf/dm-master1.toml
```

#### Note:

The console does not output logs after this command is executed. If you want to view the runtime log, you can execute `tail -f dm-master.log`.

3. For DM-master2 and DM-master3, change `name` in the configuration file to `master2` ↔ and `master3` respectively, and change `peer-urls` to `192.168.0.5:8291` and `192.168.0.6:8291` respectively. Then repeat Step 2.

#### Deploy DM-worker

You can configure DM-worker by using [command-line parameters](#) or [the configuration file](#).

#### DM-worker command-line parameters

The following is the description of the DM-worker command-line parameters:

```
./dm-worker --help
```

```
Usage of worker:
-L string
 log level: debug, info, warn, error, fatal (default "info")
-V prints version and exit
-advertise-addr string
 advertise address for client traffic (default "${worker-addr}")
-config string
 path to config file
-join string
 join to an existing cluster (usage: dm-master cluster's "${master-
↔ addr}")
-keepalive-ttl int
```

```
dm-worker's TTL for keepalive with etcd (in seconds) (default 10)
-log-file string
 log file path
-name string
 human-readable name for DM-worker member
-print-sample-config
 print sample config file of dm-worker
-worker-addr string
 listen address for client traffic
```

**Note:**

In some situations, you cannot use the above method to configure DM-worker because some configurations are not exposed to the command line. In such cases, use the configuration file instead.

#### DM-worker configuration file

The following is the DM-worker configuration file. It is recommended that you configure DM-worker by using this method.

1. Write the following configuration to `conf/dm-worker1.toml`:

```
““toml # Worker Configuration. name = “worker1”
Log configuration. log-level = “info” log-file = “dm-worker.log”
DM-worker address. worker-addr = “:8262”
The master-addr configuration of the DM-master nodes in the cluster. join =
“192.168.0.4:8261,192.168.0.5:8261,192.168.0.6:8261” ““
```

2. Execute the following command in the terminal to run DM-worker:

```
bash ./dm-worker -config conf/dm-worker1.toml
```

3. For DM-worker2, change `name` in the configuration file to `worker2`. Then repeat Step 2.

Now, a DM cluster is successfully deployed.

#### 13.6.5.5 Use Kubernetes

## 13.6.6 Tutorials

### 13.6.6.1 Create a Data Source for TiDB Data Migration

#### Note:

Before creating a data source, you need to [Deploy a DM Cluster Using TiUP](#).

The document describes how to create a data source for the data migration task of TiDB Data Migration (DM).

A data source contains the information for accessing the upstream migration task. Because a data migration task requires referring its corresponding data source to obtain the configuration information of access, you need to create the data source of a task before creating a data migration task. For specific data source management commands, refer to [Manage Data Source Configurations](#).

#### 13.6.6.1.1 Step 1: Configure the data source

1. (optional) Encrypt the data source password

In DM configuration files, it is recommended to use the password encrypted with `dmctl`. You can follow the example below to obtain the encrypted password of the data source, which can be used to write the configuration file later.

```
tiup dmctl encrypt 'abc!@#123'
```

```
MKXn0Qo3m3X0yjCnhEMtsUCm83EhGQDZ/T4=
```

2. Write the configuration file of the data source

For each data source, you need an individual configuration file to create it. You can follow the example below to create a data source whose ID is “mysql-01”. First create the configuration file `./source-mysql-01.yaml`:

```
source-id: "mysql-01" # The ID of the data source, you can refer this
 ↳ source-id in the task configuration and dmctl command to
 ↳ associate the corresponding data source.

from:
 host: "127.0.0.1"
 port: 3306
 user: "root"
```

```
password: "MKxn0Qo3m3X0yjCnhEMtsUCm83EhGQDZ/T4=" # The user password
↳ of the upstream data source. It is recommended to use the
↳ password encrypted with dmctl.
security: # The TLS configuration of
↳ the upstream data source. If not necessary, it can be deleted.
ssl-ca: "/path/to/ca.pem"
ssl-cert: "/path/to/cert.pem"
ssl-key: "/path/to/key.pem"
```

### 13.6.6.1.2 Step 2: Create a data source

You can use the following command to create a data source:

```
tiup dmctl --master-addr <master-addr> operate-source create ./source-mysql
↳ -01.yaml
```

For other configuration parameters, refer to [Upstream Database Configuration File](#).

The returned results are as follows:

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-01",
 "worker": "dm-worker-1"
 }
]
}
```

### 13.6.6.1.3 Step 3: Query the data source you created

After creating a data source, you can use the following command to query the data source:

- If you know the source-id of the data source, you can use the `dmctl config source` `<source-id>` command to directly check the configuration of the data source:

```
tiup dmctl --master-addr <master-addr> config source mysql-01
```

```
{
 "result": true,
 "msg": "",
```

```
"cfg": "enable-gtid: false
 flavor: mysql
 source-id: mysql-01
 from:
 host: 127.0.0.1
 port: 3306
 user: root
 password: '*****'
}
```

- If you do not know the `source-id`, you can use the `dmctl operate-source show` command to check the source database list, from which you can find the corresponding data source.

```
tiup dmctl --master-addr <master-addr> operate-source show
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "source is added but there is no free worker to bound
 ↪ ",
 "source": "mysql-02",
 "worker": ""
 },
 {
 "result": true,
 "msg": "",
 "source": "mysql-01",
 "worker": "dm-worker-1"
 }
]
}
```

### 13.6.6.2 Manage Data Source Configurations in TiDB Data Migration

This document introduces how to manage data source configurations, including encrypting the MySQL password, operating the data source, and changing the bindings between upstream MySQL instances and DM-workers using `dmctl`.

#### 13.6.6.2.1 Encrypt the database password

In DM configuration files, it is recommended to use the password encrypted with dmctl. For one original password, the encrypted password is different after each encryption.

```
./dmctl -encrypt 'abc!@#123'
```

```
MKXn0Qo3m3X0yjCnhEMtsUCm83EhGQDZ/T4=
```

### 13.6.6.2.2 Operate data source

You can use the `operate-source` command to load, list or remove the data source configurations to the DM cluster.

```
help operate-source
```

```
`create`/`stop`/`show` upstream MySQL/MariaDB source.
```

Usage:

```
dmctl operate-source <operate-type> [config-file...] [--print-sample-
↪ config] [flags]
```

Flags:

```
-h, --help help for operate-source
-p, --print-sample-config print sample config file of source
```

Global Flags:

```
-s, --source strings MySQL Source ID
```

Flags description

- **create:** Creates one or more upstream database sources. When creating multiple data sources fails, DM rolls back to the state where the command was not executed.
- **stop:** Stops one or more upstream database sources. When stopping multiple data sources fails, some data sources might be stopped.
- **show:** Shows the added data source and the corresponding DM-worker.
- **config-file:** Specifies the file path of `source.yaml` and can pass multiple file paths.
- **--print-sample-config:** Prints the sample configuration file. This parameter ignores other parameters.

Usage example

Use the following `operate-source` command to create a source configuration file:

```
operate-source create ./source.yaml
```

For the configuration of `source.yaml`, refer to [Upstream Database Configuration File Introduction](#).

The following is an example of the returned result:

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "dm-worker-1"
 }
]
}
```

Check data source configurations

#### Note:

The `config` command is only supported in DM v6.0 and later versions. For earlier versions, you must use the `get-config` command.

If you know the `source-id`, you can run `dmctl --master-addr <master-addr> ↔ config source <source-id>` to get the data source configuration.

```
config source mysql-replica-01
```

```
{
 "result": true,
 "msg": "",
 "cfg": "enable-gtid: false
flavor: mysql
source-id: mysql-replica-01
from:
 host: 127.0.0.1
 port: 8407
 user: root
 password: '*****'
}
```

If you don't know the source-id, you can run `dmctl --master-addr <master-addr> ↵ operate-source show` to list all data sources first.

```
operate-source show
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "source is added but there is no free worker to bound",
 "source": "mysql-replica-02",
 "worker": ""
 },
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "dm-worker-1"
 }
]
}
```

### 13.6.6.2.3 Change the bindings between upstream MySQL instances and DM-workers

You can use the `transfer-source` command to change the bindings between upstream MySQL instances and DM-workers.

```
help transfer-source
```

Transfers an upstream MySQL/MariaDB source to a free worker.

Usage:

```
dmctl transfer-source <source-id> <worker-id> [flags]
```

Flags:

```
-h, --help help for transfer-source
```

Global Flags:

```
-s, --source strings MySQL Source ID.
```

Before transferring, DM checks whether the worker to be unbound still has running tasks. If the worker has any running tasks, you need to **pause the tasks** first, change the binding, and then **resume the tasks**.

Usage example

If you do not know the bindings of DM-workers, you can run `dmctl --master-addr <master-addr> list-member --worker` to list the current bindings of all workers.

```
list-member --worker
```

```
{
 "result": true,
 "msg": "",
 "members": [
 {
 "worker": {
 "msg": "",
 "workers": [
 {
 "name": "dm-worker-1",
 "addr": "127.0.0.1:8262",
 "stage": "bound",
 "source": "mysql-replica-01"
 },
 {
 "name": "dm-worker-2",
 "addr": "127.0.0.1:8263",
 "stage": "free",
 "source": ""
 }
]
 }
 }
]
}
```

In the above example, `mysql-replica-01` is bound to `dm-worker-1`. The below command transfers the binding worker of `mysql-replica-01` to `dm-worker-2`.

```
transfer-source mysql-replica-01 dm-worker-2
```

```
{
 "result": true,
 "msg": ""
}
```

Check whether the command takes effect by running `dmctl --master-addr <master-addr> list-member --worker`.

```
list-member --worker
```

```
{
 "result": true,
 "msg": "",
 "members": [
 {
 "worker": {
 "msg": "",
 "workers": [
 {
 "name": "dm-worker-1",
 "addr": "127.0.0.1:8262",
 "stage": "free",
 "source": ""
 },
 {
 "name": "dm-worker-2",
 "addr": "127.0.0.1:8263",
 "stage": "bound",
 "source": "mysql-replica-01"
 }
]
 }
 }
]
}
```

### 13.6.6.3 Data Migration Task Configuration Guide

This document introduces how to configure a data migration task in Data Migration (DM).

#### 13.6.6.3.1 Configure data sources to be migrated

Before configuring the data sources to be migrated for the task, you need to first make sure that DM has loaded the configuration files of the corresponding data sources. The following are some operation references:

- To view the data source, you can refer to [Check the data source configuration](#).
- To create a data source, you can refer to [Create data source](#).
- To generate a data source configuration file, you can refer to [Source configuration file introduction](#).

The following example of `mysql-instances` shows how to configure data sources that need to be migrated for the data migration task:

```

***** Basic configuration *****
name: test # The name of the task. Should be globally unique.

***** Data source configuration *****
mysql-instances:
- source-id: "mysql-replica-01" # Migrate data from the data source whose
 ↪ `source-id` is `mysql-replica-01`.
- source-id: "mysql-replica-02" # Migrate data from the data source whose
 ↪ `source-id` is `mysql-replica-02`.
```

### 13.6.6.3.2 Configure the downstream TiDB cluster

The following example of `target-database` shows how to configure the target TiDB cluster to be migrated to for the data migration task:

```

***** Basic configuration *****
name: test # The name of the task. Should be globally unique.

***** Data source configuration *****
mysql-instances:
- source-id: "mysql-replica-01" # Migrate data from the data source whose
 ↪ `source-id` is `mysql-replica-01`.
- source-id: "mysql-replica-02" # Migrate data from the data source whose
 ↪ `source-id` is `mysql-replica-02`.

***** Downstream TiDB database configuration *****
target-database: # Configuration of target TiDB database.
 host: "127.0.0.1"
 port: 4000
 user: "root"
 password: "" # If the password is not null, it is recommended to use
 ↪ a password encrypted with dmctl.
```

### 13.6.6.3.3 Configure tables to be migrated

**Note:**

If you do not need to filter specific tables or migrate specific tables, skip this configuration.

To configure the block and allow list of data source tables for the data migration task, perform the following steps:

1. Configure a global filter rule set of the block and allow list in the task configuration file.

```
block-allow-list:
 bw-rule-1: # The name of the block and allow
 ↪ list rule.
 do-dbs: ["test.*", "user"] # The allow list of upstream schemas
 ↪ to be migrated. Wildcard characters (*?) are supported. You
 ↪ only need to configure either `do-dbs` or `ignore-dbs`. If
 ↪ both fields are configured, only `do-dbs` takes effect.
 # ignore-dbs: ["mysql", "account"] # The block list of upstream
 ↪ schemas to be migrated. Wildcard characters (*?) are
 ↪ supported.
 do-tables: # The allow list of upstream tables
 ↪ to be migrated. You only need to configure either `do-tables`
 ↪ or `ignore-tables`. If both fields are configured, only `do-
 ↪ tables` takes effect.
 - db-name: "test.*"
 tbl-name: "t.*"
 - db-name: "user"
 tbl-name: "information"
 bw-rule-2: # The name of the block allow list
 ↪ rule.
 ignore-tables: # The block list of data source tables
 ↪ needs to be migrated.
 - db-name: "user"
 tbl-name: "log"
```

For detailed configuration rules, see [Block and allow table lists](#).

2. Reference the block and allow list rules in the data source configuration to filter tables to be migrated.

```
mysql-instances:
 - source-id: "mysql-replica-01" # Migrate data from the data source
 ↪ whose `source-id` is `mysql-replica-01`.
```

```

block-allow-list: "bw-rule-1" # The name of the block and allow
 ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
 ↪ use `black-white-list` instead.
- source-id: "mysql-replica-02" # Migrate data from the data source
 ↪ whose `source-id` is `mysql-replica-02`.
block-allow-list: "bw-rule-2" # The name of the block and allow
 ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
 ↪ use `black-white-list` instead.

```

#### 13.6.6.3.4 Configure binlog events to be migrated

##### Note:

If you do not need to filter specific binlog events of certain schemas or tables, skip this configuration.

To configure the filters of binlog events for the data migration task, perform the following steps:

1. Configure a global filter rule set of binlog events in the task configuration file.

```

filters: # The filter rule set of data
 ↪ source binlog events. You can set multiple rules at the same
 ↪ time.
filter-rule-1: # The name of the filtering
 ↪ rule.
schema-pattern: "test_*" # The pattern of the data
 ↪ source schema name. Wildcard characters (*?) are supported.
table-pattern: "t_*" # The pattern of the data
 ↪ source table name. Wildcard characters (*?) are supported.
events: ["truncate table", "drop table"] # The event types to be
 ↪ filtered out in schemas or tables that match the `schema-
 ↪ pattern` or the `table-pattern`.
action: Ignore # Whether to migrate (Do) or
 ↪ ignore (Ignore) the binlog that matches the filtering rule.
filter-rule-2:
schema-pattern: "test"
events: ["all dml"]
action: Do

```

For detailed configuration rules, see [Binlog event filter](#).

2. Reference the binlog event filtering rules in the data source configuration to filter specified binlog events of specified tables or schemas in the data source.

```
mysql-instances:
- source-id: "mysql-replica-01" # Migrate data from the data source
 ↪ whose `source-id` is `mysql-replica-01`.
 block-allow-list: "bw-rule-1" # The name of the block and allow
 ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
 ↪ use `black-white-list` instead.
 filter-rules: ["filter-rule-1"] # The name of the rule that filters
 ↪ specific binlog events of the data source. You can configure
 ↪ multiple rules here.
- source-id: "mysql-replica-02" # Migrate data from the data source
 ↪ whose `source-id` is `mysql-replica-01`.
 block-allow-list: "bw-rule-2" # The name of the block and allow
 ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
 ↪ use `black-white-list` instead.
 filter-rules: ["filter-rule-2"] # The name of the rule that filters
 ↪ specific binlog events of the data source. You can configure
 ↪ multiple rules here.
```

### 13.6.6.3.5 Configure the mapping of data source tables to downstream TiDB tables

#### Note:

- If you do not need to migrate a certain table of the data source to the table with a different name in the downstream TiDB instance, skip this configuration.
- If it is a shard merge task, you **must** set mapping rules in the task configuration file.

To configure the routing mapping rules for migrating data source tables to specified downstream TiDB tables, perform the following steps:

1. Configure a global routing mapping rule set in the task configuration file.

```
routes: # The routing mapping rule set between
 ↪ the data source tables and downstream TiDB tables. You can set
 ↪ multiple rules at the same time.
route-rule-1: # The name of the routing mapping rule.
```

```

schema-pattern: "test_*" # The pattern of the upstream schema name
 ↪ . Wildcard characters (*?) are supported.
table-pattern: "t_*" # The pattern of the upstream table name.
 ↪ Wildcard characters (*?) are supported.
target-schema: "test" # The name of the downstream TiDB schema.
target-table: "t" # The name of the downstream TiDB table.
route-rule-2:
 schema-pattern: "test_*"
 target-schema: "test"

```

For detailed configuration rules, see [Table Routing](#).

2. Reference the routing mapping rules in the data source configuration to filter tables to be migrated.

```

mysql-instances:
- source-id: "mysql-replica-01" # Migrate data from the
 ↪ data source whose `source-id` is `mysql-replica-01`.
 block-allow-list: "bw-rule-1" # The name of the block
 ↪ and allow list rule. If the DM version is earlier than v2
 ↪ .0.0-beta.2, use `black-white-list` instead.
 filter-rules: ["filter-rule-1"] # The name of the rule
 ↪ that filters specific binlog events of the data source. You
 ↪ can configure multiple rules here.
 route-rules: ["route-rule-1", "route-rule-2"] # The name of the
 ↪ routing mapping rule. You can configure multiple rules here.
- source-id: "mysql-replica-02" # Migrate data from the
 ↪ data source whose `source-id` is `mysql-replica-02`.
 block-allow-list: "bw-rule-2" # The name of the block
 ↪ and allow list rule. If the DM version is earlier than v2
 ↪ .0.0-beta.2, use `black-white-list` instead.
 filter-rules: ["filter-rule-2"] # The name of the rule
 ↪ that filters specific binlog events of the data source. You
 ↪ can configure multiple rules here.

```

### 13.6.6.3.6 Configure a shard merge task

#### Note:

- If you need to migrate sharding DDL statements in a shard merge scenario, you **must** explicitly configure the `shard-mode` field. Otherwise, **DO NOT** configure `shard-mode` at all.

- Migrating sharding DDL statements is likely to cause many issues. Make sure you understand the principles and restrictions of DM migrating DDL statements before using this feature, and you **must** use this feature with caution.

The following example shows how to configure the task as a shard merge task:

```

***** Basic information *****
name: test # The name of the task. Should be globally
 ↪ unique.
shard-mode: "pessimistic" # The shard merge mode. Optional modes are ""/"
 ↪ pessimistic"/"optimistic". The "" mode is used by default which means
 ↪ sharding DDL merge is disabled. If the task is a shard merge task,
 ↪ set it to the "pessimistic" mode. After getting a deep understanding
 ↪ of the principles and restrictions of the "optimistic" mode, you can
 ↪ set it to the "optimistic" mode.

```

### 13.6.6.3.7 Other configurations

The following is an overall task configuration example of this document. The complete task configuration template can be found in [DM task configuration file full introduction](#).

```

***** Basic configuration *****
name: test # The name of the task. Should be globally
 ↪ unique.
shard-mode: "pessimistic" # The shard merge mode. Optional modes are ""/"
 ↪ pessimistic"/"optimistic". The "" mode is used by default which means
 ↪ sharding DDL merge is disabled. If the task is a shard merge task,
 ↪ set it to the "pessimistic" mode. After getting a deep understanding
 ↪ of the principles and restrictions of the "optimistic" mode, you can
 ↪ set it to the "optimistic" mode.
task-mode: all # The task mode. Can be set to `full` (only
 ↪ migrates full data)/`incremental` (replicates binlog synchronously)/`
 ↪ all` (replicates both full and incremental binlogs).
timezone: "UTC" # The timezone used in SQL Session. By default,
 ↪ DM uses the global timezone setting in the target cluster, which
 ↪ ensures the correctness automatically. A customized timezone does not
 ↪ affect data migration but is unnecessary.

```

```
***** Data source configuration *****
mysql-instances:
- source-id: "mysql-replica-01" # Migrate data from the data
 ↪ source whose `source-id` is `mysql-replica-01`.
 block-allow-list: "bw-rule-1" # The name of the block and
 ↪ allow list rule. If the DM version is earlier than v2.0.0-beta.2,
 ↪ use `black-white-list` instead.
 filter-rules: ["filter-rule-1"] # The name of the rule that
 ↪ filters specific binlog events of the data source. You can
 ↪ configure multiple rules here.
 route-rules: ["route-rule-1", "route-rule-2"] # The name of the routing
 ↪ mapping rule. You can configure multiple rules here.
- source-id: "mysql-replica-02" # Migrate data from the data
 ↪ source whose `source-id` is `mysql-replica-02`.
 block-allow-list: "bw-rule-2" # The name of the block and
 ↪ allow list rule. If the DM version is earlier than v2.0.0-beta.2,
 ↪ use `black-white-list` instead.
 filter-rules: ["filter-rule-2"] # The name of the rule that
 ↪ filters specific binlog events of the data source. You can
 ↪ configure multiple rules here.
 route-rules: ["route-rule-2"] # The name of the routing
 ↪ mapping rule. You can configure multiple rules here.

***** Downstream TiDB instance configuration *****
target-database: # Configuration of the downstream database instance.
 host: "127.0.0.1"
 port: 4000
 user: "root"
 password: "" # If the password is not null, it is recommended to use
 ↪ a password encrypted with dmctl.

***** Feature configuration set *****
The filter rule set of tables to be migrated from the upstream database
 ↪ instance. You can set multiple rules at the same time.
block-allow-list: # Use black-white-list if the DM version
 ↪ is earlier than v2.0.0-beta.2.
bw-rule-1: # The name of the block and allow list
 ↪ rule.
do-dbs: ["test.*", "user"] # The allow list of upstream schemas to
 ↪ be migrated. Wildcard characters (*?) are supported. You only need
 ↪ to configure either `do-dbs` or `ignore-dbs`. If both fields are
 ↪ configured, only `do-dbs` takes effect.
ignore-dbs: ["mysql", "account"] # The block list of upstream schemas
 ↪ to be migrated. Wildcard characters (*?) are supported.
do-tables: # The allow list of upstream tables to be
```

```

 ↪ migrated. You only need to configure either `do-tables` or `
 ↪ ignore-tables`. If both fields are configured, only `do-tables`
 ↪ takes effect.
- db-name: "test.*"
 tbl-name: "t.*"
- db-name: "user"
 tbl-name: "information"
bw-rule-2: # The name of the block allow list rule.
ignore-tables: # The block list of data source tables
 ↪ needs to be migrated.
- db-name: "user"
 tbl-name: "log"

The filter rule set of data source binlog events.
filters: # You can set multiple rules at
 ↪ the same time.
filter-rule-1: # The name of the filtering rule.
 schema-pattern: "test_*" # The pattern of the data source
 ↪ schema name. Wildcard characters (*?) are supported.
 table-pattern: "t_*" # The pattern of the data source
 ↪ table name. Wildcard characters (*?) are supported.
 events: ["truncate table", "drop table"] # The event types to be
 ↪ filtered out in schemas or tables that match the `schema-pattern`
 ↪ or the `table-pattern`.
 action: Ignore # Whether to migrate (Do) or
 ↪ ignore (Ignore) the binlog that matches the filtering rule.
filter-rule-2:
 schema-pattern: "test"
 events: ["all dml"]
 action: Do

The routing mapping rule set between the data source and target TiDB
 ↪ instance tables.
routes: # You can set multiple rules at the same time.
 route-rule-1: # The name of the routing mapping rule.
 schema-pattern: "test_*" # The pattern of the data source schema name.
 ↪ Wildcard characters (*?) are supported.
 table-pattern: "t_*" # The pattern of the data source table name.
 ↪ Wildcard characters (*?) are supported.
 target-schema: "test" # The name of the downstream TiDB schema.
 target-table: "t" # The name of the downstream TiDB table.
 route-rule-2:
 schema-pattern: "test_*"
 target-schema: "test"

```

### 13.6.6.4 TiDB Data Migration Shard Merge

TiDB Data Migration (DM) supports merging the DML and DDL data in the upstream MySQL/MariaDB sharded tables and migrating the merged data to the downstream TiDB tables.

If you need to migrate and merge MySQL shards of small datasets to TiDB, refer to [this tutorial](#).

#### 13.6.6.4.1 Restrictions

Currently, the shard merge feature is supported only in limited scenarios. For details, refer to [Sharding DDL usage Restrictions in the pessimistic mode](#) and [Sharding DDL usage Restrictions in the optimistic mode](#).

#### 13.6.6.4.2 Configure parameters

In the task configuration file, set `shard-mode` to `pessimistic`:

```
shard-mode: "pessimistic"
The shard merge mode. Optional modes are ""/"pessimistic"/"optimistic".
 ↳ The "" mode is used by default
which means sharding DDL merge is disabled. If the task is a shard
 ↳ merge task, set it to the "pessimistic"
mode. After getting a deep understanding of the principles and
 ↳ restrictions of the "optimistic" mode, you
can set it to the "optimistic" mode.
```

#### 13.6.6.4.3 Handle sharding DDL locks manually

In some abnormal scenarios, you need to [handle sharding DDL Locks manually](#).

### 13.6.6.5 TiDB Data Migration Table Routing

When you migrate data using TiDB Data Migration (DM), you can configure the table routing to migrate a certain table of the upstream MySQL or MariaDB instance to the specified table in the downstream.

#### Note:

- Configuring multiple different routing rules for a single table is not supported.
- The match rule of schema needs to be configured separately, which is used to migrate `CREATE/DROP SCHEMA xx`, as shown in [rule-2](#) of the [Configure table routing](#) section.

### 13.6.6.5.1 Configure table routing

```
routes:
 rule-1:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 target-schema: "test"
 target-table: "t"
 # extract-table, extract-schema, and extract-source are optional and
 # are required only when you need to extract information about sharded
 # tables, sharded schemas, and source database information.
 extract-table:
 table-regexp: "t_(.*)"
 target-column: "c_table"
 extract-schema:
 schema-regexp: "test_(.*)"
 target-column: "c_schema"
 extract-source:
 source-regexp: "(.*)"
 target-column: "c_source"
 rule-2:
 schema-pattern: "test_*"
 target-schema: "test"
```

In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following version differences:

- For DM v1.0.5 or later versions, the table routing supports the [wildcard match](#), but there can be **only one** \* in the wildcard expression, and \* **must be placed at the end**.
- For DM versions earlier than v1.0.5, the table routing supports the wildcard but does not support the [...] and [!...] expressions.

### 13.6.6.5.2 Parameter descriptions

- DM migrates the upstream MySQL or MariaDB instance tables that match the [schema-pattern/table-pattern rule provided by Table selector](#) to the downstream target-schema/target-table.
- For sharded tables that match the schema-pattern/table-pattern rules, DM extracts the table name by using the `extract-table.table-regexp` regular expression, the schema name by using the `extract-schema.schema-regexp` regular expression, and source information by using the `extract-source.source-regexp` regular expression. Then DM writes the extracted information to the corresponding `target-column` in the merged table in the downstream.

### 13.6.6.5.3 Usage examples

This section shows the usage examples in four different scenarios.

If you need to migrate and merge MySQL shards of small datasets to TiDB, refer to [this tutorial](#).

Merge sharded schemas and tables

Assuming in the scenario of sharded schemas and tables, you want to migrate the `test_{1,2,3...}.t_{1,2,3...}` tables in two upstream MySQL instances to the `test.t` table in the downstream TiDB instance.

To migrate the upstream instances to the downstream `test.t`, you must create the following routing rules:

- `rule-1` is used to migrate DML or DDL statements of the table that matches `schema`  
↪ `-pattern: "test_*` and `table-pattern: "t_*` to the downstream `test.t`.
- `rule-2` is used to migrate DDL statements of the schema that matches `schema-`  
↪ `pattern: "test_*`, such as `CREATE/DROP SCHEMA xx`.

#### Note:

- If the downstream `schema: test` already exists and is not to be deleted, you can omit `rule-2`.
- If the downstream `schema: test` does not exist and only `rule-1` is configured, then it reports the `schema test doesn't exist` error during migration.

```
rule-1:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 target-schema: "test"
 target-table: "t"
rule-2:
 schema-pattern: "test_*"
 target-schema: "test"
```

Extract table, schema, and source information and write into the merged table

Assuming in the scenario of sharded schemas and tables, you want to migrate the `test_{1,2,3...}.t_{1,2,3...}` tables in two upstream MySQL instances to the `test.t` table in the downstream TiDB instance. At the same time, you want to extract the source information of the sharded tables and write it to the downstream merged table.

To migrate the upstream instances to the downstream `test.t`, you must create routing rules similar to the previous section [Merge sharded schemas and tables](#). In addition, you need to add the `extract-table`, `extract-schema`, and `extract-source` configurations:

- `extract-table`: For a sharded table matching `schema-pattern` and `table-pattern`, DM extracts the sharded table name by using `table-regexp` and writes the name suffix without the `t_` part to `target-column` of the merged table, that is, the `c_table` column.
- `extract-schema`: For a sharded schema matching `schema-pattern` and `table-pattern`, DM extracts the sharded schema name by using `schema-regexp` and writes the name suffix without the `test_` part to `target-column` of the merged table, that is, the `c_schema` column.
- `extract-source`: For a sharded table matching `schema-pattern` and `table-pattern`, DM writes the source instance information to the `target-column` of the merged table, that is, the `c_source` column.

```
rule-1:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 target-schema: "test"
 target-table: "t"
 extract-table:
 table-regexp: "t_(.*)"
 target-column: "c_table"
 extract-schema:
 schema-regexp: "test_(.*)"
 target-column: "c_schema"
 extract-source:
 source-regexp: "(.*)"
 target-column: "c_source"
rule-2:
 schema-pattern: "test_*"
 target-schema: "test"
```

To extract the source information of upstream sharded tables to the merged table in the downstream, you **must manually create a merged table in the downstream before starting the migration**. The merged table must contain the three `target-columns` (`c_table`, `c_schema`, and `c_source`) used for specifying the source information. In addition, these columns **must be the last columns and be string types**.

```
CREATE TABLE `test`.`t` (
 a int(11) PRIMARY KEY,
 c_table varchar(10) DEFAULT NULL,
 c_schema varchar(10) DEFAULT NULL,
 c_source varchar(10) DEFAULT NULL
```

```
);
```

Assume that the upstream has the following two data sources:

Data source mysql-01:

```
mysql> select * from test_11.t_1;
+----+
| a |
+----+
| 1 |
+----+
mysql> select * from test_11.t_2;
+----+
| a |
+----+
| 2 |
+----+
mysql> select * from test_12.t_1;
+----+
| a |
+----+
| 3 |
+----+
```

Data source mysql-02:

```
mysql> select * from test_13.t_3;
+----+
| a |
+----+
| 4 |
+----+
```

After migration using DM, data in the merged table will be as follows:

```
mysql> select * from test.t;
+-----+-----+-----+-----+
| a | c_table | c_schema | c_source |
+-----+-----+-----+-----+
| 1 | 1 | 11 | mysql-01 |
| 2 | 2 | 11 | mysql-01 |
| 3 | 1 | 12 | mysql-01 |
| 4 | 3 | 13 | mysql-02 |
+-----+-----+-----+-----+
```

Incorrect examples of creating merged tables

**Note:**

If any of the following errors occur, source information of sharded tables and schemas might fail to be written to the merged table.

- `c-table` is not in the last three columns:

```
CREATE TABLE `test`.`t` (
 c_table varchar(10) DEFAULT NULL,
 a int(11) PRIMARY KEY,
 c_schema varchar(10) DEFAULT NULL,
 c_source varchar(10) DEFAULT NULL
);
```

- `c-source` is absent:

```
CREATE TABLE `test`.`t` (
 a int(11) PRIMARY KEY,
 c_table varchar(10) DEFAULT NULL,
 c_schema varchar(10) DEFAULT NULL,
);
```

- `c_schema` is not a string type:

```
CREATE TABLE `test`.`t` (
 a int(11) PRIMARY KEY,
 c_table varchar(10) DEFAULT NULL,
 c_schema int(11) DEFAULT NULL,
 c_source varchar(10) DEFAULT NULL,
);
```

### Merge sharded schemas

Assuming in the scenario of sharded schemas, you want to migrate the `test_{1,2,3...}`  $\leftrightarrow$  `.t_{1,2,3...}` tables in the two upstream MySQL instances to the `test.t_{1,2,3...}` tables in the downstream TiDB instance.

To migrate the upstream schemas to the downstream `test.t_[1,2,3]`, you only need to create one routing rule.

```
rule-1:
 schema-pattern: "test_*"
 target-schema: "test"
```

Incorrect table routing

Assuming that the following two routing rules are configured and `test_1_bak.t_1_bak` matches both `rule-1` and `rule-2`, an error is reported because the table routing configuration violates the number limitation.

```
rule-1:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 target-schema: "test"
 target-table: "t"
rule-2:
 schema-pattern: "test_1_bak"
 table-pattern: "t_1_bak"
 target-schema: "test"
 target-table: "t_bak"
```

### 13.6.6.6 TiDB Data Migration Block and Allow Lists

When you migrate data using TiDB Data Migration (DM), you can configure the block and allow lists to filter or only migrate all operations of some databases or some tables.

#### 13.6.6.6.1 Configure the block and allow lists

In the task configuration file, add the following configuration:

```
block-allow-list: # Use black-white-list if the DM version is
 ↪ earlier than or equal to v2.0.0-beta.2.
rule-1:
 do-dbs: ["test*"] # Starting with characters other than "~"
 ↪ indicates that it is a wildcard;
 # v1.0.5 or later versions support the regular
 ↪ expression rules.
 do-tables:
 - db-name: "test[123]" # Matches test1, test2, and test3.
 tbl-name: "t[1-5]" # Matches t1, t2, t3, t4, and t5.
 - db-name: "test"
 tbl-name: "t"
rule-2:
 do-dbs: ["~^test.*"] # Starting with "~" indicates that it is a
 ↪ regular expression.
 ignore-dbs: ["mysql"]
```

```
do-tables:
- db-name: "~^test.*"
 tbl-name: "~^t.*"
- db-name: "test"
 tbl-name: "t"
ignore-tables:
- db-name: "test"
 tbl-name: "log"
```

In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following version differences:

- For DM v1.0.5 or later versions, the block and allow lists support the [wildcard match](#), but there can be **only one \*** in the wildcard expression, and **\* must be placed at the end**.
- For DM versions earlier than v1.0.5, the block and allow lists only support regular expression matching.

#### 13.6.6.6.2 Parameter descriptions

- `do-dbs`: allow lists of the schemas to be migrated, similar to [replicate-do-db](#) in MySQL.
- `ignore-dbs`: block lists of the schemas to be migrated, similar to [replicate-ignore](#) ↔ `-db` in MySQL.
- `do-tables`: allow lists of the tables to be migrated, similar to [replicate-do-table](#) in MySQL. Both `db-name` and `tbl-name` must be specified.
- `ignore-tables`: block lists of the tables to be migrated, similar to [replicate-ignore](#) ↔ `-table` in MySQL. Both `db-name` and `tbl-name` must be specified.

If a value of the above parameters starts with the `~` character, the subsequent characters of this value are treated as a [regular expression](#). You can use this parameter to match schema or table names.

#### 13.6.6.6.3 Filtering process

- The filtering rules corresponding to `do-dbs` and `ignore-dbs` are similar to the [Evaluation of Database-Level Replication and Binary Logging Options](#) in MySQL.
- The filtering rules corresponding to `do-tables` and `ignore-tables` are similar to the [Evaluation of Table-Level Replication Options](#) in MySQL.

**Note:**

In DM and in MySQL, the block and allow lists filtering rules are different in the following ways:

- In MySQL, `replicate-wild-do-table` and `replicate-wild-ignore-table` support wildcard characters. In DM, some parameter values directly supports regular expressions that start with the `~` character.
- DM currently only supports binlogs in the `ROW` format, and does not support those in the `STATEMENT` or `MIXED` format. Therefore, the filtering rules in DM correspond to those in the `ROW` format in MySQL.
- MySQL determines a DDL statement only by the database name explicitly specified in the `USE` section of the statement. DM determines a statement first based on the database name section in the DDL statement. If the DDL statement does not contain such a section, DM determines the statement by the `USE` section. Suppose that the SQL statement to be determined is `USE test_db_2; CREATE TABLE test_db_1.test_table (c1 INT PRIMARY KEY);` that `replicate-do-db=test_db_1` is configured in MySQL and `do-dbs: ["test_db_1"]` is configured in DM. Then this rule only applies to DM and not to MySQL.

The filtering process of a `test.t` table is as follows:

1. Filter at the **schema** level:

- If `do-dbs` is not empty, check whether a matched schema exists in `do-dbs`.
  - If yes, continue to filter at the **table** level.
  - If not, filter `test.t`.
- If `do-dbs` is empty and `ignore-dbs` is not empty, check whether a matched schema exists in `ignore-dbs`.
  - If yes, filter `test.t`.
  - If not, continue to filter at the **table** level.
- If both `do-dbs` and `ignore-dbs` are empty, continue to filter at the **table** level.

2. Filter at the **table** level:

1. If `do-tables` is not empty, check whether a matched table exists in `do-tables`.
  - If yes, migrate `test.t`.
  - If not, filter `test.t`.

2. If `ignore-tables` is not empty, check whether a matched table exists in `ignore`  
↪ `-tables`.
  - If yes, filter `test.t`.
  - If not, migrate `test.t`.
3. If both `do-tables` and `ignore-tables` are empty, migrate `test.t`.

#### Note:

To check whether the schema `test` should be filtered, you only need to filter at the schema level.

#### 13.6.6.6.4 Usage examples

Assume that the upstream MySQL instances include the following tables:

```
`logs`.`messages_2016`
`logs`.`messages_2017`
`logs`.`messages_2018`
`forum`.`users`
`forum`.`messages`
`forum_backup_2016`.`messages`
`forum_backup_2017`.`messages`
`forum_backup_2018`.`messages`
```

The configuration is as follows:

```
block-allow-list: # Use black-white-list if the DM version is earlier than
↪ or equal to v2.0.0-beta.2.
bw-rule:
 do-dbs: ["forum_backup_2018", "forum"]
 ignore-dbs: ["~^forum_backup_"]
 do-tables:
 - db-name: "logs"
 tbl-name: "~_2018$"
 - db-name: "~^forum.*"
 tbl-name: "messages"
 ignore-tables:
 - db-name: "~.*"
 tbl-name: "^messages.*"
```

After applying the `bw-rule` rule:

Table	Whether to filter	Why filter
logs	Yes	The schema <code>.messages_2016gs</code> fails to match any <code>do-dbs</code> .
logs	Yes	The schema <code>.messages_2017gs</code> fails to match any <code>do-dbs</code> .
logs	Yes	The schema <code>.messages_2018gs</code> fails to match any <code>do-dbs</code> .
forum_backup_2016	Yes	The schema <code>forum_backup_2016</code> fails to match any <code>do-dbs</code> .
forum_backup_2017	Yes	The schema <code>forum_backup_2017</code> fails to match any <code>do-dbs</code> .
forum	Yes	1. The schema <code>forum</code> matches <code>do-dbs</code> and continues to filter at the table level. 2. The schema and table fail to match any of <code>do-tables</code> and <code>ignore-tables</code> and <code>do-tables</code> is not empty.

Table	Whether to filter	Why filter
forum	No	1. The schema matches forum
↳ .messages		↳ do-dbs and continues to filter at the table level. 2. The table messages is in the db-name: "~^ forum.*",
↳		↳ tbl-name: "messages" of do-tables.
forum_backup_2018	No	1. The schema matches forum_backup_2018
↳ .messages		↳ matches do-dbs and continues to filter at the table level. 2. The schema and table match the db-name: "~^ forum.*",
↳		↳ tbl-name: "messages" of do-tables.

### 13.6.6.7 TiDB Data Migration Binlog Event Filter

TiDB Data Migration (DM) provides the binlog event filter feature to filter out or only receive specified types of binlog events for some schemas or tables. For example, you can filter out all `TRUNCATE TABLE` or `INSERT` events. The binlog event filter feature is more fine-grained than the [block and allow lists](#) feature.

#### 13.6.6.7.1 Configure the binlog event filter

In the task configuration file, add the following configuration:

```
filters:
 rule-1:
```

```

schema-pattern: "test_*"
table-pattern: "t_*"
events: ["truncate table", "drop table"]
sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
action: Ignore

```

Starting from DM v2.0.2, you can configure the binlog event filter in the source configuration file. For details, see [Upstream Database Configuration File](#).

In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following version differences:

- For DM v1.0.5 or later versions, the binlog event filter supports the [wildcard match](#), but there can be **only one \*** in the wildcard expression, and **\* must be placed at the end**.
- For DM versions earlier than v1.0.5, the binlog event filter supports the wildcard but does not support the [...] and [!...] expressions.

### 13.6.6.7.2 Parameter descriptions

- **schema-pattern/table-pattern**: the binlog events or DDL SQL statements of upstream MySQL or MariaDB instance tables that match **schema-pattern/table-pattern** are filtered by the rules below.
- **events**: the binlog event array. You can only select one or more Events from the following table:

Events	Type	Description
all		Includes all the events below
all dml		Includes all DML events below
all ddl		Includes all DDL events below
none		Includes none of the events below
none ddl		Includes none of the DDL events below
none dml		Includes none of the DML events below
insert	DML	The INSERT DML event
update	DML	The UPDATE DML event
delete	DML	The DELETE DML event
create database	DDL	The CREATE DATABASE DDL event
drop database	DDL	The DROP DATABASE DDL event
create table	DDL	The CREATE TABLE DDL event
create index	DDL	The CREATE INDEX DDL event
drop table	DDL	The DROP TABLE DDL event
truncate table	DDL	The TRUNCATE TABLE DDL event
rename table	DDL	The RENAME TABLE DDL event

Events	Type	Description
drop index	DDL	The DROP INDEX DDL event
alter table	DDL	The ALTER TABLE DDL event

- **sql-pattern**: it is used to filter specified DDL SQL statements. The matching rule supports using a regular expression. For example, "`^DROP\\s+PROCEDURE`".
- **action**: the string (Do/Ignore). Based on the following rules, it judges whether to filter. If either of the two rules is satisfied, the binlog is filtered; otherwise, the binlog is not filtered.
  - **Do**: the allow list. The binlog is filtered in either of the following two conditions:
    - \* The type of the event is not in the **event** list of the rule.
    - \* The SQL statement of the event cannot be matched by **sql-pattern** of the rule.
  - **Ignore**: the block list. The binlog is filtered in either of the following two conditions:
    - \* The type of the event is in the **event** list of the rule.
    - \* The SQL statement of the event can be matched by **sql-pattern** of the rule.
  - When multiple rules match the same table, the rules are applied sequentially. The block list has a higher priority than the allow list. For example, if both the **Ignore** and **Do** rules are applied to the same table, the **Ignore** rule takes effect.

### 13.6.6.7.3 Usage examples

This section shows the usage examples in the scenario of sharding (sharded schemas and tables).

Filter all sharding deletion operations

To filter out all deletion operations, configure the following two filtering rules:

- **filter-table-rule** filters out the TRUNCATE TABLE, DROP TABLE and DELETE  $\hookrightarrow$  STATEMENT operations of all tables that match the `test_*.t_*` pattern.
- **filter-schema-rule** filters out the DROP DATABASE operation of all schemas that match the `test_*` pattern.

```
filters:
 filter-table-rule:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 events: ["truncate table", "drop table", "delete"]
 action: Ignore
 filter-schema-rule:
```

```
schema-pattern: "test_*"
events: ["drop database"]
action: Ignore
```

Only migrate sharding DML statements

To only migrate sharding DML statements, configure the following two filtering rules:

- `do-table-rule` only migrates the `CREATE TABLE`, `INSERT`, `UPDATE` and `DELETE` statements of all tables that match the `test_*.t_*` pattern.
- `do-schema-rule` only migrates the `CREATE DATABASE` statement of all schemas that match the `test_*` pattern.

### Note:

The reason why the `CREATE DATABASE/TABLE` statement is migrated is that you can migrate DML statements only after the schema and table are created.

```
filters:
 do-table-rule:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 events: ["create table", "all dml"]
 action: Do
 do-schema-rule:
 schema-pattern: "test_*"
 events: ["create database"]
 action: Do
```

Filter out the SQL statements that TiDB does not support

To filter out the `PROCEDURE` statements that TiDB does not support, configure the following `filter-procedure-rule`:

```
filters:
 filter-procedure-rule:
 schema-pattern: "test_*"
 table-pattern: "t_*"
 sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
 action: Ignore
```

`filter-procedure-rule` filters out the `^CREATE\\s+PROCEDURE` and `^DROP\\s+PROCEDURE` statements of all tables that match the `test_*.t_*` pattern.

Filter out the SQL statements that the TiDB parser does not support

For the SQL statements that the TiDB parser does not support, DM cannot parse them and get the `schema/table` information. So you must use the global filtering rule: `schema-↵ pattern: "*".`

#### Note:

To avoid filtering out data that need to be migrated, you must configure the global filtering rule as strictly as possible.

To filter out the `PARTITION` statements that the TiDB parser (of some version) does not support, configure the following filtering rule:

```
filters:
 filter-partition-rule:
 schema-pattern: "*"
 sql-pattern: ["ALTER\\s+TABLE[\\s\\S]*ADD\\s+PARTITION", "ALTER\\s+TABLE
 ↵ [\\s\\S]*DROP\\s+PARTITION"]
 action: Ignore
```

### 13.6.6.8 Filter DMLs Using SQL Expressions

#### 13.6.6.8.1 Overview

In the process of incremental data migration, you can filter certain types of binlog events using the [Filter Binlog Events](#) feature. For example, for archiving or auditing purposes, you can filter out `DELETE` events when migrating data to the downstream. However, Binlog Event Filter cannot judge with a greater granularity on whether to filter out a specific row of `DELETE` events.

To solve the above issue, DM supports filtering data during incremental migration using `binlog value filter` since v2.0.5. The binlog in the `ROW` format supported by DM has the values of all columns in binlog events. You can configure SQL expressions according to these values. If the SQL expressions evaluate a row change as `TRUE`, DM will not migrate the row change downstream.

For detailed operation and implementation, see [Filter DML Events Using SQL Expressions](#).

### 13.6.6.9 TiDB Data Migration Support for Online DDL Tools

In the MySQL ecosystem, tools such as `gh-ost` and `pt-osc` are widely used. TiDB Data Migration (DM) provides supports for these tools to avoid migrating unnecessary intermediate data.

This document introduces the support for common online DDL tools, usage, and precautions in DM.

For the working principles and implementation methods of DM for online DDL tools, refer to [online-ddl](#).

### 13.6.6.9.1 Restrictions

- DM only supports gh-ost and pt-osc.
- When `online-ddl` is enabled, the checkpoint corresponding to incremental replication should not be in the process of online DDL execution. For example, if an upstream online DDL operation starts at `position-A` and ends at `position-B` of the binlog, the starting point of incremental replication should be earlier than `position-A` or later than `position-B`; otherwise, an error occurs. For details, refer to [FAQ](#).

### 13.6.6.9.2 Configure parameters

In v2.0.5 and later versions, you need to use the `online-ddl` configuration item in the `task` configuration file.

- If the upstream MySQL/MariaDB (at the same time) uses the gh-ost or pt-osc tool, set `online-ddl` to `true` in the task configuration file:

```
online-ddl: true
```

#### Note:

Since v2.0.5, `online-ddl-scheme` has been deprecated, so you need to use `online-ddl` instead of `online-ddl-scheme`. That means that setting `online`  
↪ `-ddl: true` overwrites `online-ddl-scheme`, and setting `online-ddl-`  
↪ `scheme: "pt"` or `online-ddl-scheme: "gh-ost"` is converted to `online`  
↪ `-ddl: true`.

Before v2.0.5 (not including v2.0.5), you need to use the `online-ddl-scheme` configuration item in the `task` configuration file.

- If the upstream MySQL/MariaDB uses the gh-ost tool, set it in the task configuration file:

```
online-ddl-scheme: "gh-ost"
```

- If the upstream MySQL/MariaDB uses the pt tool, set it in the task configuration file:

```
online-ddl-scheme: "pt"
```

### 13.6.6.10 Manage a Data Migration Task

#### 13.6.6.10.1 Migration Task Precheck

Before using DM to migrate data from upstream to downstream, a precheck helps detect errors in the upstream database configurations and ensures that the migration goes smoothly. This document introduces the DM precheck feature, including its usage scenario, check items, and arguments.

##### Usage scenario

To run a data migration task smoothly, DM triggers a precheck automatically at the start of the task and returns the check results. DM starts the migration only after the precheck is passed.

To trigger a precheck manually, run the `check-task` command.

For example:

```
tiup dmctl check-task ./task.yaml
```

##### Descriptions of check items

After a precheck is triggered for a task, DM checks the corresponding items according to your migration mode configuration.

This section lists all the precheck items.

#### Note:

In this document, check items that must be passed are labeled “(Mandatory)”.

- If a mandatory check item does not pass, DM returns an error after the check and does not proceed with the migration task. In this case, modify the configurations according to the error message and retry the task after meeting the precheck requirements.
- If a non-mandatory check item does not pass, DM returns a warning after the check. DM automatically starts a migration task if the check result contains only warnings but no errors.

##### Common check items

Regardless of the migration mode you choose, the precheck always includes the following common check items:

- Database version
  - MySQL version > 5.5
  - MariaDB version >= 10.1.2

**Warning:**

- Migrating data from MySQL 8.0 to TiDB using DM is an experimental feature (introduced since DM v2.0). It is NOT recommended that you use it in a production environment.
- Migrating data from MariaDB to TiDB using DM is an experimental feature. It is NOT recommended that you use it in a production environment.

- Compatibility of the upstream MySQL table schema
  - Check whether the upstream tables have foreign keys, which are not supported by TiDB. A warning is returned if a foreign key is found in the precheck.
  - Check whether the upstream tables use character sets that are incompatible with TiDB. For more information, see [TiDB Supported Character Sets](#).
  - Check whether the upstream tables have primary key constraints or unique key constraints (introduced from v1.0.7).

**Warning:**

- When the upstream uses incompatible character sets, you can still continue the replication by creating tables with the utf8mb4 character set in the downstream. However, this practice is not recommended. You are advised to replace the incompatible character set used by the upstream with another character set that is supported in downstream.
- When the upstream tables have no primary key constraints or unique key constraints, the same row of data might be replicated multiple times to the downstream, which might also affect the performance of replication. In a production environment, it is recommended that you specify primary key constraints or unique key constraints for the upstream table.

Check items for full data migration

For the full data migration mode (`task-mode: full`), in addition to the [common check items](#), the precheck also includes the following check items:

- (Mandatory) dump permission of the upstream database
  - SELECT permission on INFORMATION\_SCHEMA and dump tables
  - RELOAD permission if `consistency=flush`
  - LOCK TABLES permission on the dump tables if `consistency=flush/lock`
- (Mandatory) Consistency of upstream MySQL multi-instance sharding tables
  - In the pessimistic mode, check whether the table schemas of all sharded tables are consistent in the following items:
    - \* Number of columns
    - \* Column name
    - \* Column order
    - \* Column type
    - \* Primary key
    - \* Unique index
  - In the optimistic mode, check whether the schemas of all sharded tables meet the [optimistic compatibility](#).
  - If a migration task was started successfully by the `start-task` command, the precheck of this task skips the consistency check.
- Auto-increment primary key in sharded tables
  - If sharded tables have auto-increment primary keys, the precheck returns a warning. If there are conflicts in auto-increment primary keys, see [Handle conflicts of auto-increment primary key](#) for solutions.

#### Check items for physical import

If you set `import-mode: "physical"` in the task configuration, the following check items are added to ensure that [Physical Import](#) runs normally. After following the prompts, if you find it difficult to meet the requirements of these check items, you can try to use the [logical import mode](#) to import data.

- Empty Regions in the downstream database
  - If the number of empty Regions is greater than `max(1000, 3 * the number ↪ of tables)` (the larger of “1000” and “3 times the number of tables”), the precheck returns a warning. You can adjust related PD parameters to speed up the merging of empty Regions and wait for the number of empty Regions to decrease. See [PD Scheduling Best Practices - Slow Region Merge](#).
- Region distribution in the downstream database

- Checks the number of Regions on different TiKV nodes. Assuming that the TiKV node with the lowest Region count has `a` Regions and the TiKV node with the highest Region count has `b` Regions, if `a / b` is less than 0.75, the precheck returns a warning. You can adjust related PD parameters to speed up the scheduling of Regions and wait for the number of Regions to change. See [PD Scheduling Best Practices - Leader/Region distribution is not balanced](#).
- The versions of TiDB, PD, and TiKV in the downstream database
  - Physical import must call the interfaces of TiDB, PD, and TiKV. If the versions are not compatible, the precheck returns an error.
- The free space of the downstream database
  - Estimates the total sizes of all tables in the allow list in the upstream database (`source_size`). If the free space of the downstream database is less than `source_size`, the precheck returns an error. If the free space of the downstream database is less than the number of TiKV replicas \* `source_size` \* 2, the precheck returns a warning.
- Whether the downstream database is running tasks that are incompatible with physical import
  - Currently, physical import is incompatible with [TiCDC](#) and [PITR](#) tasks. If these tasks are running in the downstream database, the precheck returns an error.

#### Check items for incremental data migration

For the incremental data migration mode (`task-mode: incremental`), in addition to the [common check items](#), the precheck also includes the following check items:

- (Mandatory) Upstream database REPLICATION permission
  - REPLICATION CLIENT permission
  - REPLICATION SLAVE permission
- Database primary-secondary configuration
  - To avoid primary-secondary replication failures, it is recommended that you specify the database ID `server_id` for the upstream database (GTID is recommended for non-AWS Aurora environments).
- (Mandatory) MySQL binlog configuration
  - Check whether binlog is enabled (required by DM).
  - Check whether `binlog_format=ROW` is configured (DM only supports the migration of binlog in the ROW format).

- Check whether `binlog_row_image=FULL` is configured (DM only supports `binlog_row_image=FULL`).
  - If `binlog_do_db` or `binlog_ignore_db` is configured, check whether the database tables to be migrated meet the conditions of `binlog_do_db` and `binlog_ignore_db`.
- (Mandatory) Check if the upstream database is in an **Online-DDL** process (in which the `ghost` table is created but the `rename` phase is not executed yet). If the upstream is in the online-DDL process, the precheck returns an error. In this case, wait until the DDL to complete and retry.

### Check items for full and incremental data migration

For the full and incremental data migration mode (`task-mode: all`), in addition to the **common check items**, the precheck also includes the **full data migration check items** and the **incremental data migration check items**.

### Ignorable check items

Prechecks can find potential risks in your environments. It is not recommended to ignore check items. If your data migration task has special needs, you can use the **ignore-checking**  $\hookrightarrow$  **-items configuration item** to skip some check items.

Check item	Description
<code>dump_privilege</code> $\hookrightarrow$	Checks the dump privilege of the user in the upstream MySQL instance.
<code>replication_privilege</code> $\hookrightarrow$	Checks the replication privilege of the user in the upstream MySQL instance.
<code>version</code>	Checks the version of the upstream database.

Check item	Description
<code>server_id</code>	Checks whether <code>server_id</code> is configured in the upstream database.
<code>binlog_enable</code> ↔	Checks whether binlog is enabled in the upstream database.
<code>table_schema</code> ↔	Checks the compatibility of the table schemas in the upstream MySQL tables.
<code>schema_of_shard</code> ↔	Checks consistency of the table schemas in the upstream MySQL multi-instance shards.
<code>auto_increment</code> ↔	Checks whether the auto-increment primary key conflicts in the upstream MySQL multi-instance shards.
<code>online_ddl</code>	Checks whether the upstream is in the process of <b>online-DDL</b> .

Check item	Description
<code>empty_region</code> ↔	Checks the number of empty Regions in the downstream database for physical import.
<code>region_distribution</code> ↔	Checks the distribution of Regions in the downstream database for physical import.
<code>downstream_versions</code> ↔	Checks the versions of TiDB, PD, and TiKV in the downstream database.
<code>free_space</code>	Checks the free space of the downstream database.
<code>downstream_multi_features</code> ↔	Checks whether the downstream database is running tasks that are incompatible with physical import.

**Note:**

More ignorable check items are supported in versions earlier than v6.0. Since v6.0, DM does not allow ignoring some check items related to data safety.

For example, if you configure the `binlog_row_image` parameter incorrectly, data might be lost during the replication.

### Configure precheck arguments

The migration task precheck supports processing in parallel. Even if the number of rows in sharded tables reaches a million level, the precheck can be completed in minutes.

To specify the number of threads for the precheck, you can configure the `threads` argument of the `mydumpers` field in the migration task configuration file.

```
mydumpers: # Configuration arguments of the dump
 ↪ processing unit
global: # Configuration name
 threads: 4 # The number of threads that access the
 ↪ upstream when the dump processing unit performs the precheck and
 ↪ exports data from the upstream database (4 by default)
 chunk-filesize: 64 # The size of the files generated by the
 ↪ dump processing unit (64 MB by default)
 extra-args: "--consistency none" # Other arguments of the dump
 ↪ processing unit. You do not need to manually configure table-list
 ↪ in `extra-args`, because it is automatically generated by DM.
```

### Note:

The value of `threads` determines the number of physical connections between the upstream database and DM. An excessively large `threads` value might increase the load of the upstream. Therefore, you need to set `threads` to a proper value.

### 13.6.6.10.2 Create a Data Migration Task

You can use the `start-task` command to create a data migration task. When the data migration task is started, DM **prechecks privileges and configurations**.

```
help start-task
```

```
Starts a task as defined in the configuration file
```

```
Usage:
```

```
dmctl start-task [-s source ...] [--remove-meta] <config-file> [flags]
```

#### Flags:

```
-h, --help help for start-task
--remove-meta whether to remove task's meta data
--start-time string specify the start time of binlog replication, e.g.
 ↪ '2021-10-21 00:01:00' or 2021-10-21T00:01:00
```

#### Global Flags:

```
--config string Path to config file.
--master-addr string Master API server address, this parameter is
 ↪ required when interacting with the dm-master
--rpc-timeout string RPC timeout, default is 10m. (default "10m")
-s, --source strings MySQL Source ID.
--ssl-ca string Path of file that contains list of trusted SSL CAs
 ↪ for connection.
--ssl-cert string Path of file that contains X509 certificate in PEM
 ↪ format for connection.
--ssl-key string Path of file that contains X509 key in PEM format
 ↪ for connection.
-V, --version Prints version and exit.
```

#### Usage example

```
start-task [-s "mysql-replica-01"] ./task.yaml
```

#### Flags description

- **-s:** (Optional) Specifies the MySQL source to execute `task.yaml`. If it is set, the command only starts the subtasks of the specified task on the MySQL source.
- **config-file:** (Required) Specifies the file path of `task.yaml`.
- **remove-meta:** (Optional) Specifies whether to remove the task's previous metadata when starting the task.
- **start-time:** (Optional) Specifies the start time of binlog replication.
  - Format: '2021-10-21 00:01:00' or 2021-10-21T00:01:00.
  - For incremental tasks, you can specify a rough starting point for the task using this flag. This flag takes precedence over the binlog position in the task configuration file and the binlog position in the downstream checkpoint.
  - When the task already has a checkpoint, if you start the task using this flag, DM automatically enables safe mode until the replication passes the checkpoint. This is to avoid the data duplication error caused by resetting the task to an earlier position.
    - \* When you reset the task to an earlier position, if the table schema at that time point is different from the downstream at the current time point, the task might report an error.

- \* When you reset the task to a later position, note that the skipped binlog might have dirty data left in the downstream.
- When you specify an earlier start time, DM starts migration from the earliest binlog position available.
- When you specify a later start time, DM reports an error: `start-time {input-time} is too late, no binlog location matches it.`

Returned results

```
start-task task.yaml
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

### 13.6.6.10.3 Query Task Status in TiDB Data Migration

This document introduces how to use the `query-status` command to query the task status, and the subtask status of DM.

Query result

```
>> query-status
```

```
{
 "result": true, # Whether the query is successful.
 "msg": "", # Describes the reason for the unsuccessful query.
 "tasks": [# Migration task list.
 {
 "taskName": "test", # The task name.
 "taskStatus": "Running", # The status of the task.
 "sources": [# The upstream MySQL list.
 "mysql-replica-01",
 "mysql-replica-02"
]
 }
],
}
```

```
{
 {
 "taskName": "test2",
 "taskStatus": "Paused",
 "sources": [
 "mysql-replica-01",
 "mysql-replica-02"
]
 }
]
```

For detailed descriptions of `taskStatus` under the `tasks` section, refer to [Task status](#).

It is recommended that you use `query-status` by the following steps:

1. Use `query-status` to check whether each on-going task is in the normal state.
2. If any error occurs in a task, use the `query-status <taskName>` command to see detailed error information. `<taskName>` in this command indicates the name of the task that encounters the error.

#### Task status

The status of a DM migration task depends on the status of each subtask assigned to DM-worker. For detailed descriptions of subtask status, see [Subtask status](#). The table below shows how the subtask status is related to task status.

For the status description and status switch relationship of “stage” of “subTaskStatus” of “sources”, see the [subtask status](#).

For operation details of “unresolvedDDLLockID” of “subTaskStatus” of “sources”, see [Handle Sharding DDL Locks Manually](#).

Subtask status

Status description

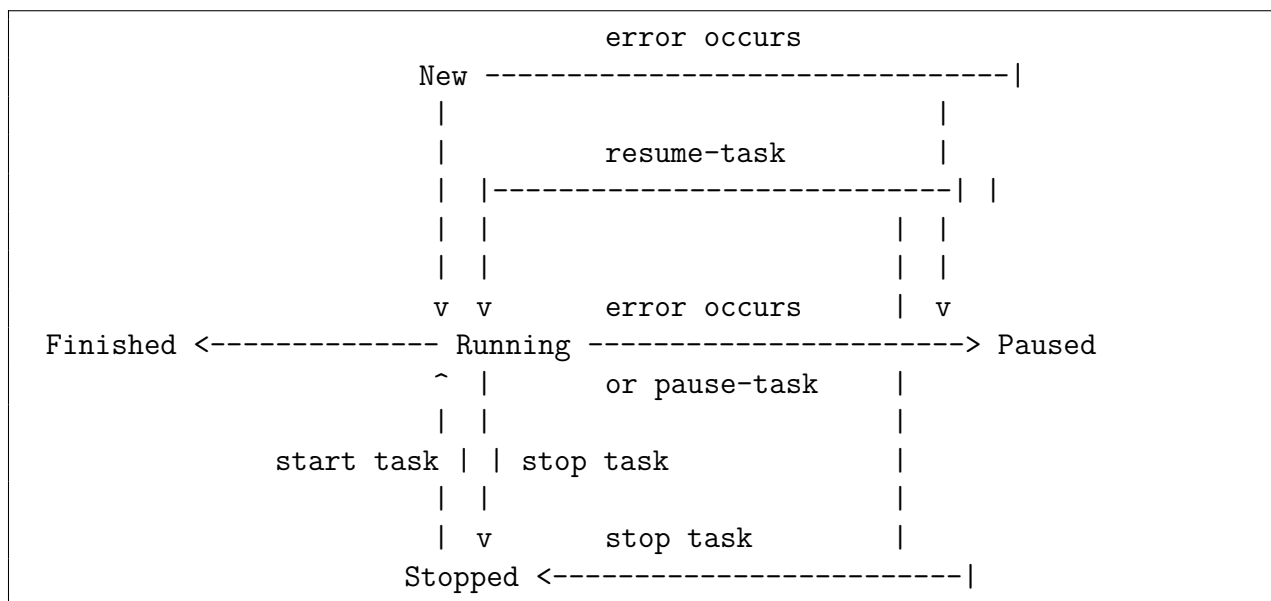

- **New:**
  - The initial status.
  - If the subtask does not encounter an error, it is switched to **Running**; otherwise it is switched to **Paused**.
- **Running:** The normal running status.
- **Paused:**
  - The paused status.
  - If the subtask encounters an error, it is switched to **Paused**.
  - If you run `pause-task` when the subtask is in the **Running** status, the task is switched to **Paused**.
  - When the subtask is in this status, you can run the `resume-task` command to resume the task.
- **Stopped:**
  - The stopped status.

- If you run `stop-task` when the subtask is in the `Running` or `Paused` status, the task is switched to `Stopped`.
- When the subtask is in this status, you cannot use `resume-task` to resume the task.

- **Finished:**

- The finished subtask status.
- Only when the full replication subtask is finished normally, the task is switched to this status.

Status switch diagram

#### 13.6.6.10.4 Pause a Data Migration Task

You can use the `pause-task` command to pause a data migration task.

`pause-task` differs from `stop-task` in that:

- `pause-task` only pauses a migration task. You can query the status information (retained in the memory) of the task using `query-status`. `stop-task` terminates a migration task and removes all information related to this task from the memory. This means you cannot use `query-status` to query the status information. `dm_meta` like “checkpoint” and data that have been migrated to the downstream are not removed.
- If `pause-task` is executed to pause the migration task, you cannot start a new task with the same name, neither can you get the relay log of the paused task removed, since this task does exist. If `stop-task` is executed to stop a task, you can start a new task with the same name, and you can get the relay log of the stopped task removed, since this task no longer exists.

- `pause-task` is usually used to pause a task for troubleshooting, while `stop-task` is to permanently remove a migration task, or to co-work with `start-task` to update the configuration information.

```
help pause-task
```

```
pause a specified running task
```

Usage:

```
dmctl pause-task [-s source ...] <task-name | task-file> [flags]
```

Flags:

```
-h, --help help for pause-task
```

Global Flags:

```
-s, --source strings MySQL Source ID
```

Usage example

```
pause-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where you want to pause the subtasks of the migration task. If it is set, this command pauses only the subtasks on the specified MySQL source.
- `task-name| task-file`: (Required) Specifies the task name or task file path.

Returned results

```
pause-task test
```

```
{
 "op": "Pause",
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

### 13.6.6.10.5 Resume a Data Migration Task

You can use the `resume-task` command to resume a data migration task in the Paused  $\leftrightarrow$  state. This is generally used in scenarios where you want to manually resume a data migration task after handling the error that get the task paused.

```
help resume-task
```

```
resume a specified paused task
```

```
Usage:
```

```
dmctl resume-task [-s source ...] <task-name | task-file> [flags]
```

```
Flags:
```

```
-h, --help help for resume-task
```

```
Global Flags:
```

```
-s, --source strings MySQL Source ID
```

Usage example

```
resume-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where you want to resume the subtask of the migration task. If it is set, the command resumes only the subtasks on the specified MySQL source.
- `task-name | task-file`: (Required) Specifies the task name or task file path.

Returned results

```
resume-task test
```

```
{
 "op": "Resume",
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

### 13.6.6.10.6 Stop a Data Migration Task

You can use the `stop-task` command to stop a data migration task. For differences between `stop-task` and `pause-task`, refer to [Pause a Data Migration Task](#).

```
help stop-task
```

stop a specified task

Usage:

```
dmctl stop-task [-s source ...] <task-name | task-file> [flags]
```

Flags:

```
-h, --help help for stop-task
```

Global Flags:

```
-s, --source strings MySQL Source ID
```

Usage example

```
stop-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where the subtasks of the migration task (that you want to stop) run. If it is set, only subtasks on the specified MySQL source are stopped.
- `task-name | task-file`: (Required) Specifies the task name or task file path.

Returned results

```
stop-task test
```

```
{
 "op": "Stop",
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

## 13.6.7 Advanced Tutorials

### 13.6.7.1 Merge and Migrate Data from Sharded Tables

#### 13.6.7.1.1 Merge and Migrate Data from Sharded Tables

This document introduces the sharding support feature provided by Data Migration (DM). This feature allows you to merge and migrate the data of tables with the same or different table schemas in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB. It supports not only migrating the upstream DML statements, but also coordinating to migrate the table schema change using DDL statements in multiple upstream sharded tables.

##### Overview

DM supports merging and migrating the data of multiple upstream sharded tables into one table in TiDB. During the migration, the DDL of each sharded table, and the DML before and after the DDL need to be coordinated. For the usage scenarios, DM supports two different modes: pessimistic mode and optimistic mode.

##### Note:

- To merge and migrate data from sharded tables, you must set `shard-mode` in the task configuration file.
- DM uses the pessimistic mode by default for the merge of the sharding support feature. (If there is no special description in the document, use the pessimistic mode by default.)
- It is not recommended to use this mode if you do not understand the principles and restrictions of the optimistic mode. Otherwise, it may cause serious consequences such as migration interruption and even data inconsistency.

##### The pessimistic mode

When an upstream sharded table executes a DDL statement, the migration of this sharded table will be suspended. After all other sharded tables execute the same DDL, the DDL will be executed in the downstream and the data migration task will restart. The advantage of this mode is that it can ensure that the data migrated to the downstream will not go wrong. For details, refer to [shard merge in pessimistic mode](#). ##### The optimistic mode

DM will automatically modify the DDL executed on a sharded table into a statement compatible with other sharded tables, and then migrate to the downstream. This will not block the DML migration of any sharded tables. The advantage of this mode is that it will

not block data migration when processing DDL. However, improper use will cause migration interruption or even data inconsistency. For details, refer to [shard merge in optimistic mode](#).

### Contrast

Pessimistic mode	Optimistic mode
Sharded tables that executes DDL suspend DML migration	Sharded tables that executes DDL continue DML migration
The DDL execution order and statements of each sharded table must be the same	Each sharded table only needs to keep the table schema compatible with each other
The DDL is migrated to the downstream after the entire shard group is consistent	The DDL of each sharded table immediately affects the downstream
Wrong DDL operations can be intercepted after the detection	Wrong DDL operations will be migrated to the downstream, which may cause inconsistency between the upstream and downstream data before the detection

### 13.6.7.1.2 Merge and Migrate Data from Sharded Tables in the Pessimistic Mode

This document introduces the sharding support feature provided by Data Migration (DM) in the pessimistic mode (the default mode). This feature allows you to merge and migrate the data of tables with the same table schema in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB.

#### Restrictions

DM has the following sharding DDL usage restrictions in the pessimistic mode:

- For a logical **sharding group** (composed of all sharded tables that need to be merged and migrated into one same downstream table), it is limited to use one task containing exactly the sources of sharded tables to perform the migration.
- In a logical **sharding group**, the same DDL statements must be executed in the same order in all upstream sharded tables (the schema name and the table name can be different), and the next DDL statement cannot be executed unless the current DDL operation is completely finished.
  - For example, if you add `column A` to `table_1` before you add `column B`, then you cannot add `column B` to `table_2` before you add `column A`. Executing the DDL statements in a different order is not supported.
- In a sharding group, the corresponding DDL statements should be executed in all upstream sharded tables.
  - For example, if DDL statements are not executed on one or more upstream sharded tables corresponding to `DM-worker-2`, then other DM-workers that have executed the DDL statements pause their migration task and wait for `DM-worker`  $\leftrightarrow$  `-2` to receive the upstream DDL statements.
- The sharding group migration task does not support `DROP DATABASE/DROP TABLE`.
  - The sync unit in DM-worker automatically ignores the `DROP DATABASE/DROP`  $\leftrightarrow$  `TABLE` statement of upstream sharded tables.
- The sharding group migration task does not support `TRUNCATE TABLE`.
  - The sync unit in DM-worker automatically ignores the `TRUNCATE TABLE` statement of upstream sharded tables.
- The sharding group migration task supports `RENAME TABLE`, but with the following limitations (online DDL is supported in another solution):
  - A table can only be renamed to a new name that is not used by any other table.
  - A single `RENAME TABLE` statement can only involve a single `RENAME` operation.
- The sharding group migration task requires each DDL statement to involve operations on only one table.

- The table schema of each sharded table must be the same at the starting point of the incremental replication task, so as to make sure the DML statements of different sharded tables can be migrated into the downstream with a definite table schema, and the subsequent sharding DDL statements can be correctly matched and migrated.
- If you need to change the **table routing** rule, you have to wait for the migration of all sharding DDL statements to complete.
  - During the migration of sharding DDL statements, an error is reported if you use `dmctl` to change `router-rules`.
- If you need to **CREATE** a new table to a sharding group where DDL statements are being executed, you have to make sure that the table schema is the same as the newly modified table schema.
  - For example, both the original `table_1` and `table_2` have two columns (a, b) initially, and have three columns (a, b, c) after the sharding DDL operation, so after the migration the newly created table should also have three columns (a, b, c).
- Because the DM-worker that has received the DDL statements will pause the task to wait for other DM-workers to receive their DDL statements, the delay of data migration will be increased.

## Background

Currently, DM uses the binlog in the ROW format to perform the migration task. The binlog does not contain the table schema information. When you use the ROW binlog to migrate data, if you have not migrated multiple upstream tables into the same downstream table, then there only exist DDL operations of one upstream table that can update the table schema of the downstream table. The ROW binlog can be considered to have the nature of self-description. During the migration process, the DML statements can be constructed accordingly with the column values and the downstream table schema.

However, in the process of merging and migrating sharded tables, if DDL statements are executed on the upstream tables to modify the table schema, then you need to perform extra operations to migrate the DDL statements so as to avoid the inconsistency between the DML statements produced by the column values and the actual downstream table schema.

Here is a simple example:

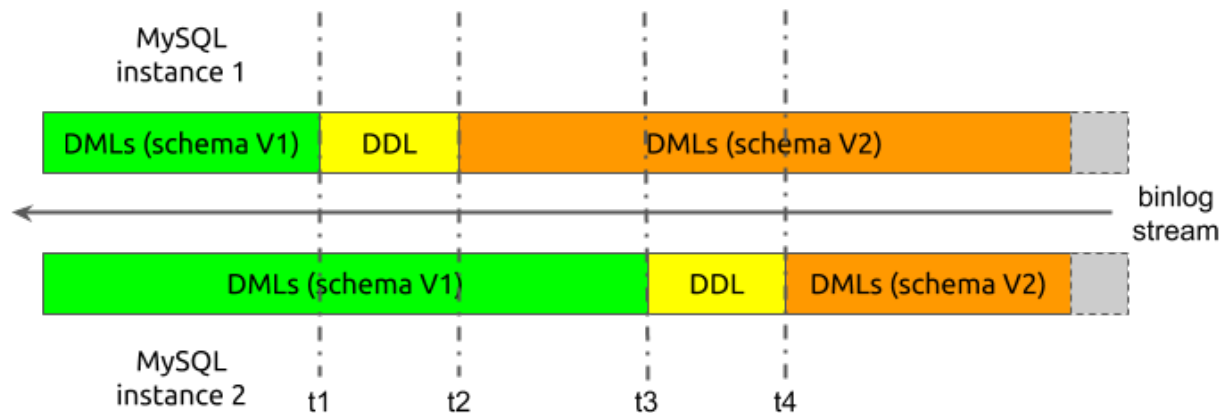

Figure 238: shard-ddl-example-1

In the above example, the merging process is simplified, where only two MySQL instances exist in the upstream and each instance has only one table. When the migration begins, the table schema version of two sharded tables is marked as `schema V1`, and the table schema version after executing DDL statements is marked as `schema V2`.

Now assume that in the migration process, the binlog data received from the two upstream sharded tables has the following time sequence:

1. When the migration begins, the sync unit in DM-worker receives the DML events of `schema V1` from the two sharded tables.
2. At  $t_1$ , the sharding DDL events from instance 1 are received.
3. From  $t_2$  on, the sync unit receives the DML events of `schema V2` from instance 1; but from instance 2, it still receives the DML events of `schema V1`.
4. At  $t_3$ , the sharding DDL events from instance 2 are received.
5. From  $t_4$  on, the sync unit receives the DML events of `schema V2` from instance 2 as well.

Assume that the DDL statements of sharded tables are not processed during the migration process. After DDL statements of instance 1 are migrated to the downstream, the downstream table schema is changed to `schema V2`. But for instance 2, the sync unit in DM-worker is still receiving DML events of `schema V1` from  $t_2$  to  $t_3$ . Therefore, when the DML statements of `schema V1` are migrated to the downstream, the inconsistency between the DML statements and the table schema can cause errors and the data cannot be migrated successfully.

### Principles

This section shows how DM migrates DDL statements in the process of merging sharded tables based on the above example in the pessimistic mode.

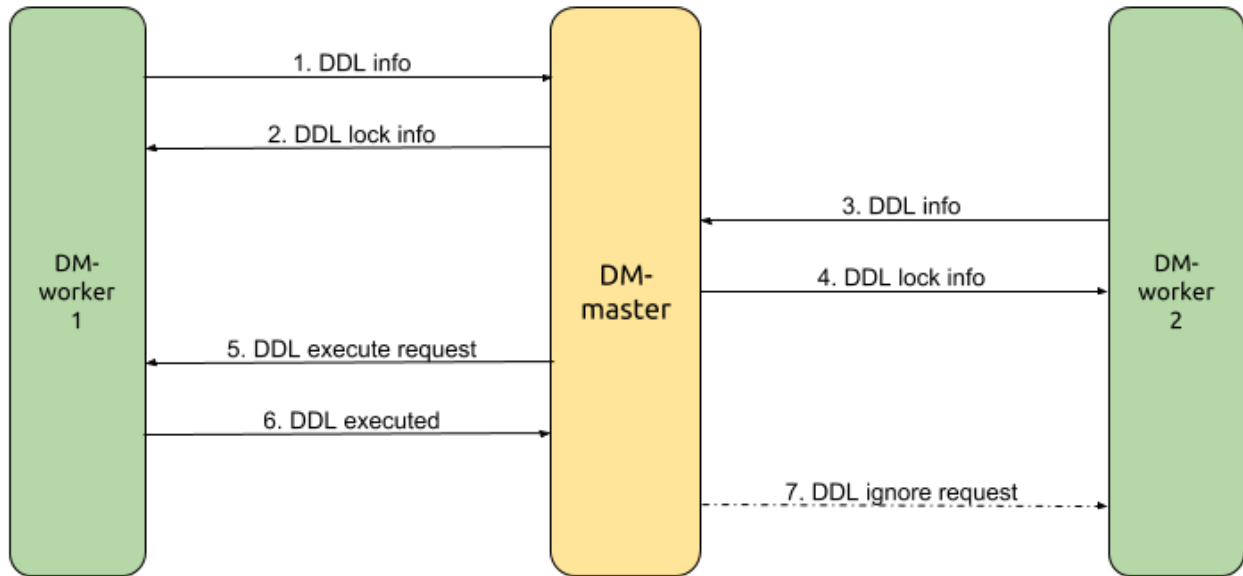

Figure 239: shard-ddl-flow

In this example, `DM-worker-1` migrates the data from MySQL instance 1 and `DM-worker-2` migrates the data from MySQL instance 2. `DM-master` coordinates the DDL migration among multiple DM-workers. Starting from `DM-worker-1` receiving the DDL statements, the DDL migration process is simplified as follows:

- `DM-worker-1` receives the DDL statement from MySQL instance 1 at  $t_1$ , pauses the data migration of the corresponding DDL and DML statements, and sends the DDL information to `DM-master`.
- `DM-master` decides that the migration of this DDL statement needs to be coordinated based on the received DDL information, creates a lock for this DDL statement, sends the DDL lock information back to `DM-worker-1` and marks `DM-worker-1` as the owner of this lock at the same time.
- `DM-worker-2` continues migrating the DML statement until it receives the DDL statement from MySQL instance 2 at  $t_3$ , pauses the data migration of this DDL statement, and sends the DDL information to `DM-master`.
- `DM-master` decides that the lock of this DDL statement already exists based on the received DDL information, and sends the lock information directly to `DM-worker-2`.
- Based on the configuration information when the task is started, the sharded table information in the upstream MySQL instances, and the deployment topology information, `DM-master` decides that it has received this DDL statement of all upstream sharded tables to be merged, and requests the owner of the DDL lock (`DM-worker-1`) to migrate this DDL statement to the downstream.
- `DM-worker-1` verifies the DDL statement execution request based on the DDL lock information received at Step #2, migrates this DDL statement to the downstream, and

sends the results to **DM-master**. If this operation is successful, **DM-worker-1** continues migrating the subsequent (starting from the binlog at **t2**) DML statements.

7. **DM-master** receives the response from the lock owner that the DDL is successfully executed, and requests all other DM-workers (**DM-worker-2**) that are waiting for the DDL lock to ignore this DDL statement and then continue to migrate the subsequent (starting from the binlog at **t4**) DML statements.

The characteristics of DM handling the sharding DDL migration among multiple DM-workers can be concluded as follows:

- Based on the task configuration and DM cluster deployment topology information, a logical sharding group is built in **DM-master** to coordinate DDL migration. The group members are DM-workers that handle each sub-task divided from the migration task).
- After receiving the DDL statement from the binlog event, each DM-worker sends the DDL information to **DM-master**.
- **DM-master** creates or updates the DDL lock based on the DDL information received from each DM-worker and the sharding group information.
- If all members of the sharding group receive a same specific DDL statement, this indicates that all DML statements before the DDL execution on the upstream sharded tables have been completely migrated, and this DDL statement can be executed. Then DM can continue to migrate the subsequent DML statements.
- After being converted by the **table router**, the DDL statement of the upstream sharded tables must be consistent with the DDL statement to be executed in the downstream. Therefore, this DDL statement only needs to be executed once by the DDL owner and all other DM-workers can ignore this DDL statement.

In the above example, only one sharded table needs to be merged in the upstream MySQL instance corresponding to each DM-worker. But in actual scenarios, there might be multiple sharded tables in multiple sharded schemas to be merged in one MySQL instance. And when this happens, it becomes more complex to coordinate the sharding DDL migration.

Assume that there are two sharded tables, namely **table\_1** and **table\_2**, to be merged in one MySQL instance:

Figure 240: shard-ddl-example-2

Because data comes from the same MySQL instance, all the data is obtained from the same binlog stream. In this case, the time sequence is as follows:

1. The sync unit in DM-worker receives the DML statements of `schema V1` from both sharded tables when the migration begins.
2. At `t1`, the sync unit in DM-worker receives the DDL statements of `table_1`.
3. From `t2` to `t3`, the received data includes the DML statements of `schema V2` from `table_1` and the DML statements of `schema V1` from `table_2`.
4. At `t3`, the sync unit in DM-worker receives the DDL statements of `table_2`.
5. From `t4` on, the sync unit in DM-worker receives the DML statements of `schema V2` from both tables.

If the DDL statements are not processed particularly during the data migration, when the DDL statement of `table_1` is migrated to the downstream and changes the downstream table schema, the DML statement of `schema V1` from `table_2` cannot be migrated successfully. Therefore, within a single DM-worker, a logical sharding group similar to that within DM-master is created, except that members of this group are different sharded tables in the same upstream MySQL instance.

But when a DM-worker coordinates the migration of the sharding group within itself, it is not totally the same as that performed by DM-master. The reasons are as follows:

- When the DM-worker receives the DDL statement of `table_1`, it cannot pause the migration and needs to continue parsing the binlog to get the subsequent DDL statements of `table_2`. This means it needs to continue parsing between `t2` and `t3`.
- During the binlog parsing process between `t2` and `t3`, the DML statements of `schema V2` from `table_1` cannot be migrated to the downstream until the sharding DDL statement is migrated and successfully executed.

In DM, the simplified migration process of sharding DDL statements within the DM worker is as follows:

1. When receiving the DDL statement of `table_1` at `t1`, the DM-worker records the DDL information and the current position of the binlog.
2. DM-worker continues parsing the binlog between `t2` and `t3`.
3. DM-worker ignores the DML statement with the `schema V2` schema that belongs to `table_1`, and migrates the DML statement with the `schema V1` schema that belongs to `table_2` to the downstream.
4. When receiving the DDL statement of `table_2` at `t3`, the DM-worker records the DDL information and the current position of the binlog.
5. Based on the information of the migration task configuration and the upstream schemas and tables, the DM-worker decides that the DDL statements of all sharded tables in the MySQL instance have been received and migrates them to the downstream to modify the downstream table schema.
6. DM-worker sets the starting point of parsing the new binlog stream to be the position saved at Step #1.
7. DM-worker resumes parsing the binlog between `t2` and `t3`.

8. DM-worker migrates the DML statement with the `schema V2` schema that belongs to `table_1` to the downstream, and ignores the DML statement with the `schema V1` schema that belongs to `table_2`.
9. After parsing the binlog position saved at Step #4, the DM-worker decides that all DML statements that have been ignored in Step #3 have been migrated to the downstream again.
10. DM-worker resumes the migration starting from the binlog position at `t4`.

You can conclude from the above analysis that DM mainly uses two-level sharding groups for coordination and control when handling migration of the sharding DDL. Here is the simplified process:

1. Each DM-worker independently coordinates the DDL statements migration for the corresponding sharding group composed of multiple sharded tables within the upstream MySQL instance.
2. After the DM-worker receives the DDL statements of all sharded tables, it sends the DDL information to `DM-master`.
3. `DM-master` coordinates the DDL migration of the sharding group composed of the DM-workers based on the received DDL information.
4. After receiving the DDL information from all DM-workers, `DM-master` requests the DDL lock owner (a specific DM-worker) to execute the DDL statement.
5. The DDL lock owner executes the DDL statement and returns the result to `DM-master`  $\leftrightarrow$  . Then the owner restarts the migration of the previously ignored DML statements during the internal coordination of DDL migration.
6. After `DM-master` confirms that the owner has successfully executed the DDL statement, it asks all other DM-workers to continue the migration.
7. All other DM-workers separately restart the migration of the previously ignored DML statements during the internal coordination of DDL migration.
8. After finishing migrating the ignored DML statements again, all DM-workers resume the normal migration process.

### 13.6.7.1.3 Merge and Migrate Data from Sharded Tables in Optimistic Mode

This document introduces the sharding support feature provided by Data Migration (DM) in the optimistic mode. This feature allows you to merge and migrate the data of tables with the same or different table schema(s) in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB.

#### Note:

If you do not have an in-depth understanding of the optimistic mode and its restrictions, it is **NOT** recommended to use this mode. Otherwise, migration interruption or even data inconsistency might occur.

## Background

DM supports executing DDL statements on sharded tables online, which is called sharding DDL, and uses the “pessimistic mode” by default. In this mode, when a DDL statement is executed in an upstream sharded table, data migration of this table is paused until the same DDL statement is executed in all other sharded tables. Only by then this DDL statement is executed in the downstream and data migration resumes.

The pessimistic mode guarantees that the data migrated to the downstream is always correct, but it pauses the data migration, which is bad for making A/B changes in the upstream. In some cases, users might spend a long time executing DDL statements in a single sharded table and change the schemas of other sharded tables only after a period of validation. In the pessimistic mode, these DDL statements block data migration and cause many binlog events to pile up.

Therefore, an “optimistic mode” is needed. In this mode, a DDL statement executed on a sharded table is automatically converted to a statement that is compatible with other sharded tables, and then immediately migrated to the downstream. In this way, the DDL statement does not block any sharded table from executing DML migration.

### Configuration of the optimistic mode

To use the optimistic mode, specify the `shard-mode` item in the task configuration file as `optimistic`. For the detailed sample configuration file, see [DM Advanced Task Configuration File](#).

### Restrictions

It takes some risks to use the optimistic mode. Follow these rules when you use it:

- Ensure that the schema of every sharded table is consistent with each other before and after you execute a batch of DDL statements.
- If you perform an A/B test, perform the test **ONLY** on one sharded table.
- After the A/B test is finished, migrate only the most direct DDL statement(s) to the final schema. Do not re-execute every right or wrong step of the test.

For example, if you have executed `ADD COLUMN A INT; DROP COLUMN A; ADD COLUMN A FLOAT;` in a sharded table, you only need to execute `ADD COLUMN A FLOAT` in other sharded tables. You do not need to execute all of the three DDL statements again.

- Observe the status of the DM migration when executing the DDL statement. When an error is reported, you need to determine whether this batch of DDL statements will cause data inconsistency.

In the optimistic mode, most of the DDL statements executed in the upstream are automatically migrated to the downstream with no extra effort required. These DDL statements are called “Type 1 DDL”.

DDL statements that change the column name, the column type, or the column default value are called “Type 2 DDL”. When you execute Type 2 DDL statements in the upstream, make sure that you execute the DDL statements in all sharded tables in the same order.

Some examples of Type 2 DDL statements are as follows:

- Alter the type of a column: `ALTER TABLE table_name MODIFY COLUMN column_name ↪ VARCHAR(20).`
- Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO ↪ column_2;.`
- Add a NOT NULL column without a default value: `ALTER TABLE table_name ADD ↪ COLUMN column_1 NOT NULL;.`
- Rename an index: `ALTER TABLE table_name RENAME INDEX index_1 TO index_2;.`

When the sharded tables execute the DDL statements above, if the execution order is different, the migration is interrupted. For example:

- Shard 1 renames a column and then alters the column type:
  1. Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO ↪ column_2;.`
  2. Alter the column type: `ALTER TABLE table_name MODIFY COLUMN column_3 ↪ VARCHAR(20);.`
- Shard 2 alters a column type and then renames the column:
  1. Alter a column type: `ALTER TABLE table_name MODIFY COLUMN column_3 ↪ VARCHAR(20).`
  2. Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO ↪ column_2;.`

In addition, the following restrictions apply to both the optimistic mode and the pessimistic mode:

- `DROP TABLE` or `DROP DATABASE` is not supported.
- `TRUNCATE TABLE` is not supported.
- Each DDL statement must involve operations on only one table.
- The DDL statement that is not supported in TiDB is also not supported in DM.
- The default value of a newly added column must not contain `current_timestamp` ↪ `,` `rand()`, `uuid()`; otherwise, data inconsistency between the upstream and the downstream might occur.

## Risks

When you use the optimistic mode for a migration task, a DDL statement is migrated to the downstream immediately. If this mode is misused, data inconsistency between the upstream and the downstream might occur.

Operations that cause data inconsistency

- The schema of each sharded table is incompatible with each other. For example:
  - Two columns of the same name are added to two sharded tables respectively, but the columns are of different types.
  - Two columns of the same name are added to two sharded tables respectively, but the columns have different default values.
  - Two generated columns of the same name are added to two sharded tables respectively, but the columns are generated using different expressions.
  - Two indexes of the same name are added to two sharded tables respectively, but the keys are different.
  - Other different table schemas with the same name.
- Execute the DDL statement that can corrupt data in the sharded table and then try to roll back.

For example, drop a column X and then add this column back.

### Example

Merge and migrate the following three sharded tables to TiDB:

tbl00		tbl01		tbl02		tbl	
ID	Name	ID	Name	ID	Name	ID	Name
1	Sarah	12	Paul	23	Bob	1	Sarah
5	Sophia	16	Jessica	24	Ben	5	Sophia
		19	Shaun			12	Paul
						16	Jessica
						19	Shaun
						23	Bob
						24	Ben

Figure 241: optimistic-ddl-fail-example-1

Add a new column `Age` in `tbl01` and set the default value of the column to 0:

```
ALTER TABLE `tbl01` ADD COLUMN `Age` INT DEFAULT 0;
```

tbl00		tbl01			tbl02		tbl		
<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>Age</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>Age</b>
1	Sarah	12	Paul	0	23	Bob	1	Sarah	0
5	Sophia	16	Jessica	0	24	Ben	5	Sophia	0
		19	Shaun	0			12	Paul	0
							16	Jessica	0
							19	Shaun	0
							23	Bob	0
							24	Ben	0

Figure 242: optimistic-ddl-fail-example-2

Add a new column `Age` in `tbl00` and set the default value of the column to `-1`:

```
ALTER TABLE `tbl00` ADD COLUMN `Age` INT DEFAULT -1;
```

tbl00			tbl01			tbl02		tbl		
<b>ID</b>	<b>Name</b>	<b>Age</b>	<b>ID</b>	<b>Name</b>	<b>Age</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>Age</b>
1	Sarah	-1	12	Paul	0	23	Bob	1	Sarah	0
5	Sophia	-1	16	Jessica	0	24	Ben	5	Sophia	0
			19	Shaun	0			12	Paul	0
								16	Jessica	0
								19	Shaun	0
								23	Bob	0
								24	Ben	0

Figure 243: optimistic-ddl-fail-example-3

By then, the `Age` column of `tbl00` is inconsistent because `DEFAULT 0` and `DEFAULT -1` are incompatible with each other. In this situation, DM will report the error, but you have

to manually fix the data inconsistency.

### Implementation principle

In the optimistic mode, after DM-worker receives the DDL statement from the upstream, it forwards the updated table schema to DM-master. DM-worker tracks the current schema of each sharded table, and DM-master merges these schemas into a composite schema that is compatible with DML statements of every sharded table. Then DM-master migrates the corresponding DDL statement to the downstream. DML statements are directly migrated to the downstream.

Figure 244: optimistic-ddl-flow

### Examples

Assume the upstream MySQL has three sharded tables (tbl00, tbl01, and tbl02). Merge and migrate these sharded tables to the tbl table in the downstream TiDB. See the following image:

tbl00		tbl01		tbl02		tbl	
ID	Name	ID	Name	ID	Name	ID	Name
1	Sarah	12	Paul	23	Bob	1	Sarah
5	Sophia	16	Jessica	24	Ben	5	Sophia
		19	Shaun			12	Paul
						16	Jessica
						19	Shaun
						23	Bob
						24	Ben

Figure 245: optimistic-ddl-example-1

Add a Level column in the upstream:

```
ALTER TABLE `tbl00` ADD COLUMN `Level` INT;
```

tbl00			tbl01		tbl02		tbl	
ID	Name	Level	ID	Name	ID	Name	ID	Name
1	Sarah	NULL	12	Paul	23	Bob	1	Sarah
5	Sophia	NULL	16	Jessica	24	Ben	5	Sophia
			19	Shaun			12	Paul
							16	Jessica
							19	Shaun
							23	Bob
							24	Ben

Figure 246: optimistic-ddl-example-2

Then TiDB will receive the DML statement from `tbl00` (with the `Level` column) and the DML statement from the `tbl01` and `tbl02` tables (without the `Level` column).

tbl00			tbl01		tbl02		tbl		
<b>ID</b>	<b>Name</b>	<b>Level</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>Level</b>
1	Sarah	NULL	12	Paul	23	Bob	1	Sarah	NULL
5	Sophia	NULL	16	Jessica	24	Ben	5	Sophia	NULL
			19	Shaun			12	Paul	NULL
							16	Jessica	NULL
							19	Shaun	NULL
							23	Bob	NULL
							24	Ben	NULL

Figure 247: optimistic-ddl-example-3

The following DML statements can be migrated to the downstream without any modification:

```
UPDATE `tbl00` SET `Level` = 9 WHERE `ID` = 1;
INSERT INTO `tbl02` (`ID`, `Name`) VALUES (27, 'Tony');
```

tbl00			tbl01		tbl02		tbl		
<b>ID</b>	<b>Name</b>	<b>Level</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>Level</b>
1	Sarah	9	12	Paul	23	Bob	1	Sarah	9
5	Sophia	NULL	16	Jessica	24	Ben	5	Sophia	NULL
			19	Shaun	27	Tony	12	Paul	NULL
							16	Jessica	NULL
							19	Shaun	NULL
							23	Bob	NULL
							24	Ben	NULL
							27	Tony	NULL

Figure 248: optimistic-ddl-example-4

Also add a Level column in tbl01:

```
ALTER TABLE `tbl01` ADD COLUMN `Level` INT;
```

tbl00			tbl01			tbl02		tbl		
ID	Name	Level	ID	Name	Level	ID	Name	ID	Name	Level
1	Sarah	9	12	Paul	NULL	23	Bob	1	Sarah	9
5	Sophia	NULL	16	Jessica	NULL	24	Ben	5	Sophia	NULL
			19	Shaun	NULL	27	Tony	12	Paul	NULL
								16	Jessica	NULL
								19	Shaun	NULL
								23	Bob	NULL
								24	Ben	NULL
								27	Tony	NULL

Figure 249: optimistic-ddl-example-5

At this time, the downstream already have had the same Level column, so DM-master performs no operation after comparing the table schemas.

Drop a Name column in tbl01:

```
ALTER TABLE `tbl01` DROP COLUMN `Name`;
```

tbl00			tbl01		tbl02		tbl		
<b>ID</b>	<b>Name</b>	<b>Level</b>	<b>ID</b>	<b>Level</b>	<b>ID</b>	<b>Name</b>	<b>ID</b>	<b>Name</b>	<b>Level</b>
1	Sarah	9	12	NULL	23	Bob	1	Sarah	9
5	Sophia	NULL	16	NULL	24	Ben	5	Sophia	NULL
			19	NULL	27	Tony	12	Paul	NULL
							16	Jessica	NULL
							19	Shaun	NULL
							23	Bob	NULL
							24	Ben	NULL
							27	Tony	NULL

Figure 250: optimistic-ddl-example-6

Then the downstream will receive the DML statements from `tbl00` and `tbl02` with the `Name` column, so this column is not immediately dropped.

In the same way, all DML statements can still be migrated to the downstream:

```
INSERT INTO `tbl01` (`ID`, `Level`) VALUES (15, 7);
UPDATE `tbl00` SET `Level` = 5 WHERE `ID` = 5;
```

tbl00			tbl01		tbl02		tbl		
ID	Name	Level	ID	Level	ID	Name	ID	Name	Level
1	Sarah	9	12	NULL	23	Bob	1	Sarah	9
5	Sophia	5	15	7	24	Ben	5	Sophia	5
			16	NULL	27	Tony	12	Paul	NULL
			19	NULL			15	NULL	7
							16	Jessica	NULL
							19	Shaun	NULL
							23	Bob	NULL
							24	Ben	NULL
							27	Tony	NULL

Figure 251: optimistic-ddl-example-7

Add a Level column in tbl02:

```
ALTER TABLE `tbl02` ADD COLUMN `Level` INT;
```

tbl00			tbl01		tbl02			tbl		
<b>ID</b>	<b>Name</b>	<b>Level</b>	<b>ID</b>	<b>Level</b>	<b>ID</b>	<b>Name</b>	<b>Level</b>	<b>ID</b>	<b>Name</b>	<b>Level</b>
1	Sarah	9	12	NULL	23	Bob	NULL	1	Sarah	9
5	Sophia	5	15	7	24	Ben	NULL	5	Sophia	5
			16	NULL	27	Tony	NULL	12	Paul	NULL
			19	NULL				15	NULL	7
								16	Jessica	NULL
								19	Shaun	NULL
								23	Bob	NULL
								24	Ben	NULL
								27	Tony	NULL

Figure 252: optimistic-ddl-example-8

By then, all sharded tables have the `Level` column.

Drop the `Name` columns in `tbl00` and `tbl02` respectively:

```
ALTER TABLE `tbl00` DROP COLUMN `Name`;
ALTER TABLE `tbl02` DROP COLUMN `Name`;
```

tbl00		tbl01		tbl02		tbl		
<b>ID</b>	<b>Level</b>	<b>ID</b>	<b>Level</b>	<b>ID</b>	<b>Level</b>	<b>ID</b>	<b>Name</b>	<b>Level</b>
1	9	12	NULL	23	NULL	1	Sarah	9
5	5	15	7	24	NULL	5	Sophia	5
		16	NULL	27	NULL	12	Paul	NULL
		19	NULL			15	NULL	7
						16	Jessica	NULL
						19	Shaun	NULL
						23	Bob	NULL
						24	Ben	NULL
						27	Tony	NULL

Figure 253: optimistic-ddl-example-9

By then, the `Name` columns are dropped from all sharded tables and can be safely dropped in the downstream:

```
ALTER TABLE `tbl` DROP COLUMN `Name`;
```

tbl00		tbl01		tbl02		tbl

#### 13.6.7.1.4 Handle Sharding DDL Locks Manually in DM

DM uses the sharding DDL lock to ensure operations are performed in the correct order. This locking mechanism resolves sharding DDL locks automatically in most cases, but you need to use the `shard-ddl-lock` command to manually handle the abnormal DDL locks in some abnormal scenarios.

#### Note:

- This document only applies to the processing of sharding DDL lock in pessimistic coordination mode.
- The commands in the Command usage sections in this document are in interactive mode. In command-line mode, you need to add the escape characters to avoid an error report.
- Do not use `shard-ddl-lock unlock` unless you are totally aware of the possible impacts brought by the command and you can accept them.
- Before manually handling the abnormal DDL locks, make sure that you have already read the DM [shard merge principles](#).

Command

## shard-ddl-lock

You can use this command to view the DDL lock and request DM-master to release the specified DDL lock. This command is only supported in DM v6.0 and later. For earlier versions, you must use the `show-ddl-locks` and `unlock-ddl-locks` commands.

```
shard-ddl-lock -h
```

```
maintain or show shard-ddl locks information
```

```
Usage:
```

```
dmctl shard-ddl-lock [task] [flags]
```

```
dmctl shard-ddl-lock [command]
```

```
Available Commands:
```

```
unlock Unlock un-resolved DDL locks forcibly
```

```
Flags:
```

```
-h, --help help for shard-ddl-lock
```

```
Global Flags:
```

```
-s, --source strings MySQL Source ID.
```

```
Use "dmctl shard-ddl-lock [command] --help" for more information about a
↪ command.
```

## Arguments description

- `shard-ddl-lock [task] [flags]`: view the DDL lock information on the current DM-master.
- `shard-ddl-lock [command]`: request DM-master to release the specified DDL lock. `[command]` only accepts `unlock` as a value.

## Usage examples

```
shard-ddl-lock [task] [flags]
```

You can use `shard-ddl-lock [task] [flags]` to view the DDL lock information on the current DM-master. For example:

```
shard-ddl-lock test
```

## Expected output

```
{
 "result": true, # The result of the
 ↪ query for the lock information.
 "msg": "", # The additional message
 ↪ for the failure to query the lock information or other
 ↪ descriptive information (for example, the lock task does not exist
 ↪).
}
```

```

"locks": [# The existing lock
 ↪ information list.
 {
 "ID": "test-`shard_db`.`shard_table`", # The lock ID, which is
 ↪ made up of the current task name and the schema/table
 ↪ information corresponding to the DDL.
 "task": "test", # The name of the task
 ↪ to which the lock belongs.
 "mode": "pessimistic" # The shard DDL mode.
 ↪ Can be set to "pessimistic" or "optimistic".
 "owner": "mysql-replica-01", # The owner of the lock
 ↪ (the ID of the first source that encounters this DDL
 ↪ operation in the pessimistic mode), which is always empty
 ↪ in the optimistic mode.
 "DDLs": [# The list of DDL
 ↪ operations corresponding to the lock in the pessimistic
 ↪ mode, which is always empty in the optimistic mode.
 "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` DROP
 ↪ COLUMN `c2`;"
],
 "synced": [# The list of sources
 ↪ that have received all sharding DDL events in the
 ↪ corresponding MySQL instance.
 "mysql-replica-01"
],
 "unsynced": [# The list of sources
 ↪ that have not yet received all sharding DDL events in the
 ↪ corresponding MySQL instance.
 "mysql-replica-02"
]
 }
]
}

```

### shard-ddl-lock unlock

This command actively requests DM-master to unlock the specified DDL lock, including requesting the owner to execute the DDL statement, requesting all other DM-workers that are not the owner to skip the DDL statement, and removing the lock information on DM-↪ master.

### Note:

Currently, `shard-ddl-lock unlock` takes effect only for the lock in the pessimistic mode.

```
shard-ddl-lock unlock -h
```

Unlock un-resolved DDL locks forcibly

Usage:

```
dmctl shard-ddl-lock unlock <lock-id> [flags]
```

Flags:

```
-a, --action string accept skip/exec values which means whether to skip
 ↪ or execute ddls (default "skip")
-d, --database string database name of the table
-f, --force-remove force to remove DDL lock
-h, --help help for unlock
-o, --owner string source to replace the default owner
-t, --table string table name
```

Global Flags:

```
-s, --source strings MySQL Source ID.
```

`shard-ddl-lock unlock` accepts the following arguments:

- `-o, --owner:`
  - Flag; string; optional
  - If it is not specified, this command requests for the default owner (the owner in the result of `shard-ddl-lock`) to execute the DDL statement; if it is specified, this command requests for the MySQL source (the alternative of the default owner) to execute the DDL statement.
  - The new owner should not be specified unless the original owner is already removed from the cluster.
- `-f, --force-remove:`
  - Flag; boolean; optional
  - If it is not specified, this command removes the lock information only when the owner succeeds to execute the DDL statement; if it is specified, this command forcefully removes the lock information even though the owner fails to execute the DDL statement (after doing this you cannot query or operate on the lock again).
- `lock-id:`

- Non-flag; string; required
- It specifies the ID of the DDL lock that needs to be unlocked (the ID in the result of `shard-ddl-lock`).

The following is an example of the `shard-ddl-lock unlock` command:

```
shard-ddl-lock unlock test-`shard_db`.`shard_table`
```

```
{
 "result": true, # The result of the
 ↪ unlocking operation.
 "msg": "", # The additional message
 ↪ for the failure to unlock the lock.
}
```

### Supported scenarios

Currently, the `shard-ddl-lock unlock` command only supports handling sharding DDL locks in the following two abnormal scenarios.

Scenario 1: Some MySQL sources are removed

The reason for the abnormal lock

Before `DM-master` tries to automatically unlock the sharding DDL lock, all the MySQL sources need to receive the sharding DDL events (for details, see [shard merge principles](#)). If the sharding DDL event is already in the migration process, and some MySQL sources have been removed and are not to be reloaded (these MySQL sources have been removed according to the application demand), then the sharding DDL lock cannot be automatically migrated and unlocked because not all the DM-workers can receive the DDL event.

### Note:

If you need to make some DM-workers offline when not in the process of migrating sharding DDL events, a better solution is to use `stop-task` to stop the running tasks first, make the DM-workers go offline, remove the corresponding configuration information from the task configuration file, and finally use `start-task` and the new task configuration to restart the migration task.

### Manual solution

Suppose that there are two instances `MySQL-1 (mysql-replica-01)` and `MySQL-2 (mysql-↪ -replica-02)` in the upstream, and there are two tables `shard_db_1.shard_table_1` and `shard_db_1.shard_table_2` in `MySQL-1` and two tables `shard_db_2.shard_table_1`

and `shard_db_2.shard_table_2` in MySQL-2. Now we need to merge the four tables and migrate them into the table `shard_db.shard_table` in the downstream TiDB.

The initial table structure is:

```
SHOW CREATE TABLE shard_db_1.shard_table_1;
+-----+-----+
| Table | Create Table |
+-----+-----+
| shard_table_1 | CREATE TABLE `shard_table_1` (
 `c1` int(11) NOT NULL,
 PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-----+-----+
```

The following DDL operation will be executed on the upstream sharded tables to alter the table structure:

```
ALTER TABLE shard_db_*.shard_table_* ADD COLUMN c2 INT;
```

The operation processes of MySQL and DM are as follows:

1. The corresponding DDL operations are executed on the two sharded tables of `mysql-↔ replica-01` to alter the table structures.

```
ALTER TABLE shard_db_1.shard_table_1 ADD COLUMN c2 INT;
```

```
ALTER TABLE shard_db_1.shard_table_2 ADD COLUMN c2 INT;
```

2. DM-worker sends the received DDL information of the two sharded tables of `mysql-↔ replica-01` to DM-master, and DM-master creates the corresponding DDL lock.
3. Use `shard-ddl-lock` to check the information of the current DDL lock.

```
» shard-ddl-lock test
{
 "result": true,
 "msg": "",
 "locks": [
 {
 "ID": "test-`shard_db`.`shard_table`",
 "task": "test",
 "mode": "pessimistic"
 "owner": "mysql-replica-01",
 "DDLs": [
 "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` ADD
 ↪ COLUMN `c2` int(11);"
```

```

],
 "synced": [
 "mysql-replica-01"
],
 "unsynced": [
 "mysql-replica-02"
]
 }
]
}

```

4. Due to the application demand, the data corresponding to `mysql-replica-02` is no longer needed to be migrated to the downstream TiDB, and `mysql-replica-02` is removed.
5. The lock whose ID is `test-`shard_db`.`shard_table`` on DM-master cannot receive the DDL information of `mysql-replica-02`.
  - The returned result `unsynced` by `shard-ddl-lock` has always included the information of `mysql-replica-02`.
6. Use `shard-ddl-lock unlock` to request DM-master to actively unlock the DDL lock.
  - If the owner of the DDL lock has gone offline, you can use the parameter `--owner` to specify another DM-worker as the new owner to execute the DDL.
  - If any MySQL source reports an error, `result` will be set to `false`, and at this point you should check carefully if the errors of each MySQL source is acceptable and within expectations.

```
shard-ddl-lock unlock test-`shard_db`.`shard_table`
```

```
{
 "result": true,
 "msg": ""
}
```

7. Use `shard-ddl-lock` to confirm if the DDL lock is unlocked successfully.

```

>> shard-ddl-lock test
{
 "result": true,
 "msg": "no DDL lock exists",
 "locks": [
]
}

```

8. Check whether the table structure is altered successfully in the downstream TiDB.

```
mysql> SHOW CREATE TABLE shard_db.shard_table;
+-----+-----+
| Table | Create Table |
+-----+-----+
| shard_table | CREATE TABLE `shard_table` (
 `c1` int(11) NOT NULL,
 `c2` int(11) DEFAULT NULL,
 PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+-----+-----+
```

9. Use `query-status` to confirm if the migration task is normal.

### Impact

After you have manually unlocked the lock by using `shard-ddl-lock unlock`, if you don't deal with the offline MySQL sources included in the task configuration information, the lock might still be unable to be migrated automatically when the next sharding DDL event is received.

Therefore, after you have manually unlocked the DDL lock, you should perform the following operations:

1. Use `stop-task` to stop the running tasks.
2. Update the task configuration file, and remove the related information of the offline MySQL source from the configuration file.
3. Use `start-task` and the new task configuration file to restart the task.

### Note:

After you run `shard-ddl-lock unlock`, if the MySQL source that went offline is reloaded and the DM-worker tries to migrate the data of the sharded tables, a match error between the data and the downstream table structure might occur.

Scenario 2: Some DM-workers stop abnormally or the network failure occurs during the DDL unlocking process

The reason for the abnormal lock

After DM-master receives the DDL events of all DM-workers, automatically running `unlock DDL lock` mainly include the following steps:

1. Ask the owner of the lock to execute the DDL and update the checkpoints of corresponding sharded tables.
2. Remove the DDL lock information stored on `DM-master` after the owner successfully executes the DDL.
3. Ask all other non-owners to skip the DDL and update the checkpoints of corresponding sharded tables after the owner successfully executes the DDL.
4. `DM-master` removes the corresponding DDL lock information after all the owners or non-owners' operations are successful.

Currently, the above unlocking process is not atomic. If the non-owner skips the DDL operation successfully, the `DM-worker` where the non-owner is located stops abnormally or a network anomaly occurs with the downstream TiDB, which can cause the checkpoint updating to fail.

When the MySQL source corresponding to the non-owner restores data migration, the non-owner tries to request the `DM-master` to re-coordinate the DDL operation that has been coordinated before the exception occurs and will never receives the corresponding DDL operation from other MySQL sources. This can cause the DDL operation to automatically unlock the corresponding lock.

#### Manual solution

Suppose that now we have the same upstream and downstream table structures and the same demand for merging tables and migration as in the manual solution of [Some MySQL sources are removed](#).

When `DM-master` automatically executes the unlocking process, the owner (`mysql-↔ replica-01`) successfully executes the DDL and continues the migration process. However, in the process of requesting the non-owner (`mysql-replica-02`) to skip the DDL operation, the checkpoint fails to update after the `DM-worker` skips the DDL operation because the corresponding `DM-worker` was restarted.

After the data migration subtask corresponding to `mysql-replica-02` restores, a new lock is created on the `DM-master`, but other MySQL sources have executed or skipped DDL operations and are performing subsequent migration.

The operation processes are:

1. Use `shard-ddl-lock` to confirm if the corresponding lock of the DDL exists on `DM-↔ master`.

Only `mysql-replica-02` is at the `synced` state.

```
» shard-ddl-lock
{
 "result": true,
 "msg": "",
 "locks": [
 {
```

```

 "ID": "test-`shard_db`.`shard_table`,
 "task": "test",
 "mode": "pessimistic"
 "owner": "mysql-replica-02",
 "DDLs": [
 "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` ADD
 ↪ COLUMN `c2` int(11);"
],
 "synced": [
 "mysql-replica-02"
],
 "unsynced": [
 "mysql-replica-01"
]
 }
]
}

```

2. Use `shard-ddl-lock` to ask DM-master to unlock the lock.

- During the unlocking process, the owner tries to execute the DDL operation to the downstream again (the original owner before restarting has executed the DDL operation to the downstream once). Make sure that the DDL operation can be executed multiple times.

```

shard-ddl-lock unlock test-`shard_db`.`shard_table`
{
 "result": true,
 "msg": "",
}

```

3. Use `shard-ddl-lock` to confirm if the DDL lock has been successfully unlocked.

4. Use `query-status` to confirm if the migration task is normal.

### Impact

After manually unlocking the lock, the following sharding DDL can be migrated automatically and normally.

#### 13.6.7.2 Migrate from Databases that Use GH-ost/PT-osc

In production scenarios, table locking during DDL execution can block the reads from or writes to the database to a certain extent. Therefore, online DDL tools are often used to execute DDLs to minimize the impact on reads and writes. Common DDL tools are [gh-ost](#) and [pt-osc](#).

When using DM to migrate data from MySQL to TiDB, you can enable online-ddl to allow collaboration of DM and gh-ost or pt-osc. For details about how to enable online-ddl and the workflow after enabling this option, see [Continuous Replication with gh-ost or pt-osc](#). This document focuses on the collaboration details of DM and online DDL tools.

### 13.6.7.2.1 Working details for DM with online DDL tools

This section describes the working details for DM with the online DDL tools [gh-ost](#) and [pt-osc](#) when implementing online-schema-change.

online-schema-change: gh-ost

When gh-ost implements online-schema-change, 3 types of tables are created:

- gho: used to apply DDLs. When the data is fully replicated and the gho table is consistent with the origin table, the origin table is replaced by renaming.
- ghc: used to store information that is related to online-schema-change.
- del: created by renaming the origin table.

In the process of migration, DM divides the above tables into 3 categories:

- ghostTable: `_*_gho`
- trashTable: `_*_ghc`, `_*_del`
- realTable: the origin table that executes online-ddl.

The SQL statements mostly used by gh-ost and the corresponding operation of DM are as follows:

1. Create the `_ghc` table:

```

Create /* gh-ost */ table `test`.`_test4_ghc` (
 id bigint auto_increment,
 last_update timestamp not null DEFAULT
 ↪ CURRENT_TIMESTAMP ON UPDATE
 ↪ CURRENT_TIMESTAMP,
 hint varchar(64) charset ascii not null,
 value varchar(4096) charset ascii not null,
 primary key(id),
 unique key hint_uidx(hint)
) auto_increment=256 ;

```

DM does not create the `_test4_ghc` table.

2. Create the `_gho` table:

```

Create /* gh-ost */ table `test`.`_test4_gho` like `test`.`test4` ;

```

DM does not create the `_test4_gho` table. DM deletes the `dm_meta.{task_name}` `↔` `_onlineddl` record in the downstream according to `ghost_schema`, `ghost_table`, and the `server_id` of `dm_worker`, and clears the related information in memory.

```
DELETE FROM dm_meta.{task_name}_onlineddl WHERE id = {server_id} and
↔ ghost_schema = {ghost_schema} and ghost_table = {ghost_table};
```

3. Apply the DDL that needs to be executed in the `_gho` table:

```
Alter /* gh-ost */ table `test`.`_test4_gho` add column c11 varchar
↔ (20) not null ;
```

DM does not perform the DDL operation of `_test4_gho`. It records this DDL in `dm_meta.{task_name}_onlineddl` and memory.

```
REPLACE INTO dm_meta.{task_name}_onlineddl (id, ghost_schema ,
↔ ghost_table , ddls) VALUES (.....);
```

4. Write data to the `_ghc` table, and replicate the origin table data to the `_gho` table:

```
INSERT /* gh-ost */ INTO `test`.`_test4_ghc` VALUES (.....);
INSERT /* gh-ost `test`.`test4` */ ignore INTO `test`.`_test4_gho` (
↔ id`, `date`, `account_id`, `conversion_price`, `
↔ ocpc_matched_conversions`, `ad_cost`, `c12`)
(SELECT `id`, `date`, `account_id`, `conversion_price`, `
↔ ocpc_matched_conversions`, `ad_cost`, `c12` FROM `test`.`test4`
↔ FORCE INDEX (`PRIMARY`)
WHERE (((`id` > _binary'1') OR ((`id` = _binary'1')))) AND ((`id` <
↔ _binary'2') OR ((`id` = _binary'2')))) lock IN share mode
) ;
```

DM does not execute DML statements that are not for **realtable**.

5. After the migration is completed, both the origin table and `_gho` table are renamed, and the online DDL operation is completed:

```
Rename /* gh-ost */ table `test`.`test4` to `test`.`_test4_del`, `test
↔`.`_test4_gho` to `test`.`test4`;
```

DM performs the following two operations:

- DM splits the above `rename` operation into two SQL statements.

```
rename test.test4 to test._test4_del;
rename test._test4_gho to test.test4;
```

- DM does not execute `rename` to `_test4_del`. When executing `rename` `↔` `ghost_table` to origin table, DM takes the following steps:

- Read the DDL recorded in memory in Step 3
- Replace `ghost_table` and `ghost_schema` with `origin_table` and its corresponding schema
- Execute the DDL that has been replaced

```
alter table test._test4_gho add column c11 varchar(20) not null;
-- Replaced with:
alter table test.test4 add column c11 varchar(20) not null;
```

### Note:

The specific SQL statements of `gh-ost` vary with the parameters used in the execution. This document only lists the major SQL statements. For more details, refer to the [gh-ost documentation](#).

#### 13.6.7.2.2 online-schema-change: pt

When `pt-osc` implements online-schema-change, 2 types of tables are created:

- `new`: used to apply DDL. When the data is fully replicated and the `new` table is consistent with the origin table, the origin table is replaced by renaming.
- `old`: created by renaming the origin table.
- 3 kinds of Trigger: `pt_osc*_ins`, `pt_osc*_upd`, `pt_osc*_del`. In the process of `pt_osc`, the new data generated by the origin table is replicated to `new` by the Trigger.

In the process of migration, DM divides the above tables into 3 categories:

- `ghostTable`: `*_new`
- `trashTable`: `*_old`
- `realTable`: the origin table that executes online-ddl.

The SQL statements mostly used by `pt-osc` and the corresponding operation of DM are as follows:

1. Create the `_new` table:

```
CREATE TABLE `test`.`_test4_new` (id int(11) NOT NULL AUTO_INCREMENT,
date date DEFAULT NULL, account_id bigint(20) DEFAULT NULL,
↪ conversion_price decimal(20,3) DEFAULT NULL,
↪ ocpc_matched_conversions bigint(20) DEFAULT NULL, ad_cost
↪ decimal(20,3) DEFAULT NULL,c12 varchar(20) COLLATE utf8mb4_bin
↪ NOT NULL,c11 varchar(20) COLLATE utf8mb4_bin NOT NULL,PRIMARY
↪ KEY (id)) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=
↪ utf8mb4 COLLATE=utf8mb4_bin ;
```

DM does not create the `_test4_new` table. DM deletes the `dm_meta.{task_name}_onlineddl` record in the downstream according to `ghost_schema`, `ghost_table`, and the `server_id` of `dm_worker`, and clears the related information in memory.

```
DELETE FROM dm_meta.{task_name}_onlineddl WHERE id = {server_id} and
↳ ghost_schema = {ghost_schema} and ghost_table = {ghost_table};
```

- Execute DDL in the `_new` table:

```
ALTER TABLE `test`.`_test4_new` add column c3 int;
```

DM does not perform the DDL operation of `_test4_new`. Instead, it records this DDL in `dm_meta.{task_name}_onlineddl` and memory.

```
REPLACE INTO dm_meta.{task_name}_onlineddl (id, ghost_schema ,
↳ ghost_table , ddls) VALUES (.....);
```

- Create 3 Triggers used for data migration:

```
CREATE TRIGGER `pt_osc_test_test4_del` AFTER DELETE ON `test`.`test4`
↳ ;
CREATE TRIGGER `pt_osc_test_test4_upd` AFTER UPDATE ON `test`.`test4`
↳ ;
CREATE TRIGGER `pt_osc_test_test4_ins` AFTER INSERT ON `test`.`test4`
↳ ;
```

DM does not execute Trigger operations that are not supported in TiDB.

- Replicate the origin table data to the `_new` table:

```
INSERT LOW_PRIORITY IGNORE INTO `test`.`_test4_new` (`id`, `date`, `
↳ account_id`, `conversion_price`, `ocpc_matched_conversions`, `
↳ ad_cost`, `c12`, `c11`) SELECT `id`, `date`, `account_id`, `
↳ conversion_price`, `ocpc_matched_conversions`, `ad_cost`, `c12`,
↳ `c11` FROM `test`.`test4` LOCK IN SHARE MODE /*pt-online-schema-
↳ change 3227 copy table*/
```

DM does not execute the DML statements that are not for **realtable**.

- After the data migration is completed, the origin table and `_new` table are renamed, and the online DDL operation is completed:

```
RENAME TABLE `test`.`test4` TO `test`.`_test4_old`, `test`.`_test4_new`
↳ TO `test`.`test4`
```

DM performs the following two operations:

- DM splits the above `rename` operation into two SQL statements:  
`sql rename test.test4 to test._test4_old; rename test._test4_new`  
`↪ to test.test4;`
- DM does not execute `rename to _test4_old`. When executing `rename`  
`↪ ghost_table to origin table`, DM takes the following steps:
  - Read the DDL recorded in memory in Step 2
  - Replace `ghost_table` and `ghost_schema` with `origin_table` and its corresponding schema
  - Execute the DDL that has been replaced

```
ALTER TABLE `test`.`_test4_new` add column c3 int;
-- Replaced with:
ALTER TABLE `test`.`test4` add column c3 int;
```

6. Delete the `_old` table and 3 Triggers of the online DDL operation:

```
DROP TABLE IF EXISTS `test`.`_test4_old`;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_del` AFTER DELETE ON `test`
↪ `.`test4` ;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_upd` AFTER UPDATE ON `test`
↪ `.`test4` ;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_ins` AFTER INSERT ON `test`
↪ `.`test4` ;
```

DM does not delete `_test4_old` and Triggers.

#### Note:

The specific SQL statements of `pt-osc` vary with the parameters used in the execution. This document only lists the major SQL statements. For more details, refer to the [pt-osc documentation](#).

### 13.6.7.2.3 Other online schema change tools

In some cases, you might need to change the default behavior of your online schema change tool. For example, you might use customized names for `ghost table` and `trash`  
`↪ table`. In other cases, you might want to use other tools instead of `gh-ost` or `pt-osc`, with the same working principles and change processes.

To achieve such customized needs, you need to write regular expressions to match the names of the `ghost table` and `trash table`.

Starting from v2.0.7, DM experimentally supports the modified online schema change tools. By setting `online-ddl=true` in the DM task configuration and configuring `shadow` ↔ `-table-rules` and `trash-table-rules`, you can match the modified temporary tables with regular expressions.

For example, if you use a customized pt-osc with the name of ghost table being `_{origin_table}_pcnew` and the name of trash table being `_{origin_table}_pcold`, you can set the custom rules as follows:

```
online-ddl: true
shadow-table-rules: ["^_(.+)_(:pcnew)$"]
trash-table-rules: ["^_(.+)_(:pcold)$"]
```

### 13.6.7.3 Migrate Data to a Downstream TiDB Table with More Columns

This document provides the additional steps to be taken when you migrate data to a downstream TiDB table with more columns than the corresponding upstream table. For regular migration steps, see the following migration scenarios:

- [Migrate MySQL of Small Datasets to TiDB](#)
- [Migrate MySQL of Large Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#)

#### 13.6.7.3.1 Use DM to migrate data to a downstream TiDB table with more columns

When replicating the upstream binlog, DM tries to use the current table schema of the downstream to parse the binlog and generate the corresponding DML statements. If the column number of the table in the upstream binlog does not match the column number in the downstream table schema, the following error occurs:

```
"errors": [
 {
 "ErrCode": 36027,
 "ErrClass": "sync-unit",
 "ErrScope": "internal",
 "ErrLevel": "high",
 "Message": "startLocation: [position: (mysql-bin.000001, 2022), gtid-
 ↳ set:09bec856-ba95-11ea-850a-58f2b4af5188:1-9], endLocation: [
 ↳ position: (mysql-bin.000001, 2022), gtid-set: 09bec856-ba95
 ↳ -11ea-850a-58f2b4af5188:1-9]: gen insert sqls failed, schema:
 ↳ log, table: messages: Column count doesn't match value count:
 ↳ 3 (columns) vs 2 (values)",
 "RawCause": "",
 "Workaround": ""
```

```
}
]
```

The following is an example upstream table schema:

```
Upstream table schema
CREATE TABLE `messages` (
 `id` int(11) NOT NULL,
 PRIMARY KEY (`id`)
)
```

The following is an example downstream table schema:

```
Downstream table schema
CREATE TABLE `messages` (
 `id` int(11) NOT NULL,
 `message` varchar(255) DEFAULT NULL, # This is the additional column that
 ↪ only exists in the downstream table.
 PRIMARY KEY (`id`)
)
```

When DM tries to use the downstream table schema to parse the binlog event generated by the upstream, DM reports the above `Column count doesn't match` error.

In such cases, you can use the `binlog-schema` command to set a table schema for the table to be migrated from the data source. The specified table schema needs to correspond to the binlog event data to be replicated by DM. If you are migrating sharded tables, for each sharded table, you need to set a table schema in DM to parse binlog event data. The steps are as follows:

1. Create a SQL file in DM and add the `CREATE TABLE` statement that corresponds to the upstream table schema to the file. For example, save the following table schema to `log.messages.sql`. For DM v6.0 or later versions, you can update the table schema by adding the `--from-source` or `--from-target` flag without creating a SQL file. For details, see [Manage Table Schemas of Tables to be Migrated](#).

```
Upstream table schema
CREATE TABLE `messages` (
 `id` int(11) NOT NULL,
 PRIMARY KEY (`id`)
)
```

2. Use the `binlog-schema` command to set the table schema for the table to be migrated from the data source. At this time, the data migration task should be in the Paused state due to the above `Column count doesn't match` error.

```
tiup dmctl --master-addr ${advertise-addr} binlog-schema update -s ${
 ↪ source-id} ${task-name} ${database-name} ${table-name} ${schema-
 ↪ file}
```

The descriptions of parameters in this command are as follows:

Parameter	Description
-	Specifies
<code>master</code>	
<code>- advertise</code>	
<code>addr</code>	
<code>addr</code>	
<code>}</code>	
	of
	any
	DM-
	master
	node
	in
	the
	clus-
	ter
	where
	dm-
	ctl is
	to be
	con-
	nected.
<code>#{</code>	
<code>advertise</code>	
<code>-</code>	
<code>addr</code>	
<code>}</code>	
	indi-
	cates
	the
	ad-
	dress
	that
	DM-
	master
	ad-
	ver-
	tises
	to
	the
	out-
	side
	world.

<u>Parameter</u>	<u>Description</u>
<code>binlog</code>	Manually
<code>↔ - set</code>	
<code>↔ schema</code>	
<code>↔ schema</code>	
<code>↔ setinfor-</code>	
<code>↔ ma-</code>	
<code>↔ tion.</code>	
<code>-s</code>	Specifies the source.
<code>{</code>	
<code>↔ source</code>	
<code>↔ -</code>	
<code>↔ id</code>	
<code>↔ }</code>	
	indicates the source ID of MySQL data.

Parameter	Description
<code>name</code>	Specifies the name of the migration task defined in the task.yaml configuration file of the data migration task.

Parameter	Description
<code>-\${database}</code>	Specifies the database.
<code>-\${name}</code>	Specifies the name of the upstream database.
<code>-\${table}</code>	Specifies the name of the upstream table.
<code>-\${file}</code>	Specifies the file to be set.

For example:

```
tiup dmctl --master-addr 172.16.10.71:8261 binlog-schema update -s
 ↪ mysql-01 task-test -d log -t message log.message.sql
```

- Use the `resume-task` command to resume the migration task in the Paused state.

```
tiup dmctl --master-addr ${advertise-addr} resume-task ${task-name}
```

4. Use the `query-status` command to confirm that the data migration task is running correctly.

```
tiup dmctl --master-addr ${advertise-addr} query-status resume-task ${
 ↪ task-name}
```

### 13.6.7.4 Continuous Data Validation in DM

This document describes how to use continuous data validation in DM, its working principles, and its limitations.

#### 13.6.7.4.1 User scenario

In the process of incrementally migrating data from the upstream database to the downstream database, there is a small probability that the flow of data leads to data corruption or data loss. For scenarios where data consistency is required, such as the credit and securities industries, after the migration is complete, you can perform full data validation to ensure data consistency.

However, in incremental migration scenarios, the upstream and downstream are continuously writing data. Because data is constantly changing in the upstream and downstream, it is difficult to perform full data validation (for example, use `sync-diff-inspector`) to all data in the tables.

In incremental migration scenarios, you can use the continuous data validation feature in DM. This feature ensures data integrity and consistency during incremental migration where data is continuously written into the downstream.

#### 13.6.7.4.2 Enable continuous data validation

You can enable continuous data validation using either of the following methods:

- Enable in the task configuration file.
- Enable using `dmctl`.

Method 1: Enable in the task configuration file

To enable continuous data validation, add the following configuration items to the task configuration file:

```
Add the following configuration items to the upstream database that
 ↪ needs to be validated:
mysql-instances:
 - source-id: "mysql1"
 block-allow-list: "bw-rule-1"
 validator-config-name: "global"
validators:
```

```
global:
mode: full # "fast" is also allowed. "none" is the default mode, which
 ↪ means no validation is performed.
worker-count: 4 # The number of validation workers in the background.
 ↪ The default value is 4.
row-error-delay: 30m # If a row cannot pass the validation within the
 ↪ specified time, it will be marked as an error row. The default
 ↪ value is 30m, which means 30 minutes.
```

The configuration items are described as follows:

- **mode**: validation mode. The possible values are `none`, `full`, and `fast`.
  - `none`: the default value, which means no validation is performed.
  - `full`: compares the changed row and the row obtained in the downstream database.
  - `fast`: only checks if the changed row exists in the downstream database.
- **worker-count**: the number of validation workers in the background. Each worker is a goroutine.
- **row-error-delay**: if a row cannot pass the validation within the specified time, it will be marked as an error row. The default value is 30 minutes.

For the complete configuration, refer to [DM Advanced Task Configuration File](#).

Method 2: Enable using `dmctl`

To enable continuous data validation, run the `dmctl validation start` command:

```
Usage:
dmctl validation start [--all-task] [task-name] [flags]

Flags:
 --all-task whether applied to all tasks
 -h, --help help for start
 --mode string specify the mode of validation: full (default),
 ↪ fast; this flag will be ignored if the validation task has been
 ↪ ever enabled but currently paused (default "full")
 --start-time string specify the start time of binlog for validation, e
 ↪ .g. '2021-10-21 00:01:00' or 2021-10-21T00:01:00
```

- **--mode**: specify the validation mode. The possible values are `fast` and `full`.
- **--start-time**: specify the start time for validation. The format follows `2021-10-21 00:01:00` or `2021-10-21T00:01:00`.
- **task**: specify the name of the task to enable continuous validation for. You can use `--all-task` to enable validation for all tasks.

For example:

```
dmctl --master-addr=127.0.0.1:8261 validation start --start-time 2021-10-21
↳ T00:01:00 --mode full my_dm_task
```

### 13.6.7.4.3 Use continuous data validation

When you use continuous data validation, you can use `dmctl` to view the status of the validation and to handle the error rows. “Error rows” refers to the rows that are found to be inconsistent between the upstream and downstream databases.

View the validation status

You can view the validation status using either of the following methods:

Method 1: run the `dmctl query-status <task-name>` command. If continuous data validation is enabled, the validation result is displayed in the `validation` field of each subtask. Example output:

```
"subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 ...
 },
 "validation": {
 "task": "test", // Task name
 "source": "mysql-01", // Source id
 "mode": "full", // Validation mode
 "stage": "Running", // Current stage. "Running" or "Stopped".
 "validatorBinlog": "(mysql-bin.000001, 5989)", // The binlog
 ↳ position of the validation
 "validatorBinlogGtid": "1642618e-cf65-11ec-9e3d-0242ac110002
 ↳ :1-30", // The GTID position of the validation
 "result": null, // When the validation is abnormal, show the
 ↳ error message
 "processedRowsStatus": "insert/update/delete: 0/0/0", //
 ↳ Statistics of the processed binlog rows.
 "pendingRowsStatus": "insert/update/delete: 0/0/0", // Statistics
 ↳ of the binlog rows that are not validated yet or that fail
 ↳ to be validated but are not marked as "error rows"
 "errorRowsStatus": "new/ignored/resolved: 0/0/0" // Statistics of
 ↳ the error rows. The three statuses are explained in the
 ↳ next section.
 }
 }
]
```

```
}
}
]
```

Method 2: run the `dmctl validation status <taskname>` command.

```
dmctl validation status [--table-stage stage] <task-name> [flags]
Flags:
-h, --help help for status
--table-stage string filter validation tables by stage: running/
 ↪ stopped
```

In the preceding command, you can use `--table-stage` to filter the tables that are being validated or stop validation. Example output:

```
{
 "result": true,
 "msg": "",
 "validators": [
 {
 "task": "test",
 "source": "mysql-01",
 "mode": "full",
 "stage": "Running",
 "validatorBinlog": "(mysql-bin.000001, 6571)",
 "validatorBinlogGtid": "",
 "result": null,
 "processedRowsStatus": "insert/update/delete: 2/0/0",
 "pendingRowsStatus": "insert/update/delete: 0/0/0",
 "errorRowsStatus": "new/ignored/resolved: 0/0/0"
 }
],
 "tableStatuses": [
 {
 "source": "mysql-01", // Source id
 "srcTable": "`db`.`test1`", // Source table name
 "dstTable": "`db`.`test1`", // Target table name
 "stage": "Running", // Validation status
 "message": "" // Error message
 }
]
}
```

If you want to view the details of the error rows, such as error types and error time, run the `dmctl validation show-error` command:

**Usage:**

```
dmctl validation show-error [--error error-state] <task-name> [flags]
```

**Flags:**

```
--error string filtering type of error: all, ignored, or unprocessed (
 ↪ default "unprocessed")
-h, --help help for show-error
```

**Example output:**

```
{
 "result": true,
 "msg": "",
 "error": [
 {
 "id": "1", // Error row id, which will be used in processing
 ↪ error rows
 "source": "mysql-replica-01", // Source id
 "srcTable": "`validator_basic`.`test`", // Source table of the
 ↪ error row
 "srcData": "[0, 0]", // Data of the error row in the source table
 "dstTable": "`validator_basic`.`test`", // Target table of the
 ↪ error row
 "dstData": "[]", // Data of the error row in the target table
 "errorType": "Expected rows not exist", // Error type
 "status": "NewErr", // Error status
 "time": "2022-07-04 13:33:02", // Discovery time of the error row
 "message": "" // Additional information
 }
]
}
```

**Handle error rows**

After continuous data validation returns error rows, you need to manually handle the error rows.

When continuous data validation finds error rows, the validation does not stop immediately. Instead, it records the error rows for you to handle. Before the error rows are processed, the default status is **unprocessed**. If you manually correct the error rows in the downstream, the validation does not automatically retrieve the latest status of the corrected data. The error rows are still recorded in the **error** field.

If you do not want to see an error row in the validation status, or if you want to mark an error row as resolved, you can locate the error row id using the **validation show-error** command and subsequently handle it with the given error id:

dmctl provides three error handling commands:

- **clear-error**: clear the error row. The **show-error** command does not show the error row anymore.

```
Usage:
 dmctl validation clear-error <task-name> <error-id|--all> [flags]

Flags:
 --all all errors
 -h, --help help for clear-error
```

- **ignore-error**: ignore the error row. This error row is marked as “ignored”.

```
Usage:
 dmctl validation ignore-error <task-name> <error-id|--all> [flags]

Flags:
 --all all errors
 -h, --help help for ignore-error
```

- **resolve-error**: the error row is manually handled and marked as “resolved”.

```
Usage:
 dmctl validation resolve-error <task-name> <error-id|--all> [flags]

Flags:
 --all all errors
 -h, --help help for resolve-error
```

#### 13.6.7.4.4 Stop continuous data validation

To stop the continuous data validation, run the **validation stop** command:

```
Usage:
 dmctl validation stop [--all-task] [task-name] [flags]

Flags:
 --all-task whether applied to all tasks
 -h, --help help for stop
```

For detailed usage, refer to [dmctl validation start](#).

### 13.6.7.4.5 Implementation

The architecture of continuous data validation (validator) in DM is as follows:

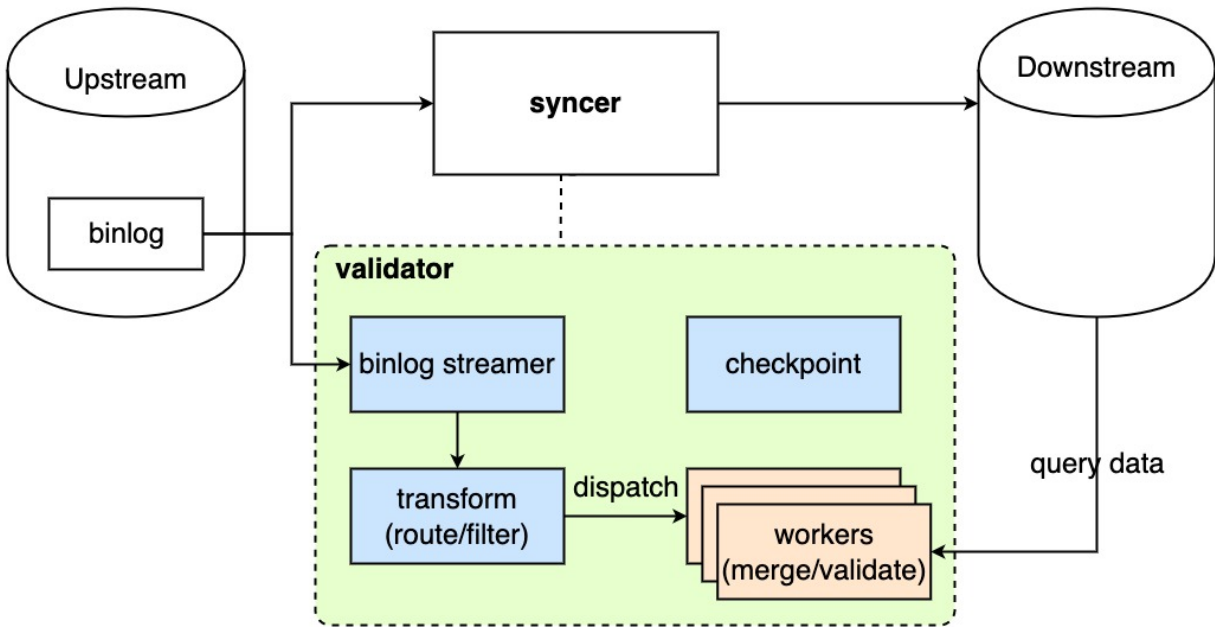

Figure 255: validator summary

The lifecycle of continuous data validation is as follows:

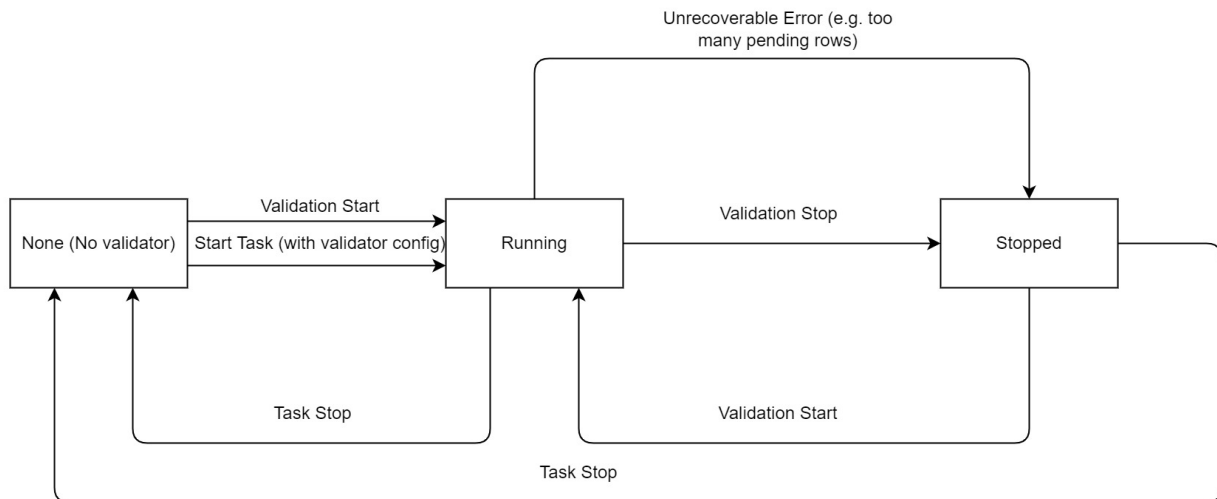

Figure 256: validator lifecycle

The detailed implementation of continuous data validation is as follows:

1. The validator pulls a binlog event from the upstream and gets the changed rows:
  - The validator only checks a event that has been incrementally migrated by the syncer. If the event has not been processed by the syncer, the validator pauses and waits for the syncer to complete processing.
  - If the event has been processed by the syncer, the validator moves on to the following steps.
2. The validator parses the binlog event and filters out the rows based on the block and allow lists, the table filters, and table routing. After that, the validator submits the changed rows to the validation worker that runs in the background.
3. The validation worker merges the changed rows that affect the same table and the same primary key to avoid validating “expired” data. The changed rows are cached in memory.
4. When the validation worker has accumulated a certain number of changed rows or when a certain time interval is passed, the validation worker queries the downstream database using the primary keys to get the current data and compares it with the changed rows.
5. The validation worker performs the data validation. If the validation mode is `full`, the validation worker compares data of the changed rows with data of the downstream database. if the validation mode is `fast`, the validation worker only checks the existence of the changed rows.
  - If the changed rows pass the validation, the changed row is removed from the memory.
  - If the changed rows fail the validation, the validator does not report an error immediately but waits for a certain time interval before validating the row again.
  - If a changed row cannot pass the validation within the specified time (specified by the user), the validator marks the row as an error row and writes it to the meta database in the downstream. You can view the information of error rows by querying the migration task. For details, refer to [View the validation status](#) and [Handle error rows](#).

#### 13.6.7.4.6 Limitations

- The source table to be validated must have a primary key or a not-null unique key.
- When DM migrates DDL from the upstream database, the following limitations apply:
  - The DDL must not change the primary key, or change the order of columns, or delete existing columns.
  - The table must not be dropped.
- Does not support tasks that use expressions to filter events.
- The precision of floating-point numbers is different between TiDB and MySQL. Differences smaller than  $10^{-6}$  are considered equal.
- Does not support the following data types:
  - JSON
  - Binary data

## 13.6.8 Maintain

### 13.6.8.1 Cluster Upgrade

#### 13.6.8.1.1 Maintain a DM Cluster Using TiUP

This document introduces how to maintain a DM cluster using the TiUP DM component.

If you have not deployed a DM cluster yet, you can refer to [Deploy a DM Cluster Using TiUP](#) for instructions.

#### Note:

- Make sure that the ports among the following components are interconnected
  - The `peer_port` (8291 by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `port` of all DM-worker nodes (8262 by default).
  - Each DM-worker node can connect to the `port` of all DM-master nodes (8261 by default).
  - The TiUP nodes can connect to the `port` of all DM-master nodes (8261 by default).
  - The TiUP nodes can connect to the `port` of all DM-worker nodes (8262 by default).

For the help information of the TiUP DM component, run the following command:

```
tiup dm --help
```

```
Deploy a DM cluster for production
```

```
Usage:
```

```
tiup dm [flags]
tiup dm [command]
```

```
Available Commands:
```

```
deploy Deploy a DM cluster for production
start Start a DM cluster
stop Stop a DM cluster
restart Restart a DM cluster
list List all clusters
destroy Destroy a specified DM cluster
```

```

audit Show audit log of cluster operation
exec Run shell command on host in the dm cluster
edit-config Edit DM cluster config
display Display information of a DM cluster
reload Reload a DM cluster's config and restart if needed
upgrade Upgrade a specified DM cluster
patch Replace the remote package with a specified package and restart
 ↪ the service
scale-out Scale out a DM cluster
scale-in Scale in a DM cluster
import Import an exist DM 1.0 cluster from dm-ansible and re-deploy
 ↪ 2.0 version
help Help about any command

```

#### Flags:

```

-h, --help help for tiup-dm
--native-ssh Use the native SSH client installed on local system
 ↪ instead of the build-in one.
--ssh-timeout int Timeout in seconds to connect host via SSH, ignored
 ↪ for operations that don't need an SSH connection. (default 5)
-v, --version version for tiup-dm
--wait-timeout int Timeout in seconds to wait for an operation to
 ↪ complete, ignored for operations that don't fit. (default 60)
-y, --yes Skip all confirmations and assumes 'yes'

```

View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup dm list
```

```

Name User Version Path PrivateKey
---- ---- -
prod-cluster tidb ${version} /root/.tiup/storage/dm/clusters/test /root/.
 ↪ tiup/storage/dm/clusters/test/ssh/id_rsa

```

Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup dm start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup dm list`.

Check the cluster status

TiUP provides the `tiup dm display` command to view the status of each component in the cluster. With this command, you do not have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup dm display prod-cluster
```

```
dm Cluster: prod-cluster
dm Version: ${version}
ID Role Host Ports OS/Arch Status
 ↪ Data Dir ↪ Deploy Dir
-- -
 ↪ -----
172.19.0.101:9093 alertmanager 172.19.0.101 9093/9094 linux/x86_64 Up /

172.19.0.101:3000 grafana 172.19.0.101 3000 linux/x86_64 Up -
 ↪ /home/tidb/deploy/grafana-3000
172.19.0.101:9090 prometheus 172.19.0.101 9090 linux/x86_64 Up /
 ↪ home/tidb/data/prometheus-9090 /home/tidb/deploy/prometheus-9090
```

The **Status** column uses **Up** or **Down** to indicate whether the service is running normally.

For the DM-master component, **|L** might be appended to a status, which indicates that the DM-master node is a Leader. For the DM-worker component, **Free** indicates that the current DM-worker node is not bound to an upstream.

#### Scale in a cluster

Scaling in a cluster means making some node(s) offline. This operation removes the specified node(s) from the cluster and deletes the remaining data files.

When you scale in a cluster, DM operations on DM-master and DM-worker components are performed in the following order:

1. Stop component processes.
2. Call the API for DM-master to delete the member.

3. Clean up the data files related to the node.

The basic usage of the scale-in command:

```
tiup dm scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two arguments: the cluster name and the node ID. The node ID can be obtained by using the `tiup dm display` command in the previous section.

For example, to scale in the DM-worker node on 172.16.5.140 (similar to scaling in DM-master), run the following command:

```
tiup dm scale-in prod-cluster -N 172.16.5.140:8262
```

Scale out a cluster

The scale-out operation has an inner logic similar to that of deployment: the TiUP DM component first ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

For example, to scale out a DM-worker node in the `prod-cluster` cluster, take the following steps (scaling out DM-master has similar steps):

1. Create a `scale.yaml` file and add information of the new worker node:

**Note:**

You need to create a topology file, which includes only the description of the new nodes, not the existing nodes. For more configuration items (such as the deployment directory), refer to this [TiUP configuration parameter example](#).

```

worker_servers:
 - host: 172.16.5.140
```

2. Perform the scale-out operation. TiUP DM adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup dm scale-out prod-cluster scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup dm display prod-cluster`.

## Rolling upgrade

### Note:

Since v2.0.5, dmctl support [Export and Import Data Sources and Task Configuration of Clusters](#).

Before upgrading, you can use `config export` to export the configuration files of clusters. After upgrading, if you need to downgrade to an earlier version, you can first redeploy the earlier cluster and then use `config import` to import the previous configuration files.

For clusters earlier than v2.0.5, you can use dmctl v2.0.5 or later to export and import the data source and task configuration files.

For clusters later than v2.0.2, currently, it is not supported to automatically import the configuration related to relay worker. You can use `start-relay` command to manually [start relay log](#).

The rolling upgrade process is made as transparent as possible to the application, and does not affect the business. The operations vary with different nodes.

### Upgrade command

You can run the `tiup dm upgrade` command to upgrade a DM cluster. For example, the following command upgrades the cluster to `${version}`. Modify `${version}` to your needed version before running this command:

```
tiup dm upgrade prod-cluster ${version}
```

### Update configuration

If you want to dynamically update the component configurations, the TiUP DM component saves a current configuration for each cluster. To edit this configuration, execute the `tiup dm edit-config <cluster-name>` command. For example:

```
tiup dm edit-config prod-cluster
```

TiUP DM opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano ↵`. After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup dm reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

## Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup dm patch --help
```

Replace the remote package with a specified package and restart the service

### Usage:

```
tiup dm patch <cluster-name> <package-path> [flags]
```

### Flags:

```
-h, --help help for patch
-N, --node strings Specify the nodes
 --overwrite Use this package in the future scale-out
 ↪ operations
-R, --role strings Specify the role
 --transfer-timeout int Timeout in seconds when transferring dm-master
 ↪ leaders (default 600)
```

### Global Flags:

```
--native-ssh Use the native SSH client installed on local system
 ↪ instead of the build-in one.
--ssh-timeout int Timeout in seconds to connect host via SSH, ignored
 ↪ for operations that don't need an SSH connection. (default 5)
--wait-timeout int Timeout in seconds to wait for an operation to
 ↪ complete, ignored for operations that don't fit. (default 60)
-y, --yes Skip all confirmations and assumes 'yes'
```

If a DM-master hotfix package is in `/tmp/dm-master-hotfix.tar.gz` and you want to replace all the DM-master packages in the cluster, run the following command:

```
tiup dm patch prod-cluster /tmp/dm-master-hotfix.tar.gz -R dm-master
```

You can also replace only one DM-master package in the cluster:

```
tiup dm patch prod-cluster /tmp/dm--hotfix.tar.gz -N 172.16.4.5:8261
```

Import and upgrade a DM 1.0 cluster deployed using DM-Ansible

### Note:

- TiUP does not support importing the DM Portal component in a DM 1.0 cluster.
- You need to stop the original cluster before importing.
- Don't run `stop-task` for tasks that need to be upgraded to 2.0.
- TiUP only supports importing to a DM cluster of v2.0.0-rc.2 or a later version.
- The `import` command is used to import data from a DM 1.0 cluster to a new DM 2.0 cluster. If you need to import DM migration tasks to an existing DM 2.0 cluster, refer to [Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+](#).
- The deployment directories of some components are different from those of the original cluster. You can execute the `display` command to view the details.
- Run `tiup update --self && tiup update dm` before importing to make sure that the TiUP DM component is the latest version.
- Only one DM-master node exists in the cluster after importing. Refer to [Scale out a cluster](#) to scale out the DM-master.

Before TiUP is released, DM-Ansible is often used to deploy DM clusters. To enable TiUP to take over the DM 1.0 cluster deployed by DM-Ansible, use the `import` command.

For example, to import a cluster deployed using DM Ansible:

```
tiup dm import --dir=/path/to/dm-ansible --cluster-version ${version}
```

Execute `tiup list dm-master` to view the latest cluster version supported by TiUP.

The process of using the `import` command is as follows:

1. TiUP generates a topology file `topology.yml` based on the DM cluster previously deployed using DM-Ansible.
2. After confirming that the topology file has been generated, you can use it to deploy the DM cluster of v2.0 or later versions.

After the deployment is completed, you can execute the `tiup dm start` command to start the cluster and begin the process of upgrading the DM kernel.

View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
 tiup dm audit [audit-id] [flags]

Flags:
 -h, --help help for audit
```

If the `[audit-id]` argument is not specified, the command shows a list of commands that have been executed. For example:

```
tiup dm audit
```

ID	Time	Command
4D5kQY	2020-08-13T05:38:19Z	tiup dm display test
4D5kNv	2020-08-13T05:36:13Z	tiup dm list
4D5kNr	2020-08-13T05:36:10Z	tiup dm deploy -p prod-cluster \${version} ./ ↳ examples/dm/minimal.yaml

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` argument as follows:

```
tiup dm audit 4D5kQY
```

Run commands on a host in the DM cluster

To run commands on a host in the DM cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
 tiup dm exec <cluster-name> [flags]

Flags:
 --command string the command run on cluster host (default "ls")
 -h, --help help for exec
 -N, --node strings Only exec on host with specified nodes
 -R, --role strings Only exec on host with specified roles
 --sudo use root permissions (default false)
```

For example, to execute `ls /tmp` on all DM nodes, run the following command:

```
tiup dm exec prod-cluster --command='ls /tmp'
```

`dmctl`

TiUP integrates the DM cluster controller `dmctl`.

Run the following command to use `dmctl`:

```
tiup dmctl [args]
```

Specify the version of `dmctl`. Modify `${version}` to your needed version before running this command:

```
tiup dmctl:${version} [args]
```

The previous `dmctl` command to add a source is `dmctl --master-addr master1:8261 ↪ operate-source create /tmp/source1.yml`. After `dmctl` is integrated into TiUP, the command is:

```
tiup dmctl --master-addr master1:8261 operate-source create /tmp/source1.
↪ yml
```

Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--native-ssh` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup dm deploy <cluster-name> <version> <topo> --native-↪ ssh`. Fill in the name of your cluster for `<cluster-name>`, the DM version to be deployed (such as `v6.5.0`) for `<version>`, and the topology file name for `<topo>`.
- Start a cluster: `tiup dm start <cluster-name> --native-ssh`.
- Upgrade a cluster: `tiup dm upgrade ... --native-ssh`

You can add `--native-ssh` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
or
export TIUP_NATIVE_SSH=1
or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--native-ssh` at the same time, `--native ↪ -ssh` has higher priority.

### Note:

During the process of cluster deployment, if you need to use a password for connection or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

### 13.6.8.1.2 Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+

This document introduces how to manually upgrade the TiDB DM tool from v1.0.x to v2.0+. The main idea is to use the global checkpoint information in v1.0.x to start a new data migration task in the v2.0+ cluster.

For how to automatically upgrade the TiDB DM tool from v1.0.x to v2.0+, refer to [Using TiUP to automatically import the 1.0 cluster deployed by DM-Ansible](#).

#### Note:

- Currently, upgrading DM from v1.0.x to v2.0+ is not supported when the data migration task is in the process of full export or full import.
- As the gRPC protocol used for interaction between the components of the DM cluster is updated greatly, you need to make sure that the DM components (including dmctl) use the same version before and after the upgrade.
- Because the metadata storage of the DM cluster (such as checkpoint, shard DDL lock status, and online DDL metadata) is updated greatly, the metadata of v1.0.x cannot be reused automatically in v2.0+. So you need to make sure the following requirements are satisfied before performing the upgrade operation:
  - All data migration tasks are not in the process of shard DDL coordination.
  - All data migration tasks are not in the process of online DDL coordination.

The steps for manual upgrade are as follows.

Step 1: Prepare v2.0+ configuration file

The prepared configuration files of v2.0+ include the configuration files of the upstream database and the configuration files of the data migration task.

Upstream database configuration file

In v2.0+, the [upstream database configuration file](#) is separated from the process configuration of the DM-worker, so you need to obtain the source configuration based on the [v1.0.x DM-worker configuration](#).

#### Note:

If `enable-gtid` in the source configuration is enabled during the upgrade from v1.0.x to v2.0+, you need to parse the binlog or relay log file to obtain the GTID sets corresponding to the binlog position.

Upgrade a v1.0.x cluster deployed by DM-Ansible

Assume that the v1.0.x DM cluster is deployed by DM-Ansible, and the following `dm_worker_servers` configuration is in the `inventory.ini` file:

```
[dm_master_servers]
dm_worker1 ansible_host=172.16.10.72 server_id=101 source_id="mysql-replica
↳ -01" mysql_host=172.16.10.81 mysql_user=root mysql_password='
↳ VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU=' mysql_port=3306
dm_worker2 ansible_host=172.16.10.73 server_id=102 source_id="mysql-replica
↳ -02" mysql_host=172.16.10.82 mysql_user=root mysql_password='
↳ VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU=' mysql_port=3306
```

Then you can convert it to the following two source configuration files:

```
The source configuration corresponding to the original dm_worker1. For
↳ example, it is named as source1.yaml.
server-id: 101 # Corresponds to the original `
↳ server_id`.
source-id: "mysql-replica-01" # Corresponds to the original `
↳ source_id`.
from:
 host: "172.16.10.81" # Corresponds to the original `
↳ mysql_host`.
 port: 3306 # Corresponds to the original `
↳ mysql_port`.
 user: "root" # Corresponds to the original `
↳ mysql_user`.
 password: "VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU=" # Corresponds to the original
↳ `mysql_password`.
```

```
The source configuration corresponding to the original dm_worker2. For
↳ example, it is named as source2.yaml.
server-id: 102 # Corresponds to the original `
↳ server_id`.
source-id: "mysql-replica-02" # Corresponds to the original `
↳ source_id`.
from:
 host: "172.16.10.82" # Corresponds to the original `
↳ mysql_host`.
 port: 3306 # Corresponds to the original `
↳ mysql_port`.
 user: "root" # Corresponds to the original `
↳ mysql_user`.
```

```
password: "VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU=" # Corresponds to the original
↪ `mysql_password`.
```

Upgrade a v1.0.x cluster deployed by binary

Assume that the v1.0.x DM cluster is deployed by binary, and the corresponding DM-worker configuration is as follows:

```
log-level = "info"
log-file = "dm-worker.log"
worker-addr = ":8262"
server-id = 101
source-id = "mysql-replica-01"
flavor = "mysql"
[from]
host = "172.16.10.81"
user = "root"
password = "VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU="
port = 3306
```

Then you can convert it to the following source configuration file:

```
server-id: 101 # Corresponds to the original `
↪ server-id`.
source-id: "mysql-replica-01" # Corresponds to the original `
↪ source-id`.
flavor: "mysql" # Corresponds to the original `
↪ flavor`.
from:
 host: "172.16.10.81" # Corresponds to the original `
↪ from.host`.
 port: 3306 # Corresponds to the original `
↪ from.port`.
 user: "root" # Corresponds to the original `
↪ from.user`.
 password: "VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU=" # Corresponds to the original
↪ `from.password`.
```

Data migration task configuration file

For [data migration task configuration guide](#), v2.0+ is basically compatible with v1.0.x. You can directly copy the configuration of v1.0.x.

Step 2: Deploy the v2.0+ cluster

**Note:**

Skip this step if you have other v2.0+ clusters available.

Use **TiUP** to deploy a new v2.0+ cluster according to the required number of nodes.

Step 3: Stop the v1.0.x cluster

If the original v1.0.x cluster is deployed by DM-Ansible, you need to use [DM-Ansible to stop the v1.0.x cluster](#).

If the original v1.0.x cluster is deployed by binary, you can stop the DM-worker and DM-master processes directly.

Step 4: Upgrade data migration task

1. Use the **operate-source** command to load the upstream database source configuration from [step 1](#) into the v2.0+ cluster.
2. In the downstream TiDB cluster, obtain the corresponding global checkpoint information from the incremental checkpoint table of the v1.0.x data migration task.
  - Assume that the v1.0.x data migration configuration does not specify `meta-schema` (or specify its value as the default `dm_meta`), and the corresponding task name is `task_v1`, the corresponding checkpoint information is in the ``dm_meta`.`task_v1_syncer_checkpoint`` table of the downstream TiDB.
  - Use the following SQL statements to obtain the global checkpoint information of all upstream database sources corresponding to the data migration task.

```
> SELECT `id`, `binlog_name`, `binlog_pos` FROM `dm_meta`.`
 ↳ task_v1_syncer_checkpoint` WHERE `is_global`=1;
+-----+-----+-----+
| id | binlog_name | binlog_pos |
+-----+-----+-----+
| mysql-replica-01 | mysql-bin|000001.000123 | 15847 |
| mysql-replica-02 | mysql-bin|000001.000456 | 10485 |
+-----+-----+-----+
```

3. Update the v1.0.x data migration task configuration file to start a new v2.0+ data migration task.
  - If the data migration task configuration file of v1.0.x is `task_v1.yaml`, copy it and rename it to `task_v2.yaml`.
  - Make the following changes to `task_v2.yaml`:
    - Modify `name` to a new name, such as `task_v2`.

- Change `task-mode` to `incremental`.
- Set the starting point of incremental replication for each source according to the global checkpoint information obtained in step 2. For example:

```
mysql-instances:
- source-id: "mysql-replica-01" # Corresponds to the `id`
 ↪ of the checkpoint information.
 meta:
 binlog-name: "mysql-bin.000123" # Corresponds to the `
 ↪ binlog_name` in the checkpoint information,
 ↪ excluding the part of `|000001`.
 binlog-pos: 15847 # Corresponds to `
 ↪ binlog_pos` in the checkpoint information.

- source-id: "mysql-replica-02"
 meta:
 binlog-name: "mysql-bin.000456"
 binlog-pos: 10485
```

#### Note:

If `enable-gtid` is enabled in the source configuration, currently you need to parse the binlog or relay log file to obtain the GTID sets corresponding to the binlog position, and set it to `binlog-  
↪ gtid` in the meta.

4. Use the `start-task` command to start the upgraded data migration task through the v2.0+ data migration task configuration file.
5. Use the `query-status` command to confirm whether the data migration task is running normally.

If the data migration task runs normally, it indicates that the DM upgrade to v2.0+ is successful.

## 13.6.8.2 Tools

### 13.6.8.2.1 Use WebUI to Manage DM migration tasks

DM WebUI is a web-based GUI platform for managing TiDB Data Migration (DM) tasks. This platform provides a simple and intuitive way to manage a large number of migration tasks, which frees you from using the `dmctl` command-line tool.

This document introduces how to access DM WebUI, the prerequisites, the use cases of each page on the interface, and the attention points.

### Warning:

- DM WebUI is currently an experimental feature. It is not recommended to use it in the production environment.
- The lifecycle of `task` in DM WebUI has been changed, and it is not recommended to use DM WebUI and `dmctl` at the same time.

DM WebUI has the following pages:

- **Migration**

- **Task:** Provides an entry to task creation, and displays the detailed information of each migration task. This page helps you monitor, create, delete, and configure migration tasks.
- **Source:** Configures the information of upstream data source for a migration task. On this page, you can manage the upstream configuration in a data migration environment, including creating and deleting upstream configuration, monitoring the task status corresponding to the upstream configuration, and modifying upstream configuration.
- **Replication Detail:** Displays the detailed status information of migration tasks. On this page, you can view the detailed configuration and status information based on a specified filter, including the configuration information and database names of the upstream and downstream, the relation of source tables and target tables.

- **Cluster**

- **Members:** Displays the list of all master and worker nodes in the DM cluster, and the binding relationship between worker nodes and the source. On this page, you can view the configuration information of the current DM cluster and the status information of each worker. In addition, basic management is also provided on this page.

The interface is as follows:

Figure 257: webui

## Access method

When **OpenAPI** is enabled, you can access the DM WebUI from any master node of the DM cluster. The access port is **8261** by default and is the same as that of DM OpenAPI. Here is an example of an access address: `http://{master_ip}:{master_port}/dashboard/`.

## Migration

**Migration** includes **Source**, **Task**, and **Replication Detail** pages.

## Source

Before creating a migration task, you need to create the data source information of the upstream for the replication task. You can create the upstream configuration in the **Source** page. When creating sources, pay attention to the following items:

- If there is a auto failover between primary and secondary instance, enable GTID in the upstream MySQL and set GTID to **True** when creating the upstream configuration; otherwise, the migration task will be interrupted during the failover (except for AWS Aurora).
- If a MySQL instance needs to be temporarily offline, you can disable the instance. However, when the MySQL instance is being disabled, other MySQL instances running migration tasks should not execute DDL operations; otherwise, the disabled instance cannot properly migrate data after it is enabled.
- When multiple migration tasks use the same upstream, it might cause additional stress. Enabling relay log can reduce the impact on the upstream, so it is recommended to enable relay log.

## Task

You can view the migration task details on the **Task** page, and create migration tasks.

View migration task details

In the task list, click the task name to view the Details page from the right. The Details page displays more detailed task status information. On this page, you can view the status of each sub-task and the current configuration information of the migration task.

In DM, each sub-task of a migration task might be at different stages, namely full dump -> full import (load) -> incremental replication (sync). Therefore, the current stage of a task is displayed with the statistics of the sub-task statuses, which can help you better understand the running status of the task.

### Create migration tasks

To create a migration task on this page, click the **Add** button on the top right corner. You can use one of the following methods to create a migration task:

- By following the WebUI instruction. Fill in the required information step by step on the WebUI. This method is suitable for beginners and for daily use.
- By using a configuration file. Paste or write a JSON-formatted configuration file to create a migration task. This method supports adjusting more parameters and is suitable for advanced users.

### Replication detail

You can view the status of the migration rules configured for a migration task on the **Replication Detail** page. This page supports querying by task, source, and database name.

The query result contains the corresponding information of the upstream table and the downstream table, so be careful using `.*` in case that too many query results slow down the page response.

### Cluster

### Members

The **Members** page displays all the master and worker nodes in the DM cluster, and the binding relationship between worker nodes and the source.

## 13.6.8.2.2 Maintain DM Clusters Using dmctl

### Note:

For DM clusters deployed using TiUP, you are recommended to directly use `tiup dmctl` to maintain the clusters.

`dmctl` is a command line tool used to maintain DM clusters. It supports both the interactive mode and the command mode.

### Interactive mode

Enter the interactive mode to interact with DM-master:

**Note:**

The interactive mode does not support Bash features. For example, you need to directly pass string flags instead of passing them in quotes.

```
./dmctl --master-addr 172.16.30.14:8261
```

```
Welcome to dmctl
Release Version: ${version}
Git Commit Hash: xx
Git Branch: release-x.x
UTC Build Time: yyyy-mm-dd hh:mm:ss
Go Version: go version gox.xx linux/amd64

» help
DM control

Usage:
 dmctl [command]

Available Commands:
 binlog manage or show binlog operations
 binlog-schema manage or show table schema in schema tracker
 check-task Checks the configuration file of the task
 config manage config operations
 decrypt Decrypts cipher text to plain text
 encrypt Encrypts plain text to cipher text
 help Gets help about any command
 list-member Lists member information
 offline-member Offlines member which has been closed
 operate-leader `evict`/`cancel-evict` the leader
 operate-source `create`/`stop`/`show` upstream MySQL/MariaDB source
 pause-relay Pauses DM-worker's relay unit
 pause-task Pauses a specified running task or all (sub)tasks bound to a
 ↪ source
 purge-relay Purges relay log files of the DM-worker according to the
 ↪ specified filename
 query-status Queries task status
 resume-relay Resumes DM-worker's relay unit
 resume-task Resumes a specified paused task or all (sub)tasks bound to a
 ↪ source
```

```
shard-ddl-lock maintain or show shard-ddl locks information
start-relay Starts workers pulling relay log for a source
start-task Starts a task as defined in the configuration file
stop-relay Stops workers pulling relay log for a source
stop-task Stops a specified task or all (sub)tasks bound to a source
transfer-source Transfers a upstream MySQL/MariaDB source to a free worker
```

Flags:

```
-h, --help Help for dmctl.
-s, --source strings MySQL Source ID.
```

Use "dmctl [command] --help" for more information about a command.

### Command mode

The command mode differs from the interactive mode in that you need to append the task operation right after the dmctl command. The parameters of the task operation in the command mode are the same as those in the interactive mode.

### Note:

- A dmctl command must be followed by only one task operation.
- Starting from v2.0.4, DM supports reading the `-master-addr` parameter from the environment variable `DM_MASTER_ADDR`.

```
./dmctl --master-addr 172.16.30.14:8261 start-task task.yaml
./dmctl --master-addr 172.16.30.14:8261 stop-task task
./dmctl --master-addr 172.16.30.14:8261 query-status
```

```
export DM_MASTER_ADDR="172.16.30.14:8261"
./dmctl query-status
```

### Available Commands:

```
binlog manage or show binlog operations
binlog-schema manage or show table schema in schema tracker
check-task Checks the configuration file of the task
config manage config operations
decrypt Decrypts cipher text to plain text
encrypt Encrypts plain text to cipher text
help Gets help about any command
list-member Lists member information
offline-member Offlines member which has been closed
```

```
operate-leader `evict`/`cancel-evict` the leader
operate-source `create`/`stop`/`show` upstream MySQL/MariaDB source
pause-relay Pauses DM-worker's relay unit
pause-task Pauses a specified running task or all (sub)tasks bound to a
 ↪ source
purge-relay Purges relay log files of the DM-worker according to the
 ↪ specified filename
query-status Queries task status
resume-relay Resumes DM-worker's relay unit
resume-task Resumes a specified paused task or all (sub)tasks bound to a
 ↪ source
shard-ddl-lock maintain or show shard-ddl locks information
start-relay Starts workers pulling relay log for a source
start-task Starts a task as defined in the configuration file
stop-relay Stops workers pulling relay log for a source
stop-task Stops a specified task or all (sub)tasks bound to a source
transfer-source Transfers a upstream MySQL/MariaDB source to a free worker
```

#### Flags:

```
--config string Path to config file.
-h, --help help for dmctl
--master-addr string Master API server address, this parameter is
 ↪ required when interacting with the dm-master
--rpc-timeout string RPC timeout, default is 10m. (default "10m")
-s, --source strings MySQL Source ID.
--ssl-ca string Path of file that contains list of trusted SSL CAs
 ↪ for connection.
--ssl-cert string Path of file that contains X509 certificate in PEM
 ↪ format for connection.
--ssl-key string Path of file that contains X509 key in PEM format
 ↪ for connection.
-V, --version Prints version and exit.
```

Use "dmctl [command] --help" for more information about a command.

### 13.6.8.3 Performance Tuning

#### 13.6.8.3.1 DM 5.4.0 Benchmark Report

The benchmark data of TiDB Data Migration (DM) v5.4.0 is nearly the same as that of DM v5.3.0. To learn the test purpose, environment, scenarios, and results of DM v5.3.0, refer to [DM 5.3.0 Benchmark Report](#).

#### 13.6.8.3.2 Optimize Configuration of DM

This document introduces how to optimize the configuration of the data migration task to improve the performance of data migration.

## Full data export

`mydumpers` is the configuration item related to full data export. This section describes how to configure performance-related options.

### `rows`

Setting the `rows` option enables concurrently exporting data from a single table using multi-thread. The value of `rows` is the maximum number of rows contained in each exported chunk. After this option is enabled, DM selects a column as the split benchmark when the data of a MySQL single table is concurrently exported. This column can be one of the following columns: the primary key column, the unique index column, and the normal index column (ordered from highest priority to lowest). Make sure this column is of integer type (for example, `INT`, `MEDIUMINT`, `BIGINT`).

The value of `rows` can be set to 10000. You can change this value according to the total number of rows in the table and the performance of the database. In addition, you need to set `threads` to control the number of concurrent threads. By default, the value of `threads` is 4. You can adjust this value as needed.

### `chunk-filesize`

During full backup, DM splits the data of each table into multiple chunks according to the value of the `chunk-filesize` option. Each chunk is saved in a file with a size of about `chunk-filesize`. In this way, data is split into multiple files and you can use the parallel processing of the DM Load unit to improve the import speed. The default value of this option is 64 (in MB). Normally, you do not need to set this option. If you set it, adjust the value of this option according to the size of the full data.

## Note:

- You cannot update the value of `mydumpers` after the migration task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using `dmctl`, update the configuration file, and re-create the task.
- `mydumpers.threads` can be replaced with the `mydumper-thread` configuration item for simplicity.
- If `rows` is set, DM ignores the value of `chunk-filesize`.

## Full data import

`loaders` is the configuration item related to full data import. This section describes how to configure performance-related options.

### `pool-size`

The `pool-size` option determines the number of threads in the DM Load unit. The default value is 16. Normally, you do not need to set this option. If you set it, adjust the value of this option according to the size of the full data and the performance of the database.

#### Note:

- You cannot update the value of `loaders` after the migration task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using `dmctl`, update the configuration file, and re-create the task.
- `loaders.pool-size` can be replaced with the `loader-thread` configuration item for simplicity.

### Incremental data replication

`syncers` is the configuration item related to incremental data replication. This section describes how to configure performance-related options.

#### `worker-count`

`worker-count` determines the number of threads for concurrent replication of DMLs in the DM Sync unit. The default value is 16. To speed up data replication, increase the value of this option appropriately.

#### `batch`

`batch` determines the number of DMLs included in each transaction when the data is replicated to the downstream database during the DM Sync unit. The default value is 100. Normally, you do not need to change the value of this option.

#### Note:

- You cannot update the value of `syncers` after the replication task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using `dmctl`, update the configuration file, and re-create the task.
- `syncers.worker-count` can be replaced with the `syncer-thread` configuration item for simplicity.
- You can change the values of `worker-count` and `batch` according to the actual scenario. For example, if there is a high network delay between DM and the downstream database, you can increase the value of `worker`  $\rightarrow$  `-count` and decrease the value of `batch` appropriately.

### 13.6.8.3.3 DM Cluster Performance Test

This document describes how to build a test scenario to do a performance test on the DM cluster, including the speed test and latency test regarding data migration.

Migration data flow

You can use a simple migration data flow, that is, MySQL -> DM -> TiDB, to test the data migration performance of the DM cluster.

Deploy test environment

- Deploy the TiDB test cluster using TiUP, with all default configurations.
- Deploy the MySQL service. Enable the ROW mode for binlog, and use default configurations for other configuration items.
- Deploy a DM cluster, with a DM-worker and a DM-master.

Performance test

Table schema

Use tables with the following schema for the performance test:

```
CREATE TABLE `sbtest` (
 `id` int(11) NOT NULL AUTO_INCREMENT,
 `k` int(11) NOT NULL DEFAULT '0',
 `c` char(120) CHARSET utf8mb4 COLLATE utf8mb4_bin NOT NULL DEFAULT '',
 `pad` char(60) CHARSET utf8mb4 COLLATE utf8mb4_bin NOT NULL DEFAULT '',
 PRIMARY KEY (`id`),
 KEY `k_1` (`k`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

Full import benchmark case

Generate test data

Use `sysbench` to create test tables upstream and generate test data for full import. Execute the following `sysbench` command to generate test data:

```
sysbench --test=oltp_insert --tables=4 --mysql-host=172.16.4.40 --mysql-
 ↪ port=3306 --mysql-user=root --mysql-db=dm_benchmark --db-driver=mysql
 ↪ --table-size=50000000 prepare
```

Create a data migration task

1. Create an upstream MySQL source and set `source-id` to `source-1`. For details, see [Load the Data Source Configurations](#).
2. Create a migration task (in `full` mode). The following is a task configuration template:

```

"yaml"

name: test-full
task-mode: full

```

# Configure the migration task using the TiDB information of your actual test environment. target-database: host: "192.168.0.1" port: 4000 user: "root" password: ""

mysql-instances: - source-id: "source-1" block-allow-list: "instance" mydumper-config-name: "global" loader-thread: 16

# Configure the name of the database where sysbench generates data. block-allow-list: instance: do-dbs: ["dm\_benchmark"]

mydumpers: global: rows: 32000 threads: 32 ""

For details about how to create a migration task, see [Create a Data Migration Task](#).

#### Note:

- To enable concurrently exporting data from a single table using multi-thread, you can use the `rows` option in the `mydumpers` configuration item. This speeds up data export.
- To test the performance under different configurations, you can tune `loader-thread` in the `mysql-instances` configuration, as well as `rows` and `threads` in the `mydumpers` configuration item.

#### Get test results

Observe the DM-worker log. When you see **all data files have been finished**, it means that full data has been imported. In this case, you can see the time consumed to import data. The sample log is as follows:

```
[INFO] [loader.go:604] ["all data files have been finished"] [task=test] [
 ↪ unit=load] ["cost time"]=52.439796ms]
```

According to the size of the test data and the time consumed to import data, you can calculate the migration speed of the full data.

#### Incremental replication benchmark case

##### Initialize tables

Use `sysbench` to create test tables in the upstream.

##### Create a data migration task

1. Create the source of the upstream MySQL. Set `source-id` to `source-1` (if the source has been created in the [full import benchmark case](#), you do not need to create it again). For details, see [Load the Data Source Configurations](#).
2. Create a DM migration task (in `all` mode). The following is an example of the task configuration file:

```

"yaml"

name: test-all
task-mode: all

```

```
Configure the migration task using the TiDB information of your actual test environ-
ment. target-database: host: "192.168.0.1" port: 4000 user: "root" password: ""
```

```
mysql-instances: - source-id: "source-1" block-allow-list: "instance" syncer-config-name:
"global"
```

```
Configure the name of the database where sysbench generates data. block-allow-list:
instance: do-dbs: ["dm_benchmark"]
```

```
syncers: global: worker-count: 16 batch: 100 ""
```

For details about how to create a data migration task, see [Create a Data Migration Task](#).

### Note:

To test the performance under different configurations, you can tune `worker`  
↪ `-count` and `batch` in the `syncers` configuration item.

Generate incremental data

To continuously generate incremental data in the upstream, run the `sysbench` command:

```
sysbench --test=oltp_insert --tables=4 --num-threads=32 --mysql-host
↪ =172.17.4.40 --mysql-port=3306 --mysql-user=root --mysql-db=
↪ dm_benchmark --db-driver=mysql --report-interval=10 --time=1800 run
```

### Note:

You can test the data migration performance under different scenarios by  
using different `sysbench` statements.

Get test results

To observe the migration status of DM, you can run the `query-status` command. To observe the monitoring metrics of DM, you can use Grafana. Here the monitoring metrics refer to `finished sqls jobs` (the number of jobs finished per unit time), and other related metrics. For more information, see [Binlog Migration Monitoring Metrics](#).

#### 13.6.8.3.4 Handle Performance Issues of TiDB Data Migration

This document introduces common performance issues that might exist in DM and how to deal with them.

Before diagnosing an issue, you can refer to the [DM Benchmark Report](#).

When diagnosing and handling performance issues, make sure that:

- The DM monitoring component is correctly configured and installed.
- You can view [monitoring metrics](#) on the Grafana monitoring dashboard.
- The component you diagnose works well; otherwise, possible monitoring metrics exceptions might interfere with the diagnosis of performance issues.

In the case of a large latency in the data migration, to quickly figure out whether the bottleneck is inside the DM component or in the TiDB cluster, you can first check DML `queue remain length` in [Write SQL Statements to Downstream](#).

relay log unit

To diagnose performance issues in the relay log unit, you can check the `binlog file gap between master and relay` monitoring metric. For more information about this metric, refer to [monitoring metrics of the relay log](#). If this metric is greater than 1 for a long time, it usually indicates that there is a performance issue; if this metric is 0, it usually indicates that there is no performance issue.

If the value of `binlog file gap between master and relay` is 0, but you suspect that there is a performance issue, you can check `binlog pos`. If `master` in this metric is much larger than `relay`, a performance issue might exist. In this case, diagnose and handle this issue accordingly.

Read binlog data

`read binlog event duration` refers to the duration that the relay log reads binlog from the upstream database (MySQL/MariaDB). Ideally, this metric is close to the network latency between DM-worker and MySQL/MariaDB instances.

- For data migration in one data center, reading binlog data is not a performance bottleneck. If the value of `read binlog event duration` is too large, check the network connection between DM-worker and MySQL/MariaDB.

- For data migration in the geo-distributed environment, try to deploy DM-worker and MySQL/MariaDB in one data center, while deploying the TiDB cluster in the target data center.

The process of reading binlog data from the upstream database includes the following sub-processes:

- The upstream MySQL/MariaDB reads the binlog data locally and sends it through the network. When no exception occurs in the MySQL/MariaDB load, this sub-process usually does not become a bottleneck.
- The binlog data is transferred from the machine where MySQL/MariaDB is located to the machine where DM-worker is located via the network. Whether this sub-process becomes a bottleneck mainly depends on the network connection between DM-worker and the upstream MySQL/MariaDB.
- DM-worker reads binlog data from the network data stream and constructs it as a binlog event. When no exception occurs in the DM-worker load, this sub-process usually does not become a bottleneck.

#### Note:

If the value of `read binlog event duration` is large, another possible reason is that the upstream MySQL/MariaDB has a low load. This means that no binlog event needs to be sent to DM for a period of time, and the relay log unit stays in a wait state, thus this value includes additional waiting time.

#### binlog data decoding and verification

After reading the binlog event into the DM memory, DM's relay processing unit decodes and verifies data. This usually does not lead to performance bottleneck; therefore, there is no related performance metric on the monitoring dashboard by default. If you need to view this metric, you can manually add a monitoring item in Grafana. This monitoring item corresponds to `dm_relay_read_transform_duration`, a metric from Prometheus.

#### Write relay log files

When writing a binlog event to a relay log file, the relevant performance metric is `write relay log duration`. This value should be microseconds when `binlog event size` is not too large. If `write relay log duration` is too large, check the write performance of the disk. To avoid low write performance, use local SSDs for DM-worker.

#### Load unit

The main operations of the Load unit are to read the SQL file data from the local and write it to the downstream. The related performance metric is `transaction execution`  $\leftrightarrow$  `latency`. If this value is too large, check the downstream performance by checking the

monitoring of the downstream database. You can also check whether there is a large network latency between DM and the downstream database.

#### Binlog replication unit

To diagnose performance issues in the Binlog replication unit, you can check the `binlog file gap between master and syncer` monitoring metric. For more information about this metric, refer to [monitoring metrics of the Binlog replication](#).

- If this metric is greater than 1 for a long time, it usually indicates that there is a performance issue.
- If this metric is 0, it usually indicates that there is no performance issue.

When `binlog file gap between master and syncer` is greater than 1 for a long time, check `binlog file gap between relay and syncer` to figure out which unit the latency mainly exists in. If this value is usually 0, the latency might exist in the relay log unit. Then you can refer to [relay log unit](#) to resolve this issue; otherwise, continue checking the Binlog replication unit.

#### Read binlog data

The Binlog replication unit decides whether to read the binlog event from the upstream MySQL/MariaDB or from the relay log file according to the configuration. The related performance metric is `read binlog event duration`, which generally ranges from a few microseconds to tens of microseconds.

- If DM's Binlog replication processing unit reads the binlog event from upstream MySQL/MariaDB, to locate and resolve the issue, refer to [read binlog data](#) in the “relay log unit” section.
- If DM's Binlog replication processing unit reads the binlog event from the relay log file, when `binlog event size` is not too large, the value of `read binlog event duration`  $\leftrightarrow$  should be microseconds. If `read binlog event duration` is too large, check the read performance of the disk. To avoid low write performance, use local SSDs for DM-worker.

#### binlog event conversion

The Binlog replication unit constructs DML, parses DDL, and performs [table router](#) conversion from binlog event data. The related metric is `transform binlog event duration`.

The duration is mainly affected by the write operations upstream. Take the `INSERT  $\leftrightarrow$  INTO` statement as an example, the time consumed to convert a single `VALUES` greatly differs from that to convert a lot of `VALUES`. The time consumed might range from tens of microseconds to hundreds of microseconds. However, usually this is not a bottleneck of the system.

#### Write SQL statements to downstream

When the Binlog replication unit writes the converted SQL statements to the downstream, the related performance metrics are `DML queue remain length` and `transaction execution latency`.

After constructing SQL statements from binlog event, DM uses `worker-count` queues to concurrently write these statements to the downstream. However, to avoid too many monitoring entries, DM performs the modulo 8 operation on the IDs of concurrent queues. This means that all concurrent queues correspond to one item from `q_0` to `q_7`.

`DML queue remain length` indicates in the concurrent processing queue, the number of DML statements that have not been consumed and have not started to be written downstream. Ideally, the curves corresponding to each `q_*` are almost the same. If not, it indicates that the concurrent load is extremely unbalanced.

If the load is not balanced, confirm whether tables need to be migrated have primary keys or unique keys. If these keys do not exist, add the primary keys or the unique keys; if these keys do exist while the load is not balanced, upgrade DM to v1.0.5 or later versions.

- When there is no noticeable latency in the entire data migration link, the corresponding curve of `DML queue remain length` is almost always 0, and the maximum does not exceed the value of `batch` in the task configuration file.
- If you find a noticeable latency in the data migration link, and the curve of `DML queue remain length` corresponding to each `q_*` is almost the same and is almost always 0, it means that DM fails to read, convert, or concurrently write the data from the upstream in time (the bottleneck might be in the relay log unit). For troubleshooting, refer to the previous sections of this document.

If the corresponding curve of `DML queue remain length` is not 0 (usually the maximum is not more than 1024), it indicates that there is a bottleneck when writing SQL statements to the downstream. You can use `transaction execution latency` to view the time consumed to execute a single transaction to the downstream.

`transaction execution latency` is usually tens of milliseconds. If this value is too large, check the downstream performance based on the monitoring of the downstream database. You can also check whether there is a large network latency between DM and the downstream database.

To view the time consumed to write a single statement such as `BEGIN`, `INSERT`, `UPDATE`, `DELETE`, or `COMMIT` to the downstream, you can also check `statement execution latency`.

#### 13.6.8.4 Manage Data Sources

##### 13.6.8.4.1 Switch DM-worker Connection between Upstream MySQL Instances

When the upstream MySQL instance that DM-worker connects to needs downtime maintenance or when the instance crashes unexpectedly, you need to switch the DM-worker connection to another MySQL instance within the same migration group.

**Note:**

- You can switch the DM-worker connection to only an instance within the same primary-secondary migration cluster.
- The MySQL instance to be newly connected to must have the binlog required by DM-worker.
- DM-worker must operate in the GTID sets mode, which means you must specify `enable-gtid: true` in the corresponding source configuration file.
- The connection switch only supports the following two scenarios. Strictly follow the procedures for each scenario. Otherwise, you might have to re-deploy the DM cluster according to the newly connected MySQL instance and perform the data migration task all over again.

For more details on GTID set, refer to [MySQL documentation](#).

**Switch DM-worker connection via virtual IP**

When DM-worker connects the upstream MySQL instance via a virtual IP (VIP), switching the VIP connection to another MySQL instance means switching the MySQL instance connected to DM-worker, without the upstream connection address changed.

**Note:**

Make necessary changes to DM in this scenario. Otherwise, when you switch the VIP connection to another MySQL instance, DM might connect to the new and old MySQL instances at the same time in different connections. In this situation, the binlog replicated to DM is not consistent with other upstream status that DM receives, causing unpredictable anomalies and even data damage.

To switch one upstream MySQL instance (when DM-worker connects to it via a VIP) to another, perform the following steps:

1. Use the `query-status` command to get the GTID sets (`syncerBinlogGtid`) corresponding to the binlog that the current processing unit of binlog replication has replicated to the downstream. Mark the sets as `gtid-S`.
2. Use the `SELECT @@GLOBAL.gtid_purged;` command on the new MySQL instance to get the GTID sets corresponding to the purged binlogs. Mark the sets as `gtid-P`.

3. Use the `SELECT @@GLOBAL.gtid_executed;` command on the new MySQL instance to get the GTID sets corresponding to all successfully executed transactions. Mark the sets as `gtid-E`.
4. Make sure that the following conditions are met. Otherwise, you cannot switch the DM-work connection to the new MySQL instance:
  - `gtid-S` contains `gtid-P`. `gtid-P` can be empty.
  - `gtid-E` contains `gtid-S`.
5. Use `pause-task` to pause all running tasks of data migration.
6. Change the VIP for it to direct at the new MySQL instance.
7. Use `resume-task` to resume the previous migration task.

Change the address of the upstream MySQL instance that DM-worker connects to

To make DM-worker connect to a new MySQL instance in the upstream by modifying the DM-worker configuration, perform the following steps:

1. Use the `query-status` command to get the GTID sets (`syncerBinlogGtid`) corresponding to the binlog that the current processing unit of binlog replication has replicated to the downstream. Mark this sets as `gtid-S`.
2. Use the `SELECT @@GLOBAL.gtid_purged;` command on the new MySQL instance to get the GTID sets corresponding to the purged binlogs. Mark this sets as `gtid-P`.
3. Use the `SELECT @@GLOBAL.gtid_executed;` command on the new MySQL instance to get the GTID sets corresponding to all successfully executed transactions. Mark this sets as `gtid-E`.
4. Make sure that the following conditions are met. Otherwise, you cannot switch the DM-work connection to the new MySQL instance:
  - `gtid-S` contains `gtid-P`. `gtid-P` can be empty.
  - `gtid-E` contains `gtid-S`.
5. Use `stop-task` to stop all running tasks of data migration.
6. Use the `operator-source stop` command to remove the source configuration corresponding to the address of the old MySQL instance from the DM cluster.
7. Update the address of the MySQL instance in the source configuration file and use the `operate-source create` command to reload the new source configuration in the DM cluster.
8. Use `start-task` to restart the migration task.

### 13.6.8.5 Manage Tasks

#### 13.6.8.5.1 Handle Failed DDL Statements in TiDB Data Migration

This document introduces how to handle failed DDL statements when you're using the TiDB Data Migration (DM) tool to migrate data.

Currently, TiDB is not completely compatible with all MySQL syntax (see [the DDL statements supported by TiDB](#)). Therefore, when DM is migrating data from MySQL to TiDB and TiDB does not support the corresponding DDL statement, an error might occur and break the migration process. In this case, you can use the `binlog` command of DM to resume the migration.

### Restrictions

Do not use this command in the following situations:

- It is unacceptable in the actual production environment that the failed DDL statement is skipped in the downstream TiDB.
- The failed DDL statement cannot be replaced with other DDL statements.
- Other DDL statements must not be injected into the downstream TiDB.

For example, `DROP PRIMARY KEY`. In this scenario, you can only create a new table in the downstream with the new table schema (after executing the DDL statement), and re-import all the data into this new table.

### Supported scenarios

During the migration, the DDL statement unsupported by TiDB is executed in the upstream and migrated to the downstream, and as a result, the migration task gets interrupted.

- If it is acceptable that this DDL statement is skipped in the downstream TiDB, then you can use `binlog skip <task-name>` to skip migrating this DDL statement and resume the migration.
- If it is acceptable that this DDL statement is replaced with other DDL statements, then you can use `binlog replace <task-name>` to replace this DDL statement and resume the migration.
- If it is acceptable that other DDL statements are injected to the downstream TiDB, then you can use `binlog inject <task-name>` to inject other DDL statements and resume the migration.

### Commands

When you use `dmctl` to manually handle the failed DDL statements, the commonly used commands include `query-status` and `binlog`.

#### `query-status`

The `query-status` command is used to query the current status of items such as the subtask and the relay unit in each MySQL instance. For details, see [query status](#).

#### `binlog`

The `binlog` command is used to manage and show binlog operations. This command is only supported in DM v6.0 and later versions. For earlier versions, use the `handle-error` command.

The usage of `binlog` is as follows:

```
binlog -h
```

manage or show binlog operations

Usage:

```
dmctl binlog [command]
```

Available Commands:

```
inject inject the current error event or a specific binlog position (
 ↪ binlog-pos) with some ddls
list list error handle command at binlog position (binlog-pos) or
 ↪ after binlog position (binlog-pos)
replace replace the current error event or a specific binlog position (
 ↪ binlog-pos) with some ddls
revert revert the current binlog operation or a specific binlog
 ↪ position (binlog-pos) operation
skip skip the current error event or a specific binlog position (
 ↪ binlog-pos) event
```

Flags:

```
-b, --binlog-pos string position used to match binlog event if matched the
 ↪ binlog operation will be applied. The format like "mysql-bin
 ↪ |000001.000003:3270"
-h, --help help for binlog
```

Global Flags:

```
-s, --source strings MySQL Source ID.
```

Use "dmctl binlog [command] --help" for more information about a command.

binlog supports the following sub-commands:

- **inject**: injects DDL statements into the current error event or a specific binlog position. To specify the binlog position, refer to **-b**, **--binlog-pos**.
- **list**: lists all valid **inject**, **skip**, and **replace** operations at the current binlog position or after the current binlog position. To specify the binlog position, refer to **-b**, **--binlog-pos**.
- **replace**: replaces the DDL statement at a specific binlog position with another DDL statement. To specify the binlog position, refer to **-b**, **--binlog-pos**.
- **revert**: reverts the **inject**, **skip** or **replace** operation at a specified binlog operation, only if the previous operation does not take effect. To specify the binlog position, refer to **-b**, **--binlog-pos**.
- **skip**: skips the DDL statement at a specific binlog position. To specify the binlog position, refer to **-b**, **--binlog-pos**.

binlog supports the following flags:

- **-b, --binlog-pos:**
  - Type: string.
  - Specifies a binlog position. When the position of the binlog event matches `binlog` ↪ `-pos`, the operation is executed. If it is not specified, DM automatically sets `binlog-pos` to the currently failed DDL statement.
  - Format: `binlog-filename:binlog-pos`, for example, `mysql-bin|000001.000003:3270` ↪ `.`
  - After the migration returns an error, the binlog position can be obtained from `position` in `startLocation` returned by `query-status`. Before the migration returns an error, the binlog position can be obtained by using `SHOW BINLOG` ↪ `EVENTS` in the upstream MySQL instance.
- **-s, --source:**
  - Type: string.
  - Specifies the MySQL instance in which the preset operation is to be executed.

Usage examples

Skip DDL if the migration gets interrupted

If you need to skip the DDL statement when the migration gets interrupted, run the `binlog skip` command:

```
binlog skip -h
```

```
skip the current error event or a specific binlog position (binlog-pos)
↪ event
```

Usage:

```
dmctl binlog skip <task-name> [flags]
```

Flags:

```
-h, --help help for skip
```

Global Flags:

```
-b, --binlog-pos string position used to match binlog event if matched the
↪ binlog operation will be applied. The format like "mysql-bin
↪ |000001.000003:3270"
-s, --source strings MySQL Source ID.
```

Non-shard-merge scenario

Assume that you need to migrate the upstream table `db1.tb11` to the downstream TiDB. The initial table schema is:

```
SHOW CREATE TABLE db1.tbl1;
```

```
+-----+-----+
| Table | Create Table |
+-----+-----+
| tbl1 | CREATE TABLE `tbl1` (
 `c1` int(11) NOT NULL,
 `c2` decimal(11,3) DEFAULT NULL,
 PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-----+-----+
```

Now, the following DDL statement is executed in the upstream to alter the table schema (namely, alter DECIMAL(11, 3) of c2 into DECIMAL(10, 3)):

```
ALTER TABLE db1.tbl1 CHANGE c2 c2 DECIMAL (10, 3);
```

Because this DDL statement is not supported by TiDB, the migration task of DM gets interrupted. Execute the `query-status <task-name>` command, and you can see the following error:

```
ERROR 8200 (HY000): Unsupported modify column: can't change decimal column
↳ precision
```

Assume that it is acceptable in the actual production environment that this DDL statement is not executed in the downstream TiDB (namely, the original table schema is retained). Then you can use `binlog skip <task-name>` to skip this DDL statement to resume the migration. The procedures are as follows:

1. Execute `binlog skip <task-name>` to skip the currently failed DDL statement:

```
» binlog skip test
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

2. Execute `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "sourceStatus": {
 "source": "mysql-replica-01",
 "worker": "worker1",
 "result": null,
 "relayStatus": null
 },
 "subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 "masterBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-10",
 "syncerBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-4",
 "blockingDDLs": [
],
 "unresolvedGroups": [
],
 "synced": true,
 "binlogType": "remote",
 "totalRows": "4",
 "totalRps": "0",
 "recentRps": "0"
 }
 }
]
 }
]
}
```

```

]
 }
]
}

```

You can see that the task runs normally and the wrong DDL is skipped.

### Shard merge scenario

Assume that you need to merge and migrate the following four tables in the upstream to one same table `shard\_db`.`shard\_table` in the downstream. The task mode is “pessimistic”.

- MySQL instance 1 contains the `shard_db_1` schema, which includes the `shard_table_1` and `shard_table_2` tables.
- MySQL instance 2 contains the `shard_db_2` schema, which includes the `shard_table_1` and `shard_table_2` tables.

The initial table schema is:

```
SHOW CREATE TABLE shard_db.shard_table;
```

```

+--
 ↪ -----+-----
 ↪
| Table | Create Table
 ↪
 ↪ |
+--
 ↪ -----+-----
 ↪
| tb | CREATE TABLE `shard_table` (
 `id` int(11) DEFAULT NULL,
 PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
 ↪ -----+-----
 ↪

```

Now, execute the following DDL statement to all upstream sharded tables to alter their character set:

```
ALTER TABLE `shard_db_*`.`shard_table_*` CHARACTER SET LATIN1 COLLATE
 ↪ LATIN1_DANISH_CI;
```

Because this DDL statement is not supported by TiDB, the migration task of DM gets interrupted. Execute the `query-status` command, and you can see the following errors reported by the `shard_db_1.shard_table_1` table in MySQL instance 1 and the `shard_db_2 ↔ .shard_table_1` table in MySQL instance 2:

```
{
 "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_1`
 ↔ CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
 "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

```
{
 "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_1`
 ↔ CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
 "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

Assume that it is acceptable in the actual production environment that this DDL statement is not executed in the downstream TiDB (namely, the original table schema is retained). Then you can use `binlog skip <task-name>` to skip this DDL statement to resume the migration. The procedures are as follows:

1. Execute `binlog skip <task-name>` to skip the currently failed DDL statements in MySQL instance 1 and 2:

```
» binlog skip test
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 },
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-02",
 "worker": "worker2"
 }
]
}
```

- Execute the `query-status` command, and you can see the errors reported by the `shard_db_1.shard_table_2` table in MySQL instance 1 and the `shard_db_2.shard_table_2` table in MySQL instance 2:

```
{
 "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`
 ↪ shard_table_2` CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
 "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to
 ↪ utf8"
}
```

```
{
 "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`
 ↪ shard_table_2` CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
 "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to
 ↪ utf8"
}
```

- Execute `binlog skip <task-name>` again to skip the currently failed DDL statements in MySQL instance 1 and 2:

```
» handle-error test skip
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 },
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-02",
 "worker": "worker2"
 }
]
}
```

- Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "sourceStatus": {
 "source": "mysql-replica-01",
 "worker": "worker1",
 "result": null,
 "relayStatus": null
 },
 "subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 "masterBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-10",
 "syncerBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-4",
 "blockingDDLs": [
],
 "unresolvedGroups": [
],
 "synced": true,
 "binlogType": "remote",
 "totalRows": "4",
 "totalRps": "0",
 "recentRps": "0"
 }
 }
]
 }
],
 {
```

```
"result": true,
"msg": "",
"sourceStatus": {
 "source": "mysql-replica-02",
 "worker": "worker2",
 "result": null,
 "relayStatus": null
},
"subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 "masterBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-10",
 "syncerBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-4",
 "blockingDDLs": [
],
 "unresolvedGroups": [
],
 "synced": true,
 "binlogType": "remote",
 "totalRows": "4",
 "totalRps": "0",
 "recentRps": "0"
 }
 }
]
}
```

You can see that the task runs normally with no error and all four wrong DDL statements are skipped.

Replace DDL if the migration gets interrupted

If you need to replace the DDL statement when the migration gets interrupted, run the `binlog replace` command:

```
binlog replace -h
```

```
replace the current error event or a specific binlog position (binlog-pos)
 ↪ with some ddls
```

Usage:

```
dmctl binlog replace <task-name> <replace-sql1> <replace-sql2>... [flags]
```

Flags:

```
-h, --help help for replace
```

Global Flags:

```
-b, --binlog-pos string position used to match binlog event if matched the
 ↪ binlog operation will be applied. The format like "mysql-bin
 ↪ |000001.000003:3270"
-s, --source strings MySQL Source ID.
```

Non-shard-merge scenario

Assume that you need to migrate the upstream table `db1.tb11` to the downstream TiDB. The initial table schema is:

```
SHOW CREATE TABLE db1.tb11;
```

```
+--
 ↪ -----+-----
 ↪
| Table | Create Table
 ↪
 ↪ |
+--
 ↪ -----+-----
 ↪
| tb | CREATE TABLE `tb11` (
 ↪ `id` int(11) DEFAULT NULL,
 ↪ PRIMARY KEY (`id`)
 ↪) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
 ↪ -----+-----
 ↪
```

Now, perform the following DDL operation in the upstream to add a new column with the UNIQUE constraint:

```
ALTER TABLE `db1`.`tbl1` ADD COLUMN new_col INT UNIQUE;
```

Because this DDL statement is not supported by TiDB, the migration task gets interrupted. Execute the `query-status` command, and you can see the following error:

```
{
 "Message": "cannot track DDL: ALTER TABLE `db1`.`tbl1` ADD COLUMN `
 ↳ new_col` INT UNIQUE KEY",
 "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
 ↳ UNIQUE KEY when altering 'db1.tbl1'",
}
```

You can replace this DDL statement with two equivalent DDL statements. The steps are as follows:

1. Replace the wrong DDL statement by the following command:

```
» binlog replace test "ALTER TABLE `db1`.`tbl1` ADD COLUMN `new_col`
 ↳ INT;ALTER TABLE `db1`.`tbl1` ADD UNIQUE(`new_col`);"
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

2. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",

```

```

"sourceStatus": {
 "source": "mysql-replica-01",
 "worker": "worker1",
 "result": null,
 "relayStatus": null
},
"subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
 ↪ 2388)",
 "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-10",
 "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
 ↪ 2388)",
 "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-4",
 "blockingDDLs": [
],
 "unresolvedGroups": [
],
 "synced": true,
 "binlogType": "remote",
 "totalRows": "4",
 "totalRps": "0",
 "recentRps": "0"
 }
 }
]
}

```

You can see that the task runs normally and the wrong DDL statement is replaced by new DDL statements that execute successfully.

### Shard merge scenario

Assume that you need to merge and migrate the following four tables in the upstream to one same table `shard\_db`.`shard\_table` in the downstream. The task mode is “pessimistic”.

- In the MySQL instance 1, there is a schema `shard_db_1`, which has two tables `shard_table_1` and `shard_table_2`.
- In the MySQL instance 2, there is a schema `shard_db_2`, which has two tables `shard_table_1` and `shard_table_2`.

The initial table schema is:

```
SHOW CREATE TABLE shard_db.shard_table;
```

```
+--
 ↪ -----+-----
 ↪
| Table | Create Table
 ↪
 ↪ |
+--
 ↪ -----+-----
 ↪
| tb | CREATE TABLE `shard_table` (
 `id` int(11) DEFAULT NULL,
 PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
 ↪ -----+-----
 ↪
```

Now, perform the following DDL operation to all upstream sharded tables to add a new column with the UNIQUE constraint:

```
ALTER TABLE `shard_db_*`.`shard_table_*` ADD COLUMN new_col INT UNIQUE;
```

Because this DDL statement is not supported by TiDB, the migration task gets interrupted. Execute the `query-status` command, and you can see the following errors reported by the `shard_db_1.shard_table_1` table in MySQL instance 1 and the `shard_db_2.shard_table_1` table in MySQL instance 2:

```
{
 "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_1`
 ↪ ADD COLUMN `new_col` INT UNIQUE KEY",
 "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
 ↪ UNIQUE KEY when altering 'shard_db_1.shard_table_1'",
}
```

```
{
 "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_1`
 ↪ ADD COLUMN `new_col` INT UNIQUE KEY",
}
```

```
"RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
 ↳ UNIQUE KEY when altering 'shard_db_2.shard_table_1'",
}
```

You can replace this DDL statement with two equivalent DDL statements. The steps are as follows:

1. Replace the wrong DDL statements respectively in MySQL instance 1 and MySQL instance 2 by the following commands:

```
» binlog replace test -s mysql-replica-01 "ALTER TABLE `shard_db_1`.`
 ↳ shard_table_1` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_1
 ↳`.`shard_table_1` ADD UNIQUE(`new_col`)"
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

```
» binlog replace test -s mysql-replica-02 "ALTER TABLE `shard_db_2`.`
 ↳ shard_table_1` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_2
 ↳`.`shard_table_1` ADD UNIQUE(`new_col`)"
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-02",
 "worker": "worker2"
 }
]
}
```

- Use `query-status <task-name>` to view the task status, and you can see the following errors reported by the `shard_db_1.shard_table_2` table in MySQL instance 1 and the `shard_db_2.shard_table_2` table in MySQL instance 2:

```
{
 "Message": "detect inconsistent DDL sequence from source ... ddls:
 ↪ [ALTER TABLE `shard_db`.`tb` ADD COLUMN `new_col` INT UNIQUE
 ↪ KEY] source: `shard_db_1`.`shard_table_2`, right DDL
 ↪ sequence should be ..."
}
```

```
{
 "Message": "detect inconsistent DDL sequence from source ... ddls:
 ↪ [ALTER TABLE `shard_db`.`tb` ADD COLUMN `new_col` INT UNIQUE
 ↪ KEY] source: `shard_db_2`.`shard_table_2`, right DDL
 ↪ sequence should be ..."
}
```

- Execute `handle-error <task-name> replace` again to replace the wrong DDL statements in MySQL instance 1 and 2:

```
» binlog replace test -s mysql-replica-01 "ALTER TABLE `shard_db_1`.`
 ↪ shard_table_2` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_1
 ↪`.`shard_table_2` ADD UNIQUE(`new_col`);"
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

```
» binlog replace test -s mysql-replica-02 "ALTER TABLE `shard_db_2`.`
 ↪ shard_table_2` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_2
 ↪`.`shard_table_2` ADD UNIQUE(`new_col`);"
```

```
{
 "result": true,
 "msg": "",
```

```
"sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-02",
 "worker": "worker2"
 }
]
```

4. Use `query-status <task-name>` to view the task status:

```
> query-status test
```

See the execution result.

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "sourceStatus": {
 "source": "mysql-replica-01",
 "worker": "worker1",
 "result": null,
 "relayStatus": null
 },
 "subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 "masterBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-10",
 "syncerBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-4",
 "blockingDDLs": [

```

```
],
 "unresolvedGroups": [
],
 "unresolvedGroups": [
],
 "synced": true,
 "binlogType": "remote",
 "totalRows": "4",
 "totalRps": "0",
 "recentRps": "0"
 }
}
]
},
{
 "result": true,
 "msg": "",
 "sourceStatus": {
 "source": "mysql-replica-02",
 "worker": "worker2",
 "result": null,
 "relayStatus": null
 },
 "subTaskStatus": [
 {
 "name": "test",
 "stage": "Running",
 "unit": "Sync",
 "result": null,
 "unresolvedDDLLockID": "",
 "sync": {
 "masterBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-10",
 "syncerBinlog": "(DESKTOP-T561TS0-bin.000001,
 ↪ 2388)",
 "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
 ↪ de45f57:1-4",
 "blockingDDLs": [
],
 "unresolvedGroups": [
],
 "unresolvedGroups": [
],

```

```

 "synced": try,
 "binlogType": "remote",
 "totalRows": "4",
 "totalRps": "0",
 "recentRps": "0"
 }
}
]
}
]
}

```

You can see that the task runs normally with no error and all four wrong DDL statements are replaced.

#### Other commands

For the usage of other commands of `binlog`, refer to the `binlog skip` and `binlog replace` examples above.

### 13.6.8.5.2 Manage Table Schemas of Tables to Be Migrated Using TiDB Data Migration

This document describes how to manage the schema of the table in DM during migration using `dmctl`.

When DM performs incremental replication, it first reads the upstream binlog, then creates SQL statements and executes them in the downstream. However, the upstream binlog does not contain the complete table schema. To generate the SQL statements, DM maintains internally the schema information of the table to be migrated. This is called the internal table schema.

To deal with some special occasions, or to handle migration interruptions caused by mismatch of the table schemas, DM provides the `binlog-schema` command to obtain, modify, and delete the internal table schema.

#### Implementation principles

The internal table schema comes from the following sources:

- For full data migration (`task-mode=all`), the migration task goes through three stages: dump/load/sync, which means full export, full import, and incremental replication. In the dump stage, DM exports the table schema information along with the data and automatically creates the corresponding table in the downstream. In the sync stage, this table schema is used as the starting table scheme for incremental replication.
- In the sync stage, when DM handles DDL statements such as `ALTER TABLE`, it updates the internal table schema at the same time.

- If the task is an incremental migration (`task-mode=incremental`), in which the downstream has completed creating the table to be migrated, DM obtains the table schema information from the downstream database. This behavior varies with DM versions.

For incremental replication, schema maintenance is complicated. During the whole data replication, the following four table schemas are involved. These schemas might be the consistent or inconsistent with one another:

Figure 258: schema

- The upstream table schema at the current time, identified as `schema-U`.
- The table schema of the binlog event currently being consumed by DM, identified as `schema-B`. This schema corresponds to the upstream table schema at a historical time.
- The table schema currently maintained in DM (the schema tracker component), identified as `schema-I`.
- The table schema in the downstream TiDB cluster, identified as `schema-D`.

In most cases, the preceding four table schemas are consistent.

When the upstream database performs a DDL operation to change the table schema, `schema-U` is changed. By applying the DDL operation to the internal schema tracker component and the downstream TiDB cluster, DM updates `schema-I` and `schema-D` in an orderly manner to keep them consistent with `schema-U`. Therefore, DM can then normally consume the binlog event corresponding to the `schema-B` table schema. That is, after the DDL operation is successfully migrated, `schema-U`, `schema-B`, `schema-I`, and `schema-D` are still consistent.

Note the following situations that might cause inconsistency:

- During the migration with [optimistic mode sharding DDL support](#) enabled, the `schema-D` of the downstream table might be inconsistent with the `schema-B` and `schema-I` of some upstream sharded tables. In such cases, DM still keeps `schema-I` and `schema-B` consistent to ensure that the binlog event corresponding to DML can be parsed normally.
- When the downstream table has more columns than the upstream table, `schema-D` might be inconsistent with `schema-B` and `schema-I`. In the full data migration (`task-mode=all`), DM automatically handles inconsistency. In the incremental migration (`task-mode=incremental`), because the task is on a first start and there is no internal schema information yet, DM automatically reads the downstream schema (`schema-D`) and updates `schema-I` (this behavior varies with DM versions). After that, if DM uses `schema-I` to parse `schema-B`'s binlog, it will report `Column count doesn't match value count` error. For details, refer to [Migrate Data to a Downstream TiDB Table with More Columns](#).

You can run the `binlog-schema` command to obtain, modify, or delete the `schema-I` table schema maintained in DM.

#### Note:

The `binlog-schema` command is supported only in DM v6.0 or later versions. For earlier versions, you must use the `operate-schema` command.

#### Command

```
help binlog-schema
```

```
manage or show table schema in schema tracker
```

#### Usage:

```
dmctl binlog-schema [command]
```

#### Available Commands:

```
delete delete table schema structure
list show table schema structure
update update tables schema structure
```

#### Flags:

```
-h, --help help for binlog-schema
```

#### Global Flags:

```
-s, --source strings MySQL Source ID.
```

Use "dmctl binlog-schema [command] --help" for more information about a  
↔ command.

#### Note:

- Because a table schema might change during data migration, to obtain a predictable table schema, currently the `binlog-schema` command can be used only when the data migration task is in the `Paused` state.
- To avoid data loss due to mishandling, it is **strongly recommended** to get and backup the table schema firstly before you modify the schema.

#### Parameters

- `delete`: Deletes the table schema.
- `list`: Lists the table schema.
- `update`: Updates the table schema.
- `-s` or `--source`:
  - Required.
  - Specifies the MySQL source that the operation is applied to.

#### Usage example

Get the table schema

To get the table schema, run the `binlog-schema list` command:

```
help binlog-schema list
```

```
show table schema structure
```

**Usage:**

```
dmctl binlog-schema list <task-name> <database> <table> [flags]
```

**Flags:**

```
-h, --help help for list
```

**Global Flags:**

```
-s, --source strings MySQL Source ID.
```

If you want to get the table schema of the ``db_single`.`t1`` table corresponding to the `mysql-replica-01` MySQL source in the `db_single` task, run the following command:

```
binlog-schema list -s mysql-replica-01 task_single db_single t1
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "CREATE TABLE `t1` (`c1` int(11) NOT NULL, `c2` int(11)
 ↪ DEFAULT NULL, PRIMARY KEY (`c1`)) ENGINE=InnoDB DEFAULT
 ↪ CHARSET=latin1 COLLATE=latin1_bin",
 "source": "mysql-replica-01",
 "worker": "127.0.0.1:8262"
 }
]
}
```

Update the table schema

To update the table schema, run the `binlog-schema update` command:

```
help binlog-schema update
```

```
update tables schema structure
```

**Usage:**

```
dmctl binlog-schema update <task-name> <database> <table> [schema-file] [
 ↪ flags]
```

**Flags:**

```
--flush flush the table info and checkpoint immediately (default
 ↪ true)
--from-source use the schema from upstream database as the schema of
 ↪ the specified tables
```

```
--from-target use the schema from downstream database as the schema of
 ↪ the specified tables
-h, --help help for update
--sync sync the table info to master to resolve shard ddl lock,
 ↪ only for optimistic mode now (default true)
```

Global Flags:

```
-s, --source strings MySQL Source ID.
```

If you want to set the table schema of the ``db_single`.`t1`` table corresponding to the `mysql-replica-01` MySQL source in the `db_single` task as follows:

```
CREATE TABLE `t1` (
 `c1` int(11) NOT NULL,
 `c2` bigint(11) DEFAULT NULL,
 PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin
```

Save the `CREATE TABLE` statement above as a file (for example, `db_single.t1-schema.sql`), and run the following command:

```
operate-schema set -s mysql-replica-01 task_single -d db_single -t t1
 ↪ db_single.t1-schema.sql
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "127.0.0.1:8262"
 }
]
}
```

Delete the table schema

To delete the table schema, run the `binlog-schema delete` command:

```
help binlog-schema delete
```

```
delete table schema structure
```

Usage:

```
dmctl binlog-schema delete <task-name> <database> <table> [flags]
```

**Flags:**

```
-h, --help help for delete
```

**Global Flags:**

```
-s, --source strings MySQL Source ID.
```

**Note:**

After the table schema maintained in DM is deleted, if a DDL/DML statement related to this table needs to be migrated to the downstream, DM will try to get the table schema from the following three sources in an orderly manner:

- The `table_info` field in the checkpoint table
- The meta information in the optimistic sharding DDL
- The corresponding table in the downstream TiDB

If you want to delete the table schema of the ``db_single`.`t1`` table corresponding to the `mysql-replica-01` MySQL source in the `db_single` task, run the following command:

```
binlog-schema delete -s mysql-replica-01 task_single db_single t1
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "127.0.0.1:8262"
 }
]
}
```

### 13.6.8.6 Export and Import Data Sources and Task Configuration of Clusters

`config` command is used to export and import data sources and task configuration of clusters.

**Note:**

For clusters earlier than v2.0.5, you can use dmctl v2.0.5 or later to export and import the data source and task configuration files.

```
» help config
Commands to import/export config
Usage:
 dmctl config [command]
Available Commands:
 export Export the configurations of sources and tasks.
 import Import the configurations of sources and tasks.
Flags:
 -h, --help help for config
Global Flags:
 -s, --source strings MySQL Source ID.
Use "dmctl config [command] --help" for more information about a command.
```

### 13.6.8.6.1 Export the data source and task configuration of clusters

You can use `export` command to export the data source and task configuration of clusters to specified files.

```
config export [--dir directory]
```

Parameter explanation

- `dir`:
  - optional
  - specifies the file path for exporting
  - the default value is `./configs`

Returned results

```
config export -d /tmp/configs
```

```
export configs to directory `/tmp/configs` succeed
```

### 13.6.8.6.2 import the data source and task configuration of clusters

You can use `import` command to import the data source and task configuration of clusters from specified files.

```
config import [--dir directory]
```

#### Note:

For clusters later than v2.0.2, currently, it is not supported to automatically import the configuration related to relay worker. You can use `start-relay` command to manually [start relay log](#).

#### Parameter explanation

- `dir`:
  - optional
  - specifies the file path for importing
  - the default value is `./configs`

#### Returned results

```
config import -d /tmp/configs
```

```
start creating sources
start creating tasks
import configs from directory `/tmp/configs` succeed
```

### 13.6.8.7 Handle Alerts in TiDB Data Migration

This document introduces how to deal with the alert information in DM.

#### 13.6.8.7.1 Alerts related to high availability

##### DM\_master\_all\_down

- Description:

If all DM-master nodes are offline, this alert is triggered.
- Solution:

You can take the following steps to handle the alert:

1. Check the environment of the cluster.
2. Check the logs of all DM-master nodes for troubleshooting.

#### DM\_worker\_offline

- Description:  
If a DM-worker node is offline for more than one hour, this alert is triggered. In a high-availability architecture, this alert might not directly interrupt the task but increases the risk of interruption.
- Solution:  
You can take the following steps to handle the alert:
  1. View the working status of the corresponding DM-worker node.
  2. Check whether the node is connected.
  3. Troubleshoot errors through logs.

#### DM\_DDL\_error

- Description:  
This error occurs when DM is processing the sharding DDL operations.
- Solution:  
Refer to [Troubleshoot DM](#).

#### DM\_pending\_DDL

- Description:  
If a sharding DDL operation is pending for more than one hour, this alert is triggered.
- Solution:  
In some scenarios, the pending sharding DDL operation might be what users expect. Otherwise, refer to [Handle Sharding DDL Locks Manually in DM](#) for solution.

### 13.6.8.7.2 Alert rules related to task status

#### DM\_task\_state

- Description:  
When a sub-task of DM-worker is in the `Paused` state for over 20 minutes, an alert is triggered.
- Solution:  
Refer to [Troubleshoot DM](#).

### 13.6.8.7.3 Alert rules related to relay log

#### DM\_relay\_process\_exits\_with\_error

- Description:

When the relay log processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

Refer to [Troubleshoot DM](#).

#### DM\_remain\_storage\_of\_relay\_log

- Description:

When the free space of the disk where the relay log is located is less than 10G, an alert is triggered.

- Solutions:

You can take the following methods to handle the alert:

- Delete unwanted data manually to increase free disk space.
- Reconfigure the [automatic data purge strategy of the relay log](#) or [purge data manually](#).
- Execute the command `pause-relay` to pause the relay log pulling process. After there is enough free disk space, resume the process by running the command `resume-relay`. Note that you must not purge upstream binlog files that have not been pulled after the relay log pulling process is paused.

#### DM\_relay\_log\_data\_corruption

- Description:

When the relay log processing unit validates the binlog event read from the upstream and detects abnormal checksum information, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

Refer to [Troubleshoot DM](#).

#### DM\_fail\_to\_read\_binlog\_from\_master

- Description:  
If an error occurs when the relay log processing unit tries to read the binlog event from the upstream, this unit moves to the **Paused** state, and an alert is triggered.
- Solution:  
Refer to [Troubleshoot DM](#).

#### DM\_fail\_to\_write\_relay\_log

- Description:  
If an error occurs when the relay log processing unit tries to write the binlog event into the relay log file, this unit moves to the **Paused** state, and an alert is triggered.
- Solution:  
Refer to [Troubleshoot DM](#).

#### DM\_binlog\_file\_gap\_between\_master\_relay

- Description:  
When the number of the binlog files in the current upstream MySQL/MariaDB exceeds that of the latest binlog files pulled by the relay log processing unit by **more than 1** for 10 minutes, and an alert is triggered.
- Solution:  
Refer to [Troubleshoot DM](#).

### 13.6.8.7.4 Alert rules related to Dump/Load

#### DM\_dump\_process\_exists\_with\_error

- Description:  
When the Dump processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.
- Solution:  
Refer to [Troubleshoot DM](#).

#### DM\_load\_process\_exists\_with\_error

- Description:

When the Load processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

Refer to [Troubleshoot DM](#).

#### 13.6.8.7.5 Alert rules related to binlog replication

##### DM\_sync\_process\_exists\_with\_error

- Description:

When the binlog replication processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

Refer to [Troubleshoot DM](#).

##### DM\_binlog\_file\_gap\_between\_master\_syncer

- Description:

When the number of the binlog files in the current upstream MySQL/MariaDB exceeds that of the latest binlog files processed by the relay log processing unit by **more than** 1 for 10 minutes, an alert is triggered.

- Solution:

Refer to [Handle Performance Issues](#).

##### DM\_binlog\_file\_gap\_between\_relay\_syncer

- Description:

When the number of the binlog files in the current relay log processing unit exceeds that of the latest binlog files processed by the binlog replication processing unit by **more than** 1 for 10 minutes, an alert is triggered.

- Solution:

Refer to [Handle Performance Issues](#).

### 13.6.8.8 Daily Check for TiDB Data Migration

This document summarizes how to perform a daily check on TiDB Data Migration (DM).

- Method 1: Execute the `query-status` command to check the running status of the task and the error output (if any). For details, see [Query Status](#).
- Method 2: If Prometheus and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. For example, suppose that the Grafana's address is `172.16.10.71`, go to <http://172.16.10.71:3000>, enter the Grafana dashboard, and select the DM Dashboard to check monitoring metrics of DM. For more information of these metrics, see [DM Monitoring Metrics](#).
- Method 3: Check the running status of DM and the error (if any) using the log file.
  - DM-master log directory: It is specified by the `--log-file` DM-master process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-master node.
  - DM-worker log directory: It is specified by the `--log-file` DM-worker process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-worker node.

## 13.6.9 Reference

### 13.6.9.1 Architecture

#### 13.6.9.1.1 DM-worker Introduction

DM-worker is a tool used to migrate data from MySQL/MariaDB to TiDB.

It has the following features:

- Acts as a secondary database of any MySQL or MariaDB instance
- Reads the binlog events from MySQL/MariaDB and persists them to the local storage
- A single DM-worker supports migrating the data of one MySQL/MariaDB instance to multiple TiDB instances
- Multiple DM-workers support migrating the data of multiple MySQL/MariaDB instances to one TiDB instance

DM-worker processing unit

A DM-worker task contains multiple logic units, including relay log, the dump processing unit, the load processing unit, and binlog replication.

Relay log

The relay log persistently stores the binlog data from the upstream MySQL/MariaDB and provides the feature of accessing binlog events for the binlog replication.

Its rationale and features are similar to the relay log of MySQL. For details, see [MySQL Relay Log](#).

#### Dump processing unit

The dump processing unit dumps the full data from the upstream MySQL/MariaDB to the local disk.

#### Load processing unit

The load processing unit reads the dumped files of the dump processing unit and then loads these files to the downstream TiDB.

#### Binlog replication/sync processing unit

Binlog replication/sync processing unit reads the binlog events of the upstream MySQL/MariaDB or the binlog events of the relay log, transforms these events to SQL statements, and then applies these statements to the downstream TiDB.

#### Privileges required by DM-worker

This section describes the upstream and downstream database users' privileges required by DM-worker, and the user privileges required by the respective processing unit.

#### Upstream database user privileges

The upstream database (MySQL/MariaDB) user must have the following privileges:

Privilege	Scope
SELECT	Tables
RELOAD	Global
REPLICATION SLAVE	Global
REPLICATION CLIENT	Global

If you need to migrate the data from db1 to TiDB, execute the following GRANT statement:

```
GRANT RELOAD,REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO 'your_user'@'
↳ your_wildcard_of_host'
GRANT SELECT ON db1.* TO 'your_user'@'your_wildcard_of_host';
```

If you also need to migrate the data from other databases into TiDB, make sure the same privileges are granted to the user of the respective databases.

#### Downstream database user privileges

The downstream database (TiDB) user must have the following privileges:

Privilege	Scope
SELECT	Tables
INSERT	Tables
UPDATE	Tables

Privilege	Scope
DELETE	Tables
CREATE	Databases, tables
DROP	Databases, tables
ALTER	Tables
INDEX	Tables

Execute the following GRANT statement for the databases or tables that you need to migrate:

```
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,ALTER,INDEX ON db.table TO '
 ↪ your_user'@'your_wildcard_of_host';
GRANT ALL ON dm_meta.* TO 'your_user'@'your_wildcard_of_host';
```

Minimal privilege required by each processing unit

	Minimal upstream (MySQL/MariaDB) privilege	Minimal downstream (TiDB) privilege	Minimal sys- tem privi- lege
Relay log	REPLICATION SLAVE (reads the binlog) REPLICATION ↪ CLIENT (show master ↪ status, show slave status)	NULL	Read/Write local files
Dump	SELECTRELOAD (flushes tables with Read lock and unlocks tables )	NULL	Write local files
Load	NULL	SELECT (Query the checkpoint his- tory) CREATE (creates a database/table) DELETE ↪ (deletes check- point) INSERT (Inserts the Dump data)	Read/Write local files

Processing unit	Minimal upstream MySQL/MariaDB privilege	Minimal downstream (TiDB) privilege	Minimal system privilege
Binlog replication	REPLICATION SLAVE (reads the binlog) REPLICATION CLIENT (show master status, show slave status)	SELECT (shows the index and column) INSERT (DML) UPDATE DELETE CREATE (creates a database/table) DROP (drops databases/tables) ALTER (alters a table) INDEX (creates/-drops an index)	Read/Write local files

**Note:**

These privileges are not immutable and they change as the request changes.

### 13.6.9.1.2 DM Safe Mode

Safe mode is a special operation mode for DM to perform incremental replication. In safe mode, when the DM incremental replication component replicates binlog events, DM forcibly rewrites all the `INSERT` and `UPDATE` statements before executing them in the downstream.

During safe mode, one binlog event can be replicated repeatedly to the downstream with idempotence guaranteed. Thus, the incremental replication is *safe*.

After resuming a data replication task from a checkpoint, DM might repeatedly replicate some binlog events, which leads to the following issues:

- During incremental replication, the operation of executing DML and the operation of writing checkpoints are not simultaneous. The operation of writing checkpoints and

writing data into the downstream database is not atomic. Therefore, **when DM exits abnormally, checkpoints might only record the restoration point before the exit point.**

- When DM restarts a replication task and resumes incremental replication from a checkpoint, some data between the checkpoint and the exit point might already be processed before the abnormal exit. This causes **some SQL statements to be executed repeatedly.**
- If an `INSERT` statement is executed repeatedly, the primary key or the unique index might encounter a conflict, which leads to a replication failure. If an `UPDATE` statement is executed repeatedly, the filter condition might not be able to locate the previously updated records.

In safe mode, DM can rewrite SQL statements to resolve the preceding issues.

#### Working principle

In safe mode, DM guarantees the idempotency of binlog events by rewriting SQL statements. Specifically, the following SQL statements are rewritten:

- `INSERT` statements are rewritten to `REPLACE` statements.
- `UPDATE` statements are analyzed to obtain the value of the primary key or the unique index of the row updated. `UPDATE` statements are then rewritten to `DELETE + REPLACE` statements in the following two steps: DM deletes the old record using the primary key or unique index, and inserts the new record using the `REPLACE` statement.

`REPLACE` is a MySQL-specific syntax for inserting data. When you insert data using `REPLACE`, and the new data and existing data have a primary key or unique constraint conflict, MySQL deletes all the conflicting records and executes the insert operation, which is equivalent to “force insert”. For details, see [REPLACE statement](#) in MySQL documentation.

Assume that a `dummydb.dummytbl` table has a primary key `id`. Execute the following SQL statements repeatedly on this table:

```
INSERT INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123, 999, '
↳ abc');
UPDATE dummydb.dummytbl SET int_value = 888999 WHERE int_value = 999; --
↳ Suppose there is no other record with int_value = 999
UPDATE dummydb.dummytbl SET id = 999 WHERE id = 888; -- Update the primary
↳ key
```

With safe mode enabled, when the preceding SQL statements are executed again in the downstream, they are rewritten as follows:

```
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123, 999,
↳ 'abc');
DELETE FROM dummydb.dummytbl WHERE id = 123;
```

```
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123,
 ↪ 888999, 'abc');
DELETE FROM dummydb.dummytbl WHERE id = 888;
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (999,
 ↪ 888888, 'abc888');
```

In the preceding statements, UPDATE is rewritten as DELETE + REPLACE, rather than DELETE + INSERT. If INSERT is used here, when you insert a duplicate record with `id = 999`, the database reports a primary key conflict. This is why REPLACE is used instead. The new record will replace the existing record.

By rewriting SQL statements, DM overwrites the existing row data using the new row data when performing duplicate insert or update operations. This guarantees that insert and update operations are executed repeatedly.

#### Enable safe mode

You can enable safe mode either automatically or manually. This section describes the detailed steps.

#### Automatically enable

When DM resumes an incremental replication task from a checkpoint (For example, DM worker restart or network reconnection), DM automatically enables safe mode for a period (60 seconds by default).

Whether to enable safe mode is related to `safemode_exit_point` in the checkpoint. When an incremental replication task is paused abnormally, DM tries to replicate all DML statements in the memory to the downstream and records the latest binlog position among the DML statements as `safemode_exit_point`, which is saved to the last checkpoint.

The detailed logic is as follows:

- If the checkpoint contains `safemode_exit_point`, the incremental replication task is paused abnormally. When DM resumes the task, the binlog position of the checkpoint to be resumed (**begin position**) is earlier than `safemode_exit_point`, which represents the binlog events between the begin position and the `safemode_exit_point` might have been processed in the downstream. So, during the resume process, some binlog events might be executed repeatedly. Therefore, enabling safe mode can make these binlog positions **safe**. After the binlog position exceeds the `safemode_exit_point`, DM automatically disables safe mode unless safe mode is enabled manually.
- If the checkpoint does not contain `safemode_exit_point`, there are two cases:
  1. This is a new task, or this task is paused as expected.
  2. This task is paused abnormally but DM fails to record `safemode_exit_point`, or the DM process exits abnormally.

In the second case, DM does not know which binlog events after the checkpoint are executed in the downstream. To ensure that repeatedly executed binlog events do not cause any problems, DM automatically enables safe mode during the first two checkpoint intervals. The default interval between two checkpoints is 30 seconds, which means when a normal incremental replication task starts, safe mode is enforced for the first 60 seconds (2 \* 30 seconds).

Usually, it is not recommended to change the checkpoint interval to adjust the safe mode period at the beginning of the incremental replication task. However, if you do need a change, you can **manually enable safe mode** (recommended) or change the `checkpoint-flush-interval` item in syncer configuration.

### Manually enable

You can set the `safe-mode` item in the syncer configuration to enable safe mode during the entire replication process. `safe-mode` is a bool type parameter and is `false` by default. If it is set to `true`, DM enables safe mode for the whole incremental replication process.

The following is a task configuration example with safe mode enabled:

```
syncers: # The running configurations of the sync
 ↪ processing unit.
global: # Configuration name.
Other configuration items are not provided in this example.
safe-mode: true # Enables safe mode for the whole
 ↪ incremental replication process.
Other configuration items are not provided in this example.
----- Instance configuration -----
mysql-instances:
-
 source-id: "mysql-replica-01"
 # Other configuration items are not provided in this example.
 syncer-config-name: "global" # Name of the syncers configuration.
```

### Notes for safe mode

If you want to enable safe mode during the entire replication process for safety reasons, be aware of the following:

- **Incremental replication in safe mode consumes extra overhead.** Frequent `DELETE + REPLACE` operations result in frequent changes to primary keys or unique indexes, which creates a greater performance overhead than executing `UPDATE` statements only.
- **Safe mode forces the replacement of records with the same primary key, which might result in data loss in the downstream.** When you merge and migrate shards from the upstream to the downstream, incorrect configuration might lead to a large number of primary key or unique key conflicts. If safe mode is enabled in

this situation, the downstream might lose lots of data without showing any exception, resulting in severe data inconsistency.

- **Safe mode relies on the primary key or unique index to detect conflicts.** If the downstream table has no primary key or unique index, DM cannot use `REPLACE ↪` to replace and insert records. In this case, even if safe mode is enabled and DM rewrites `INSERT` to `REPLACE` statements, duplicate records are still inserted into the downstream.

In summary, if the upstream database has data with duplicate primary keys, and your application tolerates loss of duplicate records and performance overhead, you can enable safe mode to ignore data duplication.

### 13.6.9.1.3 Data Migration Relay Log

The Data Migration (DM) relay log consists of several sets of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

After relay log is enabled, DM-worker automatically migrates the upstream binlog to the local configuration directory (the default migration directory is `<deploy_dir>/<relay_log>` if DM is deployed using TiUP). The default value of `<relay_log>` is `relay-dir` and can be modified in [Upstream Database Configuration File](#). Since v5.4.0, you can configure the local configuration directory through `relay-dir` in the [DM-worker configuration file](#), which takes precedence over the configuration file of the upstream database.

User scenarios

In MySQL, storage space is limited, so the binlog is automatically purged when the maximum retention time is reached. After the upstream database purges the binlog, DM fails to pull the purged binlog and the migration task fails. For each migration task, DM creates a connection in the upstream to pull binlog. Too many connections might cause a heavy workload on the upstream database.

When the relay log is enabled, multiple migration task with the same upstream database can reuse the relay log that has been pulled to the local disk. This **relieves the pressure on the upstream database**.

For full and incremental data migration tasks (`task-mode=all`), DM needs to first migrate full data and then perform incremental migration based on binlog. If the full migration phase takes long, the upstream binlog might be purged, which results in incremental migration failure. To avoid this situation, you can enable the relay log feature so that DM automatically retains enough log in the local disk and **ensures the incremental migration task can be performed normally**.

It is generally recommended to enable relay log, but be aware of the following potential issue:

Because relay log must be written to the disk, it consumes external IO and CPU resources. This prolongs the whole data replication process and increases the data replication latency. For **latency-sensitive** scenarios, it is not recommended to enable relay log.

**Note:**

In DM v2.0.7 and later versions, relay log writes are optimized. The latency and CPU resource consumption is relatively low.

## Use relay log

This section describes how to enable and disable relay log, query relay log status, and purge relay log.

## Enable and disable relay log

In v5.4.0 and later versions, you can enable relay log by setting `enable-relay` to `true`. Since v5.4.0, when binding the upstream data source, DM-worker checks the `enable-relay` item in the configuration of the data source. If `enable-relay` is `true`, the relay log feature is enabled for this data source.

For the detailed configuration method, see [Upstream Database Configuration File](#).

In addition, you can also dynamically adjust the `enable-relay` configuration of the data source using the `start-relay` or `stop-relay` command to enable or disable relay log in time.

```
start-relay -s mysql-replica-01
```

```
{
 "result": true,
 "msg": ""
}
```

**Note:**

In DM v2.0.x later than DM v2.0.2 and in v5.3.0, the configuration item `enable-relay` in the source configuration file is no longer valid, and you can only use `start-relay` and `stop-relay` to enable and disable relay log. If DM finds that `enable-relay` is set to `true` when [loading the data source configuration](#), it outputs the following message:

```
Please use `start-relay` to specify which workers should pull
↪ relay log of relay-enabled sources.
```

**Warning:**

This startup method is marked as deprecated in v6.1 and might be removed in a future release. You can see the following prompt in the output of the relevant command: `start-relay/stop-relay` with worker name will be ↪ deprecated soon. You can try stopping relay first and use ↪ `start-relay` without worker name instead.

In the command `start-relay`, you can configure one or more DM-workers to migrate relay logs for the specified data source, but the DM-workers specified in the parameter must be free or have been bound to the upstream data source. Examples are as follows:

```
start-relay -s mysql-replica-01 worker1 worker2
```

```
{
 "result": true,
 "msg": ""
}
```

```
stop-relay -s mysql-replica-01 worker1 worker2
```

```
{
 "result": true,
 "msg": ""
}
```

In DM versions earlier than v2.0.2 (not including v2.0.2), DM checks the configuration item `enable-relay` in the source configuration file when binding a DM-worker to an upstream data source. If `enable-relay` is set to `true`, DM enables the relay log feature for the data source.

See [Upstream Database Configuration File](#) for how to set the configuration item `enable-relay`.

Query relay log status

You can use the command `query-status -s` to query the status of the relay log:

```
query-status -s mysql-replica-01
```

Expected output

```
{
 "result": true,
 "msg": "",
}
```

```
"sources": [
 {
 "result": true,
 "msg": "no sub task started",
 "sourceStatus": {
 "source": "mysql-replica-01",
 "worker": "worker2",
 "result": null,
 "relayStatus": {
 "masterBinlog": "(mysql-bin.000005, 916)",
 "masterBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
 ↪ :1-28",
 "relaySubDir": "09bec856-ba95-11ea-850a-58f2b4af5188
 ↪ .000001",
 "relayBinlog": "(mysql-bin.000005, 4)",
 "relayBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
 ↪ :1-28",
 "relayCatchUpMaster": false,
 "stage": "Running",
 "result": null
 }
 },
 "subTaskStatus": [
],
},
{
 "result": true,
 "msg": "no sub task started",
 "sourceStatus": {
 "source": "mysql-replica-01",
 "worker": "worker1",
 "result": null,
 "relayStatus": {
 "masterBinlog": "(mysql-bin.000005, 916)",
 "masterBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
 ↪ :1-28",
 "relaySubDir": "09bec856-ba95-11ea-850a-58f2b4af5188
 ↪ .000001",
 "relayBinlog": "(mysql-bin.000005, 916)",
 "relayBinlogGtid": "",
 "relayCatchUpMaster": true,
 "stage": "Running",
 "result": null
 }
 }
},
```

```
 "subTaskStatus": [
]
 }
]
 }
}
```

### Pause and resume relay log

You can use the command `pause-relay` to pause the pulling process of relay logs and use the command `resume-relay` to resume the process. You need to specify the `source-id` of the upstream data source when executing these two commands. See the following examples:

```
pause-relay -s mysql-replica-01 -s mysql-replica-02
```

### Expected output

```
{
 "op": "PauseRelay",
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 },
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-02",
 "worker": "worker2"
 }
]
}
```

```
resume-relay -s mysql-replica-01
```

### Expected output

```
{
 "op": "ResumeRelay",
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

```
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 }
]
}
```

## Purge relay logs

DM provides two ways to purge relay logs: manual purge and automatic purge. Neither of these two methods purges active relay logs.

### Note:

- **Active relay log:** The relay log is being used by a data migration task. An active relay log is currently only updated and written in the Syncer Unit. If a data migration task in All mode spends more time on full export/import than the expiration time configured in the purge of the data source, the relay log is still purged.
- **Expired relay log:** The difference between the last modification time of the relay log file and the current time is greater than the value of the `expires` field in the configuration file.

## Automatic purge

You can enable automatic purge and configure its strategy in the source configuration file. See the following example:

```
relay log purge strategy
purge:
 interval: 3600
 expires: 24
 remain-space: 15
```

- `purge.interval`
  - The interval of automatic purge in the background, in seconds.
  - “3600” by default, indicating a background purge task is performed every 3600 seconds.
- `purge.expires`

- The number of hours for which the relay log (that has been previously written to the relay processing unit, and that is not being used or will not be read later by the currently running data migration task) can be retained before being purged in the automatic background purge.
  - “0” by default, indicating data purge is not performed according to the update time of the relay log.
- `purge.remain-space`
    - The amount of remaining disk space in GB less than which the specified DM-worker machine tries to purge the relay log that can be purged securely in the automatic background purge. If it is set to 0, data purge is not performed according to the remaining disk space.
    - “15” by default, indicating when the available disk space is less than 15 GB, DM-master tries to purge the relay log securely.

### Manual purge

Manual purge means using the `purge-relay` command provided by `dmctl` to specify `subdir` and the binlog name thus to purge all the relay logs **before** the specified binlog. If the `-subdir` option in the command is not specified, all relay logs **before** the current relay log sub-directory are purged.

Assuming that the directory structure of the current relay log is as follows:

```
$ tree .
.
|-- deb76a2b-09cc-11e9-9129-5242cf3bb246.000001
| |-- mysql-bin.000001
| |-- mysql-bin.000002
| |-- mysql-bin.000003
| `-- relay.meta
|-- deb76a2b-09cc-11e9-9129-5242cf3bb246.000003
| |-- mysql-bin.000001
| `-- relay.meta
|-- e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
| |-- mysql-bin.000001
| `-- relay.meta
`-- server-uuid.index

$ cat server-uuid.index
deb76a2b-09cc-11e9-9129-5242cf3bb246.000001
e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
deb76a2b-09cc-11e9-9129-5242cf3bb246.000003
```

- Executing the following `purge-relay` command in `dmctl` purges all relay log files **before** `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002/mysql-bin.000001`, which

are all relay log files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000001`. Files in `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002` and `deb76a2b-09cc-11e9-9129-5242cf3bb246.000003` are retained.

```
purge-relay -s mysql-replica-01 --filename mysql-bin.000001 --sub-dir
↳ e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
```

- Executing the following `purge-relay` command in `dmctl` purges all relay log files **before the current** (`deb76a2b-09cc-11e9-9129-5242cf3bb246.000003`) directory's `mysql-bin.000001`, which are all relay log files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000001` and `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002`. Files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000003` are retained.

```
purge-relay -s mysql-replica-01 --filename mysql-bin.000001
```

## Internal mechanism of relay log

This section introduces the internal mechanism of relay log.

### Directory structure

An example of the directory structure of the local storage for a relay log:

```
<deploy_dir>/<relay_log>/
|-- 7e427cc0-091c-11e9-9e45-72b7c59d52d7.000001
| |-- mysql-bin.000001
| |-- mysql-bin.000002
| |-- mysql-bin.000003
| |-- mysql-bin.000004
| `-- relay.meta
|-- 842965eb-091c-11e9-9e45-9a3bff03fa39.000002
| |-- mysql-bin.000001
| `-- relay.meta
`-- server-uuid.index
```

- `subdir`:
  - DM-worker stores the binlog migrated from the upstream database in the same directory. Each directory is a `subdir`.
  - `subdir` is named in the format of `<Upstream database UUID>.<Local subdir serial number>`.
  - After a switch between primary and secondary instances in the upstream, DM-worker generates a new `subdir` directory with an incremental serial number.
  - In the above example, for the `7e427cc0-091c-11e9-9e45-72b7c59d52d7.000001` directory, `7e427cc0-091c-11e9-9e45-72b7c59d52d7` is the upstream database UUID and `000001` is the local `subdir` serial number.

- `server-uuid.index`: records a list of the currently available `subdir` directories.
- `relay.meta`: stores the information of the migrated binlog in each `subdir`. For example,

```
cat c0149e17-dff1-11e8-b6a8-0242ac110004.000001/relay.meta
```

```
binlog-name = "mysql-bin.000010" # The name of the
 ↪ currently migrated binlog.
binlog-pos = 63083620 # The position of
 ↪ the currently migrated binlog.
binlog-gtid = "c0149e17-dff1-11e8-b6a8-0242ac110004:1-3328" # GTID of
 ↪ the currently migrated binlog.
```

There might also be multiple GTIDs:

```
cat 92acbd8a-c844-11e7-94a1-1866daf8accc.000001/relay.meta
```

```
binlog-name = "mysql-bin.018393"
binlog-pos = 277987307
binlog-gtid = "3ccc475b-2343-11e7-be21-6c0b84d59f30:1-14,406a3f61-690d
 ↪ -11e7-87c5-6c92bf46f384:1-94321383,53bfca22-690d-11e7-8a62-18
 ↪ ded7a37b78:1-495,686e1ab6-c47e-11e7-a42c-6c92bf46f384
 ↪ :1-34981190,03fc0263-28c7-11e7-a653-6c0b84d59f30:1-7041423,05474
 ↪ d3c-28c7-11e7-8352-203db246dd3d:1-170,10b039fc-c843-11e7-8f6a
 ↪ -1866daf8d810:1-308290454"
```

The position where DM receives the binlog

- DM obtains the earliest position that each migration task needs from the saved checkpoint (in the downstream `dm_meta` schema by default). If this position is later than any of the following positions, DM starts to migrate from this position.
- If the local relay log is valid, which means that the relay log contains valid `server` ↪ `-uuid.index`, `subdir`, and `relay.meta` files, DM-worker recovers the migration from the position recorded in `relay.meta`.
- If there is no valid local relay log, but the upstream data source configuration file specifies `relay-binlog-name` or `relay-binlog-gtid`:
  - In non-GTID mode, if `relay-binlog-name` is specified, DM-worker starts to migrate from the specified binlog file.
  - In GTID mode, if `relay-binlog-gtid` is specified, DM-worker starts to migrate from the specified GTID.
- If there is no valid local relay log and the `relay-binlog-name` or `relay-binlog-gtid` is not specified in the DM configuration file:

- In non-GTID mode, DM-worker starts to migrate from the earliest binlog that each subtask is migrating, until the latest binlog is migrated.
- In GTID mode, DM-worker starts to migrate from the earliest GTID that each subtask is migrating, until the latest GTID is migrated.

**Note:**

If the upstream relay log is purged, an error occurs. In this case, you need to configure `relay-binlog-gtid` to specify the start position of the migration.

#### 13.6.9.1.4 Special Handling of DM DDLs

When TiDB Data Migration (DM) migrates data, it parses the DDL statements and handles them according to the statement type and the current migration stage.

Skip DDL statements

The following statements are not supported by DM, so DM skips them directly after parsing.

```

<tr>
 <th>Description</th>
 <th>SQL</th>
</tr>
<tr>
 <td>transaction</td>
 <td><code>^SAVEPOINT</code></td>
</tr>
<tr>
 <td>skip all flush sqls</td>
 <td><code>^FLUSH</code></td>
</tr>
<tr>
 <td rowspan="3">table maintenance</td>
 <td><code>^OPTIMIZE\\s+TABLE</code></td>
</tr>
<tr>
 <td><code>^ANALYZE\\s+TABLE</code></td>
</tr>
<tr>
 <td><code>^REPAIR\\s+TABLE</code></td>
</tr>
<tr>
 <td>temporary table</td>

```

```

 <td><code>^DROP\\s+(\\|\\|*\\|!40005\\s+)?TEMPORARY\\s+(\\|*\\|\\|\\s+)?TABLE
 ↪ </code></td>
</tr>
<tr>
 <td rowspan="2">trigger</td>
 <td><code>^CREATE\\s+(DEFINER\\s?=\\.+)?TRIGGER</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+TRIGGER</code></td>
</tr>
<tr>
 <td rowspan="3">procedure</td>
 <td><code>^DROP\\s+PROCEDURE</code></td>
</tr>
<tr>
 <td><code>^CREATE\\s+(DEFINER\\s?=\\.+)?PROCEDURE</code></td>
</tr>
<tr>
 <td><code>^ALTER\\s+PROCEDURE</code></td>
</tr>
<tr>
 <td rowspan="3">view</td>
 <td><code>^CREATE\\s*(OR REPLACE)?\\s+(ALGORITHM\\s?=\\.+)?(DEFINER\\s
 ↪ ?\\.+)?\\s+(SQL SECURITY DEFINER)?VIEW</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+VIEW</code></td>
</tr>
<tr>
 <td><code>^ALTER\\s+(ALGORITHM\\s?=\\.+)?(DEFINER\\s?=\\.+)?(SQL SECURITY
 ↪ DEFINER)?VIEW</code></td>
</tr>
<tr>
 <td rowspan="4">function</td>
 <td><code>^CREATE\\s+(AGGREGATE)?\\s*?FUNCTION</code></td>
</tr>
<tr>
 <td><code>^CREATE\\s+(DEFINER\\s?=\\.+)?FUNCTION</code></td>
</tr>
<tr>
 <td><code>^ALTER\\s+FUNCTION</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+FUNCTION</code></td>
</tr>

```

```
<tr>
 <td rowspan="3">tableSpace</td>
 <td><code>^CREATE\\s+TABLESPACE</code></td>
</tr>
<tr>
 <td><code>^ALTER\\s+TABLESPACE</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+TABLESPACE</code></td>
</tr>
<tr>
 <td rowspan="3">event</td>
 <td><code>^CREATE\\s+(DEFINER\\s?=\\.+)?EVENT</code></td>
</tr>
<tr>
 <td><code>^ALTER\\s+(DEFINER\\s?=\\.+)?EVENT</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+EVENT</code></td>
</tr>
<tr>
 <td rowspan="7">account management</td>
 <td><code>^GRANT</code></td>
</tr>
<tr>
 <td><code>^REVOKE</code></td>
</tr>
<tr>
 <td><code>^CREATE\\s+USER</code></td>
</tr>
<tr>
 <td><code>^ALTER\\s+USER</code></td>
</tr>
<tr>
 <td><code>^RENAME\\s+USER</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+USER</code></td>
</tr>
<tr>
 <td><code>^DROP\\s+USER</code></td>
</tr>
```

Rewrite DDL statements

The following statements are rewritten before being replicated to the downstream.

Original statement	Rewritten statement
<code>^CREATE DATABASE...</code>	<code>^CREATE DATABASE...IF NOT EXISTS</code>
<code>^CREATE TABLE...</code>	<code>^CREATE TABLE..IF NOT EXISTS</code>
<code>^DROP DATABASE...</code>	<code>^DROP DATABASE...IF EXISTS</code>
<code>^DROP TABLE...</code>	<code>^DROP TABLE...IF EXISTS</code>
<code>^DROP INDEX...</code>	<code>^DROP INDEX...IF EXISTS</code>

### Shard merge migration tasks

When DM merges and migrates tables in pessimistic or optimistic mode, the behavior of DDL replication is different from that in other scenarios. For details, refer to [Pessimistic Mode](#) and [Optimistic Mode](#).

### Online DDL

The Online DDL feature also handles DDL events in a special way. For details, refer to [Migrate from Databases that Use GH-ost/PT-osc](#).

## 13.6.9.2 Mechanism

### 13.6.9.2.1 DML Replication Mechanism in Data Migration

This document introduces how the core processing unit Sync in DM processes DML statements read from the data source or relay log. This document introduces the complete processing flow of DML events in DM, including the logic of binlog reading, filtering, routing, transformation, optimization, and execution. This document also explains the DML optimization logic and DML execution logic in detail.

#### DML processing flow

The Sync unit processes DML statements as follows:

1. Read the binlog event from the MySQL, MariaDB, or relay log.
2. Transform the binlog event read from the data source:
  1. **Binlog filter**: filter binlog events according to binlog expressions, configured by `filters`.
  2. **Table routing**: transform the “database/table” name according to the “database/table” routing rule, configured by `routes`.
  3. **Expression filter**: filter binlog events according to SQL expressions, configured by `expression-filter`.
3. Optimize the DML execution plan:

1. **Compactor**: merge multiple operations on the same record (with the same primary key) into one operation. This feature is enabled by `syncer.compact`.
  2. **Causality**: perform conflict detection on different records (with different primary keys) to improve the concurrency of replication.
  3. **Merger**: merge multiple binlog events into one DML statement, enabled by `syncer`  $\leftrightarrow$  `.multiple-rows`.
4. Execute the DML to the downstream.
  5. Periodically save the binlog position or GTID to the checkpoint.

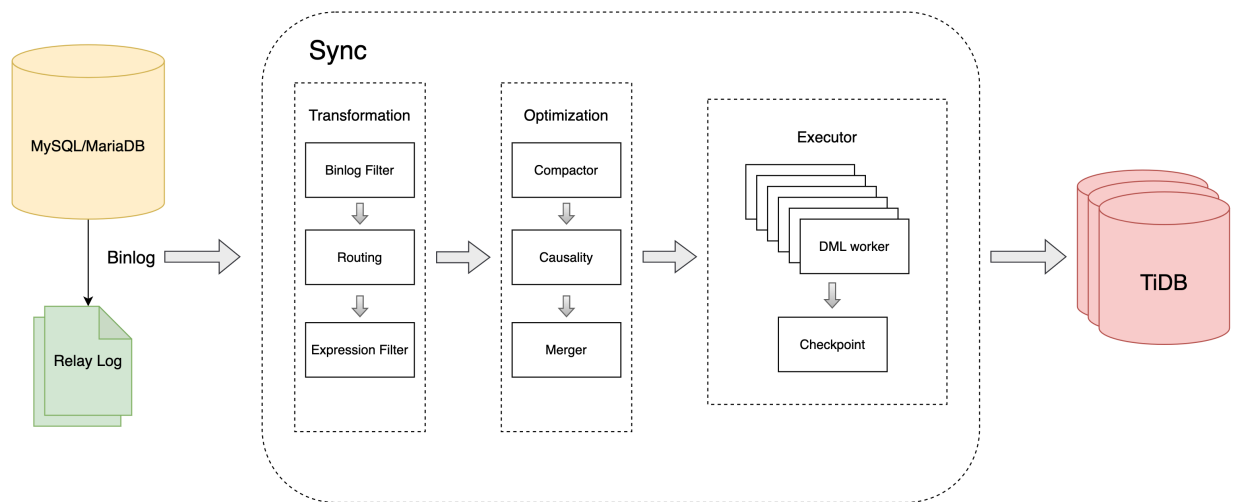

Figure 259: DML processing logic

### DML optimization logic

The Sync unit implements the DML optimization logic through three steps: Compactor, Causality, and Merger.

#### Compactor

According to the binlog records of the upstream, DM captures the changes of the records and replicates them to the downstream. When the upstream makes multiple changes to the same record (`INSERT/UPDATE/DELETE`) in a short period of time, DM can compress multiple changes into one change through Compactor to reduce the pressure on the downstream and improve the throughput. For example:

```

INSERT + UPDATE => INSERT
INSERT + DELETE => DELETE
UPDATE + UPDATE => UPDATE
UPDATE + DELETE => DELETE
DELETE + INSERT => UPDATE

```

The Compactor feature is disabled by default. To enable it, you can set `syncer.compact` to `true` in the `sync` configuration module of the replication task, as shown below:

```
syncers: # The configuration parameters of the sync
 ↪ processing unit
global: # Configuration name
 ... # Other configurations are omitted
compact: true
```

## Causality

The sequential replication model of MySQL binlog requires that binlog events be replicated in the order of binlog. This replication model cannot meet the requirements of high QPS and low replication latency. In addition, because not all operations involved in binlog have conflicts, sequential replication is not necessary in those cases.

DM recognizes the binlog that needs to be executed sequentially through conflict detection, and ensures that these binlog are executed sequentially while maximizing the concurrency of other binlog. This helps improve the performance of binlog replication.

Causality adopts an algorithm similar to the union-find algorithm to classify each DML and group DMLs that are related to each other.

## Merger

According to the MySQL binlog protocol, each binlog corresponds to a change operation of one row of data. Through Merger, DM can merge multiple binlogs into one DML and execute it to the downstream, reducing the network interaction. For example:

```
INSERT tb(a,b) VALUES(1,1);
+ INSERT tb(a,b) VALUES(2,2);
= INSERT tb(a,b) VALUES(1,1),(2,2);
 UPDATE tb SET a=1, b=1 WHERE a=1;
+ UPDATE tb SET a=2, b=2 WHERE a=2;
= INSERT tb(a,b) VALUES(1,1),(2,2) ON DUPLICATE UPDATE a=VALUES(a), b=VALUES
 ↪ (b)
 DELETE tb WHERE a=1
+ DELETE tb WHERE a=2
= DELETE tb WHERE (a) IN (1),(2);
```

The Merger feature is disabled by default. To enable it, you can set `syncer.multiple-rows` to `true` in the `sync` configuration module of the replication task, as shown below:

```
syncers: # The configuration parameters of the sync
 ↪ processing unit
global: # Configuration name
 ... # Other configurations are omitted
multiple-rows: true
```

DML execution logic

After the Sync unit optimizes the DML, it performs the execution logic.

DML generation

DM has an embedded schema tracker that records the schema information of the upstream and downstream:

- When DM receives a DDL statement, DM updates the table schema of the internal schema tracker.
- When DM receives a DML statement, DM generates the corresponding DML according to the table schema of the schema tracker.

The logic of generating DML is as follows:

1. The Sync unit records the initial table structure of the upstream:
  - When starting a full and incremental task, Sync uses the **table structure exported during the upstream full data migration** as the initial table structure of the upstream.
  - When starting an incremental task, because MySQL binlog does not record the table structure information, Sync uses the **table structure of the corresponding table in the downstream** as the initial table structure of the upstream.
2. The user's upstream and downstream table structures might be inconsistent, for example, the downstream might have additional columns than the upstream, or the upstream and downstream primary keys are inconsistent. Therefore, to ensure the correctness of data replication, DM records the **primary key and unique key information of the corresponding table in the downstream**.
3. DM generates DML:
  - Use the **the upstream table structure recorded in the schema tracker** to generate the column names of the DML statement.
  - Use the **column values recorded in the binlog** to generate the column values of the DML statement.
  - Use the **downstream primary key or unique key recorded in the schema tracker** to generate the `WHERE` condition of the DML statement. When the table structure has no unique key, DM uses all the column values recorded in the binlog as the `WHERE` condition.

Worker count

Causality can divide binlog into multiple groups through conflict detection and execute them concurrently to the downstream. DM controls the concurrency by setting `worker`  $\leftrightarrow$  `-count`. When the CPU usage of the downstream TiDB is not high, increasing the concurrency can effectively improve the throughput of data replication.

You can modify the number of threads that concurrently migrate DML by modifying the `syncer.worker-count` configuration item.

#### Batch

DM batches multiple DMLs into a single transaction and executes it to the downstream. When a DML worker receives a DML, it adds the DML to the cache. When the number of DMLs in the cache reaches the preset threshold, or the DML worker does not receive DML for a long time, the DML worker executes the DMLs in the cache to the downstream.

You can modify the number of DMLs contained in a transaction by modifying the `syncer.batch` configuration item.

#### checkpoint

The operation of executing DML and updating checkpoint is not atomic.

In DM, checkpoint is updated every 30 seconds by default. Because there are multiple DML worker processes, the checkpoint process calculates the binlog position of the earliest replication progress of all DML workers, and uses this position as the current replication checkpoint. All binlogs earlier than this position are guaranteed to be successfully executed to the downstream.

#### Notes

##### Transaction consistency

DM replicates data at the row level and does not guarantee transaction consistency. In DM, an upstream transaction is split into multiple rows and distributed to different DML workers for concurrent execution. Therefore, when the DM replication task reports an error and pauses, or when the user manually pauses the task, the downstream might be in an intermediate state. That is, the DML statements in an upstream transaction might be partially replicated to the downstream, which might cause the downstream to be in an inconsistent state.

To ensure that the downstream is in a consistent state when the task is paused as much as possible, starting from DM v5.3.0, DM waits for 10 seconds before pausing the task to ensure that all transactions from the upstream are replicated to the downstream. However, if a transaction is not replicated to the downstream within 10 seconds, the downstream might still be in an inconsistent state.

##### Safe mode

The operation of DML execution and checkpoint update is not atomic, and the operation of checkpoint update and writing data to the downstream is also not atomic. When DM exits abnormally, the checkpoint might only record a recovery point before the exit time. Therefore, when the task is restarted, DM might write the same data multiple times, which means that DM actually provides the “at least once processing” logic, and the same data might be processed more than once.

To make sure the data is reentrant, DM enters the safe mode when it restarts from an abnormal exit.

When the safe mode is enabled, to make sure that data can be processed multiple times, DM performs the following conversions:

- Rewrite the `INSERT` statement of the upstream to the `REPLACE` statement.
- Rewrite the `UPDATE` statement of the upstream to the `DELETE + REPLACE` statement.

Exactly-once processing

Currently, DM only guarantees eventual consistency and does not support “exactly-once processing” and “keeping the original order of transactions”.

### 13.6.9.3 Command Line

#### 13.6.9.3.1 TiDB Data Migration Command-line Flags

This document introduces DM’s command-line flags.

DM-master

`--advertise-addr`

- The external address of DM-master used to receive client requests
- The default value is "`{master-addr}`"
- Optional flag. It can be in the form of "`domain-name:port`"

`--advertise-peer-urls`

- The external address for communication between DM-master nodes
- The default value is "`{peer-urls}`"
- Optional flag. It can be in the form of "`http(s)://domain-name:port`"

`--config`

- The configuration file path of DM-master
- The default value is ""
- Optional flag

`--data-dir`

- The directory used to store data of DM-master
- The default value is "`default.{name}`"
- Optional flag

`--initial-cluster`

- The "{node name}={external address}" list used to bootstrap DM-master cluster
- The default value is "{name}={advertise-peer-urls}"
- This flag needs to be specified if the join flag is not specified. A configuration example of a 3-node cluster is "dm-master-1=http://172.16.15.11:8291,dm-master-2=http ↪ ://172.16.15.12:8291,dm-master-3=http://172.16.15.13:8291"

#### `--join`

- The existing cluster's `advertise-addr` list when a DM-master node joins this cluster
- The default value is ""
- This flag needs to be specified if the `initial-cluster` flag is not specified. Suppose a new node joins a cluster that has 2 nodes, a configuration example is "172.16.15.11:8261,172.16.15.12:8261"

#### `--log-file`

- The output file name of the log
- The default value is ""
- Optional flag

#### `-L`

- The log level
- The default value is "info"
- Optional flag

#### `--master-addr`

- The address on which DM-master listens to the client's requests
- The default value is ""
- Required flag

#### `--name`

- The name of a DM-master node
- The default value is "dm-master-{hostname}"
- Required flag

#### `--peer-urls`

- The listening address for communications between DM-master nodes
- The default value is "http://127.0.0.1:8291"

- Required flag

DM-worker

`--advertise-addr`

- The external address of DM-worker used to receive client requests
- The default value is "`{worker-addr}`"
- Optional flag. It can be in the form of "`domain-name:port`"

`--config`

- The configuration file path of DM-worker
- The default value is ""
- Optional flag

`--join`

- The `{advertise-addr}` list of DM-master nodes in a cluster when a DM-worker registers to this cluster
- The default value is ""
- Required flag. A configuration example of 3-node (DM-master node) cluster is "`172.16.15.11:8261,172.16.15.12:8261,172.16.15.13:8261`"

`--log-file`

- The output file name of the log
- The default value is ""
- Optional flag

`-L`

- The log level
- The default value is "`info`"
- Optional flag

`--name`

- The name of a DM-worker node
- The default value is "`{advertise-addr}`"
- Required flag

`--worker-addr`

- The address on which DM-worker listens to the client's requests
- The default value is ""
- Required flag

`dmctl`

`--config`

- The configuration file path of dmctl
- The default value is ""
- Optional flag

`--master-addr`

- The `{advertise-addr}` of any DM-master node in the cluster to be connected by dmctl
- The default value is ""
- It is a required flag when dmctl interacts with DM-master

`--encrypt`

- Encrypts the plaintext database password into ciphertext
- The default value is ""
- When this flag is specified, it is only used to encrypt the plaintext without interacting with the DM-master

`--decrypt`

- Decrypts ciphertext encrypted with dmctl into plaintext
- The default value is ""
- When this flag is specified, it is only used to decrypt the ciphertext without interacting with the DM-master

#### 13.6.9.4 Configuration Files

### 13.6.9.4.1 Data Migration Configuration File Overview

This document gives an overview of configuration files of DM (Data Migration).

DM process configuration files

- `dm-master.toml`: The configuration file of running the DM-master process, including the topology information and the logs of the DM-master. For more details, refer to [DM-master Configuration File](#).
- `dm-worker.toml`: The configuration file of running the DM-worker process, including the topology information and the logs of the DM-worker. For more details, refer to [DM-worker Configuration File](#).
- `source.yaml`: The configuration of the upstream database such as MySQL and MariaDB. For more details, refer to [Upstream Database Configuration File](#).

DM migration task configuration

Data migration task creation

You can take the following steps to create a data migration task:

1. [Load the data source configuration into the DM cluster using dmctl](#).
2. Refer to the description in the [Task Configuration Guide](#) and create the configuration file `your_task.yaml`.
3. [Create the data migration task using dmctl](#).

Important concepts

This section shows description of some important concepts.

Concept	Description	Configuration File
<b>source</b> ↔ <code>-id</code>	Uniquely represents a MySQL or MariaDB instance, or a migration group with the primary-secondary structure. The maximum length of <code>source-id</code> is 32.	<code>source_id</code> of <code>source.yaml</code> ; <code>source-id</code> of <code>task.yaml</code>
DM-master ID	Uniquely represents a DM-master (by the <code>master-addr</code> parameter of <code>dm-master.toml</code> )	<code>master-addr</code> of <code>dm-master.toml</code>
DM-worker ID	Uniquely represents a DM-worker (by the <code>worker-addr</code> parameter of <code>dm-worker.toml</code> )	<code>worker-addr</code> of <code>dm-worker.toml</code>

#### 13.6.9.4.2 Upstream Database Configuration File of TiDB Data Migration

This document introduces the configuration file of the upstream database, including a configuration file template and the description of each configuration parameter in this file.

## Configuration file template

The following is a configuration file template of the upstream database:

```
source-id: "mysql-replica-01"

Whether to enable GTID.
enable-gtid: false

Whether to enable relay log.
enable-relay: false # Since DM v2.0.2, this configuration item is
 ↪ deprecated. To enable the relay log feature, use the `start-relay`
 ↪ command instead.
relay-binlog-name: "" # The file name from which DM-worker starts to pull
 ↪ the binlog.
relay-binlog-gtid: "" # The GTID from which DM-worker starts to pull the
 ↪ binlog.
relay-dir: "relay-dir" # The directory used to store relay log. The
 ↪ default value is "relay-dir". This configuration item is marked as
 ↪ deprecated since v6.1 and replaced by a parameter of the same name in
 ↪ the dm-worker configuration.

from:
 host: "127.0.0.1"
 port: 3306
 user: "root"
 password: "ZqMLjZ2j5khNe1DEfDoUhkD5aV5fIJ0e0fiog9w=" # The user password
 ↪ of the upstream database. It is recommended to use the password
 ↪ encrypted with dmctl.
 security: # The TLS configuration of the upstream
 ↪ database
 ssl-ca: "/path/to/ca.pem"
 ssl-cert: "/path/to/cert.pem"
 ssl-key: "/path/to/key.pem"

purge:
interval: 3600
expires: 0
remain-space: 15

checker:
check-enable: true
backoff-rollback: 5m0s
backoff-max: 5m0s # The maximum value of backoff, should be larger
 ↪ than 1s
```

```
Configure binlog event filters. New in DM v2.0.2
case-sensitive: false
filters:
- schema-pattern: dmctl
table-pattern: t_1
events: []
sql-pattern:
- alter table .* add column `aaa` int
action: Ignore
```

### Note:

In DM v2.0.1, DO NOT set `enable-gtid` and `enable-relay` to `true` at the same time. Otherwise, it may cause loss of incremental data.

## Configuration parameters

This section describes each configuration parameter in the configuration file.

### Global configuration

Parameter	Description
<code>source-id</code>	Represents a MySQL instance ID.
<code>enable-gtid</code>	Determines whether to pull binlog from the upstream using GTID. The default value is <code>false</code> . In general, you do not need to configure <code>enable-gtid</code> manually. However, if GTID is enabled in the upstream database, and the primary/secondary switch is required, you need to set <code>enable-gtid</code> to <code>true</code> .
<code>enable-relay</code>	Determines whether to enable the relay log feature. The default value is <code>false</code> . Since DM v2.0.2, this configuration item is deprecated. To <b>enable the relay log feature</b> , use the <code>start-relay</code> command instead.

Parameter	Description
<code>relay-binlog</code> ↔ <code>-name</code>	Specifies the file name from which DM-worker starts to pull the binlog. For example, "mysql-bin.000002". It only works when <code>enable_gtid</code> is <code>false</code> . If this parameter is not specified, DM-worker will start pulling from the earliest binlog file being replicated. Manual configuration is generally not required.
<code>relay-binlog</code> ↔ <code>-gtid</code>	Specifies the GTID from which DM-worker starts to pull the binlog. For example, "e9a1fc22-ec08-11e9-b2ac-0242" ↔ "ac110003:1-7849". It only works when <code>enable_gtid</code> is <code>true</code> . If this parameter is not specified, DM-worker will start pulling from the latest GTID being replicated. Manual configuration is generally not required.
<code>relay-dir</code>	Specifies the relay log directory.
<code>host</code>	Specifies the host of the upstream database.
<code>port</code>	Specifies the port of the upstream database.
<code>user</code>	Specifies the username of the upstream database.
<code>password</code>	Specifies the user password of the upstream database. It is recommended to use the password encrypted with <code>dmctl</code> .
<code>security</code>	Specifies the TLS config of the upstream database. The configured file paths of the certificates must be accessible to all nodes. If the configured file paths are local paths, then all the nodes in the cluster need to store a copy of the certificates in the same path of each host.

### Relay log cleanup strategy configuration (`purge`)

Generally, there is no need to manually configure these parameters unless there is a large amount of relay logs and disk capacity is insufficient.

Parameter	Description	Default value
<code>interval</code>	Sets the time interval at which relay logs are regularly checked for expiration, in seconds.	3600

Parameter	Description	Default value
<code>expires</code>	Sets the expiration time for relay logs, in hours. The relay log that is not written by the relay processing unit, or does not need to be read by the existing data migration task will be deleted by DM if it exceeds the expiration time. If this parameter is not specified, the automatic purge is not performed.	0
<code>remain-space</code>	Sets the minimum amount of free disk space, in gigabytes. When the available disk space is smaller than this value, DM-worker tries to delete relay logs.	15

#### Note:

The automatic data purge strategy only takes effect when `interval` is not 0 and at least one of the two configuration items `expires` and `remain-space` is not 0.

#### Task status checker configuration (`checker`)

DM periodically checks the current task status and error message to determine if resuming the task will eliminate the error. If needed, DM automatically retries to resume the task. DM adjusts the checking interval using the exponential backoff strategy. Its behaviors can be adjusted by the following configuration.

Parameter	Description
<code>check-enable</code>	Whether to enable this feature.
<code>backoff-rollback</code>	If the current checking interval of backoff strategy is larger than this value and the task status is normal, DM will try to decrease the interval.
<code>backoff-max</code>	The maximum value of checking interval of backoff strategy, must be larger than 1 second.

#### Binlog event filter

Starting from DM v2.0.2, you can configure binlog event filters in the source configuration file.

Parameter	Description
<code>case-sensitive</code>	Determines whether the filtering rules are case-sensitive. The default value is <code>false</code> .
<code>filters</code>	Sets binlog event filtering rules. For details, see <a href="#">Binlog event filter parameter explanation</a> .

### 13.6.9.4.3 DM Advanced Task Configuration File

This document introduces the advanced task configuration file of Data Migration (DM), including [global configuration](#) and [instance configuration](#).

Important concepts

For description of important concepts including `source-id` and the DM-worker ID, see [Important concepts](#).

Task configuration file template (advanced)

The following is the task configuration file template which allows you to perform **advanced** data migration tasks.

```

----- Global setting -----
***** Basic configuration *****
name: test # The name of the task. Should be globally
 ↪ unique.
task-mode: all # The task mode. Can be set to `full` (only
 ↪ migrates full data)/`incremental` (replicates binlogs synchronously)/`
 ↪ all` (replicates both full data and incremental binlogs).
shard-mode: "pessimistic" # The shard merge mode. Optional modes are ""/"
 ↪ pessimistic"/"optimistic". The "" mode is used by default which means
 ↪ sharding DDL merge is disabled. If the task is a shard merge task,
 ↪ set it to the "pessimistic" mode.
 # After understanding the principles and
 ↪ restrictions of the "optimistic" mode,
 ↪ you can set it to the "optimistic" mode.
meta-schema: "dm_meta" # The downstream database that stores the `meta`
 ↪ information.
timezone: "Asia/Shanghai" # The timezone used in SQL Session. By default,
 ↪ DM uses the global timezone setting in the target cluster, which
 ↪ ensures the correctness automatically. A customized timezone does not
 ↪ affect data migration but is unnecessary.
case-sensitive: false # Determines whether the schema/table is case-
 ↪ sensitive.

```

```
online-ddl: true # Supports automatic processing of upstream "gh-
 ↳ ost" and "pt".
online-ddl-scheme: "gh-ost" # `online-ddl-scheme` is deprecated, so it is
 ↳ recommended to use `online-ddl`.
clean-dump-file: true # Whether to clean up the files generated during
 ↳ data dump. Note that these include `metadata` files.
collation_compatible: "loose" # The mode to sync the default collation in `
 ↳ CREATE` SQL statements. The supported values are "loose" (by default)
 ↳ or "strict". When the value is "strict", DM explicitly appends the
 ↳ corresponding collation of the upstream to the SQL statements; when
 ↳ the value is "loose", DM does not modify the SQL statements. In "
 ↳ strict" mode, if the downstream does not support the default
 ↳ collation in the upstream, the downstream might report an error.
ignore-checking-items: [] # Ignorable checking items. For the complete
 ↳ list of ignorable checking items, see DM precheck: https://docs.
 ↳ pingcap.com/tidb/stable/dm-precheck#ignorable-checking-items.

target-database: # Configuration of the downstream database
 ↳ instance.
host: "192.168.0.1"
port: 4000
user: "root"
password: "/Q7B9DizNLLTTfiZHv9WoEAKamfpIUs=" # It is recommended to use a
 ↳ password encrypted with `dmctl encrypt`.
max-allowed-packet: 67108864 # Sets the "max_allowed_packet"
 ↳ limit of the TiDB client (that is, the limit of the maximum accepted
 ↳ packet) when DM internally connects to the TiDB server. The unit is
 ↳ bytes. (67108864 by default)
 # Since DM v2.0.0, this
 ↳ configuration item is
 ↳ deprecated, and DM
 ↳ automatically obtains the "
 ↳ max_allowed_packet" value
 ↳ from TiDB.

session: # The session variables of TiDB,
 ↳ supported since v1.0.6. For details, go to `https://pingcap.com/docs
 ↳ /stable/system-variables`.
```

```
sql_mode: "ANSI_QUOTES,NO_ZERO_IN_DATE,NO_ZERO_DATE" # Since DM v2.0.0,
 ↳ if this item does not appear in the configuration file, DM
 ↳ automatically fetches a proper value for "sql_mode" from the
 ↳ downstream TiDB. Manual configuration of this item has a higher
 ↳ priority.
```

```
tidb_skip_utf8_check: 1 # Since DM v2.0.0, if this item
 ↳ does not appear in the configuration file, DM automatically
 ↳ fetches a proper value for "tidb_skip_utf8_check" from the
```

```
 ↪ downstream TiDB. Manual configuration of this item has a higher
 ↪ priority.
tidb_constraint_check_in_place: 0
security: # The TLS configuration of the downstream TiDB
ssl-ca: "/path/to/ca.pem"
ssl-cert: "/path/to/cert.pem"
ssl-key: "/path/to/key.pem"

***** Feature configuration set *****
The routing mapping rule set between the upstream and downstream
 ↪ tables.
routes:
route-rule-1: # The name of the routing mapping rule.
schema-pattern: "test_*" # The pattern of the upstream schema name,
 ↪ wildcard characters (*?) are supported.
table-pattern: "t_*" # The pattern of the upstream table name,
 ↪ wildcard characters (*?) are supported.
target-schema: "test" # The name of the downstream schema.
target-table: "t" # The name of the downstream table.
Optional. Used for extracting the source information of sharded
 ↪ schemas and tables and writing the information to the user-defined
 ↪ columns in the downstream. If these options are configured, you
 ↪ need to manually create a merged table in the downstream. For
 ↪ details, see description of table routing in <https://docs.pingcap
 ↪ .com/tidb/dev/dm-table-routing>.
extract-table: # Extracts and writes
 ↪ the table name suffix without the t_ part to the c-table column of
 ↪ the merged table. For example, 01 is extracted and written to the
 ↪ c-table column for the sharded table t_01.
table-regexp: "t_(.*)"
target-column: "c_table"
extract-schema: # Extracts and writes
 ↪ the schema name suffix without the test_ part to the c_schema
 ↪ column of the merged table. For example, 02 is extracted and
 ↪ written to the c_schema column for the sharded schema test_02.
schema-regexp: "test_(.*)"
target-column: "c_schema"
extract-source: # Extracts and writes
 ↪ the source instance information to the c_source column of the
 ↪ merged table. For example, mysql-replica-01 is extracted and
 ↪ written to the c_source column for the data source mysql-replica
 ↪ -01.
source-regexp: "(.*)"
target-column: "c_source"
```

```
route-rule-2:
 schema-pattern: "test_*"
 target-schema: "test"

The binlog event filter rule set of the matched table of the upstream
↳ database instance.
filters:
 filter-rule-1:
 # The name of the filtering rule.
 schema-pattern: "test_*"
 # The pattern of the upstream
 ↳ schema name, wildcard characters (*) are supported.
 table-pattern: "t_*"
 # The pattern of the upstream
 ↳ schema name, wildcard characters (*) are supported.
 events: ["truncate table", "drop table"] # What event types to match.
 action: Ignore
 # Whether to migrate (Do) or
 ↳ ignore (Ignore) the binlog that matches the filtering rule.
 filter-rule-2:
 schema-pattern: "test_*"
 events: ["all dml"]
 action: Do

expression-filter:
 # Defines the filter rules for row changes
 ↳ when migrating data. Supports defining multiple rules.
 # Filter the value of inserted `c` in `expr_filter`.`tbl` when it is even.
 even_c:
 # The name of the filter rule.
 schema: "expr_filter"
 # The name of upstream database to be
 ↳ matched. Wildcard match or regular match is not supported.
 table: "tbl"
 # The name of upstream table to be matched.
 ↳ Wildcard match or regular match is not supported.
 insert-value-expr: "c % 2 = 0"

The filter rule set of tables to be migrated from the upstream
↳ database instance. You can set multiple rules at the same time.
block-allow-list:
 # Use black-white-list if the DM version is
 ↳ earlier than or equal to v2.0.0-beta.2.
 bw-rule-1:
 # The name of the block allow list rule.
 do-dbs: ["~test.*", "user"] # The allow list of upstream schemas needs
 ↳ to be migrated.
 ignore-dbs: ["mysql", "account"] # The block list of upstream schemas
 ↳ needs to be migrated.
 do-tables:
 # The allow list of upstream tables needs
 ↳ to be migrated.
 - db-name: "~test.*"
 tbl-name: "~t.*"
 - db-name: "user"
 tbl-name: "information"
```

```
bw-rule-2: # The name of the block allow list rule.
 ignore-tables: # The block list of upstream tables needs
 ↪ to be migrated.
 - db-name: "user"
 tbl-name: "log"

Configuration arguments of the dump processing unit.
mydumpers:
 global: # The configuration name of the processing
 ↪ unit.
 threads: 4 # The number of threads that access the
 ↪ upstream when the dump processing unit performs the precheck and
 ↪ exports data from the upstream database (4 by default)
 chunk-filesize: 64 # The size of the file generated by the
 ↪ dump processing unit (64 MB by default).
 extra-args: "--consistency none" # Other arguments of the dump
 ↪ processing unit. You do not need to manually configure table-list
 ↪ in `extra-args`, because it is automatically generated by DM.

Configuration arguments of the load processing unit.
loaders:
 global: # The configuration name of the processing
 ↪ unit.
 pool-size: 16 # The number of threads that concurrently
 ↪ execute dumped SQL files in the load processing unit (16 by
 ↪ default). When multiple instances are migrating data to TiDB at
 ↪ the same time, slightly reduce the value according to the load.
 # The directory that stores full data exported from the upstream ("./
 ↪ dumped_data" by default).
 # Supoprts a local filesystem path or an Amazon S3 path. For example, "
 ↪ s3://dm_bucket/dumped_data?endpoint=s3-website.us-east-2.amazonaws
 ↪ .com&access_key=s3accesskey&secret_access_key=s3secretkey&
 ↪ force_path_style=true"
 dir: "./dumped_data"

 # The import mode during the full import phase. The following modes are
 ↪ supported:
 # - "logical" (default). Uses TiDB Lightning's logical import mode to
 ↪ import data. Document: https://docs.pingcap.com/tidb/stable/tidb-
 ↪ lightning-logical-import-mode
 # - "physical". Uses TiDB Lightning's physical import mode to import
 ↪ data. Document: https://docs.pingcap.com/zh/tidb/stable/tidb-
 ↪ lightning-physical-import-mode
 # The "physical" mode is still an experimental feature and is not
 ↪ recommended in production.
```

```
import-mode: "logical"
Methods to resolve conflicts in logical import.
- "replace" (default). Uses the new data to replace the existing data.
- "ignore". Keeps the existing data, and ignores the new data.
- "error". Reports errors when inserting duplicated data, and then
 ↪ stops the replication task.
on-duplicate-logical: "replace"

Methods to resolve conflicts in physical import.
- "none". Corresponds to the "none" strategy of conflict detection in
 ↪ TiDB Lightning's physical import.
(https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
 ↪ mode-usage#conflict-detection).
Conflicting data is not resolved in this method. "none" has the best
 ↪ performance, but
might lead to inconsistent data in the downstream database.
- "manual". Corresponds to the "remove" strategy of conflict detection
 ↪ in TiDB Lightning's physical import.
(https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
 ↪ mode-usage#conflict-detection).
When the import encounter conflicting data, DM removes all
 ↪ conflicting records from
the target table and records the data in the `${meta-schema}_${name}.
 ↪ conflict_error_v1`
table. In this configuration file, the conflicting data is recorded
 ↪ in the
`dm_meta_test.conflict_error_v1` table. When the full import phase is
 ↪ completed, the
tasks is paused and you are prompted to query this table and manually
 ↪ resolve the
conflicts. You need to resume the task and enter the incremental
 ↪ phase using the `resume-task` command.
on-duplicate-physical: "none"
The directory used for local KV sorting in the physical import mode.
 ↪ The default value of this
configuration is the same as the `dir` configuration. For details,
 ↪ refer to TiDB Lightning document: https://docs.pingcap.com/tidb/
 ↪ stable/tidb-lightning-physical-import-mode#environment-
 ↪ requirements
sorting-dir-physical: "./dumped_data"
Disk quota. Corresponds to the disk-quota configuration of TiDB
 ↪ Lightning. For details, refer to TiDB Lightning document: https://
 ↪ docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-mode-
 ↪ usage#configure-disk-quota-new-in-v620
disk-quota-physical: "0"
```

```
DM performs `ADMIN CHECKSUM TABLE <table>` for each table to verify
 ↳ data integrity after the import.
- "required" (default): performs admin checksum after the import. If
 ↳ checksum fails,
DM pauses the task and you need to manually handle the failure.
- "optional": performs admin checksum after the import. If checksum
 ↳ fails, DM logs a
warning and continues to migrate data. The task is not paused.
- "off": does not perform admin checksum after the import.
If checksum fails, the import is abnormal, which means the data is
 ↳ inconsistent or lost.
Therefore, it is recommended to always enable checksum.
checksum-physical: "required"

Configuration arguments of the sync processing unit.
syncers:
 global: # The configuration name of the processing
 ↳ unit.
 worker-count: 16 # The number of concurrent threads that
 ↳ apply binlogs which have been transferred to the local (16 by
 ↳ default). Adjusting this parameter has no effect on the
 ↳ concurrency of upstream pull logs, but has a significant effect on
 ↳ the downstream database.
 batch: 100 # The number of SQL statements in a
 ↳ transaction batch that the sync processing unit replicates to the
 ↳ downstream database (100 by default). Generally, it is recommended
 ↳ to set the value less than 500.
 enable-ansi-quotes: true # Enable this argument if `sql-mode: "
 ↳ ANSI_QUOTES"` is set in the `session`

If set to true, `INSERT` statements from upstream are rewritten to `
 ↳ REPLACE` statements, and `UPDATE` statements are rewritten to `
 ↳ DELETE` and `REPLACE` statements. This ensures that DML statements
 ↳ can be imported repeatedly during data migration when there is
 ↳ any primary key or unique index in the table schema.
safe-mode: false
The duration of the automatic safe mode.
If this value is not set or set to "", the default value is twice of `
 ↳ checkpoint-flush-interval` (30s by default), which is 60s.
If this value is set to "0s", DM reports an error when it
 ↳ automatically enters the safe mode.
If this value is set to a normal value, such as "1m30s", when the task
 ↳ pauses abnormally, when DM fails to
record safemode_exit_point, or when DM exits unexpectedly, the
 ↳ duration of the automatic safe mode is set to
```

```
1 minute 30 seconds.
safe-mode-duration: "60s"

If set to true, DM compacts as many upstream statements on the same
 ↪ rows as possible into a single statements without increasing
 ↪ latency.
For example, `INSERT INTO tb(a,b) VALUES(1,1); UPDATE tb SET b=11
 ↪ WHERE a=1`;` will be compacted to `INSERT INTO tb(a,b) VALUES
 ↪ (1,11);`, where "a" is the primary key
`UPDATE tb SET b=1 WHERE a=1; UPDATE tb(a,b) SET b=2 WHERE a=1;` will
 ↪ be compacted to `UPDATE tb(a,b) SET b=2 WHERE a=1;`, where "a" is
 ↪ the primary key
`DELETE FROM tb WHERE a=1; INSERT INTO tb(a,b) VALUES(1,1);` will be
 ↪ compacted to `REPLACE INTO tb(a,b) VALUES(1,1);`, where "a" is the
 ↪ primary key
compact: false
If set to true, DM combines as many statements of the same type as
 ↪ possible into a single statement and generates a single SQL
 ↪ statement with multiple rows of data.
For example, `INSERT INTO tb(a,b) VALUES(1,1); INSERT INTO tb(a,b)
 ↪ VALUES(2,2);` will become `INSERT INTO tb(a,b) VALUES(1,1),(2,2);`
`UPDATE tb SET b=11 WHERE a=1; UPDATE tb(a,b) set b=22 WHERE a=2;`
 ↪ will become `INSERT INTO tb(a,b) VALUES(1,11),(2,22) ON DUPLICATE
 ↪ KEY UPDATE a=VALUES(a), b= VALUES(b);`, where "a" is the primary
 ↪ key
`DELETE FROM tb WHERE a=1; DELETE FROM tb WHERE a=2` will become `
 ↪ DELETE FROM tb WHERE (a) IN (1),(2)`, where "a" is the primary key
multiple-rows: true

Configuration arguments of continuous data validation (validator).
validators:
global: # Configuration name.
 # full: validates the data in each row is correct.
 # fast: validates whether the row is successfully migrated to the
 ↪ downstream.
 # none: does not validate the data.
mode: full # Possible values are "full", "fast", and "none". The
 ↪ default value is "none", which does not validate the data.
worker-count: 4 # The number of validation workers in the background.
 ↪ The default value is 4.
row-error-delay: 30m # If a row cannot pass the validation within the
 ↪ specified time, it will be marked as an error row. The default
 ↪ value is 30m, which means 30 minutes.

----- Instance configuration -----
```

mysql-instances:

```
-
source-id: "mysql-replica-01" # The `source-id` in source.
 ↪ toml.
meta: # The position where the
 ↪ binlog replication starts when `task-mode` is `incremental` and
 ↪ the downstream database checkpoint does not exist. If the
 ↪ checkpoint exists, the checkpoint is used. If neither the `meta`
 ↪ configuration item nor the downstream database checkpoint exists,
 ↪ the migration starts from the latest binlog position of the
 ↪ upstream.

binlog-name: binlog.000001
binlog-pos: 4
binlog-gtid: "03fc0263-28c7-11e7-a653-6c0b84d59f30:1-7041423,05474d3c
 ↪ -28c7-11e7-8352-203db246dd3d:1-170" # You need to set this
 ↪ argument if you specify `enable-gtid: true` for the source of
 ↪ the incremental task.

route-rules: ["route-rule-1", "route-rule-2"] # The name of the mapping
 ↪ rule between the table matching the upstream database instance and
 ↪ the downstream database.
filter-rules: ["filter-rule-1", "filter-rule-2"] # The name of
 ↪ the binlog event filtering rule of the table matching the upstream
 ↪ database instance.
block-allow-list: "bw-rule-1" # The name of the block and
 ↪ allow lists filtering rule of the table matching the upstream
 ↪ database instance. Use black-white-list if the DM version is
 ↪ earlier than or equal to v2.0.0-beta.2.
expression-filters: ["even_c"] # Use expression filter rule
 ↪ named even_c.
mydumper-config-name: "global" # The name of the mydumpers
 ↪ configuration.
loader-config-name: "global" # The name of the loaders
 ↪ configuration.
syncer-config-name: "global" # The name of the syncers
 ↪ configuration.
validator-config-name: "global" # The name of the validators
 ↪ configuration.

-
source-id: "mysql-replica-02" # The `source-id` in source.
 ↪ toml.
mydumper-thread: 4 # The number of threads that
 ↪ the dump processing unit uses for dumping data. `mydumper-thread`
```

```
↳ corresponds to the `threads` configuration item of the mydumpers
↳ configuration. `mydumper-thread` has overriding priority when the
↳ two items are both configured.
loader-thread: 16 # The number of threads that
↳ the load processing unit uses for loading data. `loader-thread`
↳ corresponds to the `pool-size` configuration item of the loaders
↳ configuration. `loader-thread` has overriding priority when the
↳ two items are both configured. When multiple instances are
↳ migrating data to TiDB at the same time, reduce the value
↳ according to the load.
syncer-thread: 16 # The number of threads that
↳ the sync processing unit uses for replicating incremental data. `
↳ syncer-thread` corresponds to the `worker-count` configuration
↳ item of the syncers configuration. `syncer-thread` has overriding
↳ priority when the two items are both configured. When multiple
↳ instances are migrating data to TiDB at the same time, reduce the
↳ value according to the load.
```

## Configuration order

1. Edit the [global configuration](#).
2. Edit the [instance configuration](#) based on the global configuration.

## Global configuration

### Basic configuration

Refer to the comments in the [template](#) to see more details. Detailed explanations about `task-mode` are as follows:

- Description: the task mode that can be used to specify the data migration task to be executed.
- Value: string (`full`, `incremental`, or `all`).
  - `full` only makes a full backup of the upstream database and then imports the full data to the downstream database.
  - `incremental`: Only replicates the incremental data of the upstream database to the downstream database using the binlog. You can set the `meta` configuration item of the instance configuration to specify the starting position of incremental replication.
  - `all`: `full` + `incremental`. Makes a full backup of the upstream database, imports the full data to the downstream database, and then uses the binlog to make an incremental replication to the downstream database starting from the exported position during the full backup process (binlog position).

## Feature configuration set

Arguments in each feature configuration set are explained in the comments in the [template](#).

Parameter	Description
<code>routes</code>	The routing mapping rule set between the upstream and downstream tables. If the names of the upstream and downstream schemas and tables are the same, this item does not need to be configured. See <a href="#">Table Routing</a> for usage scenarios and sample configurations.
<code>filters</code>	The binlog event filter rule set of the matched table of the upstream database instance. If binlog filtering is not required, this item does not need to be configured. See <a href="#">Binlog Event Filter</a> for usage scenarios and sample configurations.
<code>block-allow- ↪ list</code>	The filter rule set of the block allow list of the matched table of the upstream database instance. It is recommended to specify the schemas and tables that need to be migrated through this item, otherwise all schemas and tables are migrated. See <a href="#">Binlog Event Filter</a> and <a href="#">Block &amp; Allow Lists</a> for usage scenarios and sample configurations.
<code>mydumpers</code>	Configuration arguments of dump processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure <code>thread</code> only using <code>mydumper-thread</code> .
<code>loaders</code>	Configuration arguments of load processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure <code>pool-size</code> only using <code>loader-thread</code> .
<code>syncers</code>	Configuration arguments of sync processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure <code>worker-count</code> only using <code>syncer-thread</code> .

## Instance configuration

This part defines the subtask of data migration. DM supports migrating data from one or multiple MySQL instances in the upstream to the same instance in the downstream.

For the configuration details of the above options, see the corresponding part in [Feature configuration set](#), as shown in the following table.

Option	Corresponding part
route-rules	routes
filter-rules	filters
block-allow-list	block-allow-list
mydumper-config-name	mydumpers
loader-config-name	loaders
syncer-config-name	syncers

### 13.6.9.4.4 DM-master Configuration File

This document introduces the configuration of DM-master, including a configuration file template and a description of each configuration parameter in this file.

#### Configuration file template

The following is a configuration file template of DM-master.

```
name = "dm-master"

log configuration
log-level = "info"
log-file = "dm-master.log"

DM-master listening address
master-addr = ":8261"
advertise-addr = "127.0.0.1:8261"

URLs for peer traffic
peer-urls = "http://127.0.0.1:8291"
advertise-peer-urls = "http://127.0.0.1:8291"

cluster configuration
initial-cluster = "master1=http://127.0.0.1:8291,master2=http
↳ ://127.0.0.1:8292,master3=http://127.0.0.1:8293"
join = ""

ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/cert.pem"
ssl-key = "/path/to/key.pem"
```

```
cert-allowed-cn = ["dm"]
```

## Configuration parameters

This section introduces the configuration parameters of DM-master.

### Global configuration

Parameter	Description
<code>name</code>	The name of the DM-master.
<code>log-level</code>	Specifies a log level from <code>debug</code> , <code>info</code> , <code>warn</code> , <code>error</code> , and <code>fatal</code> . The default log level is <code>info</code> .
<code>log-file</code>	Specifies the log file directory. If the parameter is not specified, the logs are printed onto the standard output.
<code>master-addr</code>	Specifies the address of DM-master which provides services. You can omit the IP address and specify the port number only, such as “:8261”.
<code>advertise- ↔ addr</code>	Specifies the address that DM-master advertises to the outside world.
<code>peer-urls</code>	Specifies the peer URL of the DM-master node.
<code>advertise- ↔ peer-urls</code>	Specifies the peer URL that DM-master advertises to the outside world. The value of <code>advertise-peer-urls</code> is by default the same as that of <code>peer-urls</code> .
<code>initial- ↔ cluster</code>	The value of <code>initial-cluster</code> is the combination of the <code>advertise-peer-urls</code> value of all DM-master nodes in the initial cluster.
<code>join</code>	The value of <code>join</code> is the combination of the <code>advertise-peer-urls</code> value of the existed DM-master nodes in the cluster. If the DM-master node is newly added, replace <code>initial-cluster</code> with <code>join</code> .
<code>ssl-ca</code>	The path of the file that contains list of trusted SSL CAs for DM-master to connect with other components.
<code>ssl-cert</code>	The path of the file that contains X509 certificate in PEM format for DM-master to connect with other components.
<code>ssl-key</code>	The path of the file that contains X509 key in PEM format for DM-master to connect with other components.

Parameter	Description
<code>cert-allowed</code>	Common Name list. ↪ <code>-cn</code>

### 13.6.9.4.5 DM-worker Configuration File

This document introduces the configuration of DM worker, including a configuration file template and a description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of the DM-worker:

```
Worker Configuration.
name = "worker1"

Log configuration.
log-level = "info"
log-file = "dm-worker.log"

DM-worker listen address.
worker-addr = ":8262"
advertise-addr = "127.0.0.1:8262"
join = "http://127.0.0.1:8261,http://127.0.0.1:8361,http://127.0.0.1:8461"

keepalive-ttl = 60
relay-keepalive-ttl = 1800 # New in DM v2.0.2.
relay-dir = "relay_log" # New in 5.4.0. When you use a relative path,
 ↪ check the deployment and start method of DM-worker to determine the
 ↪ full path.

ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/cert.pem"
ssl-key = "/path/to/key.pem"
cert-allowed-cn = ["dm"]
```

Configuration parameters

Global

Parameter	Description
<code>name</code>	The name of the DM-worker.
<code>log-level</code>	Specifies a log level from <code>debug</code> , <code>info</code> , <code>warn</code> , <code>error</code> , and <code>fatal</code> . The default log level is <code>info</code> .

Parameter	Description
<code>log-file</code>	Specifies the log file directory. If this parameter is not specified, the logs are printed onto the standard output.
<code>worker-addr</code>	Specifies the address of DM-worker which provides services. You can omit the IP address and specify the port number only, such as “:8262”.
<code>advertise- ↪ addr</code>	Specifies the address that DM-worker advertises to the outside world.
<code>join</code>	Corresponds to one or more <code>master-addrs</code> in the DM-master configuration file.
<code>keepalive- ↪ ttl</code>	The keepalive time (in seconds) of a DM-worker node to the DM-master node if the upstream data source of the DM-worker node does not enable the relay log. The default value is 60s.
<code>relay- ↪ keepalive ↪ -ttl</code>	The keepalive time (in seconds) of a DM-worker node to the DM-master node if the upstream data source of the DM-worker node enables the relay log. The default value is 1800s. This parameter is added since DM v2.0.2.
<code>relay-dir</code>	When relay log is enabled in the bound upstream data source, DM-worker stores the relay log in this directory. This parameter is new in v5.4.0 and takes precedence over the configuration of the upstream data source.
<code>ssl-ca</code>	The path of the file that contains list of trusted SSL CAs for DM-worker to connect with other components.
<code>ssl-cert</code>	The path of the file that contains X509 certificate in PEM format for DM-worker to connect with other components.
<code>ssl-key</code>	The path of the file that contains X509 key in PEM format for DM-worker to connect with other components.
<code>cert-allowed ↪ -cn</code>	Common Name list.

#### 13.6.9.4.6 Table Selector of TiDB Data Migration

Table selector provides a match rule based on [wildcard characters](#) for schema/table. To

match a specified table, configure `schema-pattern/table-pattern`.

Wildcard character

Table selector uses the following two wildcard characters in `schema-pattern/table-pattern`:

- The asterisk character (`*`, also called “star”)
  - `*` matches zero or more characters. For example, `doc*` matches `doc` and `document` but not `dodo`.
  - `*` can only be placed at the end of the word. For example, `doc*` is supported, while `do*c` is not supported.
- The question mark (`?`)
  - ? matches exactly one character except the empty character.

Match rules

- `schema-pattern` cannot be empty.
- `table-pattern` can be empty. When you configure it as empty, only `schema` is matched according to `schema-pattern`.
- When `table-pattern` is not empty, the `schema` is matched according to `schema-pattern` and `table` is matched according to `table-pattern`. Only when both `schema` and `table` are successfully matched, you can get the match result.

Usage examples

- Matching all schemas and tables that have a `schema_` prefix in the schema name:

```
schema-pattern: "schema_*"
table-pattern: ""
```

- Matching all tables that have a `schema_` prefix in the schema name and a `table_` prefix in the table name:

```
schema-pattern = "schema_*"
table-pattern = "table_*
```

### 13.6.9.5 Maintain DM Clusters Using OpenAPI

DM provides the OpenAPI feature for easily querying and operating the DM cluster, which is similar to the feature of [dmctl tools](#).

To enable OpenAPI, perform one of the following operations:

- If your DM cluster has been deployed directly using binary, add the following configuration to the DM-master configuration file.

```
openapi = true
```

- If your DM cluster has been deployed using TiUP, add the following configuration to the topology file:

```
server_configs:
 master:
 openapi: true
```

#### Note:

- DM provides the [specification document](#) that meets the OpenAPI 3.0.0 standard. This document contains all the request parameters and returned values. You can copy the document yaml and preview it in [Swagger Editor](#).
- After you deploy the DM-master nodes, you can access `http://{master ↵ -addr}/api/v1/docs` to preview the documentation online.

You can use the APIs to perform the following maintenance operations on the DM cluster:

#### 13.6.9.5.1 APIs for managing clusters

- [Get the information of a DM-master node](#)
- [Stop a DM-master node](#)
- [Get the information of a DM-worker node](#)
- [Stop a DM-worker node](#)

### 13.6.9.5.2 APIs for managing data sources

- Create a data source
- Get a data source
- Delete the data source
- Update a data source
- Enable a data source
- Disable a data source
- Get the information of a data source
- Get the data source list
- Start the relay-log feature for data sources
- Stop the relay-log feature for data sources
- Purge relay-log files that are no longer required
- Change the bindings between the data source and DM-workers
- Get the list of schema names of a data source
- Get the list of table names of a specified schema in a data source

### 13.6.9.5.3 APIs for managing replication tasks

- Create a replication task
- Get a replication task
- Delete a replication task
- Update a replication task
- Start a replication task
- Stop a replication task
- Get the information of a replication task
- Get the replication task list
- Get the migration rules of a replication task
- Get the list of schema names of the data source that is associated with a replication task
- Get the list of table names of a specified schema in the data source that is associated with a replication task
- Get the CREATE statement for schemas of the data source that is associated with a replication task
- Update the CREATE statement for schemas of the data source that is associated with a replication task
- Delete a schema of the data source that is associated with a replication task

The following sections describe the specific usage of the APIs.

### 13.6.9.5.4 API error message template

After sending an API request, if an error occurs, the returned error message is in the following format:

```
{
 "error_msg": "",
 "error_code": ""
}
```

From the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

#### 13.6.9.5.5 Get the information of a DM-master node

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

```
GET /api/v1/cluster/masters
```

Example

```
curl -X 'GET' \
 'http://127.0.0.1:8261/api/v1/cluster/masters' \
 -H 'accept: application/json'
```

```
{
 "total": 1,
 "data": [
 {
 "name": "master1",
 "alive": true,
 "leader": true,
 "addr": "127.0.0.1:8261"
 }
]
}
```

#### 13.6.9.5.6 Stop a DM-master node

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

```
DELETE /api/v1/cluster/masters/{master-name}
```

Example

```
curl -X 'DELETE' \
 'http://127.0.0.1:8261/api/v1/cluster/masters/master1' \
 -H 'accept: */*'
```

### 13.6.9.5.7 Get the information of a DM-worker node

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

GET /api/v1/cluster/workers

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/cluster/workers' \
-H 'accept: application/json'
```

```
{
 "total": 1,
 "data": [
 {
 "name": "worker1",
 "addr": "127.0.0.1:8261",
 "bound_stage": "bound",
 "bound_source_name": "mysql-01"
 }
]
}
```

### 13.6.9.5.8 Stop a DM-worker node

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

DELETE /api/v1/cluster/workers/{worker-name}

Example

```
curl -X 'DELETE' \
'http://127.0.0.1:8261/api/v1/cluster/workers/worker1' \
-H 'accept: */*'
```

### 13.6.9.5.9 Create a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Request URI

POST /api/v1/sources

Example

```
curl -X 'POST' \
 'http://127.0.0.1:8261/api/v1/sources' \
 -H 'accept: application/json' \
 -H 'Content-Type: application/json' \
 -d '{
 "source_name": "mysql-01",
 "host": "127.0.0.1",
 "port": 3306,
 "user": "root",
 "password": "123456",
 "enable": true,
 "enable_gtid": false,
 "security": {
 "ssl_ca_content": "",
 "ssl_cert_content": "",
 "ssl_key_content": "",
 "cert_allowed_cn": [
 "string"
]
 },
 "purge": {
 "interval": 3600,
 "expires": 0,
 "remain_space": 15
 }
 }'
```

```
{
 "source_name": "mysql-01",
 "host": "127.0.0.1",
 "port": 3306,
 "user": "root",
 "password": "123456",
 "enable": true,
 "enable_gtid": false,
 "security": {
 "ssl_ca_content": "",
 "ssl_cert_content": "",
 "ssl_key_content": "",
 "cert_allowed_cn": [
 "string"
]
 },
 "purge": {
```

```
"interval": 3600,
"expires": 0,
"remain_space": 15
},
"status_list": [
 {
 "source_name": "mysql-replica-01",
 "worker_name": "worker-1",
 "relay_status": {
 "master_binlog": "(mysql-bin.000001, 1979)",
 "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_dir": "./sub_dir",
 "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_catch_up_master": true,
 "stage": "Running"
 },
 "error_msg": "string"
 }
]
}
```

#### 13.6.9.5.10 Get a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Request URI

GET /api/v1/sources/{source-name}

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/sources/source-1?with_status=true' \
-H 'accept: application/json'
```

```
{
 "source_name": "mysql-01",
 "host": "127.0.0.1",
 "port": 3306,
 "user": "root",
 "password": "123456",
 "enable_gtid": false,
 "enable": false,
 "flavor": "mysql",
 "task_name_list": [
 "task1"
]
}
```

```
],
"security": {
 "ssl_ca_content": "",
 "ssl_cert_content": "",
 "ssl_key_content": "",
 "cert_allowed_cn": [
 "string"
]
},
"purge": {
 "interval": 3600,
 "expires": 0,
 "remain_space": 15
},
"status_list": [
 {
 "source_name": "mysql-replica-01",
 "worker_name": "worker-1",
 "relay_status": {
 "master_binlog": "(mysql-bin.000001, 1979)",
 "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_dir": "./sub_dir",
 "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_catch_up_master": true,
 "stage": "Running"
 },
 "error_msg": "string"
 }
],
"relay_config": {
 "enable_relay": true,
 "relay_binlog_name": "mysql-bin.000002",
 "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_dir": "./relay_log"
}
}
```

#### 13.6.9.5.11 Delete the data source

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

DELETE /api/v1/sources/{source-name}

### Example

```
curl -X 'DELETE' \
 'http://127.0.0.1:8261/api/v1/sources/mysql-01?force=true' \
 -H 'accept: application/json'
```

### 13.6.9.5.12 Update a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

#### Note:

When you use this API to update the data source configuration, make sure that there are no running tasks under the current data source.

#### Request URI

PUT /api/v1/sources/{source-name}

#### Example

```
curl -X 'PUT' \
 'http://127.0.0.1:8261/api/v1/sources/mysql-01' \
 -H 'accept: application/json' \
 -H 'Content-Type: application/json' \
 -d '{
 "source": {
 "source_name": "mysql-01",
 "host": "127.0.0.1",
 "port": 3306,
 "user": "root",
 "password": "123456",
 "enable_gtid": false,
 "enable": false,
 "flavor": "mysql",
 "task_name_list": [
 "task1"
],
 "security": {
 "ssl_ca_content": "",
 "ssl_cert_content": "",
 "ssl_key_content": "",
 "cert_allowed_cn": [

```

```
 "string"
]
},
"purge": {
 "interval": 3600,
 "expires": 0,
 "remain_space": 15
},
"relay_config": {
 "enable_relay": true,
 "relay_binlog_name": "mysql-bin.000002",
 "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_dir": "./relay_log"
}
}
}'
```

```
{
 "source_name": "mysql-01",
 "host": "127.0.0.1",
 "port": 3306,
 "user": "root",
 "password": "123456",
 "enable": true,
 "enable_gtid": false,
 "security": {
 "ssl_ca_content": "",
 "ssl_cert_content": "",
 "ssl_key_content": "",
 "cert_allowed_cn": [
 "string"
]
 },
 "purge": {
 "interval": 3600,
 "expires": 0,
 "remain_space": 15
 }
}
```

### 13.6.9.5.13 Enable a data source

This is a synchronous interface that enables a data source on a successful request and starts all subtasks of the task that rely on this data source in batch.

Request URI

POST /api/v1/sources/{source-name}/enable

Example

```
curl -X 'POST' \
'http://127.0.0.1:8261/api/v1/sources/mysql-01/enable' \
-H 'accept: */*' \
-H 'Content-Type: application/json'
```

#### 13.6.9.5.14 Disable a data source

This is a synchronous interface that deactivates this data source on a successful request and stops all subtasks of the task that rely on it in batch.

Request URI

POST /api/v1/sources/{source-name}/disable

Example

```
curl -X 'POST' \
'http://127.0.0.1:8261/api/v1/sources/mysql-01/disable' \
-H 'accept: */*' \
-H 'Content-Type: application/json'
```

#### 13.6.9.5.15 Get the data source list

This API is a synchronous interface. If the request is successful, the data source list is returned.

Request URI

GET /api/v1/sources

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/sources?with_status=true' \
-H 'accept: application/json'
```

```
{
 "data": [
 {
 "enable_gtid": false,
 "host": "127.0.0.1",
 "password": "*****",
 "port": 3306,
 "purge": {
```

```
 "expires": 0,
 "interval": 3600,
 "remain_space": 15
 },
 "security": null,
 "source_name": "mysql-01",
 "user": "root"
},
{
 "enable_gtid": false,
 "host": "127.0.0.1",
 "password": "*****",
 "port": 3307,
 "purge": {
 "expires": 0,
 "interval": 3600,
 "remain_space": 15
 },
 "security": null,
 "source_name": "mysql-02",
 "user": "root"
}
],
"total": 2
}
```

#### 13.6.9.5.16 Get the information of a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

GET /api/v1/sources/{source-name}/status

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/sources/mysql-replica-01/status' \
-H 'accept: application/json'
```

```
{
 "total": 1,
 "data": [
 {
 "source_name": "mysql-replica-01",
 "worker_name": "worker-1",
```

```
"relay_status": {
 "master_binlog": "(mysql-bin.000001, 1979)",
 "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_dir": "./sub_dir",
 "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_catch_up_master": true,
 "stage": "Running"
},
"error_msg": "string"
}
]
}
```

#### 13.6.9.5.17 Start the relay-log feature for data sources

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can [get the information of a data source](#).

Request URI

POST /api/v1/sources/{source-name}/relay/enable

Example

```
curl -X 'POST' \
'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/enable' \
-H 'accept: */*' \
-H 'Content-Type: application/json' \
-d '{
 "worker_name_list": [
 "worker-1"
],
 "relay_binlog_name": "mysql-bin.000002",
 "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
 "relay_dir": "./relay_log"
}'
```

#### 13.6.9.5.18 Stop the relay-log feature for data sources

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can [get the information of a data source](#).

Request URI

POST /api/v1/sources/{source-name}/relay/disable

Example

```
curl -X 'POST' \
 'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/disable' \
 -H 'accept: */*' \
 -H 'Content-Type: application/json' \
 -d '{
 "worker_name_list": [
 "worker-1"
]
 }'
```

### 13.6.9.5.19 Purge relay log files that are no longer required

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can [get the information of a data source](#).

Request URI

POST /api/v1/sources/{source-name}/relay/purge

Example

```
curl -X 'POST' \
 'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/purge' \
 -H 'accept: */*' \
 -H 'Content-Type: application/json' \
 -d '{
 "relay_binlog_name": "mysql-bin.000002",
 "relay_dir": "string"
 }'
```

### 13.6.9.5.20 Change the bindings between the data source and DM-workers

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can [get the information of a DM-worker node](#).

Request URI

POST /api/v1/sources/{source-name}/transfer

Example

```
curl -X 'POST' \
 'http://127.0.0.1:8261/api/v1/sources/mysql-01/transfer' \
 -H 'accept: */*' \
 -H 'Content-Type: application/json' \
 -d '{
 "worker_name_list": [
 "worker-1"
]
 }'
```

```
-d '{
 "worker_name": "worker-1"
}'
```

#### 13.6.9.5.21 Get the list of schema names of a data source

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

GET /api/v1/sources/{source-name}/schemas

Example

```
curl -X 'GET' \
 'http://127.0.0.1:8261/api/v1/sources/source-1/schemas' \
 -H 'accept: application/json'
```

```
[
 "db1"
]
```

#### 13.6.9.5.22 Get the list of table names of a specified schema in a data source

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

GET /api/v1/sources/{source-name}/schemas/{schema-name}

Example

```
curl -X 'GET' \
 'http://127.0.0.1:8261/api/v1/sources/source-1/schemas/db1' \
 -H 'accept: application/json'
```

```
[
 "table1"
]
```

#### 13.6.9.5.23 Create a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200. A successful request will return the information of the corresponding replication task.

Request URI

POST /api/v1/tasks

Example

```
curl -X 'POST' \
'http://127.0.0.1:8261/api/v1/tasks' \
-H 'accept: application/json' \
-H 'Content-Type: application/json' \
-d '{
 "task": {
 "name": "task-1",

#### 13.6.9.5.24 Get a replication task

This API is a synchronous interface. If the request is successful, the information of the corresponding replication task is returned.

Request URI

GET /api/v1/tasks/{task-name}?with\_status=true

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/tasks/task-1?with_status=true' \
-H 'accept: application/json'
```

```
{
 "name": "task-1",
 "task_mode": "all",
 "shard_mode": "pessimistic",
 "meta_schema": "dm-meta",
 "enhance_online_schema_change": true,
 "on_duplicate": "overwrite",
 "target_config": {

 }
]
}
}
```

#### 13.6.9.5.25 Delete a replication task

This interface is a synchronous interface and the Status Code of the returned body is 204 upon successful request.

Request URI

DELETE /api/v1/tasks/{task-name}

Example

```
curl -X 'DELETE' \
'http://127.0.0.1:8261/api/v1/tasks/task-1' \
-H 'accept: application/json'
```

#### 13.6.9.5.26 Update a replication task

This interface is a synchronous interface and a successful request returns the information of the task.

##### Note:

When you use this API to update the task configuration, make sure that the task is stopped and has run into incremental sync and that only some of the fields can be updated.

Request URI

PUT /api/v1/tasks/{task-name}

Example

```
curl -X 'PUT' \
 'http://127.0.0.1:8261/api/v1/tasks/task-1' \
 -H 'accept: application/json' \
 -H 'Content-Type: application/json' \
 -d '{

### 13.6.9.5.27 Start a replication task

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 204. To learn the latest status of a task, You can [get the information of a replication task](#).

Request URI

POST /api/v1/tasks/{task-name}/start

Example

```
curl -X 'POST' \
 'http://127.0.0.1:8261/api/v1/tasks/task-1/start' \
 -H 'accept: */*'
```

### 13.6.9.5.28 Stop a replication task

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn the latest status of a task, You can [get the information of a replication task](#).

Request URI

POST /api/v1/tasks/{task-name}/stop

Example

```
curl -X 'POST' \
 'http://127.0.0.1:8261/api/v1/tasks/task-1/stop' \
 -H 'accept: */*'
```

### 13.6.9.5.29 Get the information of a replication task

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

GET /api/v1/tasks/task-1/status

Example

```
curl -X 'GET' \
 'http://127.0.0.1:8261/api/v1/tasks/task-1/status?stage=running' \
 -H 'accept: application/json'
```

```
{
 "total": 1,
 "data": [
 {

 }
}
]
```

### 13.6.9.5.30 Get the replication task list

This API is a synchronous interface and a successful request returns a list of the corresponding tasks.

Request URI

GET /api/v1/tasks

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/tasks' \
-H 'accept: application/json'
```

```
{
 "total": 2,
 "data": [
 {

 }
]
}
]
```

### 13.6.9.5.31 Get the migration rules of a replication task

This API is a synchronous interface and a successful request returns a list of the migration rules of this task.

Request URI

GET /api/v1/tasks/{task-name}/sources/{source-name}/migrate\_targets

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/
 ↪ migrate_targets' \
-H 'accept: application/json'
```

```
{
 "total": 0,
 "data": [
 {
 "source_schema": "db1",
 "source_table": "tb1",
 "target_schema": "db1",
 "target_table": "tb1"
 }
]
}
```

```
}
]
}
```

### 13.6.9.5.32 Get the list of schema names of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas
```

Example

```
curl -X 'GET' \
 'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas' \
 -H 'accept: application/json'
```

```
[
 "db1"
]
```

### 13.6.9.5.33 Get the list of table names of a specified schema in the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-name
↪ }
```

Example

```
curl -X 'GET' \
 'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1' \
 -H 'accept: application/json'
```

```
[
 "table1"
]
```

### 13.6.9.5.34 Get the CREATE statement for schemas of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding CREATE statement is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-name
↪ }/{table-name}
```

Example

```
curl -X 'GET' \
'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1/
↪ table1' \
-H 'accept: application/json'
```

```
{
"schema_name": "db1",
"table_name": "table1",
"schema_create_sql": "CREATE TABLE `t1` (`id` int(11) NOT NULL
↪ AUTO_INCREMENT,PRIMARY KEY (`id`) /*! [clustered_index] CLUSTERED
↪ */) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin"
}
```

### 13.6.9.5.35 Update the CREATE statement for schemas of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200.

Request URI

```
POST /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-
↪ name}/{table-name}
```

Example

```
curl -X 'PUT' \
'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/task-1/schemas/db1/
↪ table1' \
-H 'accept: */*' \
-H 'Content-Type: application/json' \
-d '{
"sql_content": "CREATE TABLE `t1` (`c1` int(11) DEFAULT NULL, `c2` int
↪ (11) DEFAULT NULL, `c3` int(11) DEFAULT NULL) ENGINE=InnoDB DEFAULT
↪ CHARSET=utf8mb4 COLLATE=utf8mb4_bin;",
"flush": true,
"sync": true
}
```

```
}'
```

### 13.6.9.5.36 Delete a schema of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200.

Request URI

```
DELETE /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-
↳ name}/{table-name}
```

Example

```
curl -X 'DELETE' \
'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1/
↳ table1' \
-H 'accept: */*'
```

### 13.6.9.6 Compatibility Catalog of TiDB Data Migration

DM supports migrating data from different sources to TiDB clusters. Based on the data source type, DM has four compatibility levels:

- **Generally available (GA):** The application scenario has been verified and passed the GA test.
- **Experimental:** Although the application scenario has been verified, the test does not cover all scenarios or involves only a limited number of users. The application scenario might encounter problems occasionally.
- **Not tested:** DM is expected to be always compatible with MySQL during iteration. However, due to resource constraints, not all MySQL forks are tested with DM. Therefore, the *not tested* source or target is technically compatible with DM, but is not fully tested, which means you need to verify its compatibility before you use.
- **Incompatible:** DM is proved to be incompatible with the data source and the application is not recommended for use in production environments.

#### 13.6.9.6.1 Data sources

Data source	Compatibility level	Remarks
MySQL 5.5	Not tested	
MySQL 5.6	GA	
MySQL 5.7	GA	
MySQL 8.0	Experimental	
MariaDB < 10.1.2	Incompatible	Incompatible with binlog of the time type

Data source	Compatibility level	Remarks
MariaDB 10.1.2 ~ 10.5.10	Experimental	
MariaDB > 10.5.10	Incompatible	Permission errors reported in the check procedure

### 13.6.9.6.2 Target databases

#### Warning:

DM v5.3.0 is not recommended. If you have enabled GTID replication but do not enable relay log in DM v5.3.0, data replication fails with low probability.

Target database	Compatibility level	DM version
TiDB 6.0	GA	5.3.1
TiDB 5.4	GA	5.3.1
TiDB 5.3	GA	5.3.1
TiDB 5.2	GA	2.0.7, recommended: 5.4
TiDB 5.1	GA	2.0.4, recommended: 5.4
TiDB 5.0	GA	2.0.4, recommended: 5.4
TiDB 4.x	GA	2.0.1, recommended: 2.0.7
TiDB 3.x	GA	2.0.1, recommended: 2.0.7
MySQL	Experimental	
MariaDB	Experimental	

### 13.6.9.7 Secure

#### 13.6.9.7.1 Enable TLS for DM Connections

This document describes how to enable encrypted data transmission for DM connections, including connections between the DM-master, DM-worker, and dmctl components, and connections between DM and the upstream or downstream database.

Enable encrypted data transmission between DM-master, DM-worker, and dmctl

This section introduces how to enable encrypted data transmission between DM-master, DM-worker, and dmctl.

Configure and enable encrypted data transmission

1. Prepare certificates.

It is recommended to prepare a server certificate for DM-master and DM-worker separately. Make sure that the two components can authenticate each other. You can

choose to share one client certificate for dmctl.

To generate self-signed certificates, you can use `openssl`, `cfssl` and other tools based on `openssl`, such as `easy-rsa`.

If you choose `openssl`, you can refer to [generating self-signed certificates](#).

## 2. Configure certificates.

### Note:

You can configure DM-master, DM-worker, and dmctl to use the same set of certificates.

- DM-master

Configure in the configuration file or command-line arguments:

```
ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/master-cert.pem"
ssl-key = "/path/to/master-key.pem"
```

- DM-worker

Configure in the configuration file or command-line arguments:

```
ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/worker-cert.pem"
ssl-key = "/path/to/worker-key.pem"
```

- dmctl

After enabling encrypted transmission in a DM cluster, if you need to connect to the cluster using dmctl, specify the client certificate. For example:

```
./dmctl --master-addr=127.0.0.1:8261 --ssl-ca /path/to/ca.pem --ssl
 ↪ -cert /path/to/client-cert.pem --ssl-key /path/to/client-key
 ↪ .pem
```

### Verify component caller's identity

The Common Name is used for caller verification. In general, the callee needs to verify the caller's identity, in addition to verifying the key, the certificates, and the CA provided by the caller. For example, DM-worker can only be accessed by DM-master, and other visitors are blocked even though they have legitimate certificates.

To verify component caller's identity, you need to mark the certificate user identity using **Common Name (CN)** when generating the certificate, and to check the caller's identity by configuring the **Common Name** list for the callee.

- DM-master

Configure in the configuration file or command-line arguments:

```
cert-allowed-cn = ["dm"]
```

- DM-worker

Configure in the configuration file or command-line arguments:

```
cert-allowed-cn = ["dm"]
```

### Reload certificates

To reload the certificates and the keys, DM-master, DM-worker, and dmctl reread the current certificates and the key files each time a new connection is created.

When the files specified by `ssl-ca`, `ssl-cert` or `ssl-key` are updated, restart DM components to reload the certificates and the key files and reconnect with each other.

Enable encrypted data transmission between DM components and the upstream or downstream database

This section introduces how to enable encrypted data transmission between DM components and the upstream or downstream database.

Enable encrypted data transmission for upstream database

1. Configure the upstream database, enable the encryption support, and set the server certificate. For detailed operations, see [Using encrypted connections](#).
2. Set the MySQL client certificate in the source configuration file:

#### Note:

Make sure that all DM-master and DM-worker components can read the certificates and the key files via specified paths.

```
from:
 security:
 ssl-ca: "/path/to/mysql-ca.pem"
 ssl-cert: "/path/to/mysql-cert.pem"
 ssl-key: "/path/to/mysql-key.pem"
```

Enable encrypted data transmission for downstream TiDB

1. Configure the downstream TiDB to use encrypted connections. For detailed operations, refer to [Configure TiDB server to use secure connections](#).

2. Set the TiDB client certificate in the task configuration file:

**Note:**

Make sure that all DM-master and DM-worker components can read the certificates and the key files via specified paths.

```
target-database:
 security:
 ssl-ca: "/path/to/tidb-ca.pem"
 ssl-cert: "/path/to/tidb-client-cert.pem"
 ssl-key: "/path/to/tidb-client-key.pem"
```

### 13.6.9.7.2 Generate Self-signed Certificates for TiDB Data Migration

This document provides an example of using `openssl` to generate a self-signed certificate for TiDB Data Migration (DM). You can also generate certificates and keys that meet requirements according to your demands.

Assume that the topology of the instance cluster is as follows:

Name	Host IP	Services
node1	172.16.10.11	DM-master1
node2	172.16.10.12	DM-master2
node3	172.16.10.13	DM-master3
node4	172.16.10.14	DM-worker1
node5	172.16.10.15	DM-worker2
node6	172.16.10.16	DM-worker3

Install OpenSSL

- For Debian or Ubuntu OS:

```
apt install openssl
```

- For RedHat or CentOS OS:

```
yum install openssl
```

You can also refer to OpenSSL's official [download document](#) for installation.

Generate the CA certificate

A certificate authority (CA) is a trusted entity that issues digital certificates. In practice, contact your administrator to issue the certificate or use a trusted CA. CA manages multiple certificate pairs. Here you only need to generate an original pair of certificates as follows.

1. Generate the CA key:

```
openssl genrsa -out ca-key.pem 4096
```

2. Generate the CA certificates:

```
openssl req -new -x509 -days 1000 -key ca-key.pem -out ca.pem
```

3. Validate the CA certificates:

```
openssl x509 -text -in ca.pem -noout
```

Issue certificates for individual components

Certificates that might be used in the cluster

- The **master** certificate used by DM-master to authenticate DM-master for other components.
- The **worker** certificate used by DM-worker to authenticate DM-worker for other components.
- The **client** certificate used by dmctl to authenticate clients for DM-master and DM-worker.

Issue certificates for DM-master

To issue a certificate to a DM-master instance, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out master-key.pem 2048
```

2. Make a copy of the OpenSSL configuration template file (Refer to the actual location of your template file because it might have more than one location):

```
cp /usr/lib/ssl/openssl.cnf .
```

If you do not know the actual location, look for it in the root directory:

```
find / -name openssl.cnf
```

3. Edit `openssl.cnf`, add `req_extensions = v3_req` under the `[ req ]` field, and add `subjectAltName = @alt_names` under the `[ v3_req ]` field. Finally, create a new field and edit the information of Subject Alternative Name (SAN) according to the cluster topology description above.

```
[alt_names]
IP.1 = 127.0.0.1
IP.2 = 172.16.10.11
IP.3 = 172.16.10.12
IP.4 = 172.16.10.13
```

The following checking items of SAN are currently supported:

- IP
- DNS
- URI

**Note:**

If a special IP such as `0.0.0.0` is to be used for connection or communication, you must also add it to `alt_names`.

4. Save the `openssl.cnf` file, and generate the certificate request file: (When giving input to Common Name (e.g. `server FQDN` or `YOUR name`) `[]` :, you assign a Common Name (CN) to the certificate, such as `dm`. It is used by the server to validate the identity of the client. Each component does not enable the validation by default. You can enable it in the configuration file.)

```
openssl req -new -key master-key.pem -out master-cert.pem -config
↳ openssl.cnf
```

5. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA ca.pem -CAkey ca-key.pem -
↳ CACreateserial -in master-cert.pem -out master-cert.pem -
↳ extensions v3_req -extfile openssl.cnf
```

6. Verify that the certificate includes the SAN field (optional):

```
openssl x509 -text -in master-cert.pem -noout
```

7. Confirm that the following files exist in your current directory:

```
ca.pem
master-cert.pem
master-key.pem
```

**Note:**

The process of issuing certificates for the DM-worker instance is similar and will not be repeated in this document.

Issue certificates for the client (dmctl)

To issue a certificate to the client (dmctl), perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out client-key.pem 2048
```

2. Generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key client-key.pem -out client-cert.pem
```

3. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA ca.pem -CAkey ca-key.pem -
↳ Ccreateserial -in client-cert.pem -out client-cert.pem
```

### 13.6.9.8 Monitoring and Alerts

#### 13.6.9.8.1 Data Migration Monitoring Metrics

If your DM cluster is deployed using TiUP, the **monitoring system** is also deployed at the same time. This document describes the monitoring metrics provided by DM-worker.

Task

In the Grafana dashboard, the default name of DM is `DM-task`.

`overview`

**Overview** contains some monitoring metrics of all the DM-worker and DM-master instances or sources in the currently selected task. The current default alert rule is only for a single DM-worker/DM-master instance/source.

Metric name	Description	Alert	Severity level
task state	The state of subtasks for migration	N/A	N/A
storage capacity	The total storage capacity of the disk occupied by relay logs	N/A	N/A
storage remain	The remaining storage capacity of the disk occupied by relay logs	N/A	N/A
binlog file gap between master and relay load	The number of binlog files by which the relay processing unit is behind the upstream master	N/A	N/A
progress	The percentage of the completed loading process of the load unit. The value is between 0%~100%	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and syncer	The number of binlog files by which the binlog replication unit is behind the upstream master	N/A	N/A
shard lock resolving	Whether the current subtask is waiting for sharding DDL migration. A value greater than 0 means that the current subtask is waiting for sharding DDL migration	N/A	N/A

### Operation errors

Metric name	Description	Alert	Severity level
before any operate error	The number of errors before any operation	N/A	N/A
source bound error	The number of errors of data source binding operations	N/A	N/A

---

Metric name	Description	Alert	Severity level
start error	The number of errors during the start of a subtask	N/A	N/A
pause error	The number of errors during the pause of a subtask	N/A	N/A
resume error	The number of errors during the resuming of a subtask	N/A	N/A
auto-resume error	The number of errors during the auto-resuming of a subtask	N/A	N/A
update error	The number of errors during the update of a subtask	N/A	N/A
stop error	The number of errors during the stop of a subtask	N/A	N/A

---

High availability

Metric name	Description	Alert	Severity level
number of dm-masters start leader components per minute	The number of DM-master attempts to enable leader related components per minute	N/A	N/A
number of workers in different state	The number of DM-workers in different states	Some DM-worker(s) has (have) been offline for more than one hour	critical
workers' state	The state of the DM-worker	N/A	N/A
number of worker event error	The number of different types of DM-worker errors	N/A	N/A
shard ddl error per minute	The number of different types of sharding DDL errors per minute	Any sharding DDL error occurs	critical

Metric name	Description	Alert	Severity level
number of pending shard ddl	The number of pending sharding DDL operations	Any pending sharding DDL operation has existed for more than one hour	critical

#### Task state

Metric name	Description	Alert	Severity level
task state	The state of subtasks	An alert occurs when the sub-task has been in the <b>Paused</b> state for more than 20 minutes	critical

## Dump/Load unit

The following metrics show only when `task-mode` is in the `full` or `all` mode.

Metric name	Description	Alert	Severity level
dump progress	The percentage of the completed dumping process of the dump unit. The value range is 0%~100%	N/A	N/A
load progress	The percentage of the completed loading process of the load unit. The value range is 0%~100%	N/A	N/A
checksum progress	The percentage of the completed checksum process after the load unit finishes dumping. The value range is 0%~100%	N/A	N/A

Metric name	Description	Alert	Severity level
total bytes for load unit	The bytes processed in the parsing, in generating data KV, and in generating index KV stages of the import process by the load unit	N/A	N/A
chunk process duration	The duration of the load unit processing the data source file chunk (in seconds)	N/A	N/A
data file size	The total size of the data files (includes the INSERT INTO statement) in the full data imported by the load unit	N/A	N/A
dump process exits with error	The dump unit encounters an error within the DM-worker and exits	Immediate alerts	Critical
load process exits with error	The load unit encounters an error within the DM-worker and exits	Immediate alerts	Critical

## Binlog replication

The following metrics show only when `task-mode` is in the `incremental` or `all` mode.

Metric name	Description	Alert	Severity level
remaining time to sync	The predicted remaining time it takes for <code>syncer</code> to be completely migrated with the upstream master (in minutes)	N/A	N/A
replicate lag gauge	The latency time it takes to replicate the binlog from upstream to downstream (in seconds)	N/A	N/A
replicate lag histogram	The histogram of replicating the binlog from upstream to downstream (in seconds). Note that due to different statistical mechanisms, the data might be inaccurate	N/A	N/A

Metric name	Description	Alert	Severity level
process exist with error	The binlog replication unit encounters an error within the DM-worker and exits	Immediate alerts	Critical

Metric name	Description	Alert	Severity level
binlog file gap between master and syncer	The number of binlog files by which the <b>syncer</b> processing unit is behind the upstream master	An alert occurs when the number of binlog files by which the <b>syncer</b> processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical

Metric name	Description	Alert	Severity level
binlog file gap between relay and syncer	The number of binlog files by which <b>syncer</b> is behind <b>relay</b>	An alert occurs when the number of binlog files by which the <b>syncer</b> $\hookrightarrow$ processing unit is behind the <b>relay</b> processing unit exceeds one ( $>1$ ) and the condition lasts over 10 minutes	critical

Metric name	Description	Alert	Severity level
binlog event QPS	The number of binlog events received per unit of time (this number does not include the events that need to be skipped)	N/A	N/A
skipped binlog event QPS	The number of binlog events received per unit of time that need to be skipped	N/A	N/A
read binlog event duration	The duration that the binlog replication unit reads the binlog from the relay log or the upstream MySQL (in seconds)	N/A	N/A
transform binlog event duration	The duration that the binlog replication unit parses and transforms the binlog into SQL statements (in seconds)	N/A	N/A

Metric name	Description	Alert	Severity level
dispatch binlog event duration	The duration that the binlog replication unit dispatches a binlog event (in seconds)	N/A	N/A
transaction execution latency	The duration that the binlog replication unit executes the transaction to the downstream (in seconds)	N/A	N/A
binlog event size	The size of a binlog event that the binlog replication unit reads from the relay log or the upstream MySQL	N/A	N/A
DML queue remain length	The length of the remaining DML job queue	N/A	N/A
total sqls jobs	The number of newly added jobs per unit of time	N/A	N/A
finished sqls jobs	The number of finished jobs per unit of time	N/A	N/A

Metric name	Description	Alert	Severity level
statement execution latency	The duration that the binlog replication unit executes the statement to the downstream (in seconds)	N/A	N/A
add job duration	The duration that the binlog replication unit adds a job to the queue (in seconds)	N/A	N/A
DML conflict detect duration	The duration that the binlog replication unit detects the conflict in DML (in seconds)	N/A	N/A
skipped event duration	The duration that the binlog replication unit skips a binlog event (in seconds)	N/A	N/A
unsynced tables	The number of tables that have not received the shard DDL statement in the current subtask	N/A	N/A

Metric name	Description	Alert	Severity level
shard lock resolving	Whether the current subtask is waiting for the shard DDL lock to be resolved. A value greater than 0 indicates that it is waiting for the shard DDL lock to be resolved.	N/A	N/A
ideal QPS	The highest QPS that can be achieved when the running time of DM is 0	N/A	N/A
binlog event row finished	The number of rows in a binlog event	N/A	N/A
transaction total	The number of finished transactions in total	N/A	N/A
replication transaction batch	The number of sql rows in the transaction executed to the downstream	N/A	N/A
flush checkpoints time interval	The time interval for flushing the checkpoints (in seconds)	N/A	N/A

## Relay log

**Note:**

Currently, DM v2.0 does not support enabling the relay log feature.

Metric name	Description	Alert	Severity level
storage capacity	The storage capacity of the disk occupied by the relay log	N/A	N/A
storage remain	The remaining storage capacity of the disk occupied by the relay log	An alert is needed once the value is smaller than 10G	critical
process exits with error	The relay log encounters an error within the DM-worker and exits	Immediate alerts	critical
relay log data corruption	The number of corrupted relay log files	Immediate alerts	emergency

Metric name	Description	Alert	Severity level
fail to read binlog from master	The number of errors encountered when the relay log reads the binlog from the upstream MySQL	Immediate alerts	Critical
fail to write relay log	The number of errors encountered when the relay log writes the binlog to disks	Immediate alerts	Critical
binlog file index	The largest index number of relay log files. For example, “value = 1” indicates “relay-log.000001”	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and relay	The number of binlog files in the relay log that are behind the upstream master	An alert occurs when the number of binlog files by which the relay processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical
binlog pos	The write offset of the latest relay log file	N/A	N/A

Metric name	Description	Alert	Severity level
read binlog event duration	The duration that the relay log reads binlog from the upstream MySQL (in seconds)	N/A	N/A
write relay log duration	The duration that the relay log writes binlog into the disks each time (in seconds)	N/A	N/A
binlog event size	The size of a single binlog event that the relay log writes into the disks	N/A	N/A

## Instance

In the Grafana dashboard, the default name of an instance is `DM-instance`.

## Relay log

Metric name	Description	Alert	Severity level
storage capacity	The total storage capacity of the disk occupied by the relay log	N/A	N/A

Metric name	Description	Alert	Severity level
storage re-main	The remaining storage capacity within the disk occupied by the relay log	An alert occurs once the value is smaller than 10G	critical
process exits with error	The relay log encounters an error in DM-worker and exits	Immediate alerts	critical
relay log data corruption	The number of corrupted relay logs	Immediate alerts	emergency
fail to read binlog from master	The number of errors encountered when relay log reads the binlog from the upstream MySQL	Immediate alerts	critical
fail to write relay log	The number of errors encountered when the relay log writes the binlog to disks	Immediate alerts	critical

Metric name	Description	Alert	Severity level
binlog file index	The largest index number of relay log files. For example, “value = 1” indicates “relay-log.000001”	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and relay	The number of binlog files by which the <b>relay</b> processing unit is behind the upstream master	An alert occurs when the number of binlog files by which the <b>relay</b> processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical
binlog pos	The write offset of the latest relay log file	N/A	N/A

Metric name	Description	Alert	Severity level
read binlog duration	The duration that the relay log reads the binlog from the upstream MySQL (in seconds)	N/A	N/A
write relay log duration	The duration that the relay log writes the binlog into the disk each time (in seconds)	N/A	N/A
binlog size	The size of a single binlog event that the relay log writes into the disks	N/A	N/A

## Task

Metric name	Description	Alert	Severity level
task state	The state of subtasks for migration	An alert occurs when the sub-task has been paused for more than 10 minutes	critical

Metric name	Description	Alert	Severity level
load progress	The percentage of the completed loading process of the load unit. The value range is 0%~100%	N/A	N/A
binlog file gap between master and syncer shard lock resolving	The number of binlog files by which the binlog replication unit is behind the upstream master and syncer master Whether the current subtask is waiting for sharding DDL migration. A value greater than 0 means that the current subtask is waiting for sharding DDL migration.	N/A	N/A

### 13.6.9.8.2 DM Alert Information

The [alert system](#) is deployed by default when you deploy a DM cluster using TiUP.

For more information about DM alert rules and the solutions, refer to [handle alerts](#).

Both DM alert information and monitoring metrics are based on Prometheus. For more

information about their relationship, refer to [DM monitoring metrics](#).

### 13.6.9.9 Handle Errors in TiDB Data Migration

This document introduces the error system and how to handle common errors when you use DM.

#### 13.6.9.9.1 Error system

In the error system, usually, the information of a specific error is as follows:

- **code**: error code.

DM uses the same error code for the same error type. An error code does not change as the DM version changes.

Some errors might be removed during the DM iteration, while the error codes are not. DM uses a new error code instead of an existing one for a new error.

- **class**: error type.

It is used to mark the component where an error occurs (error source).

The following table displays all error types, error sources, and error samples.

Error Type	Error Source	Error Sample
database	Database operations	[code=10003:class=database:scope=downstream:level=medium] database driver: invalid connection
functional	Underlying functions of DM	[code=11005:class=functional:scope=internal:level=high] not allowed operation: alter multiple tables in one statement
config	Incorrect configuration	[code=20005:class=config:scope=internal:level=medium] empty source-id not valid
binlog-op	Binlog operations	[code=22001:class=binlog-op:scope=internal:level=high] empty UUIDs not valid
checkpoint	checkpoint operations	[code=24002:class=checkpoint:scope=internal:level=high] save point bin.1234 is older than current pos bin.1371
task-check	Performing task check	[code=26003:class=task-check:scope=internal:level=medium] new table router error

```

relay-event-lib| Executing the basic functions of the relay module | [code=28001:
↪ class=relay-event-lib:scope=internal:level=high] parse server-uuid.
↪ index |
relay-unit | relay processing unit | [code=30015:class=relay-unit:scope=
↪ upstream:level=high] TCPReader get event: ERROR 1236 (HY000): Could
↪ not open log file |
dump-unit | dump processing unit | [code=32001:class=dump-unit:scope=internal
↪ :level=high] mydumper runs with error: CRITICAL **: 15:12:17.559:
↪ Error connecting to database: Access denied for user 'root'@'172.17.0.1'
↪ (using password: NO) |

scheduler | Scheduling operations (of data migration tasks) | [code=46001:class=
↪ scheduler:scope=internal:level=high],"the scheduler has not started"
|
dmctl | An error occurs within dmctl or when it interacts with other components |
[code=48001:class=dmctl:scope=internal:level=high],"can not create grpc
↪ connection" |

```

- **scope:** Error scope.

It is used to mark the scope and source of DM objects when an error occurs. **scope** includes four types: **not-set**, **upstream**, **downstream**, and **internal**.

If the logic of the error directly involves requests between upstream and downstream databases, the scope is set to **upstream** or **downstream**; otherwise, it is currently set to **internal**.

- **level:** Error level.

The severity level of the error, including **low**, **medium**, and **high**.

- The **low** level error usually relates to user operations and incorrect inputs. It does not affect migration tasks.
- The **medium** level error usually relates to user configurations. It affects some newly started services; however, it does not affect the existing DM migration status.
- The **high** level error usually needs your attention, since you need to resolve it to avoid the possible interruption of a migration task.

- **message:** Error descriptions.

Detailed descriptions of the error. To wrap and store every additional layer of error message on the error call chain, the `errors.Wrap` mode is adopted. The message description wrapped at the outermost layer indicates the error in DM and the message description wrapped at the innermost layer indicates the error source.

- **workaround:** Error handling methods (optional)

The handling methods for this error. For some confirmed errors (such as configuration errors), DM gives the corresponding manual handling methods in `workaround`.

- Error stack information (optional)

Whether DM outputs the error stack information depends on the error severity and the necessity. The error stack records the complete stack call information when the error occurs. If you cannot figure out the error cause based on the basic information and the error message, you can trace the execution path of the code when the error occurs using the error stack.

For the complete list of error codes, refer to the [error code lists](#).

### 13.6.9.9.2 Troubleshooting

If you encounter an error while running DM, take the following steps to troubleshoot this error:

1. Execute the `query-status` command to check the task running status and the error output.
2. Check the log files related to the error. The log files are on the DM-master and DM-worker nodes. To get key information about the error, refer to the [error system](#). Then check the [Handle Common Errors](#) section to find the solution.
3. If the error is not covered in this document, and you cannot solve the problem by checking the log or monitoring metrics, [get support](#) from PingCAP or the community.
4. After the error is resolved, restart the task using `dmctl`.

```
resume-task ${task name}
```

However, you need to reset the data migration task in some cases. For details, refer to [Reset the Data Migration Task](#).

### 13.6.9.3 Handle common errors

Error Code

Error Description	How to
↪ Handle	

code=10001	Abnormal database operation.	Further analyze the error message and error stack.
code=10002	The <code>bad connection</code> error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is not sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, check the network or TiDB status.
code=10003	The <code>invalid connection</code> error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is partly sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, further check the error message and analyze the information based on the actual situation.
code=10005	Occurs when performing the <code>QUERY</code> type SQL statements.	
code=10006	Occurs when performing the <code>EXECUTE</code> type SQL statements, including DDL statements and DML statements of the <code>INSERT</code> , <code>UPDATE</code> or <code>DELETE</code> type.	For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.
code=11006	Occurs when the built-in parser of DM parses the incompatible DDL statements.	Refer to <a href="#">Data Migration - incompatible DDL statements</a> for solution.
code=20010	Occurs when decrypting the database password that is provided in task configuration.	Check whether the downstream database password provided in the configuration task is <a href="#">correctly encrypted using dmctl</a> .
code=26002	The task check fails to establish database connection.	For more detailed error information, check the error message which usually includes the error code and error information returned for database operations. Check whether the machine where DM-master is located has permission to access the upstream.
code=32001	Abnormal dump processing unit	If the error message contains <code>mydumper: ↪ argument list too long.</code> , configure the table to be exported by manually adding the <code>--regex</code> regular expression in the Mydumper argument <code>extra-args</code> in the <code>task.yaml</code> file according to the block-allow list. For example, to export all tables named <code>hello</code> , add <code>↪ regex '.*\\.hello\$'</code> ; to export all tables, add <code>--regex '.*'</code> .
code=38008	An error occurs in the gRPC communication among DM components.	Check <code>class</code> . Find out the error occurs in the interaction of which components. Determine the type of communication error. If the error occurs when establishing gRPC connection, check

whether the communication server is working normally. |

What can I do when a migration task is interrupted with the `invalid connection` error returned?

Reason

The `invalid connection` error indicates that anomalies have occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy) and that a part of the data for the current request has been sent to TiDB.

Solutions

Because DM has the feature of concurrently migrating data to the downstream in migration tasks, several errors might occur when a task is interrupted. You can check these errors by using `query-status`.

- If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
- If DM does not or fails to retry automatically because of version problems, use `stop-task` to stop the task and then use `start-task` to restart the task.

A migration task is interrupted with the `driver: bad connection` error returned

Reason

The `driver: bad connection` error indicates that anomalies have occurred in the connection between DM and the upstream TiDB database (such as network failure and TiDB restart) and that the data of the current request has not yet been sent to TiDB at that moment.

Solution

The current version of DM automatically retries on error. If you use the previous version which does not support automatically retry, you can execute the `stop-task` command to stop the task. Then execute `start-task` to restart the task.

The relay unit throws error `event from * in * diff from passed-in event *` or a migration task is interrupted with failing to get or parse binlog errors like `get binlog error ERROR 1236 (HY000) and binlog checksum mismatch, data may be corrupted` returned

Reason

During the DM process of relay log pulling or incremental replication, this two errors might occur if the size of the upstream binlog file exceeds **4 GB**.

**Cause:** When writing relay logs, DM needs to perform event verification based on binlog positions and the size of the binlog file, and store the replicated binlog positions as checkpoints. However, the official MySQL uses `uint32` to store binlog positions. This means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

Solutions

For relay units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.
2. Stop the DM-worker.
3. Copy the corresponding binlog file in the upstream to the relay log directory as the relay log file.
4. In the relay log directory, update the corresponding `relay.meta` file to pull from the next binlog file. If you have specified `enable_gtid` to `true` for the DM-worker, you need to modify the GTID corresponding to the next binlog file when updating the `relay.meta` file. Otherwise, you don't need to modify the GTID.

Example: when the error occurs, `binlog-name = "mysql-bin.004451"` and `binlog-pos = 2453`. Update them respectively to `binlog-name = "mysql-bin.004452"`  
↪ and `binlog-pos = 4`, and update `binlog-gtid` to `f0e914ef-54cf-11e7-813d-6c92bf2fa791:1-138218058`.

5. Restart the DM-worker.

For binlog replication processing units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.
2. Stop the migration task using `stop-task`.
3. Update the `binlog_name` in the global checkpoints and in each table checkpoint of the downstream `dm_meta` database to the name of the binlog file in error; update `binlog_pos` to a valid position value for which migration has completed, for example, 4.

Example: the name of the task in error is `dm_test`, the corresponding `ssource-id` is `replica-1`, and the corresponding binlog file is `mysql-bin|000001.004451`. Execute the following command:

```
UPDATE dm_test_syncer_checkpoint SET binlog_name='mysql-bin
↪ |000001.004451', binlog_pos = 4 WHERE id='replica-1';
```

4. Specify `safe-mode: true` in the `syncers` section of the migration task configuration to ensure re-entrant.
5. Start the migration task using `start-task`.
6. View the status of the migration task using `query-status`. You can restore `safe-mode` to the original value and restart the migration task when migration is done for the original error-triggering relay log files.

Access denied for user 'root'@'172.31.43.27' (using password: YES) shows when you query the task or check the log

For database related passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. For how to encrypt the plaintext password, see [Encrypt the database password using dmctl](#).

In addition, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also [prechecks the corresponding privileges automatically](#) while starting the data migration task.

The load processing unit reports the error `packet for query is too large`. Try adjusting the `'max_allowed_packet'` variable

#### Reasons

- Both MySQL client and MySQL/TiDB server have the quota limits for `max_allowed_packet`  $\leftrightarrow$  . If any `max_allowed_packet` exceeds a limit, the client receives the error message. Currently, for the latest version of DM and TiDB server, the default value of `max_allowed_packet` is 64M.
- The full data import processing unit in DM does not support splitting the SQL file exported by the Dump processing unit in DM.

#### Solutions

- It is recommended to set the `statement-size` option of `extra-args` for the Dump processing unit:

According to the default `--statement-size` setting, the default size of `Insert`  $\leftrightarrow$  `Statement` generated by the Dump processing unit is about 1M. With this default setting, the load processing unit does not report the error `packet for query is`  $\leftrightarrow$  `too large`. Try adjusting the `'max_allowed_packet'` variable in most cases.

Sometimes you might receive the following WARN log during the data dump. This WARN log does not affect the dump process. This only means that wide tables are dumped.

```
Row bigger than statement_size for xxx
```

- If the single row of the wide table exceeds 64M, you need to modify the following configurations and make sure the configurations take effect.
  - Execute `set @@global.max_allowed_packet=134217728` (134217728 = 128 MB) in the TiDB server.
  - First add the `max-allowed-packet: 134217728` (128 MB) to the `target-`  $\leftrightarrow$  `database` section in the DM task configuration file. Then, execute the `stop-task` command and execute the `start-task` command.

### 13.6.9.10 TiDB Data Migration Glossary

This document lists the terms used in the logs, monitoring, configurations, and documentation of TiDB Data Migration (DM).

#### 13.6.9.10.1 B

##### Binlog

In TiDB DM, binlogs refer to the binary log files generated in the TiDB database. It has the same indications as that in MySQL or MariaDB. Refer to [MySQL Binary Log](#) and [MariaDB Binary Log](#) for details.

##### Binlog event

Binlog events are information about data modification made to a MySQL or MariaDB server instance. These binlog events are stored in the binlog files. Refer to [MySQL Binlog Event](#) and [MariaDB Binlog Event](#) for details.

##### Binlog event filter

**Binlog event filter** is a more fine-grained filtering feature than the block and allow lists filtering rule. Refer to [binlog event filter](#) for details.

##### Binlog position

The binlog position is the offset information of a binlog event in a binlog file. Refer to [MySQL SHOW BINLOG EVENTS](#) and [MariaDB SHOW BINLOG EVENTS](#) for details.

##### Binlog replication processing unit/sync unit

Binlog replication processing unit is the processing unit used in DM-worker to read upstream binlogs or local relay logs, and to migrate these logs to the downstream. Each subtask corresponds to a binlog replication processing unit. In the current documentation, the binlog replication processing unit is also referred to as the sync processing unit.

##### Block & allow table list

Block & allow table list is the feature that filters or only migrates all operations of some databases or some tables. Refer to [block & allow table lists](#) for details. This feature is similar to [MySQL Replication Filtering](#) and [MariaDB Replication Filters](#).

#### 13.6.9.10.2 C

##### Checkpoint

A checkpoint indicates the position from which a full data import or an incremental replication task is paused and resumed, or is stopped and restarted.

- In a full import task, a checkpoint corresponds to the offset and other information of the successfully imported data in a file that is being imported. A checkpoint is updated synchronously with the data import task.

- In an incremental replication, a checkpoint corresponds to the **binlog position** and other information of a **binlog event** that is successfully parsed and migrated to the downstream. A checkpoint is updated after the DDL operation is successfully migrated or 30 seconds after the last update.

In addition, the `relay.meta` information corresponding to a **relay processing unit** works similarly to a checkpoint. A relay processing unit pulls the **binlog event** from the upstream and writes this event to the **relay log**, and writes the **binlog position** or the GTID information corresponding to this event to `relay.meta`.

#### 13.6.9.10.3 D

Dump processing unit/dump unit

The dump processing unit is the processing unit used in DM-worker to export all data from the upstream. Each subtask corresponds to a dump processing unit.

#### 13.6.9.10.4 G

GTID

The GTID is the global transaction ID of MySQL or MariaDB. With this feature enabled, the GTID information is recorded in the binlog files. Multiple GTIDs form a GTID set. Refer to [MySQL GTID Format and Storage](#) and [MariaDB Global Transaction ID](#) for details.

#### 13.6.9.10.5 L

Load processing unit/load unit

The load processing unit is the processing unit used in DM-worker to import the fully exported data to the downstream. Each subtask corresponds to a load processing unit. In the current documentation, the load processing unit is also referred to as the import processing unit.

#### 13.6.9.10.6 M

Migrate/migration

The process of using the TiDB Data Migration tool to copy the **full data** of the upstream database to the downstream database.

In the case of clearly mentioning “full”, not explicitly mentioning “full or incremental”, and clearly mentioning “full + incremental”, use migrate/migration instead of replicate/replication.

### 13.6.9.10.7 R

#### Relay log

The relay log refers to the binlog files that DM-worker pulls from the upstream MySQL or MariaDB, and stores in the local disk. The format of the relay log is the standard binlog file, which can be parsed by tools such as [mysqlbinlog](#) of a compatible version. Its role is similar to [MySQL Relay Log](#) and [MariaDB Relay Log](#).

For more details such as the relay log's directory structure, initial migration rules, and data purge in TiDB DM, see [TiDB DM relay log](#).

#### Relay processing unit

The relay processing unit is the processing unit used in DM-worker to pull binlog files from the upstream and write data into relay logs. Each DM-worker instance has only one relay processing unit.

#### Replicate/replication

The process of using the TiDB Data Migration tool to copy the **incremental data** of the upstream database to the downstream database.

In the case of clearly mentioning “incremental”, use `replicate/replication` instead of `migrate/migration`.

### 13.6.9.10.8 S

#### Safe mode

Safe mode is the mode in which DML statements can be imported more than once when the primary key or unique index exists in the table schema. In this mode, some statements from the upstream are migrated to the downstream only after they are re-written. The `INSERT` statement is re-written as `REPLACE`; the `UPDATE` statement is re-written as `DELETE` and `REPLACE`.

This mode is enabled in any of the following situations:

- The safe mode remains enabled when the `safe-mode` parameter in the task configuration file is set to `true`.
- In shard merge scenarios, the safe mode remains enabled before DDL statements are replicated in all sharded tables.
- If the argument `--consistency none` is configured for the dump processing unit of a full migration task, it cannot be determined whether the binlog changes at the beginning of the export affect the exported data or not. Therefore, the safe mode remains enabled for the incremental replication of these binlog changes.
- If the task is paused by error and then resumed, the operations on some data might be executed twice.

#### Shard DDL

The shard DDL is the DDL statement that is executed on the upstream sharded tables. It needs to be coordinated and migrated by TiDB DM in the process of merging the sharded tables. In the current documentation, the shard DDL is also referred to as the sharding DDL.

#### Shard DDL lock

The shard DDL lock is the lock mechanism that coordinates the migration of shard DDL. Refer to [the implementation principles of merging and migrating data from sharded tables in the pessimistic mode](#) for details. In the current documentation, the shard DDL lock is also referred to as the sharding DDL lock.

#### Shard group

A shard group is all the upstream sharded tables to be merged and migrated to the same table in the downstream. Two-level shard groups are used for implementation of TiDB DM. Refer to [the implementation principles of merging and migrating data from sharded tables in the pessimistic mode](#) for details. In the current documentation, the shard group is also referred to as the sharding group.

#### Subtask

The subtask is a part of a data migration task that is running on each DM-worker instance. In different task configurations, a single data migration task might have one subtask or multiple subtasks.

#### Subtask status

The subtask status is the status of a data migration subtask. The current status options include `New`, `Running`, `Paused`, `Stopped`, and `Finished`. Refer to [subtask status](#) for more details about the status of a data migration task or subtask.

### 13.6.9.10.9 T

#### Table routing

The table routing feature enables DM to migrate a certain table of the upstream MySQL or MariaDB instance to the specified table in the downstream, which can be used to merge and migrate sharded tables. Refer to [table routing](#) for details.

#### Task

The data migration task, which is started after you successfully execute a `start-task`  $\hookrightarrow$  command. In different task configurations, a single migration task can run on a single DM-worker instance or on multiple DM-worker instances at the same time.

#### Task status

The task status refers to the status of a data migration task. The task status depends on the statuses of all its subtasks. Refer to [subtask status](#) for details.

### 13.6.9.11 Example

### 13.6.9.11.1 Migrate Data Using Data Migration

This guide shows how to migrate data using the Data Migration (DM) tool.

Step 1: Deploy the DM cluster

It is recommended to [deploy the DM cluster using TiUP](#). You can also [deploy the DM cluster using binary](#) for trial or test.

#### Note:

- For database passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. See [Encrypt the database password using dmctl](#).
- The user of the upstream and downstream databases must have the corresponding read and write privileges.

Step 2: Check the cluster information

After the DM cluster is deployed using TiUP, the configuration information is like what is listed below.

- The configuration information of related components in the DM cluster:

Component	Host	Port
dm_worker1	172.16.10.72	8262
dm_worker2	172.16.10.73	8262
dm_master	172.16.10.71	8261

- The information of upstream and downstream database instances:

Database instance	Host	Port	Username	Encrypted password
Upstream MySQL-1	172.16.10.81	3306	root	VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=
Upstream MySQL-2	172.16.10.82	3306	root	VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=
Downstream TiDB	172.16.10.83	4000	root	

The list of privileges needed on the MySQL host can be found in the [precheck](#) documentation.

Step 3: Create data source

1. Write MySQL-1 related information to `conf/source1.yaml`:

```
MySQL1 Configuration.

source-id: "mysql-replica-01"
This indicates that whether DM-worker uses Global Transaction
 ↪ Identifier (GTID) to pull binlog. Before you use this
 ↪ configuration item, make sure that the GTID mode is enabled in
 ↪ the upstream MySQL.
enable-gtid: false

from:
 host: "172.16.10.81"
 user: "root"
 password: "VjX8cEeTX+qcvZ3bPa04h0C80pe/1aU="
 port: 3306
```

2. Execute the following command in the terminal, and use `tiup dmctl` to load the MySQL-1 data source configuration to the DM cluster:

```
tiup dmctl --master-addr 172.16.10.71:8261 operate-source create conf/
 ↪ source1.yaml
```

3. For MySQL-2, modify the relevant information in the configuration file and execute the same `dmctl` command.

#### Step 4: Configure the data migration task

The following example assumes that you need to migrate all the `test_table` table data in the `test_db` database of both the upstream MySQL-1 and MySQL-2 instances, to the downstream `test_table` table in the `test_db` database of TiDB, in the full data plus incremental data mode.

Edit the `task.yaml` task configuration file as below:

```
The task name. You need to use a different name for each of the
 ↪ multiple tasks that
run simultaneously.
name: "test"
The full data plus incremental data (all) migration mode.
task-mode: "all"
The downstream TiDB configuration information.
target-database:
 host: "172.16.10.83"
 port: 4000
 user: "root"
 password: ""
```

```
Configuration of all the upstream MySQL instances required by the
↳ current data migration task.
mysql-instances:
-
 # The ID of upstream instances or the migration group. You can refer to
 ↳ the configuration of `source_id` in the "inventory.ini" file or in
 ↳ the "dm-master.toml" file.
 source-id: "mysql-replica-01"
 # The configuration item name of the block and allow lists of the name of
 ↳ the
 # database/table to be migrated, used to quote the global block and allow
 # lists configuration that is set in the global block-allow-list below.
 block-allow-list: "global" # Use black-white-list if the DM version is
 ↳ earlier than or equal to v2.0.0-beta.2.
 # The configuration item name of the dump processing unit, used to quote
 ↳ the global configuration of the dump unit.
 mydumper-config-name: "global"
-
 source-id: "mysql-replica-02"
 block-allow-list: "global" # Use black-white-list if the DM version is
 ↳ earlier than or equal to v2.0.0-beta.2.
 mydumper-config-name: "global"

The global configuration of block and allow lists. Each instance can
↳ quote it by the
configuration item name.
block-allow-list: # Use black-white-list if the DM version
↳ is earlier than or equal to v2.0.0-beta.2.
global:
 do-tables: # The allow list of upstream tables to be
 ↳ migrated.
 - db-name: "test_db" # The database name of the table to be
 ↳ migrated.
 tbl-name: "test_table" # The name of the table to be migrated.

The global configuration of the dump unit. Each instance can quote it
↳ by the configuration item name.
mydumpers:
 global:
 extra-args: ""
```

Step 5: Start the data migration task

To detect possible errors of data migration configuration in advance, DM provides the

precheck feature:

- DM automatically checks the corresponding privileges and configuration while starting the data migration task.
- You can also use the `check-task` command to manually precheck whether the upstream MySQL instance configuration satisfies the DM requirements.

For details about the precheck feature, see [Precheck the upstream MySQL instance configuration](#).

#### Note:

Before starting the data migration task for the first time, you should have got the upstream configured. Otherwise, an error is reported while you start the task.

Run the `tiup dmctl` command to start the data migration tasks. `task.yaml` is the configuration file that is edited above.

```
tiup dmctl --master-addr 172.16.10.71:8261 start-task ./task.yaml
```

- If the above command returns the following result, it indicates the task is successfully started.

```
{
 "result": true,
 "msg": "",
 "workers": [
 {
 "result": true,
 "worker": "172.16.10.72:8262",
 "msg": ""
 },
 {
 "result": true,
 "worker": "172.16.10.73:8262",
 "msg": ""
 }
]
}
```

- If you fail to start the data migration task, modify the configuration according to the returned prompt and then run the `start-task task.yaml` command to restart the task.

#### Step 6: Check the data migration task

If you need to check the task state or whether a certain data migration task is running in the DM cluster, run the following command in `tiup dmctl`:

```
tiup dmctl --master-addr 172.16.10.71:8261 query-status
```

#### Step 7: Stop the data migration task

If you do not need to migrate data any more, run the following command in `tiup dmctl` to stop the task:

```
tiup dmctl --master-addr 172.16.10.71:8261 stop-task test
```

`test` is the task name that you set in the `name` configuration item of the `task.yaml` configuration file.

#### Step 8: Monitor the task and check logs

Assuming that Prometheus, Alertmanager, and Grafana are successfully deployed along with the DM cluster deployment using TiUP, and the Grafana address is `172.16.10.71`. To view the alert information related to DM, you can open <http://172.16.10.71:9093> in a browser and enter into Alertmanager; to check monitoring metrics, go to <http://172.16.10.71:3000>, and choose the DM dashboard.

While the DM cluster is running, DM-master, DM-worker, and `dmctl` output the monitoring metrics information through logs. The log directory of each component is as follows:

- DM-master log directory: It is specified by the `--log-file DM-master` process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-master node.
- DM-worker log directory: It is specified by the `--log-file DM-worker` process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-worker node.

### 13.6.9.11.2 Create a Data Migration Task

This document describes how to create a simple data migration task after the DM cluster is successfully deployed.

#### Sample scenario

Suppose that you create a data migration task based on this sample scenario:

- Deploy two MySQL instances with binlog enabled and one TiDB instance locally
- Use a DM-master of the DM cluster to manage the cluster and data migration tasks.

The information of each node is as follows.

Instance	Server Address	Port
MySQL1	127.0.0.1	3306
MySQL2	127.0.0.1	3307
TiDB	127.0.0.1	4000
DM-master	127.0.0.1	8261

Based on this scenario, the following sections describe how to create a data migration task.

### Start upstream MySQL

Prepare 2 runnable MySQL instances. You can also use Docker to quickly start MySQL. The commands are as follows:

```
docker run --rm --name mysql-3306 -p 3306:3306 -e MYSQL_ALLOW_EMPTY_PASSWORD
↳ =true mysql:5.7.22 --log-bin=mysql-bin --port=3306 --bind-address
↳ =0.0.0.0 --binlog-format=ROW --server-id=1 --gtid_mode=ON --enforce-
↳ gtid-consistency=true > mysql.3306.log 2>&1 &
docker run --rm --name mysql-3307 -p 3307:3307 -e MYSQL_ALLOW_EMPTY_PASSWORD
↳ =true mysql:5.7.22 --log-bin=mysql-bin --port=3307 --bind-address
↳ =0.0.0.0 --binlog-format=ROW --server-id=1 --gtid_mode=ON --enforce-
↳ gtid-consistency=true > mysql.3307.log 2>&1 &
```

### Prepare data

- Write example data into mysql-3306:

```
drop database if exists `sharding1`;
create database `sharding1`;
use `sharding1`;
create table t1 (id bigint, uid int, name varchar(80), info varchar
↳ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
↳ utf8mb4;
create table t2 (id bigint, uid int, name varchar(80), info varchar
↳ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
↳ utf8mb4;
insert into t1 (id, uid, name) values (1, 10001, 'Gabriel García
↳ Márquez'), (2, 10002, 'Cien años de soledad');
insert into t2 (id, uid, name) values (3, 20001, 'José Arcadio Buendía'
↳), (4, 20002, 'Úrsula Iguarán'), (5, 20003, 'José Arcadio');
```

- Write example data into mysql-3307:

```
drop database if exists `sharding2`;
create database `sharding2`;
use `sharding2`;
```

```
create table t2 (id bigint, uid int, name varchar(80), info varchar
↳ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
↳ utf8mb4;
create table t3 (id bigint, uid int, name varchar(80), info varchar
↳ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
↳ utf8mb4;
insert into t2 (id, uid, name, info) values (6, 40000, 'Remedios
↳ Moscote', '{}');
insert into t3 (id, uid, name, info) values (7, 30001, 'Aureliano José
↳ ', '{}'), (8, 30002, 'Santa Sofía de la Piedad', '{}'), (9,
↳ 30003, '17 Aurelianos', NULL);
```

Start downstream TiDB

To run a TiDB server, use the following command:

```
wget https://download.pingcap.org/tidb-community-server-v6.6.0-linux-amd64.
↳ tar.gz
tar -xzvf tidb-latest-linux-amd64.tar.gz
mv tidb-latest-linux-amd64/bin/tidb-server ./
./tidb-server
```

### Warning:

The deployment method of TiDB in this document **do not apply** to production or development environments.

Configure the MySQL data source

Before starting a data migration task, you need to configure the MySQL data source.

Encrypt the password

### Note:

- You can skip this step if the database does not have a password.
- You can use the plaintext password to configure the source information in DM v1.0.6 and later versions.

For safety reasons, it is recommended to configure and use encrypted passwords. You can use `dmctl` to encrypt the MySQL/TiDB password. Suppose the password is “123456”:

```
./dmctl encrypt "123456"
```

```
fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg=
```

Save this encrypted value, and use it for creating a MySQL data source in the following steps.

Edit the source configuration file

Write the following configurations to `conf/source1.yaml`.

```
MySQL1 Configuration.

source-id: "mysql-replica-01"

Indicates whether GTID is enabled
enable-gtid: true

from:
 host: "127.0.0.1"
 user: "root"
 password: "fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg="
 port: 3306
```

In MySQL2 data source, copy the above configurations to `conf/source2.yaml`. You need to change name to `mysql-replica-02` and change `password` and `port` to appropriate values.

Create a source

To load the data source configurations of MySQL1 into the DM cluster using `dmctl`, run the following command in the terminal:

```
./dmctl --master-addr=127.0.0.1:8261 operate-source create conf/source1.
↪ yaml
```

For MySQL2, replace the configuration file in the above command with that of MySQL2.

Create a data migration task

After importing **prepared data**, there are several sharded tables on both MySQL1 and MySQL2 instances. These tables have identical structure and the same prefix “t” in the table names; the databases where these tables are located are all prefixed with “sharding”; and there is no conflict between the primary keys or the unique keys (in each sharded table, the primary keys or the unique keys are different from those of other tables).

Now, suppose that you need to migrate these sharded tables to the `db_target.t_target` table in TiDB. The steps are as follows.

1. Create the configuration file of the task:

```

name: test
task-mode: all
shard-mode: "pessimistic"
target-database:
 host: "127.0.0.1"
 port: 4000
 user: "root"
 password: "" # It is recommended to use password encrypted with dmctl
 ↪ if the password is not empty.

mysql-instances:
- source-id: "mysql-replica-01"
 block-allow-list: "instance" # This configuration applies to DM
 ↪ versions higher than v2.0.0-beta.2. Use black-white-list
 ↪ otherwise.
 route-rules: ["sharding-route-rules-table", "sharding-route-rules-
 ↪ schema"]
 mydumper-thread: 4
 loader-thread: 16
 syncer-thread: 16
- source-id: "mysql-replica-02"
 block-allow-list: "instance" # This configuration applies to DM
 ↪ versions higher than v2.0.0-beta.2. Use black-white-list
 ↪ otherwise.
 route-rules: ["sharding-route-rules-table", "sharding-route-rules-
 ↪ schema"]
 mydumper-thread: 4
 loader-thread: 16
 syncer-thread: 16
block-allow-list: # This configuration applies to DM versions higher
 ↪ than v2.0.0-beta.2. Use black-white-list otherwise.
instance:
 do-dbs: ["~^sharding[\\d]+"]
 do-tables:
 - db-name: "~^sharding[\\d]+"
 tbl-name: "~^t[\\d]+"
routes:
 sharding-route-rules-table:
 schema-pattern: sharding*
 table-pattern: t*
 target-schema: db_target
 target-table: t_target
```

```
sharding-route-rules-schema:
 schema-pattern: sharding*
 target-schema: db_target
```

2. To create a task using dmctl, write the above configurations to the `conf/task.yaml` file:

```
./dmctl --master-addr 127.0.0.1:8261 start-task conf/task.yaml
```

```
{
 "result": true,
 "msg": "",
 "sources": [
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-01",
 "worker": "worker1"
 },
 {
 "result": true,
 "msg": "",
 "source": "mysql-replica-02",
 "worker": "worker2"
 }
]
}
```

Now, you have successfully created a task to migrate the sharded tables from the MySQL1 and MySQL2 instances to TiDB.

Verify data

You can modify data in the upstream MySQL sharded tables. Then use [sync-diff-inspector](#) to check whether the upstream and downstream data are consistent. Consistent data means that the migration task works well, which also indicates that the cluster works well.

### 13.6.9.11.3 Best Practices of Data Migration in the Shard Merge Scenario

This document describes the features and limitations of [TiDB Data Migration \(DM\)](#) in the shard merge scenario and provides a data migration best practice guide for your application (the default “pessimistic” mode is used).

Use a separate data migration task

In the [Merge and Migrate Data from Sharded Tables](#) document, the definition of “sharding group” is given: A sharding group consists of all upstream tables that need to be merged and migrated into the same downstream table.

The current sharding DDL mechanism has some [usage restrictions](#) to coordinate the schema changes brought by DDL operations in different sharded tables. If these restrictions are violated due to unexpected reasons, you need to [handle sharding DDL locks manually in DM](#), or even redo the entire data migration task.

To mitigate the impact on data migration when an exception occurs, it is recommended to merge and migrate each sharding group as a separate data migration task. **This might enable that only a small number of data migration tasks need to be handled manually while others remain unaffected.**

Handle sharding DDL locks manually

You can easily conclude from [Merge and Migrate Data from Sharded Tables](#) that DM’s sharding DDL lock is a mechanism for coordinating the execution of DDL operations to the downstream from multiple upstream sharded tables.

Therefore, when you find any sharding DDL lock on DM-master through `shard-ddl-lock`  $\hookrightarrow$  `command`, or any `unresolvedGroups` or `blockingDDLs` on some DM-workers through `query-status` `command`, do not rush to manually release the sharding DDL lock through `shard-ddl-lock unlock` `commands`.

Instead, you can:

- Follow the corresponding manual solution to handle the scenario if the failure of automatically releasing the sharding DDL lock is one of the [listed abnormal scenarios](#).
- Redo the entire data migration task if it is an unsupported scenario: First, empty the data in the downstream database and the `dm_meta` information associated with the migration task; then, re-execute the full and incremental data replication.

Handle conflicts between primary keys or unique indexes across multiple sharded tables

Data from multiple sharded tables might cause conflicts between the primary keys or unique indexes. You need to check each primary key or unique index based on the sharding logic of these sharded tables. The following are three cases related to primary keys or unique indexes:

- **Shard key:** Usually, the same shard key only exists in one sharded table, which means no data conflict is caused on shard key.
- **Auto-increment primary key:** The auto-increment primary key of each sharded tables counts separately, so their range might overlap. In this case, you need to refer to the next section [Handle conflicts of auto-increment primary key](#) to solve it.
- **Other primary keys or unique indexes:** you need to analyze them based on the business logic. If data conflict, you can also refer to the next section [Handle conflicts of auto-increment primary key](#) to solve it.

Handle conflicts of auto-increment primary key

This section introduces two recommended solutions to handle conflicts of auto-increment primary key.

Remove the PRIMARY KEY attribute from the column

Assume that the upstream schemas are as follows:

```
CREATE TABLE `tbl_no_pk` (
 `auto_pk_c1` bigint(20) NOT NULL,
 `uk_c2` bigint(20) NOT NULL,
 `content_c3` text,
 PRIMARY KEY (`auto_pk_c1`),
 UNIQUE KEY `uk_c2` (`uk_c2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

If the following requirements are satisfied:

- The `auto_pk_c1` column has no impact on the application and does not depend on the column's PRIMARY KEY attribute.
- The `uk_c2` column has the UNIQUE KEY attribute, and it is globally unique in all upstream sharded tables.

Then you can perform the following steps to fix the `ERROR 1062 (23000): Duplicate ↪ entry '***' for key 'PRIMARY'` error that is possibly caused by the `auto_pk_c1` column when you merge sharded tables.

1. Before the full data migration, create a table in the downstream database for merging and migrating data, and modify the PRIMARY KEY attribute of the `auto_pk_c1` column to normal index.

```
CREATE TABLE `tbl_no_pk_2` (
 `auto_pk_c1` bigint(20) NOT NULL,
 `uk_c2` bigint(20) NOT NULL,
 `content_c3` text,
 INDEX (`auto_pk_c1`),
 UNIQUE KEY `uk_c2` (`uk_c2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

2. Add the following configuration in `task.yaml` to skip the check of auto-increment primary key conflict:

```
ignore-checking-items: ["auto_increment_ID"]
```

3. Start the full and incremental data replication task.

4. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from the upstream has already been merged and migrated to the downstream database.

Use a composite primary key

Assume that the upstream schemas are as follows:

```
CREATE TABLE `tbl_multi_pk` (
 `auto_pk_c1` bigint(20) NOT NULL,
 `uuid_c2` bigint(20) NOT NULL,
 `content_c3` text,
 PRIMARY KEY (`auto_pk_c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

If the following requirements are satisfied:

- The application does not depend on the PRIMARY KEY attribute of the `auto_pk_c1` column.
- The composite primary key that consists of the `auto_pk_c1` and `uuid_c2` columns is globally unique.
- It is acceptable to use a composite primary key in the application.

Then you can perform the following steps to fix the `ERROR 1062 (23000): Duplicate entry '***' for key 'PRIMARY'` error that is possibly caused by the `auto_pk_c1` column when you merge sharded tables.

1. Before the full data migration, create a table in the downstream database for merging and migrating data. Do not specify the PRIMARY KEY attribute for the `auto_pk_c1`  $\leftrightarrow$  column, but use the `auto_pk_c1` and `uuid_c2` columns to make up a composite primary key.

```
CREATE TABLE `tbl_multi_pk_c2` (
 `auto_pk_c1` bigint(20) NOT NULL,
 `uuid_c2` bigint(20) NOT NULL,
 `content_c3` text,
 PRIMARY KEY (`auto_pk_c1`,`uuid_c2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

2. Start the full and incremental data migration task.
3. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from upstream has already been merged and migrated to the downstream database.

## Special processing when the upstream RDS contains sharded tables

If the upstream data source is an RDS and it contains sharded tables, the table names in MySQL binlog might be invisible when connecting to a SQL client. For example, if the upstream is a UCloud distributed database, the table name in the binlog might have an extra prefix `_0001`. Therefore, you need to configure **table routing** based on the table names in binlog, instead of those in the SQL client.

### Create/drop tables in the upstream

In **Merge and Migrate Data from Sharded Tables**, it is clear that the coordination of sharding DDL lock depends on whether the downstream database receives the DDL statements of all upstream sharded tables. In addition, DM currently **does not support** dynamically creating or dropping sharded tables in the upstream. Therefore, to create or drop sharded tables in the upstream, it is recommended to perform the following steps.

#### Create sharded tables in the upstream

If you need to create a new sharded table in the upstream, perform the following steps:

1. Wait for the coordination of all executed sharding DDL in the upstream sharded tables to finish.
2. Run `stop-task` to stop the data migration task.
3. Create a new sharded table in the upstream.
4. Make sure that the configuration in the `task.yaml` file allows the newly added sharded table to be merged in one downstream table with other existing sharded tables.
5. Run `start-task` to start the task.
6. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from upstream has already been merged and migrated to the downstream database.

#### Drop sharded tables in the upstream

If you need to drop a sharded table in the upstream, perform the following steps:

1. Drop the sharded table, run `SHOW BINLOG EVENTS` to fetch the `End_log_pos` corresponding to the `DROP TABLE` statement in the binlog events, and mark it as *Pos-M*.
2. Run `query-status` to fetch the position (`syncerBinlog`) corresponding to the binlog event that has been processed by DM, and mark it as *Pos-S*.
3. When *Pos-S* is greater than *Pos-M*, it means that DM has processed all of the `DROP TABLE` statements, and the data of the table before dropping has been migrated to the downstream, so the subsequent operation can be performed. Otherwise, wait for DM to finish migrating the data.

4. Run `stop-task` to stop the task.
5. Make sure that the configuration in the `task.yaml` file ignores the dropped sharded table in the upstream.
6. Run `start-task` to start the task.
7. Run `query-status` to verify whether the data migration task is successfully processed.

#### Speed limits and traffic flow control

When data from multiple upstream MySQL or MariaDB instances is merged and migrated to the same TiDB cluster in the downstream, every DM-worker corresponding to each upstream instance executes full and incremental data replication concurrently. This means that the default degree of concurrency (`pool-size` in full data migration and `worker-count` in incremental data replication) accumulates as the number of DM-workers increases, which might overload the downstream database. In this case, you need to conduct a preliminary performance analysis based on TiDB and DM monitoring metrics and adjust the value of each concurrency parameter. In the future, DM is expected to support partially automated traffic flow control.

### 13.6.9.12 Troubleshoot

#### 13.6.9.12.1 TiDB Data Migration FAQs

This document collects the frequently asked questions (FAQs) about TiDB Data Migration (DM).

Does DM support migrating data from Alibaba RDS or other cloud databases?

Currently, DM only supports decoding the standard version of MySQL or MariaDB binlog. It has not been tested for Alibaba Cloud RDS or other cloud databases. If you are confirmed that its binlog is in standard format, then it is supported.

It is a known issue that for an upstream table with no primary key in Alibaba Cloud RDS, its binlog still contains a hidden primary key column, which is inconsistent with the original table structure.

Here are some known incompatible issues:

- In **Alibaba Cloud RDS**, for an upstream table with no primary key, its binlog still contains a hidden primary key column, which is inconsistent with the original table structure.
- In **HUAWEI Cloud RDS**, directly reading binlog files is not supported. For more details, see [Can HUAWEI Cloud RDS Directly Read Binlog Backup Files?](#)

Does the regular expression of the block and allow list in the task configuration support non-capturing (?!)?

Currently, DM does not support it and only supports the regular expressions of the Golang standard library. See regular expressions supported by Golang via [re2-syntax](#).

If a statement executed upstream contains multiple DDL operations, does DM support such migration?

DM will attempt to split a single statement containing multiple DDL change operations into multiple statements containing only one DDL operation, but might not cover all cases. It is recommended to include only one DDL operation in a statement executed upstream, or verify it in the test environment. If it is not supported, you can file an [issue](#) to the DM repository.

How to handle incompatible DDL statements?

When you encounter a DDL statement unsupported by TiDB, you need to manually handle it using `dmctl` (skipping the DDL statement or replacing the DDL statement with a specified DDL statement). For details, see [Handle failed DDL statements](#).

**Note:**

Currently, TiDB is not compatible with all the DDL statements that MySQL supports. See [MySQL Compatibility](#).

Does DM replicate view-related DDL statements and DML statements to TiDB?

Currently, DM does not replicate view-related DDL statements to the downstream TiDB cluster, nor does it replicate view-related DML statements to the downstream TiDB cluster.

How to reset the data migration task?

When an exception occurs during data migration and the data migration task cannot be resumed, you need to reset the task and re-migrate the data:

1. Execute the `stop-task` command to stop the abnormal data migration task.
2. Purge the data migrated to the downstream.
3. Use one of the following ways to restart the data migration task.
  - Specify a new task name in the task configuration file. Then execute `start-task {↔ task-config-file}`.
  - Execute `start-task --remove-meta {task-config-file}`.

How to handle the error returned by the DDL operation related to the `gh-ost` table, after `online-ddl-scheme: "gh-ost"` is set?

```
[unit=Sync] ["error information"="{\"msg\": \"[code=36046:class=sync-unit:
↳ scope=internal:level=high] online ddls on ghost table `xxx`.`
↳ _xxxx_gho`\\ngithub.com/pingcap/dm/pkg/terror.(*Error).Generate
↳
```

The above error can be caused by the following reason:

In the last `rename ghost_table to origin table` step, DM reads the DDL information in memory, and restores it to the DDL of the origin table.

However, the DDL information in memory is obtained in either of the two ways:

- DM **processes the gh-ost table during the alter ghost\_table operation** and records the DDL information of `ghost_table`;
- When DM-worker is restarted to start the task, DM reads the DDL from `dm_meta.{task_name}_onlineddl`.  
↳ `task_name}_onlineddl`.

Therefore, in the process of incremental replication, if the specified Pos has skipped the `alter ghost_table` DDL but the Pos is still in the online-ddl process of `gh-ost`, the `ghost_table` is not written into memory or `dm_meta.{task_name}_onlineddl` correctly. In such cases, the above error is returned.

You can avoid this error by the following steps:

1. Remove the `online-ddl-scheme` configuration of the task.
2. Configure `_{table_name}_gho`, `_{table_name}_ghc`, and `_{table_name}_del` in `block-allow-list.ignore-tables`.
3. Execute the upstream DDL in the downstream TiDB manually.
4. After the Pos is replicated to the position after the `gh-ost` process, re-enable the `online`  
↳ `-ddl-scheme` and comment out `block-allow-list.ignore-tables`.

How to add tables to the existing data migration tasks?

If you need to add tables to a data migration task that is running, you can address it in the following ways according to the stage of the task.

### Note:

Because adding tables to an existing data migration task is complex, it is recommended that you perform this operation only when necessary.

In the **Dump** stage

Since MySQL cannot specify a snapshot for export, it does not support updating data migration tasks during the export and then restarting to resume the export through the checkpoint. Therefore, you cannot dynamically add tables that need to be migrated at the **Dump** stage.

If you really need to add tables for migration, it is recommended to restart the task directly using the new configuration file.

In the **Load** stage

During the export, multiple data migration tasks usually have different binlog positions. If you merge the tasks in the **Load** stage, they might not be able to reach consensus on binlog positions. Therefore, it is not recommended to add tables to a data migration task in the **Load** stage.

In the **Sync** stage

When the data migration task is in the **Sync** stage, if you add additional tables to the configuration file and restart the task, DM does not re-execute full export and import for the newly added tables. Instead, DM continues incremental replication from the previous checkpoint.

Therefore, if the full data of the newly added table has not been imported to the downstream, you need to use a separate data migration task to export and import the full data to the downstream.

Record the position information in the global checkpoint (`is_global=1`) corresponding to the existing migration task as `checkpoint-T`, such as (`mysql-bin.000100, 1234`). Record the position information of the full export `metadata` (or the checkpoint of another data migration task in the **Sync** stage) of the table to be added to the migration task as `checkpoint-S`, such as (`mysql-bin.000099, 5678`). You can add the table to the migration task by the following steps:

1. Use `stop-task` to stop an existing migration task. If the table to be added belongs to another running migration task, stop that task as well.
2. Use a MySQL client to connect the downstream TiDB database and manually update the information in the checkpoint table corresponding to the existing migration task to the smaller value between `checkpoint-T` and `checkpoint-S`. In this example, it is (`mysql-bin.000099, 5678`).
  - The checkpoint table to be updated is `{task-name}_syncer_checkpoint` in the `{dm_meta}` schema.
  - The checkpoint rows to be updated match `id=(source-id)` and `is_global=1`.
  - The checkpoint columns to be updated are `binlog_name` and `binlog_pos`.
3. Set `safe-mode: true` for the `syncers` in the task to ensure reentrant execution.

4. Start the task using `start-task`.
5. Observe the task status through `query-status`. When `syncerBinlog` exceeds the larger value of `checkpoint-T` and `checkpoint-S`, restore `safe-mode` to the original value and restart the task. In this example, it is `(mysql-bin.000100, 1234)`.

How to handle the error packet for query is too large. Try adjusting the `'max_allowed_packet'` variable that occurs during the full import?

Set the parameters below to a value larger than the default 67108864 (64M).

- The global variable of the TiDB server: `max_allowed_packet`.
- The configuration item in the task configuration file: `target-database.max-allowed`  
↪ `-packet`. For details, refer to [DM Advanced Task Configuration File](#).

How to handle the error `Error 1054: Unknown column 'binlog_gtid' in 'field list'` that occurs when existing DM migration tasks of an DM 1.0 cluster are running on a DM 2.0 or newer cluster?

Since DM v2.0, if you directly run the `start-task` command with the task configuration file of the DM 1.0 cluster to continue the incremental data replication, the error `Error 1054: Unknown column 'binlog_gtid' in 'field list'` occurs.

This error can be handled by [manually importing DM migration tasks of a DM 1.0 cluster to a DM 2.0 cluster](#).

Why does TiUP fail to deploy some versions of DM (for example, v2.0.0-hotfix)?

You can use the `tiup list dm-master` command to view the DM versions that TiUP supports to deploy. TiUP does not manage DM versions which are not shown by this command.

How to handle the error `parse mydumper metadata error: EOF` that occurs when DM is replicating data?

You need to check the error message and log files to further analyze this error. The cause might be that the dump unit does not produce the correct metadata file due to a lack of permissions.

Why does DM report no fatal error when replicating sharded schemas and tables, but downstream data is lost?

Check the configuration items `block-allow-list` and `table-route`:

- You need to configure the names of upstream databases and tables under `block-allow`  
↪ `-list`. You can add “~” before `do-tables` to use regular expressions to match names.
- `table-route` uses wildcard characters instead of regular expressions to match table names. For example, `table_parttern_[0-63]` only matches 7 tables, from `table_parttern_0` to `table_pattern_6`.

Why does the `replicate lag` monitor metric show no data when DM is not replicating from upstream?

In DM 1.0, you need to enable `enable-heartbeat` to generate the monitor data. In DM 2.0 and later versions, it is expected to have no data in the monitor metric `replicate lag` because this feature is not supported.

How to handle the error `fail to initial unit Sync of subtask` when DM is starting a task, with the `RawCause` in the error message showing `context deadline exceeded`?

This is a known issue in DM 2.0.0 version and will be fixed in DM 2.0.1 version. It is likely to be triggered when a replication task has a lot of tables to process. If you use TiUP to deploy DM, you can upgrade DM to the nightly version to fix this issue. Or you can download the 2.0.0-hotfix version from [the release page of DM](#) on GitHub and manually replace the executable files.

How to handle the error `duplicate entry` when DM is replicating data?

You need to first check and confirm the following things:

- `disable-detect` is not configured in the replication task ( in v2.0.7 and earlier versions).
- The data is not inserted manually or by other replication programs.
- No DML filter associated with this table is configured.

To facilitate troubleshooting, you can first collect general log files of the downstream TiDB instance and then ask for technical support at [TiDB Community slack channel](#). The following example shows how to collect general log files:

```
Enable general log collection
curl -X POST -d "tidb_general_log=1" http://{TiDBIP}:10080/settings
Disable general log collection
curl -X POST -d "tidb_general_log=0" http://{TiDBIP}:10080/settings
```

When the `duplicate entry` error occurs, you need to check the log files for the records that contain conflict data.

Why do some monitoring panels show `No data point`?

It is normal for some panels to have no data. For example, when there is no error reported, no DDL lock, or the relay log feature is not enabled, the corresponding panels show `No data point`. For detailed description of each panel, see [DM Monitoring Metrics](#).

In DM v1.0, why does the command `sql-skip` fail to skip some statements when the task is in error?

You need to first check whether the binlog position is still advancing after you execute `sql-skip`. If so, it means that `sql-skip` has taken effect. The reason why this error keeps occurring is that the upstream sends multiple unsupported DDL statements. You can use `sql-skip -s <sql-pattern>` to set a pattern to match these statements.

Sometimes, the error message contains the `parse statement` information, for example:

```
if the DDL is not needed, you can use a filter rule with \"*\n\" schema-
 ↳ pattern to ignore it.\n\t : parse statement: line 1 column 11 near \"
 ↳ EVENT `event_del_big_table` \r\nDISABLE\" %!!(MISSING)(EXTRA string=
 ↳ ALTER EVENT `event_del_big_table` \r\nDISABLE
```

The reason for this type of error is that the TiDB parser cannot parse DDL statements sent by the upstream, such as `ALTER EVENT`, so `sql-skip` does not take effect as expected. You can add **binlog event filters** in the configuration file to filter those statements and set `schema-pattern: "*" . Starting from DM v2.0.1, DM pre-filters statements related to EVENT.`

Since DM v6.0, `binlog` replaces `sql-skip` and `handle-error`. You can use the `binlog` command instead to avoid this issue.

Why do `REPLACE` statements keep appearing in the downstream when DM is replicating?

You need to check whether the **safe mode** is automatically enabled for the task. If the task is automatically resumed after an error, or if there is high availability scheduling, then the safe mode is enabled because it is within 1 minutes after the task is started or resumed.

You can check the DM-worker log file and search for a line containing **change count**. If the **new count** in the line is not zero, the safe mode is enabled. To find out why it is enabled, check when it happens and if any errors are reported before.

In DM v2.0, why does the full import task fail if DM restarts during the task?

In DM v2.0.1 and earlier versions, if DM restarts before the full import completes, the bindings between upstream data sources and DM-worker nodes might change. For example, it is possible that the intermediate data of the dump unit is on DM-worker node A but the load unit is run by DM-worker node B, thus causing the operation to fail.

The following are two solutions to this issue:

- If the data volume is small (less than 1 TB) or the task merges sharded tables, take these steps:
  1. Clean up the imported data in the downstream database.
  2. Remove all files in the directory of exported data.
  3. Delete the task using `dmctl` and run the command `start-task --remove-meta` to create a new task.

After the new task starts, it is recommended to ensure that there is no redundant DM worker node and avoid restarting or upgrading the DM cluster during the full import.

- If the data volume is large (more than 1 TB), take these steps:
  1. Clean up the imported data in the downstream database.
  2. Deploy TiDB-Lightning to the DM worker nodes that process the data.

3. Use the Local-backend mode of TiDB-Lightning to import data that DM dump units export.
4. After the full import completes, edit the task configuration file in the following ways and restart the task:
  - Change `task-mode` to `incremental`.
  - Set the value of `mysql-instance.meta.pos` to the position recorded in the metadata file that the dump unit outputs.

Why does DM report the error `ERROR 1236 (HY000): The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION = 1, but the master has purged binary logs containing GTIDs that the slave requires.` if it restarts during an incremental task?

This error indicates that the upstream binlog position recorded in the metadata file output by the dump unit has been purged during the full migration.

If this issue occurs, you need to pause the task, delete all migrated data in the downstream database, and start a new task with the `--remove-meta` option.

You can avoid this issue in advance by configuring in the following ways:

1. Increase the value of `expire_logs_days` in the upstream MySQL database to avoid wrongly purging needed binlog files before the full migration task completes. If the data volume is large, it is recommended to use dumping and TiDB-Lightning at the same time to speed up the task.
2. Enable the relay log feature for this task so that DM can read data from relay logs even though the binlog position is purged.

Why does the Grafana dashboard of a DM cluster display `failed to fetch dashboard` if the cluster is deployed using TiUP v1.3.0 or v1.3.1?

This is a known bug of TiUP, which is fixed in TiUP v1.3.2. The following are two solutions to this issue:

- Solution one:
  1. Upgrade TiUP to a later version using the command `tiup update --self && ↪ tiup update dm`.
  2. Scale in and then scale out Grafana nodes in the cluster to restart the Grafana service.
- Solution two:
  1. Back up the `deploy/grafana-$port/bin/public` folder.
  2. Download the [TiUP DM offline package](#) and unpack it.
  3. Unpack the `grafana-v4.0.3-*.tar.gz` in the offline package.
  4. Replace the folder `deploy/grafana-$port/bin/public` with the `public` folder in `grafana-v4.0.3-*.tar.gz`.

5. Execute `tiup dm restart $cluster_name -R grafana` to restart the Grafana service.

In DM v2.0, why does the query result of the command `query-status` show that the Syncer checkpoint GTIDs are inconsecutive if the task has `enable-relay` and `enable-gtid` enabled at the same time?

This is a known bug in DM, which is fixed in DM v2.0.2. The bug is triggered when the following two conditions are fully met at the same time:

1. Parameters `enable-relay` and `enable-gtid` are set to `true` in the source configuration file.
2. The upstream database is a **MySQL secondary database**. If you execute the command `show binlog events in '<newest-binlog>' limit 2` to query the `previous_gtids` of the database, the result is inconsecutive, such as the following example:

```
mysql> show binlog events in 'mysql-bin.000005' limit 2;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info
+-----+-----+-----+-----+-----+-----+
| mysql-bin.000005 | 4 | Format_desc | 123452 | 123 | Server ver:
| | | | | | 5.7.32-35-log, Binlog ver: 4
+-----+-----+-----+-----+-----+-----+
| mysql-bin.000005 | 123 | Previous_gtids | 123452 | 194 | d3618e68
| | | | | | -6052-11eb-a68b-0242ac110002:6-7
+-----+-----+-----+-----+-----+-----+

```

The bug occurs if you run `query-status <task>` in `dmctl` to query task information and find that `subTaskStatus.sync.syncerBinlogGtid` is inconsecutive but `subTaskStatus.sync.masterBinlogGtid` is consecutive. See the following example:

```

 "sync": {
 "masterBinlog": "(mysql-bin.000007, 1979)",
 "masterBinlogGtid": "ddb8974e-6064-11eb-8357-0242
 ↪ ac110002:1-25",
 "syncerBinlog": "(mysql-bin|000001.000008, 1979)",
 "syncerBinlogGtid": "ddb8974e-6064-11eb-8357-0242
```

```
 ↪ ac110002:1-25",
 ...
 "synced": true,
 "binlogType": "local"
 }
}
]
}
]
```

In the example, the `syncerBinlogGtid` of the data source `mysql1` is inconsecutive. In this case, you can do one of the following to handle the data loss:

- If upstream binlogs from the current time to the position recorded in the metadata of the full export task have not been purged, you can take these steps:
  1. Stop the current task and delete all data sources with inconsecutive GTIDs.
  2. Set `enable-relay` to `false` in all source configuration files.
  3. For data sources with inconsecutive GTIDs (such as `mysql1` in the above example), change the task to an incremental task and configure related `mysql-instances`.
    - ↪ `meta` with metadata information of each full export task, including the `binlog`
    - ↪ `-name`, `binlog-pos`, and `binlog-gtid` information.
  4. Set `syncers.safe-mode` to `true` in `task.yaml` of the incremental task and restart the task.
  5. After the incremental task replicates all missing data to the downstream, stop the task and change `safe-mode` to `false` in the `task.yaml`.
  6. Restart the task again.
- If upstream binlogs have been purged but local relay logs remain, you can take these steps:
  1. Stop the current task.
  2. For data sources with inconsecutive GTIDs (such as `mysql1` in the above example), change the task to an incremental task and configure related `mysql-instances`.
    - ↪ `meta` with metadata information of each full export task, including the `binlog`
    - ↪ `-name`, `binlog-pos`, and `binlog-gtid` information.
  3. In the `task.yaml` of the incremental task, change the previous value of `binlog-gtid` to the previous value of `previous_gtids`. For the above example, change `1-y` to `6-y`.
  4. Set `syncers.safe-mode` to `true` in the `task.yaml` and restart the task.
  5. After the incremental task replicates all missing data to the downstream, stop the task and change `safe-mode` to `false` in the `task.yaml`.
  6. Restart the task again.
  7. Restart the data source and set either `enable-relay` or `enable-gtid` to `false` in the source configuration file.

- If none of the above conditions is met or if the data volume of the task is small, you can take these steps:
  1. Clean up imported data in the downstream database.
  2. Restart the data source and set either `enable-relay` or `enable-gtid` to `false` in the source configuration file.
  3. Create a new task and run the command `start-task task.yaml --remove-↪ meta` to migrate data from the beginning again.

For data sources that can be replicated normally (such as `mysql2` in the above example) in the first and second solutions above, configure related `mysql-instances.meta` with `syncerBinlog` and `syncerBinlogGtid` information from `subTaskStatus.sync` when setting the incremental task.

In DM v2.0, how do I handle the error “heartbeat config is different from previous used: serverID not equal” when switching the connection between DM-workers and MySQL instances in a virtual IP environment with the `heartbeat` feature enabled?

The `heartbeat` feature is disabled by default in DM v2.0 and later versions. If you enable the feature in the task configuration file, it interferes with the high availability feature. To solve this issue, you can disable the `heartbeat` feature by setting `enable-heartbeat` to `false` in the task configuration file, and then reload the task configuration file. DM will forcibly disable the `heartbeat` feature in subsequent releases.

Why does a DM-master fail to join the cluster after it restarts and DM reports the error “fail to start embed etcd, RawCause: member xxx has already been bootstrapped”?

When a DM-master starts, DM records the etcd information in the current directory. If the directory changes after the DM-master restarts, DM cannot get access to the etcd information, and thus the restart fails.

To solve this issue, you are recommended to maintain DM clusters using TiUP. In the case that you need to deploy using binary files, you need to configure `data-dir` with absolute paths in the configuration file of the DM-master, or pay attention to the current directory where you run the command.

Why DM-master cannot be connected when I use `dmctl` to execute commands?

When using `dmctl` execute commands, you might find the connection to DM master fails (even if you have specified the parameter value of `--master-addr` in the command), and the error message is like `RawCause: context deadline exceeded, Workaround: please ↪ check your network connection..` But after checking the network connection using commands like `telnet <master-addr>`, no exception is found.

In this case, you can check the environment variable `https_proxy` (note that it is `https`). If this variable is configured, `dmctl` automatically connects the host and port specified by `https_proxy`. If the host does not have a corresponding proxy forwarding service, the connection fails.

To solve this issue, check whether `https_proxy` is mandatory. If not, cancel the setting. Otherwise, add the environment variable setting `https_proxy="" ./dmctl --master-addr ↪ "x.x.x.x:8261"` before the original `dmctl` commands.

#### Note:

The environment variables related to proxy include `http_proxy`, `https_proxy`, and `no_proxy`. If the connection error persists after you perform the above steps, check whether the configuration parameters of `http_proxy` and `no_proxy` are correct.

How to handle the returned error when executing `start-relay` command for DM versions from 2.0.2 to 2.0.6?

```
flush local meta, Rawcause: open relay-dir/xxx.000001/relay.metayyyy: no
↪ such file or directory
```

The above error might be made in the following cases:

- DM has been upgraded from v2.0.1 and earlier to v2.0.2 - v2.0.6, and relay log is started before the upgrade and restarted after the upgrade.
- Execute the `stop-relay` command to pause the relay log and then restart it.

You can avoid this error by the following options:

- Restart relay log:

```
» stop-relay -s sourceID workerName
» start-relay -s sourceID workerName
```

- Upgrade DM to v2.0.7 or later versions.

Why does the load unit report the `Unknown character set` error?

TiDB does not support all MySQL character sets. Therefore, DM reports this error if an unsupported character set is used when creating the table schema during a full import. To bypass this error, you can create the table schema in the downstream in advance using the [character sets supported by TiDB](#) according to the specific data.

### 13.6.9.12.2 Handle Errors in TiDB Data Migration

This document introduces the error system and how to handle common errors when you use DM.

#### Error system

In the error system, usually, the information of a specific error is as follows:

- **code:** error code.

DM uses the same error code for the same error type. An error code does not change as the DM version changes.

Some errors might be removed during the DM iteration, while the error codes are not. DM uses a new error code instead of an existing one for a new error.

- **class:** error type.

It is used to mark the component where an error occurs (error source).

The following table displays all error types, error sources, and error samples.

Error Type	Error Source	Error Sample
database	Database operations	[code=10003:class=database:scope=downstream ↪ :level=medium] database driver: invalid connection
functional	Underlying functions of DM	[code=11005:class=functional:scope= ↪ =internal:level=high] not allowed operation: alter multiple tables ↪ in one statement
config	Incorrect configuration	[code=20005:class=config:scope=internal: ↪ level=medium] empty source-id not valid
binlog-op	Binlog operations	[code=22001:class=binlog-op:scope=internal: ↪ level=high] empty UUIDs not valid
checkpoint	checkpoint operations	[code=24002:class=checkpoint:scope= ↪ internal:level=high] save point bin.1234 is older than current pos ↪ bin.1371
task-check	Performing task check	[code=26003:class=task-check:scope= ↪ internal:level=medium] new table router error
relay-event-lib	Executing the basic functions of the relay module	[code=28001: ↪ class=relay-event-lib:scope=internal:level=high] parse server-uuid. ↪ index
relay-unit	relay processing unit	[code=30015:class=relay-unit:scope= ↪ upstream:level=high] TCPReader get event: ERROR 1236 (HY000): Could ↪ not open log file

```
dump-unit | dump processing unit | [code=32001:class=dump-unit:scope=internal
↳ :level=high] mydumper runs with error: CRITICAL **: 15:12:17.559:
↳ Error connecting to database: Access denied for user 'root'@'172.17.0.1'
↳ (using password: NO) |
load-unit | load processing unit | [code=34002:class=load-unit:scope=internal
↳ :level=high] corresponding ending of sql: ')' not found |
sync-unit | sync processing unit | [code=36027:class=sync-unit:scope=internal
↳ :level=high] Column count doesn't match value count: 9 (columns)vs
↳ 10 (values) |
dm-master | DM-master service | [code=38008:class=dm-master:scope=internal
↳ :level=high] grpc request error: rpc error: code = Unavailable desc
↳ = all SubConns are in TransientFailure, latest connection error:
↳ connection error: desc = "transport: Error while dialing dial tcp
↳ 172.17.0.2:8262: connect: connection refused" |
dm-worker | DM-worker service | [code=40066:class=dm-worker:scope=internal
↳ :level=high] ExecuteDDL timeout, try use query-status to query
↳ whether the DDL is still blocking |
dm-tracer | DM-tracer service | [code=42004:class=dm-tracer:scope=internal:
↳ level=medium] trace event test.1 not found |
schema-tracker | schema-tracker (during incremental data replication) | [code
↳ =44006:class=schema-tracker:scope=internal:level=high], "cannot track
↳ DDL: ALTER TABLE test DROP COLUMN col1" |
scheduler | Scheduling operations (of data migration tasks) | [code=46001:class=
↳ scheduler:scope=internal:level=high], "the scheduler has not started"
|
dmctl | An error occurs within dmctl or when it interacts with other components |
[code=48001:class=dmctl:scope=internal:level=high], "can not create grpc
↳ connection" |
```

- **scope:** Error scope.

It is used to mark the scope and source of DM objects when an error occurs. `scope` includes four types: `not-set`, `upstream`, `downstream`, and `internal`.

If the logic of the error directly involves requests between upstream and downstream databases, the scope is set to `upstream` or `downstream`; otherwise, it is currently set to `internal`.

- **level:** Error level.

The severity level of the error, including `low`, `medium`, and `high`.

- The `low` level error usually relates to user operations and incorrect inputs. It does not affect migration tasks.
- The `medium` level error usually relates to user configurations. It affects some newly started services; however, it does not affect the existing DM migration status.
- The `high` level error usually needs your attention, since you need to resolve it to avoid the possible interruption of a migration task.

- **message:** Error descriptions.

Detailed descriptions of the error. To wrap and store every additional layer of error message on the error call chain, the [errors.Wrap](#) mode is adopted. The message description wrapped at the outermost layer indicates the error in DM and the message description wrapped at the innermost layer indicates the error source.

- **workaround:** Error handling methods (optional)

The handling methods for this error. For some confirmed errors (such as configuration errors), DM gives the corresponding manual handling methods in **workaround**.

- Error stack information (optional)

Whether DM outputs the error stack information depends on the error severity and the necessity. The error stack records the complete stack call information when the error occurs. If you cannot figure out the error cause based on the basic information and the error message, you can trace the execution path of the code when the error occurs using the error stack.

For the complete list of error codes, refer to the [error code lists](#).

## Troubleshooting

If you encounter an error while running DM, take the following steps to troubleshoot this error:

1. Execute the `query-status` command to check the task running status and the error output.
2. Check the log files related to the error. The log files are on the DM-master and DM-worker nodes. To get key information about the error, refer to the [error system](#). Then check the [Handle Common Errors](#) section to find the solution.
3. If the error is not covered in this document, and you cannot solve the problem by checking the log or monitoring metrics, [get support](#) from PingCAP or the community.
4. After the error is resolved, restart the task using `dmctl`.

```
resume-task ${task name}
```

However, you need to reset the data migration task in some cases. For details, refer to [Reset the Data Migration Task](#).

## Handle common errors

|

### Error Code

Error Description	How to
-------------------	--------

<p><code>code=10001</code>   Abnormal database operation.   Further analyze the error message and error stack.  </p>	
<p><code>code=10002</code>   The <code>bad connection</code> error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is not sent to TiDB.   DM provides automatic recovery for such error. If the recovery is not successful for a long time, check the network or TiDB status.  </p>	
<p><code>code=10003</code>   The <code>invalid connection</code> error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is partly sent to TiDB.   DM provides automatic recovery for such error. If the recovery is not successful for a long time, further check the error message and analyze the information based on the actual situation.  </p>	
<p><code>code=10005</code>   Occurs when performing the <code>QUERY</code> type SQL statements.    </p>	
<p><code>code=10006</code>   Occurs when performing the <code>EXECUTE</code> type SQL statements, including DDL statements and DML statements of the <code>INSERT</code>, <code>UPDATE</code> or <code>DELETE</code> type. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.  </p>	
<p><code>code=11006</code>   Occurs when the built-in parser of DM parses the incompatible DDL statements.   Refer to <a href="#">Data Migration - incompatible DDL statements</a> for solution.  </p>	
<p><code>code=20010</code>   Occurs when decrypting the database password that is provided in task configuration.   Check whether the downstream database password provided in the configuration task is <a href="#">correctly encrypted using dmctl</a>.  </p>	
<p><code>code=26002</code>   The task check fails to establish database connection. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.   Check whether the machine where DM-master is located has permission to access the upstream.  </p>	
<p><code>code=32001</code>   Abnormal dump processing unit   If the error message contains <code>mydumper: ↪ argument list too long.</code>, configure the table to be exported by manually adding the <code>--regex</code> regular expression in the Mydumper argument <code>extra-args</code> in the <code>task.yaml</code> file according to the block-allow list. For example, to export all tables named <code>hello</code>, add <code>↪ regex '.*\\.hello\$'</code>; to export all tables, add <code>--regex '.*'</code>.  </p>	
<p><code>code=38008</code>   An error occurs in the gRPC communication among DM components.   Check <code>class</code>. Find out the error occurs in the interaction of which components. Determine the type of communication error. If the error occurs when establishing gRPC connection, check whether the communication server is working normally.  </p>	

What can I do when a migration task is interrupted with the `invalid connection` error returned?

### Reason

The `invalid connection` error indicates that anomalies have occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy) and that a part of the data for the current request has been sent to TiDB.

### Solutions

Because DM has the feature of concurrently migrating data to the downstream in migration tasks, several errors might occur when a task is interrupted. You can check these errors by using `query-status`.

- If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
- If DM does not or fails to retry automatically because of version problems, use `stop-task` → `task` to stop the task and then use `start-task` to restart the task.

A migration task is interrupted with the `driver: bad connection` error returned

### Reason

The `driver: bad connection` error indicates that anomalies have occurred in the connection between DM and the upstream TiDB database (such as network failure and TiDB restart) and that the data of the current request has not yet been sent to TiDB at that moment.

### Solution

The current version of DM automatically retries on error. If you use the previous version which does not support automatically retry, you can execute the `stop-task` command to stop the task. Then execute `start-task` to restart the task.

The relay unit throws error `event from * in * diff from passed-in event *` or a migration task is interrupted with failing to get or parse binlog errors like `get binlog error ERROR 1236 (HY000) and binlog checksum mismatch`, data may be corrupted returned

### Reason

During the DM process of relay log pulling or incremental replication, this two errors might occur if the size of the upstream binlog file exceeds **4 GB**.

**Cause:** When writing relay logs, DM needs to perform event verification based on binlog positions and the size of the binlog file, and store the replicated binlog positions as checkpoints. However, the official MySQL uses `uint32` to store binlog positions. This means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

### Solutions

For relay units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the DM-worker.
3. Copy the corresponding binlog file in the upstream to the relay log directory as the relay log file.
4. In the relay log directory, update the corresponding `relay.meta` file to pull from the next binlog file. If you have specified `enable_gtid` to `true` for the DM-worker, you need to modify the GTID corresponding to the next binlog file when updating the `relay.meta` file. Otherwise, you don't need to modify the GTID.

Example: when the error occurs, `binlog-name = "mysql-bin.004451"` and `binlog-pos = 2453`. Update them respectively to `binlog-name = "mysql-bin.004452"` and `binlog-pos = 4`, and update `binlog-gtid` to `f0e914ef-54cf-11e7-813d-6c92bf2fa791:1-138218058`.

5. Restart the DM-worker.

For binlog replication processing units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.
2. Stop the migration task using `stop-task`.
3. Update the `binlog_name` in the global checkpoints and in each table checkpoint of the downstream `dm_meta` database to the name of the binlog file in error; update `binlog_pos` to a valid position value for which migration has completed, for example, 4.

Example: the name of the task in error is `dm_test`, the corresponding `ssource-id` is `replica-1`, and the corresponding binlog file is `mysql-bin|000001.004451`. Execute the following command:

```
UPDATE dm_test_syncer_checkpoint SET binlog_name='mysql-bin
↳ |000001.004451', binlog_pos = 4 WHERE id='replica-1';
```

4. Specify `safe-mode: true` in the `syncers` section of the migration task configuration to ensure re-entrant.
5. Start the migration task using `start-task`.
6. View the status of the migration task using `query-status`. You can restore `safe-mode` to the original value and restart the migration task when migration is done for the original error-triggering relay log files.

Access denied for user 'root'@'172.31.43.27' (using password: YES) shows when you query the task or check the log

For database related passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. For how to encrypt the plaintext password, see [Encrypt the database password using dmctl](#).

In addition, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also [prechecks the corresponding privileges automatically](#) while starting the data migration task.

The load processing unit reports the error `packet for query is too large`. Try adjusting the `'max_allowed_packet'` variable

#### Reasons

- Both MySQL client and MySQL/TiDB server have the quota limits for `max_allowed_packet`  $\leftrightarrow$  . If any `max_allowed_packet` exceeds a limit, the client receives the error message. Currently, for the latest version of DM and TiDB server, the default value of `max_allowed_packet` is 64M.
- The full data import processing unit in DM does not support splitting the SQL file exported by the Dump processing unit in DM.

#### Solutions

- It is recommended to set the `statement-size` option of `extra-args` for the Dump processing unit:

According to the default `--statement-size` setting, the default size of `Insert`  $\leftrightarrow$  `Statement` generated by the Dump processing unit is about 1M. With this default setting, the load processing unit does not report the error `packet for query is`  $\leftrightarrow$  `too large`. Try adjusting the `'max_allowed_packet'` variable in most cases.

Sometimes you might receive the following `WARN` log during the data dump. This `WARN` log does not affect the dump process. This only means that wide tables are dumped.

```
Row bigger than statement_size for xxx
```

- If the single row of the wide table exceeds 64M, you need to modify the following configurations and make sure the configurations take effect.
  - Execute `set @@global.max_allowed_packet=134217728` (134217728 = 128 MB) in the TiDB server.
  - First add the `max-allowed-packet: 134217728` (128 MB) to the `target-`  $\leftrightarrow$  `database` section in the DM task configuration file. Then, execute the `stop-task` command and execute the `start-task` command.

### 13.6.9.13 TiDB Data Migration Release Notes

Since DM v5.4, the Release Notes of TiDB Data Migration have been merged into TiDB Release Notes of the same version number.

- To read the DM Release Notes of v5.4 or a later version, see the DM related content in the corresponding TiDB Release Notes.
- To read the DM Release Notes of v5.3.0 or an earlier version, refer to the following links.

## 13.7 TiDB Lightning

### 13.7.1 TiDB Lightning Overview

[TiDB Lightning](#) is a tool used for importing data at TB scale to TiDB clusters. It is often used for initial data import to TiDB clusters.

TiDB Lightning supports the following file formats:

- Files exported by [Dumpling](#)
- CSV files
- [Apache Parquet files generated by Amazon Aurora](#)

TiDB Lightning can read data from the following sources:

- Local
- [Amazon S3](#)
- [Google Cloud Storage](#)

### 13.7.1.1 TiDB Lightning architecture

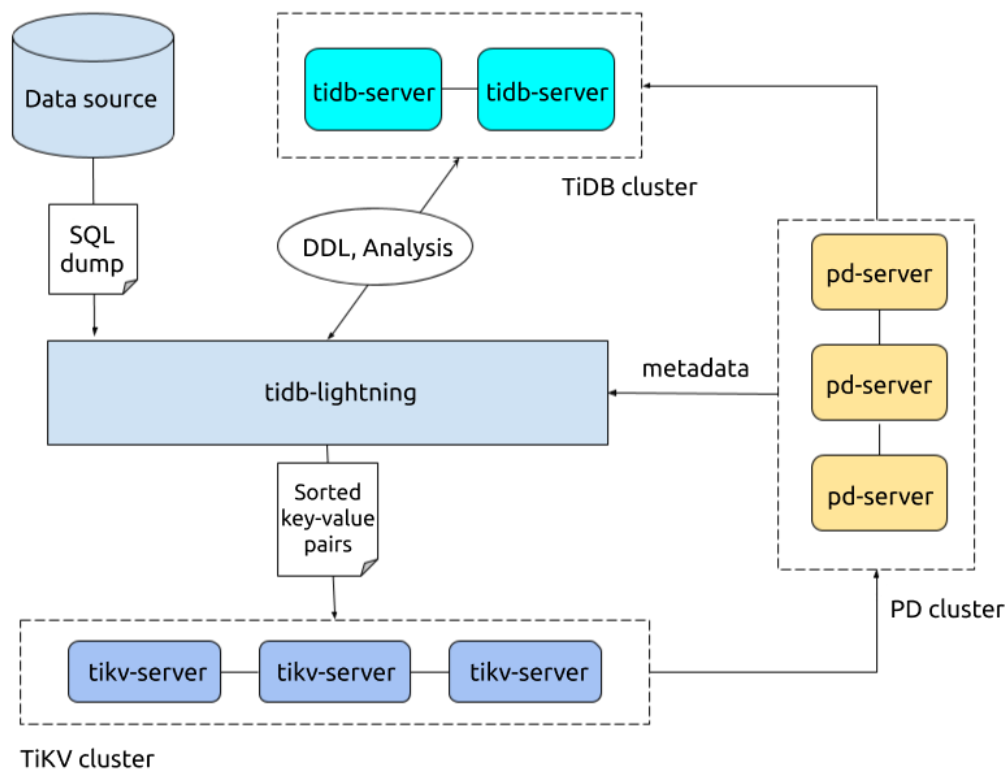

Figure 260: Architecture of TiDB Lightning tool set

TiDB Lightning supports two import modes, configured by `backend`. The import mode determines the way data is imported into TiDB.

- **Physical Import Mode:** TiDB Lightning first encodes data into key-value pairs and stores them in a local temporary directory, then uploads these key-value pairs to each TiKV node, and finally calls the TiKV Ingest interface to insert data into TiKV's RocksDB. If you need to perform initial import, consider the physical import mode, which has higher import speed. The backend for the physical import mode is `local`.
- **Logical Import Mode:** TiDB Lightning first encodes the data into SQL statements and then runs these SQL statements directly for data import. If the cluster to be imported is in production, or if the target table to be imported already contains data, use the logical import mode. The backend for the logical import mode is `tidb`.

Import mode	Physical Import Mode	Logical Import
Backend	<code>local</code>	<code>tidb</code>
Speed	Fast (100~500 GiB/hour)	Low (10~50 G
Resource consumption	High	Low
Network bandwidth consumption	High	Low
ACID compliance during import	No	Yes
Target tables	Must be empty	Can contain d
TiDB cluster version	$\geq 4.0.0$	All
Whether the TiDB cluster can provide service during import	<b>Limited service</b>	Yes

The preceding performance data is used to compare the import performance difference between the two modes. The actual import speed is affected by various factors such as hardware configuration, table schema, and the number of indexes.

### 13.7.2 Get Started with TiDB Lightning

This tutorial assumes you use several new and clean CentOS 7 instances. You can use VMware, VirtualBox or other tools to deploy a virtual machine locally or a small cloud virtual machine on a vendor-supplied platform. Because TiDB Lightning consumes a large amount of computer resources, it is recommended that you allocate at least 16 GB memory and CPU of 32 cores for running it with the best performance.

#### **Warning:**

The deployment method in this tutorial is only recommended for test and trial. **Do not apply it in the production or development environment.**

#### 13.7.2.1 Prepare full backup data

First, use `dumpling` to export data from MySQL:

```
tiup dumpling -h 127.0.0.1 -P 3306 -u root -t 16 -F 256MB -B test -f 'test.
↳ t[12]' -o /data/my_database/
```

In the above command:

- `-B test`: means the data is exported from the `test` database.
- `-f test.t[12]`: means only the `test.t1` and `test.t2` tables are exported.
- `-t 16`: means 16 threads are used to export the data.
- `-F 256MB`: means a table is partitioned into chunks and one chunk is 256 MB.

After executing this command, the full backup data is exported to the `/data/`  
↳ `my_database` directory.

## 13.7.2.2 Deploy TiDB Lightning

### 13.7.2.2.1 Step 1: Deploy a TiDB cluster

Before the data import, you need to deploy a TiDB cluster. In this tutorial, TiDB v5.4.0 is used as an example. For the deployment method, refer to [Deploy a TiDB Cluster Using TiUP](#).

### 13.7.2.2.2 Step 2: Download TiDB Lightning installation package

The TiDB Lightning installation package is included in the TiDB Toolkit. To download the TiDB Toolkit, see [Download TiDB Tools](#).

#### Note:

TiDB Lightning is compatible with TiDB clusters of earlier versions. It is recommended that you download the latest stable version of the TiDB Lightning installation package.

### 13.7.2.2.3 Step 3: Start `tidb-lightning`

1. Upload `bin/tidb-lightning` and `bin/tidb-lightning-ctl` in the package to the server where TiDB Lightning is deployed.
2. Upload the [prepared data source](#) to the server.
3. Configure `tidb-lightning.toml` as follows:

```
[lightning]
Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
Configure the import mode
backend = "local"
Sets the directory for temporarily storing the sorted key-value pairs
↪ .
The target directory must be empty.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
Local source data directory
data-source-dir = "/data/my_datasource/"

Configures the wildcard rule. By default, all tables in the mysql,
↪ sys, INFORMATION_SCHEMA, PERFORMANCE_SCHEMA, METRICS_SCHEMA, and
↪ INSPECTION_SCHEMA system databases are filtered.
If this item is not configured, the "cannot find schema" error occurs
↪ when system tables are imported.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA
↪ .*']

[tidb]
Information of the target cluster
host = "172.16.31.2"
port = 4000
user = "root"
password = "rootroot"
Table schema information is fetched from TiDB via this status-port.
status-port = 10080
The PD address of the cluster
pd-addr = "172.16.31.3:2379"
```

4. After configuring the parameters properly, use a `nohup` command to start the `tidb` ↪ `-lightning` process. If you directly run the command in the command-line, the process might exit because of the `SIGHUP` signal received. Instead, it's preferable to run a bash script that contains the `nohup` command:

```
#!/bin/bash
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out &
```

#### 13.7.2.2.4 Step 4: Check data integrity

After the import is completed, TiDB Lightning exits automatically. If the import is successful, you can find `tidb lightning exit` in the last line of the log file.

If any error occurs, refer to [TiDB Lightning FAQs](#).

#### 13.7.2.3 Summary

This tutorial briefly introduces what TiDB Lightning is and how to quickly deploy a TiDB Lightning cluster to import full backup data to the TiDB cluster.

For detailed features and usage about TiDB Lightning, refer to [TiDB Lightning Overview](#).

### 13.7.3 Deploy TiDB Lightning

This document describes the hardware requirements of using TiDB Lightning to import data, and how to deploy it manually. Requirements on hardware resources vary with the import modes. For details, refer to the following docs:

- [Physical Import Mode Requirements and Limitations](#)
- [Logical Import Mode Requirements and Limitations](#)

#### 13.7.3.1 Online deployment using TiUP (recommended)

1. Install TiUP using the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
↪ install.sh | sh
```

This command automatically adds TiUP to the `PATH` environment variable. You need to start a new terminal session or run `source ~/.bashrc` before you can use TiUP. (According to your environment, you may need to run `source ~/.profile`. For the specific command, check the output of TiUP.)

2. Install TiDB Lightning using TiUP:

```
tiup install tidb-lightning
```

#### 13.7.3.2 Manual deployment

### 13.7.3.2.1 Download TiDB Lightning binaries

Refer to [Download TiDB Tools](#) and download TiDB Lightning binaries. TiDB Lightning is completely compatible with early versions of TiDB. It is recommended to use the latest version of TiDB Lightning.

Unzip the TiDB Lightning binary package to obtain the `tidb-lightning` executable file:

```
tar -zxvf tidb-lightning- $\{version\}$ -linux-amd64.tar.gz
chmod +x tidb-lightning
```

In this command,

- `-B test`: means the data is exported from the `test` database.
- `-f test.t[12]`: means only the `test.t1` and `test.t2` tables are exported.
- `-t 16`: means 16 threads are used to export the data.
- `-F 256MB`: means a table is partitioned into chunks and one chunk is 256 MB.

If the data source consists of CSV files, see [CSV support](#) for configuration.

### 13.7.3.3 Deploy TiDB Lightning

This section describes how to [deploy TiDB Lightning manually](#).

#### 13.7.3.3.1 Deploy TiDB Lightning manually

Step 1: Deploy a TiDB cluster

Before importing data, you need to have a deployed TiDB cluster. It is highly recommended to use the latest stable version.

You can find deployment instructions in [TiDB Quick Start Guide](#).

Step 2: Download the TiDB Lightning installation package

Refer to the [Download TiDB Tools](#) document to download the TiDB Lightning package.

#### Note:

TiDB Lightning is compatible with TiDB clusters of earlier versions. It is recommended that you download the latest stable version of the TiDB Lightning installation package.

Step 3: Start `tidb-lightning`

1. Upload bin/tidb-lightning and bin/tidb-lightning-ctl from the tool set.
2. Mount the data source onto the same machine.
3. Configure tidb-lightning.toml. For configurations that do not appear in the template below, TiDB Lightning writes a configuration error to the log file and exits.

sorted-kv-dir sets the temporary storage directory for the sorted Key-Value files. The directory must be empty, and the storage space **must be greater than the size of the dataset to be imported**. See [Downstream storage space requirements](#) for details.

```
[lightning]
The concurrency number of data. It is set to the number of logical
 ↪ CPU
cores by default. When deploying together with other components, you
 ↪ can
set it to 75% of the size of logical CPU cores to limit the CPU usage
 ↪ .
region-concurrency =

Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
Sets the backend to the "local" mode.
backend = "local"
Sets the directory of temporary local storage.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
Local source data directory
data-source-dir = "/data/my_database"

[tidb]
Configuration of any TiDB server from the cluster
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
Table schema information is fetched from TiDB via this status-port.
status-port = 10080
An address of pd-server.
pd-addr = "172.16.31.4:2379"
```

The above only shows the essential settings. See the [Configuration](#) section for the full list of settings.

#### 4. Run `tidb-lightning`.

```
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

### 13.7.3.4 Upgrade TiDB Lightning

You can upgrade TiDB Lightning by replacing the binaries alone without further configurations. After the upgrade, you need to restart TiDB Lightning. For details, see [How to properly restart TiDB Lightning](#).

If an import task is running, we recommend you to wait until it finishes before upgrading TiDB Lightning. Otherwise, there might be chances that you need to reimport from scratch, because there is no guarantee that checkpoints work across versions.

## 13.7.4 TiDB Lightning Requirements for the Target Database

Before using TiDB Lightning, you need to check whether the environment meets the requirements. This helps reduce errors during import and ensures import success.

### 13.7.4.1 Privileges of the target database

Based on the import mode and features enabled, the target database users should be granted with different privileges. The following table provides a reference.

	Feature	Scope	Required privilege	Remarks

	Mandatory			
	Basic functions	Target table	CREATE, SELECT, INSERT, UPDATE, DELETE, DROP, ALTER	DROP is required only when <code>tidb-lightning-ctl</code> runs the <code>checkpoint-destroy-all</code> command

	Target database		CREATE	
--	-----------------	--	--------	--

```
<td rowspan="4">Mandatory</td>
<td>Logical Import Mode</td>
<td>information_schema.columns</td>
<td>SELECT</td>
<td></td>
```

```
<td rowspan="3">Physical Import Mode</td>
<td>mysql.tidb</td>
<td>SELECT</td>
<td></td>
```

```
<td>-</td>
<td>SUPER</td>
<td></td>
```

```
<td>-</td>
<td>RESTRICTED_VARIABLES_ADMIN,RESTRICTED_TABLES_ADMIN</td>
<td>Required when the target TiDB enables SEM</td>
```

```
<td>Recommended</td>
<td>Conflict detection, max-error</td>
<td>Schema configured for lightning.task-info-schema-name</td>
<td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP</td>
<td>If not required, the value must be set to ""</td>
```

```
<td>Optional</td>
<td>Parallel import</td>
<td>Schema configured for lightning.meta-schema-name</td>
<td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP</td>
<td>If not required, the value must be set to ""</td>
```

```
<td>Optional</td>
<td>checkpoint.driver = "mysql"</td>
<td>checkpoint.schema setting</td>
<td>SELECT,INSERT,UPDATE,DELETE,CREATE,DROP</td>
<td>Required when checkpoint information is stored in databases, instead
 ↪ of files</td>
```

#### 13.7.4.2 Storage space of the target database

The target TiKV cluster must have enough disk space to store the imported data. In addition to the [standard hardware requirements](#), the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For

example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has x 2 because:

- Indexes might take extra space.
- RocksDB has a space amplification effect.

It is difficult to calculate the exact data volume exported by Dumping from MySQL. However, you can estimate the data volume by using the following SQL statement to summarize the data-length field in the information\_schema.tables table:

Calculate the size of all schemas, in MiB. Replace `${schema_name}` with your schema name.

```
SELECT table_schema, SUM(data_length)/1024/1024 AS data_length, SUM(
 ↪ index_length)/1024/1024 AS index_length, SUM(data_length+index_length
 ↪)/1024/1024 AS sum FROM information_schema.tables WHERE table_schema
 ↪ = "${schema_name}" GROUP BY table_schema;
```

Calculate the size of the largest table, in MiB. Replace `${schema_name}` with your schema name.

```
SELECT table_name, table_schema, SUM(data_length)/1024/1024 AS data_length,
 ↪ SUM(index_length)/1024/1024 AS index_length, sum(data_length+
 ↪ index_length)/1024/1024 AS sum FROM information_schema.tables WHERE
 ↪ table_schema = "${schema_name}" GROUP BY table_name, table_schema
 ↪ ORDER BY sum DESC LIMIT 5;
```

## 13.7.5 Data Sources

### 13.7.5.1 TiDB Lightning Data Sources

TiDB Lightning supports importing data from multiple data sources to TiDB clusters, including CSV, SQL, and Parquet files.

To specify the data source for TiDB Lightning, use the following configuration:

```
[mydumper]
Local source data directory or the URI of the external storage such as
 ↪ S3. For more information about the URI of the external storage, see
 ↪ https://docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-
 ↪ format.
data-source-dir = "/data/my_database"
```

When TiDB Lightning is running, it looks for all files that match the pattern of `data-source-dir`.

File	Type	Pattern
Schema file	Contains the CREATE TABLE DDL statement	<pre> \${   ↪ db_name   ↪ }.   ↪ TABLE ↪ {   ↪ table_name   ↪ }-   ↪ schema   ↪ .   ↪ sql </pre>
Schema file	Contains the CREATE DATABASE DDL statement	<pre> \${   ↪ db_name   ↪ }-   ↪ DATABASE ↪ schema   ↪ -   ↪ create   ↪ .   ↪ sql </pre>
Data file	If the data file contains data for a whole table, the file is imported into a table named	<pre> \${db_name}.\${table_name}.\${csv sql parquet} </pre>

File	Type	Pattern
Data file	If the data for a table is split into multiple data files, each data file must be suffixed with a number in its filename	<code>\${db_name}.\${table_name}.001.\${csv sql parquet}</code>
Compressed file	If the file contains a compression suffix, such as <code>gzip</code> , <code>snappy</code> , or <code>zstd</code> , TiDB Lightning will decompress the file before importing it.	<code>\${db_name}.\${table_name}.\${csv sql parquet}.\${compression}</code>

TiDB Lightning processes data in parallel as much as possible. Because files must be read in sequence, the data processing concurrency is at the file level (controlled by `region`  $\leftrightarrow$  `-concurrency`). Therefore, when the imported file is large, the import performance is poor. It is recommended to limit the size of the imported file to no greater than 256 MiB to achieve the best performance.

### 13.7.5.1.1 CSV

## Schema

CSV files are schema-less. To import CSV files into TiDB, you must provide a table schema. You can provide schema by either of the following methods:

- Create files named `${db_name}.${table_name}-schema.sql` and `${db_name}-schema-create.sql` that contain DDL statements.
- Manually create the table schema in TiDB.

## Configuration

You can configure the CSV format in the `[mydumper.csv]` section in the `tidb-lightning.toml` file. Most settings have a corresponding option in the [LOAD DATA](#) statement of MySQL.

```
[mydumper.csv]
The field separator. Can be one or multiple characters. The default is
↳ ', '.
If the data might contain commas, it is recommended to use '|+|' or
↳ other uncommon
character combinations as a separator.
separator = ','
Quoting delimiter. Empty value means no quoting.
delimiter = ''
Line terminator. Can be one or multiple characters. Empty value (
↳ default) means
both "\n" (LF) and "\r\n" (CRLF) are line terminators.
terminator = ''
Whether the CSV file contains a header.
If `header` is true, the first line is skipped and mapped
to the table columns.
header = true
Whether the CSV file contains any NULL value.
If `not-null` is true, all columns from CSV cannot be parsed as NULL.
not-null = false
When `not-null` is false (that is, CSV can contain NULL),
fields equal to this value will be treated as NULL.
null = '\N'
Whether to parse backslash as escape character.
backslash-escape = true
Whether to treat `separator` as the line terminator and trim all
↳ trailing separators.
trim-last-separator = false
```

If the input of a string field such as `separator`, `delimiter`, or `terminator` involves special characters, you can use a backslash to escape the special characters. The escape sequence must be a *double-quoted* string ("..."). For example, `separator = "\u001f"` means

using the ASCII character 0X1F as the separator.

You can use *single-quoted* strings ('...') to suppress backslash escaping. For example, `terminator = '\n'` means using the two-character string, a backslash (\) followed by the letter n, as the terminator, rather than the LF \n.

For more details, see the [TOML v1.0.0 specification](#).

#### `separator`

- Defines the field separator.
- Can be one or multiple characters, but must not be empty.
- Common values:
  - ', ' for CSV (comma-separated values).
  - "\t" for TSV (tab-separated values).
  - "\u0001" to use the ASCII character 0x01.
- Corresponds to the `FIELDS TERMINATED BY` option in the `LOAD DATA` statement.

#### `delimiter`

- Defines the delimiter used for quoting.
- If `delimiter` is empty, all fields are unquoted.
- Common values:
  - '"' quotes fields with double-quote. The same as [RFC 4180](#).
  - '' disables quoting.
- Corresponds to the `FIELDS ENCLOSED BY` option in the `LOAD DATA` statement.

#### `terminator`

- Defines the line terminator.
- If `terminator` is empty, both "\n" (Line Feed) and "\r\n" (Carriage Return + Line Feed) are used as the line terminator.
- Corresponds to the `LINES TERMINATED BY` option in the `LOAD DATA` statement.

#### `header`

- Whether *all* CSV files contain a header row.
- If `header` is `true`, the first row is used as the *column names*. If `header` is `false`, the first row is treated as an ordinary data row.

### not-null and null

- The `not-null` setting controls whether all fields are non-nullable.
- If `not-null` is `false`, the string specified by `null` is transformed to the SQL NULL instead of a specific value.
- Quoting does not affect whether a field is null.

For example, in the following CSV file:

```
A,B,C
\N,"\N",
```

In the default settings (`not-null = false`; `null = '\N'`), the columns `A` and `B` are both converted to NULL after being imported to TiDB. The column `C` is an empty string `' '` but not NULL.

### backslash-escape

- Whether to parse backslash inside fields as escape characters.
- If `backslash-escape` is true, the following sequences are recognized and converted:

Sequence	Converted to
<code>\0</code>	Null character (U+0000)
<code>\b</code>	Backspace (U+0008)
<code>\n</code>	Line feed (U+000A)
<code>\r</code>	Carriage return (U+000D)
<code>\t</code>	Tab (U+0009)
<code>\Z</code>	Windows EOF (U+001A)

In all other cases (for example, `\"`), the backslash is stripped, leaving the next character (`"`) in the field. The character left has no special roles (for example, delimiters) and is just an ordinary character.

- Quoting does not affect whether backslash is parsed as an escape character.
- Corresponds to the `FIELDS ESCAPED BY '\'` option in the `LOAD DATA` statement.

### trim-last-separator

- Whether to treat `separator` as the line terminator and trim all trailing separators.
- For example, in the following CSV file:

```
A,,B,,
```

- When `trim-last-separator = false`, this is interpreted as a row of 5 fields ('A', '', 'B', '', '').
- When `trim-last-separator = true`, this is interpreted as a row of 3 fields ('A' ↪ ', ', 'B').

- This option is deprecated. Use the `terminator` option instead.

If your existing configuration is:

```
separator = ','
trim-last-separator = true
```

It is recommended to change the configuration to:

```
separator = ','
terminator = ",\n" # Use ",\n" or ",\r\n" according to your actual
 ↪ file.
```

### Non-configurable options

TiDB Lightning does not support every option supported by the `LOAD DATA` statement. For example:

- There cannot be line prefixes (`LINES STARTING BY`).
- The header cannot be skipped (`IGNORE n LINES`) and must be valid column names.

### Strict format

TiDB Lightning works best when the input files have a uniform size of around 256 MiB. When the input is a single huge CSV file, TiDB Lightning can only process the file in one thread, which slows down the import speed.

This can be fixed by splitting the CSV into multiple files first. For the generic CSV format, there is no way to quickly identify where a row starts or ends without reading the whole file. Therefore, TiDB Lightning by default does *not* automatically split a CSV file. However, if you are certain that the CSV input adheres to certain restrictions, you can enable the `strict-format` setting to allow TiDB Lightning to split the file into multiple 256 MiB-sized chunks for parallel processing.

```
[mydumper]
strict-format = true
```

In a strict CSV file, every field occupies only a single line. In other words, one of the following must be true:

- Delimiter is empty.
- Every field does not contain the terminator itself. In the default configuration, this means every field does not contain CR (`\r`) or LF (`\n`).

If a CSV file is not strict, but `strict-format` is wrongly set to `true`, a field spanning multiple lines may be cut in half into two chunks, causing parse failure, or even quietly importing corrupted data.

Common configuration examples

### CSV

The default setting is already tuned for CSV following RFC 4180.

```
[mydumper.csv]
separator = ',' # If the data might contain a comma (','), it is recommended
 ↪ to use '|' or other uncommon character combinations as the
 ↪ separator.
delimiter = ''
header = true
not-null = false
null = '\N'
backslash-escape = true
```

Example content:

```
ID,Region,Count
1,"East",32
2,"South",\N
3,"West",10
4,"North",39
```

### TSV

```
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
```

Example content:

ID	Region	Count
1	East	32
2	South	NULL
3	West	10
4	North	39

## TPC-H DBGEN

```
[mydumper.csv]
separator = '|'
delimiter = ''
terminator = "\\n"
header = false
not-null = true
backslash-escape = false
```

Example content:

```
1|East|32|
2|South|0|
3|West|10|
4|North|39|
```

### 13.7.5.1.2 SQL

When TiDB Lightning processes a SQL file, because TiDB Lightning cannot quickly split a single SQL file, it cannot improve the import speed of a single file by increasing concurrency. Therefore, when you import data from SQL files, avoid a single huge SQL file. TiDB Lightning works best when the input files have a uniform size of around 256 MiB.

### 13.7.5.1.3 Parquet

TiDB Lightning currently only supports Parquet files generated by Amazon Aurora or Apache Hive. To identify the file structure in S3, use the following configuration to match all data files:

```
[[mydumper.files]]
The expression needed for parsing Amazon Aurora parquet files
pattern = '(?i)^(?:[~/]*)*([a-z0-9_+])\.[a-z0-9_+]/(?:[~/]*)*(?:[a-z0
 ↪ -9\-.] + \. (parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

Note that this configuration only shows how to match the parquet files exported by Aurora snapshot. You need to export and process the schema file separately.

For more information on `mydumper.files`, refer to [Match customized file](#).

### 13.7.5.1.4 Compressed files

TiDB Lightning currently supports compressed files exported by Dumping or compressed files that follow the naming rules. Currently, TiDB Lightning supports the following

compression algorithms: `gzip`, `snappy`, and `zstd`. When the file name follows the naming rules, TiDB Lightning automatically identifies the compression algorithm and imports the file after streaming decompression, without additional configuration.

#### Note:

- Because TiDB Lightning cannot concurrently decompress a single large compressed file, the size of the compressed file affects the import speed. It is recommended that a source file is no greater than 256 MiB after decompression.
- TiDB Lightning only imports individually compressed data files and does not support importing a single compressed file with multiple data files included.
- TiDB Lightning does not support `parquet` files compressed through another compression tool, such as `db.table.parquet.snappy`. If you want to compress `parquet` files, you can configure the compression format for the `parquet` file writer.
- TiDB Lightning v6.4.0 and later versions only support `.bak` files and the following compressed data files: `gzip`, `snappy`, and `zstd`. Other types of files cause errors. For those unsupported files, you need to modify the file names in advance, or move those files out of the import data directory to avoid such errors.

#### 13.7.5.1.5 Match customized files

TiDB Lightning only recognizes data files that follow the naming pattern. In some cases, your data file might not follow the naming pattern, and thus data import is completed in a short time without importing any file.

To resolve this issue, you can use `[[mydumper.files]]` to match data files in your customized expression.

Take the Aurora snapshot exported to S3 as an example. The complete path of the Parquet file is `S3://some-bucket/some-subdir/some-database/some-database.some-table`  
↪ `/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet`.

Usually, `data-source-dir` is set to `S3://some-bucket/some-subdir/some-database/` to import the `some-database` database.

Based on the preceding Parquet file path, you can write a regular expression like `(?i)^(?:[~/]*/*)([a-z0-9_+]\.([a-z0-9_+])/(?:[~/]*/*)(?:[a-z0-9\-\_]+\.(parquet)))$` to match the files. In the match group, `index=1` is `some-database`, `index=2` is `some-table`, and `index=3` is `parquet`.

You can write the configuration file according to the regular expression and the corresponding index so that TiDB Lightning can recognize the data files that do not follow the default naming convention. For example:

```
[[mydumper.files]]
The expression needed for parsing the Amazon Aurora parquet file
pattern = '(?i)^(?:[~/]*)*([a-z0-9_]+\.[a-z0-9_]+)/(?:[~/]*)*(?:[a-z0
 ↪ -9\-.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

- **schema:** The name of the target database. The value can be:
  - The group index obtained by using a regular expression, such as \$1.
  - The name of the database that you want to import, such as db1. All matched files are imported into db1.
- **table:** The name of the target table. The value can be:
  - The group index obtained by using a regular expression, such as \$2.
  - The name of the table that you want to import, such as table1. All matched files are imported into table1.
- **type:** The file type. Supports sql, parquet, and csv. The value can be:
  - The group index obtained by using a regular expression, such as \$3.
- **key:** The file number, such as 001 in \${db\_name}.\${table\_name}.001.csv.
  - The group index obtained by using a regular expression, such as \$4.

### 13.7.5.1.6 Import data from Amazon S3

The following examples show how to import data from Amazon S3 using TiDB Lightning. For more parameter configurations, see [external storage URI](#).

- Use the locally configured permissions to access S3 data:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
 ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
 -d 's3://my-bucket/sql-backup'
```

- Use the path-style request to access S3 data:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
 ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
 -d 's3://my-bucket/sql-backup?force-path-style=true&endpoint=http
 ↪ ://10.154.10.132:8088'
```

- Use a specific AWS IAM role ARN to access S3 data:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/test-data?role-arn=arn:aws:iam::888888888888:
↪ role/my-role'
```

- Use access keys of an AWS IAM user to access S3 data:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/test-data?access_key={my_access_key}&
↪ secret_access_key={my_secret_access_key}'
```

- Use the combination of AWS IAM role access keys and session tokens to access S3 data:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/test-data?access_key={my_access_key}&
↪ secret_access_key={my_secret_access_key}&session-token={
↪ my_session_token}'
```

## 13.7.6 Physical Import Mode

### 13.7.6.1 Physical Import Mode

Physical import mode is an efficient and fast import mode that inserts data directly into TiKV nodes as key-value pairs without going through the SQL interface. When using the physical import mode, a single instance of Lightning can import up to 10 TiB of data. The supported amount of imported data theoretically increases as the number of Lightning instances increases. It is verified by users that [parallel importing](#) based on Lightning can effectively handle up to 20 TiB of data.

Before you use the physical import mode, make sure to read [Requirements and restrictions](#).

The backend for the physical import mode is `local`.

### 13.7.6.1.1 Implementation

1. Before importing data, TiDB Lightning automatically switches the TiKV nodes to “import mode”, which improves write performance and stops auto-compaction. TiDB Lightning determines whether to pause global scheduling according to the TiDB cluster version.
  - When the TiDB cluster  $\geq$  v6.1.0 and TiDB Lightning  $\geq$  v6.2.0, TiDB Lightning pauses scheduling for the region that stores the target table data. After the import is completed, TiDB Lightning recovers scheduling.
  - When the TiDB cluster  $<$  v6.1.0 or TiDB Lightning  $<$  v6.2.0, TiDB Lightning pauses global scheduling.

2. TiDB Lightning creates table schemas in the target database and fetches the metadata.
3. Each table is divided into multiple contiguous **blocks**, so that TiDB Lightning can import data from large tables (greater than 200 GB) in parallel.
4. TiDB Lightning prepares an “engine file” for each block to handle key-value pairs. TiDB Lightning reads the SQL dump in parallel, converts the data source to key-value pairs in the same encoding as TiDB, sorts the key-value pairs and writes them to a local temporary storage file.
5. When an engine file is written, TiDB Lightning starts to split and schedule data on the target TiKV cluster, and then imports data to TiKV cluster.

The engine file contains two types of engines: **data engine** and **index engine**. Each engine corresponds to a type of key-value pairs: row data and secondary index. Normally, row data is completely ordered in the data source, and the secondary index is unordered. Therefore, the data engine files are imported immediately after the corresponding block is written, and all index engine files are imported only after the entire table is encoded.

6. After all engine files are imported, TiDB Lightning compares the checksum between the local data source and the downstream cluster, and ensures that the imported data is not corrupted. Then TiDB Lightning analyzes the new data (**ANALYZE**) to optimize the future operations. Meanwhile, `tidb-lightning` adjusts the `AUTO_INCREMENT` value to prevent conflicts in the future.

The auto-increment ID is estimated by the **upper bound** of the number of rows, and is proportional to the total size of the table data file. Therefore, the auto-increment ID is usually larger than the actual number of rows. This is normal because the auto-increment ID **is not necessarily contiguous**.

7. After all steps are completed, TiDB Lightning automatically switches the TiKV nodes to “normal mode”. If global scheduling is paused, TiDB Lightning also recovers global scheduling. After that, the TiDB cluster can provide services normally.

### 13.7.6.1.2 Requirements and restrictions

Environment requirements

#### Operating system:

It is recommended to use fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, tikv-server) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

#### Memory and CPU:

It is recommended that you allocate CPU more than 32 cores and memory greater than 64 GiB to get better performance.

#### Note:

When you import a large amount of data, one concurrent import may consume about 2 GiB memory. The total memory usage can be `region-concurrency`  $\times$  2 GiB. `region-concurrency` is the same as the number of logical CPUs by default. If the memory size (GiB) is less than twice of the CPU or OOM occurs during the import, you can decrease `region-concurrency` to avoid OOM.

**Storage:** The `sorted-kv-dir` configuration item specifies the temporary storage directory for the sorted key-value files. The directory must be empty, and the storage space must be greater than the size of the dataset to be imported. For better import performance, it is recommended to use a directory different from `data-source-dir` and use flash storage and exclusive I/O for the directory.

**Network:** A 10Gbps Ethernet card is recommended.

Version requirements

- TiDB Lightning  $\geq$  v4.0.3.
- TiDB  $\geq$  v4.0.0.
- If the target TiDB cluster is v3.x or earlier, you need to use Importer-backend to complete the data import. In this mode, `tidb-lightning` needs to send the parsed key-value pairs to `tikv-importer` via gRPC, and `tikv-importer` will complete the data import.

Limitations

- Do not use the physical import mode to directly import data to TiDB clusters in production. It has severe performance implications. If you need to do so, refer to [Pause scheduling on the table level](#).
- Do not use multiple TiDB Lightning instances to import data to the same TiDB cluster by default. Use [Parallel Import](#) instead.
- When you use multiple TiDB Lightning to import data to the same target cluster, do not mix the import modes. That is, do not use the physical import mode and the logical import mode at the same time.
- During the process of importing data, do not perform DDL and DML operations in the target table. Otherwise the import will fail or the data will be inconsistent. At the same time, it is not recommended to perform read operations, because the data you read might be inconsistent. You can perform read and write operations after the import operation is completed.
- A single Lightning process can import a single table of 10 TB at most. Parallel import can use 10 Lightning instances at most.

#### Tips for using with other components

- When you use TiDB Lightning with TiFlash, note the following:
  - Whether you have created a TiFlash replica for a table, you can use TiDB Lightning to import data to the table. However, the import might take longer than the normal import. The import time is influenced by the network bandwidth of the server TiDB Lightning is deployed on, the CPU and disk load on the TiFlash node, and the number of TiFlash replicas.
- TiDB Lightning character sets:
  - TiDB Lightning earlier than v5.4.0 cannot import tables of `charset=GBK`.
- When you use TiDB Lightning with TiCDC, note the following:
  - TiCDC cannot capture the data inserted in the physical import mode.

### 13.7.6.2 Use Physical Import Mode

This document introduces how to use the [physical import mode](#) in TiDB Lightning, including writing the configuration file, tuning performance, and configuring disk quota.

#### 13.7.6.2.1 Configure and use the physical import mode

You can use the following configuration file to execute data import using the physical import mode:

```
[lightning]
log
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14

Checks the cluster minimum requirements before start.
check-requirements = true

[mydumper]
The local data source directory or the URI of the external storage. For
 ↳ more information about the URI of the external storage, see https://docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
data-source-dir = "/data/my_database"

[tikv-importer]
Import mode. "local" means using the physical import mode.
backend = "local"

The method to resolve the conflicting data.
duplicate-resolution = 'remove'

The directory of local KV sorting.
sorted-kv-dir = "./some-dir"

Limits the bandwidth in which TiDB Lightning writes data into each TiKV
node in the physical import mode. 0 by default, which means no limit.
store-write-bwlimit = "128MiB"

[tidb]
The information of the target cluster. The address of any tidb-server
 ↳ from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
Configure the password to connect to TiDB. Either plaintext or Base64
 ↳ encoded.
password = ""
Required. Table schema information is fetched from TiDB via this status
 ↳ -port.
status-port = 10080
Required. The address of any pd-server from the cluster.
```

```
pd-addr = "172.16.31.4:2379"
tidb-lightning imports the TiDB library, and generates some logs.
Set the log level of the TiDB library.
log-level = "error"

[post-restore]
Specifies whether to perform `ADMIN CHECKSUM TABLE <table>` for each
 ↪ table to verify data integrity after importing.
The following options are available:
- "required" (default): Perform admin checksum after importing. If
 ↪ checksum fails, TiDB Lightning will exit with failure.
- "optional": Perform admin checksum. If checksum fails, TiDB Lightning
 ↪ will report a WARN log but ignore any error.
- "off": Do not perform checksum after importing.
Note that since v4.0.8, the default value has changed from "true" to "
 ↪ required".
Note:
1. Checksum failure usually means import exception (data loss or data
 ↪ inconsistency), so it is recommended to always enable Checksum.
2. For backward compatibility, bool values "true" and "false" are also
 ↪ allowed for this field.
"true" is equivalent to "required" and "false" is equivalent to "off".
checksum = "required"

Specifies whether to perform `ANALYZE TABLE <table>` for each table
 ↪ after checksum is done.
Options available for this field are the same as `checksum`. However,
 ↪ the default value for this field is "optional".
analyze = "optional"
```

For the complete configuration file, refer to [the configuration file and command line parameters](#).

### 13.7.6.2.2 Conflict detection

Conflicting data refers to two or more records with the same PK/UK column data. When the data source contains conflicting data, the actual number of rows in the table is different from the total number of rows returned by the query using unique index.

TiDB Lightning offers three strategies for detecting conflicting data:

- **record**: only records conflicting records to the `lightning_task_info.conflict_error_v1` ↪ table on the target TiDB. Note that the required version of the target TiKV is v5.2.0 or later versions; otherwise, it falls back to 'none'.

- **remove** (recommended): records all conflicting records, like the **record** strategy. But it removes all conflicting records from the target table to ensure a consistent state in the target TiDB.
- **none**: does not detect duplicate records. **none** has the best performance in the three strategies, but might lead to inconsistent data in the target TiDB.

Before v5.3, Lightning does not support conflict detection. If there is conflicting data, the import process fails at the checksum step. When conflict detection is enabled, regardless of the **record** or **remove** strategy, if there is conflicting data, Lightning skips the checksum step (because it always fails).

Suppose an `order_line` table has the following schema:

```
CREATE TABLE IF NOT EXISTS `order_line` (
 `ol_o_id` int(11) NOT NULL,
 `ol_d_id` int(11) NOT NULL,
 `ol_w_id` int(11) NOT NULL,
 `ol_number` int(11) NOT NULL,
 `ol_i_id` int(11) NOT NULL,
 `ol_supply_w_id` int(11) DEFAULT NULL,
 `ol_delivery_d` datetime DEFAULT NULL,
 `ol_quantity` int(11) DEFAULT NULL,
 `ol_amount` decimal(6,2) DEFAULT NULL,
 `ol_dist_info` char(24) DEFAULT NULL,
 PRIMARY KEY (`ol_w_id`,`ol_d_id`,`ol_o_id`,`ol_number`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

If Lightning detects conflicting data during the import, you can query the `lightning_task_info` → `.conflict_error_v1` table as follows:

```
mysql> select table_name,index_name,key_data,row_data from
 ↪ conflict_error_v1 limit 10;
+--
 ↪ -----+-----+-----+-----
 ↪
 | table_name | index_name | key_data | row_data
 ↪
+--
 ↪ -----+-----+-----+-----
 ↪
 | `tpcc`.`order_line` | PRIMARY | 21829216 | (2677, 10, 10, 11, 75656, 10,
 ↪ NULL, 5, 5831.97, "HT5DN3EVb6kWTd4L37bsbogj") |
 | `tpcc`.`order_line` | PRIMARY | 49931672 | (2677, 10, 10, 11, 75656, 10,
 ↪ NULL, 5, 5831.97, "HT5DN3EVb6kWTd4L37bsbogj") |
 | `tpcc`.`order_line` | PRIMARY | 21829217 | (2677, 10, 10, 12, 76007, 10,
 ↪ NULL, 5, 9644.36, "bHuVoRfidQ0q2rJ6ZC9Hd12E") |
```

```

| `tpcc`.`order_line` | PRIMARY | 49931673 | (2677, 10, 10, 12, 76007, 10,
 ↳ NULL, 5, 9644.36, "bHuVoRfidQ0q2rJ6ZC9Hd12E") |
| `tpcc`.`order_line` | PRIMARY | 21829218 | (2677, 10, 10, 13, 85618, 10,
 ↳ NULL, 5, 7427.98, "t3rsesgi9rVAKi9tf6an5Rpv") |
| `tpcc`.`order_line` | PRIMARY | 49931674 | (2677, 10, 10, 13, 85618, 10,
 ↳ NULL, 5, 7427.98, "t3rsesgi9rVAKi9tf6an5Rpv") |
| `tpcc`.`order_line` | PRIMARY | 21829219 | (2677, 10, 10, 14, 15873, 10,
 ↳ NULL, 5, 133.21, "z1vH0e31tQydJGhfNYNa4ScD") |
| `tpcc`.`order_line` | PRIMARY | 49931675 | (2677, 10, 10, 14, 15873, 10,
 ↳ NULL, 5, 133.21, "z1vH0e31tQydJGhfNYNa4ScD") |
| `tpcc`.`order_line` | PRIMARY | 21829220 | (2678, 10, 10, 1, 44644, 10,
 ↳ NULL, 5, 8463.76, "TWKJBt5iJA4eF7FIVxnugNmz") |
| `tpcc`.`order_line` | PRIMARY | 49931676 | (2678, 10, 10, 1, 44644, 10,
 ↳ NULL, 5, 8463.76, "TWKJBt5iJA4eF7FIVxnugNmz") |
+--
 ↳ -----+-----+-----
 ↳
10 rows in set (0.14 sec)

```

You can manually identify the records that need to be retained and insert these records into the table.

### 13.7.6.2.3 Pause scheduling on the table level

Starting from v6.2.0, TiDB Lightning implements a mechanism to limit the impact of data import on online applications. With the new mechanism, TiDB Lightning does not pause the global scheduling, but only pauses scheduling for the region that stores the target table data. This significantly reduces the impact of the import on online applications.

TiDB Lightning does not support importing data into a table that already contains data.

The TiDB cluster must be v6.1.0 or later versions. For earlier versions, TiDB Lightning keeps the old behavior, which pauses scheduling globally and severely impacts the online application during the import.

By default, TiDB Lightning pauses the cluster scheduling for the minimum range possible. However, under the default configuration, the cluster performance still might be affected by fast import. To avoid this, you can configure the following options to control the import speed and other factors that might impact the cluster performance:

```

[tikv-importer]
Limits the bandwidth in which TiDB Lightning writes data into each TiKV
 ↳ node in the physical import mode.
store-write-bwlimit = "128MiB"

[tidb]
Use smaller concurrency to reduce the impact of Checksum and Analyze on
 ↳ the transaction latency.

```

```
distsql-scan-concurrency = 3
```

```
[cron]
```

```
Prevent TiKV from switching to import mode.
switch-mode = '0'
```

You can measure the impact of data import on TPCC results by simulating the online application using TPCC and importing data into a TiDB cluster using TiDB Lightning. The test result is as follows:

Concurrency	TPM	P99	P90	AVG
1	20%~30%	60%~80%	30%~50%	30%~40%
8	15%~25%	70%~80%	35%~45%	20%~35%
16	20%~25%	55%~85%	35%~40%	20%~30%
64	No significant impact			
256	No significant impact			

The percentage in the preceding table indicates the impact of data import on TPCC results.

- For the TPM column, the number indicates the percentage of TPM decrease.
- For the P99, P90, and AVG columns, the number indicates the percentage of latency increase.

The test results show that the smaller the concurrency, the larger the impact of data import on TPCC results. When the concurrency is 64 or more, the impact of data import on TPCC results is negligible.

Therefore, if your TiDB cluster has a latency-sensitive application and a low concurrency, it is strongly recommended **not** to use TiDB Lightning to import data into the cluster. This will cause a significant impact on the online application.

#### 13.7.6.2.4 Performance tuning

The most direct and effective ways to improve import performance of the physical import mode are as follows:

- Upgrade the hardware of the node where Lightning is deployed, especially the CPU and the storage device of `sorted-key-dir`.
- Use the **parallel import** feature to achieve horizontal scaling.

TiDB Lightning provides some concurrency-related configurations to affect import performance in the physical import mode. However, from long-term experience, it is recommended to keep the following four configuration items in the default value. Adjusting the four configuration items does not bring significant performance boost.

```
[lightning]
The maximum concurrency of engine files.
Each table is split into one "index engine" to store indices, and
 ↪ multiple
"data engines" to store row data. These settings control the maximum
concurrent number for each type of engines.
The two settings controls the maximum concurrency of the two engine
 ↪ files.
index-concurrency = 2
table-concurrency = 6

The concurrency of data. The default value is the number of logical
 ↪ CPUs.
region-concurrency =

The maximum concurrency of I/O. When the concurrency is too high, the
 ↪ disk
cache may be frequently refreshed, causing the cache miss and read
 ↪ speed
to slow down. For different storage mediums, this parameter may need to
 ↪ be
adjusted to achieve the best performance.
io-concurrency = 5
```

During the import, each table is split into one “index engine” to store indices, and multiple “data engines” to store row data.

`index-concurrency` controls the maximum concurrency of the index engine. When you adjust `index-concurrency`, make sure that `index-concurrency * the number of ↪ source files of each table > region-concurrency` to ensure that the CPU is fully utilized. The ratio is usually between 1.5 ~ 2. Do not set `index-concurrency` too high and not lower than 2 (default). Too high `index-concurrency` causes too many pipelines to be built, which causes the index-engine import stage to pile up.

The same goes for `table-concurrency`. Make sure that `table-concurrency * the ↪ number of source files of each table > region-concurrency` to ensure that the CPU is fully utilized. A recommended value is around `region-concurrency * 4 / the ↪ number of source files of each table` and not lower than 4.

If the table is large, Lightning will split the table into multiple batches of 100 GiB. The concurrency is controlled by `table-concurrency`.

`index-concurrency` and `table-concurrency` has little effect on the import speed. You can leave them in the default value.

`io-concurrency` controls the concurrency of file read. The default value is 5. At any given time, only 5 handles are performing read operations. Because the file read speed is

usually not a bottleneck, you can leave this configuration in the default value.

After the file data is read, Lightning needs to do some post-processing, such as encoding and sorting the data locally. The concurrency of these operations is controlled by `region`  $\leftrightarrow$  `-concurrency`. The default value is the number of CPU cores. You can leave this configuration in the default value. It is recommended to deploy Lightning on a separate server from other components. If you must deploy Lightning together with other components, you need to lower the value of `region-concurrency` according to the load.

The `num-threads` configuration of TiKV can also affect the performance. For new clusters, it is recommended to set `num-threads` to the number of CPU cores.

### 13.7.6.2.5 Configure disk quota New in v6.2.0

When you import data in the physical import mode, TiDB Lightning creates a large number of temporary files on the local disk to encode, sort, and split the original data. When the local disk space is insufficient, TiDB Lightning reports an error and exits because of write failure.

To avoid this situation, you can configure disk quota for TiDB Lightning. When the size of the temporary files exceeds the disk quota, TiDB Lightning pauses the process of reading the source data and writing temporary files. TiDB Lightning prioritizes writing the sorted key-value pairs to TiKV. After deleting the local temporary files, TiDB Lightning continues the import process.

To enable disk quota, add the following configuration to your configuration file:

```
[tikv-importer]
MaxInt64 by default, which is 9223372036854775807 bytes.
disk-quota = "10GB"
backend = "local"

[cron]
The interval of checking disk quota. 60 seconds by default.
check-disk-quota = "30s"
```

`disk-quota` limits the storage space used by TiDB Lightning. The default value is `MaxInt64`, which is 9223372036854775807 bytes. This value is much larger than the disk space you might need for the import, so leaving it as the default value is equivalent to not setting the disk quota.

`check-disk-quota` is the interval of checking disk quota. The default value is 60 seconds. When TiDB Lightning checks the disk quota, it acquires an exclusive lock for the relevant data, which blocks all the import threads. Therefore, if TiDB Lightning checks the disk quota before every write, it significantly slows down the write efficiency (as slow as a single-thread write). To achieve efficient write, disk quota is not checked before every write; instead, TiDB Lightning pauses all the import threads and checks the disk quota every `check-disk-quota` interval. That is, if the value of `check-disk-quota` is set to a large value, the disk space

used by TiDB Lightning might exceed the disk quota you set, which leaves the disk quota ineffective. Therefore, it is recommended to set the value of `check-disk-quota` to a small value. The specific value of this item is determined by the environment in which TiDB Lightning is running. In different environments, TiDB Lightning writes temporary files at different speeds. Theoretically, the faster the speed, the smaller the value of `check-disk-quota` should be.

## 13.7.7 Logical Import Mode

### 13.7.7.1 Logical Import Mode Introduction

The logical import mode is one of the two import modes supported by TiDB Lightning. In the logical import mode, TiDB Lightning first encodes data into SQL statements and then runs the SQL statements to import data.

If your TiDB cluster already contains data and provides service for external applications, it is recommended to import data in the logical import mode. The behavior of the logical import mode is the same as executing normal SQL statements, and thus it guarantees ACID compliance.

The backend for the logical import mode is `tidb`.

#### 13.7.7.1.1 Environment requirements

##### Operating system:

It is recommended to use fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, `tikv-server`) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

##### Memory and CPU:

It is recommended that you allocate CPU more than 4 cores and memory greater than 8 GiB to get better performance. It is verified that TiDB Lightning does not have significant memory usage (no more than 5 GiB) in the logical import mode. However, if you increase the value of `region-concurrency`, TiDB Lightning might consume more memory.

**Network:** A 1 Gbps or 10 Gbps Ethernet card is recommended.

#### 13.7.7.1.2 Limitations

When you use multiple TiDB Lightning to import data to the same target, do not mix the backends. That is, do not use the physical import mode and the logical import mode to import data to a single TiDB cluster at the same time.

### 13.7.7.2 Use Logical Import Mode

This document introduces how to use the **logical import mode** in TiDB Lightning, including writing the configuration file and tuning performance.

#### 13.7.7.2.1 Configure and use the logical import mode

You can use the logical import mode via the following configuration file to import data:

```
[lightning]
log
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14

Checks the cluster minimum requirements before start.
check-requirements = true

[mydumper]
The local data source directory or the URI of the external storage. For
 ↳ more information about the URI of the external storage, see https://docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
 ↳ docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
data-source-dir = "/data/my_database"

[tikv-importer]
Import mode. "tidb" means using the logical import mode.
backend = "tidb"

The operation of inserting duplicate data in the logical import mode.
- replace: replace existing data with new data
- ignore: keep existing data and ignore new data
- error: pause the import and report an error
on-duplicate = "replace"

[tidb]
The information of the target cluster. The address of any tidb-server
 ↳ from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
Configure the password to connect to TiDB. Either plaintext or Base64
 ↳ encoded.
password = ""
tidb-lightning imports the TiDB library, and generates some logs.
```

```
Set the log level of the TiDB library.
log-level = "error"
```

For the complete configuration file, refer to [TiDB Lightning Configuration](#).

### 13.7.7.2.2 Conflict detection

Conflicting data refers to two or more records with the same data in the PK or UK column. When the data source contains conflicting data, the actual number of rows in the table is different from the total number of rows returned by the query using the unique index.

In the logical import mode, you can configure the strategy for resolving conflicting data by setting the `on-duplicate` configuration item. Based on the strategy, TiDB Lightning imports data with different SQL statements.

Strategy	Default behavior of conflicting data	The corresponding SQL statement
<code>replace</code>	Replacing existing data with new data.	<code>REPLACE INTO ...</code>
<code>ignore</code>	Keeping existing data and ignoring new data.	<code>INSERT IGNORE INTO ...</code>
<code>error</code>	Pausing the import and reporting an error.	<code>INSERT INTO ...</code>

### 13.7.7.2.3 Performance tuning

- In the logical import mode, the performance of TiDB Lightning largely depends on the write performance of the target TiDB cluster. If the cluster hits a performance bottleneck, refer to [Highly Concurrent Write Best Practices](#).
- If the target TiDB cluster does not hit a write bottleneck, consider increasing the value of `region-concurrency` in TiDB Lightning configuration. The default value of `region-concurrency` is the number of CPU cores. The meaning of `region-concurrency` is different between the physical import mode and the logical import mode. In the logical import mode, `region-concurrency` is the write concurrency.

Example configuration:

```
[lightning]
region-concurrency = 32
```

- Adjusting the `raftstore.apply-pool-size` and `raftstore.store-pool-size` configuration items in the target TiDB cluster might improve the import speed.

## 13.7.8 TiDB Lightning Prechecks

Starting from TiDB 5.3.0, TiDB Lightning provides the ability to check the configuration before running a migration task. It is enabled by default. This feature automatically

performs some routine checks for disk space and execution configuration. The main purpose is to ensure that the whole subsequent import process goes smoothly.

The following table describes each check item and detailed explanation.

Check Items	Supported Version	Description
Cluster version and status	$\geq 5.3.0$	Check whether the cluster can be connected in the configuration, and whether the TiKV/PD/TiFlash version supports the physical import mode.

Check Items	Supported Version	Description
Permissions	5.3.0	When the data source is cloud storage (Amazon S3), check whether TiDB Lightning has the necessary permissions and make sure that the import will not fail due to lack of permissions.

Check Items	Supported Ver- sion	Description
Disk space	$\geq$ 5.3.0	Check whether there is enough space on the local disk and on the TiKV cluster for importing data. TiDB Lightning samples the data sources and estimates the percentage of the index size from the sample result.

Check Items	Supported Version	Description
Region distribution status	>= 5.3.0	Check whether the Regions in the TiKV cluster are distributed evenly and whether there are too many empty Regions. If the number of empty Regions exceeds $\max(1000, \text{number of tables} * 3)$ , i.e. greater than the bigger one of "1000"

Check Items	Version	Description
Exceedingly Large CSV files in the data file	5.3.0	When there are CSV files larger than 10 GiB in the backup file and auto-slicing is not enabled (Strict-Format=false), it will impact the import performance. The purpose of this check is to remind you to ensure the

Check Items	Supported Version	Description
Recovery from break-points	≥ 5.3.0	This check ensures that no changes are made to the source file or schema in the database during the break-point recovery process that would result in importing the wrong data.

Check Items	Supported Ver- sion	Description
Import into an existing table	$\geq$ 5.3.0	When importing into an already created table, it checks, as much as possible, whether the source file matches the existing table. Check if the number of columns matches. If the source file has column names, check if the column

Check Items	Supported Version	Description
Whether the target table is empty	≥ 5.3.1	<p>TiDB Lightning automatically exits with an error if the target table is not empty. If parallel import mode is enabled (incremental ↪ - ↪ import ↪ ↪ = ↪ ↪ true ↪ ), this check item will be skipped.</p>

### 13.7.9 Table Filter

The TiDB migration tools operate on all the databases by default, but oftentimes only a subset is needed. For example, you only want to work with the schemas in the form of `foo*` and `bar*` and nothing else.

Since TiDB 4.0, all TiDB migration tools share a common filter syntax to define subsets. This document describes how to use the table filter feature.

#### 13.7.9.1 Usage

##### 13.7.9.1.1 CLI

Table filters can be applied to the tools using multiple `-f` or `--filter` command line parameters. Each filter is in the form of `db.table`, where each part can be a wildcard (further explained in the [next section](#)). The following lists the example usage.

- **BR:**

```
./br backup full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

```
./br restore full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

- **Dumpling:**

```
./dumpling -f 'foo*.*' -f 'bar*.*' -P 3306 -o /tmp/data/
```

- **TiDB Lightning:**

```
./tidb-lightning -f 'foo*.*' -f 'bar*.*' -d /tmp/data/ --backend tidb
```

##### 13.7.9.1.2 TOML configuration files

Table filters in TOML files are specified as [array of strings](#). The following lists the example usage.

- **TiDB Lightning:**

```
[mydumper]
filter = ['foo*.*', 'bar*.*']
```

- **TiCDC:**

```
[filter]
rules = ['foo*.*', 'bar*.*']

[[sink.dispatchers]]
matcher = ['db1.*', 'db2.*', 'db3.*']
dispatcher = 'ts'
```

## 13.7.9.2 Syntax

### 13.7.9.2.1 Plain table names

Each table filter rule consists of a “schema pattern” and a “table pattern”, separated by a dot (.). Tables whose fully-qualified name matches the rules are accepted.

```
db1.tbl1
db2.tbl2
db3.tbl3
```

A plain name must only consist of valid [identifier characters](#), such as:

- digits (0 to 9)
- letters (a to z, A to Z)
- \$
- -
- non ASCII characters (U+0080 to U+10FFFF)

All other ASCII characters are reserved. Some punctuations have special meanings, as described in the next section.

### 13.7.9.2.2 Wildcards

Each part of the name can be a wildcard symbol described in [fnmatch\(3\)](#):

- \* — matches zero or more characters
- ? — matches one character
- [a-z] — matches one character between “a” and “z” inclusively
- [!a-z] — matches one character except “a” to “z”.

```
db[0-9].tbl[0-9a-f][0-9a-f]
data.*
.backup_
```

“Character” here means a Unicode code point, such as:

- U+00E9 (é) is 1 character.
- U+0065 U+0301 (é) are 2 characters.
- U+1F926 U+1F3FF U+200D U+2640 U+FE0F ( ) are 5 characters.

### 13.7.9.2.3 File import

To import a file as the filter rule, include an @ at the beginning of the rule to specify the file name. The table filter parser treats each line of the imported file as additional filter rules.

For example, if a file `config/filter.txt` has the following content:

```
employees.*
*.WorkOrder
```

the following two invocations are equivalent:

```
./dumpling -f '@config/filter.txt'
./dumpling -f 'employees.*' -f '*.WorkOrder'
```

A filter file cannot further import another file.

### 13.7.9.2.4 Comments and blank lines

Inside a filter file, leading and trailing white-spaces of every line are trimmed. Furthermore, blank lines (empty strings) are ignored.

A leading # marks a comment and is ignored. # not at start of line is considered syntax error.

```
this line is a comment
db.table # but this part is not comment and may cause error
```

### 13.7.9.2.5 Exclusion

An ! at the beginning of the rule means the pattern after it is used to exclude tables from being processed. This effectively turns the filter into a block list.

```
.
#^ note: must add the *.* to include all tables first
!*.Password
!employees.salaries
```

### 13.7.9.2.6 Escape character

To turn a special character into an identifier character, precede it with a backslash \.

```
db\.with\.dots.*
```

For simplicity and future compatibility, the following sequences are prohibited:

- `\` at the end of the line after trimming whitespaces (use `[ ]` to match a literal whitespace at the end).
- `\` followed by any ASCII alphanumeric character (`[0-9a-zA-Z]`). In particular, C-like escape sequences like `\0`, `\r`, `\n` and `\t` currently are meaningless.

### 13.7.9.2.7 Quoted identifier

Besides `\`, special characters can also be suppressed by quoting using `"` or ```.

```
"db.with.dots"."tbl\1"
`db.with.dots`.`tbl\2`
```

The quotation mark can be included within an identifier by doubling itself.

```
"foo""bar"`.`foo``bar`
equivalent to:
foo\"bar.foo\"bar
```

Quoted identifiers cannot span multiple lines.

It is invalid to partially quote an identifier:

```
"this is "invalid*.*
```

### 13.7.9.2.8 Regular expression

In case very complex rules are needed, each pattern can be written as a regular expression delimited with `/`:

```
/^db\d{2,}$/.|^tbl\d{2,}$/
```

These regular expressions use the [Go dialect](#). The pattern is matched if the identifier contains a substring matching the regular expression. For instance, `/b/` matches `db01`.

#### Note:

Every `/` in the regular expression must be escaped as `\/`, including inside `[...]`. You cannot place an unescaped `/` between `\Q...E`.

### 13.7.9.3 Multiple rules

When a table name matches none of the rules in the filter list, the default behavior is to ignore such unmatched tables.

To build a block list, an explicit `*.*` must be used as the first rule, otherwise all tables will be excluded.

```
every table will be filtered out
./dumping -f '!*.Password'

only the "Password" table is filtered out, the rest are included.
./dumping -f '*.*' -f '!*.Password'
```

In a filter list, if a table name matches multiple patterns, the last match decides the outcome. For instance:

```
rule 1
employees.*
rule 2
!*.dep*
rule 3
*.departments
```

The filtered outcome is as follows:

Table name	Rule 1	Rule 2	Rule 3	Outcome
irrelevant.table				Default (reject)
employees.employees				Rule 1 (accept)
employees.dept_emp				Rule 2 (reject)
employees.departments				Rule 3 (accept)
else.departments				Rule 3 (accept)

#### Note:

In TiDB tools, the system schemas are always excluded in the default configuration. The system schemas are:

- INFORMATION\_SCHEMA
- PERFORMANCE\_SCHEMA
- METRICS\_SCHEMA
- INSPECTION\_SCHEMA
- mysql
- sys

### 13.7.10 TiDB Lightning Checkpoints

Importing a large database usually takes hours or days, and if such long running processes spuriously crashes, it can be very time-wasting to redo the previously completed tasks. To solve this, TiDB Lightning uses *checkpoints* to store the import progress, so that `tidb-lightning` continues importing from where it left off after restarting.

This document describes how to enable, configure, store, and control *checkpoints*.

#### 13.7.10.1 Enable and configure checkpoints

```
[checkpoint]
Whether to enable checkpoints.
While importing data, TiDB Lightning records which tables have been
↳ imported, so
even if TiDB Lightning or some other component crashes, you can start
↳ from a known
good state instead of restarting from scratch.
enable = true

Where to store the checkpoints.
- file: store as a local file (requires v2.1.1 or later)
- mysql: store into a remote MySQL-compatible database
driver = "file"

The schema name (database name) to store the checkpoints
Enabled only when `driver = "mysql"`.
schema = "tidb_lightning_checkpoint"

The data source name (DSN) indicating the location of the checkpoint
↳ storage.
For the "file" driver, the DSN is a path. If the path is not specified
↳ , Lightning would
default to "/tmp/CHECKPOINT_SCHEMA.pb".
For the "mysql" driver, the DSN is a URL in the form of "USER:PASS@tcp
↳ (HOST:PORT)/".
If the URL is not specified, the TiDB server from the [tidb] section is
↳ used to
store the checkpoints. You should specify a different MySQL-compatible
database server to reduce the load of the target TiDB cluster.
#dsn = "/tmp/tidb_lightning_checkpoint.pb"

Whether to keep the checkpoints after all data are imported. If false,
↳ the
checkpoints are deleted. Keeping the checkpoints can aid debugging but
might leak metadata about the data source.
```

```
keep-after-success = false
```

### 13.7.10.2 Checkpoints storage

TiDB Lightning supports two kinds of checkpoint storage: a local file or a remote MySQL-compatible database.

- With `driver = "file"`, checkpoints are stored in a local file at the path given by the `dsn` setting. Checkpoints are updated rapidly, so we highly recommend placing the checkpoint file on a drive with very high write endurance, such as a RAM disk.
- With `driver = "mysql"`, checkpoints can be saved in any databases compatible with MySQL 5.7 or later, including MariaDB and TiDB. By default, the checkpoints are saved in the target database.

While using the target database as the checkpoints storage, Lightning is importing large amounts of data at the same time. This puts extra stress on the target database and sometimes leads to communication timeout. Therefore, **it is strongly recommended to install a temporary MySQL server to store these checkpoints**. This server can be installed on the same host as `tidb-lightning` and can be uninstalled after the importer progress is completed.

### 13.7.10.3 Checkpoints control

If `tidb-lightning` exits abnormally due to unrecoverable errors (for example, data corruption), it refuses to reuse the checkpoints until the errors are resolved. This is to prevent worsening the situation. The checkpoint errors can be resolved using the `tidb-lightning-ctl` program.

#### 13.7.10.3.1 `--checkpoint-error-destroy`

```
tidb-lightning-ctl --checkpoint-error-destroy='`schema`.`table`'
```

This option allows you to restart importing the table from scratch. The schema and table names must be quoted with backquotes and are case-sensitive.

- If importing the table ``schema`.`table`` failed previously, this option executes the following operations:
  1. DROPs the table ``schema`.`table`` from the target database, which means removing all imported data.
  2. Resets the checkpoints record of this table to be “not yet started”.
- If there is no errors involving the table ``schema`.`table``, this operation does nothing.

It is the same as applying the above on every table. This is the most convenient, safe and conservative solution to fix the checkpoint error problem:

```
tidb-lightning-ctl --checkpoint-error-destroy=all
```

### 13.7.10.3.2 --checkpoint-error-ignore

```
tidb-lightning-ctl --checkpoint-error-ignore='`schema`.`table`'
tidb-lightning-ctl --checkpoint-error-ignore=all
```

If importing the table ``schema`.`table`` failed previously, this clears the error status as if nothing ever happened. The `all` variant applies this operation to all tables.

#### Note:

Use this option only when you are sure that the error can indeed be ignored. If not, some imported data can be lost. The only safety net is the final “checksum” check, and thus you need to keep the “checksum” option always enabled when using `--checkpoint-error-ignore`.

### 13.7.10.3.3 --checkpoint-remove

```
tidb-lightning-ctl --checkpoint-remove='`schema`.`table`'
tidb-lightning-ctl --checkpoint-remove=all
```

This option simply removes all checkpoint information about one table or all tables, regardless of their status.

### 13.7.10.3.4 --checkpoint-dump

```
tidb-lightning-ctl --checkpoint-dump=output/directory
```

This option dumps the content of the checkpoint into the given directory, which is mainly used for debugging by the technical staff. This option is only enabled when `driver = "mysql"`  $\hookrightarrow$  `"`.

## 13.7.11 Use TiDB Lightning to Import Data in Parallel

Since v5.3.0, the **physical import mode** of TiDB Lightning supports the parallel import of a single table or multiple tables. By simultaneously running multiple TiDB Lightning instances, you can import data in parallel from different single tables or multiple tables. In

this way, TiDB Lightning provides the ability to scale horizontally, which greatly reduces the time required to import large amount of data.

In technical implementation, TiDB Lightning records the meta data of each instance and the data of each imported table in the target TiDB, and coordinates the Row ID allocation range of different instances, the record of global Checksum, and the configuration changes and recovery of TiKV and PD.

You can use TiDB Lightning to import data in parallel in the following scenarios:

- Import sharded schemas and sharded tables. In this scenario, multiple tables from multiple upstream database instances are imported into the downstream TiDB database by different TiDB Lightning instances in parallel.
- Import single tables in parallel. In this scenario, single tables stored in a certain directory or cloud storage (such as Amazon S3) are imported into the downstream TiDB cluster by different TiDB Lightning instances in parallel. This is a new feature introduced in TiDB 5.3.0.

#### Note:

- Parallel import only supports initialized empty tables in TiDB and does not support migrating data to tables with data written by existing services. Otherwise, data inconsistencies may occur.
- Parallel import is usually used in the physical import mode. You need to configure `incremental-import = true`.
- Apply only one backend at a time when using multiple TiDB Lightning instances to import data to the same target. For example, you cannot import data to the same TiDB cluster in both the physical and logical import modes at the same time.

#### 13.7.11.1 Considerations

To use parallel import, you need to configure `incremental-import = true`. When TiDB Lightning is started, it registers meta data in the downstream TiDB cluster and automatically detects whether there are other instances migrating data to the target cluster at the same time. If there is, it automatically enters the parallel import mode.

But when migrating data in parallel, you need to take the following into consideration:

- Handle conflicts between primary keys or unique indexes across multiple sharded tables
- Optimize import performance

#### 13.7.11.1.1 Handle conflicts between primary keys or unique indexes

When using **the physical import mode** to import data in parallel, ensure that there are no primary key or unique index conflicts between data sources, and between the tables in the target TiDB cluster, and there are no data writes in the target table during import. Otherwise, TiDB Lightning will fail to guarantee the correctness of the imported data, and the target table will contain inconsistent indexes after the import is completed.

#### 13.7.11.1.2 Optimize import performance

Because TiDB Lightning needs to upload the generated Key-Value data to the TiKV node where each copy of the corresponding Region is located, the import speed is limited by the size of the target cluster. It is recommended to ensure that the number of TiKV instances in the target TiDB cluster and the number of TiDB Lightning instances are greater than  $n:1$  ( $n$  is the number of copies of the Region). At the same time, the following requirements should be met to achieve optimal import performance:

- Deploy each TiDB Lightning instance on a dedicated machine. Since one TiDB Lightning instance consumes all CPU resources by default, deploying multiple instances on a single machine cannot improve performance.
- The total size of source files for each TiDB Lightning instance performing parallel import should be smaller than 5 TiB
- The total number of TiDB Lightning instances should be smaller than 10.

When using TiDB Lightning to import shared databases and tables in parallel, choose an appropriate number of TiDB Lightning instances according to the amount of data.

- If the MySQL data volume is less than 2 TiB, you can use one TiDB Lightning instance for parallel import.
- If the MySQL data volume exceeds 2 TiB and the total number of MySQL instances is smaller than 10, it is recommended that you use one TiDB Lightning instance for each MySQL instance, and the number of parallel TiDB Lightning instances should not exceed 10.
- If the MySQL data volume exceeds 2 TiB and the total number of MySQL instances exceeds 10, it is recommended that you allocate 5 to 10 TiDB Lightning instances for importing the data exported by these MySQL instances.

Next, this document uses two examples to detail the operation steps of parallel import in different scenarios:

- Example 1: Use Dumpling + TiDB Lightning to import sharded databases and tables into TiDB in parallel
- Example 2: Import single tables in parallel

### 13.7.11.1.3 Restrictions

TiDB Lightning exclusively uses some resources when it is running. If you need to deploy multiple TiDB Lightning instances on a single machine (which is not recommended for production environments), or on a disk shared by multiple machines, be aware of the following usage restrictions.

- Set `tikv-importer.sorted-kv-dir` to a unique path for each TiDB Lightning instance. Multiple instances sharing the same path can lead to unintended behavior and may result in import failures or data errors.
- Store each TiDB Lightning checkpoint separately. For more information about checkpoint configurations, see [TiDB Lightning Checkpoints](#).
  - If you set `checkpoint.driver = "file"` (default), make sure that the path to the checkpoint is unique for each instance.
  - If you set `checkpoint.driver = "mysql"`, you need to set a unique schema for each instance.
- The log file for each TiDB Lightning should be set to a unique path. Sharing the same log file will impact log querying and troubleshooting.
- If you use the [Web Interface](#) or Debug API, you need to set `lightning.status-addr` to a unique address for each instance; otherwise, the TiDB Lightning process fails to start due to port conflict.

### 13.7.11.2 Example 1: Use Dumpling + TiDB Lightning to Import Sharded Databases and Tables into TiDB in Parallel

In this example, assume that the upstream is a MySQL cluster with 10 sharded tables, with a total size of 10 TiB. You can Use 5 TiDB Lightning instances to perform parallel import, and each instance imports 2 TiB. It is estimated that the total import time (excluding the time required for Dumpling export) can be reduced from about 40 hours to about 10 hours.

Assume that the upstream library is named `my_db`, and the name of each sharded table is `my_table_01 ~ my_table_10`. You want to merge and import them into the downstream `my_db.my_table` table. The specific steps are described in the following sections.

#### 13.7.11.2.1 Step 1: Use Dumpling to export data

Export two sharded tables on the 5 nodes where TiDB Lightning is deployed:

- If the two sharded tables are in the same MySQL instance, you can use the `--filter ↪` parameter of Dumpling to directly export them. When using TiDB Lightning to import, you can specify `data-source-dir` as the directory where Dumpling exports data to;

- If the data of the two sharded tables are distributed on different MySQL nodes, you need to use Dumping to separately export them. The exported data needs to be placed in the same parent directory but in different sub-directories. When using TiDB Lightning to perform parallel import, you need to specify `data-source-dir` as the parent directory.

For more information on how to use Dumping to export data, see [Dumping](#).

### 13.7.11.2.2 Step 2: Configure TiDB Lightning data sources

Create a configuration file `tidb-lightning.toml`, and then add the following content:

```
[lightning]
status-addr = ":8289"

[mydumper]
Specify the path for Dumping to export data. If Dumping performs
 ↳ several times and the data belongs to different directories, you can
 ↳ place all the exported data in the same parent directory and specify
 ↳ this parent directory here.
data-source-dir = "/path/to/source-dir"

[tikv-importer]
Whether to allow importing data into tables that already have data. The
 ↳ default value is `false`.
When using parallel import, because multiple TiDB Lightning instances
 ↳ import a table at the same time, this configuration item must be set
 ↳ to `true`.
incremental-import = true
"local": The default mode. It applies to large dataset import, for
 ↳ example, greater than 1 TiB. However, during the import, downstream
 ↳ TiDB is not available to provide services.
"tidb": You can use this mode for small dataset import, for example,
 ↳ smaller than 1 TiB. During the import, downstream TiDB is available
 ↳ to provide services.
backend = "local"

Specify the path for local sorting data.
sorted-kv-dir = "/path/to/sorted-dir"
```

If the data source is stored in external storage such as Amazon S3 or GCS, you need to configure additional parameters for connection. You can specify parameters for such configuration. For example, the following example assumes that data is stored in Amazon S3:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=local
↪ --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/sql-backup'
```

For more parameter descriptions, see [external storage URI](#).

### 13.7.11.2.3 Step 3: Start TiDB Lightning to import data

During parallel import, the server configuration requirements for each TiDB Lightning node are the same as the non-parallel import mode. Each TiDB Lightning node needs to consume the same resources. It is recommended to deploy them on different servers. For detailed deployment steps, see [Deploy TiDB Lightning](#).

Start TiDB Lightning on each server in turn. If you use `nohup` to directly start it from the command line, it might exit due to the `SIGHUP` signal. So it is recommended to put `nohup` in the script, for example:

```
!/bin/bash
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out &
```

During parallel import, TiDB Lightning automatically performs the following checks after starting the task.

- Check whether there is enough space on the local disk (controlled by the `sort-kv-dir` configuration) and on the TiKV cluster for importing data. To learn the required disk space, see [Downstream storage space requirements](#) and [Resource requirements](#). TiDB Lightning samples the data sources and estimates the percentage of the index size from the sample result. Because indexes are included in the estimation, there might be cases where the size of the source data is less than the available space on the local disk, but still the check fails.
- Check whether the regions in the TiKV cluster are distributed evenly and whether there are too many empty regions. If the number of empty regions exceeds  $\max(1000, \text{number of tables} * 3)$ , i.e. greater than the bigger one of “1000” or “3 times the number of tables”, then the import cannot be executed.
- Check whether the data is imported in order from the data sources. The size of `mydumper.batch-size` is automatically adjusted based on the result of the check. Therefore, the `mydumper.batch-size` configuration is no longer available.

You can also turn off the check and perform a forced import with the `lightning.check` ↪ `-requirements` configuration. For more detailed checks, see [TiDB Lightning prechecks](#)

### 13.7.11.2.4 Step 4: Check the import progress

After starting the import, you can check the progress in either of the following ways:

- Check the progress through the `grep` log keyword `progress`. It is updated every 5 minutes by default.

- Check the progress through the monitoring console. For details, see [TiDB Lightning Monitoring](#).

Wait for all TiDB Lightning instances to finish, then the entire import is completed.

### 13.7.11.3 Example 2: Import single tables in parallel

TiDB Lightning also supports parallel import of single tables. For example, import multiple single tables stored in Amazon S3 by different TiDB Lightning instances into the downstream TiDB cluster in parallel. This method can speed up the overall import speed. When remote storages such as Amazon S3 is used, the configuration parameters of TiDB Lightning are the same as those of BR. For more details, see [external storage URI](#).

#### Note:

In the local environment, you can use the `--filesize` or `--where` parameter of Dumping to divide the data of a single table into different parts and export it to the local disks of multiple servers in advance. This way, you can still perform parallel import. The configuration is the same as Example 1.

Assuming that the source files are stored in Amazon S3, the table files are `my_db.my_table.00001.sql ~ my_db.my_table.10000.sql`, a total of 10,000 SQL files. If you want to use 2 TiDB Lightning instances to speed up the import, you need to add the following settings in the configuration file:

```
[[mydumper.files]]
the db schema file
pattern = '(?i)^(?:[~/]*)*my_db-schema-create\.sql'
schema = "my_db"
type = "schema-schema"

[[mydumper.files]]
the table schema file
pattern = '(?i)^(?:[~/]*)*my_db\.my_table-schema\.sql'
schema = "my_db"
table = "my_table"
type = "table-schema"

[[mydumper.files]]
Only import 00001-05000 and ignore other files
pattern = '(?i)^(?:[~/]*)*my_db\.my_table\.(0[0-4][0-9][0-9][0-9]|05000)\.
 ↪ sql'
schema = "my_db"
```

```
table = "my_table"
type = "sql"

[tikv-importer]
Whether to allow importing data into tables that already have data. The
 ↪ default value is `false`.
When using parallel import, because multiple TiDB Lightning instances
 ↪ import a table at the same time, this configuration item must be set
 ↪ to `true`.
incremental-import = true
```

You can modify the configuration of the other instance to only import the 05001 ~  
↪ 10000 data files.

For other steps, see the relevant steps in Example 1.

### 13.7.11.4 Handle errors

#### 13.7.11.4.1 Some TiDB Lightning nodes exit abnormally

If one or more TiDB Lightning nodes exit abnormally during a parallel import, identify the cause based on the logged error, and handle the error according to the error type:

- If the error shows normal exit (for example, exit in response to a kill command) or termination by the operating system due to OOM, adjust the configuration and then restart the TiDB Lightning nodes.
- If the error has no impact on data accuracy, for example, network timeout, perform the following steps:
  1. Run the `checkpoint-error-ignore` command with the setting `--checkpoint-error-ignore=all` on all failed nodes to clean errors in the checkpoint source data.
  2. Restart these nodes to continue importing data from checkpoints.
- If you see errors in the log that result in data inaccuracies, such as a checksum mismatch indicating invalid data in the source file, you can perform the following steps to resolve this issue:
  1. Run the `checkpoint-error-destroy` command on all Lightning nodes, including successful nodes. This command removes the imported data from failed tables and resets the checkpoint status of these tables to “not yet started”.
  2. Reconfigure and import the data of failed tables by using the `filter` parameter on all TiDB Lightning nodes, including normally exiting nodes.

When you reconfigure the Lightning parallel import task, do not include the `checkpoint-error-destroy` command in the startup script of each Lightning node. Otherwise, this command deletes shared metadata used by multiple parallel import tasks, which might cause issues during data import. For example, if a second Lightning import task is started, it will delete the metadata written by the first task, leading to abnormal data import.

#### 13.7.11.4.2 During an import, an error “Target table is calculating checksum. Please wait until the checksum is finished and try again” is reported

Some parallel imports involve a large number of tables or tables with a small volume of data. In this case, it is possible that before one or more tasks start processing a table, other tasks of this table have finished and data checksum is in progress. At this time, an error `Target table is calculating checksum. Please wait until the checksum is finished and try again` is reported. In this case, you can wait for the completion of checksum and then restart the failed tasks. The error disappears and data accuracy is not affected.

### 13.7.12 TiDB Lightning Error Resolution

Starting from v5.4.0, you can configure TiDB Lightning to skip errors like invalid type conversion and unique key conflicts, and to continue the data processing as if those wrong row data does not exist. A report will be generated for you to read and manually fix errors afterward. This is ideal for importing from a slightly dirty data source, where locating the errors manually is difficult and restarting TiDB Lightning on every encounter is costly.

This document introduces how to use the type error feature (`lightning.max-error`) and the duplicate resolution feature (`tikv-importer.duplicate-resolution`). It also introduces the database where these errors are stored (`lightning.task-info-schema-name`). At the end of this document, an example is provided.

#### 13.7.12.1 Type error

You can use the `lightning.max-error` configuration to increase the tolerance of errors related to data types. If this configuration is set to  $N$ , TiDB Lightning allows and skips up to  $N$  errors from the data source before it exists. The default value 0 means that no error is allowed.

These errors are recorded in a database. After the import is completed, you can view the errors in the database and process them manually. For more information, see [Error Report](#).

```
[lightning]
max-error = 0
```

The above configuration covers the following errors:

- Invalid values (example: set 'Text' to an INT column).

- Numeric overflow (example: set 500 to a TINYINT column)
- String overflow (example: set 'Very Long Text' to a VARCHAR(5) column).
- Zero date-time (namely '0000-00-00' and '2021-12-00').
- Set NULL to a NOT NULL column.
- Failed to evaluate a generated column expression.
- Column count mismatch. The number of values in the row does not match the number of columns of the table.
- Unique/Primary key conflict in TiDB-backend, when `on-duplicate = "error"`.
- Any other SQL errors.

The following errors are always fatal, and cannot be skipped by changing `max-error`:

- Syntax error (such as unclosed quotation marks) in the original CSV, SQL or Parquet file.
- I/O, network or system permission errors.

Unique/Primary key conflict in the physical import mode is handled separately and explained in the next section.

### 13.7.12.2 Error report

If TiDB Lightning encounters errors during the import, it outputs a statistics summary about these errors in both your terminal and the log file when it exits.

- The error report in the terminal is similar to the following table:

#	ERROR TYPE	ERROR COUNT	ERROR DATA TABLE
1	Data Type	1000	lightning_task_info.type_error_v1

- The error report in the TiDB Lightning log file is as follows:

```
[2022/03/13 05:33:57.736 +08:00] [WARN] [errormanager.go:459] ["Detect
↳ 1000 data type errors in total, please refer to table `
↳ lightning_task_info`.`type_error_v1` for more details"]
```

All errors are written to tables in the `lightning_task_info` database in the downstream TiDB cluster. After the import is completed, if the error data is collected, you can view the errors in the database and process them manually.

You can change the database name by configuring `lightning.task-info-schema-name`.

```
[lightning]
task-info-schema-name = 'lightning_task_info'
```

TiDB Lightning creates 3 tables in this database:

```
CREATE TABLE syntax_error_v1 (
 task_id bigint NOT NULL,
 create_time datetime(6) NOT NULL DEFAULT now(6),
 table_name varchar(261) NOT NULL,
 path varchar(2048) NOT NULL,
 offset bigint NOT NULL,
 error text NOT NULL,
 context text
);

CREATE TABLE type_error_v1 (
 task_id bigint NOT NULL,
 create_time datetime(6) NOT NULL DEFAULT now(6),
 table_name varchar(261) NOT NULL,
 path varchar(2048) NOT NULL,
 offset bigint NOT NULL,
 error text NOT NULL,
 row_data text NOT NULL
);

CREATE TABLE conflict_error_v1 (
 task_id bigint NOT NULL,
 create_time datetime(6) NOT NULL DEFAULT now(6),
 table_name varchar(261) NOT NULL,
 index_name varchar(128) NOT NULL,
 key_data text NOT NULL,
 row_data text NOT NULL,
 raw_key mediumblob NOT NULL,
 raw_value mediumblob NOT NULL,
 raw_handle mediumblob NOT NULL,
 raw_row mediumblob NOT NULL,
 KEY (task_id, table_name)
);
```

**type\_error\_v1** records all **type errors** managed by the **max-error** configuration. There is one row per error.

**conflict\_error\_v1** records all unique/primary key conflict in the Local-backend. There are 2 rows per pair of conflicts.

---

Column	Type	Conflict	Description
--------	------	----------	-------------

task_id	bigint		The TiDB Lightning task ID that generates this error
create_time	datetime(6)		The time at which the error is recorded

Column	Syntax	Type	Conflict	Description
table_name				The name of the table that contains the error, in the form of ``db`.`tbl``
path				The path of the file that contains the error
offset				The byte position in the file where the error is found
error				The error message
context				The text that surrounds the error
index_name				The name of the unique key in conflict. It is 'PRIMARY' for primary key conflicts.
key_data				The formatted key handle of the row that causes the error. The content is for human reference only, and not intended to be machine-readable.
row_data				The formatted row data that causes the error. The content is for human reference only, and not intended to be machine-readable
raw_key				The key of the conflicted KV pair
raw_value				The value of the conflicted KV pair
raw_handle				The row handle of the conflicted row
raw_row				The encoded value of the conflicted row

### Note:

The error report records the file offset, not line/column number which is inefficient to obtain. You can quickly jump near a byte position (using 183 as example) using the following commands:

- shell, printing the first several lines.

```
head -c 183 file.csv | tail
```

- shell, printing the next several lines:

```
tail -c +183 file.csv | head
```

- vim — :goto 183 or 183go

### 13.7.12.3 Example

In this example, a data source is prepared with some known errors.

1. Prepare the database and table schema.

```
mkdir example && cd example
```

```
echo 'CREATE SCHEMA example;' > example-schema-create.sql
echo 'CREATE TABLE t(a TINYINT PRIMARY KEY, b VARCHAR(12) NOT NULL
↳ UNIQUE);' > example.t-schema.sql
```

## 2. Prepare the data.

```
cat <<EOF > example.t.1.sql

INSERT INTO t (a, b) VALUES
(0, NULL), -- column is NOT NULL
(1, 'one'),
(2, 'two'),
(40, 'forty'), -- conflicts with the other 40 below
(54, 'fifty-four'), -- conflicts with the other 'fifty-four' below
(77, 'seventy-seven'), -- the string is longer than 12 characters
(600, 'six hundred'), -- the number overflows TINYINT
(40, 'forty'), -- conflicts with the other 40 above
(42, 'fifty-four'); -- conflicts with the other 'fifty-four' above

EOF
```

## 3. Configure TiDB Lightning to enable strict SQL mode, use the Local-backend to import data, delete duplicates, and skip up to 10 errors.

```
cat <<EOF > config.toml

[lightning]
max-error = 10

[tikv-importer]
backend = 'local'
sorted-kv-dir = '/tmp/lightning-tmp/'
duplicate-resolution = 'remove'

[mydumper]
data-source-dir = '.'

[tidb]
host = '127.0.0.1'
port = 4000
user = 'root'
password = ''
sql-mode = 'STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE'

EOF
```

4. Run TiDB Lightning. This command will exit successfully because all errors are skipped.

```
tiup tidb-lightning -c config.toml
```

5. Verify that the imported table only contains the two normal rows:

```
$ mysql -u root -h 127.0.0.1 -P 4000 -e 'select * from example.t'
+----+-----+
| a | b |
+----+-----+
| 1 | one |
| 2 | two |
+----+-----+
```

6. Check whether the `type_error_v1` table has caught the three rows involving type conversion:

```
$ mysql -u root -h 127.0.0.1 -P 4000 -e 'select * from
↳ lightning_task_info.type_error_v1;' -E

***** 1. row *****
 task_id: 1635888701843303564
 create_time: 2021-11-02 21:31:42.620090
 table_name: `example`.`t`
 path: example.t.1.sql
 offset: 46
 error: failed to cast value as varchar(12) CHARACTER SET utf8mb4
 ↳ COLLATE utf8mb4_bin for column `b` (#2): [table:1048]Column
 ↳ 'b' cannot be null
 row_data: (0,NULL)

***** 2. row *****
 task_id: 1635888701843303564
 create_time: 2021-11-02 21:31:42.627496
 table_name: `example`.`t`
 path: example.t.1.sql
 offset: 183
 error: failed to cast value as varchar(12) CHARACTER SET utf8mb4
 ↳ COLLATE utf8mb4_bin for column `b` (#2): [types:1406]Data
 ↳ Too Long, field len 12, data len 13
 row_data: (77, 'seventy-seven')

***** 3. row *****
 task_id: 1635888701843303564
 create_time: 2021-11-02 21:31:42.629929
```

```

table_name: `example`.`t`
 path: example.t.1.sql
 offset: 253
 error: failed to cast value as tinyint(4) for column `a` (#1): [
 ↪ types:1690]constant 600 overflows tinyint
 row_data: (600, 'six hundred')

```

7. Check whether the `conflict_error_v1` table has caught the four rows that have unique/primary key conflicts:

```

$ mysql -u root -h 127.0.0.1 -P 4000 -e 'select * from
 ↪ lightning_task_info.conflict_error_v1;' --binary-as-hex -E

***** 1. row *****
 task_id: 1635888701843303564
create_time: 2021-11-02 21:31:42.669601
 table_name: `example`.`t`
 index_name: PRIMARY

```

### 13.7.13 Troubleshoot TiDB Lightning

This document summarizes the common problems you might encounter when you use TiDB Lightning and their solutions.

#### 13.7.13.1 Import speed is too slow

Normally it takes 2 minutes per thread for TiDB Lightning to import a 256 MB data file. If the speed is much slower than this, there is an error. You can check the time taken for each data file from the log mentioning `restore chunk ... takes`. This can also be observed from metrics on Grafana.

There are several reasons why TiDB Lightning becomes slow:

**Cause 1:** `region-concurrency` is set too high, which causes thread contention and reduces performance.

1. The setting can be found from the start of the log by searching `region-concurrency`.
2. If TiDB Lightning shares the same machine with other services (for example, TiKV Importer), `region-concurrency` must be **manually** set to 75% of the total number of CPU cores.
3. If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning may not be able to read this out. In this case, `region-concurrency` must also be **manually** reduced.

**Cause 2:** The table schema is too complex.

Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Dumping output. If the indices are negligible, you may first remove them from the schema, and add them back using `CREATE INDEX` after the import is complete.

**Cause 3:** Each file is too large.

TiDB Lightning works the best when the data source is broken down into multiple files of size around 256 MB so that the data can be processed in parallel. If each file is too large, TiDB Lightning might not respond.

If the data source is CSV, and all CSV files have no fields containing newline control characters (U+000A and U+000D), you can turn on “strict format” to let TiDB Lightning automatically split the large files.

```
[mydumper]
strict-format = true
```

**Cause 4:** TiDB Lightning is too old.

Try the latest version. Maybe there is new speed improvement.

### 13.7.13.2 The `tidb-lightning` process suddenly quits while running in background

It is potentially caused by starting `tidb-lightning` incorrectly, which causes the system to send a `SIGHUP` signal to stop the `tidb-lightning` process. In this situation, `tidb-lightning.log` usually outputs the following log:

```
[2018/08/10 07:29:08.310 +08:00] [INFO] [main.go:41] ["got signal to exit"]
↳ [signal=hangup]
```

It is not recommended to directly use `nohup` in the command line to start `tidb-lightning`. You can [start `tidb-lightning`](#) by executing a script.

In addition, if the last log of TiDB Lightning shows that the error is “Context canceled”, you need to search for the first “ERROR” level log. This “ERROR” level log is usually followed by “got signal to exit”, which indicates that TiDB Lightning received an interrupt signal and then exited.

### 13.7.13.3 The TiDB cluster uses lots of CPU resources and runs very slowly after using TiDB Lightning

If `tidb-lightning` abnormally exited, the cluster might be stuck in the “import mode”, which is not suitable for production. The current mode can be retrieved using the following command:

```
tidb-lightning-ctl --config tidb-lightning.toml --fetch-mode
```

You can force the cluster back to “normal mode” using the following command:

```
tidb-lightning-ctl --config tidb-lightning.toml --fetch-mode
```

### 13.7.13.4 TiDB Lightning reports an error

#### 13.7.13.4.1 could not find first pair, this shouldn't happen

This error occurs possibly because the number of files opened by TiDB Lightning exceeds the system limit when TiDB Lightning reads the sorted local files. In the Linux system, you can use the `ulimit -n` command to confirm whether the value of this system limit is too small. It is recommended that you adjust this value to 1000000 (`ulimit -n 1000000`) during the import.

#### 13.7.13.4.2 checksum failed: checksum mismatched remote vs local

**Cause:** The checksum of a table in the local data source and the remote imported database differ. This error has several deeper reasons. You can further locate the reason by checking the log that contains `checksum mismatched`.

The lines that contain `checksum mismatched` provide the information `total_kvs: x ↔ vs y`, where `x` indicates the number of key-value pairs (KV pairs) calculated by the target cluster after the import is completed, and `y` indicates the number of key-value pairs generated by the local data source.

- If `x` is greater, it means that there are more KV pairs in the target cluster.
  - It is possible that this table is not empty before the import and therefore affects the data checksum. It is also possible that TiDB Lightning has previously failed and shut down, but did not restart correctly.
- If `y` is greater, it means that there are more KV pairs in the local data source.
  - If the checksum of the target database is all 0, it means that no import has occurred. It is possible that the cluster is too busy to receive any data.
  - It is possible that the exported data contains duplicate data, such as the UNIQUE and PRIMARY KEYs with duplicate values, or that the downstream table structure is case-insensitive while the data is case-sensitive.
- Other possible reasons
  - If the data source is machine-generated and not backed up by Dumping, make sure the data conforms to the table limits. For example, the AUTO\_INCREMENT column needs to be positive and not 0.

**Solutions:**

1. Delete the corrupted data using `tidb-lightning-ctl`, check the table structure and the data, and restart TiDB Lightning to import the affected tables again.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error
↪ -destroy=all
```

2. Consider using an external database to store the checkpoints (change `[checkpoint]` ↪ `dsn`) to reduce the target database's load.
3. If TiDB Lightning was improperly restarted, see also the “[How to properly restart TiDB Lightning](#)” section in the FAQ.

#### 13.7.13.4.3 Checkpoint for ... has invalid status: (error code)

**Cause:** `Checkpoint` is enabled, and TiDB Lightning or TiKV Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed.

The error code is an integer smaller than 25, with possible values of 0, 3, 6, 9, 12, 14, 15, 17, 18, 20, and 21. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later step the exit occurs at.

#### Solutions:

If the error was caused by invalid data source, delete the imported data using `tidb-lightning-ctl` and start Lightning again.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error-
↪ destroy=all
```

See the [Checkpoints control](#) section for other options.

#### 13.7.13.4.4 ResourceTemporarilyUnavailable("Too many open engines ...: ...")

**Cause:** The number of concurrent engine files exceeds the limit specified by `tikv-importer`. This could be caused by misconfiguration. Additionally, if `tidb-lightning` exited abnormally, an engine file might be left at a dangling open state, which could cause this error as well.

#### Solutions:

1. Increase the value of `max-open-engines` setting in `tikv-importer.toml`. This value is typically dictated by the available memory. This could be calculated by using:  
Max Memory Usage  $\text{max-open-engines} \times \text{write-buffer-size} \times \text{max-write-}$   
↪ `buffer-number`
2. Decrease the value of `table-concurrency + index-concurrency` so it is less than `max-open-engines`.

- Restart `tikv-importer` to forcefully remove all engine files (default to `./data.import`  $\leftrightarrow$  `/`). This also removes all partially imported tables, which requires TiDB Lightning to clear the outdated checkpoints.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error
 \leftrightarrow -destroy=all
```

#### 13.7.13.4.5 cannot guess encoding for input file, please convert to UTF-8 manually

**Cause:** TiDB Lightning only recognizes the UTF-8 and GB-18030 encodings for the table schemas. This error is emitted if the file isn't in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical `ALTER TABLE` executions.

##### Solutions:

- Fix the schema so that the file is entirely in either UTF-8 or GB-18030.
- Manually `CREATE` the affected tables in the target database.
- Set `[mydumper] character-set = "binary"` to skip the check. Note that this might introduce mojibake into the target database.

#### 13.7.13.4.6 [sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 ...}'

**Cause:** A table contains a column with the `timestamp` type, but the time value itself does not exist. This is either because of DST changes or the time value has exceeded the supported range (Jan 1, 1970 to Jan 19, 2038).

##### Solutions:

- Ensure TiDB Lightning and the source database are using the same time zone.  
When executing TiDB Lightning directly, the time zone can be forced using the `$TZ` environment variable.
- When exporting data using Mydumper, make sure to include the `--skip-tz-utc` flag.
- Ensure the entire cluster is using the same and latest version of `tzdata` (version 2018i or above).

```
Manual deployment, and force Asia/Shanghai.
TZ='Asia/Shanghai' bin/tidb-lightning -config tidb-lightning.toml
```

On CentOS, run `yum info tzdata` to check the installed version and whether there is an update. Run `yum upgrade tzdata` to upgrade the package.

#### 13.7.13.4.7 [Error 8025: entry too large, the max entry size is 6291456]

**Cause:** A single row of key-value pairs generated by TiDB Lightning exceeds the limit set by TiDB.

**Solution:**

Currently, the limitation of TiDB cannot be bypassed. You can only ignore this table to ensure the successful import of other tables.

#### 13.7.13.4.8 Encounter rpc error: code = Unimplemented ... when TiDB Lightning switches the mode

**Cause:** Some node(s) in the cluster does not support `switch-mode`. For example, if the TiFlash version is earlier than `v4.0.0-rc.2`, [switch-mode is not supported](#).

**Solutions:**

- If there are TiFlash nodes in the cluster, you can update the cluster to `v4.0.0-rc.2` or higher versions.
- Temporarily disable TiFlash if you do not want to upgrade the cluster.

#### 13.7.13.4.9 tidb lightning encountered error: TiDB version too old, expected '>=4.0.0', found '3.0.18'

TiDB Lightning Local-backend only supports importing data to TiDB clusters of `v4.0.0` and later versions. If you try to use Local-backend to import data to a `v2.x` or `v3.x` cluster, the above error is reported. At this time, you can modify the configuration to use Importer-backend or TiDB-backend for data import.

Some nightly versions might be similar to `v4.0.0-beta.2`. These nightly versions of TiDB Lightning actually support Local-backend. If you encounter this error when using a nightly version, you can skip the version check by setting the configuration `check-requirements = false`. Before setting this parameter, make sure that the configuration of TiDB Lightning supports the corresponding version; otherwise, the import might fail.

#### 13.7.13.4.10 restore table test.district failed: unknown columns in header [...]

This error occurs usually because the CSV data file does not contain a header (the first row is not column names but data). Therefore, you need to add the following configuration to the TiDB Lightning configuration file:

```
[mydumper.csv]
header = false
```

#### 13.7.13.4.11 Unknown character set

TiDB does not support all MySQL character sets. Therefore, TiDB Lightning reports this error if an unsupported character set is used when creating the table schema during an import. To bypass this error, you can create the table schema in the downstream in advance using the [character sets supported by TiDB](#) according to the specific data.

#### 13.7.13.4.12 invalid compression type ...

- TiDB Lightning v6.4.0 and later versions only support .bak files and the following compressed data files: `gzip`, `snappy`, and `zstd`. Other types of files cause errors. For those unsupported files, you need to modify the file names in advance, or move those files out of the import data directory to avoid such errors. For more details, see [Compressed files](#).

### 13.7.13.5 TiDB Lightning Configuration

This document provides samples for global configuration and task configuration, and describes the usage of command-line parameters.

#### 13.7.13.5.1 Configuration files

TiDB Lightning has two configuration classes: “global” and “task”, and they have compatible structures. Their distinction arises only when the [server mode](#) is enabled. When server mode is disabled (the default), TiDB Lightning will only execute one task, and the same configuration file is used for both global and task configurations.

TiDB Lightning (Global)

```
tidb-lightning global configuration

[lightning]
The HTTP port for displaying the web interface, pulling Prometheus
 ↪ metrics, exposing debug data, and submitting import tasks (in server
 ↪ mode). Setting it to 0 disables the port.
status-addr = ':8289'

Server mode. Defaults to false, which means an import task starts
 ↪ immediately after you execute the command.
If this value is set to true, after you execute the command, TiDB
 ↪ Lightning waits until you submit an import task in the web interface.
See the "TiDB Lightning Web Interface" section for details.
server-mode = false

Logging
level = "info"
```

```
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14
```

### TiDB Lightning (Task)

```
tidb-lightning task configuration

[lightning]
Checks whether the cluster satisfies the minimum requirement before
↳ starting.
#check-requirements = true

The maximum number of engines to be opened concurrently.
Each table is split into one "index engine" to store indices, and
↳ multiple
"data engines" to store row data. These settings control the maximum
concurrent number for each type of engines.
These values affect the memory and disk usage of tikv-importer.
The sum of these two values must not exceed the max-open-engines
↳ setting
for tikv-importer.
index-concurrency = 2
table-concurrency = 6

The concurrency number of data. It is set to the number of logical CPU
cores by default. When deploying together with other components, you
↳ can
set it to 75% of the size of logical CPU cores to limit the CPU usage.
region-concurrency =

The maximum I/O concurrency. Excessive I/O concurrency causes an
↳ increase in
I/O latency because the disk's internal buffer is frequently refreshed,
which causes the cache miss and slows down the read speed. Depending on
↳ the storage
medium, this value might need to be adjusted for optimal performance.
io-concurrency = 5

The maximum number of non-fatal errors to tolerate before stopping TiDB
↳ Lightning.
Non-fatal errors are localized to a few rows, and ignoring those rows
↳ allows the import process to continue.
Setting this to N means that TiDB Lightning will stop as soon as
```

```
 ↪ possible when the (N+1)-th error is encountered.
The skipped rows will be inserted into tables inside the "task info"
 ↪ schema on the target TiDB, which can be configured below.
The default value is `MaxInt64` bytes, that is, 9223372036854775807
 ↪ bytes.
max-error = 0
task-info-schema-name is the name of the schema or database that stores
 ↪ TiDB Lightning execution results.
To disable error recording, set this to an empty string.
task-info-schema-name = 'lightning_task_info'

In parallel import mode, the schema name that stores the meta
 ↪ information for each TiDB Lightning instance in the target cluster.
 ↪ By default, the value is "lightning_metadata".
Configure this parameter only if parallel import is enabled.
Note:
- The value set for this parameter must be the same for each TiDB
 ↪ Lightning instance that participates in the same parallel import;
 ↪ otherwise, the correctness of the imported data cannot be ensured.
- If parallel import mode is enabled, make sure that the user used for
 ↪ import (for the tidb.user configuration) has permissions to create
 ↪ and access the databases corresponding to this configuration.
- TiDB Lightning removes this schema after the import is completed. So
 ↪ do not use any existing schema name to configure this parameter.
meta-schema-name = "lightning_metadata"

[security]
Specifies certificates and keys for TLS connections within the cluster.
Public certificate of the CA. Leave empty to disable TLS.
ca-path = "/path/to/ca.pem"
Public certificate of this service.
cert-path = "/path/to/lightning.pem"
Private key of this service.
key-path = "/path/to/lightning.key"

[checkpoint]
Whether to enable checkpoints.
While importing data, TiDB Lightning records which tables have been
 ↪ imported, so
even if TiDB Lightning or another component crashes, you can start from
 ↪ a known
good state instead of restarting from scratch.
enable = true
The schema name (database name) to store the checkpoints.
schema = "tidb_lightning_checkpoint"
```

```
Where to store the checkpoints.
- file: store as a local file.
- mysql: store into a remote MySQL-compatible database
driver = "file"
The data source name (DSN) indicating the location of the checkpoint
 ↪ storage.
For the "file" driver, the DSN is a path. If the path is not specified,
 ↪ TiDB Lightning would
default to "/tmp/CHECKPOINT_SCHEMA.pb".
For the "mysql" driver, the DSN is a URL in the form of "USER:PASS@tcp(
 ↪ HOST:PORT)/".
If the URL is not specified, the TiDB server from the [tidb] section is
 ↪ used to
store the checkpoints. You should specify a different MySQL-compatible
database server to reduce the load of the target TiDB cluster.
dsn = "/tmp/tidb_lightning_checkpoint.pb"
Whether to keep the checkpoints after all data are imported. If false,
 ↪ the
checkpoints will be deleted. Keeping the checkpoints can aid debugging
 ↪ but
will leak metadata about the data source.
keep-after-success = false

[tikv-importer]
"local": Physical import mode, used by default. It applies to large
 ↪ dataset import, for example, greater than 1 TiB. However, during the
 ↪ import, downstream TiDB is not available to provide services.
"tidb": Logical import mode. You can use this mode for small dataset
 ↪ import, for example, smaller than 1 TiB. During the import,
 ↪ downstream TiDB is available to provide services.
backend = "local"
Whether to enable multiple TiDB Lightning instances (in physical import
 ↪ mode) to import data to one or more target tables in parallel. The
 ↪ default value is `false`.
When you use parallel import mode, you must set the parameter to `true
 ↪ `, but the premise is that no data exists in the target table, that
 ↪ is, all data can only be imported by TiDB Lightning. Note that this
 ↪ parameter **is not for incremental data import** and is only used in
 ↪ scenarios where the target table is empty.
incremental-import = false

The listening address of tikv-importer when backend is "importer".
 ↪ Change it to the actual address.
addr = "172.16.31.10:8287"
Action to do when trying to insert a conflicting record in the logical
```

```
↳ import mode. For more information on the conflict detection, see the
↳ document: https://docs.pingcap.com/tidb/dev/tidb-lightning-logical-
↳ import-mode-usage#conflict-detection
- replace: use new entry to replace the existing entry
- ignore: keep the existing entry, and ignore the new entry
- error: report error and quit the program
on-duplicate = "replace"

Whether to detect and resolve duplicate records (unique key conflict)
↳ in the physical import mode.
The following resolution algorithms are supported:
- record: After the data is written to the target table, add the
↳ duplicate records from the target table to the `lightning_task_info.
↳ conflict_error_v1` table in the target TiDB. Note that the required
↳ version of the target TiKV is no earlier than v5.2.0; otherwise it
↳ falls back to 'none'.
- none: does not detect duplicate records, which has the best
↳ performance of the three algorithms. But if there are duplicate
↳ records in the data source, it might lead to inconsistent data in the
↳ target TiDB.
- remove: records all duplicate records in the target table to the
↳ lightning_task_info database, like the 'record' algorithm. But it
↳ removes all duplicate records from the target table to ensure a
↳ consistent state in the target TiDB.
duplicate-resolution = 'none'
The number of KV pairs sent in one request in the physical import mode.
send-kv-pairs = 32768
Whether to enable compression when sending KV pairs to TiKV in the
↳ physical import mode. Currently, only the Gzip compression algorithm
↳ is supported. To use this algorithm, you can fill in either "gzip" or
↳ "gz" for this parameter. By default, the compression is not enabled.
↳ This configuration is an experimental feature. It is not recommended
↳ to use it in production environments.
compress-kv-pairs = ""
The directory of local KV sorting in the physical import mode. If the
↳ disk
performance is low (such as in HDD), it is recommended to set the
↳ directory
on a different disk from `data-source-dir` to improve import speed.
sorted-kv-dir = ""
The concurrency that TiKV writes KV data in the physical import mode.
When the network transmission speed between TiDB Lightning and TiKV
exceeds 10 Gigabit, you can increase this value accordingly.
range-concurrency = 16
Limits the bandwidth in which TiDB Lightning writes data into each TiKV
```

```
node in the physical import mode. 0 by default, which means no limit.
store-write-bwlimit = "128MiB"

Specifies the disk quota for local temporary files when physical import
 ↳ mode is used.
When the disk quota is insufficient, TiDB Lightning stops reading
 ↳ source data and writing temporary files,
but prioritizes writing the already sorted key-value pairs to TiKV.
After TiDB Lightning deletes the local temporary files, the import
 ↳ process continues.
This option takes effect only when you set the `backend` option to `
 ↳ local`.
The default value is `MaxInt64` bytes, that is, 9223372036854775807
 ↳ bytes.
disk-quota = "10GB"

[mydumper]
Block size for file reading. Keep it longer than the longest string of
 ↳ the data source.
read-block-size = "64KiB" # default value

The engine file needs to be imported sequentially. Due to parallel
 ↳ processing,
multiple data engines will be imported at nearly the same time, and
 ↳ this
creates a queue and wastes resources. Therefore, TiDB Lightning
 ↳ slightly
increases the size of the first few batches to properly distribute
resources. The scale up factor is controlled by this parameter, which
expresses the ratio of duration between the "import" and "write" steps
with full concurrency. This can be calculated by using the ratio
(import duration/write duration) of a single table of size around 1 GiB
 ↳ .
The exact timing can be found in the log. If "import" is faster, the
 ↳ batch
size variance is smaller, and a ratio of zero means a uniform batch
 ↳ size.
This value should be in the range (0 <= batch-import-ratio < 1).
batch-import-ratio = 0.75

Local source data directory or the URI of the external storage. For
 ↳ more information about the URI of the external storage, see https://docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
 ↳ docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
data-source-dir = "/data/my_database"
```

```
The character set of the schema files, containing CREATE TABLE
 ↪ statements;
only supports one of:
- utf8mb4: the schema files must be encoded as UTF-8; otherwise, an
 ↪ error is reported.
- gb18030: the schema files must be encoded as GB-18030; otherwise,
an error is reported
- auto: (default) automatically detects whether the schema is UTF-8
 ↪ or
GB-18030. An error is reported if the encoding is neither.
- binary: do not try to decode the schema files
character-set = "auto"

Specifies the character set of the source data file. Lightning converts
 ↪ the source file from the specified character set to UTF-8 encoding
 ↪ when importing.
Currently, this configuration only specifies the character set of the
 ↪ CSV files with the following options supported:
- utf8mb4: Indicates that the source data file uses UTF-8 encoding.
- GB18030: Indicates that the source data file uses the GB-18030
 ↪ encoding.
- GBK: The source data file uses GBK encoding (GBK encoding is an
 ↪ extension of the GB-2312 character set, also known as Code Page 936).
- binary: Indicates that Lightning does not convert the encoding (by
 ↪ default).
If left blank, the default value "binary" is used, that is to say,
 ↪ Lightning does not convert the encoding.
Note that Lightning does not predict about the character set of the
 ↪ source data file and only converts the source file and import the
 ↪ data based on this configuration.
If the value of this configuration is not the same as the actual
 ↪ encoding of the source data file, a failed import, data loss or data
 ↪ disorder might appear.
data-character-set = "binary"
Specifies the replacement character in case of incompatible characters
 ↪ during the character set conversion of the source data file.
This configuration must not be duplicated with field separators, quote
 ↪ definers, and line breaks.
The default value is "\uFFFD", which is the "error" Rune or Unicode
 ↪ replacement character in UTF-8 encoding.
Changing the default value might result in potential degradation of
 ↪ parsing performance for the source data file.
data-invalid-char-replace = "\uFFFD"

the input data in a "strict" format speeds up processing.
```

```
"strict-format = true" requires that:
in CSV, every value cannot contain literal new lines (U+000A and U+000D
 ↪ , or \r and \n) even
when quoted, which means new lines are strictly used to separate rows.
"Strict" format allows TiDB Lightning to quickly locate split positions
 ↪ of a large file for parallel processing.
However, if the input data is not "strict", it may split a valid data
 ↪ in half and
corrupt the result.
The default value is false for safety instead of speed.
strict-format = false

If strict-format is true, TiDB Lightning splits large CSV files into
 ↪ multiple chunks to process in
parallel. max-region-size is the maximum size of each chunk after
 ↪ splitting.
max-region-size = "256MiB" # default value

Only import tables if these wildcard rules are matched. See the
 ↪ corresponding section for details.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
 ↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA.*']

Configures how CSV files are parsed.
[mydumper.csv]
Separator between fields. Must not be empty.
separator = ','
Quoting delimiter. Empty value means no quoting.
delimiter = ''
Line terminator. Empty value means both "\n" (LF) and "\r\n" (CRLF) are
 ↪ line terminators.
terminator = ''
Whether the CSV files contain a header.
If `header` is true, TiDB Lightning treats the first row as a table
 ↪ header and does not import it as data. If `header` is false, the
 ↪ first row is also imported as CSV data.
header = true
Whether the column names in the CSV file header are matched to those
 ↪ defined in the target table.
The default value is `true`, which means that you have confirmed that
 ↪ the column names in the CSV header are consistent with those in the
 ↪ target table, so that even if the order of the columns is different
 ↪ between the two, TiDB Lightning can still import the data
 ↪ successfully by mapping the column names.
If the column names between the CSV table header and the target table
```

```
 ↪ do not match (for example, some column names in the CSV table header
 ↪ cannot be found in the target table) but the column order is the same
 ↪ , set this configuration to `false`.
In this scenario, TiDB Lightning will ignore the CSV header to avoid
 ↪ errors and import the data directly in the order of the columns in
 ↪ the target table.
Therefore, if the columns are not in the same order, you need to
 ↪ manually adjust the order of the columns in the CSV file to be
 ↪ consistent with that in the target table before importing; otherwise
 ↪ data discrepancies might occur.
It is important to note that this parameter only applies if the `header
 ↪ ` parameter is set to `true`. If `header` is set to `false`, it means
 ↪ that the CSV file does not contain a header, so this parameter is
 ↪ not relevant.
header-schema-match = true
Whether the CSV contains any NULL value.
If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
When `not-null` is false (that is, CSV can contain NULL),
fields equal to this value will be treated as NULL.
null = '\N'
Whether to interpret backslash escapes inside fields.
backslash-escape = true
If a line ends with a separator, remove it.
trim-last-separator = false

[[mydumper.files]]
Expression used for parsing AWS Aurora parquet files
pattern = '(?i)^(?:[~/]*/*)*([a-z0-9_]+\.[a-z0-9_]+)/(?:[~/]*/*)*(?:[a-
 ↪ z0-9_\.]+\. (parquet))$'
schema = '$1'
table = '$2'
type = '$3'

[tidb]
Configuration of any TiDB server from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
Configure the password to connect to TiDB. The password can either be
 ↪ plaintext or Base64 encoded.
password = ""
Table schema information is fetched from TiDB via this status-port.
status-port = 10080
Address of any PD server from the cluster.
```

```
pd-addr = "172.16.31.4:2379"
tidb-lightning imports TiDB as a library and generates some logs itself
↳ .
This setting controls the log level of the TiDB library.
log-level = "error"

Sets the TiDB session variable to speed up the Checksum and Analyze
↳ operations.
See https://pingcap.com/docs/dev/reference/performance/statistics/#
↳ control-analyze-concurrency
for the meaning of each setting
build-stats-concurrency = 20
distsql-scan-concurrency = 15
index-serial-scan-concurrency = 20
checksum-table-concurrency = 2

The default SQL mode used to parse and execute the SQL statements.
sql-mode = "ONLY_FULL_GROUP_BY,NO_ENGINE_SUBSTITUTION"
Sets maximum packet size allowed for SQL connections.
Set this to 0 to automatically fetch the `max_allowed_packet` variable
↳ from server on every connection.
max-allowed-packet = 67_108_864

Whether to use TLS for SQL connections. Valid values are:
* "" - force TLS (same as "cluster") if [tidb.security]
↳ section is populated, otherwise same as "false"
* "false" - disable TLS
* "cluster" - force TLS and verify the server's certificate with the
↳ CA specified in the [tidb.security] section
* "skip-verify" - force TLS but do not verify the server's certificate
↳ (insecure!)
* "preferred" - same as "skip-verify", but if the server does not
↳ support TLS, fallback to unencrypted connection
tls = ""

Specifies certificates and keys for TLS-enabled MySQL connections.
Defaults to a copy of the [security] section.
[tidb.security]
Public certificate of the CA. Set to empty string to disable TLS for
↳ SQL.
ca-path = "/path/to/ca.pem"
Public certificate of this service. Default to copy of `security.cert-
↳ path`
cert-path = "/path/to/lightning.pem"
Private key of this service. Default to copy of `security.key-path`
```

```
key-path = "/path/to/lightning.key"

In the physical import mode, when data importing is complete, tidb-
↳ lightning can
automatically perform the Checksum and Analyze operations. It is
↳ recommended
to leave these as true in the production environment.
The execution order: Checksum -> Analyze.
In the logical import mode, Checksum and Analyze is not needed, and
↳ they are always
skipped in the actual operation.
[post-restore]
Specifies whether to perform `ADMIN CHECKSUM TABLE <table>` for each
↳ table to verify data integrity after importing.
The following options are available:
- "required" (default value): Perform admin checksum. If checksum fails
↳ , TiDB Lightning will exit with failure.
- "optional": Perform admin checksum. If checksum fails, TiDB Lightning
↳ will report a WARN log but ignore any error.
- "off": Do not perform checksum.
Note that since v4.0.8, the default value has changed from "true" to "
↳ required".
For backward compatibility, bool values "true" and "false" are also
↳ allowed for this field.
"true" is equivalent to "required" and "false" is equivalent to "off".
checksum = "required"
Specifies whether to perform `ANALYZE TABLE <table>` for each table
↳ after checksum is done.
Options available for this field are the same as `checksum`. However,
↳ the default value for this field is "optional".
analyze = "optional"

If the value is set to `true`, a level-1 compaction is performed
every time a table is imported.
The default value is `false`.
level-1-compact = false

If the value is set to `true`, a full compaction on the whole
TiKV cluster is performed at the end of the import.
The default value is `false`.
compact = false

Configures the background periodic actions.
Supported units: h (hour), m (minute), s (second).
[cron]
```

```
Duration between which TiDB Lightning automatically refreshes the
↳ import mode
status. Should be shorter than the corresponding TiKV setting.
switch-mode = "5m"
Duration between which an import progress is printed to the log.
log-progress = "5m"
The time interval for checking the local disk quota when you use the
↳ physical import mode.
The default value is 60 seconds.
check-disk-quota = "60s"
```

### 13.7.13.5.2 Command line parameters

Usage of `tidb-lightning`

Parameter	Explanation	Corresponding set-
<code>-config file</code>	Reads global configuration from <i>file</i> . If not specified, the default configuration would be used.	ing
<code>-V</code>	Prints program version	

Parameter	Explanation	Corresponding set-
-d <i>directory</i>	Directory or <b>external storage</b> URI of the data dump to read from	mydumper ↔ . ↔ data ↔ - ↔ source ↔ - ↔ dir ↔
-L <i>level</i>	Log level: de- bug, info, warn, error, fatal (de- fault = info)	lightning ↔ . ↔ log ↔ - ↔ level ↔
-f <i>rule</i>	<b>Table</b> <b>filter</b> <b>rules</b> (can be speci- fied multi- ple times)	mydumper ↔ . ↔ filter ↔

Parameter	Explanation	Corresponding set-variable
– <i>backend</i>	Select an import port mode.	<code>local</code>
<i>back-end</i>	<code>local</code> refers to the physical import mode; <code>tidb</code> refers to the logical import mode.	

Parameter	Explanation	Corresponding set-
<code>-log-file</code>	Log file	<code>lightning</code>
<code>file</code>	file	<code>↔ .</code>
<code>file</code>	path.	<code>↔ log</code>
	By default,	<code>↔ -</code>
	it is	<code>↔ file</code>
	<code>/tmp/</code>	<code>↔</code>
	<code>↔ lightning</code>	
	<code>↔ .</code>	
	<code>↔ log</code>	
	<code>↔ .{</code>	
	<code>↔ timestamp</code>	
	<code>↔ }.</code>	
	If set to '-', it means that the log files will be output to stdout.	
<code>-</code>	Listening	<code>lightning</code>
<code>status-addr</code>	address	<code>↔ .</code>
<code>ip:port</code>	of the TiDB	<code>↔ status</code>
	Lightning server	<code>↔ -</code>
		<code>↔ port</code>
<code>-</code>	Address	<code>tikv-</code>
<code>importerof</code>	TiKV	<code>↔ importer</code>
<code>host:port</code>	Im-	<code>↔ .</code>
	porter	<code>↔ addr</code>
		<code>↔</code>

Parameter	Explanation	Corresponding set-
<code>-pd-urls</code>	PD endpoints <i>host:port</i>	<code>tidb.</code> ↔ <code>pd</code>
	address	↔ <code>addr</code>
<code>-tidb-host</code>	TiDB server <i>host</i>	<code>tidb.</code> ↔ <code>host</code>
<code>-tidb-port</code>	TiDB server port <i>port</i> (default = 4000)	<code>tidb.</code> ↔ <code>port</code>
<code>-tidb-status-port</code>	TiDB status port <i>port</i> (default = 10080)	<code>tidb.</code> ↔ <code>status</code>
<code>-tidb-user</code>	TiDB user name <i>user</i>	<code>tidb.</code> ↔ <code>user</code>
	to connect to TiDB	↔

Parameter	Explanation	Corresponding set-
<code>-tidb-</code>	Password	<code>tidb.</code>
<code>password</code>	to	$\leftrightarrow$ <code>password</code>
<i>password</i>	connect	$\leftrightarrow$
	to TiDB. The password can either be plain-text or Base64 encoded.	
<code>-</code>	Whether	<code>checkpoint</code>
<code>enable-</code>	to	$\leftrightarrow$ <code>.</code>
<code>checkpoint</code>	enable	$\leftrightarrow$ <code>enable</code>
<i>bool</i>	checkpoints (default = true)	$\leftrightarrow$

Parameter	Explanation	Corresponding set-
– <i>analyze level</i>	Analyze tables after im-port-ing. Available values are “re-quired”, “op-tional” (de-fault value), and “off”	post-restore . analyze .
– <i>checksum level</i>	Compare checksum after im-port-ing. Available values are “re-quired” (de-fault value), “op-tional”, and “off”	post-restore . checksum .

Parameter	Explanation	Corresponding set-

	tion	

Parameter	Explanation	Corresponding set-ting
-	Start	<code>lightning</code>
server-	TiDB	<code>↔ .</code>
mode	Light-	<code>↔ server</code>
	ning	<code>↔ -</code>
	in	<code>↔ mode</code>
	server	<code>↔</code>
	mode	

If a command line parameter and the corresponding setting in the configuration file are both provided, the command line parameter will be used. For example, running `./tidb ↔ -lightning -L debug --config cfg.toml` would always set the log level to “debug” regardless of the content of `cfg.toml`.

### 13.7.13.5.3 Usage of `tidb-lightning-ctl`

This tool can execute various actions given one of the following parameters:

Parameter	Explanation
-	Performs compact a full com-
	paction
-	Switches
switch-	every
mode	TiKV
<i>mode</i>	store
	to the
	given
	mode:
	nor-
	mal,
	im-
	port

Parameter	Explanation
<code>-fetch-mode</code>	Prints the current mode of every TiKV store
<code>-import-engine <i>uuid</i></code>	Imports the closed engine file from TiKV Importer into the TiKV cluster
<code>-cleanup-engine <i>uuid</i></code>	Deletes the engine file from TiKV Importer
<code>-checkpoint-dump <i>folder</i></code>	Dumps current checkpoint as CSVs into the folder

Parameter	Explanation
<code>checkpoint-error-destroy-table-name</code>	Removes the checkpoint and drops the table if it caused error
<code>checkpoint-error-ignore-table-name</code>	Ignores error recorded in the checkpoint involving the given table
<code>checkpoint-remove-table-name</code>	Unconditionally moves the checkpoint of the table

The *tablename* must either be a qualified table name in the form ``db`.`tbl`` (including the backquotes), or the keyword “all”.

Additionally, all parameters of `tidb-lightning` described in the section above are valid in `tidb-lightning-ctl`.

### 13.7.13.6 TiDB Lightning Command Line Flags

You can configure TiDB Lightning either using the configuration file or in command line. This document describes the command line flags of TiDB Lightning.

### 13.7.13.6.1 Command line flags

#### tidb-lightning

You can configure the following parameters using `tidb-lightning`:

Parameter	Description	Corresponding configuration
<code>--config &lt;file&gt;</code>	Read the configuration file. If this parameter is not specified, TiDB Lightning uses the default configuration.	
<code>-V</code>	Print the program version.	

Parameter	Description	Corresponding configuration item
-d < directory >	Local directory or external storage URI of data files.	mydumper ↔ . ↔ data ↔ - ↔ source ↔ - ↔ dir ↔
-L < level >	Log level: debug, info, warn, error, or fatal.	lightning ↔ . ↔ level ↔ , ↔ info, ↔ warn, ↔ error ↔ , ↔ or ↔ fatal ↔ . ↔ info ↔ by default.
-f < rule >	Table filter rules. Can be specified multiple times.	mydumper ↔ . ↔ filter ↔

Parameter	Description	Corresponding configuration
--	Select	tikv-
↔ backend	dimension	↔ importer
↔ <	port	↔ .
↔ backend	mode.	↔ backend
↔ >	local	↔
	refers	
	to	
	physical	
	import	
	port	
	mode;	
	tidb	
	refers	
	to	
	logical	
	import	
	port	
	mode.	

Parameter	Description	Corresponding configuration
<code>--log</code>	Log file	<code>lightning</code>
<code>-</code>	file	<code>.</code>
<code>filepath</code>		<code>log</code>
<code>&lt;</code>	By default, it is	<code>-</code>
<code>filefault</code> ,		<code>file</code>
<code>&gt;</code>		
	<code>/tmp/</code>	
	<code>lightning</code>	
	<code>.</code>	
	<code>log</code>	
	<code>{</code>	
	<code>timestamp</code>	
	<code>}</code> .	
	If set to '-', it means that the log files will be output to stdout.	
<code>--</code>	Listening address of the TiDB	<code>lightning</code>
<code>status</code>		<code>.</code>
<code>-</code>	address of the TiDB	<code>status</code>
<code>addr</code>		<code>-</code>
<code>&lt;</code>	TiDB	<code>port</code>
<code>ip</code>	Lightning	
<code>:</code>	ning	
<code>port</code>	server	
<code>&gt;</code>		

Parameter	Description	Corresponding configuration
-- tikv- importer	Address of TiKV importer	tikv-importer
< TiKV		.
host	Importer address	addr
:	Importer	
port		
>		
--pd- PD	tidb.	
url	Endpoint of PD	pd
< point		-
host	PD address	addr
:	Address	
port		
>		
-- TiDB	tidb.	
tidbserver	Host of TiDB	host
- host		
host		
<		
host		
>		
-- TiDB	tidb.	
tidbserver	Host of TiDB	host
- port		
port(de-		
< fault		
port=		
> 4000)		
-- TiDB	tidb.	
tidbstatus	Status of TiDB	status
- port		-
status(de-		port
< fault		
port=		
> 10080)		

Parameter	Description	Corresponding configuration
-- User	tidb.	
↪ tidbname	↪ user	
↪ - to	↪	
↪ user con-		
↪ < nect		
↪ userto		
↪ > TiDB		
-- Password	tidb.	
↪ tidbto	↪ password	
↪ - con-	↪	
↪ password		
↪ < to		
↪ password	TiDB.	
↪ > The		
	pass-	
	word	
	can	
	either	
	be	
	plain-	
	text	
	or	
	Base64	
	en-	
	coded.	
-- Whether	checkpoint	
↪ enable	↪ .	
↪ - enable	↪ enable	
↪ checkpoint	↪	
↪ < points		
↪ bool(de-		
↪ > fault		
	=	
	true)	

Parameter	Description	Corresponding configuration
-- analyze	Analyze post-restore	analyze
↔ <	after	.
↔ level	importing. Available values are "required", "optional" (default value), and "off".	analyze
↔ >		
-- compare	Compare post-restore	compare
↔ <	checksum	.
↔ level	after	checksum
↔ >	importing. Available values are "required" (default value), "optional", and "off".	

Parameter	Description	Corresponding configuration
<code>--check-requirements</code>	Check lightning cluster requirements before starting (default = true)	<code>lightning.check-requirements</code>
<code>--ca</code>	CA certificate path for TLS connection	<code>security.ca</code>
<code>--cert</code>	Certificate path for TLS connection	<code>security.cert</code>
<code>--key</code>	Private key path for TLS connection	<code>security.key</code>

Parameter	Description	Corresponding configuration
-- Start lightning server	Start lightning server	lightning
↔ - Lightning mode	Lightning mode	↔ . ↔ server ↔ - ↔ mode
↔ in server mode	in server mode	↔ mode

If you specify both a command line parameter and the corresponding setting in the configuration file, the command line parameter takes precedence. For example, running `./tidb ↪ -lightning -L debug --config cfg.toml` would always set the log level to “debug” regardless of the content of `cfg.toml`.

### 13.7.13.6.2 tidb-lightning-ctl

All parameters of `tidb-lightning` apply to `tidb-lightning-ctl`. In addition, you can also configure the following parameters using `tidb-lightning-ctl`:

Parameter	Description
-- Perform compact	Perform compact
↔ - Switch TiKV mode	Switch TiKV mode
↔ < to the given mode:	< to the given mode:
↔ > normal or import.	> normal or import.

Parameter	Description
-- Print	
↪ fetch	the
↪ - cur-	
↪ mode	erent
↪ mode	of
	every
	TiKV
	store.
-- Import	
↪ import	the
↪ - closed	
↪ engine	engine
↪ < file	
↪ uuid	from
↪ > TiKV	
	Im-
	porter
	into
	the
	TiKV
	clus-
	ter.
-- Delete	
↪ clean	up
↪ - engine	
↪ engine	file
↪ < from	
↪ uuid	TiKV
↪ > Im-	
	porter.

Parameter	Description
<code>--</code>	Remove
<code>↪ checkpoint</code>	the
<code>↪ - check-</code>	
<code>↪ errorpoint.</code>	
<code>↪ - If it</code>	
<code>↪ destroys</code>	
<code>↪ &lt; an</code>	
<code>↪ table_name</code>	
<code>↪ &gt; drop</code>	
	the
	table.
<code>--</code>	Ignore
<code>↪ checkpoint</code>	
<code>↪ - error</code>	
<code>↪ errorrecorded</code>	
<code>↪ - in the</code>	
<code>↪ ignorecheck-</code>	
<code>↪ &lt; point</code>	
<code>↪ table_name</code>	
<code>↪ &gt; vol-</code>	
	ing
	the
	given
	table.
<code>--</code>	Unconditionally
<code>↪ checkpoint</code>	
<code>↪ - move</code>	
<code>↪ remove</code>	
<code>↪ &lt; check-</code>	
<code>↪ table_name</code>	
<code>↪ &gt; of the</code>	
	table.

The `<table_name>` must either be a qualified table name in the form ``db`.`tbl`` (including the backquotes), or the keyword `all`.

### 13.7.13.7 TiDB Lightning Monitoring

`tidb-lightning` supports metrics collection via [Prometheus](#). This document introduces the monitor configuration and monitoring metrics of TiDB Lightning.

#### 13.7.13.7.1 Monitor configuration

If TiDB Lightning is manually installed, follow the instructions below.

The metrics of `tidb-lightning` can be gathered directly by Prometheus as long as it is discovered. You can set the metrics port in `tidb-lightning.toml`:

```
[lightning]
HTTP port for debugging and Prometheus metrics pulling (0 to disable)
pprof-port = 8289
...

```

and in `tikv-importer.toml`:

```
Listening address of the status server.
status-server-address = '0.0.0.0:8286'

```

You need to configure Prometheus to make it discover the servers. For instance, you can directly add the server address to the `scrape_configs` section:

```
...
scrape_configs:
- job_name: 'tidb-lightning'
 static_configs:
 - targets: ['192.168.20.10:8289']
- job_name: 'tikv-importer'
 static_configs:
 - targets: ['192.168.20.9:8286']

```

### 13.7.13.7.2 Grafana dashboard

[Grafana](#) is a web interface to visualize Prometheus metrics as dashboards.

Row 1: Speed

Figure 261: Panels in first row

Panel	Series	Description
Import speed	write from TiDB Lightning	Speed of sending KV's from TiDB Lightning to TiKV Importer, which depends on each table's complexity
Import speed	upload to tikv	Total upload speed from TiKV Importer to all TiKV replicas
Chunk process duration		Average time needed to completely encode one single data file

Sometimes the import speed will drop to zero allowing other parts to catch up. This is

normal.

Row 2: Progress

Figure 262: Panels in second row

Panel	Description
Import progress	Percentage of data files encoded so far
Checksum progress	Percentage of tables are verified to be imported successfully
Failures	Number of failed tables and their point of failure, normally empty

Row 3: Resource

Figure 263: Panels in third row

Panel	Description
Memory usage	Amount of memory occupied by each service

Panel	Description
Number of TiDB Lightning Goroutines	Number of running goroutines used by TiDB Lightning
CPU%	Number of logical CPU cores utilized by each service

Row 4: Quota

Figure 264: Panels in fourth row

Panel	Series	Description
Idle work- ers	io	Number of unused io- concurrency , nor- mally close to con- figured value (de- fault 5), and close to 0 means the disk is too slow

Panel	Series	Description
Idle work- ers	closed- engine	Number of engines which is closed but not yet cleaned up, nor- mally close to index + table- concurrency (de- fault 8), and close to 0 means TiDB Light- ning is faster than TiKV Im- porter, which will cause TiDB Light- ning to stall

Panel	Series	Description
Idle work- ers	table	Number of unused <b>table-</b> ↳ concurrency ↳ , nor- mally 0 until the end of process
Idle work- ers	index	Number of unused <b>index-</b> ↳ concurrency ↳ , nor- mally 0 until the end of process
Idle work- ers	region	Number of unused <b>region</b> ↳ - ↳ concurrency ↳ , nor- mally 0 until the end of process

Panel	Series	Description
External re-sources	KV Encoder	Counts active KV encoders, normally the same as region ↔ - ↔ concurrency ↔ until the end of process
External re-sources	Importer Engines	Counts opened engine files, should never exceed the max-open engines setting ↔ open ↔ - ↔ engines ↔ setting

### Row 5: Read speed

Figure 265: Panels in fifth row

Panel	Series	Description
Chunk parser read block duration	read block	Time taken to read one block of bytes to prepare for parsing
Chunk parser read block duration	apply worker	Time elapsed to wait for an idle io-concurrency
SQL process duration	row encode	Time taken to parse and encode a single row
SQL process duration	block deliver	Time taken to send a block of KV pairs to TiKV Importer

If any of the duration is too high, it indicates that the disk used by TiDB Lightning is too slow or busy with I/O.

Row 6: Storage

Figure 266: Panels in sixth row

Panel	Series	Description
SQL process rate	data deliver rate	Speed of delivery of data KV pairs to TiKV Importer
SQL process rate	index deliver rate	Speed of delivery of index KV pairs to TiKV Importer
SQL process rate	total deliver rate	The sum of two rates above

Panel	Series	Description
Total bytes	parser read size	Number of bytes being read by TiDB Lightning
Total bytes	data deliver size	Number of bytes of data KV pairs already delivered to TiKV Importer
Total bytes	index deliver size	Number of bytes of index KV pairs already delivered to TiKV Importer

Panel	Series	Description
Total bytes	storage_size / 3	Total size occupied by the TiKV cluster, divided by 3 (the default number of replicas)

Row 7: Import speed

Figure 267: Panels in seventh row

Panel	Series	Description
Delivery duration	Range delivery	Time taken to upload a range of KV pairs to the TiKV cluster

Panel	Series	Description
Delivery duration	SST delivery	Time taken to upload an SST file to the TiKV cluster
SST process duration	Split SST	Time taken to split the stream of KV pairs into SST files
SST process duration	SST upload	Time taken to upload an SST file
SST process duration	SST ingest	Time taken to ingest an uploaded SST file
SST process duration	SST size	File size of an SST file

### 13.7.13.7.3 Monitoring metrics

This section explains the monitoring metrics of `tikv-importer` and `tidb-lightning`, if you need to monitor other metrics not covered by the default Grafana dashboard.

`tikv-importer`

Metrics provided by `tikv-importer` are listed under the namespace `tikv_import_*`.

- **`tikv_import_rpc_duration`** (Histogram)

Bucketed histogram for the duration of an RPC action. Labels:

- **request**: what kind of RPC is executed
  - \* **switch\_mode**: switched a TiKV node to import/normal mode
  - \* **open\_engine**: opened an engine file
  - \* **write\_engine**: received data and written into an engine
  - \* **close\_engine**: closed an engine file
  - \* **import\_engine**: imported an engine file into the TiKV cluster
  - \* **cleanup\_engine**: deleted an engine file
  - \* **compact\_cluster**: explicitly compacted the TiKV cluster
  - \* **upload**: uploaded an SST file
  - \* **ingest**: ingested an SST file
  - \* **compact**: explicitly compacted a TiKV node
- **result**: the execution result of the RPC
  - \* **ok**
  - \* **error**

- **`tikv_import_write_chunk_bytes`** (Histogram)

Bucketed histogram for the uncompressed size of a block of KV pairs received from TiDB Lightning.

- **`tikv_import_write_chunk_duration`** (Histogram)

Bucketed histogram for the time needed to receive a block of KV pairs from TiDB Lightning.

- **`tikv_import_upload_chunk_bytes`** (Histogram)

Bucketed histogram for the compressed size of a chunk of SST file uploaded to TiKV.

- **`tikv_import_upload_chunk_duration`** (Histogram)

Bucketed histogram for the time needed to upload a chunk of SST file to TiKV.

- **`tikv_import_range_delivery_duration`** (Histogram)

Bucketed histogram for the time needed to deliver a range of KV pairs into a dispatch  $\hookrightarrow$  `-job`.

- **`tikv_import_split_sst_duration`** (Histogram)

Bucketed histogram for the time needed to split off a range from the engine file into a single SST file.

- **tikv\_import\_sst\_delivery\_duration** (Histogram)  
Bucketed histogram for the time needed to deliver an SST file from a `dispatch-job` to an `ImportSSTJob`.
- **tikv\_import\_sst\_recv\_duration** (Histogram)  
Bucketed histogram for the time needed to receive an SST file from a `dispatch-job` in an `ImportSSTJob`.
- **tikv\_import\_sst\_upload\_duration** (Histogram)  
Bucketed histogram for the time needed to upload an SST file from an `ImportSSTJob` to a TiKV node.
- **tikv\_import\_sst\_chunk\_bytes** (Histogram)  
Bucketed histogram for the compressed size of the SST file uploaded to a TiKV node.
- **tikv\_import\_sst\_ingest\_duration** (Histogram)  
Bucketed histogram for the time needed to ingest an SST file into TiKV.
- **tikv\_import\_each\_phase** (Gauge)  
Indicates the running phase. Possible values are 1, meaning running inside the phase, and 0, meaning outside the phase. Labels:
  - **phase**: `prepare/import`
- **tikv\_import\_wait\_store\_available\_count** (Counter)  
Counts the number of times a TiKV node is found to have insufficient space when uploading SST files. Labels:
  - **store\_id**: The TiKV store ID.

#### `tidb-lightning`

Metrics provided by `tidb-lightning` are listed under the namespace `lightning_*`.

- **lightning\_importer\_engine** (Counter)  
Counts open and closed engine files. Labels:
  - **type**:
    - \* `open`
    - \* `closed`
- **lightning\_idle\_workers** (Gauge)  
Counts idle workers. Labels:

– **name:**

- \* **table:** the remainder of **table-concurrency**, normally 0 until the end of the process
- \* **index:** the remainder of **index-concurrency**, normally 0 until the end of the process
- \* **region:** the remainder of **region-concurrency**, normally 0 until the end of the process
- \* **io:** the remainder of **io-concurrency**, normally close to configured value (default 5), and close to 0 means the disk is too slow
- \* **closed-engine:** number of engines which have been closed but not yet cleaned up, normally close to **index + table-concurrency** (default 8). A value close to 0 means TiDB Lightning is faster than TiKV Importer, which might cause TiDB Lightning to stall

• **lightning\_kv\_encoder** (Counter)

Counts open and closed KV encoders. KV encoders are in-memory TiDB instances that convert SQL INSERT statements into KV pairs. The net values need to be bounded in a healthy situation. Labels:

– **type:**

- \* **open**
- \* **closed**

• **lightning\_tables** (Counter)

Counts processed tables and their statuses. Labels:

– **state:** the status of the table, indicating which phase should be completed

- \* **pending:** not yet processed
- \* **written:** all data encoded and sent
- \* **closed:** all corresponding engine files closed
- \* **imported:** all engine files have been imported into the target cluster
- \* **altered\_auto\_inc:** AUTO\_INCREMENT ID altered
- \* **checksum:** checksum performed
- \* **analyzed:** statistics analysis performed
- \* **completed:** the table has been fully imported and verified

– **result:** the result of the current phase

- \* **success:** the phase completed successfully
- \* **failure:** the phase failed (did not complete)

• **lightning\_engines** (Counter)

Counts number of engine files processed and their status. Labels:

– **state:** the status of the engine, indicating which phase should be completed

- \* **pending**: not yet processed
- \* **written**: all data encoded and sent
- \* **closed**: engine file closed
- \* **imported**: the engine file has been imported into the target cluster
- \* **completed**: the engine has been fully imported
- **result**: the result of the current phase
  - \* **success**: the phase completed successfully
  - \* **failure**: the phase failed (did not complete)
- **lightning\_chunks** (Counter)  
Counts number of chunks processed and their status. Labels:
  - **state**: a chunk's status, indicating which phase the chunk is in
    - \* **estimated**: (not a state) this value gives total number of chunks in current task
    - \* **pending**: loaded but not yet processed
    - \* **running**: data are being encoded and sent
    - \* **finished**: the entire chunk has been processed
    - \* **failed**: errors happened during processing
- **lightning\_import\_seconds** (Histogram)  
Bucketed histogram for the time needed to import a table.
- **lightning\_row\_read\_bytes** (Histogram)  
Bucketed histogram for the size of a single SQL row.
- **lightning\_row\_encode\_seconds** (Histogram)  
Bucketed histogram for the time needed to encode a single SQL row into KV pairs.
- **lightning\_row\_kv\_deliver\_seconds** (Histogram)  
Bucketed histogram for the time needed to deliver a set of KV pairs corresponding to one single SQL row.
- **lightning\_block\_deliver\_seconds** (Histogram)  
Bucketed histogram for the time needed to deliver a block of KV pairs to Importer.
- **lightning\_block\_deliver\_bytes** (Histogram)  
Bucketed histogram for the uncompressed size of a block of KV pairs delivered to Importer.
- **lightning\_chunk\_parser\_read\_block\_seconds** (Histogram)  
Bucketed histogram for the time needed by the data file parser to read a block.

- **lightning\_checksum\_seconds** (Histogram)  
Bucketed histogram for the time needed to compute the checksum of a table.
- **lightning\_apply\_worker\_seconds** (Histogram)  
Bucketed histogram for the time needed to acquire an idle worker (see also the `lightning_idle_workers` gauge). Labels:
  - **name:**
    - \* `table`
    - \* `index`
    - \* `region`
    - \* `io`
    - \* `closed-engine`

### 13.7.13.8 TiDB Lightning Web Interface

TiDB Lightning provides a webpage for viewing the import progress and performing some simple task management. This is called the *server mode*.

To enable server mode, either start `tidb-lightning` with the `--server-mode` flag

```
tiup tidb-lightning --server-mode --status-addr :8289
```

or set the `lightning.server-mode` setting in the configuration file.

```
[lightning]
server-mode = true
status-addr = ':8289'
```

After TiDB Lightning is launched, visit `http://127.0.0.1:8289` to control the program (the actual URL depends on the `status-addr` setting).

In server mode, TiDB Lightning does not start running immediately. Rather, users submit (multiple) *tasks* via the web interface to import data.

#### 13.7.13.8.1 Front page

Figure 268: Front page of the web interface

Functions of the title bar, from left to right:

Icon	Function
“TiDB Lightning”	Click to go back to the front page

Icon	Function
	Display any error message from <i>previous</i> task List current and queued tasks; a badge may appear here to indicate number of queued tasks
+	Submit a task
/	Pause/resume current execution
	Configure auto-refresh of the web page

Three panels below the title bar show all tables in different states:

- Active: these tables are currently being imported
- Completed: these tables have been imported successfully or failed
- Pending: these tables are not yet processed

Each panel contains cards describing the status of the table.

### 13.7.13.8.2 Submit task

Click the + button on the title bar to submit a task.

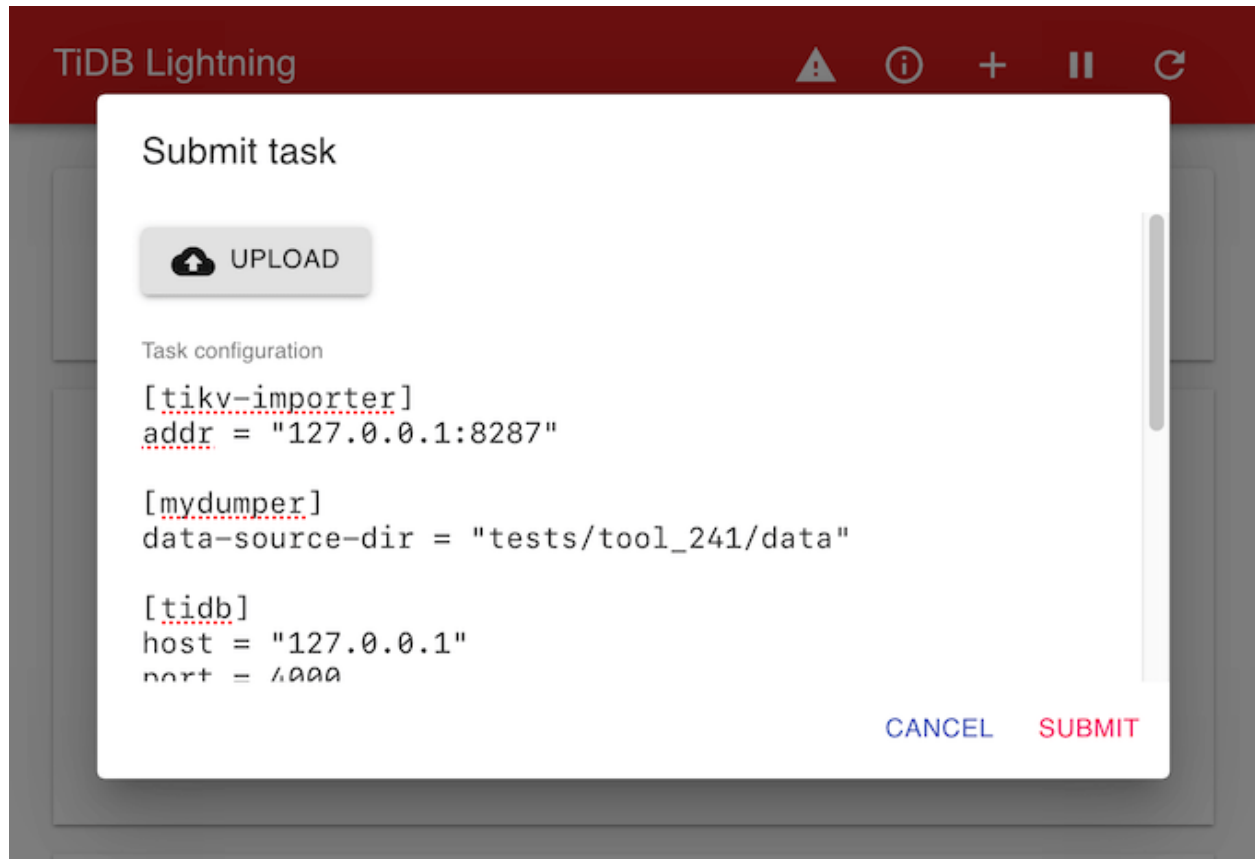

Figure 269: Submit task dialog

Tasks are TOML files described as **task configurations**. One could also open a local TOML file by clicking **UPLOAD**.

Click **SUBMIT** to run the task. If a task is already running, the new task will be queued and executed after the current task succeeds.

### 13.7.13.8.3 Table progress

Click the > button of a table card on the front page to view the detailed progress of a table.

Figure 270: Table progress

The page shows the import progress of every engine and data files associated with the table.

Click **TiDB Lightning** on the title bar to go back to the front page.

#### 13.7.13.8.4 Task management

Click the  button on the title bar to manage the current and queued tasks.

Task Label	Timestamp	Configuration (JSON)
Current	8/12/2019 2:57:53 AM	{ "id": 1565549873900573000, "lightning": { "table-concurrency": 1, "index-concurrency": 2, "region-concurrency": 4, "io-concurrency": 5, "check-requirements": false }, "tidb": { "host": "127.0.0.1", "port": 4000, "user": "root", "status-port": 10080, "pd-addr": "127.0.0.1:2379", "sql-mode": "ONLY_FULL_GROUP_BY STRICT_TRANS_TABLES M
Queue	8/12/2019 2:58:28 AM	

Figure 271: Task management page

Each task is labeled by the time it was submitted. Clicking the task would show the configuration formatted as JSON.

Manage tasks by clicking the  button next to a task. You can stop a task immediately, or reorder queued tasks.

### 13.7.13.9 TiDB Lightning FAQs

This document lists the frequently asked questions (FAQs) and answers about TiDB Lightning.

#### 13.7.13.9.1 What is the minimum TiDB/TiKV/PD cluster version supported by TiDB Lightning?

The version of TiDB Lightning should be the same as the cluster. If you use the Local-backend mode, the earliest available version is 4.0.0. If you use the Importer-backend mode or the TiDB-backend mode, the earliest available version is 2.0.9, but it is recommended to use the 3.0 stable version.

#### 13.7.13.9.2 Does TiDB Lightning support importing multiple schemas (databases)?

Yes.

### 13.7.13.9.3 What are the privilege requirements for the target database?

For details about the permissions, see [Prerequisites for using TiDB Lightning](#).

### 13.7.13.9.4 TiDB Lightning encountered an error when importing one table. Will it affect other tables? Will the process be terminated?

If only one table has an error encountered, the rest will still be processed normally.

### 13.7.13.9.5 How to properly restart TiDB Lightning?

If you are using Importer-backend, depending on the status of `tikv-importer`, the basic sequence of restarting TiDB Lightning is like this:

If `tikv-importer` is still running:

1. [Stop `tidb-lightning`](#).
2. Perform the intended modifications, such as fixing the source data, changing settings, replacing hardware etc.
3. If the modification previously has changed any table, [remove the corresponding checkpoint](#) too.
4. Start `tidb-lightning`.

If `tikv-importer` needs to be restarted:

1. [Stop `tidb-lightning`](#).
2. [Stop `tikv-importer`](#).
3. Perform the intended modifications, such as fixing the source data, changing settings, replacing hardware etc.
4. Start `tikv-importer`.
5. Start `tidb-lightning` *and wait until the program fails with CHECKSUM error, if any.*
  - Restarting `tikv-importer` would destroy all engine files still being written, but `tidb-lightning` did not know about it. As of v3.0 the simplest way is to let `tidb-lightning` go on and retry.
6. [Destroy the failed tables and checkpoints](#)
7. Start `tidb-lightning` again.

If you are using Local-backend or TiDB-backend, the operations are the same as those of using Importer-backend when the `tikv-importer` is still running.

### 13.7.13.9.6 How to ensure the integrity of the imported data?

TiDB Lightning by default performs checksum on the local data source and the imported tables. If there is checksum mismatch, the process would be aborted. These checksum information can be read from the log.

You could also execute the `ADMIN CHECKSUM TABLE` SQL command on the target table to recompute the checksum of the imported data.

```
ADMIN CHECKSUM TABLE `schema`.`table`;
```

```
+-----+-----+-----+-----+-----+
| Db_name | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+-----+-----+-----+-----+-----+
| schema | table | 5505282386844578743 | 3 | 96 |
+-----+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

### 13.7.13.9.7 What kinds of data source formats are supported by TiDB Lightning?

TiDB Lightning supports:

- Importing files exported by [Dumpling](#), CSV files, and [Apache Parquet files generated by Amazon Aurora](#).
- Reading data from a local disk or from the Amazon S3 storage.

### 13.7.13.9.8 Could TiDB Lightning skip creating schema and tables?

Starting from v5.1, TiDB Lightning can automatically recognize the schema and tables in the downstream. If you use TiDB Lightning earlier than v5.1, you need to set `no-schema = true` in the `[mydumper]` section in `tidb-lightning.toml`. This makes TiDB Lightning skip the `CREATE TABLE` invocations and fetch the metadata directly from the target database. TiDB Lightning will exit with error if a table is actually missing.

### 13.7.13.9.9 Can the Strict SQL Mode be disabled to allow importing invalid data?

Yes. By default, the `sql_mode` used by TiDB Lightning is `"STRICT_TRANS_TABLES, NO_ENGINE_SUBSTITUTION"`, which disallows invalid data such as the date `1970-00-00`. The mode can be changed by modifying the `sql-mode` setting in the `[tidb]` section in `tidb-lightning.toml`.

```
...
[tidb]
sql-mode = ""
...
```

#### **13.7.13.9.10 Can one `tikv-importer` serve multiple `tidb-lightning` instances?**

Yes, as long as every `tidb-lightning` instance operates on different tables.

#### **13.7.13.9.11 How to stop the `tikv-importer` process?**

To stop the `tikv-importer` process, you can choose the corresponding operation according to your deployment method.

- For manual deployment: if `tikv-importer` is running in foreground, press `Ctrl+C` to exit. Otherwise, obtain the process ID using the `ps aux | grep tikv-importer` command and then terminate the process using the `kill ${PID}` command.

#### **13.7.13.9.12 How to stop the `tidb-lightning` process?**

To stop the `tidb-lightning` process, you can choose the corresponding operation according to your deployment method.

- For manual deployment: if `tidb-lightning` is running in foreground, press `Ctrl+C` to exit. Otherwise, obtain the process ID using the `ps aux | grep tidb-lightning` command and then terminate the process using the `kill -2 ${PID}` command.

#### **13.7.13.9.13 Can TiDB Lightning be used with 1-Gigabit network card?**

TiDB Lightning is best used with a 10-Gigabit network card.

1-Gigabit network cards can only provide a total bandwidth of 120 MB/s, which has to be shared among all target TiKV stores. TiDB Lightning can easily saturate all bandwidth of the 1-Gigabit network in physical import mode and bring down the cluster because PD is unable to be contacted anymore.

#### **13.7.13.9.14 Why TiDB Lightning requires so much free space in the target TiKV cluster?**

With the default settings of 3 replicas, the space requirement of the target TiKV cluster is 6 times the size of data source. The extra multiple of “2” is a conservative estimation because the following factors are not reflected in the data source:

- The space occupied by indices
- Space amplification in RocksDB

### 13.7.13.9.15 Can TiKV Importer be restarted while TiDB Lightning is running?

No. TiKV Importer stores some information of engines in memory. If `tikv-importer` is restarted, `tidb-lightning` will be stopped due to lost connection. At this point, you need to **destroy the failed checkpoints** as those TiKV Importer-specific information is lost. You can restart TiDB Lightning afterwards.

See also [How to properly restart TiDB Lightning?](#) for the correct sequence.

### 13.7.13.9.16 How to completely destroy all intermediate data associated with TiDB Lightning?

1. Delete the checkpoint file.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-
 ↪ remove=all
```

If, for some reason, you cannot run this command, try manually deleting the file `/tmp ↪ /tidb_lightning_checkpoint.pb`.

2. If you are using Local-backend, delete the `sorted-kv-dir` directory in the configuration. If you are using Importer-backend, delete the entire `import` directory on the machine hosting `tikv-importer`.
3. Delete all tables and databases created on the TiDB cluster, if needed.
4. Clean up the residual metadata. You need to clean up the metadata schema manually if either of the following conditions exist.
  - For TiDB Lightning v5.1.x and v5.2.x versions, the `tidb-lightning-ctl` command does not clean up the metadata schema in the target cluster. You need to clean it up manually.
  - If you have deleted the checkpoint files manually, you need to clean up the downstream metadata schema manually; otherwise, the correctness of subsequent imports might be affected.

Use the following command to clean up the metadata:

```
DROP DATABASE IF EXISTS `lightning_metadata`;
```

### 13.7.13.9.17 How to get the runtime goroutine information of TiDB Lightning

1. If `status-port` has been specified in the configuration file of TiDB Lightning, skip this step. Otherwise, you need to send the `USR1` signal to TiDB Lightning to enable `status-port`.

Get the process ID (PID) of TiDB Lightning using commands like `ps`, and then run the following command:

```
kill -USR1 <lightning-pid>
```

Check the log of TiDB Lightning. The log of starting HTTP server / start HTTP → server / started HTTP server shows the newly enabled status-port.

2. Access `http://<lightning-ip>:<status-port>/debug/pprof/goroutine?debug=2` to get the goroutine information.

### 13.7.13.9.18 Why is TiDB Lightning not compatible with Placement Rules in SQL?

TiDB Lightning is not compatible with **Placement Rules in SQL**. When TiDB Lightning imports data that contains placement policies, TiDB Lightning reports an error.

The reason is explained as follows:

The purpose of placement rule in SQL is to control the data location of certain TiKV nodes at the table or partition level. TiDB Lightning imports data in text files into the target TiDB cluster. If the data files is exported with the definition of placement rules, during the import process, TiDB Lightning must create the corresponding placement rule policy in the target cluster based on the definition. When the source cluster and the target cluster have different topology, this might cause problems.

Suppose the source cluster has the following topology:

#### Source cluster

Figure 272: TiDB Lightning FAQ - source cluster topology

The source cluster has the following placement policy:

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east" REGIONS="us-east,us-
↪ west";
```

**Situation 1:** The target cluster has 3 replicas, and the topology is different from the source cluster. In such cases, when TiDB Lightning creates the placement policy in the target cluster, it will not report an error. However, the semantics in the target cluster is wrong.

### Target cluster

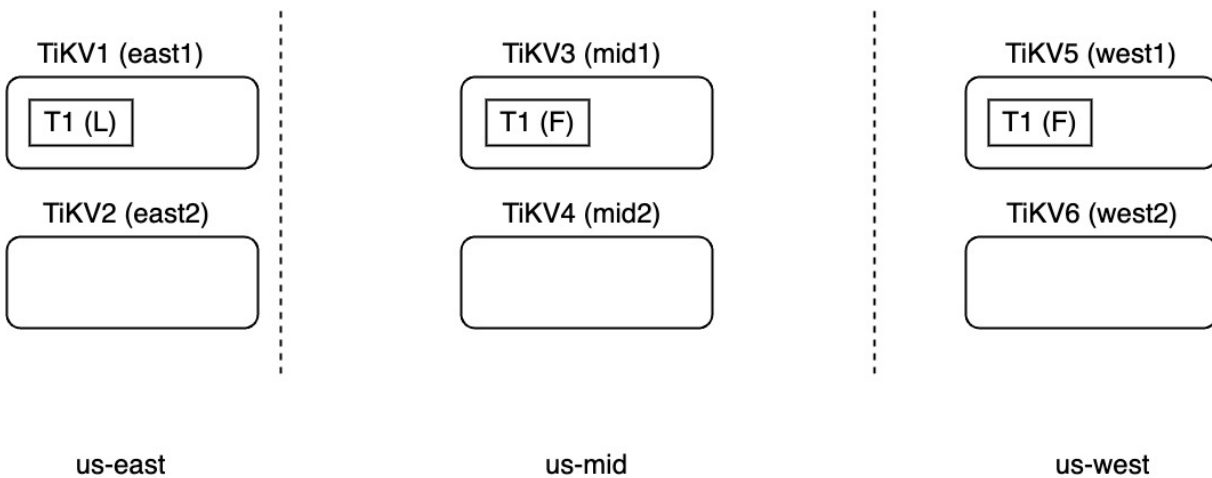

Figure 273: TiDB Lightning FAQ - situation 1

**Situation 2:** The target cluster locates the follower replica in another TiKV node in region “us-mid” and does not have the region “us-west” in the topology. In such cases, when creating the placement policy in the target cluster, TiDB Lightning will report an error.

## Target cluster

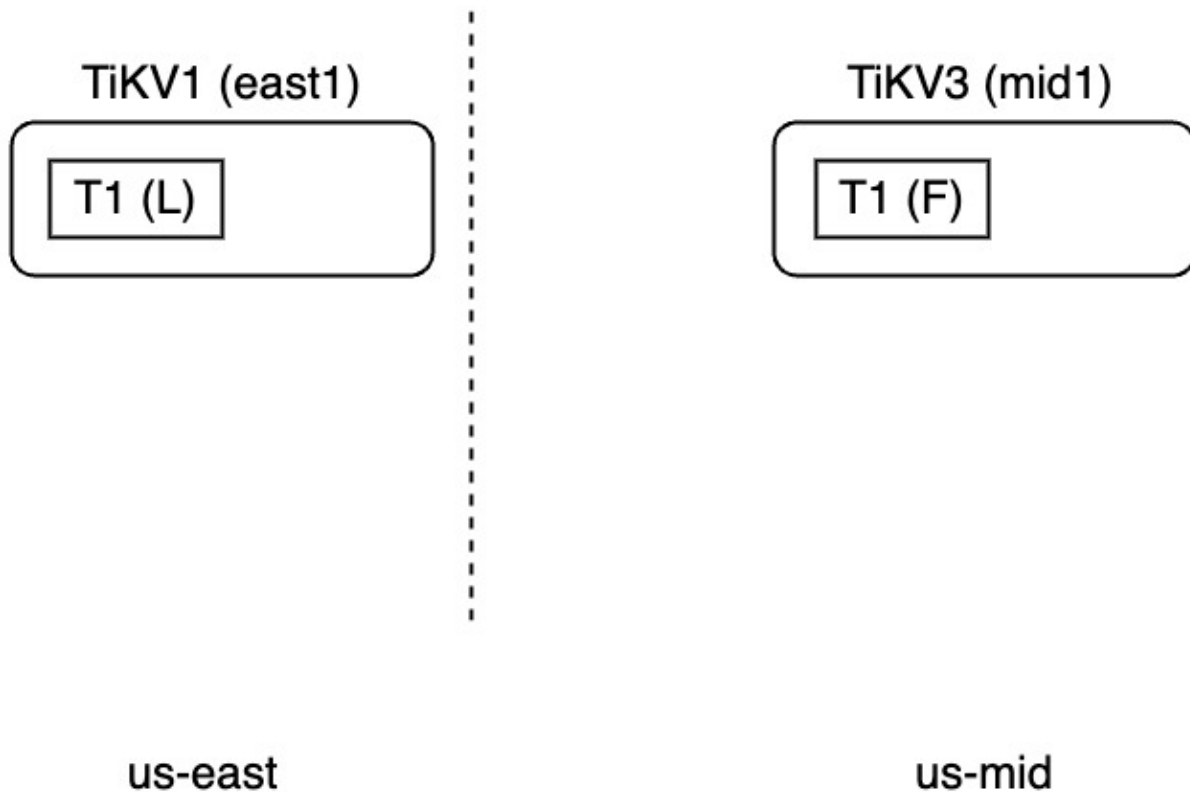

Figure 274: TiDB Lightning FAQ - situation 2

### Workaround:

To use placement rules in SQL with TiDB Lightning, you need to make sure that the related labels and objects have been created in the target TiDB cluster **before** you import data into the target table. Because the placement rules in SQL acts at the PD and TiKV layer, TiDB Lightning can get the necessary information to find out which TiKV should be used to store the imported data. In this way, this placement rule in SQL is transparent to TiDB Lightning.

The steps are as follows:

1. Plan the data distribution topology.

2. Configure the required labels for TiKV and PD.
3. Create the placement rule policy and apply the created policy to the target table.
4. Use TiDB Lightning to import data into the target table.

### 13.7.13.10 TiDB Lightning Glossary

This page explains the special terms used in TiDB Lightning’s logs, monitoring, configurations, and documentation.

#### 13.7.13.10.1 A

Analyze

An operation to rebuild the [statistics](#) information of a TiDB table, which is running the [ANALYZE TABLE](#) statement.

Because TiDB Lightning imports data without going through TiDB, the statistics information is not automatically updated. Therefore, TiDB Lightning explicitly analyzes every table after importing. This step can be omitted by setting the `post-restore.analyze` configuration to `false`.

`AUTO_INCREMENT_ID`

Every table has an associated `AUTO_INCREMENT_ID` counter to provide the default value of an auto-incrementing column. In TiDB, this counter is additionally used to assign row IDs.

Because TiDB Lightning imports data without going through TiDB, the `AUTO_INCREMENT_ID`  $\leftrightarrow$  counter is not automatically updated. Therefore, TiDB Lightning explicitly alters `AUTO_INCREMENT_ID` to a valid value. This step is always performed, even if the table has no `AUTO_INCREMENT` columns.

#### 13.7.13.10.2 B

Back end

Back end is the destination where TiDB Lightning sends the parsed result. Also spelled as “backend”.

See [TiDB Lightning architecture](#) for details.

#### 13.7.13.10.3 C

Checkpoint

TiDB Lightning continuously saves its progress into a local file or a remote database while importing. This allows it to resume from an intermediate state should it crashes in the process. See the [Checkpoints](#) section for details.

Checksum

In TiDB Lightning, the checksum of a table is a set of 3 numbers calculated from the content of each KV pair in that table. These numbers are respectively:

- the number of KV pairs,
- total length of all KV pairs, and
- the bitwise-XOR of [CRC-64-ECMA](#) value each pair.

TiDB Lightning **validates the imported data** by comparing the **local** and **remote checksums** of every table. The program would stop if any pair does not match. You can skip this check by setting the `post-restore.checksum` configuration to `false`.

See also the [FAQs](#) for how to properly handle checksum mismatch.

#### Chunk

A continuous range of source data, normally equivalent to a single file in the data source.

When a file is too large, TiDB Lightning might split a file into multiple chunks.

#### Compaction

An operation that merges multiple small SST files into one large SST file, and cleans up the deleted entries. TiKV automatically compacts data in background while TiDB Lightning is importing.

#### Note:

For legacy reasons, you can still configure TiDB Lightning to explicitly trigger a compaction every time a table is imported. However, this is not recommended and the corresponding settings are disabled by default.

See [RocksDB's wiki page on Compaction](#) for its technical details.

#### 13.7.13.10.4 D

##### Data engine

An **engine** for sorting actual row data.

When a table is very large, its data is placed into multiple data engines to improve task pipelining and save space of TiKV Importer. By default, a new data engine is opened for every 100 GB of SQL data, which can be configured through the `mydumper.batch-size` setting.

TiDB Lightning processes multiple data engines concurrently. This is controlled by the `lightning.table-concurrency` setting.

### 13.7.13.10.5 E

Engine

In TiKV Importer, an engine is a RocksDB instance for sorting KV pairs.

TiDB Lightning transfers data to TiKV Importer through engines. It first opens an engine, sends KV pairs to it (with no particular order), and finally closes the engine. The engine sorts the received KV pairs after it is closed. These closed engines can then be further uploaded to the TiKV stores for ingestion.

Engines use TiKV Importer's `import-dir` as temporary storage, which are sometimes referred to as “engine files”.

See also [data engine](#) and [index engine](#).

### 13.7.13.10.6 F

Filter

A configuration list that specifies which tables to be imported or excluded.

See [Table Filter](#) for details.

### 13.7.13.10.7 I

Import mode

A configuration that optimizes TiKV for writing at the cost of degraded read speed and space usage.

TiDB Lightning automatically switches to and off the import mode while running. However, if TiKV gets stuck in import mode, you can use `tidb-lightning-ctl` to [force revert](#) to [normal mode](#).

Index engine

An [engine](#) for sorting indices.

Regardless of number of indices, every table is associated with exactly one index engine.

TiDB Lightning processes multiple index engines concurrently. This is controlled by the `lightning.index-concurrency` setting. Since every table has exactly one index engine, this also configures the maximum number of tables to process at the same time.

Ingest

An operation which inserts the entire content of an [SST file](#) into the RocksDB (TiKV) store.

Ingestion is a very fast operation compared with inserting KV pairs one by one. This operation is the determinant factor for the performance of TiDB Lightning.

See [RocksDB's wiki page on Creating and Ingesting SST files](#) for its technical details.

#### 13.7.13.10.8 K

KV pair

Abbreviation of “key-value pair”.

KV encoder

A routine which parses SQL or CSV rows to KV pairs. Multiple KV encoders run in parallel to speed up processing.

#### 13.7.13.10.9 L

Local checksum

The **checksum** of a table calculated by TiDB Lightning itself before sending the KV pairs to TiKV Importer.

#### 13.7.13.10.10 N

Normal mode

The mode where **import mode** is disabled.

#### 13.7.13.10.11 P

Post-processing

The period of time after the entire data source is parsed and sent to TiKV Importer. TiDB Lightning is waiting for TiKV Importer to upload and **ingest** the **SST files**.

#### 13.7.13.10.12 R

Remote checksum

The **checksum** of a table calculated by TiDB after it has been imported.

#### 13.7.13.10.13 S

Scattering

An operation that randomly reassigns the leader and the peers of a **Region**. Scattering ensures that the imported data are distributed evenly among TiKV stores. This reduces stress on PD.

Splitting

An engine is typically very large (around 100 GB), which is not friendly to TiKV if treated as a single **region**. TiKV Importer splits an engine into multiple small **SST files** (configurable by TiKV Importer’s `import.region-split-size` setting) before uploading.

SST file

SST is the abbreviation of “sorted string table”. An SST file is RocksDB’s (and thus TiKV’s) native storage format of a collection of KV pairs.

TiKV Importer produces SST files from a closed [engine](#). These SST files are uploaded and then [ingested](#) into TiKV stores.

## 13.8 Use Dumping to Export Data

This document introduces the data export tool - [Dumping](#). Dumping exports data stored in TiDB/MySQL as SQL or CSV data files and can be used to make a logical full backup or export. Dumping also supports exporting data to Amazon S3.

You can get Dumping using [TiUP](#) by running `tiup install dumping`. Afterwards, you can use `tiup dumping ...` to run Dumping.

The Dumping installation package is included in the TiDB Toolkit. To download the TiDB Toolkit, see [Download TiDB Tools](#).

For detailed usage of Dumping, use the `--help` option or refer to [Option list of Dumping](#).

When using Dumping, you need to execute the export command on a running cluster.

TiDB also provides other tools that you can choose to use as needed.

- For backups of SST files (key-value pairs) or backups of incremental data that are not sensitive to latency, refer to [BR](#).
- For real-time backups of incremental data, refer to [TiCDC](#).
- All exported data can be imported back to TiDB using [TiDB Lightning](#).

### Note:

PingCAP previously maintained a fork of the [mydumper project](#) with enhancements specific to TiDB. This fork has since been replaced by [Dumping](#), which has been rewritten in Go, and supports more optimizations that are specific to TiDB. It is strongly recommended that you use Dumping instead of mydumper.

For more information on Mydumper, refer to [v4.0 Mydumper documentation](#).

Compared to Mydumper, Dumping has the following improvements:

- Support exporting data in multiple formats, including SQL and CSV.
- Support the [table-filter](#) feature, which makes it easier to filter data.
- Support exporting data to Amazon S3 cloud storage.

- More optimizations are made for TiDB:
  - Support configuring the memory limit of a single TiDB SQL statement.
  - If Dumpling can connect directly to PD, Dumpling supports automatic adjustment of TiDB GC time for TiDB v4.0.0 and later versions.
  - Use TiDB's hidden column `_tidb_rowid` to optimize the performance of concurrent data export from a single table.
  - For TiDB, you can set the value of `tidb_snapshot` to specify the time point of the data backup. This ensures the consistency of the backup, instead of using `FLUSH TABLES WITH READ LOCK` to ensure the consistency.

**Note:**

Dumpling cannot connect to PD in the following scenarios:

- The TiDB cluster is running on Kubernetes (unless Dumpling itself is run inside the Kubernetes environment).
- The TiDB cluster is running on TiDB Cloud.

In such cases, you need to manually [adjust the TiDB GC time](#) to avoid export failure.

## 13.8.1 Export data from TiDB or MySQL

### 13.8.1.1 Required privileges

- `SELECT`: Required when exporting tables.
- `RELOAD`: Required when using `consistency flush`. Note that only TiDB supports this privilege. When the upstream is an RDS database or a managed service, you can ignore this privilege.
- `LOCK TABLES`: Required when using `consistency lock`. This privilege must be granted for all the databases and tables to be exported.
- `REPLICATION CLIENT`: Required when exporting metadata to record data snapshot. This privilege is optional and you can ignore it if you do not need to export metadata.

### 13.8.1.2 Export to SQL files

This document assumes that there is a TiDB instance on the `127.0.0.1:4000` host and that this TiDB instance has a root user without a password.

Dumpling exports data to SQL files by default. You can also export data to SQL files by adding the `--filetype sql` flag:

```
dumpling -u root -P 4000 -h 127.0.0.1 --filetype sql -t 8 -o /tmp/test -r
↪ 200000 -F 256MiB
```

In the command above:

- The `-h`, `-P`, and `-u` option respectively mean the address, the port, and the user. If a password is required for authentication, you can use `-p $YOUR_SECRET_PASSWORD` to pass the password to Dumpling.
- The `-o` (or `--output`) option specifies the export directory of the storage, which supports a local file path or an [external storage URI](#).
- The `-t` option specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and also increases the database's memory consumption. Therefore, it is not recommended to set the number too large. Usually, it's less than 64.
- The `-r` option specifies the maximum number of rows in a single file. With this option specified, Dumpling enables the in-table concurrency to speed up the export and reduce the memory usage. When the upstream database is TiDB v3.0 or later versions, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting and the specific `-r` value does not affect the split algorithm. When the upstream database is MySQL and the primary key is of the `int` type, specifying `-r` can also enable the in-table concurrency.
- The `-F` option is used to specify the maximum size of a single file (the unit here is MiB; inputs like 5GiB or 8KB are also acceptable). It is recommended to keep its value to 256 MiB or less if you plan to use TiDB Lightning to load this file into a TiDB instance.

#### Note:

If the size of a single exported table exceeds 10 GB, it is **strongly recommended to use** the `-r` and `-F` options.

### 13.8.1.3 Export to CSV files

You can export data to CSV files by adding the `--filetype csv` argument.

When you export data to CSV files, you can use `--sql <SQL>` to filter the records with the SQL statements. For example, you can export all records that match `id < 100` in `test.sbtest1` using the following command:

```
./dumpling -u root -P 4000 -h 127.0.0.1 -o /tmp/test --filetype csv --sql '
↪ select * from `test`.`sbtest1` where id < 100' -F 100MiB --output-
↪ filename-template 'test.sbtest1.{{.Index}}'
```

In the command above:

- The `--sql` option can be used only for exporting to CSV files. The command above executes the `SELECT * FROM <table-name> WHERE id <100` statement on all tables to be exported. If a table does not have the specified field, the export fails.
- When you use the `--sql` option, Dumping cannot obtain the exported table and schema information. You can specify the file name format of the CSV files using the `--output-filename-template` option, which facilitates the subsequent use of **TiDB Lightning** to import the data file. For example, `--output-filename-template='↔ test.sbtest1.{{.Index}}'` specifies that the exported CSV files are named as `test.sbtest1.000000000` or `test.sbtest1.000000001`.
- You can use options like `--csv-separator` and `--csv-delimiter` to configure the CSV file format. For details, refer to the [Dumping option list](#).

**Note:**

*Strings* and *keywords* are not distinguished by Dumping. If the imported data is the Boolean type, the value of `true` is converted to 1 and the value of `false` is converted to 0.

#### 13.8.1.4 Compress the exported data files

You can use the `--compress <format>` option to compress the CSV and SQL data and table structure files exported by Dumping. This parameter supports the following compression algorithms: `gzip`, `snappy`, and `zstd`. The compression is disabled by default.

- This option only compresses individual data and table structure files. It cannot compress the entire folder and generate a single compressed package.
- This option can save disk space, but it also slows down the export speed and increases CPU consumption. Use this option with caution in scenarios where the export speed is critical.
- For TiDB Lightning v6.5.0 and later versions, you can use compressed files exported by Dumping as the data source without additional configuration.

#### 13.8.1.5 Format of exported files

- **metadata:** The start time of the exported files and the position of the master binary log.

```
cat metadata
```

```
Started dump at: 2020-11-10 10:40:19
SHOW MASTER STATUS:
 Log: tidb-binlog
 Pos: 420747102018863124
Finished dump at: 2020-11-10 10:40:20
```

- {schema}-schema-create.sql: The SQL file used to create the schema

```
cat test-schema-create.sql
```

```
CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 */;
```

- {schema}.{table}-schema.sql: The SQL file used to create the table

```
cat test.t1-schema.sql
```

```
CREATE TABLE `t1` (
 `id` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

- {schema}.{table}.{0001}.{sql|csv}: The data source file

```
cat test.t1.0.sql
```

```
/*!40101 SET NAMES binary*/;
INSERT INTO `t1` VALUES
(1);
```

- \*-schema-view.sql、\*-schema-trigger.sql、\*-schema-post.sql: Other exported files

### 13.8.1.6 Export data to Amazon S3 cloud storage

Starting from v4.0.8, Dumpling supports exporting data to cloud storages. If you need to back up data to Amazon S3, you need to specify the Amazon S3 storage path in the `-o` parameter.

You need to create an Amazon S3 bucket in the specified region (see the [Amazon documentation - How do I create an S3 Bucket](#)). If you also need to create a folder in the bucket, see the [Amazon documentation - Creating a folder](#).

Pass `SecretKey` and `AccessKey` of the account with the permission to access the Amazon S3 backend storage to the Dumpling node as environment variables.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

Dumpling also supports reading credential files from `~/.aws/credentials`. Parameters for exporting data to Amazon S3 using Dumpling are the same as the parameters used in BR. For more parameter descriptions, see [external storage URI](#).

```
./dumpling -u root -P 4000 -h 127.0.0.1 -r 200000 -o "s3://${Bucket}/${
↳ Folder}"
```

### 13.8.1.7 Filter the exported data

#### 13.8.1.7.1 Use the `--where` option to filter data

By default, Dumpling exports all databases except system databases (including `mysql`, `sys`, `INFORMATION_SCHEMA`, `PERFORMANCE_SCHEMA`, `METRICS_SCHEMA`, and `INSPECTION_SCHEMA`). You can use `--where <SQL where expression>` to select the records to be exported.

```
./dumpling -u root -P 4000 -h 127.0.0.1 -o /tmp/test --where "id < 100"
```

The above command exports the data that matches `id < 100` from each table. Note that you cannot use the `--where` parameter together with `--sql`.

#### 13.8.1.7.2 Use the `--filter` option to filter data

Dumpling can filter specific databases or tables by specifying the table filter with the `--filter` option. The syntax of table filters is similar to that of `.gitignore`. For details, see [Table Filter](#).

```
./dumpling -u root -P 4000 -h 127.0.0.1 -o /tmp/test -r 200000 --filter "
↳ employees.*" --filter "*.WorkOrder"
```

The above command exports all the tables in the `employees` database and the `WorkOrder` tables in all databases.

#### 13.8.1.7.3 Use the `-B` or `-T` option to filter data

Dumpling can also export specific databases with the `-B` option or specific tables with the `-T` option.

**Note:**

- The `--filter` option and the `-T` option cannot be used at the same time.
- The `-T` option can only accept a complete form of inputs like `database`  $\rightarrow$  `-name.table-name`, and inputs with only the table name are not accepted. Example: Dumpling cannot recognize `-T WorkOrder`.

Examples:

- `-B employees` exports the `employees` database.
- `-T employees.WorkOrder` exports the `employees.WorkOrder` table.

### 13.8.1.8 Improve export efficiency through concurrency

The exported file is stored in the `./export-<current local time>` directory by default. Commonly used options are as follows:

- The `-t` option specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and also increases the database's memory consumption. Therefore, it is not recommended to set the number too large.
- The `-r` option specifies the maximum number of records (or the number of rows in the database) for a single file. When it is enabled, Dumpling enables concurrency in the table to improve the speed of exporting large tables. When the upstream database is TiDB v3.0 or later versions, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting and the specific `-r` value does not affect the split algorithm. When the upstream database is MySQL and the primary key is of the `int` type, specifying `-r` can also enable the in-table concurrency.
- The `--compress <format>` option specifies the compression format of the dump. It supports the following compression algorithms: `gzip`, `snappy`, and `zstd`. This option can speed up dumping of data if storage is the bottleneck or if storage capacity is a concern. The drawback is an increase in CPU usage. Each file is compressed individually.

With the above options specified, Dumpling can have a quicker speed of data export.

### 13.8.1.9 Adjust Dumpling's data consistency options

#### Note:

The default value is `auto` for the data consistency option. In most scenarios, you do not need to adjust the default data consistency options of Dumpling.

Dumpling uses the `--consistency <consistency level>` option to control the way in which data is exported for “consistency assurance”. When using snapshot for consistency, you can use the `--snapshot` option to specify the timestamp to be backed up. You can also use the following levels of consistency:

- **flush**: Use `FLUSH TABLES WITH READ LOCK` to temporarily interrupt the DML and DDL operations of the replica database, to ensure the global consistency of the backup connection, and to record the binlog position (POS) information. The lock is released after all backup connections start transactions. It is recommended to perform full backups during off-peak hours or on the MySQL replica database.
- **snapshot**: Get a consistent snapshot of the specified timestamp and export it.
- **lock**: Add read locks on all tables to be exported.
- **none**: No guarantee for consistency.
- **auto**: Use `flush` for MySQL and `snapshot` for TiDB.

After everything is done, you can see the exported file in `/tmp/test`:

```
ls -lh /tmp/test | awk '{print $5 "\t" $9}'
```

```
140B metadata
66B test-schema-create.sql
300B test.sbtest1-schema.sql
190K test.sbtest1.0.sql
300B test.sbtest2-schema.sql
190K test.sbtest2.0.sql
300B test.sbtest3-schema.sql
190K test.sbtest3.0.sql
```

### 13.8.1.10 Export historical data snapshots of TiDB

Dumpling can export the data of a certain `tidb_snapshot` with the `--snapshot` option specified.

The `--snapshot` option can be set to a TSO (the `Position` field output by the `SHOW ↵ MASTER STATUS` command) or a valid time of the `datetime` data type (in the form of `YYYY-MM-DD hh:mm:ss`), for example:

```
./dumpling --snapshot 417773951312461825
./dumpling --snapshot "2020-07-02 17:12:45"
```

The TiDB historical data snapshots when the TSO is `417773951312461825` and the time is `2020-07-02 17:12:45` are exported.

### 13.8.1.11 Control the memory usage of exporting large tables

When Dumping is exporting a large single table from TiDB, Out of Memory (OOM) might occur because the exported data size is too large, which causes connection abort and export failure. You can use the following parameters to reduce the memory usage of TiDB:

- Setting `-r` to split the data to be exported into chunks. This reduces the memory overhead of TiDB's data scan and enables concurrent table data dump to improve export efficiency. When the upstream database is TiDB v3.0 or later versions, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting and the specific `-r` value does not affect the split algorithm.
- Reduce the value of `--tidb-mem-quota-query` to 8589934592 (8 GB) or lower. `--tidb-mem-quota-query` controls the memory usage of a single query statement in TiDB.
- Adjust the `--params "tidb_distsql_scan_concurrency=5"` parameter. `tidb_distsql_scan_concurrency` is a session variable which controls the concurrency of the scan operations in TiDB.

### 13.8.1.12 Manually set the TiDB GC time

When exporting data from TiDB (more than 1 TB), if the TiDB version is later than or equal to v4.0.0 and Dumping can access the PD address of the TiDB cluster, Dumping automatically extends the GC time without affecting the original cluster.

However, in either of the following scenarios, Dumping cannot automatically adjust the GC time:

- The data size is very large (more than 1 TB).
- Dumping cannot connect directly to PD, for example, if the TiDB cluster is on TiDB Cloud or on Kubernetes that is separated from Dumping.

In such scenarios, you must manually extend the GC time in advance to avoid export failure due to GC during the export process.

To manually adjust the GC time, use the following SQL statement:

```
SET GLOBAL tidb_gc_life_time = '720h';
```

After Dumping exits, regardless of whether the export is successful or not, you must set the GC time back to its original value (the default value is 10m).

```
SET GLOBAL tidb_gc_life_time = '10m';
```

## 13.8.2 Option list of Dumping

Options Usage	Default value
-V or -- ↪ version	
-B or -- ↪ database	
-T or -- ↪ tables ↪ - ↪ list	
-f or -- ↪ filter	[\*.\*,!/^( ↪ mysql ↪ &#124; ↪ sys ↪ &#124; ↪ INFORMATION_SCHEMA ↪ &#124; ↪ PERFORMANCE_SCHEMA ↪ &#124; ↪ METRICS_SCHEMA ↪ &#124; ↪ INSPECTION_SCHEMA ↪ )\$ ↪ /\. \*] ↪ (export all databases or tables exclud- ing system schemas) false (case- insensitive)
-- ↪ case ↪ - ↪ sensitive ↪	
-- whether table-filter is case-sensitive	false

Options Usage	Default value
<b>-h</b> or    The IP address of the connected database host -- ↪ <b>host</b> ↪	“127.0.0.1”
<b>-t</b> or    The number of concurrent backup threads -- ↪ <b>threads</b> ↪	4
<b>-r</b> or    Split the table into rows with a specified number of rows (generally --       applicable for concurrent operations of splitting a large table into ↪ <b>rows</b> multiple files. When the upstream database is TiDB v3.0 or later ↪       versions, a <b>-r</b> value greater than 0 indicates that the TiDB region information is used for splitting and the specific <b>-r</b> value does not affect the split algorithm.	
<b>-L</b> or    Log output address. If it is empty, the log will be output to the --       console ↪ <b>logfile</b> ↪	“”
--       Log level {debug,info,warn,error,dpanic,panic,fatal} ↪ <b>loglevel</b> ↪	“info”
--       Log output format {text,json} ↪ <b>logfmt</b> ↪	“text”
<b>-d</b> or    Do not export data (suitable for scenarios where only the schema is --no-    exported) ↪ <b>data</b> ↪	
--no-    Export CSV files of the tables without generating header ↪ <b>header</b> ↪	
<b>-W</b> or    Do not export the views --no- ↪ <b>views</b> ↪	true
<b>-m</b> or    Do not export the schema with only the data exported --no- ↪ <b>schemas</b> ↪	

Options Usage	Default value
<p><b>-s</b> or    Control the size of the <b>INSERT</b> statements; the unit is bytes</p> <p>--</p> <p>↳ <b>statement</b></p> <p>↳ -</p> <p>↳ <b>size</b></p> <p>↳</p>	
<p><b>-F</b> or    The file size of the divided tables. The unit must be specified such as 128B, 64KiB, 32MiB, and 1.5GiB.</p> <p>--</p> <p>↳ <b>filesize</b></p> <p>↳</p>	
<p>--        Exported file type (csv/sql)</p> <p>↳ <b>filetype</b></p> <p>↳</p>	“sql”
<p><b>-o</b> or    The path of exported local files or <a href="#">external storage URI</a></p> <p>--</p> <p>↳ <b>output</b></p> <p>↳</p>	“./export- \${time}”
<p><b>-S</b> or    Export data according to the specified SQL statement. This command does not support concurrent export.</p> <p>--<b>sql</b>    flush: use FTWRL before the dump snapshot: dump the TiDB data</p> <p>--        consistency-specific snapshot of a TSO lock: execute <b>lock tables read on</b></p> <p>↳ <b>consistency</b> all tables to be dumped none: dump without adding locks, which cannot guarantee consistency auto: use <b>-consistency flush</b> for MySQL; use <b>-consistency snapshot</b> for TiDB</p> <p>--        Snapshot TSO; valid only when <b>consistency=snapshot</b></p> <p>↳ <b>snapshot</b></p> <p>↳</p>	“auto”
<p>--        Specify the scope of the table backup through the <b>where</b> condition</p> <p>↳ <b>where</b></p> <p>↳</p>	
<p><b>-p</b> or    The password of the connected database host</p> <p>--</p> <p>↳ <b>password</b></p> <p>↳</p>	
<p><b>-P</b> or    The port of the connected database host</p> <p>--</p> <p>↳ <b>port</b></p> <p>↳</p>	4000
<p><b>-u</b> or    The username of the connected database host</p> <p>--</p> <p>↳ <b>user</b></p> <p>↳</p>	“root”

Options Usage	Default value
<pre>--      Export the CREATE DATABASE statements of the empty databases ↳ dump ↳ - ↳ empty ↳ - ↳ database ↳ --ca    The address of the certificate authority file for TLS connection --      The address of the client certificate file for TLS connection ↳ cert ↳ --key   The address of the client private key file for TLS connection --csv   Delimiter of character type variables in CSV files</pre>	<pre>true ""</pre>
<pre>↳ - ↳ delimiter ↳ --csv   Separator of each value in CSV files. It is not recommended to use ↳ -    the default ','. It is recommended to use ' +' or other uncommon ↳ separator character combinations ↳ --csv   Representation of null values in CSV files</pre>	<pre>',' "\N"</pre>

It supports the following compression ↪ compress algorithms: gzip, snappy, and zstd. ↪</pre>	"

## 13.9 TiCDC

### 13.9.1 TiCDC Overview

[TiCDC](#) is a tool used for replicating incremental data of TiDB. Specifically, TiCDC pulls TiKV change logs, sorts captured data, and exports row-based incremental data to downstream databases.

#### 13.9.1.1 Usage scenarios

- Provides data high availability and disaster recovery solutions for multiple TiDB clusters, ensuring eventual data consistency between primary and secondary clusters in case of disaster.
- Replicates real-time data changes to homogeneous systems so as to provide data sources for various scenarios such as monitoring, caching, global indexing, data analysis, and primary-secondary replication between heterogeneous databases.

#### 13.9.1.2 Major features

### 13.9.1.2.1 Key capabilities

- Replicate incremental data from one TiDB cluster to another TiDB cluster with second-level RPO and minute-level RTO.
- Replicate data bidirectionally between TiDB clusters, based on which you can create a multi-active TiDB solution using TiCDC.
- Replicate incremental data from a TiDB cluster to a MySQL database (or other MySQL-compatible databases) with low latency.
- Replicate incremental data from a TiDB cluster to a Kafka cluster. The recommended data format includes [Canal-JSON](#) and [Avro](#).
- Replicate tables with the ability to filter databases, tables, DMLs, and DDLs.
- Be highly available with no single point of failure. Supports dynamically adding and deleting TiCDC nodes.
- Support cluster management through [Open API](#), including querying task status, dynamically modifying task configuration, and creating or deleting tasks.

### 13.9.1.2.2 Replication order

- For all DDL or DML statements, TiCDC outputs them **at least once**.
- When the TiKV or TiCDC cluster encounters a failure, TiCDC might send the same DDL/DML statement repeatedly. For duplicated DDL/DML statements:
  - MySQL sink can execute DDL statements repeatedly. For DDL statements that can be executed repeatedly in the downstream, such as `truncate table`, the statement is executed successfully. For those that cannot be executed repeatedly, such as `create table`, the execution fails, and TiCDC ignores the error and continues the replication.
  - Kafka sink
    - \* Kafka sink provides different strategies for data distribution. You can distribute data to different Kafka partitions based on the table, primary key, or timestamp. This ensures that the updated data of a row is sent to the same partition in order.
    - \* All these distribution strategies send Resolved TS messages to all topics and partitions periodically. This indicates that all messages earlier than the Resolved TS have been sent to the topics and partitions. The Kafka consumer can use the Resolved TS to sort the messages received.
    - \* Kafka sink sends duplicated messages sometimes, but these duplicated messages do not affect the constraints of **Resolved Ts**. For example, if a change-feed is paused and then resumed, Kafka sink might send `msg1`, `msg2`, `msg3`, `msg2`, and `msg3` in order. You can filter the duplicated messages from Kafka consumers.

### 13.9.1.2.3 Replication consistency

- MySQL sink
  - TiCDC enables redo log to ensure eventual consistency of data replication.
  - TiCDC **ensures** that the order of single-row updates is consistent with that in the upstream.
  - TiCDC does **not ensure** that the execution order of downstream transactions is the same as that of upstream transactions.

**Note:**

Since v6.2, you can use the sink uri parameter `transaction-atomicity` to control whether to split single-table transactions. Splitting single-table transactions can greatly reduce the latency and memory consumption of replicating large transactions.

### 13.9.1.3 TiCDC architecture

As an incremental data replication tool for TiDB, TiCDC is highly available through PD's etcd. The replication process is as follows:

1. Multiple TiCDC processes pull data changes from TiKV nodes.
2. Data changes pulled from TiKV are sorted and merged internally.
3. Data changes are replicated to multiple downstream systems through multiple replication tasks (changefeeds).

The architecture of TiCDC is shown in the following figure:

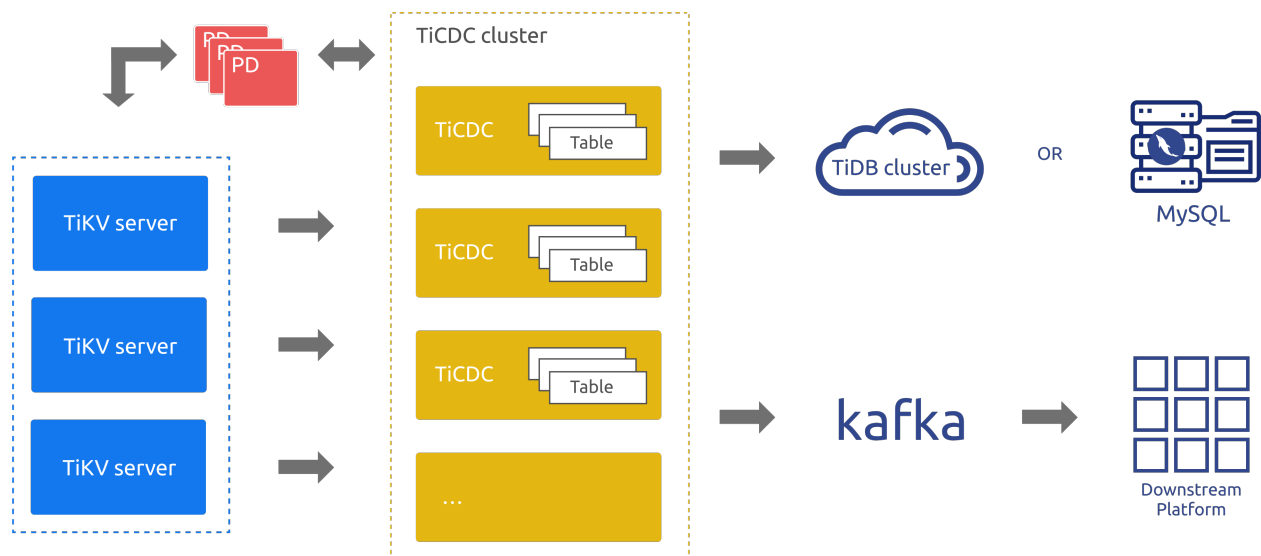

Figure 275: TiCDC architecture

The components in the preceding architecture diagram are described as follows:

- **TiKV Server:** TiKV nodes in a TiDB cluster. When data changes, TiKV nodes send the changes as change logs (KV change logs) to TiCDC nodes. If TiCDC nodes find the change logs not continuous, they will actively request the TiKV nodes to provide change logs.
- **TiCDC:** TiCDC nodes where the TiCDC processes run. Each node runs a TiCDC process. Each process pulls data changes from one or more tables in TiKV nodes, and replicates the changes to the downstream system through the sink component.
- **PD:** The scheduling module in a TiDB cluster. This module is in charge of scheduling cluster data and usually consists of three PD nodes. PD provides high availability through the etcd cluster. In the etcd cluster, TiCDC stores its metadata, such as node status information and changefeed configurations.

As shown in the preceding architecture diagram, TiCDC supports replicating data to TiDB, MySQL, and Kafka databases.

#### 13.9.1.4 Best practices

- When you use TiCDC to replicate data between two TiDB clusters and the network latency between the clusters is higher than 100 ms, it is recommended that you deploy TiCDC in the region (IDC) where the downstream TiDB cluster is located.
- TiCDC only replicates the table that has at least one **valid index**. A **valid index** is defined as follows:
  - A primary key (**PRIMARY KEY**) is a valid index.
  - A unique index (**UNIQUE INDEX**) is valid if every column of the index is explicitly defined as non-nullable (**NOT NULL**) and the index does not have the virtual generated column (**VIRTUAL GENERATED COLUMNS**).
- To use TiCDC in disaster recovery scenarios, you need to configure **redo log**.
- When you replicate a wide table with a large single row (greater than 1K), it is recommended that you configure **per-table-memory-quota** so that **per-table-memory- $\rightarrow$  quota = ticdcTotalMemory / (tableCount \* 2)**. **ticdcTotalMemory** is the memory of a TiCDC node, and **tableCount** is the number of target tables that a TiCDC node replicates.

#### Note:

Since v4.0.8, TiCDC supports replicating tables **without a valid index** by modifying the task configuration. However, this compromises the guarantee of data consistency to some extent. For more details, see [Replicate tables without a valid index](#).

#### 13.9.1.4.1 Unsupported scenarios

Currently, the following scenarios are not supported:

- The TiKV cluster that uses RawKV alone.
- The **DDL operation CREATE SEQUENCE** and the **SEQUENCE function** in TiDB. When the upstream TiDB uses **SEQUENCE**, TiCDC ignores **SEQUENCE** DDL operations/functions performed upstream. However, DML operations using **SEQUENCE** functions can be correctly replicated.

TiCDC only provides partial support for scenarios of large transactions in the upstream. For details, refer to [Does TiCDC support replicating large transactions? Is there any risk?](#).

### 13.9.2 Deploy and Maintain TiCDC

This document describes how to deploy and maintain a TiCDC cluster, including the hardware and software recommendations. You can either deploy TiCDC along with a new TiDB cluster or add the TiCDC component to an existing TiDB cluster.

#### 13.9.2.1 Software and hardware recommendations

In production environments, the recommendations of software and hardware for TiCDC are as follows:

Linux OS	Version
Red Hat Enterprise Linux	7.3 or later versions
CentOS	7.3 or later versions

---

CPU	Memory	Disk type	Network	Number of TiCDC cluster instances (minimum requirements for production environment)
16 core+	64 GB+	SSD	10 Giga-bit network card (2 preferred)	2

---

For more information, see [Software and Hardware Recommendations](#).

### 13.9.2.2 Deploy a new TiDB cluster that includes TiCDC using TiUP

When you deploy a new TiDB cluster using TiUP, you can also deploy TiCDC at the same time. You only need to add the `cdc_servers` section in the configuration file that TiUP uses to start the TiDB cluster. The following is an example:

```
cdc_servers:
- host: 10.0.1.20
 gc-ttl: 86400
 data_dir: "/cdc-data"
- host: 10.0.1.21
```

```
gc-ttl: 86400
data_dir: "/cdc-data"
```

More references:

- For detailed operations, see [Edit the initialization configuration file](#).
- For detailed configurable fields, see [Configure `cdc\_servers` using TiUP](#).
- For detailed steps to deploy a TiDB cluster, see [Deploy a TiDB Cluster Using TiUP](#).

**Note:**

Before installing TiCDC, ensure that you have [manually configured the SSH mutual trust and sudo without password](#) between the TiUP control machine and the TiCDC host.

### 13.9.2.3 Add or scale out TiCDC to an existing TiDB cluster using TiUP

The method of scaling out a TiCDC cluster is similar to that of deploying one. It is recommended to use TiUP to perform the scale-out.

1. Create a `scale-out.yml` file to add the TiCDC node information. The following is an example:

```
cdc_servers:
- host: 10.1.1.1
 gc-ttl: 86400
 data_dir: /tidb-data/cdc-8300
- host: 10.1.1.2
 gc-ttl: 86400
 data_dir: /tidb-data/cdc-8300
- host: 10.0.1.4
 gc-ttl: 86400
 data_dir: /tidb-data/cdc-8300
```

2. Run the scale-out command on the TiUP control machine:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

For more use cases, see [Scale out a TiCDC cluster](#).

### 13.9.2.4 Delete or scale in TiCDC from an existing TiDB cluster using TiUP

It is recommended that you use TiUP to scale in TiCDC nodes. The following is the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

For more use cases, see [Scale in a TiCDC cluster](#).

### 13.9.2.5 Upgrade TiCDC using TiUP

You can upgrade TiDB clusters using TiUP, during which TiCDC is upgraded as well. After you execute the upgrade command, TiUP automatically upgrades the TiCDC component. The following is an example:

```
tiup update --self && \
tiup update --all && \
tiup cluster upgrade <cluster-name> <version> --transfer-timeout 600
```

#### Note:

In the preceding command, you need to replace `<cluster-name>` and `<version>` with the actual cluster name and cluster version. For example, the version can be `v6.6.0`.

#### 13.9.2.5.1 Upgrade cautions

When you upgrade a TiCDC cluster, you need to pay attention to the following:

- TiCDC v4.0.2 reconfigured `changefeed`. For details, see [Configuration file compatibility notes](#).
- If you encounter any problem during the upgrade, you can refer to [upgrade FAQs](#) for solutions.
- Since v6.3.0, TiCDC supports rolling upgrade. During the upgrade, the replication latency is stable and does not fluctuate significantly. Rolling upgrade takes effect automatically if the following conditions are met:
  - TiCDC is v6.3.0 or later.
    - TiUP is v1.11.3 or later.
    - At least two TiCDC instances are running in the cluster.

### 13.9.2.6 Modify TiCDC cluster configurations using TiUP

This section describes how to use the `tiup cluster edit-config` command to modify the configurations of TiCDC. In the following example, it is assumed that you need to change the default value of `gc-ttl` from 86400 to 172800 (48 hours).

1. Run the `tiup cluster edit-config` command. Replace `<cluster-name>` with the actual cluster name:

```
shell tiup cluster edit-config <cluster-name>
```

2. In the vi editor, modify the `cdc server-configs`:

```
server_configs:
 tidb: {}
 tikv: {}
 pd: {}
 tiflash: {}
 tiflash-learner: {}
 pump: {}
 drainer: {}
 cdc:
 gc-ttl: 172800
```

In the preceding command, `gc-ttl` is set to 48 hours.

3. Run the `tiup cluster reload -R cdc` command to reload the configuration.

### 13.9.2.7 Stop and start TiCDC using TiUP

You can use TiUP to easily stop and start TiCDC nodes. The commands are as follows:

- Stop TiCDC: `tiup cluster stop -R cdc`
- Start TiCDC: `tiup cluster start -R cdc`
- Restart TiCDC: `tiup cluster restart -R cdc`

### 13.9.2.8 Enable TLS for TiCDC

See [Enable TLS Between TiDB Components](#).

### 13.9.2.9 View TiCDC status using the command-line tool

Run the following command to view the TiCDC cluster status. Note that you need to replace `v<CLUSTER_VERSION>` with the TiCDC cluster version, such as `v6.5.0`:

```
tiup ctl:v<CLUSTER_VERSION> cdc capture list --server=http://10.0.10.25:8300
```

```
[
 {
 "id": "806e3a1b-0e31-477f-9dd6-f3f2c570abdd",
 "is-owner": true,
 "address": "127.0.0.1:8300",
 "cluster-id": "default"
 },
 {
 "id": "ea2a4203-56fe-43a6-b442-7b295f458ebc",
 "is-owner": false,
 "address": "127.0.0.1:8301",
 "cluster-id": "default"
 }
]
```

- `id`: Indicates the ID of the service process.
- `is-owner`: Indicates whether the service process is the owner node.
- `address`: Indicates the address via which the service process provides interface to the outside.
- `cluster-id`: Indicates the ID of the TiCDC cluster. The default value is `default`.

### 13.9.3 Changefeed

#### 13.9.3.1 Changefeed Overview

A changefeed is a replication task in TiCDC, which replicates the data change logs of specified tables in a TiDB cluster to the designated downstream. You can run and manage multiple changefeeds in a TiCDC cluster.

##### 13.9.3.1.1 Changefeed state transfer

The state of a replication task represents the running status of the replication task. During the running of TiCDC, replication tasks might fail with errors, be manually paused, resumed, or reach the specified `TargetTs`. These behaviors can lead to the change of the replication task state. This section describes the states of TiCDC replication tasks and the transfer relationships between states.

Figure 276: TiCDC state transfer

The states in the preceding state transfer diagram are described as follows:

- **Normal**: The replication task runs normally and the checkpoint-ts proceeds normally.
- **Stopped**: The replication task is stopped, because the user manually pauses the changefeed. The changefeed in this state blocks GC operations.
- **Error**: The replication task returns an error. The replication cannot continue due to some recoverable errors. The changefeed in this state keeps trying to resume until the state transfers to **Normal**. The changefeed in this state blocks GC operations.
- **Finished**: The replication task is finished and has reached the preset **TargetTs**. The changefeed in this state does not block GC operations.
- **Failed**: The replication task fails. Due to some unrecoverable errors, the replication task cannot resume and cannot be recovered. The changefeed in this state does not block GC operations.

The numbers in the preceding state transfer diagram are described as follows.

- Run the `changefeed pause` command.
- Run the `changefeed resume` command to resume the replication task.
- Recoverable errors occur during the `changefeed` operation, and the operation is resumed automatically.
- Run the `changefeed resume` command to resume the replication task.

- Unrecoverable errors occur during the `changefeed` operation.
- `changefeed` has reached the preset `TargetTs`, and the replication is automatically stopped.
- `changefeed` suspended longer than the duration specified by `gc-ttl`, and cannot be resumed.
- `changefeed` experienced an unrecoverable error when trying to execute automatic recovery.

### 13.9.3.1.2 Operate changefeeds

You can manage a TiCDC cluster and its replication tasks using the command-line tool `cdc cli`. For details, see [Manage TiCDC changefeeds](#).

You can also use the HTTP interface (the TiCDC OpenAPI feature) to manage a TiCDC cluster and its replication tasks. For details, see [TiCDC OpenAPI](#).

If your TiCDC is deployed using TiUP, you can start `cdc cli` by running the `tiup ctl`  $\hookrightarrow$  `:v<CLUSTER_VERSION> cdc` command. Replace `v<CLUSTER_VERSION>` with the TiCDC cluster version, such as `v6.5.0`. You can also run `cdc cli` directly.

## 13.9.3.2 Create Changefeeds

### 13.9.3.2.1 Replicate Data to MySQL-compatible Databases

This document describes how to replicate incremental data to the downstream TiDB database or other MySQL-compatible databases using TiCDC. It also introduces how to use the eventually consistent replication feature in disaster scenarios.

Create a replication task

Create a replication task by running the following command:

```
cdc cli changefeed create \
 --server=http://10.0.10.25:8300 \
 --sink-uri="mysql://root:123456@127.0.0.1:3306/" \
 --changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"mysql://root:123456@127.0.0.1:3306/","opts":{},"create-
 \hookrightarrow time":"2020-03-12T22:04:08.103600025+08:00","start-ts
 \hookrightarrow ":415241823337054209,"target-ts":0,"admin-job-type":0,"sort-engine": "
 \hookrightarrow unified","sort-dir":".","config":{"case-sensitive":true,"filter":{"
 \hookrightarrow rules":["*.*"],"ignore-txn-start-ts":null,"ddl-allow-list":null},"
 \hookrightarrow mounter":{"worker-num":16},"sink":{"dispatchers":null},"scheduler":{"
 \hookrightarrow type":"table-number","polling-time":-1},"state":"normal","history":
 \hookrightarrow null,"error":null}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the replication task. The format must match the `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. For details, see [Configure sink URI with mysql/tidb](#).
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the changefeed configuration file. For details, see [TiCDC Changefeed Configuration Parameters](#).

### Configure sink URI for MySQL or TiDB

Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[userinfo@][host]:[port] [/path]?[query_parameters]
```

#### Note:

`/path` is not used for the MySQL sink.

### Sample configuration for MySQL:

```
--sink-uri="mysql://root:123456@127.0.0.1:3306"
```

The following are descriptions of sink URI parameters and parameter values that can be configured for MySQL or TiDB:

Parameter/Parameter value	Description
<code>root</code>	The username of the downstream database.
<code>123456</code>	The password of the downstream database (can be encoded using Base64).
<code>127.0.0.1</code>	The IP address of the downstream database.
<code>3306</code>	The port for the downstream data.
<code>worker-count</code>	The number of SQL statements that can be concurrently executed to the downstream (optional, 16 by default).

Parameter/Parameter value	Description
<code>max-txn-row</code>	The size of a transaction batch that can be executed to the downstream (optional, 256 by default).
<code>ssl-ca</code>	The path of the CA certificate file needed to connect to the downstream MySQL instance (optional).
<code>ssl-cert</code>	The path of the certificate file needed to connect to the downstream MySQL instance (optional).
<code>ssl-key</code>	The path of the certificate key file needed to connect to the downstream MySQL instance (optional).
<code>time-zone</code>	The time zone used when connecting to the downstream MySQL instance, which is effective since v4.0.8. This is an optional parameter. If this parameter is not specified, the time zone of TiCDC service processes is used. If this parameter is set to an empty value, no time zone is specified when TiCDC connects to the downstream MySQL instance and the default time zone of the downstream is used.
<code>transaction-atomicity</code>	The atomicity level of a transaction. This is an optional parameter, with the default value of <code>none</code> . When the value is <code>table</code> , TiCDC ensures the atomicity of a single-table transaction. When the value is <code>none</code> , TiCDC splits the single-table transaction.

To encode the database password in the sink URI using Base64, use the following command:

```
echo -n '123456' | base64 # '123456' is the password to be encoded.
```

The encoded password is MTIzNDU2:

```
MTIzNDU2
```

### Note:

When the sink URI contains special characters such as `! * ' ( ) ; : @ & ↵ = + $ , / ? % # [ ]`, you need to escape the special characters, for example, in [URI Encoder](#).

Eventually consistent replication in disaster scenarios

Starting from v6.1.1, this feature becomes GA. Starting from v5.3.0, TiCDC supports backing up incremental data from an upstream TiDB cluster to an object storage or an NFS of the downstream cluster. When the upstream cluster encounters a disaster and becomes unavailable, TiCDC can restore the downstream data to the recent eventually consistent state. This is the eventually consistent replication capability provided by TiCDC. With this capability, you can switch applications to the downstream cluster quickly, avoiding long-time downtime and improving service continuity.

Currently, TiCDC can replicate incremental data from a TiDB cluster to another TiDB cluster or a MySQL-compatible database system (including Aurora, MySQL, and MariaDB). In case the upstream cluster crashes, TiCDC can restore data in the downstream cluster within 5 minutes, given the conditions that TiCDC replicates data normally before the crash, and the replication lag is small. It allows data loss of 10s at most, that is, RTO  $\leq$  5 min, and P95 RPO  $\leq$  10s.

TiCDC replication lag increases in the following scenarios:

- The TPS increases significantly in a short time.
- Large or long transactions occur in the upstream.
- The TiKV or TiCDC cluster in the upstream is reloaded or upgraded.
- Time-consuming DDL statements, such as `add index`, are executed in the upstream.
- The PD is configured with aggressive scheduling strategies, resulting in frequent transfer of Region leaders, or frequent Region merge or Region split.

#### Note:

Starting from v6.1.1, the eventually consistent replication feature of TiCDC supports Amazon S3-compatible object storage. Starting from v6.1.4, this feature supports GCS- and Azure-compatible object storage.

#### Prerequisites

- Prepare a highly available object storage or NFS for storing TiCDC's real-time incremental data backup files. These files can be accessed in case of a disaster in the upstream.
- Enable this feature for changefeeds that need to have eventual consistency in disaster scenarios. To enable it, you can add the following configuration to the changefeed configuration file.

```
[consistent]
Consistency level. Options include:
```

```
- none: the default value. In a non-disaster scenario, eventual
 ↳ consistency is only guaranteed if and only if finished-ts is
 ↳ specified.
- eventual: Uses redo log to guarantee eventual consistency in case of
 ↳ the primary cluster disasters.
level = "eventual"

Individual redo log file size, in MiB. By default, it's 64. It is
 ↳ recommended to be no more than 128.
max-log-size = 64

The interval for flushing or uploading redo logs to Amazon S3, in
 ↳ milliseconds. It is recommended that this configuration be equal to
 ↳ or greater than 2000.
flush-interval = 2000

The path under which redo log backup is stored. The scheme can be nfs
 ↳ (NFS directory), or Amazon S3, GCS, and Azure (uploaded to object
 ↳ storage).
storage = "$SCHEME://logbucket/test-changefeed?endpoint=http://$ENDPOINT/"
```

## Disaster recovery

When a disaster happens in the primary cluster, you need to recover manually in the secondary cluster by running the `cdc redo` command. The recovery process is as follows.

1. Ensure that all the TiCDC processes have exited. This is to prevent the primary cluster from resuming service during data recovery and prevent TiCDC from restarting data synchronization.
2. Use `cdc` binary for data recovery. Run the following command:

```
cdc redo apply --tmp-dir="/tmp/cdc/redo/apply" \
 --storage="s3://logbucket/test-changefeed?endpoint=http
 ↳ ://10.0.10.25:24927/" \
 --sink-uri="mysql://normal:123456@10.0.10.55:3306/"
```

In this command:

- **tmp-dir**: Specifies the temporary directory for downloading TiCDC incremental data backup files.
- **storage**: Specifies the address for storing the TiCDC incremental data backup files, either an URI of object storage or an NFS directory.
- **sink-uri**: Specifies the secondary cluster address to restore the data to. Scheme can only be `mysql`.

### 13.9.3.2.2 Replicate Data to Kafka

This document describes how to create a changefeed that replicates incremental data to Apache Kafka using TiCDC.

Create a replication task

Create a replication task by running the following command:

```
cdc cli changefeed create \
 --server=http://10.0.10.25:8300 \
 --sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=canal-json&kafka-
 ↪ version=2.4.0&partition-num=6&max-message-bytes=67108864&
 ↪ replication-factor=1" \
 --changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"kafka://127.0.0.1:9092/topic-name?protocol=canal-json&
 ↪ kafka-version=2.4.0&partition-num=6&max-message-bytes=67108864&
 ↪ replication-factor=1","opts":{},"create-time":"2020-03-12T22
 ↪ :04:08.103600025+08:00","start-ts":415241823337054209,"target-ts":0,"
 ↪ admin-job-type":0,"sort-engine":"unified","sort-dir":".","config":{"
 ↪ case-sensitive":true,"filter":{"rules":["*.*"],"ignore-txn-start-ts":
 ↪ null,"ddl-allow-list":null},"mounter":{"worker-num":16},"sink":{"
 ↪ dispatchers":null},"scheduler":{"type":"table-number","polling-time
 ↪ ":-1}},"state":"normal","history":null,"error":null}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the replication task. The format must match the `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. For details, see [Configure sink URI with kafka](#).
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the changefeed configuration file. For details, see [TiCDC Changefeed Configuration Parameters](#).

Configure sink URI for Kafka

Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
```

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=canal-json&kafka-
↳ version=2.4.0&partition-num=6&max-message-bytes=67108864&replication-
↳ factor=1"
```

The following are descriptions of sink URI parameters and values that can be configured for Kafka:

Parameter/Parameter value	Description
127.0.0.1	The IP address of the downstream Kafka services.
9092	The port for the downstream Kafka.
topic-name	Variable. The name of the Kafka topic.
kafka-version	The version of the downstream Kafka (optional, 2.4.0 by default. Currently, the earliest supported Kafka version is 0.11.0.2 and the latest one is 3.2.0. This value needs to be consistent with the actual version of the downstream Kafka).
kafka-client-id	Specifies the Kafka client ID of the replication task (optional. TiCDC_sarama_producer_replication ID by default).
partition-num	The number of the downstream Kafka partitions (optional. The value must be <b>no greater than</b> the actual number of partitions; otherwise, the replication task cannot be created successfully. 3 by default).
max-message-bytes	The maximum size of data that is sent to Kafka broker each time (optional, 10MB by default). From v5.0.6 and v4.0.6, the default value has changed from 64MB and 256MB to 10MB.
replication- ↳ factor	The number of Kafka message replicas that can be saved (optional, 1 by default).
required-acks	A parameter used in the <b>Produce</b> request, which notifies the broker of the number of replica acknowledgements it needs to receive before responding. Value options are 0 ( <b>NoResponse</b> : no response, only TCP ACK is provided), 1 ( <b>WaitForLocal</b> : responds only after local commits are submitted successfully), and -1 ( <b>WaitForAll</b> : responds after all replicated replicas are committed successfully. You can configure the minimum number of replicated replicas using the <a href="#">min.insync.replicas</a> configuration item of the broker). (Optional, the default value is -1).
compression	The compression algorithm used when sending messages (value options are none, lz4, gzip, snappy, and zstd; none by default).

Parameter/Parameter value	Description
<code>protocol</code>	The protocol with which messages are output to Kafka. The value options are <code>canal-json</code> , <code>open-protocol</code> , <code>canal</code> , <code>avro</code> and <code>maxwell</code> .
<code>auto-create-topic</code>	Determines whether TiCDC creates the topic automatically when the <code>topic-name</code> passed in does not exist in the Kafka cluster (optional, <code>true</code> by default).
<code>enable-tidb- ↪ extension</code>	Optional. <code>false</code> by default. When the output protocol is <code>canal-json</code> , if the value is <code>true</code> , TiCDC sends Resolved events and adds the TiDB extension field to the Kafka message. From v6.1.0, this parameter is also applicable to the <code>avro</code> protocol. If the value is <code>true</code> , TiCDC adds <b>three TiDB extension fields</b> to the Kafka message.
<code>max-batch-size</code>	New in v4.0.9. If the message protocol supports outputting multiple data changes to one Kafka message, this parameter specifies the maximum number of data changes in one Kafka message. It currently takes effect only when Kafka's <code>protocol</code> is <code>open-protocol</code> (optional, <code>16</code> by default).
<code>enable-tls</code>	Whether to use TLS to connect to the downstream Kafka instance (optional, <code>false</code> by default).
<code>ca</code>	The path of the CA certificate file needed to connect to the downstream Kafka instance (optional).
<code>cert</code>	The path of the certificate file needed to connect to the downstream Kafka instance (optional).
<code>key</code>	The path of the certificate key file needed to connect to the downstream Kafka instance (optional).
<code>sasl-user</code>	The identity (authcid) of SASL/PLAIN or SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional).
<code>sasl-password</code>	The password of SASL/PLAIN or SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional). If it contains special characters, they need to be URL encoded.
<code>sasl-mechanism</code>	The name of SASL authentication needed to connect to the downstream Kafka instance. The value can be <code>plain</code> , <code>scram-sha-256</code> , <code>scram-sha-512</code> , or <code>gssapi</code> .
<code>sasl-gssapi-auth- ↪ type</code>	The gssapi authentication type. Values can be <code>user</code> or <code>keytab</code> (optional).
<code>sasl-gssapi- ↪ keytab-path</code>	The gssapi keytab path (optional).
<code>sasl-gssapi- ↪ kerberos- ↪ config-path</code>	The gssapi kerberos configuration path (optional).

Parameter/Parameter value	Description
<code>sasl-gssapi-</code> ↪ <code>service-name</code>	The gssapi service name (optional).
<code>sasl-gssapi-user</code>	The user name of gssapi authentication (optional).
<code>sasl-gssapi-</code> ↪ <code>password</code>	The password of gssapi authentication (optional). If it contains special characters, they need to be URL encoded.
<code>sasl-gssapi-realm</code>	The gssapi realm name (optional).
<code>sasl-gssapi-</code> ↪ <code>disable-</code> ↪ <code>pafxfast</code>	Whether to disable the gssapi PA-FX-FAST (optional).
<code>dial-timeout</code>	The timeout in establishing a connection with the downstream Kafka. The default value is <code>10s</code> .
<code>read-timeout</code>	The timeout in getting a response returned by the downstream Kafka. The default value is <code>10s</code> .
<code>write-timeout</code>	The timeout in sending a request to the downstream Kafka. The default value is <code>10s</code> .
<code>avro-decimal-</code> ↪ <code>handling-mode</code>	Only effective with the <code>avro</code> protocol. Determines how Avro handles the <code>DECIMAL</code> field. The value can be <code>string</code> or <code>precise</code> , indicating either mapping the <code>DECIMAL</code> field to a string or a precise floating number.
<code>avro-bigint-</code> ↪ <code>unsigned-</code> ↪ <code>handling-mode</code>	Only effective with the <code>avro</code> protocol. Determines how Avro handles the <code>BIGINT UNSIGNED</code> field. The value can be <code>string</code> or <code>long</code> , indicating either mapping the <code>BIGINT UNSIGNED</code> field to a 64-bit signed number or a string.

### Best practices

- It is recommended that you create your own Kafka Topic. At a minimum, you need to set the maximum amount of data of each message that the Topic can send to the Kafka broker, and the number of downstream Kafka partitions. When you create a changefeed, these two settings correspond to `max-message-bytes` and `partition-num`, respectively.
- If you create a changefeed with a Topic that does not yet exist, TiCDC will try to create the Topic using the `partition-num` and `replication-factor` parameters. It is recommended that you specify these parameters explicitly.
- In most cases, it is recommended to use the `canal-json` protocol.

### Note:

When `protocol` is `open-protocol`, TiCDC tries to avoid generating messages that exceed `max-message-bytes` in length. However, if a row is so large that

a single change alone exceeds `max-message-bytes` in length, to avoid silent failure, TiCDC tries to output this message and prints a warning in the log.

TiCDC uses the authentication and authorization of Kafka

The following are examples when using Kafka SASL authentication:

- SASL/PLAIN

```
shell --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-user=alice-user&sasl-password=alice-secret&sasl-mechanism=plain"
```

- SASL/SCRAM

SCRAM-SHA-256 and SCRAM-SHA-512 are similar to the PLAIN method. You just need to specify `sasl-mechanism` as the corresponding authentication method.

- SASL/GSSAPI

SASL/GSSAPI user authentication:

```
shell --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-mechanism=gssapi&sasl-gssapi-auth-type=user&sasl-gssapi-kerberos-
↪ config-path=/etc/krb5.conf&sasl-gssapi-service-name=kafka&sasl-gssapi-
↪ user=alice/for-kafka&sasl-gssapi-password=alice-secret&sasl-gssapi-realm
↪ =example.com"
```

Values of `sasl-gssapi-user` and `sasl-gssapi-realm` are related to the [principle](#) specified in kerberos. For example, if the principle is set as `alice/for-kafka@example.com`, then `sasl-gssapi-user` and `sasl-gssapi-realm` are specified as `alice/for-kafka` and `example.com` respectively.

SASL/GSSAPI keytab authentication:

```
shell --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-mechanism=gssapi&sasl-gssapi-auth-type=keytab&sasl-gssapi-kerberos
↪ -config-path=/etc/krb5.conf&sasl-gssapi-service-name=kafka&sasl-gssapi-
↪ user=alice/for-kafka&sasl-gssapi-keytab-path=/var/lib/secret/alice.key&
↪ sasl-gssapi-realm=example.com"
```

For more information about SASL/GSSAPI authentication methods, see [Configuring GSSAPI](#).

- TLS/SSL encryption

If the Kafka broker has TLS/SSL encryption enabled, you need to add the `-enable`  $\hookrightarrow$  `-tls=true` parameter to `--sink-uri`. If you want to use self-signed certificates, you also need to specify `ca`, `cert` and `key` in `--sink-uri`.

- ACL authorization

The minimum set of permissions required for TiCDC to function properly is as follows.

- The `Create` and `Write` permissions for the Topic [resource type](#).
- The `DescribeConfigs` permission for the Cluster resource type.

### Integrate TiCDC with Kafka Connect (Confluent Platform)

To use the [data connectors](#) provided by Confluent to stream data to relational or non-relational databases, you need to use the `avro` protocol and provide a URL for [Confluent Schema Registry](#) in `schema-registry`.

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?&protocol=avro&replication-
 \hookrightarrow factor=3" --schema-registry="http://127.0.0.1:8081" --config
 \hookrightarrow changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
]
```

For detailed integration guide, see [Quick Start Guide on Integrating TiDB with Confluent Platform](#).

Customize the rules for Topic and Partition dispatchers of Kafka Sink

Matcher rules

In the example of the previous section:

- For the tables that match the matcher rule, they are dispatched according to the policy specified by the corresponding topic expression. For example, the `test3.aa` table is dispatched according to “Topic expression 2”; the `test5.aa` table is dispatched according to “Topic expression 3”.
- For a table that matches multiple matcher rules, it is dispatched according to the first matching topic expression. For example, the `test1.aa` table is distributed according to “Topic expression 1”.
- For tables that do not match any matcher rule, the corresponding data change events are sent to the default topic specified in `--sink-uri`. For example, the `test10.aa` table is sent to the default topic.

- For tables that match the matcher rule but do not specify a topic dispatcher, the corresponding data changes are sent to the default topic specified in `--sink-uri`. For example, the `test6.aa` table is sent to the default topic.

### Topic dispatchers

You can use `topic = "xxx"` to specify a Topic dispatcher and use topic expressions to implement flexible topic dispatching policies. It is recommended that the total number of topics be less than 1000.

The format of the Topic expression is `[prefix]{schema}[middle][{table}][suffix]`.

- `prefix`: optional. Indicates the prefix of the Topic Name.
- `{schema}`: required. Used to match the schema name.
- `middle`: optional. Indicates the delimiter between schema name and table name.
- `{table}`: optional. Used to match the table name.
- `suffix`: optional. Indicates the suffix of the Topic Name.

`prefix`, `middle` and `suffix` can only include the following characters: `a-z`, `A-Z`, `0-9`, `.`, `_` and `-`. `{schema}` and `{table}` are both lowercase. Placeholders such as `{Schema}` and `{TABLE}` are invalid.

Some examples:

- `matcher = ['test1.table1', 'test2.table2'], topic = "hello_{schema}_{table}"`
  - The data change events corresponding to `test1.table1` are sent to the topic named `hello_test1_table1`.
  - The data change events corresponding to `test2.table2` are sent to the topic named `hello_test2_table2`.
- `matcher = ['test3.*', 'test4.*'], topic = "hello_{schema}_world"`
  - The data change events corresponding to all tables in `test3` are sent to the topic named `hello_test3_world`.
  - The data change events corresponding to all tables in `test4` are sent to the topic named `hello_test4_world`.
- `matcher = ['*.*'], topic = "{schema}_{table}"`
  - All tables listened by TiCDC are dispatched to separate topics according to the “`schema_table`” rule. For example, for the `test.account` table, TiCDC dispatches its data change log to a Topic named `test_account`.

### Dispatch DDL events

#### Schema-level DDLs

DDLs that are not related to a specific table are called schema-level DDLs, such as `create database` and `drop database`. The events corresponding to schema-level DDLs are sent to the default topic specified in `--sink-uri`.

#### Table-level DDLs

DDLs that are related to a specific table are called table-level DDLs, such as `alter table` and `create table`. The events corresponding to table-level DDLs are sent to the corresponding topic according to dispatcher configurations.

For example, for a dispatcher like `matcher = ['test.*'], topic = {schema}_{table}`, DDL events are dispatched as follows:

- If a single table is involved in the DDL event, the DDL event is sent to the corresponding topic as is. For example, for the DDL event `drop table test.table1`, the event is sent to the topic named `test_table1`.
- If multiple tables are involved in the DDL event (`rename table / drop table / drop view` may involve multiple tables), the DDL event is split into multiple events and sent to the corresponding topics. For example, for the DDL event `rename table test.table1 to test.table10, test.table2 to test.table20`, the event `rename table test.table1 to test.table10` is sent to the topic named `test_table1` and the event `rename table test.table2 to test.table20` is sent to the topic named `test.table2`.

#### Partition dispatchers

You can use `partition = "xxx"` to specify a partition dispatcher. It supports four dispatchers: `default`, `ts`, `index-value`, and `table`. The dispatcher rules are as follows:

- `default`: When multiple unique indexes (including the primary key) exist or the Old Value feature is enabled, events are dispatched in the `table` mode. When only one unique index (or the primary key) exists, events are dispatched in the `index-value` mode.
- `ts`: Use the commitTs of the row change to hash and dispatch events.
- `index-value`: Use the value of the primary key or the unique index of the table to hash and dispatch events.
- `table`: Use the schema name of the table and the table name to hash and dispatch events.

#### Note:

Since v6.1.0, to clarify the meaning of the configuration, the configuration used to specify the partition dispatcher has been changed from `dispatcher` to `partition`, with `partition` being an alias for `dispatcher`. For example, the following two rules are exactly equivalent.

```
[sink]
dispatchers = [
 {matcher = ['*.*'], dispatcher = "ts"},
 {matcher = ['*.*'], partition = "ts"},
]
```

However, `dispatcher` and `partition` cannot appear in the same rule. For example, the following rule is invalid.

```
{matcher = ['*.*'], dispatcher = "ts", partition = "table"},
```

Scale out the load of a single large table to multiple TiCDC nodes

This feature splits a single large table into multiple data ranges based on the number of Regions, and distributes these data ranges to multiple TiCDC nodes so that multiple TiCDC nodes can replicate the large single table at the same time. This feature can solve the following two problems:

- A single TiCDC node cannot replicate a large single table in time.
- The resources (such as CPU and memory) consumed by TiCDC nodes are not evenly distributed.

### Warning:

- Scaling out a single large table is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an [issue](#) on GitHub.
- TiCDC v6.6.0 only supports scaling out a large single table on Kafka changefeeds.

Sample configuration:

```
[scheduler]
region-per-span = 50000
```

### 13.9.3.2.3 Replicate Data to Storage Services

**Warning:**

This feature is experimental. It is not recommended to use it in the production environment.

Since v6.5.0, TiCDC supports saving row change events to storage services, including Amazon S3, Azure Blob Storage, and NFS. This document describes how to create a change-feed that replicates incremental data to such storage services using TiCDC, and how data is stored. The organization of this document is as follows:

- [How to replicate data to storage services.](#)
- [How data is stored in storage services.](#)

Replicate change data to storage services

Run the following command to create a changefeed task:

```
cdc cli changefeed create \
 --server=http://10.0.10.25:8300 \
 --sink-uri="s3://logbucket/storage_test?protocol=canal-json" \
 --changefeed-id="simple-replication-task"
```

The output is as follows:

```
Info: {"upstream_id":7171388873935111376,"namespace":"default","id":"simple-
 ↪ replication-task","sink_uri":"s3://logbucket/storage_test?protocol=
 ↪ canal-json","create_time":"2022-11-29T18:52:05.566016967+08:00","
 ↪ start_ts":437706850431664129,"engine":"unified","config":{"
 ↪ case_sensitive":true,"enable_old_value":true,"force_replicate":false
 ↪ ,"ignore_ineligible_table":false,"check_gc_safe_point":true,"
 ↪ enable_sync_point":false,"sync_point_interval":600000000000,"
 ↪ sync_point_retention":8640000000000,"filter":{"rules":["*.*"],"
 ↪ event_filters":null},"mounter":{"worker_num":16},"sink":{"protocol":
 ↪ canal-json,"schema_registry":"","csv":{"delimiter":",","quote
 ↪ ":"\"","null":"\\N","include_commit_ts":false},"column_selectors":
 ↪ null,"transaction_atomicity":"none","encoder_concurrency":16,"
 ↪ terminator":"\r\n","date_separator":"none","
 ↪ enable_partition_separator":false},"consistent":{"level":"none","
 ↪ max_log_size":64,"flush_interval":2000,"storage":""}},"state":"normal
 ↪ ","creator_version":"v6.5.0-master-dirty"}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the changefeed. The format must match the `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the changefeed. For details, see [Configure sink URI](#).
- `--start-ts`: The starting TSO of the changefeed. TiCDC starts pulling data from this TSO. The default value is the current time.
- `--target-ts`: The ending TSO of the changefeed. TiCDC stops pulling data until this TSO. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: The configuration file of the changefeed. For details, see [TiCDC changefeed configuration parameters](#).

## Configure sink URI

This section describes how to configure storage services in the changefeed URI, including Amazon S3, Azure Blob Storage, and NFS.

### Configure Amazon S3 or Azure Blob Storage

The URI parameters of Amazon S3 and Azure Blob Storage in TiCDC are the same as their URL parameters in BR. For details, see [Backup storage URI format](#).

### Configure NFS

The following configuration saves row change events to NFS:

```
--sink-uri="file:///my-directory/prefix"
```

## Optional parameters

Other optional parameters in the URI are as follows:

Parameter	Description	Default value	Value range
<code>worker- ↪ count</code>	Concurrency for saving data changes to cloud storage in the downstream.	16	[1, 512]
<code>flush- ↪ interval ↪</code>	Interval for saving data changes to cloud storage in the downstream.	5s	[2s, 10m]

Parameter	Description	Default value	Value range
<code>file-size</code>	A data change file is stored to cloud storage if the number of bytes exceeds the value of this parameter.	67108864	[1048576, ↪ ↪ 536870912] ↪
<code>protocol</code>	The protocol format of the messages sent to the downstream.	N/A	<code>canal-</code> ↪ <code>json</code> and <code>csv</code>

### Note:

Data change files are saved to the downstream when either `flush-interval` or `file-size` meets the requirements.

### Storage path structure

This section describes the storage path structure of data change records, metadata, and DDL events.

#### Data change records

Data change records are saved to the following path:

```
{scheme}://{prefix}/{schema}/{table}/{table-version-separator}/{partition-
↪ separator}/{date-separator}/CDC{num}.{extension}
```

- **scheme**: specifies the data transmission protocol, or the storage type, for example, `s3://xxxxx`.
- **prefix**: specifies the user-defined parent directory, for example, `s3://bucket/bbb/ccc`.
- **schema**: specifies the schema name, for example, `s3://bucket/bbb/ccc/test`.

- **table**: specifies the table name, for example, `s3://bucket/bbb/ccc/test/table1`.
- **table-version-separator**: specifies the separator that separates the path by the table version, for example, `s3://bucket/bbb/ccc/test/table1/9999`.
- **partition-separator**: specifies the separator that separates the path by the table partition, for example, `s3://bucket/bbb/ccc/test/table1/9999/20`.
- **date-separator**: classifies the files by the transaction commit date. Value options are:
  - **none**: no **date-separator**. For example, all files with `test.table1` version being 9999 are saved to `s3://bucket/bbb/ccc/test/table1/9999`.
  - **year**: the separator is the year of the transaction commit date, for example, `s3://bucket/bbb/ccc/test/table1/9999/2022`.
  - **month**: the separator is the year and month of the transaction commit date, for example, `s3://bucket/bbb/ccc/test/table1/9999/2022-01`.
  - **day**: the separator is the year, month, and day of the transaction commit date, for example, `s3://bucket/bbb/ccc/test/table1/9999/2022-01-02`.
- **num**: saves the serial number of the file that records the data change, for example, `s3://bucket/bbb/ccc/test/table1/9999/2022-01-02/CDC000005.csv`.
- **extension**: specifies the extension of the file. TiDB v6.5.0 supports the CSV and Canal-JSON formats.

### Note:

The table version changes in the following two cases:

- After a DDL operation is performed, the table version is the TSO when the DDL is executed in the upstream TiDB. However, the change of the table version does not mean the change of the table schema. For example, adding a comment to a column does not cause the `schema.json` file content to change.
- The changefeed process restarts. The table version is the checkpoint TSO when the process restarts. When there are many tables and the process restarts, it takes a long time to traverse all directories and find the position where each table was written last time. Therefore, data is written to a new directory with the version being the checkpoint TSO, instead of to the earlier directory.

### Metadata

Metadata is saved in the following path:

```
{protocol}://{prefix}/metadata
```

Metadata is a JSON-formatted file, for example:

```
{
 "checkpoint-ts":433305438660591626
}
```

- `checkpoint-ts`: Transactions with `commit-ts` smaller than `checkpoint-ts` are written to the target storage in the downstream.

DDL events

When DDL events cause the table version to change, TiCDC switches to a new path to write data change records. For example, when the version of `test.table1` changes from 9999 to 10000, data will be written to the path `s3://bucket/bbb/ccc/test/table1 ↪ /10000/2022-01-02/CDC000001.csv`. In addition, when DDL events occur, TiCDC generates a `schema.json` file to save the table schema information.

Table schema information is saved in the following path:

```
{scheme}://{prefix}/{schema}/{table}/{table-version-separator}/schema.json
```

The following is a `schema.json` file:

```
{
 "Table": "table1",
 "Schema": "test",
 "Version": 1,
 "TableVersion": 10000,
 "Query": "ALTER TABLE test.table1 ADD OfficeLocation blob(20)",
 "TableColumns": [
 {
 "ColumnName": "Id",
 "ColumnType": "INT",
 "ColumnNullable": "false",
 "ColumnIsPk": "true"
 },
 {
 "ColumnName": "LastName",
 "ColumnType": "CHAR",
 "ColumnLength": "20"
 },
 {
 "ColumnName": "FirstName",
 "ColumnType": "VARCHAR",
 "ColumnLength": "30"
 },
 {
```

```
 "ColumnName": "HireDate",
 "ColumnType": "DATETIME"
 },
 {
 "ColumnName": "OfficeLocation",
 "ColumnType": "BLOB",
 "ColumnLength": "20"
 }
],
"TableColumnsTotal": "5"
}
```

- **Table:** Table name.
- **Schema:** Schema name.
- **Version:** Protocol version of the storage sink.
- **TableVersion:** Table version.
- **Query:** DDL statement.
- **TableColumns:** An array of one or more maps, each of which describes a column in the source table.
  - **ColumnName:** Column name.
  - **ColumnType:** Column type. For details, see [Data type](#).
  - **ColumnLength:** Column length. For details, see [Data type](#).
  - **ColumnPrecision:** Column precision. For details, see [Data type](#).
  - **ColumnScale:** The number of digits following the decimal point (the scale). For details, see [Data type](#).
  - **ColumnNullable:** The column can be NULL when the value of this option is true.
  - **ColumnIsPk:** The column is part of the primary key when the value of this option is true.
- **TableColumnsTotal:** The size of the `TableColumns` array.

## Data type

This section describes the data types used in the `schema.json` file. The data types are defined as `T(M[, D])`. For details, see [Data Types](#).

## Integer types

Integer types in TiDB are defined as `IT[(M)] [UNSIGNED]`, where

- `IT` is the integer type, which can be `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, `BIGINT`, or `BIT`.
- `M` is the display width of the type.

Integer types are defined as follows in `schema.json`:

```
{
 "ColumnName": "COL1",
 "ColumnType": "{IT} [UNSIGNED]",
 "ColumnPrecision": "{M}"
}
```

Decimal types

Decimal types in TiDB are defined as `DT[(M,D)] [UNSIGNED]`, where

- `DT` is the floating-point type, which can be `FLOAT`, `DOUBLE`, `DECIMAL`, or `NUMERIC`.
- `M` is the precision of the data type, or the total number of digits.
- `D` is the number of digits following the decimal point.

Decimal types are defined as follows in `schema.json`:

```
{
 "ColumnName": "COL1",
 "ColumnType": "{DT} [UNSIGNED]",
 "ColumnPrecision": "{M}",
 "ColumnScale": "{D}"
}
```

Date and time types

Date types in TiDB are defined as `DT`, where

- `DT` is the date type, which can be `DATE` or `YEAR`.

The date types are defined as follows in `schema.json`:

```
{
 "ColumnName": "COL1",
 "ColumnType": "{DT}"
}
```

The time types in TiDB are defined as `TT[(M)]`, where

- `TT` is the time type, which can be `TIME`, `DATETIME`, or `TIMESTAMP`.
- `M` is the precision of seconds in the range from 0 to 6.

The time types are defined as follows in `schema.json`:

```
{
 "ColumnName": "COL1",
 "ColumnType": "{TT}",
 "ColumnScale": "{M}"
}
```

### String types

The string types in TiDB are defined as `ST[(M)]`, where

- `ST` is the string type, which can be `CHAR`, `VARCHAR`, `TEXT`, `BINARY`, `BLOB`, or `JSON`.
- `M` is the maximum length of the string.

The string types are defined as follows in `schema.json`:

```
{
 "ColumnName": "COL1",
 "ColumnType": "{ST}",
 "ColumnLength": "{M}"
}
```

### Enum and Set types

The Enum and Set types are defined as follows in `schema.json`:

```
{
 "ColumnName": "COL1",
 "ColumnType": "{ENUM/SET}",
}
```

## 13.9.3.3 Manage Changefeeds

This document describes how to create and manage TiCDC changefeeds by using the TiCDC command-line tool `cdc cli`. You can also manage changefeeds via the HTTP interface of TiCDC. For details, see [TiCDC OpenAPI](#).

### 13.9.3.3.1 Create a replication task

Run the following command to create a replication task:

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
↪ task"
```

```

Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7178706266519722477,"namespace":"default","id":"simple-
 ↪ replication-task","sink_uri":"mysql://root:xxxxx@127.0.0.1:4000/?time
 ↪ -zone=","create_time":"2022-12-19T15:05:46.679218+08:00","start_ts
 ↪ ":438156275634929669,"engine":"unified","config":{"case_sensitive":
 ↪ true,"enable_old_value":true,"force_replicate":false,"
 ↪ ignore_ineligible_table":false,"check_gc_safe_point":true,"
 ↪ enable_sync_point":true,"bdr_mode":false,"sync_point_interval
 ↪ ":30000000000,"sync_point_retention":3600000000000,"filter":{"rules
 ↪ ":["test.*"],"event_filters":null},"mounter":{"worker_num":16},"sink
 ↪ ":{"protocol":"","schema_registry":"","csv":{"delimiter":"","quote
 ↪ ":"\\","null":"\\N","include_commit_ts":false},"column_selectors":
 ↪ null,"transaction_atomicity":"none","encoder_concurrency":16,"
 ↪ terminator":"\\r\\n","date_separator":"none","
 ↪ enable_partition_separator":false},"consistent":{"level":"none","
 ↪ max_log_size":64,"flush_interval":2000,"storage":""}},"state":"normal
 ↪ ","creator_version":"v6.5.0"}

```

### 13.9.3.3.2 Query the replication task list

Run the following command to query the replication task list:

```
cdc cli changefeed list --server=http://10.0.10.25:8300
```

```

[{"
 "id": "simple-replication-task",
 "summary": {
 "state": "normal",
 "tso": 417886179132964865,
 "checkpoint": "2020-07-07 16:07:44.881",
 "error": null
 }
}]

```

- **checkpoint** indicates that TiCDC has already replicated data before this time point to the downstream.
- **state** indicates the state of the replication task.
  - **normal**: The replication task runs normally.
  - **stopped**: The replication task is stopped (manually paused).
  - **error**: The replication task is stopped (by an error).
  - **removed**: The replication task is removed. Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, run the `changefeed query` command.

- **finished**: The replication task is finished (data is replicated to the `target-ts`). Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, run the `changefeed query` command.

### 13.9.3.3.3 Query a specific replication task

To query a specific replication task, run the `changefeed query` command. The query result includes the task information and the task state. You can specify the `--simple` or `-s` argument to simplify the query result that will only include the basic replication state and the checkpoint information. If you do not specify this argument, detailed task configuration, replication states, and replication table information are output.

```
cdc cli changefeed query -s --server=http://10.0.10.25:8300 --changefeed-id=
↳ simple-replication-task
```

```
{
 "state": "normal",
 "tso": 419035700154597378,
 "checkpoint": "2020-08-27 10:12:19.579",
 "error": null
}
```

In the preceding command and result:

- **state** is the replication state of the current changefeed. Each state must be consistent with the state in `changefeed list`.
- **tso** represents the largest transaction TSO in the current changefeed that has been successfully replicated to the downstream.
- **checkpoint** represents the corresponding time of the largest transaction TSO in the current changefeed that has been successfully replicated to the downstream.
- **error** records whether an error has occurred in the current changefeed.

```
cdc cli changefeed query --server=http://10.0.10.25:8300 --changefeed-id=
↳ simple-replication-task
```

```
{
 "info": {
 "sink-uri": "mysql://127.0.0.1:3306/?max-txn-row=20\u0026worker-number
 ↳ =4",
 "opts": {},
 "create-time": "2020-08-27T10:33:41.687983832+08:00",
 "start-ts": 419036036249681921,
 "target-ts": 0,
 "admin-job-type": 0,
 }
}
```

```
"sort-engine": "unified",
"sort-dir": ".",
"config": {
 "case-sensitive": true,
 "enable-old-value": false,
 "filter": {
 "rules": [
 "*.*"
],
 "ignore-txn-start-ts": null,
 "ddl-allow-list": null
 },
 "mounter": {
 "worker-num": 16
 },
 "sink": {
 "dispatchers": null,
 },
 "scheduler": {
 "type": "table-number",
 "polling-time": -1
 }
},
"state": "normal",
"history": null,
"error": null
},
"status": {
 "resolved-ts": 419036036249681921,
 "checkpoint-ts": 419036036249681921,
 "admin-job-type": 0
},
"count": 0,
"task-status": [
 {
 "capture-id": "97173367-75dc-490c-ae2d-4e990f90da0f",
 "status": {
 "tables": {
 "47": {
 "start-ts": 419036036249681921
 }
 }
 },
 "operation": null,
 "admin-job-type": 0
 }
]
```

```
}
]
}
```

In the preceding command and result:

- **info** is the replication configuration of the queried changefeed.
- **status** is the replication state of the queried changefeed.
  - **resolved-ts**: The largest transaction TS in the current changefeed. Note that this TS has been successfully sent from TiKV to TiCDC.
  - **checkpoint-ts**: The largest transaction TS in the current changefeed. Note that this TS has been successfully written to the downstream.
  - **admin-job-type**: The status of a changefeed:
    - \* 0: The state is normal.
    - \* 1: The task is paused. When the task is paused, all replicated processors exit. The configuration and the replication status of the task are retained, so you can resume the task from **checkpoint-ts**.
    - \* 2: The task is resumed. The replication task resumes from **checkpoint-ts**.
    - \* 3: The task is removed. When the task is removed, all replicated processors are ended, and the configuration information of the replication task is cleared up. Only the replication status is retained for later queries.
- **task-status** indicates the state of each replication sub-task in the queried changefeed.

#### 13.9.3.3.4 Pause a replication task

Run the following command to pause a replication task:

```
cdc cli changefeed pause --server=http://10.0.10.25:8300 --changefeed-id
↪ simple-replication-task
```

In the preceding command:

- **--changefeed-id=uuid** represents the ID of the changefeed that corresponds to the replication task you want to pause.

#### 13.9.3.3.5 Resume a replication task

Run the following command to resume a paused replication task:

```
cdc cli changefeed resume --server=http://10.0.10.25:8300 --changefeed-id
↪ simple-replication-task
```

- **--changefeed-id=uuid** represents the ID of the changefeed that corresponds to the replication task you want to resume.

- `--overwrite-checkpoint-ts`: starting from v6.2.0, you can specify the starting TSO of resuming the replication task. TiCDC starts pulling data from the specified TSO. The argument accepts `now` or a specific TSO (such as 434873584621453313). The specified TSO must be in the range of (GC safe point, CurrentTSO]. If this argument is not specified, TiCDC replicates data from the current `checkpoint-ts` by default.
- `--no-confirm`: when the replication is resumed, you do not need to confirm the related information. Defaults to `false`.

#### Note:

- If the TSO specified in `--overwrite-checkpoint-ts` (`t2`) is larger than the current checkpoint TSO in the changefeed (`t1`), data between `t1` and `t2` will not be replicated to the downstream. This causes data loss. You can obtain `t1` by running `cdc cli changefeed query`.
- If the TSO specified in `--overwrite-checkpoint-ts` (`t2`) is smaller than the current checkpoint TSO in the changefeed (`t1`), TiCDC pulls data from an old time point (`t2`), which might cause data duplication (for example, if the downstream is MQ sink).

#### 13.9.3.3.6 Remove a replication task

Run the following command to remove a replication task:

```
cdc cli changefeed remove --server=http://10.0.10.25:8300 --changefeed-id
↳ simple-replication-task
```

In the preceding command:

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to remove.

#### 13.9.3.3.7 Update task configuration

Starting from v4.0.4, TiCDC supports modifying the configuration of the replication task (not dynamically). To modify the changefeed configuration, pause the task, modify the configuration, and then resume the task.

```
cdc cli changefeed pause -c test-cf --server=http://10.0.10.25:8300
cdc cli changefeed update -c test-cf --server=http://10.0.10.25:8300 --sink-
↳ uri="mysql://127.0.0.1:3306/?max-txn-row=20&worker-number=8" --config
↳ =changefeed.toml
cdc cli changefeed resume -c test-cf --server=http://10.0.10.25:8300
```

Currently, you can modify the following configuration items:

- `sink-uri` of the changefeed.
- The changefeed configuration file and all configuration items in the file.
- Whether to use the file sorting feature and the sorting directory.
- The `target-ts` of the changefeed.

### 13.9.3.3.8 Manage processing units of replication sub-tasks (processor)

- Query the processor list:

```
cdc cli processor list --server=http://10.0.10.25:8300
```

```
[
 {
 "id": "9f84ff74-abf9-407f-a6e2-56aa35b33888",
 "capture-id": "b293999a-4168-4988-a4f4-35d9589b226b",
 "changefeed-id": "simple-replication-task"
 }
]
```

- Query a specific changefeed which corresponds to the status of a specific replication task:

```
cdc cli processor query --server=http://10.0.10.25:8300 --changefeed-id
↳ =simple-replication-task --capture-id=b293999a-4168-4988-a4f4-35
↳ d9589b226b
```

```
{
 "status": {
 "tables": {
 "56": { # 56 ID of the replication table, corresponding to
 ↳ tidb_table_id of a table in TiDB
 "start-ts": 417474117955485702
 }
 },
 "operation": null,
 "admin-job-type": 0
 },
 "position": {
 "checkpoint-ts": 417474143881789441,
 "resolved-ts": 417474143881789441,
 "count": 0
 }
}
```

In the preceding command:

- `status.tables`: Each key number represents the ID of the replication table, corresponding to `tidb_table_id` of a table in TiDB.
- `resolved-ts`: The largest TSO among the sorted data in the current processor.
- `checkpoint-ts`: The largest TSO that has been successfully written to the downstream in the current processor.

### 13.9.3.3.9 Output the historical value of a Row Changed Event

In the default configuration, the Row Changed Event of TiCDC Open Protocol output in a replication task only contains the changed value, not the value before the change. Therefore, the output value cannot be used by the consumer ends of TiCDC Open Protocol as the historical value of a Row Changed Event.

Starting from v4.0.5, TiCDC supports outputting the historical value of a Row Changed Event. To enable this feature, specify the following configuration in the changefeed configuration file at the root level:

```
enable-old-value = true
```

This feature is enabled by default since v5.0. To learn the output format of the TiCDC Open Protocol after this feature is enabled, see [TiCDC Open Protocol - Row Changed Event](#).

### 13.9.3.3.10 Replicate tables with the new framework for collations enabled

Starting from v4.0.15, v5.0.4, v5.1.1 and v5.2.0, TiCDC supports tables that have enabled [new framework for collations](#).

### 13.9.3.3.11 Replicate tables without a valid index

Since v4.0.8, TiCDC supports replicating tables that have no valid index by modifying the task configuration. To enable this feature, configure in the changefeed configuration file as follows:

```
enable-old-value = true
force-replicate = true
```

#### Warning:

For tables without a valid index, operations such as `INSERT` and `REPLACE` are not reentrant, so there is a risk of data redundancy. TiCDC guarantees that data is distributed only at least once during the replication process. Therefore, enabling this feature to replicate tables without a valid index will

definitely cause data redundancy. If you do not accept data redundancy, it is recommended to add an effective index, such as adding a primary key column with the `AUTO RANDOM` attribute.

### 13.9.3.3.12 Unified Sorter

**Note:**

Starting from v6.0.0, TiCDC uses the DB Sorter engine by default, and no longer uses the Unified Sorter. It is recommended that you do not configure the `sort engine` item.

Unified sorter is the sorting engine in TiCDC. It can mitigate OOM problems caused by the following scenarios:

- The data replication task in TiCDC is paused for a long time, during which a large amount of incremental data is accumulated and needs to be replicated.
- The data replication task is started from an early timestamp so it becomes necessary to replicate a large amount of incremental data.

For the changefeeds created using `cdc cli` after v4.0.13, Unified Sorter is enabled by default; for the changefeeds that have existed before v4.0.13, the previous configuration is used.

To check whether or not the Unified Sorter feature is enabled on a changefeed, you can run the following example command (assuming the IP address of the PD instance is `http://10.0.10.25:2379`):

```
cdc cli --server="http://10.0.10.25:8300" changefeed query --changefeed-id=
↳ simple-replication-task | grep 'sort-engine'
```

In the output of the above command, if the value of `sort-engine` is “unified”, it means that Unified Sorter is enabled on the changefeed.

**Note:**

- If your servers use mechanical hard drives or other storage devices that have high latency or limited bandwidth, the performance of Unified Sorter will be affected significantly.

- By default, Unified Sorter uses `data_dir` to store temporary files. It is recommended to ensure that the free disk space is greater than or equal to 500 GiB. For production environments, it is recommended to ensure that the free disk space on each node is greater than (the maximum `checkpoint-ts` delay allowed by the business) \* (upstream write traffic at business peak hours). In addition, if you plan to replicate a large amount of historical data after `changefeed` is created, make sure that the free space on each node is greater than the amount of the replicated data.

### 13.9.3.4 Changefeed Log Filters

TiCDC supports filtering data by tables and events. This document introduces how to use the two types of filters.

#### 13.9.3.4.1 Table filter

Table filter is a feature that allows you to keep or filter out specific databases and tables by specifying the following configurations:

```
[filter]
Filter rules
rules = ['*.*', '!test.*']
```

Common filter rules:

- `rules = ['*.*']`
  - Replicate all tables (not including system tables)
- `rules = ['test1.*']`
  - Replicate all tables in the `test1` database
- `rules = ['*.*', '!scm1.tb12']`
  - Replicate all tables except for the `scm1.tb12` table
- `rules = ['scm1.tb12', 'scm1.tb13']`
  - Only replicate tables `scm1.tb12` and `scm1.tb13`
- `rules = ['scm1.tidb_*']`
  - Replicate all tables in the `scm1` database whose names start with `tidb_`

For more information, see [Table filter syntax](#).

### 13.9.3.4.2 Event filter rules

Starting in v6.2.0, TiCDC supports event filter. You can configure event filter rules to filter out the DML and DDL events that meet the specified conditions.

The following is an example of event filter rules:

```
[filter]
The event filter rules must be under the `[filter]` configuration. You
↳ can configure multiple event filters at the same time.

[[filter.event-filters]]
matcher = ["test.worker"] # matcher is an allow list, which means this rule
↳ only applies to the worker table in the test database.
ignore-event = ["insert"] # Ignore insert events.
ignore-sql = ["^drop", "add column"] # Ignore DDLs that start with "drop" or
↳ contain "add column".
ignore-delete-value-expr = "name = 'john'" # Ignore delete DMLs that contain
↳ the condition "name = 'john'".
ignore-insert-value-expr = "id >= 100" # Ignore insert DMLs that contain the
↳ condition "id >= 100".
ignore-update-old-value-expr = "age < 18 or name = 'lili'" # Ignore update
↳ DMLs whose old value contains "age < 18" or "name = 'lili'".
ignore-update-new-value-expr = "gender = 'male' and age > 18" # Ignore
↳ update DMLs whose new value contains "gender = 'male'" and "age >
↳ 18".
```

Description of configuration parameters:

- **matcher**: the database and table that this event filter rule applies to. The syntax is the same as [table filter](#).
- **ignore-event**: the event type to be ignored. This parameter accepts an array of strings. You can configure multiple event types. Currently, the following event types are supported:

Event	Type	Alias	Description
all dml			Matches all DML events
all ddl			Matches all DDL events
insert	DML		Matches <b>insert</b> DML event
update	DML		Matches <b>update</b> DML event
delete	DML		Matches <b>delete</b> DML event
create schema	DDL	create database	Matches <b>create database</b> event

Event	Type	Alias	Description
drop schema	DDL	drop database	Matches drop database event
create table	DDL		Matches create table event
drop table	DDL		Matches drop table event
rename table	DDL		Matches rename table event
truncate table	DDL		Matches truncate table event
alter table	DDL		Matches alter table event, including all clauses of alter table, create index and drop index
add table partition	DDL		Matches add table partition event
drop table partition	DDL		Matches drop table partition event
truncate table partition	DDL		Matches truncate table ↔ partition event
create view	DDL		Matches create view event
drop view	DDL		Matches drop view event

- **ignore-sql**: the DDL statements to be ignored. This parameter accepts an array of strings, in which you can configure multiple regular expressions. This rule only applies to DDL events.
- **ignore-delete-value-expr**: this parameter accepts a SQL expression. This rule only applies to delete DML events with the specified value.
- **ignore-insert-value-expr**: this parameter accepts a SQL expression. This rule only applies to insert DML events with the specified value.
- **ignore-update-old-value-expr**: this parameter accepts a SQL expression. This rule only applies to update DML events whose old value contains the specified value.
- **ignore-update-new-value-expr**: this parameter accepts a SQL expression. This rule only applies to update DML events whose new value contains the specified value.

**Note:**

- When TiDB updates a value in the column of the clustered index, TiDB splits an UPDATE event into a DELETE event and an INSERT event. TiCDC does not identify such events as an UPDATE event and thus cannot correctly filter out such events.
- When you configure a SQL expression, make sure all tables that matches `matcher` contain all the columns specified in the SQL expression. Otherwise, the replication task cannot be created. In addition, if the table schema changes during the replication, which results in a table no longer containing a required column, the replication task fails and cannot be resumed automatically. In such a situation, you must manually modify the configuration and resume the task.

#### 13.9.3.4.3 DDL allow list

Currently, TiCDC uses an allow list to replicate DDL statements. Only the DDL statements in the allow list are replicated to the downstream. The DDL statements not in the allow list are not replicated to the downstream.

The allow list of DDL statements supported by TiCDC is as follows:

- create database
- drop database
- create table
- drop table
- add column
- drop column
- create index / add index
- drop index
- truncate table
- modify column
- rename table
- alter column default value
- alter table comment
- rename index
- add partition
- drop partition
- truncate partition
- create view
- drop view
- alter table character set
- alter database character set
- recover table
- add primary key

- drop primary key
- rebase auto id
- alter table index visibility
- exchange partition
- reorganize partition
- alter table ttl
- alter table remove ttl

### 13.9.3.5 Bidirectional Replication

Starting from v6.5.0, TiCDC supports bi-directional replication among two TiDB clusters. Based on this feature, you can create a multi-active TiDB solution using TiCDC.

This section describes how to use bi-directional replication taking two TiDB clusters as an example.

#### 13.9.3.5.1 Deploy bi-directional replication

TiCDC only replicates incremental data changes that occur after a specified timestamp to the downstream cluster. Before starting the bi-directional replication, you need to take the following steps:

1. (Optional) According to your needs, import the data of the two TiDB clusters into each other using the data export tool [Dumpling](#) and data import tool [TiDB Lightning](#).
2. Deploy two TiCDC clusters between the two TiDB clusters. The cluster topology is as follows. The arrows in the diagram indicate the directions of data flow.

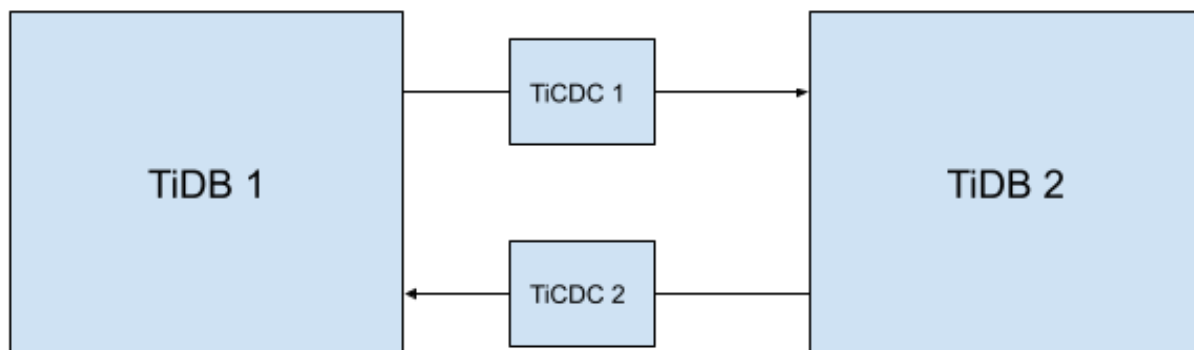

Figure 277: TiCDC bidirectional replication

3. Specify the starting time point of data replication for the upstream and downstream clusters.

1. Check the time point of the upstream and downstream clusters. In the case of two TiDB clusters, make sure that data in the two clusters are consistent at certain time points. For example, the data of TiDB A at `ts=1` and the data of TiDB B at `ts=2` are consistent.
2. When you create the changefeed, set the `--start-ts` of the changefeed for the upstream cluster to the corresponding `tso`. That is, if the upstream cluster is TiDB A, set `--start-ts=1`; if the upstream cluster is TiDB B, set `--start-ts ↪ =2`.
4. In the configuration file specified by the `--config` parameter, add the following configuration:

```
Whether to enable the bi-directional replication mode
bdr-mode = true
```
5. (Optional) If you need to track the data source, set a unique data source ID for each cluster using the `tidb_source_id` system variable.

After the configuration takes effect, the clusters can perform bi-directional replication.

#### 13.9.3.5.2 Execute DDL

After the bidirectional replication is enabled, TiCDC does not replicate any DDL statements. You need to execute DDL statements in the upstream and downstream clusters respectively.

Note that some DDL statements might cause table structure changes or data change time sequence problems, which might lead to data inconsistency after the replication. Therefore, after enabling bidirectional replication, only the DDL statements in the following table can be executed without stopping the write operations of the application.

---

Event	Errors	Note
create database	Yes	After you manually execute the DDL statements in the upstream and downstream clusters, the errors can be automatically recovered.

Event	Errors	Note
drop database	Yes	<p>Does it cause change-feed errors?</p> <p>You need to manually restart the change-feed and specify --  ↳ <code>overwrite</code>  ↳ <code>-</code>  ↳ <code>checkpoint</code>  ↳ <code>-</code>  ↳ <code>ts</code>  ↳  as the <code>commitTs</code>  ↳  of the DDL statement to recover the errors.</p>

---

Event	Errors	Note
create table	Yes	After you manually execute the DDL statements in the upstream and downstream clusters, the errors can be automatically recovered.

Event	Errors	Note
drop table	Yes	<p>Does it cause change-feed error?</p> <p>You need to manually restart the change-feed and specify --  ↳ <code>overwrite</code>  ↳ <code>-</code>  ↳ <code>checkpoint</code>  ↳ <code>-</code>  ↳ <code>ts</code>  ↳  as the <code>commitTs</code>  ↳  of the DDL statement to recover the errors.</p>

---

Event	Errors	Note
Does it cause change- feed er-		
alter ta- ble com- ment rename	No	
in- dex alter	No	
ta- ble in- dex visi- bil- ity		

Event	Errors	Note
add partition	Yes	After you manually execute the DDL statements in the upstream and downstream clusters, the errors can be automatically recovered.
drop partition	No	

---

Event	Errors	Note
create view	No	Does it cause change- feed er-
drop view	No	
alter col- umn de- fault value	No	

Event	Errors	Note
Does it cause change-feed er-		
reorgan-	Yes	After you manually execute the DDL statements in the upstream and downstream clusters, the errors can be automatically recovered.
alter table ttl	No	

Event	Errors	Note
alter table remove ttl	No	
add index	No	<b>not unique</b>
drop index	No	<b>not unique</b>

If you need to execute DDL statements that are not in the preceding table, take the following steps:

1. Pause the write operations in the tables that need to execute DDL in all clusters.
2. After the write operations of the corresponding tables in all clusters have been replicated to other clusters, manually execute all DDL statements in each TiDB cluster.
3. After the DDL statements are executed, resume the write operations.

### 13.9.3.5.3 Stop bi-directional replication

After the application has stopped writing data, you can insert a special record into each cluster. By checking the two special records, you can make sure that data in two clusters are consistent.

After the check is completed, you can stop the changefeed to stop bi-directional replication.

### 13.9.3.5.4 Limitations

- For the limitations of DDL, see [Execute DDL](#).

- Bi-directional replication clusters cannot detect write conflicts, which might cause undefined behaviors. Therefore, you must ensure that there are no write conflicts from the application side.
- Bi-directional replication supports more than two clusters, but does not support multiple clusters in cascading mode, that is, a cyclic replication like TiDB A -> TiDB B -> TiDB C -> TiDB A. In such a topology, if one cluster fails, the whole data replication will be affected. Therefore, to enable bi-directional replication among multiple clusters, you need to connect each cluster with every other clusters, for example, TiDB A <-> TiDB B, TiDB B <-> TiDB C, TiDB C <-> TiDB A.

## 13.9.4 Monitor and Alert

### 13.9.4.1 Key Monitoring Metrics of TiCDC

If you use TiUP to deploy the TiDB cluster, you can see a sub-dashboard for TiCDC in the monitoring system which is deployed at the same time. You can get an overview of TiCDC's current status from the TiCDC dashboard, where the key metrics are displayed. This document provides a detailed description of these key metrics.

The metric description in this document is based on the following replication task example, which replicates data to MySQL using the default configuration.

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
↳ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
↳ task"
```

The TiCDC dashboard contains four monitoring panels. See the following screenshot:

Figure 278: TiCDC Dashboard - Overview

The description of each panel is as follows:

- **Server**: The summary information of TiKV nodes and TiCDC nodes in the TiDB cluster
- **Changefeed**: The detailed information of TiCDC replication tasks
- **Events**: The detail information about the data flow within the TiCDC cluster
- **TiKV**: TiKV information related to TiCDC

### 13.9.4.1.1 Server

The following is an example of the **Server** panel:

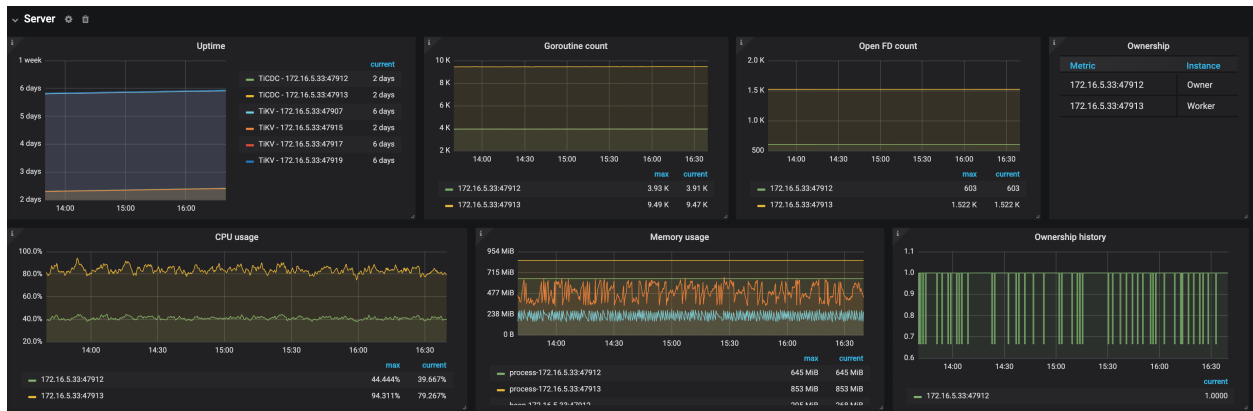

Figure 279: TiCDC Dashboard - Server metrics

The description of each metric in the **Server** panel is as follows:

- Uptime: The time for which TiKV nodes and TiCDC nodes have been running
- Goroutine count: The number of goroutines of a TiCDC node
- Open FD count: The number of file handles opened by TiCDC nodes
- Ownership: The current status of nodes in the TiCDC cluster
- Ownership history: The ownership history of the TiCDC cluster
- CPU usage: The CPU usage of TiCDC nodes
- Memory usage: The memory usage of TiCDC nodes

### 13.9.4.1.2 Changefeed

The following is an example of the **Changefeed** panel:

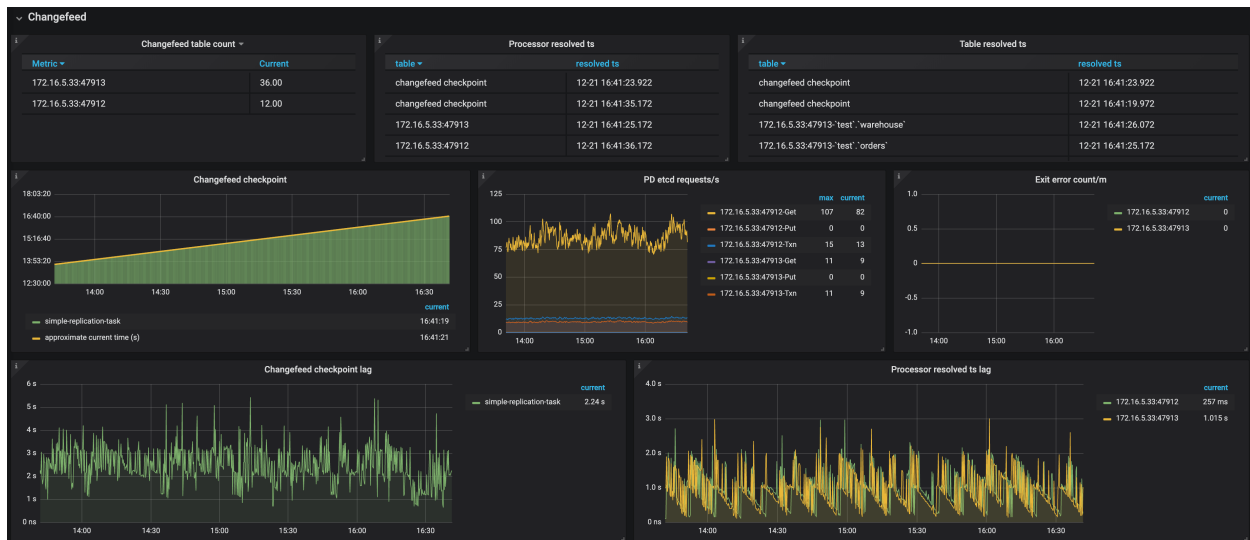

Figure 280: TiCDC Dashboard - Changefeed metrics 1

- Changefeed table count: The number of tables that each TiCDC node needs to replicate in the replication task
- Processor resolved ts: The timestamps that have been resolved in the TiCDC cluster
- Table resolved ts: The replication progress of each table in the replication task
- Changefeed checkpoint: The progress of replicating data to the downstream. Normally, the green bars are connected to the yellow line
- PD etcd requests/s: The number of requests that a TiCDC node sends to PD per second
- Exit error count/m: The number of errors that interrupt the replication task per minute
- Changefeed checkpoint lag: The progress lag of data replication (the unit is second) between the upstream and the downstream
- Processor resolved ts lag: The progress lag of data replication (the unit is second) between the upstream and TiCDC nodes

Figure 281: TiCDC Dashboard - Changefeed metrics 2

- Sink write duration: The histogram of the time spent by TiCDC writing a transaction change to the downstream
- Sink write duration percentile: The time (P95, P99, and P999) spent by TiCDC writing a transaction change to the downstream within one second
- Flush sink duration: The histogram of the time spent by TiCDC asynchronously flushing data to the downstream
- Flush sink duration percentile: The time (P95, P99, and P999) spent by TiCDC asynchronously flushing data to the downstream within one second

Figure 282: TiCDC Dashboard - Changefeed metrics 3

- MySQL sink conflict detect duration: The histogram of the time spent on detecting MySQL sink conflicts
- MySQL sink conflict detect duration percentile: The time (P95, P99, and P999) spent on detecting MySQL sink conflicts within one second
- MySQL sink worker load: The workload of MySQL sink workers of TiCDC nodes

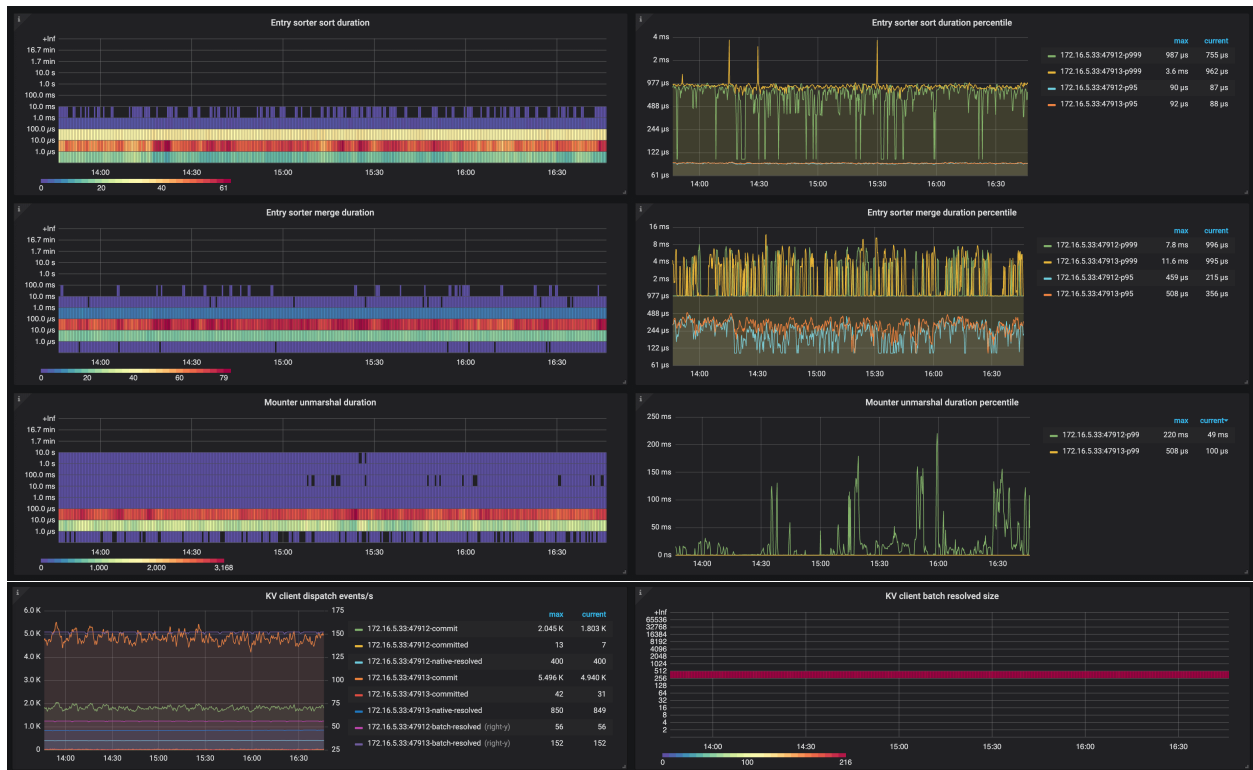

Figure 283: TiCDC Dashboard - Changefeed metrics 4

- **Changefeed catch-up ETA:** The estimated time needed for the replication task to catch up with the upstream cluster data. When the upstream write speed is faster than the TiCDC replication speed, the metric might be extremely large. Because TiCDC replication speed is subject to many factors, this metric is for reference only and might not be the actual replication time.

### 13.9.4.1.3 Events

The following is an example of the **Events** panel:

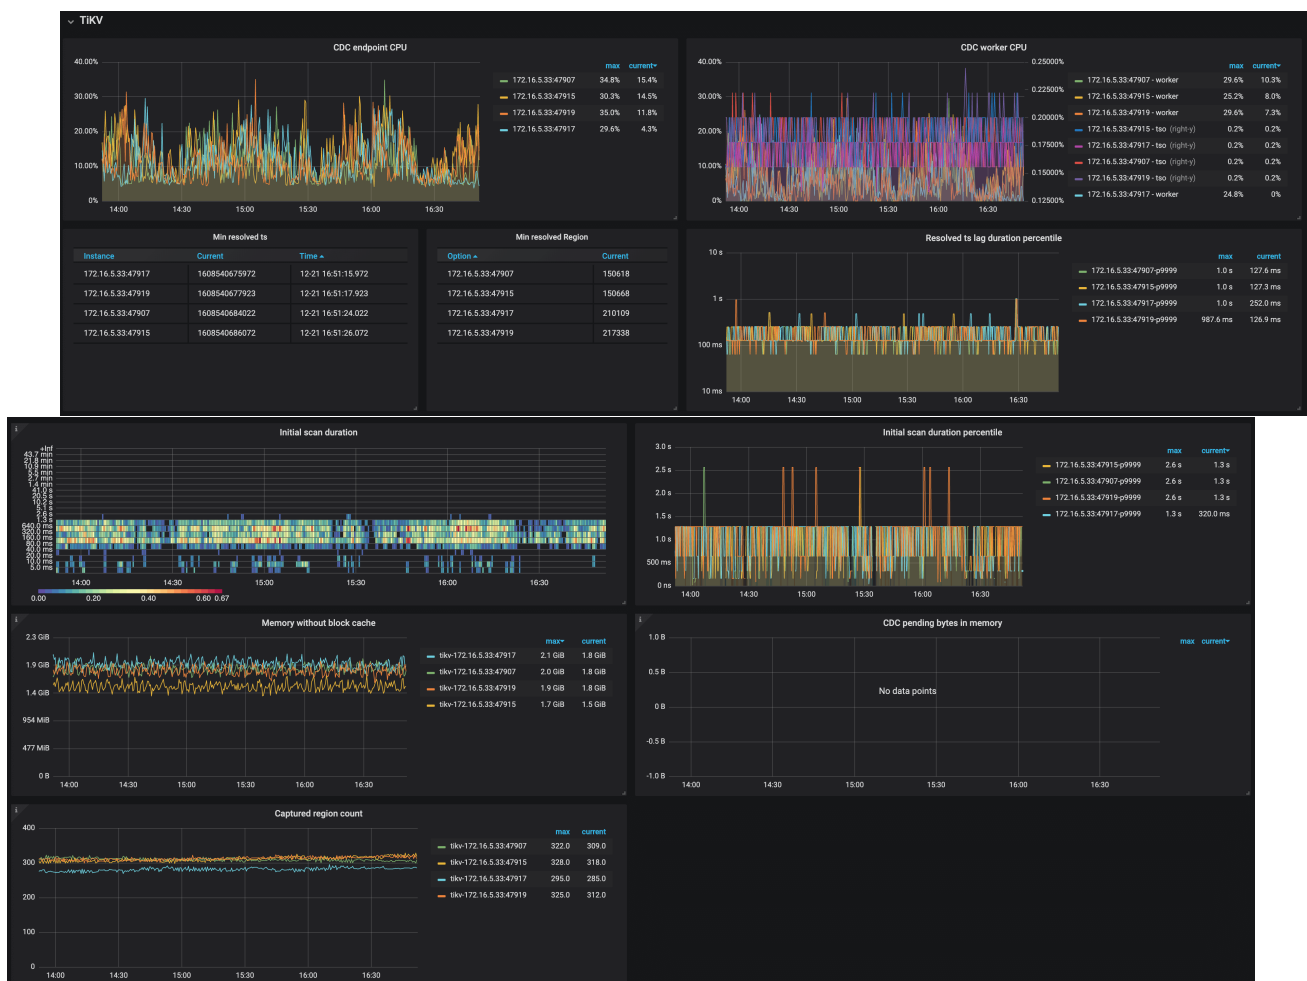

The description of each metric in the **Events** panel is as follows:

- Eventfeed count: The number of Eventfeed RPC requests of TiCDC nodes
- Event size percentile: The event size (P95, P99, and P999) which TiCDC receives from TiKV within one second
- Eventfeed error/m: The number of errors reported by Eventfeed RPC requests of TiCDC nodes per minute
- KV client receive events/s: The number of events that the KV client module of TiCDC nodes receives from TiKV per second
- Puller receive events/s: The number of events that the Puller module of TiCDC nodes receives from the KV client per second
- Puller output events/s: The number of events that the Puller module of TiCDC nodes sends to the Sorter module per second
- Sink flush rows/s: The number of events that TiCDC nodes write to the downstream per second
- Puller buffer size: The number of events that TiCDC nodes cache in the Puller module
- Entry sorter buffer size: The number of events that TiCDC nodes cache in the Sorter module
- Processor/Mounter buffer size: The number of events that TiCDC nodes cache in the Processor module and the Mounter module
- Sink row buffer size: The number of events that TiCDC nodes cache in the Sink module
- Entry sorter sort duration: The histogram of the time spent by TiCDC nodes sorting events
- Entry sorter sort duration percentile: The time (P95, P99, and P999) spent by TiCDC

- sorting events within one second
- Entry sorter merge duration: The histogram of the time spent by TiCDC nodes merging sorted events
- Entry sorter merge duration percentile: The time (P95, P99, and P999) spent by TiCDC merging sorted events within one second
- Mounter unmarshal duration: The histogram of the time spent by TiCDC nodes unmarshaling events
- Mounter unmarshal duration percentile: The time (P95, P99, and P999) spent by TiCDC unmarshaling events within one second
- KV client dispatch events/s: The number of events that the KV client module dispatches among the TiCDC nodes
- KV client batch resolved size: The batch size of resolved timestamp messages that TiKV sends to TiCDC

### 13.9.4.1.4 TiKV

The following is an example of the **TiKV** panel:

The description of each metric in the **TiKV** panel is as follows:

- CDC endpoint CPU: The CPU usage of the CDC endpoint threads on TiKV nodes
- CDC worker CPU: The CPU usage of the CDC worker threads on TiKV nodes
- Min resolved ts: The minimum resolved timestamp on TiKV nodes
- Min resolved region: The Region ID of the minimum resolved timestamp on TiKV nodes
- Resolved ts lag duration percentile: The lag between the minimum resolved timestamp on TiKV nodes and the current time
- Initial scan duration: The histogram of the time spent on incremental scan when TiKV nodes connect to TiCDC nodes
- Initial scan duration percentile: The time (P95, P99, and P999) spent on the incremental scan of TiKV nodes within one second
- Memory without block cache: The memory usage of TiKV nodes excluding the RocksDB block cache
- CDC pending bytes in memory: The memory usage of CDC module on TiKV nodes
- Captured region count: The number of event-capturing Regions on TiKV nodes

#### 13.9.4.2 TiCDC Alert Rules

This document describes the TiCDC alert rules and the corresponding solutions. In descending order, the severity levels are: **Critical**, **Warning**.

##### 13.9.4.2.1 Critical alerts

This section introduces critical alerts and solutions.

###### `cdc_checkpoint_high_delay`

For critical alerts, you need to pay close attention to abnormal monitoring metrics.

- Alert rule:  
 $(\text{time}() - \text{ticdc\_processor\_checkpoint\_ts} / 1000) > 600$
- Description:  
A replication task is delayed more than 10 minutes.
- Solution:  
See [TiCDC Handle Replication Interruption](#).

##### 13.9.4.2.2 `cdc_resolvedts_high_delay`

- Alert rule:  
 $(\text{time}() - \text{ticdc\_processor\_resolved\_ts} / 1000) > 300$
- Description:  
The Resolved TS of a replication task is delayed more than 5 minutes.

- Solution:  
See [TiCDC Handle Replication Interruption](#).

`ticdc_processor_exit_with_error_count`

- Alert rule:  
`changes(ticdc_processor_exit_with_error_count[1m])> 0`
- Description:  
A replication task reports an error and exits.
- Solution:  
See [TiCDC Handle Replication Interruption](#).

#### 13.9.4.2.3 Warning alerts

Warning alerts are a reminder for an issue or error.

`cdc_multiple_owners`

- Alert rule:  
`sum(rate(ticdc_owner_ownership_counter[30s]))>= 2`
- Description:  
There are multiple owners in the TiCDC cluster.
- Solution:  
Collect TiCDC logs to locate the root cause.

`ticdc_mounter_unmarshal_and_mount_time_more_than_1s`

- Alert rule:  
`histogram_quantile(0.9, rate(ticdc_mounter_unmarshal_and_mount_bucket[1m  
↪ ]))* 1000 > 1000`

- Description:  
It takes a replication task more than 1 second to unmarshal the data changes.
- Solution:  
Collect TiCDC logs to locate the root cause.

`cdc_sink_execute_duration_time_more_than_10s`

- Alert rule:

```
histogram_quantile(0.9, rate(ticdc_sink_txn_exec_duration_bucket[1m]))>
↔ 10
```

- Description:

It takes a replication task more than 10 seconds to write data to the downstream database.

- Solution:

Check whether there are problems in the downstream database.

`cdc_processor_checkpoint_tso_no_change_for_1m`

- Alert rule:

```
changes(ticdc_processor_checkpoint_ts[1m])< 1
```

- Description:

A replication task has not advanced for more than 1 minute.

- Solution:

See [TiCDC Handle Replication Interruption](#).

`ticdc_puller_entry_sorter_sort_bucket`

- Alert rule:

```
histogram_quantile(0.9, rate(ticdc_puller_entry_sorter_sort_bucket{ }[1m
↔]))> 1
```

- Description:

The delay of TiCDC puller entry sorter is too high.

- Solution:

Collect TiCDC logs to locate the root cause.

`ticdc_puller_entry_sorter_merge_bucket`

- Alert rule:

```
histogram_quantile(0.9, rate(ticdc_puller_entry_sorter_merge_bucket{ }[1
↔ m]))> 1
```

- Description:  
The delay of TiCDC puller entry sorter merge is too high.

- Solution:  
Collect TiCDC logs to locate the root cause.

`tikv_cdc_min_resolved_ts_no_change_for_1m`

- Alert rule:  
`changes(tikv_cdc_min_resolved_ts[1m]) < 1 and ON (instance) tikv_cdc_region_resolve_s  
↔ {status="resolved"} > 0`

- Description:  
The minimum Resolved TS 1 of TiKV CDC has not advanced for 1 minute.

- Solution:  
Collect TiKV logs to locate the root cause.

`tikv_cdc_scan_duration_seconds_more_than_10min`

- Alert rule:  
`histogram_quantile(0.9, rate(tikv_cdc_scan_duration_seconds_bucket{ }[1m  
↔ ])) > 600`

- Description:  
The TiKV CDC module has scanned for incremental replication for more than 10 minutes.

- Solution:  
Collect TiCDC monitoring metrics and TiKV logs to locate the root cause.

`ticdc_sink_mysql_execution_error`

- Alert rule:  
`changes(ticdc_sink_mysql_execution_error[1m]) > 0`

- Description:  
An error occurs when a replication task writes data to the downstream MySQL.

- Solution:  
There are many possible root causes. See [Troubleshoot TiCDC](#).

ticdc\_memory\_abnormal

- Alert rule:  
`go_memstats_heap_alloc_bytes{job="ticdc"} > 1e+10`
- Description:  
 The TiCDC heap memory usage exceeds 10 GiB.
- Solution:  
 Collect TiCDC logs to locate the root cause.

### 13.9.4.3 Architecture and Principles of TiCDC

#### 13.9.4.3.1 TiCDC architecture

Consisting of multiple TiCDC nodes, a TiCDC cluster uses a distributed and stateless architecture. The design of TiCDC and its components is as follows:

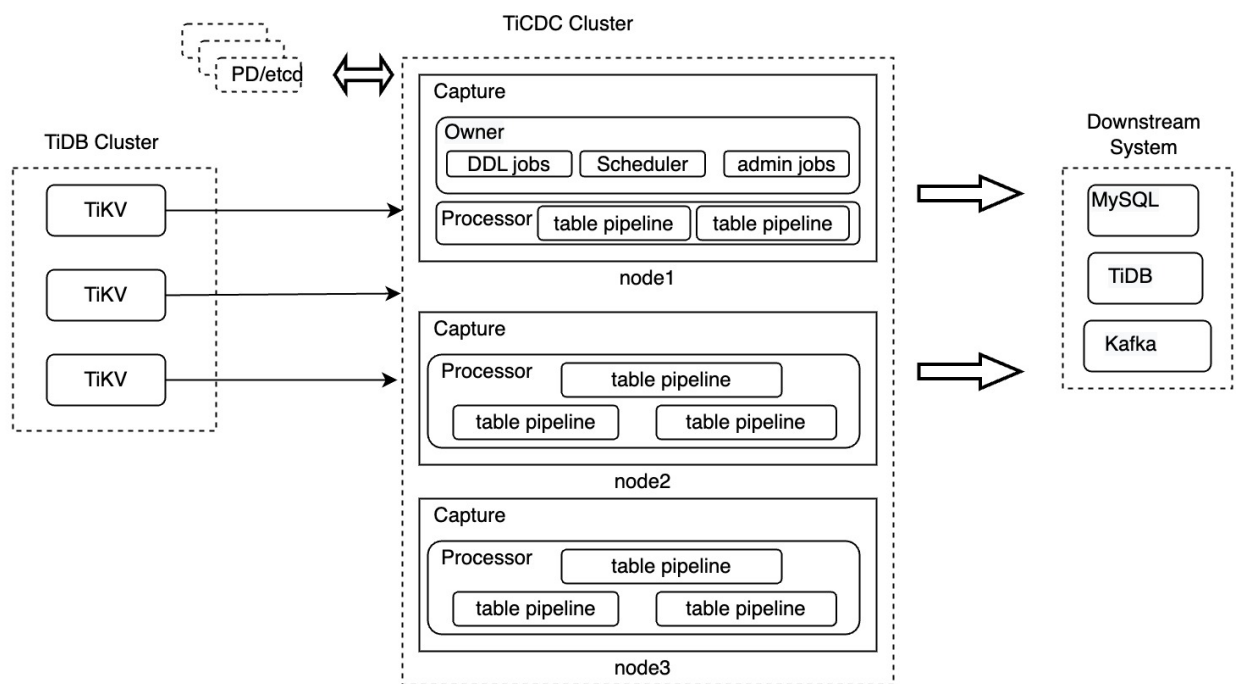

Figure 284: TiCDC architecture

#### 13.9.4.3.2 TiCDC components

In the preceding diagram, a TiCDC cluster consists of multiple nodes running TiCDC instances. Each TiCDC instance carries a Capture process. One of the Capture processes is

elected as the owner Capture, which is responsible for scheduling workload, replicating DDL statements, and performing management tasks.

Each Capture process contains one or multiple Processor threads for replicating data from tables in the upstream TiDB. Because table is the minimum unit of data replication in TiCDC, a Processor is composed of multiple table pipelines.

Each pipeline contains the following components: Puller, Sorter, Mounter, and Sink.

Figure 285: TiCDC architecture

These components work in serial with each other to complete the replication process, including pulling data, sorting data, loading data, and replicating data from the upstream to the downstream. The components are described as follows:

- Puller: pulls DDL and row changes from TiKV nodes.
- Sorter: sorts the changes received from TiKV nodes in ascending order of timestamps.
- Mounter: converts the changes into a format that TiCDC sink can process based on the schema information.
- Sink: replicates the changes to the downstream system.

To realize high availability, each TiCDC cluster runs multiple TiCDC nodes. These nodes regularly report their status to the etcd cluster in PD, and elect one of the nodes as the owner of the TiCDC cluster. The owner node schedules data based on the status stored in etcd and writes the scheduling results to etcd. The Processor completes tasks according to the status in etcd. If the node running the Processor fails, the cluster schedules tables to other nodes. If the owner node fails, the Capture processes in other nodes will elect a new owner. See the following figure:

*TiCDC architecture*

### 13.9.4.3.3 Changefeeds and tasks

Changefeed and Task in TiCDC are two logical concepts. The specific description is as follows:

- **Changefeed:** Represents a replication task. It carries the information about the tables to be replicated and the downstream.
- **Task:** After TiCDC receives a replication task, it splits this task into several subtasks. Such a subtask is called Task. These Tasks are assigned to the Capture processes of the TiCDC nodes for processing.

For example:

```
cdc cli changefeed create --server="http://127.0.0.1:8300" --sink-uri="kafka
↳ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&partition-num=6&max-
↳ message-bytes=67108864&replication-factor=1"
cat changefeed.toml
.....
[sink]
dispatchers = [
 {matcher = ['test1.tab1', 'test2.tab2'], topic = "{schema}_{table}"},
 {matcher = ['test3.tab3', 'test4.tab4'], topic = "{schema}_{table}"},
]
```

For a detailed description of the parameters in the preceding `cdc cli changefeed create` command, see [TiCDC Changefeed Configuration Parameters](#).

The preceding `cdc cli changefeed create` command creates a changefeed task that replicates `test1.tab1`, `test1.tab2`, `test3.tab3`, and `test4.tab4` to the Kafka cluster. The processing flow after TiCDC receives this command is as follows:

1. TiCDC sends this task to the owner Capture process.
2. The owner Capture process saves information about this changefeed task in etcd in PD.
3. The owner Capture process splits the changefeed task into several Tasks and notifies other Capture processes of the Tasks to be completed.
4. The Capture processes start pulling data from TiKV nodes, process the data, and complete replication.

The following is the TiCDC architecture diagram with Changefeed and Task included:

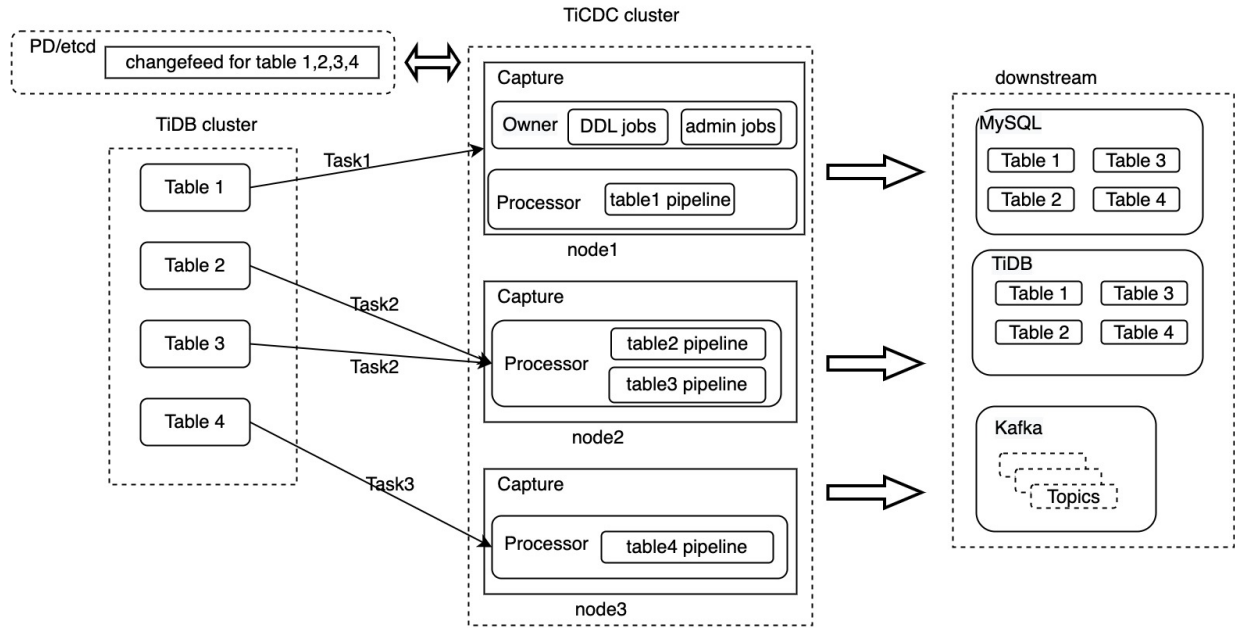

Figure 286: TiCDC architecture

In the preceding diagram, a changefeed is created to replicate four tables to downstream. This changefeed is split into three Tasks, which are sent to the three Capture processes respectively in the TiCDC cluster. After TiCDC processes the data, the data is replicated to the downstream system.

TiCDC supports replicating data to MySQL, TiDB, and Kafka databases. The preceding diagram only illustrates the process of data transfer at the changefeed level. The following sections describe in detail how TiCDC processes data, using Task1 that replicates table `table1` as an example.

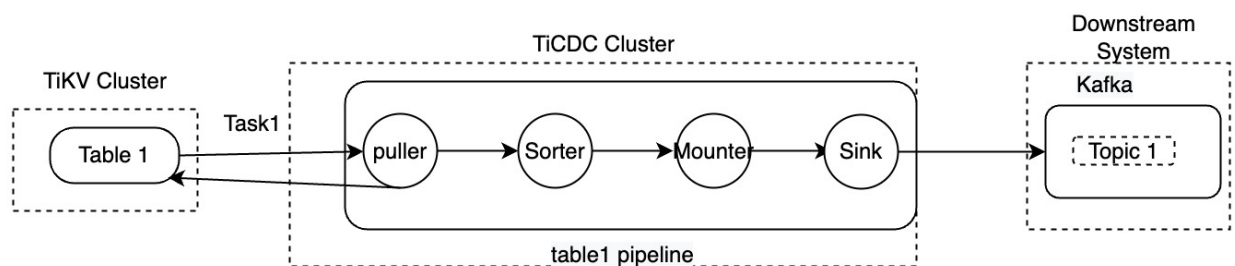

Figure 287: TiCDC architecture

1. Push data: When a data change occurs, TiKV pushes data to the Puller module.
2. Scan incremental data: The Puller module pulls data from TiKV when it finds the data changes received not continuous.

3. Sort data: The Sorter module sorts the data received from TiKV based on the timestamps and sends the sorted data to the Mounter module.
4. Mount data: After receiving the data changes, the Mounter module loads the data in a format that TiCDC sink can understand.
5. Replicate data: The Sink module replicates the data changes to the downstream.

The upstream of TiCDC is the distributed relational database TiDB that supports transactions. When TiCDC replicates data, it should ensure the consistency of data and that of transactions when replicating multiple tables, which is a great challenge. The following sections introduce the key technologies and concepts used by TiCDC to address this challenge.

#### 13.9.4.3.4 Key concepts of TiCDC

For the downstream relational databases, TiCDC ensures the consistency of transactions in a single table and eventual transaction consistency in multiple tables. In addition, TiCDC ensures that any data change that has occurred in the upstream TiDB cluster can be replicated to the downstream at least once.

##### Architecture-related concepts

- Capture: The process that runs the TiCDC node. Multiple Capture processes constitute a TiCDC cluster. Each Capture process is responsible for replicating data changes in TiKV, including receiving and actively pulling data changes, and replicating the data to the downstream.
- Capture Owner: The owner Capture among multiple Capture processes. Only one owner role exists in a TiCDC cluster at a time. The Capture Owner is responsible for scheduling data within the cluster.
- Processor: The logical thread inside Capture. Each Processor is responsible for processing the data of one or more tables in the same replication stream. A Capture node can run multiple Processors.
- Changefeed: A task that replicates data from an upstream TiDB cluster to a downstream system. A changefeed contains multiple Tasks, and each Task is processed by a Capture node.

##### Timestamp-related concepts

TiCDC introduces a series of timestamps (TS) to indicate the status of data replication. These timestamps are used to ensure that data is replicated to the downstream at least once and that the consistency of data is guaranteed.

##### ResolvedTS

This timestamp exists in both TiKV and TiCDC.

- ResolvedTS in TiKV: Represents the start time of the earliest transaction in a Region leader, that is,  $\text{ResolvedTS} = \max(\text{ResolvedTS}, \min(\text{StartTS}))$ . Because a TiDB

cluster contains multiple TiKV nodes, the minimum ResolvedTS of the Region leader on all TiKV nodes is called the global ResolvedTS. The TiDB cluster ensures that all transactions before the global ResolvedTS are committed. Alternatively, you can assume that there are no uncommitted transactions before this timestamp.

- ResolvedTS in TiCDC:
  - table ResolvedTS: Each table has a table-level ResolvedTS, which indicates all data changes in the table that are smaller than the Resolved TS have been received. To make it simple, this timestamp is the same as the minimum value of the ResolvedTS of all Regions corresponding to this table on the TiKV node.
  - global ResolvedTS: The minimum ResolvedTS of all Processors on all TiCDC nodes. Because each TiCDC node has one or more Processors, each Processor corresponds to multiple table pipelines.

For TiCDC, the ResolvedTS sent by TiKV is a special event in the format of  $\langle \leftrightarrow \text{resolvedTS: timestamp} \rangle$ . In general, the ResolvedTS satisfies the following constraints:

```
table ResolvedTS >= global ResolvedTS
```

### CheckpointTS

This timestamp exists only in TiCDC. It means that the data changes that occur before this timestamp have been replicated to the downstream system.

- table CheckpointTS: Because TiCDC replicates data in tables, the table checkpointTS indicates all data changes that occur before CheckpointTS have been replicated at the table level.
- processor CheckpointTS: Indicates the minimum table CheckpointTS on a Processor.
- global CheckpointTS: Indicates the minimum CheckpointTS among all Processors.

Generally, a checkpointTS satisfies the following constraint:

```
table CheckpointTS >= global CheckpointTS
```

Because TiCDC only replicates data smaller than the global ResolvedTS to the downstream, the complete constraint is as follows:

```
table ResolvedTS >= global ResolvedTS >= table CheckpointTS >= global
 \leftrightarrow CheckpointTS
```

After data changes and transactions are committed, the ResolvedTS on the TiKV node will continue to advance, and the Puller module on the TiCDC node keeps receiving data pushed by TiKV. The Puller module also decides whether to scan incremental data based on

the data changes it has received, which ensures that all data changes are sent to the TiCDC node.

The Sorter module sorts data received by the Puller module in ascending order according to the timestamp. This process ensures data consistency at the table level. Next, the Mounter module assembles the data changes from the upstream into a format that the Sink module can consume, and sends it to the Sink module. The Sink module replicates the data changes between the CheckpointTS and the ResolvedTS to the downstream in the order of the timestamp, and advances the checkpointTS after the downstream receives the data changes.

The preceding sections only cover data changes of DML statements and do not include DDL statements. The following sections introduce the timestamp related to DDL statements.

#### Barrier TS

Barrier TS is generated when there are DDL change events or a Syncpoint is used.

- DDL change events: Barrier TS ensures that all changes before the DDL statement are replicated to the downstream. After this DDL statement is executed and replicated, TiCDC starts replicating other data changes. Because DDL statements are processed by the Capture Owner, the Barrier TS corresponding to a DDL statement is only generated by the owner node.
- Syncpoint: When you enable the Syncpoint feature of TiCDC, a Barrier TS is generated by TiCDC according to the `sync-point-interval` you specified. When all table changes before this Barrier TS are replicated, TiCDC inserts the current global CheckpointTS as the primary TS to the table recording tsMap in downstream. Then TiCDC continues data replication.

After a Barrier TS is generated, TiCDC ensures that only data changes that occur before this Barrier TS are replicated to downstream. Before these data changes are replicated to downstream, the replication task does not proceed. The owner TiCDC checks whether all target data has been replicated by continuously comparing the global CheckpointTS and the Barrier TS. If the global CheckpointTS equals to the Barrier TS, TiCDC continues replication after performing a designated operation (such as executing a DDL statement or recording the global CheckpointTS downstream). Otherwise, TiCDC waits for all data changes that occur before the Barrier TS to be replicated to the downstream.

#### 13.9.4.3.5 Major processes

This section describes the major processes of TiCDC to help you better understand its working principles.

Note that the following processes occur only within TiCDC and are transparent to users. Therefore, you do not need to care about which TiCDC node you are starting.

#### Start TiCDC

- For a TiCDC node that is not an owner, it works as follows:
  1. Starts the Capture process.
  2. Starts the Processor.
  3. Receives the Task scheduling command executed by the Owner.
  4. Starts or stops tablePipeline according to the scheduling command.
- For an owner TiCDC node, it works as follows:
  1. Starts the Capture process.
  2. The node is elected as the Owner and the corresponding thread is started.
  3. Reads the changefeed information.
  4. Starts the changefeed management process.
  5. Reads the schema information in TiKV according to the changefeed configuration and the latest CheckpointTS to determine the tables to be replicated.
  6. Reads the list of tables currently replicated by each Processor and distributes the tables to be added.
  7. Updates the replication progress.

## Stop TiCDC

Usually, you stop a TiCDC node when you need to upgrade it or perform some planned maintenance operations. The process of stopping a TiCDC node is as follows:

1. The node receives the command to stop itself.
2. The node sets its service status to unavailable.
3. The node stops receiving new replication tasks.
4. The node notifies the Owner node to transfer its data replication tasks to other nodes.
5. The node stops after the replication tasks are transferred to other nodes.

### 13.9.4.4 TiCDC Server Configurations

This document describes the CLI and configuration file parameters used in TiCDC.

#### 13.9.4.4.1 cdc server CLI parameters

The following are descriptions of options available in a `cdc server` command:

- **addr**: The listening address of TiCDC, the HTTP API address, and the Prometheus address of the TiCDC service. The default value is `127.0.0.1:8300`.
- **advertise-addr**: The advertised address via which clients access TiCDC. If unspecified, the value is the same as that of **addr**.
- **pd**: A comma-separated list of PD endpoints.
- **config**: The address of the configuration file that TiCDC uses (optional). This option is supported since TiCDC v5.0.0. This option can be used in the TiCDC deployment since TiUP v1.4.0. For detailed configuration description, see [TiCDC Changefeed Configurations](#)

- **data-dir**: Specifies the directory that TiCDC uses when it needs to use disks to store files. The sort engine used by TiCDC and redo logs use this directory to store temporary files. It is recommended to ensure that the free disk space for this directory is greater than or equal to 500 GiB. If you are using TiUP, you can configure `data_dir` in the `cdc_servers` section, or directly use the default `data_dir` path in `global`.
- **gc-ttl**: The TTL (Time To Live) of the service level GC safepoint in PD set by TiCDC, and the duration that the replication task can suspend, in seconds. The default value is 86400, which means 24 hours. Note: Suspending of the TiCDC replication task affects the progress of TiCDC GC safepoint, which means that it affects the progress of upstream TiDB GC, as detailed in [Complete Behavior of TiCDC GC safepoint](#).
- **log-file**: The path to which logs are output when the TiCDC process is running. If this parameter is not specified, logs are written to the standard output (stdout).
- **log-level**: The log level when the TiCDC process is running. The default value is "info".
- **ca**: Specifies the path of the CA certificate file in PEM format for TLS connection (optional).
- **cert**: Specifies the path of the certificate file in PEM format for TLS connection (optional).
- **cert-allowed-cn**: Specifies the path of the common name in PEM format for TLS connection (optional).
- **key**: Specifies the path of the private key file in PEM format for TLS connection (optional).
- **tz**: Time zone used by the TiCDC service. TiCDC uses this time zone when it internally converts time data types such as `TIMESTAMP` or when it replicates data to the downstream. The default is the local time zone in which the process runs. If you specify `time-zone` (in `sink-uri`) and `tz` at the time, the internal TiCDC processes use the time zone specified by `tz`, and the sink uses the time zone specified by `time-zone` for replicating data to the downstream.
- **cluster-id**: (optional) The ID of the TiCDC cluster. The default value is `default`. `cluster-id` is the unique identifier of a TiCDC cluster. TiCDC nodes with the same `cluster-id` belong to the same cluster. The length of a `cluster-id` is 128 characters at most. `cluster-id` must follow the pattern of `^[a-zA-Z0-9]+(-[a-zA-Z0-9]+)*$` and cannot be one of the following: `owner`, `capture`, `task`, `changefeed`, `job`, and `meta`.

#### 13.9.4.4.2 cdc server configuration file parameters

The following are configurations in the configuration file of `cdc server`:

```
addr = "127.0.0.1:8300"
advertise-addr = ""
log-file = ""
log-level = "info"
data-dir = ""
gc-ttl = 86400 # 24 h
tz = "System"
```

```
cluster-id = "default"

[security]
 ca-path = ""
 cert-path = ""
 key-path = ""

capture-session-ttl = 10 # 10s
owner-flush-interval = 50000000 # 50 ms
processor-flush-interval = 50000000 # 50 ms
per-table-memory-quota = 10485760 # 10 MiB

[log]
 error-output = "stderr"
 [log.file]
 max-size = 300 # 300 MiB
 max-days = 0
 max-backups = 0

[sorter]
 num-concurrent-worker = 4
 chunk-size-limit = 999
 max-memory-percentage = 30
 max-memory-consumption = 17179869184
 num-workerpool-goroutine = 16
 sort-dir = "/tmp/sorter"

[kv-client]
worker-concurrent = 8
worker-pool-size = 0
region-scan-limit = 40
region-retry-duration = 60000000000
```

### 13.9.4.5 CLI and Configuration Parameters of TiCDC Changefeeds

#### 13.9.4.5.1 Changefeed CLI parameters

This section introduces the command-line parameters of TiCDC changefeeds by illustrating how to create a replication (changefeed) task:

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
↳ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
↳ task"
```

```

Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7178706266519722477,"namespace":"default","id":"simple-
 ↪ replication-task","sink_uri":"mysql://root:xxxxx@127.0.0.1:4000/?time
 ↪ -zone=","create_time":"2022-12-19T15:05:46.679218+08:00","start_ts
 ↪ ":438156275634929669,"engine":"unified","config":{"case_sensitive":

 ↪ ignore_ineligible_table":false,"check_gc_safe_point":true,"
 ↪ enable_sync_point":true,"bdr_mode":false,"sync_point_interval
 ↪ ":30000000000,"sync_point_retention":3600000000000,"filter":{"rules
 ↪ ":["test.*"],"event_filters":null},"mounter":{"worker_num":16},"sink
 ↪ ":{"protocol":"","schema_registry":"","csv":{"delimiter":",","quote
 ↪ ":"\"","null":"\\N","include_commit_ts":false},"column_selectors":
 ↪ null,"transaction_atomicity":"none","encoder_concurrency":16,"
 ↪ terminator":"\r\n","date_separator":"none","
 ↪ enable_partition_separator":false},"consistent":{"level":"none","
 ↪ max_log_size":64,"flush_interval":2000,"storage":""},"state":"normal
 ↪ ","creator_version":"v6.5.0"}

```

- `--changefeed-id`: The ID of the replication task. The format must match the `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. Configure `--sink-uri` according to the following format. Currently, the scheme supports `mysql`, `tidb`, and `kafka`.

```
[scheme]://[userinfo@][host]:[port][path]?[query_parameters]
```

When the sink URI contains special characters such as `! * ' ( ) ; : @ & = + $ ↪ , / ? % # [ ]`, you need to escape the special characters, for example, in [URI Encoder](#).

- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the configuration file of the changefeed.

### 13.9.4.5.2 Changefeed configuration parameters

This section introduces the configuration of a replication task.

```
Specifies the memory quota (in bytes) that can be used in the capture
 ↪ server by the sink manager.
If the value is exceeded, the overused part will be recycled by the go
 ↪ runtime.
The default value is `1073741824` (1 GB).
memory-quota = 1073741824

Specifies whether the database names and tables in the configuration
 ↪ file are case-sensitive.
The default value is true.
This configuration item affects configurations related to filter and
 ↪ sink.
case-sensitive = true

Specifies whether to output the old value. New in v4.0.5. Since v5.0,
 ↪ the default value is `true`.
enable-old-value = true

Specifies whether to enable the Syncpoint feature, which is supported
 ↪ since v6.3.0 and is disabled by default.
Since v6.4.0, only the changefeed with the SYSTEM_VARIABLES_ADMIN or
 ↪ SUPER privilege can use the TiCDC Syncpoint feature.
Note: This configuration item only takes effect if the downstream is
 ↪ Kafka or a storage service.
enable-sync-point = false

Specifies the interval at which Syncpoint aligns the upstream and
 ↪ downstream snapshots.
The format is in h m s. For example, "1h30m30s".
The default value is "10m" and the minimum value is "30s".
Note: This configuration item only takes effect if the downstream is
 ↪ Kafka or a storage service.
sync-point-interval = "5m"

Specifies how long the data is retained by Syncpoint in the downstream
 ↪ table. When this duration is exceeded, the data is cleaned up.
The format is in h m s. For example, "24h30m30s".
The default value is "24h".
Note: This configuration item only takes effect if the downstream is
 ↪ Kafka or a storage service.
sync-point-retention = "1h"

[mounter]
The number of threads with which the mounter decodes KV data. The
```

```
 ↪ default value is 16.
worker-num = 16

[filter]
Ignores the transaction of specified start_ts.
ignore-txn-start-ts = [1, 2]

Filter rules.
Filter syntax: <https://docs.pingcap.com/tidb/stable/table-filter#
 ↪ syntax>.
rules = ['*.*', '!test.*']

Specifies the transaction that will be ignored with the specified
 ↪ start_ts.
The default value is an empty list.
IgnoreTxnStartTs = []

Event filter rules.
The detailed syntax is described in the event filter rules section.
The first event filter rule.
[[filter.event-filters]]
matcher = ["test.worker"] # matcher is an allow list, which means this rule
 ↪ only applies to the worker table in the test database.
ignore-event = ["insert"] # Ignore insert events.
ignore-sql = ["^drop", "add column"] # Ignore DDLs that start with "drop" or
 ↪ contain "add column".
ignore-delete-value-expr = "name = 'john'" # Ignore delete DMLs that contain
 ↪ the condition "name = 'john'".
ignore-insert-value-expr = "id >= 100" # Ignore insert DMLs that contain the
 ↪ condition "id >= 100".
ignore-update-old-value-expr = "age < 18" # Ignore update DMLs whose old
 ↪ value contains "age < 18".
ignore-update-new-value-expr = "gender = 'male'" # Ignore update DMLs whose
 ↪ new value contains "gender = 'male'".

The second event filter rule.
matcher = ["test.fruit"] # matcher is an allow list, which means this rule
 ↪ only applies to the fruit table in the test database.
ignore-event = ["drop table"] # Ignore drop table events.
ignore-sql = ["delete"] # Ignore delete DMLs.
ignore-insert-value-expr = "price > 1000 and origin = 'no where'" # Ignore
 ↪ insert DMLs that contain the conditions "price > 1000" and "origin =
 ↪ 'no where'".

[scheduler]
```

```
Splits a table into multiple replication ranges based on the number of
↳ Regions, and these ranges can be replicated by multiple TiCDC nodes.
Note: This configuration item only takes effect on Kafka changefeeds
↳ and is not supported on MySQL changefeeds.
The value is "false" by default. Set it to "true" to enable this
↳ feature.
enable-table-across-nodes = false
When you enable this feature, it takes effect for tables with the
↳ number of Regions greater than the `region-threshold` value.
region-threshold = 100000
When you enable this feature, it takes effect for tables with the
↳ number of rows modified per minute greater than the `write-key-
↳ threshold` value.
Note:
1. Scaling out a single large table is an experimental feature. It is
↳ not recommended that you use it in the production environment.
2. This parameter only takes effect on Kafka changefeeds and is not
↳ supported on MySQL changefeeds.
3. TiCDC does not split tables with fewer Regions than this parameter
↳ value into multiple replication ranges.
region-per-span = 50000

[sink]
For the sink of MQ type, you can use dispatchers to configure the event
↳ dispatcher.
Since v6.1.0, TiDB supports two types of event dispatchers: partition
↳ and topic. For more information, see <partition and topic link>.
The matching syntax of matcher is the same as the filter rule syntax.
↳ For details about the matcher rules, see <>.
Note: This configuration item only takes effect if the downstream is MQ
↳ .
dispatchers = [
 {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1",
 ↳ partition = "ts" },
 {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2",
 ↳ partition = "index-value" },
 {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3",
 ↳ partition = "table"},
 {matcher = ['test6.*'], partition = "ts"}
]

The protocol configuration item specifies the protocol format of the
↳ messages sent to the downstream.
When the downstream is Kafka, the protocol can only be canal-json or
↳ avro.
```

```
When the downstream is a storage service, the protocol can only be
↳ canal-json or csv.
Note: This configuration item only takes effect if the downstream is
↳ Kafka or a storage service.
protocol = "canal-json"

The following three configuration items are only used when you
↳ replicate data to storage sinks and can be ignored when replicating
↳ data to MQ or MySQL sinks.
Row terminator, used for separating two data change events. The default
↳ value is an empty string, which means "\r\n" is used.
terminator = ''

Date separator type used in the file directory. Value options are `none
↳ `, `year`, `month`, and `day`. `none` is the default value and means
↳ that the date is not separated. For more information, see <https://
↳ docs.pingcap.com/tidb/dev/ticdc-sink-to-cloud-storage#data-change-
↳ records>.
Note: This configuration item only takes effect if the downstream is a
↳ storage service.
date-separator = 'none'

Whether to use partitions as the separation string. The default value
↳ is false, which means that partitions in a table are not stored in
↳ separate directories. For more information, see <https://docs.pingcap
↳ .com/tidb/dev/ticdc-sink-to-cloud-storage#data-change-records>.
Note: This configuration item only takes effect if the downstream is a
↳ storage service.
enable-partition-separator = false

Schema registry URL.
Note: This configuration item only takes effect if the downstream is MQ
↳ .
schema-registry = "http://localhost:80801/subjects/{subject-name}/
↳ versions/{version-number}/schema"

Specifies the number of encoder threads used when encoding data.
Note: This configuration item only takes effect if the downstream is MQ
↳ .
The default value is 16.
encoder-concurrency = 16

Specifies whether to enable kafka-sink-v2 that uses the kafka-go sink
↳ library.
Note: This configuration item only takes effect if the downstream is MQ
↳ .
```

```
The default value is false.
enable-kafka-sink-v2 = false

Since v6.5.0, TiCDC supports saving data changes to storage services in
 ↳ CSV format. Ignore the following configurations if you replicate
 ↳ data to MQ or MySQL sinks.
[sink.csv]
The character used to separate fields in the CSV file. The value must
 ↳ be an ASCII character and defaults to ``,`.
delimiter = ','
The quotation character used to surround fields in the CSV file. The
 ↳ default value is `""`. If the value is empty, no quotation is used.
quote = ""
The character displayed when a CSV column is null. The default value is
 ↳ `\\N`.
null = '\\N'
Whether to include commit-ts in CSV rows. The default value is false.
include-commit-ts = false

Specifies the replication consistency configurations for a changefeed
 ↳ when using the redo log. For more information, see https://docs.pingcap.com/tidb/stable/ticdc-sink-to-mysql#eventually-consistent-replication-in-disaster-scenarios.
Note: The consistency-related configuration items only take effect when
 ↳ the downstream is a database and the redo log feature is enabled.
[sink.consistent]
The data consistency level. Available options are "none" and "eventual
 ↳ ". "none" means that the redo log is disabled.
The default value is "none".
level = "none"
The max redo log size in MB.
The default value is 64.
max-log-size = 64
The flush interval for redo log. The default value is 2000 milliseconds
 ↳ .
flush-interval = 2000
The storage URI of the redo log.
The default value is empty.
storage = ""
Specifies whether to store the redo log in a file.
The default value is false.
use-file-backend = false
```

#### 13.9.4.6 Output Protocols

### 13.9.4.6.1 TiCDC Avro Protocol

Avro is a data exchange format protocol defined by [Apache Avro™](#) and chosen by [Confluent Platform](#) as the default data exchange format. This document describes the implementation of the Avro data format in TiCDC, including TiDB extension fields, definition of the Avro data format, and the interaction between Avro and [Confluent Schema Registry](#).

Use Avro

When using Message Queue (MQ) as a downstream sink, you can specify Avro in `sink-uri`. TiCDC captures TiDB DML events, creates Avro messages from these events, and sends the messages downstream. When Avro detects a schema change, it registers the latest schema with Schema Registry.

The following is a configuration example using Avro:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
↳ kafka-avro" --sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=
↳ avro" --schema-registry=http://127.0.0.1:8081 --config
↳ changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

The value of `--schema-registry` supports the `https` protocol and `username:password` authentication, for example, `--schema-registry=https://username:password@schema-registry-uri.com`. The username and password must be URL-encoded.

TiDB extension fields

By default, Avro only collects data of changed rows in DML events and does not collect the type of data changes or TiDB-specific CommitTS (the unique identifiers of transactions). To address this issue, TiCDC introduces the following three TiDB extension fields to the Avro protocol message. When `enable-tidb-extension` is set to `true` (`false` by default) in `sink-uri`, TiCDC adds these three fields to the Avro messages during message generation.

- `_tidb_op`: The DML type. “c” indicates insert and “u” indicates updates.
- `_tidb_commit_ts`: The unique identifier of a transaction.
- `_tidb_commit_physical_time`: The physical timestamp in a transaction identifier.

The following is a configuration example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
↳ kafka-avro-enable-extension" --sink-uri="kafka://127.0.0.1:9092/topic
↳ -name?protocol=avro&enable-tidb-extension=true" --schema-registry=
↳ http://127.0.0.1:8081 --config changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

Definition of the data format

TiCDC converts a DML event into a Kafka event, and the Key and Value of an event are encoded according to the Avro protocol.

Key data format

```
{
 "name": "{{TableName}}",
 "namespace": "{{Namespace}}",
 "type": "record",
 "fields": [
 {{ColumnValueBlock}},
 {{ColumnValueBlock}},
]
}
```

- `{{TableName}}` indicates the name of the table where the event occurs.
- `{{Namespace}}` is the namespace of Avro.
- `{{ColumnValueBlock}}` defines the format of each column of data.

The `fields` in the key contains only primary key columns or unique index columns.

Value data format

```
{
 "name": "{{TableName}}",
 "namespace": "{{Namespace}}",
 "type": "record",
 "fields": [
 {{ColumnValueBlock}},
 {{ColumnValueBlock}},
]
}
```

The data format of Value is the same as that of Key, by default. However, `fields` in the Value contains all columns, not just the primary key columns.

After you enable `enable-tidb-extension`, the data format of the Value will be as follows:

```
{
 "name": "{{TableName}}",
 "namespace": "{{Namespace}}",
 "type": "record",
 "fields": [
 {{ColumnValueBlock}},
 {{ColumnValueBlock}},
 {
 "name": "_tidb_op",
 "type": "string"
 },
 {
 "name": "_tidb_commit_ts",
 "type": "long"
 },
 {
 "name": "_tidb_commit_physical_time",
 "type": "long"
 }
]
}
```

Compared with the Value data format with `enable-tidb-extension` disabled, three new fields are added: `_tidb_op`, `_tidb_commit_ts`, and `_tidb_commit_physical_time`.

#### Column data format

The Column data is the `{{ColumnValueBlock}}` part of the Key/Value data format. TiCDC generates the Column data format based on the SQL Type. The basic Column data format is as follows:

```
{
 "name": "{{ColumnName}}",
 "type": {
 "connect.parameters": {
 "tidb_type": "{{TIDB_TYPE}}"
 },
 "type": "{{AVRO_TYPE}}"
 }
}
```

If one column can be NULL, the Column data format can be:

```
{
 "default": null,
 "name": "{{ColumnName}}",
}
```

```

"type": [
 "null",
 {
 "connect.parameters": {
 "tidb_type": "{{TIDB_TYPE}}"
 },
 "type": "{{AVRO_TYPE}}"
 }
]
}

```

- `{{ColumnName}}` indicates the column name.
- `{{TIDB_TYPE}}` indicates the type in TiDB, which is not a one-to-one mapping with the SQL type.
- `{{AVRO_TYPE}}` indicates the type in [avro spec](#).

---

#### SQL

SQL TYPE	TIDB_TYPE	AVRO_TYPE	Description
BOOL	INT	int	
TINYINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
SMALLINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
MEDIUMINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
INT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED and AVRO_TYPE is long.
BIGINT	BIGINT	long	When it is unsigned, TIDB_TYPE is BIGINT UNSIGNED. If <code>avro-bigint-unsigned-handling-mode</code> is string, AVRO_TYPE is string.
TINYBLOB	BLOB	bytes	-
BLOB	BLOB	bytes	-
MEDIUMBLOB	BLOB	bytes	-
LOB	BLOB	bytes	-
BINARY	BLOB	bytes	-
VARBINARY	BLOB	bytes	-
TINYTEXT	TEXT	string	-
TEXT	TEXT	string	-
MEDIUMTEXT	TEXT	string	-
LONGTEXT	TEXT	string	-
CHAR	TEXT	string	-
VARCHAR	TEXT	string	-
FLOAT	FLOAT	double	-
DOUBLE	DOUBLE	double	-
DATE	DATE	string	-
DATETIME	DATETIME	string	-

---

SQL TYPE	TIDB_TYPE	AVRO_TYPE	Description
TIMESTAMP	TIMESTAMP	string	-
TIME	TIME	string	-
YEAR	YEAR	int	-
BIT	BIT	bytes	-
JSON	JSON	string	-
ENUM	ENUM	string	-
SET	SET	string	-
DECIMAL	DECIMAL	bytes	When <code>avro-decimal-handling-mode</code> is string, AVRO_TYPE is string.

---

In the Avro protocol, two other `sink-uri` parameters might affect the Column data format as well: `avro-decimal-handling-mode` and `avro-bigint-unsigned-handling-mode`.

- `avro-decimal-handling-mode` controls how Avro handles decimal fields, including:
  - string: Avro handles decimal fields as strings.
  - precise: Avro handles decimal fields as bytes.
- `avro-bigint-unsigned-handling-mode` controls how Avro handles BIGINT UNSIGNED fields, including:
  - string: Avro handles BIGINT UNSIGNED fields as strings.
  - long: Avro handles BIGINT UNSIGNED fields as 64-bit signed integers. When the value is greater than 9223372036854775807, overflow will occur.

The following is a configuration example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
↳ kafka-avro-string-option" --sink-uri="kafka://127.0.0.1:9092/topic-
↳ name?protocol=avro&avro-decimal-handling-mode=string&avro-bigint-
↳ unsigned-handling-mode=string" --schema-registry=http
↳ ://127.0.0.1:8081 --config changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

Most SQL types are mapped to the base Column data format. Some other SQL types extend the base data format to provide more information.

BIT(64)

```
{
 "name": "{{ColumnName}}",
 "type": {
 "connect.parameters": {
 "tidb_type": "BIT",
 "length": "64"
 },
 "type": "bytes"
 }
}
```

ENUM/SET(a,b,c)

```
{
 "name": "{{ColumnName}}",
 "type": {
 "connect.parameters": {
 "tidb_type": "ENUM/SET",
 "allowed": "a,b,c"
 },
 "type": "string"
 }
}
```

DECIMAL(10, 4)

```
{
 "name": "{{ColumnName}}",
 "type": {
 "connect.parameters": {
 "tidb_type": "DECIMAL",
 },
 "logicalType": "decimal",
 "precision": 10,
 "scale": 4,
 "type": "bytes"
 }
}
```

DDL events and schema changes

Avro does not generate DDL events downstream. It checks whether a schema changes each time a DML event occurs. If a schema changes, Avro generates a new schema and registers it with the Schema Registry. If the schema change does not pass the compatibility check, the registration fails. Avro does not resolve any schema compatibility issues.

Note that, even if a schema change passes the compatibility check and a new version is registered, the data producers and consumers still need to perform an upgrade to ensure normal running of the system.

Assume that the default compatibility policy of Confluent Schema Registry is `BACKWARD` and add a non-empty column to the source table. In this situation, Avro generates a new schema but fails to register it with Schema Registry due to compatibility issues. At this time, the changefeed enters an error state.

For more information about schemas, refer to [Schema Registry related documents](#).

Topic distribution

Schema Registry supports three [Subject Name Strategies](#): `TopicNameStrategy`, `RecordNameStrategy`, and `TopicRecordNameStrategy`. Currently, TiCDC Avro only supports `TopicNameStrategy`, which means that a Kafka topic can only receive data in one data format. Therefore, TiCDC Avro prohibits mapping multiple tables to the same topic. When you create a changefeed, an error will be reported if the topic rule does not include the `{schema}` and `{table}` placeholders in the configured distribution rule.

#### 13.9.4.6.2 TiCDC Canal-JSON Protocol

Canal-JSON is a data exchange format protocol defined by [Alibaba Canal](#). In this document, you can learn how Canal-JSON data formats are implemented in TiCDC, including the TiDB extension field, the definitions of the Canal-JSON data formats, and comparison with the official Canal.

Use Canal-JSON

When using Message Queue (MQ) as the downstream Sink, you can specify Canal-JSON in `sink-uri`. TiCDC wraps and constructs Canal-JSON messages with Event as the basic unit, and sends TiDB data change Events to the downstream.

There are three types of Events:

- DDL Event: Represents a DDL change record. It is sent after an upstream DDL statement is successfully executed. The DDL Event is sent to the MQ Partition with the index being 0.
- DML Event: Represents a row data change record. This type of Event is sent when a row change occurs. It contains the information about the row after the change occurs.
- WATERMARK Event: Represents a special time point. It indicates that the Events received before this point is complete. It applies only to the TiDB extension field and takes effect when you set `enable-tidb-extension` to `true` in `sink-uri`.

The following is an example of using Canal-JSON:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
↳ kafka-canal-json" --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka
↳ -version=2.4.0&protocol=canal-json"
```

## TiDB extension field

The Canal-JSON protocol is originally designed for MySQL. It does not contain important fields such as the TiDB-specific unique identifier for the CommitTS transaction. To solve this problem, TiCDC appends a TiDB extension field to the Canal-JSON protocol format. After you set `enable-tidb-extension` to `true` (`false` by default) in `sink-uri`, TiCDC behaves as follows when generating Canal-JSON messages:

- TiCDC sends DML Event and DDL Event messages that contain a field named `_tidb`.
- TiCDC sends WATERMARK Event messages.

The following is an example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
↳ kafka-canal-json-enable-tidb-extension" --sink-uri="kafka
↳ ://127.0.0.1:9092/topic-name?kafka-version=2.4.0&protocol=canal-json&
↳ enable-tidb-extension=true"
```

## Definitions of message formats

This section describes the formats of DDL Event, DML Event and WATERMARK Event, and how the data is resolved on the consumer side.

### DDL Event

TiCDC encodes a DDL Event into the following Canal-JSON format.

```
{
 "id": 0,
 "database": "test",
 "table": "",
 "pkNames": null,
 "isDdl": true,
 "type": "QUERY",
 "es": 1639633094670,
 "ts": 1639633095489,
 "sql": "drop database if exists test",
 "sqlType": null,
 "mysqlType": null,
 "data": null,
 "old": null,
 "_tidb": { // TiDB extension field
 "commitTs": 163963309467037594
 }
}
```

The fields are explained as follows.

Field	Type	Description
id	Number	The default value is 0 in TiCDC.
database	String	The name of the database where the row is located
table	String	The name of the table where the row is located
pkNames	Array	The names of all the columns that make up the primary key
isDdl	Bool	Whether the message is a DDL event
type	String	Event types defined by Canal-JSON
es	Number	13-bit (millisecond) timestamp when the event that generated the message happened
ts	Number	13-bit (millisecond) timestamp when TiCDC generated the message
sql	String	When isDdl is <b>true</b> , records the corresponding DDL statement
sqlType	Object	When isDdl is <b>false</b> , records how the data type of each column is represented in Java
mysqlType	object	When isDdl is <b>false</b> , records how the data type of each column is represented in MySQL
data	Object	When isDdl is <b>false</b> , records the name of each column and its data value
old	Object	Only if the message is generated by an update Event, records the name of each column and the data value before the update
_tidb	Object	TiDB extension field. It exists only if you set <b>enable-tidb-extension</b> to <b>true</b> . The value of <b>commitTs</b> is the TSO of the transaction that caused the row to change.

## DML Event

TiCDC encodes a row of DML data change event as follows:

```
{
 "id": 0,
 "database": "test",
 "table": "tp_int",
 "pkNames": [
 "id"
],
 "isDdl": false,
 "type": "INSERT",
 "es": 1639633141221,
 "ts": 1639633142960,
 "sql": "",
 "sqlType": {
 "c_bigint": -5,
 "c_int": 4,
 "c_mediumint": 4,
 "c_smallint": 5,
 }
}
```

```
 "c_tinyint": -6,
 "id": 4
 },
 "mysqlType": {
 "c_bigint": "bigint",
 "c_int": "int",
 "c_mediumint": "mediumint",
 "c_smallint": "smallint",
 "c_tinyint": "tinyint",
 "id": "int"
 },
 "data": [
 {
 "c_bigint": "9223372036854775807",
 "c_int": "2147483647",
 "c_mediumint": "8388607",
 "c_smallint": "32767",
 "c_tinyint": "127",
 "id": "2"
 }
],
 "old": null,
 "_tidb": { // TiDB extension field
 "commitTs": 163963314122145239
 }
}
```

## WATERMARK Event

TiCDC sends a WATERMARK Event only when you set `enable-tidb-extension` to `true`. The value of the `type` field is `TIDB_WATERMARK`. The Event contains the `_tidb` field, and the field contains only one parameter `watermarkTs`. The value of `watermarkTs` is the TSO recorded when the Event is sent.

When you receive an Event of this type, all Events with `commitTs` less than `watermarkTs` have been sent. Because TiCDC provides the “At Least Once” semantics, data might be sent repeatedly. If a subsequent Event with `commitTs` less than `watermarkTs` is received, you can safely ignore this Event.

The following is an example of the WATERMARK Event.

```
{
 "id": 0,
 "database": "",
 "table": "",
 "pkNames": null,
 "isDdl": false,
```

```
"type": "TIDB_WATERMARK",
"es": 1640007049196,
"ts": 1640007050284,
"sql": "",
"sqlType": null,
"mysqlType": null,
"data": null,
"old": null,
"_tidb": { // TiDB extension field
 "watermarkTs": 429918007904436226
}
}
```

Data resolution on the consumer side

As you can see from the example above, Canal-JSON has a uniform data format, with different field filling rules for different Event types. You can use a uniform method to resolve this JSON format data, and then determine the Event type by checking the field values.

- When `isDdl` is `true`, the message contains a DDL Event.
- When `isDdl` is `false`, you need to further check the `type` field. If `type` is `TIDB_WATERMARK`, it is a WATERMARK Event; otherwise, it is a DML Event.

Field descriptions

The Canal-JSON format records the corresponding data type in the `mysqlType` field and the `sqlType` field.

MySQL Type field

In the `mysqlType` field, the Canal-JSON format records the string of MySQL Type in each column. For more information, see [TiDB Data Types](#).

SQL Type field

In the `sqlType` field, the Canal-JSON format records Java SQL Type of each column, which is the data type corresponding to the data in JDBC. Its value can be calculated by MySQL Type and the specific data value. The mapping is as follows:

MySQL Type	Java SQL Type Code
Boolean	-6
Float	7
Double	8
Decimal	3
Char	1
Varchar	12
Binary	2004
Varbinary	2004
	2532

MySQL Type	Java SQL Type Code
Tinytext	2005
Text	2005
Mediumtext	2005
Longtext	2005
Tinyblob	2004
Blob	2004
Mediumblob	2004
Longblob	2004
Date	91
Datetime	93
Timestamp	93
Time	92
Year	12
Enum	4
Set	-7
Bit	-7
JSON	12

### Integer types

You need to consider whether **integer types** have the **Unsigned** constraint and the value size, which corresponds to different Java SQL Type Codes respectively, as shown in the following table.

MySQL Type String	Value Range	Java SQL Type Code
tinyint	[-128, 127]	-6
tinyint unsigned	[0, 127]	-6
tinyint unsigned	[128, 255]	5
smallint	[-32768, 32767]	5
smallint unsigned	[0, 32767]	5
smallint unsigned	[32768, 65535]	4
mediumint	[-8388608, 8388607]	4
mediumint unsigned	[0, 8388607]	4
mediumint unsigned	[8388608, 16777215]	4
int	[-2147483648, 2147483647]	4
int unsigned	[0, 2147483647]	4
int unsigned	[2147483648, 4294967295]	-5
bigint	[-9223372036854775808, 9223372036854775807]	-5
bigint unsigned	[0, 9223372036854775807]	-5
bigint unsigned	[9223372036854775808, 18446744073709551615]	3

The following table shows the mapping relationships between Java SQL Types in TiCDC

and their codes.

Java SQL Type	Java SQL Type Code
CHAR	1
DECIMAL	3
INTEGER	4
SMALLINT	5
REAL	7
DOUBLE	8
VARCHAR	12
DATE	91
TIME	92
TIMESTAMP	93
BLOB	2004
CLOB	2005
BIGINT	-5
TINYINT	-6
Bit	-7

For more information about Java SQL Types, see [Java SQL Class Types](#).

Comparison of TiCDC Canal-JSON and the official Canal

The way that TiCDC implements the Canal-JSON data format, including the `Update` Event and the `mysqlType` field, differs from the official Canal. The following table shows the main differences.

Item	TiCDC Canal-JSON	Canal
Event of Update Type	The <code>old</code> field contains all the column data	The <code>old</code> field contains only the modified column data
<code>mysqlType</code> field	For types with parameters, it does not contain the information of the type parameter	For types with parameters, it contains the full information of the type parameter

Event of Update Type

For an Event of Update Type:

- In TiCDC, the `old` field contains all the column data
- In the official Canal, the `old` field contains only the modified column data

Assume that the following SQL statements are executed sequentially in the upstream TiDB:

```
create table tp_int
(
 id int auto_increment,
 c_tinyint tinyint null,
 c_smallint smallint null,
 c_mediumint mediumint null,
 c_int int null,
 c_bigint bigint null,
 constraint pk
 primary key (id)
);

insert into tp_int(c_tinyint, c_smallint, c_mediumint, c_int, c_bigint)
values (127, 32767, 8388607, 2147483647, 9223372036854775807);

update tp_int set c_int = 0, c_tinyint = 0 where c_smallint = 32767;
```

For the update statement, TiCDC outputs an Event message with type as UPDATE, as shown below. The update statement only modifies the `c_int` and `c_tinyint` columns. The old field in the output event message contains all the column data.

```
{
 "id": 0,
 ...
 "type": "UPDATE",
 ...
 "sqlType": {
 ...
 },
 "mysqlType": {
 ...
 },
 "data": [
 {
 "c_bigint": "9223372036854775807",
 "c_int": "0",
 "c_mediumint": "8388607",
 "c_smallint": "32767",
 "c_tinyint": "0",
 "id": "2"
 }
],
 "old": [// In TiCDC, this field contains all
 ↪ the column data.
 {
```

```
 "c_bigint": "9223372036854775807",
 "c_int": "2147483647", // Modified column
 "c_mediumint": "8388607",
 "c_smallint": "32767",
 "c_tinyint": "127", // Modified column
 "id": "2"
 }
]
}
```

For the official Canal, the old field in the output event message contains only the modified column data, as shown below.

```
{
 "id": 0,
 ...
 "type": "UPDATE",
 ...
 "sqlType": {
 ...
 },
 "mysqlType": {
 ...
 },
 "data": [
 {
 "c_bigint": "9223372036854775807",
 "c_int": "0",
 "c_mediumint": "8388607",
 "c_smallint": "32767",
 "c_tinyint": "0",
 "id": "2"
 }
],
 "old": [// In Canal, this field contains only
 ↪ the modified column data.
 {
 "c_int": "2147483647", // Modified column
 "c_tinyint": "127", // Modified column
 }
]
}
```

mysqlType field

For the mysqlType field, if a type contains parameters, the official Canal contains the

full information of the type parameter. TiCDC does not contain such information.

In the following example, the table-defining SQL statement contains a parameter for each column, such as the ones for `decimal`, `char`, `varchar` and `enum`. By comparing the Canal-JSON formats generated by TiCDC and the official Canal, you can see that TiCDC only contains the basic MySQL information in the `mysqlType` field. If you need the full information of the type parameter, you need to implement it by other means.

Assume that the following SQL statements are executed sequentially in the upstream TiDB:

```
create table t (
 id int auto_increment,
 c_decimal decimal(10, 4) null,
 c_char char(16) null,
 c_varchar varchar(16) null,
 c_binary binary(16) null,
 c_varbinary varbinary(16) null,
 c_enum enum('a','b','c') null,
 c_set set('a','b','c') null,
 c_bit bit(64) null,
 constraint pk
 primary key (id)
);

insert into t (c_decimal, c_char, c_varchar, c_binary, c_varbinary, c_enum,
 ↪ c_set, c_bit)
values (123.456, "abc", "abc", "abc", "abc", 'a', 'a,b', b'1000001');
```

The output of TiCDC is as follows:

```
{
 "id": 0,
 ...
 "isDdl": false,
 "sqlType": {
 ...
 },
 "mysqlType": {
 "c_binary": "binary",
 "c_bit": "bit",
 "c_char": "char",
 "c_decimal": "decimal",
 "c_enum": "enum",
 "c_set": "set",
 "c_varbinary": "varbinary",
 "c_varchar": "varchar",
```

```
 "id": "int"
 },
 "data": [
 {
 ...
 }
],
 "old": null,
}
```

The output of the official Canal is as follows:

```
{
 "id": 0,
 ...
 "isDdl": false,
 "sqlType": {
 ...
 },
 "mysqlType": {
 "c_binary": "binary(16)",
 "c_bit": "bit(64)",
 "c_char": "char(16)",
 "c_decimal": "decimal(10, 4)",
 "c_enum": "enum('a','b','c')",
 "c_set": "set('a','b','c')",
 "c_varbinary": "varbinary(16)",
 "c_varchar": "varchar(16)",
 "id": "int"
 },
 "data": [
 {
 ...
 }
],
 "old": null,
}
```

## Changes in TiCDC Canal-JSON

### Changes in the Old field of the Delete events

From v5.4.0, the `old` field of the `Delete` events has changed.

The following is a `Delete` event message. Before v5.4.0, the `old` field contains the same content as the “`data`” field. In v5.4.0 and later versions, the `old` field is set to null. You can get the deleted data by using the “`data`” field.

```
{
 "id": 0,
 "database": "test",
 ...
 "type": "DELETE",
 ...
 "sqlType": {
 ...
 },
 "mysqlType": {
 ...
 },
 "data": [
 {
 "c_bigint": "9223372036854775807",
 "c_int": "0",
 "c_mediumint": "8388607",
 "c_smallint": "32767",
 "c_tinyint": "0",
 "id": "2"
 }
],
 "old": null,
 // The following is an example before v5.4.0. The `old` field contains
 // ↔ the same content as the "data" field.
 "old": [
 {
 "c_bigint": "9223372036854775807",
 "c_int": "0",
 "c_mediumint": "8388607",
 "c_smallint": "32767",
 "c_tinyint": "0",
 "id": "2"
 }
]
}
```

### 13.9.4.6.3 TiCDC Open Protocol

TiCDC Open Protocol is a row-level data change notification protocol that provides data sources for monitoring, caching, full-text indexing, analysis engines, and primary-secondary replication between different databases. TiCDC complies with TiCDC Open Protocol and replicates data changes of TiDB to third-party data medium such as MQ (Message Queue).

TiCDC Open Protocol uses Event as the basic unit to replicate data change events to the downstream. The Event is divided into three categories:

- Row Changed Event: Represents the data change in a row. When a row is changed, this Event is sent and contains information about the changed row.
- DDL Event: Represents the DDL change. This Event is sent after a DDL statement is successfully executed in the upstream. The DDL Event is broadcasted to every MQ Partition.
- Resolved Event: Represents a special time point before which the Event received is complete.

### Restrictions

- In most cases, the Row Changed Event of a version is sent only once, but in special situations such as node failure and network partition, the Row Changed Event of the same version might be sent multiple times.
- On the same table, the Row Changed Events of each version which is first sent are incremented in the order of timestamps (TS) in the Event stream.
- Resolved Events are periodically broadcasted to each MQ Partition. The Resolved Event means that any Event with a TS earlier than Resolved Event TS has been sent to the downstream.
- DDL Events are broadcasted to each MQ Partition.
- Multiple Row Changed Events of a row are sent to the same MQ Partition.

### Message format

A Message contains one or more Events, arranged in the following format:

Key:

Offset(Byte)	0~7	8~15	16~(15+length1)	...	...
Parameter	Protocol version	Length1	Event Key1	LengthN	Event KeyN

Value:

Offset(Byte)	0~7	8~(7+length1)	...	...
Parameter	Length1	Event Value1	LengthN	Event ValueN

- **LengthN** represents the length of the Nth key/value.
- The length and protocol version are the big-endian `int64` type.
- The version of the current protocol is 1.

### Event format

This section introduces the formats of Row Changed Event, DDL Event, and Resolved Event.

### Row Changed Event

- **Key:**

```
{
 "ts":<TS>,
 "scm":<Schema Name>,
 "tbl":<Table Name>,
 "t":1
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that causes the row change.
Schema Name	String	The name of the schema where the row is in.
Table Name	String	The name of the table where the row is in.

- **Value:**

**Insert** event. The newly added row data is output.

```
{
 "u":{
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 },
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 }
 }
}
```

**Update** event. The newly added row data (“u”) and the row data before the update (“p”) are output. The latter (“p”) is output only when the old value feature is enabled.

```
{
 "u":{
 <Column Name>:{
```

```
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 },
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 }
},
"p":{
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 },
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 }
}
}
```

**Delete** event. The deleted row data is output. When the old value feature is enabled, the **Delete** event includes all the columns of the deleted row data; when this feature is disabled, the **Delete** event only includes the **HandleKey** column.

```
{
 "d":{
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 },
 <Column Name>:{
 "t":<Column Type>,
 "h":<Where Handle>,
 "f":<Flag>,
 "v":<Column Value>
 }
 }
}
```

```

 }
 }
}

```

Parameter	Type	Description
Column Name	String	The column name.
Column Type	Number	The column type. For details, see <a href="#">Column Type Code</a> .
Where Handle	Boolean	Determines whether this column can be the filter condition of the <code>Where</code> clause. When this column is unique on the table, <code>Where Handle</code> is <code>true</code> .
Flag	Number	The bit flags of columns. For details, see <a href="#">Bit flags of columns</a> .
Column Value	Any	The Column value.

## DDL Event

- **Key:**

```

{
 "ts":<TS>,
 "scm":<Schema Name>,
 "tbl":<Table Name>,
 "t":2
}

```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that performs the DDL change.
Schema Name	String	The schema name of the DDL change, which might be an empty string.
Table Name	String	The table name of the DDL change, which might be an empty string.

- **Value:**

```
{
 "q":<DDL Query>,
 "t":<DDL Type>
}
```

Parameter	Type	Description
DDL Query	String	DDL Query SQL
DDL Type	String	The DDL type. For details, see <a href="#">DDL Type Code</a> .

Resolved Event

- **Key:**

```
{
 "ts":<TS>,
 "t":3
}
```

Parameter	Type	Description
TS	Number	The Resolved timestamp. Any TS earlier than this Event has been sent.

- **Value:** None

Examples of the Event stream output

This section shows and displays the output logs of the Event stream.

Suppose that you execute the following SQL statement in the upstream and the MQ Partition number is 2:

```
CREATE TABLE test.t1(id int primary key, val varchar(16));
```

From the following Log 1 and Log 3, you can see that the DDL Event is broadcasted to all MQ Partitions, and that the Resolved Event is periodically broadcasted to each MQ Partition.

```
1. [partition=0] [key="{\"ts\":415508856908021766,\"scm\": \"test\", \"tbl\" : \"t1\", \"t\":2}"] [value="{\"q\": \"CREATE TABLE test.t1(id int primary key, val varchar(16))\", \"t\":3}"]
2. [partition=0] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
3. [partition=1] [key="{\"ts\":415508856908021766,\"scm\": \"test\", \"tbl\" : \"t1\", \"t\":2}"] [value="{\"q\": \"CREATE TABLE test.t1(id int primary key, val varchar(16))\", \"t\":3}"]
```

```
4. [partition=1] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
INSERT INTO test.t1(id, val) VALUES (1, 'aa');
INSERT INTO test.t1(id, val) VALUES (2, 'aa');
UPDATE test.t1 SET val = 'bb' WHERE id = 2;
INSERT INTO test.t1(id, val) VALUES (3, 'cc');
COMMIT;
```

- From the following Log 5 and Log 6, you can see that Row Changed Events on the same table might be sent to different partitions based on the primary key, but changes to the same row are sent to the same partition so that the downstream can easily process the Event concurrently.
- From Log 6, multiple changes to the same row in a transaction are only sent in one Row Changed Event.
- Log 8 is a repeated event of Log 7. Row Changed Event might be repeated, but the first Event of each version is sent orderly.

```
5. [partition=0] [key="{\"ts\":415508878783938562,\"scm\": \"test\", \"tbl
↳ \": \"t1\", \"t\":1}"] [value="{\"u\": {\"id\": {\"t\":3, \"h\":true, \"v
↳ \":1}, \"val\": {\"t\":15, \"v\": \"YWE=\\\"}}}]"]
6. [partition=1] [key="{\"ts\":415508878783938562,\"scm\": \"test\", \"tbl
↳ \": \"t1\", \"t\":1}"] [value="{\"u\": {\"id\": {\"t\":3, \"h\":true, \"v
↳ \":2}, \"val\": {\"t\":15, \"v\": \"YmI=\\\"}}}]"]
7. [partition=0] [key="{\"ts\":415508878783938562,\"scm\": \"test\", \"tbl
↳ \": \"t1\", \"t\":1}"] [value="{\"u\": {\"id\": {\"t\":3, \"h\":true, \"v
↳ \":3}, \"val\": {\"t\":15, \"v\": \"Y2M=\\\"}}}]"]
8. [partition=0] [key="{\"ts\":415508878783938562,\"scm\": \"test\", \"tbl
↳ \": \"t1\", \"t\":1}"] [value="{\"u\": {\"id\": {\"t\":3, \"h\":true, \"v
↳ \":3}, \"val\": {\"t\":15, \"v\": \"Y2M=\\\"}}}]"]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
DELETE FROM test.t1 WHERE id = 1;
UPDATE test.t1 SET val = 'dd' WHERE id = 3;
UPDATE test.t1 SET id = 4, val = 'ee' WHERE id = 2;
COMMIT;
```

- Log 9 is the Row Changed Event of the Delete type. This type of Event only contains primary key columns or unique index columns.

- Log 13 and Log 14 are Resolved Events. The Resolved Event means that in this Partition, any events smaller than the Resolved TS (including Row Changed Event and DDL Event) have been sent.

```

9. [partition=0] [key="{\"ts\":415508881418485761,\"scm\": \"test\", \"tbl
 ↪ \": \"t1\", \"t\":1}"] [value="{\"d\": {\"id\": {\"t\":3, \"h\":true, \"v
 ↪ \":1}}}]
10. [partition=1] [key="{\"ts\":415508881418485761,\"scm\": \"test\", \"tbl
 ↪ \": \"t1\", \"t\":1}"] [value="{\"d\": {\"id\": {\"t\":3, \"h\":true, \"v
 ↪ \":2}}}]
11. [partition=0] [key="{\"ts\":415508881418485761,\"scm\": \"test\", \"tbl
 ↪ \": \"t1\", \"t\":1}"] [value="{\"u\": {\"id\": {\"t\":3, \"h\":true, \"v
 ↪ \":3}, \"val\": {\"t\":15, \"v\": \"ZGQ=\\\"}}}]
12. [partition=0] [key="{\"ts\":415508881418485761,\"scm\": \"test\", \"tbl
 ↪ \": \"t1\", \"t\":1}"] [value="{\"u\": {\"id\": {\"t\":3, \"h\":true, \"v
 ↪ \":4}, \"val\": {\"t\":15, \"v\": \"ZWU=\\\"}}}]
13. [partition=0] [key="{\"ts\":415508881038376963, \"t\":3}"] [value=]
14. [partition=1] [key="{\"ts\":415508881038376963, \"t\":3}"] [value=]

```

### Protocol parsing for consumers

Currently, TiCDC does not provide the standard parsing library for TiCDC Open Protocol, but the Golang version and Java version of parsing examples are provided. You can refer to the data format provided in this document and the following examples to implement the protocol parsing for consumers.

- [Golang examples](#)
- [Java examples](#)

### Column type code

Column Type Code represents the column data type of the Row Changed Event.

Type	Code	Output Example	Description
TINYINT/BOOLEAN	1	{“t”:1, “v”:1}	
SMALLINT	2	{“t”:2, “v”:1}	
INT	3	{“t”:3, “v”:123}	
FLOAT	4	{“t”:4, “v”:153.123}	
DOUBLE	5	{“t”:5, “v”:153.123}	
NULL	6	{“t”:6, “v”:null}	
TIMESTAMP	7	{“t”:7, “v”:“1973-12-30 15:30:00”}	

Type	Code	Output Example	Description
BIGINT	8	{“t”:8,“v”:123}	
MEDIUMINT	9	{“t”:9,“v”:123}	
DATE	10/14	{“t”:10,“v”:“2000-01-01”}	
TIME	11	{“t”:11,“v”:“23:59:59”}	
DATETIME	12	{“t”:12,“v”:“2015-12-20 23:58:58”}	
YEAR	13	{“t”:13,“v”:1970}	
VARCHAR/VARBINARY	14/253	{“t”:15,“v”:“The test”}	When the upstream type is VARBINARY, invisible characters are escaped.
BIT	16	{“t”:16,“v”:81}	
JSON	245	{“t”:245,“v”:“{“key1\“:\”value1\”}”}	
DECIMAL	246	{“t”:246,“v”:“129012.1230000”}	
ENUM	247	{“t”:247,“v”:1}	
SET	248	{“t”:248,“v”:3}	

Type	Code	Output Example	Description
TINYTEXT/TINYBLOB	249	{“t”:249,“v”:“The5rWL6K+VdGV4dA==”}	value is encoded in Base64.
MEDIUMTEXT/MEDIUMBLOB	250	{“t”:250,“v”:“The5rWL6K+VdGV4dA==”}	value is encoded in Base64.
LONGTEXT/LONGBLOB	251	{“t”:251,“v”:“The5rWL6K+VdGV4dA==”}	value is encoded in Base64.
TEXT/BLOB	252	{“t”:252,“v”:“The5rWL6K+VdGV4dA==”}	value is encoded in Base64.

Type	Code	Output Example	Description
CHAR/BINARY	254	{“t”:254,“v”:“\ttest”} / {“t”:254,“v”:“\\x89PNG\\r\\n\\x1a\\n”}	When the upstream type is BINARY, invisible characters are escaped.
GEOMETRY	255		Unsupported

## DDL Type Code

DDL Type Code represents the DDL statement type of the DDL Event.

Type	Code
Create Schema	1
Drop Schema	2
Create Table	3
Drop Table	4
Add Column	5
Drop Column	6
Add Index	7
Drop Index	8
Add Foreign Key	9

Type	Code
Drop Foreign Key	10
Truncate Table	11
Modify Column	12
Rebase Auto ID	13
Rename Table	14
Set Default Value	15
Shard RowID	16
Modify Table Comment	17
Rename Index	18
Add Table Partition	19
Drop Table Partition	20
Create View	21
Modify Table Charset And Collate	22
Truncate Table Partition	23
Drop View	24
Recover Table	25
Modify Schema Charset And Collate	26
Lock Table	27
Unlock Table	28
Repair Table	29
Set TiFlash Replica	30
Update TiFlash Replica Status	31
Add Primary Key	32
Drop Primary Key	33
Create Sequence	34
Alter Sequence	35
Drop Sequence	36

### Bit flags of columns

The bit flags represent specific attributes of columns.

Bit	Value	Name	Description
1	0x01	BinaryFlag	Whether the column is a binary-encoded column.
2	0x02	HandleKeyFlag	Whether the column is a Handle index column.
3	0x04	GeneratedColumnFlag	Whether the column is a generated column.
4	0x08	PrimaryKeyFlag	Whether the column is a primary key column.
5	0x10	UniqueKeyFlag	Whether the column is a unique index column.
6	0x20	MultipleKeyFlag	Whether the column is a composite index column.
7	0x40	NullableFlag	Whether the column is a nullable column.
8	0x80	UnsignedFlag	Whether the column is an unsigned column.

Example:

If the value of a column flag is 85, the column is a nullable column, a unique index column, a generated column, and a binary-encoded column.

```
85 == 0b_101_0101
 == NullableFlag | UniqueKeyFlag | GeneratedColumnFlag | BinaryFlag
```

If the value of a column is 46, the column is a composite index column, a primary key column, a generated column, and a Handle key column.

```
46 == 0b_010_1110
 == MultipleKeyFlag | PrimaryKeyFlag | GeneratedColumnFlag | HandleKeyFlag
```

#### Note:

- `BinaryFlag` is meaningful only when the column type is BLOB/TEXT (including TINYBLOB/TINYTEXT and BINARY/CHAR). When the upstream column is the BLOB type, the `BinaryFlag` value is set to 1. When the upstream column is the TEXT type, the `BinaryFlag` value is set to 0.
- To replicate a table from the upstream, TiCDC selects a **valid index** as the Handle index. The `HandleKeyFlag` value of the Handle index column is set to 1.

#### 13.9.4.6.4 TiCDC CSV Protocol

When using a cloud storage service as the downstream sink, you can send DML events to the cloud storage service in CSV format.

Use CSV

The following is an example of the configuration when using the CSV protocol:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
↳ csv-test" --sink-uri="s3://bucket/prefix" --config changefeed.toml
```

The configuration in the `changefeed.toml` file is as follows:

```
[sink]
protocol = "csv"
terminator = "\n"

[sink.csv]
delimiter = ','
```

```
quote = ''
null = '\N'
include-commit-ts = true
```

### Transactional constraints

- In a single CSV file, the `commit-ts` of a row is equal to or smaller than that of the subsequent row.
- The same transactions of a single table are stored in the same CSV file.
- Multiple tables of the same transaction can be stored in different CSV files.

### Definition of the data format

In the CSV file, each column is defined as follows:

- Column 1: The operation-type indicator, including I, U, and D. I means INSERT, U means UPDATE, and D means DELETE.
- Column 2: Table name.
- Column 3: Schema name.
- Column 4: The `commit-ts` of the source transaction. This column is optional.
- Column 5 to the last column: One or more columns that represent data to be changed.

Assume that table `hr.employee` is defined as follows:

```
CREATE TABLE `employee` (
 `Id` int NOT NULL,
 `LastName` varchar(20) DEFAULT NULL,
 `FirstName` varchar(30) DEFAULT NULL,
 `HireDate` date DEFAULT NULL,
 `OfficeLocation` varchar(20) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

The DML events of this table are stored in the CSV format as follows:

```
"I","employee","hr",433305438660591626,101,"Smith","Bob","2014-06-04","New
↪ York"
"U","employee","hr",433305438660591627,101,"Smith","Bob","2015-10-08","Los
↪ Angeles"
"D","employee","hr",433305438660591629,101,"Smith","Bob","2017-03-13","
↪ Dallas"
"I","employee","hr",433305438660591630,102,"Alex","Alice","2017-03-14","
↪ Shanghai"
"U","employee","hr",433305438660591630,102,"Alex","Alice","2018-06-15","
↪ Beijing"
```

### Data type mapping

MySQL type	CSV type	Example	Description
BOOLEAN/TINYINT/SMALLINT ↔ /INT/MEDIUMINT/BIGINT	Integer	123	-
FLOAT/DOUBLE	Float	153.123	-
NULL	Null	\N	-
TIMESTAMP/DATETIME	String	"1973-12-30 ↔ 15:30:00.123456" ↔	Format: yyyy-MM-dd HH:mm:ss.%06d
DATE	String	"2000-01-01"	Format: yyyy-MM-dd
TIME	String	"23:59:59"	Format: yyyy-MM-dd
YEAR	Integer	1970	-
VARCHAR/JSON/TINYTEXT ↔ /MEDIUMTEXT/LONGTEXT ↔ /TEXT/CHAR	String	"test"	UTF-8 encoded
VARBINARY/TINYBLOB ↔ /MEDIUMBLOB/LONGBLOB ↔ /BLOB/BINARY	String	"6Zi/5pav"	base64 encoded
BIT	Integer	81	-
DECIMAL	String	"129012.1230000" ↔	-
ENUM	String	"a"	-
SET	String	"a,b"	-

### 13.9.4.7 TiCDC OpenAPI

TiCDC provides the OpenAPI feature for querying and operating the TiCDC cluster, which is similar to the feature of `cdc cli tool`.

You can use the APIs to perform the following maintenance operations on the TiCDC cluster:

- [Get the status information of a TiCDC node](#)
- [Check the health status of a TiCDC cluster](#)
- [Create a replication task](#)
- [Remove a replication task](#)
- [Update the replication configuration](#)
- [Query the replication task list](#)
- [Query a specific replication task](#)
- [Pause a replication task](#)
- [Resume a replication task](#)
- [Query the replication subtask list](#)
- [Query a specific replication subtask](#)
- [Query the TiCDC service process list](#)

- Evict an owner node
- Manually trigger the load balancing of all tables in a replication task
- Manually schedule a table to another node
- Dynamically adjust the log level of the TiCDC server

The request body and returned value of all APIs are in JSON format. The following sections describe the specific usage of the APIs.

In the following examples, the listening IP address of the TiCDC server is `127.0.0.1` and the port is `8300`. You can bind a specified IP and port via `--addr=ip:port` when starting the TiCDC server.

#### 13.9.4.7.1 API error message template

After sending an API request, if an error occurs, the returned error message is in the following format:

```
{
 "error_msg": "",
 "error_code": ""
}
```

From the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

#### 13.9.4.7.2 Get the status information of a TiCDC node

This API is a synchronous interface. If the request is successful, the status information of the corresponding node is returned.

Request URI

```
GET /api/v1/status
```

Example

The following request gets the status information of the TiCDC node whose IP address is `127.0.0.1` and port number is `8300`.

```
curl -X GET http://127.0.0.1:8300/api/v1/status
```

```
{
 "version": "v5.2.0-master-dirty",
 "git_hash": "f191cd00c53fdf7a2b1c9308a355092f9bf8824e",
 "id": "c6a43c16-0717-45af-afd6-8b3e01e44f5d",
 "pid": 25432,
 "is_owner": true
}
```

The fields of the above output are described as follows:

- `version`: The current TiCDC version number.
- `git_hash`: The Git hash value.
- `id`: The capture ID of the node.
- `pid`: The capture process PID of the node.
- `is_owner`: Indicates whether the node is an owner.

### 13.9.4.7.3 Check the health status of a TiCDC cluster

This API is a synchronous interface. If the cluster is healthy, 200 OK is returned.

Request URI

GET `/api/v1/health`

Example

```
curl -X GET http://127.0.0.1:8300/api/v1/health
```

### 13.9.4.7.4 Create a replication task

This API is an asynchronous interface. If the request is successful, 202 Accepted is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

POST `/api/v1/changefeeds`

Parameter description

Compared to the optional parameters for creating a replication task using the `cli` command, the optional parameters for creating such task using the API are not as complete. This API supports the following parameters.

Parameters for the request body

Parameter name	Description
<code>changefeed_id</code>	STRING type. The ID of the replication task. (Optional)
<code>start_ts</code>	UINT64 type. Specifies the start TSO of the changefeed. (Optional)
<code>target_ts</code>	UINT64 type. Specifies the target TSO of the changefeed. (Optional)
<code>sink_uri</code>	STRING type. The downstream address of the replication task. <b>(Required)</b>
<code>force_replicate</code>	BOOLEAN type. Determines whether to forcibly replicate the tables without unique indexes. (Optional)
<code>ignore_ineligible_table</code>	BOOLEAN type. Determines whether to ignore the tables that cannot be replicated. (Optional)
<code>filter_rules</code>	STRING type array. The rules for table schema filtering. (Optional)
<code>ignore_txn_start_ts</code>	UINT64 type array. Ignores the transaction of a specified <code>start_ts</code> .

(Optional) |  
`mounter_worker_num` | INT type. The mounter thread number. (Optional) |  
`sink_config` | The configuration parameters of sink. (Optional) |

The meaning and format of `changefeed_id`, `start_ts`, `target_ts`, and `sink_uri` are the same as those described in the [Use cdc cli to create a replication task](#) document. For the detailed description of these parameters, see this document. Note that when you specify the certificate path in `sink_uri`, make sure you have uploaded the corresponding certificate to the corresponding TiCDC server.

Some other parameters in the above table are described further as follows.

`force_replicate`: This parameter defaults to `false`. When it is specified as `true`, TiCDC tries to forcibly replicate tables that do not have a unique index.

`ignore_ineligible_table`: This parameter defaults to `false`. When it is specified as `true`, TiCDC ignores tables that cannot be replicated.

`filter_rules`: The rules for table schema filtering, such as `filter_rules = ['foo ↪ *.*', 'bar*.*']`. For details, see the [Table Filter](#) document.

`ignore_txn_start_ts`: When this parameter is specified, the specified `start_ts` is ignored. For example, `ignore-txn-start-ts = [1, 2]`.

`mounter_worker_num`: The thread number of mounter. Mounter is used to decode the data output from TiKV. The default value is 16.

The configuration parameters of sink are as follows:

```
{
 "dispatchers": [
 {"matcher": ["test1.*", "test2.*"], "dispatcher": "ts"},
 {"matcher": ["test3.*", "test4.*"], "dispatcher": "rowid"}
],
 "protocol": "canal-json"
}
```

`dispatchers`: For the sink of MQ type, you can use dispatchers to configure the event dispatcher. Four dispatchers are supported: `default`, `ts`, `rowid`, and `table`. The dispatcher rules are as follows:

- `default`: When multiple unique indexes (including the primary key) exist or the Old Value feature is enabled, events are dispatched in the `table` mode. When only one unique index (or the primary key) exists, events are dispatched in the `rowid` mode.
- `ts`: Uses the commitTs of the row change to create the hash value and dispatch events.
- `rowid`: Uses the name and value of the selected `HandleKey` column to create the hash value and dispatch events.
- `table`: Uses the schema name of the table and the table name to create the hash value and dispatch events.

**matcher:** The matching syntax of matcher is the same as the filter rule syntax.

**protocol:** For the sink of MQ type, you can specify the protocol format of the message. Currently the following protocols are supported: `canal-json`, `open-protocol`, `canal`, `avro`, and `maxwell`.

Example

The following request creates a replication task with an ID of `test5` and a `sink_uri` of `blackhole://`.

```
curl -X POST -H "Content-type:application/json" http://127.0.0.1:8300/
 ↪ api/v1/changefeeds -d '{"changefeed_id":"test5","sink_uri":"blackhole
 ↪ ://"}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

#### 13.9.4.7.5 Remove a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

```
DELETE /api/v1/changefeeds/{changefeed_id}
```

Parameter description

Path parameters

Parameter name	Description
<code>changefeed_id</code>	The ID of the replication task (changefeed) to be removed.

Example

The following request removes the replication task with the ID `test1`.

```
curl -X DELETE http://127.0.0.1:8300/api/v1/changefeeds/test1
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

#### 13.9.4.7.6 Update the replication configuration

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

To modify the changefeed configuration, follow the steps of `pause the replication task` -> `modify the configuration` -> `resume the replication task`.

Request URI

PUT `/api/v1/changefeeds/{changefeed_id}`

Parameter description

Path parameters

Parameter name	Description
<code>changefeed_id</code>	The ID of the replication task (changefeed) to be updated.

Parameters for the request body

Currently, only the following configuration can be modified via the API.

Parameter name | Description |

```

:----- | :----- |
target_ts | UINT64 type. Specifies the target TSO of the changefeed. (Optional) |
sink_uri | STRING type. The downstream address of the replication task. (Optional) |
filter_rules | STRING type array. The rules for table schema filtering. (Optional) |
ignore_txn_start_ts | UINT64 type array. Ignores the transaction of a specified start_ts. (Optional) |
mounter_worker_num | INT type. The mounter thread number. (Optional) |
sink_config | The configuration parameters of sink. (Optional) |

```

The meanings of the above parameters are the same as those in the [Create a replication task](#) section. See that section for details.

Example

The following request updates the `mounter_worker_num` of the replication task with the ID `test1` to 32.

```

curl -X PUT -H "'Content-type':'application/json'" http://127.0.0.1:8300/
↳ api/v1/changefeeds/test1 -d '{"mounter_worker_num":32}'

```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

### 13.9.4.7.7 Query the replication task list

This API is a synchronous interface. If the request is successful, the basic information of all nodes in the TiCDC cluster is returned.

Request URI

GET `/api/v1/changefeeds`

Parameter description

Query parameters

Parameter name	Description
<code>state</code>	When this parameter is specified, the replication status information only of this state is returned. (Optional)

The value options for `state` are `all`, `normal`, `stopped`, `error`, `failed`, and `finished`.

If this parameter is not specified, the basic information of replication tasks whose state is `normal`, `stopped`, or `failed` is returned by default.

Example

The following request queries the basic information of all replication tasks whose state is `normal`.

```
curl -X GET http://127.0.0.1:8300/api/v1/changefeeds?state=normal
```

```
[
 {
 "id": "test1",
 "state": "normal",
 "checkpoint_tso": 426921294362574849,
 "checkpoint_time": "2021-08-10 14:04:54.242",
 "error": null
 },
 {
 "id": "test2",
 "state": "normal",
 "checkpoint_tso": 426921294362574849,
 "checkpoint_time": "2021-08-10 14:04:54.242",
 "error": null
 }
]
```

The fields in the returned result above are described as follows:

- `id`: The ID of the replication task.
- `state`: The current `state` of the replication task.
- `checkpoint_tso`: The TSO representation of the current checkpoint of the replication task.
- `checkpoint_time`: The formatted time representation of the current checkpoint of the replication task.
- `error`: The error information of the replication task.

#### 13.9.4.7.8 Query a specific replication task

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication task is returned.

Request URI

```
GET /api/v1/changefeeds/{changefeed_id}
```

Parameter description

Path parameters

Parameter name	Description
<code>changefeed_id</code>	The ID of the replication task (changefeed) to be queried.

Example

The following request queries the detailed information of the replication task with the ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v1/changefeeds/test1
```

```
{
 "id": "test1",
 "sink_uri": "blackhole://",
 "create_time": "2021-08-10 11:41:30.642",
 "start_ts": 426919038970232833,
 "target_ts": 0,
 "checkpoint_tso": 426921014615867393,
 "checkpoint_time": "2021-08-10 13:47:07.093",
 "sort_engine": "unified",
 "state": "normal",
 "error": null,
 "error_history": null,
 "creator_version": "",
 "task_status": [
 {
 "capture_id": "d8924259-f52f-4dfb-97a9-c48d26395945",
 "table_ids": [
 63,
 65
],
 "table_operations": {}
 }
]
}
```

### 13.9.4.7.9 Pause a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

```
POST /api/v1/changefeeds/{changefeed_id}/pause
```

Parameter description

Path parameters

Parameter name	Description
<code>changefeed_id</code>	The ID of the replication task (changefeed) to be paused.

Example

The following request pauses the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/pause
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

### 13.9.4.7.10 Resume a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

```
POST /api/v1/changefeeds/{changefeed_id}/resume
```

Parameter description

Path parameters

Parameter name	Description
<code>changefeed_id</code>	The ID of the replication task (changefeed) to be resumed.

Example

The following request resumes the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/resume
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

### 13.9.4.7.11 Query the replication subtask list

This API is a synchronous interface. If the request is successful, the basic information of all replication subtasks (`processor`) is returned.

Request URI

```
GET /api/v1/processors
```

Example

```
curl -X GET http://127.0.0.1:8300/api/v1/processors
```

```
[
 {
 "changefeed_id": "test1",
 "capture_id": "561c3784-77f0-4863-ad52-65a3436db6af"
 }
]
```

### 13.9.4.7.12 Query a specific replication subtask

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication subtask (`processor`) is returned.

Request URI

```
GET /api/v1/processors/{changefeed_id}/{capture_id}
```

Parameter description

Path parameters

Parameter name	Description
<code>changefeed_id</code>	The changefeed ID of the replication subtask to be queried.
<code>capture_id</code>	The capture ID of the replication subtask to be queried.

Example

The following request queries the detailed information of a subtask whose `changefeed_id` is `test` and `capture_id` is `561c3784-77f0-4863-ad52-65a3436db6af`. A subtask can be identified by `changefeed_id` and `capture_id`.

```
curl -X GET http://127.0.0.1:8300/api/v1/processors/test1/561c3784-77f0
↪ -4863-ad52-65a3436db6af
```

```
{
 "checkpoint_ts": 426919123303006208,
 "resolved_ts": 426919123369066496,
 "table_ids": [
```

```
 63,
 65
],
 "error": null
}
```

#### 13.9.4.7.13 Query the TiCDC service process list

This API is a synchronous interface. If the request is successful, the basic information of all replication processes (capture) is returned.

Request URI

GET /api/v1/captures

Example

```
curl -X GET http://127.0.0.1:8300/api/v1/captures
```

```
[
 {
 "id": "561c3784-77f0-4863-ad52-65a3436db6af",
 "is_owner": true,
 "address": "127.0.0.1:8300"
 }
]
```

#### 13.9.4.7.14 Evict an owner node

This API is an asynchronous interface. If the request is successful, 202 Accepted is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

POST /api/v1/owner/resign

Example

The following request evicts the current owner node of TiCDC and triggers a new round of elections to generate a new owner node.

```
curl -X POST http://127.0.0.1:8300/api/v1/owner/resign
```

If the request is successful, 202 Accepted is returned. If the request fails, an error message and error code are returned.

#### 13.9.4.7.15 Manually trigger the load balancing of all tables in a replication task

This API is an asynchronous interface. If the request is successful, 202 Accepted is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

POST /api/v1/changefeeds/{changefeed\_id}/tables/rebalance\_table

Parameter description

Path parameters

Parameter name	Description
changefeed_id	The ID of the replication task (changefeed) to be scheduled.

Example

The following request triggers the load balancing of all tables in the changefeed with the ID test1.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/tables/
↪ rebalance_table
```

If the request is successful, 202 Accepted is returned. If the request fails, an error message and error code are returned.

#### 13.9.4.7.16 Manually schedule a table to another node

This API is an asynchronous interface. If the request is successful, 202 Accepted is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

POST /api/v1/changefeeds/{changefeed\_id}/tables/move\_table

Parameter description

Path parameters

Parameter name	Description
changefeed_id	The ID of the replication task (changefeed) to be scheduled.

Parameters for the request body

Parameter name	Description
<code>target_capture_id</code>	The ID of the target capture.
<code>table_id</code>	The ID of the table to be scheduled.

#### Example

The following request schedules the table with the ID 49 in the changefeed with the ID `test1` to the capture with the ID `6f19a6d9-0f8c-4dc9-b299-3ba7c0f216f5`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
 ↪ api/v1/changefeeds/changefeed-test1/tables/move_table -d '{"
 ↪ capture_id":"6f19a6d9-0f8c-4dc9-b299-3ba7c0f216f5","table_id":49}'
```

If the request is successful, 202 Accepted is returned. If the request fails, an error message and error code are returned.

#### 13.9.4.7.17 Dynamically adjust the log level of the TiCDC server

This API is a synchronous interface. If the request is successful, 202 OK is returned.

Request URI

POST `/api/v1/log`

Request parameters

Parameters for the request body

Parameter name	Description
<code>log_level</code>	The log level you want to set.

`log_level` supports the [log levels provided by zap](#): “debug”, “info”, “warn”, “error”, “dpanic”, “panic”, and “fatal”.

#### Example

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
 ↪ api/v1/log -d '{"log_level":"debug"}'
```

If the request is successful, 202 OK is returned. If the request fails, an error message and error code are returned.

#### 13.9.4.8 Guide for Developing a Storage Sink Consumer

This document describes how to design and implement a TiDB data change consumer.

**Note:**

The storage sink cannot handle the `DROP DATABASE` DDL. Therefore, avoid executing this DDL. If you do need to execute this DDL, execute it manually in the downstream MySQL.

TiCDC does not provide any standard way for implementing a consumer. This document provides a consumer example program written in Golang. This program can read data from the storage service and write the data to a MySQL-compatible database. You can refer to the data format and instructions provided in this example to implement a consumer on your own.

[Consumer program written in Golang](#)

**13.9.4.8.1 Design a consumer**

The following diagram shows the overall consumption process of the consumer:

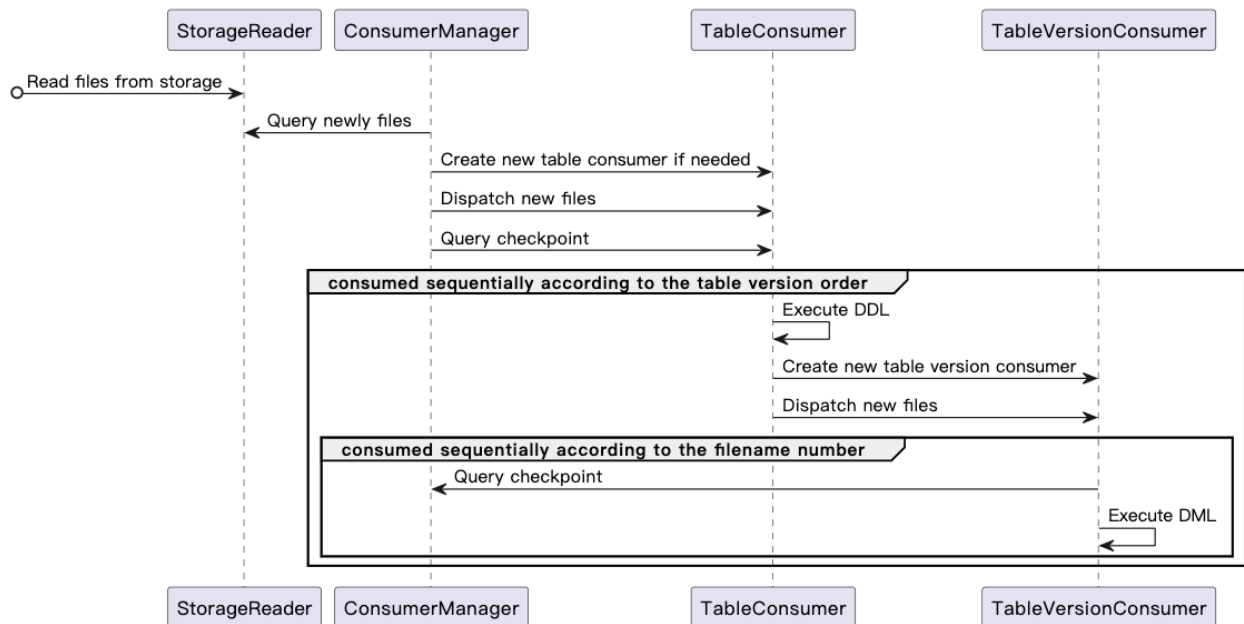

Figure 288: TiCDC storage consumer overview

The components of the consumer and their features are described as follows:

```
type StorageReader struct {
}
```

```
// Read the files from storage.
// Add new files and delete files that do not exist in storage.
func (c *StorageReader) ReadFiles() {}

// Query newly added files and the latest checkpoint from storage. One file
 ↪ can only be returned once.
func (c *StorageReader) ExposeNewFiles() (int64, []string) {}

// ConsumerManager is responsible for assigning tasks to TableConsumer.
// Different consumers can consume data concurrently,
// but data of one table must be processed by the same TableConsumer.
type ConsumerManager struct {
 // StorageCheckpoint is recorded in the metadata file, and it can be
 ↪ fetched by calling `StorageReader.ExposeNewFiles()`.
 // This checkpoint indicates that the data whose transaction commit time
 ↪ is less than this checkpoint has been stored in storage.
 StorageCheckpoint int64
 // This checkpoint indicates where the consumer has consumed.
 // ConsumerManager periodically collects TableConsumer.Checkpoint,
 // then Checkpoint is updated to the minimum value of all TableConsumer.
 ↪ Checkpoint.
 Checkpoint int64

 tableFiles[schema][table]*TableConsumer
}

// Query newly added files from StorageReader.
// For a newly created table, create a TableConsumer for it.
// If any, send new files to the corresponding TableConsumer.
func (c *ConsumerManager) Dispatch() {}
type TableConsumer struct {
 // This checkpoint indicates where this TableConsumer has consumed.
 // Its initial value is ConsumerManager.Checkpoint.
 // TableConsumer.Checkpoint is equal to TableVersionConsumer.Checkpoint.
 Checkpoint int64

 schema,table string
 // Must be consumed sequentially according to the order of table versions.
 verConsumers map[version int64]*TableVersionConsumer
 currentVer, previousVer int64
}

// Send newly added files to the corresponding TableVersionConsumer.
// For any DDL, assign a TableVersionConsumer for the new table version.
func (tc *TableConsumer) Dispatch() {}
```

```
// If DDL query is empty or its tableVersion is less than TableConsumer.
 ↪ Checkpoint,
// - ignore this DDL, and consume the data under the table version.
// Otherwise,
// - execute the DDL first, and then consume the data under the table
 ↪ version.
// - For tables that are dropped, auto-recycling is performed after the drop
 ↪ table DDL is executed.
func (tc *TableConsumer) ExecutedDDL() {}

type TableVersionConsumer struct {
 // This checkpoint indicates where the TableVersionConsumer has consumed.
 // Its initial value is TableConsumer.Checkpoint.
 Checkpoint int64

 schema,table,version string
 // For the same table version, data in different partitions can be
 ↪ consumed concurrently.
 # partitionNum int64
 // Must be consumed sequentially according to the data file number.
 fileSet map[filename string]*TableVersionConsumer
 currentVersion
}
// If data commit ts is less than TableConsumer.Checkpoint
// or bigger than ConsumerManager.StorageCheckpoint,
// - ignore this data.
// Otherwise,
// - process this data and write it to MySQL.
func (tc *TableVersionConsumer) ExecutedDML() {}
```

#### 13.9.4.8.2 Process DDL events

The consumer traverses the directory for the first time. The following is an example:

```
— metadata
— test
 — tbl_1
 — 437752935075545091
 — CDC000001.json
 — schema.json
```

The consumer parses the table schema of the `schema.json` file and obtains the DDL Query statements:

- If no Query statement is found or `TableVersion` is less than the consumer checkpoint, the consumer skips this statement.
- If Query statements exist or `TableVersion` is equal to or greater than the consumer checkpoint, the consumer executes the DDL statements in the downstream MySQL.

Then the consumer starts replicating the `CDC000001.json` file.

In the following example, the DDL Query statement in the `test/tbl_1/437752935075545091/`  
↪ `schema.json` file is not empty:

```
{
 "Table": "test",
 "Schema": "tbl_1",
 "Version": 1,
 "TableVersion": 437752935075545091,
 "Query": "create table tbl_1 (Id int primary key, LastName char(20),
 ↪ FirstName varchar(30), HireDate datetime, OfficeLocation Blob(20))
 ↪ ",
 "TableColumns": [
 {
 "ColumnName": "Id",
 "ColumnType": "INT",
 "ColumnNullable": "false",
 "ColumnIsPk": "true"
 },
 {
 "ColumnName": "LastName",
 "ColumnType": "CHAR",
 "ColumnLength": "20"
 },
 {
 "ColumnName": "FirstName",
 "ColumnType": "VARCHAR",
 "ColumnLength": "30"
 },
 {
 "ColumnName": "HireDate",
 "ColumnType": "DATETIME"
 },
 {
 "ColumnName": "OfficeLocation",
 "ColumnType": "BLOB",
 "ColumnLength": "20"
 }
],
 "TableColumnsTotal": "5"
}
```

```
}

```

When the consumer traverses the directory again, it finds a new version directory of the table. Note that the consumer can consume data in the new directory only after all files in the `test/tbl_1/437752935075545091` directory have been consumed.

```

— metadata
— test
 — tbl_1
 — 437752935075545091
 — CDC000001.json
 — schema.json
 — 437752935075546092
 — CDC000001.json
 — schema.json

```

The consumption logic is consistent. Specifically, the consumer parses the table schema of the `schema.json` file and obtains and processes DDL Query statements accordingly. Then the consumer starts replicating the `CDC000001.json` file.

### 13.9.4.8.3 Process DML events

After DDL events are properly processed, you can process DML events in the `{schema}↔{/}{table}/{table-version-separator}/` directory based on the specific file format (CSV or Canal-JSON) and file number.

TiCDC ensures that data is replicated at least once. Therefore, there might be duplicate data. You need to compare the commit `ts` of the change data with the consumer checkpoint. If the commit `ts` is less than the consumer checkpoint, you need to perform deduplication.

### 13.9.4.9 TiCDC Compatibility

This section describes compatibility issues related to TiCDC and how to handle them.

#### 13.9.4.9.1 CLI and configuration file compatibility

- In TiCDC v4.0.0, `ignore-txn-commit-ts` is removed and `ignore-txn-start-ts` is added, which uses `start_ts` to filter transactions.
- In TiCDC v4.0.2, `db-dbs/db-tables/ignore-dbs/ignore-tables` are removed and `rules` is added, which uses new filter rules for databases and tables. For detailed filter syntax, see [Table Filter](#).
- Starting from TiCDC v6.2.0, `cdc cli` can directly interact with TiCDC server via TiCDC Open API. You can specify the address of the TiCDC server using the `--↔ server` parameter. `--pd` is deprecated.
- Since v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.

### 13.9.4.9.2 Handle compatibility issues

This section describes compatibility issues related to TiCDC and how to handle them.

Incompatibility issue caused by using the TiCDC v5.0.0-rc `cdc cli` tool to operate a v4.0.x cluster

When using the `cdc cli` tool of TiCDC v5.0.0-rc to operate a v4.0.x TiCDC cluster, you might encounter the following abnormal situations:

- If the TiCDC cluster is v4.0.8 or an earlier version, using the v5.0.0-rc `cdc cli` tool to create a replication task might cause cluster anomalies and get the replication task stuck.
- If the TiCDC cluster is v4.0.9 or a later version, using the v5.0.0-rc `cdc cli` tool to create a replication task will cause the old value and unified sorter features to be unexpectedly enabled by default.

Solutions:

Use the `cdc` executable file corresponding to the TiCDC cluster version to perform the following operations:

1. Delete the changefeed created using the v5.0.0-rc `cdc cli` tool. For example, run the `tiup cdc:v4.0.9 cli changefeed remove -c xxxx --pd=xxxxx --force` command.
2. If the replication task is stuck, restart the TiCDC cluster. For example, run the `tiup ↪ cluster restart <cluster_name> -R cdc` command.
3. Re-create the changefeed. For example, run the `tiup cdc:v4.0.9 cli changefeed ↪ create --sink-uri=xxxx --pd=xxx` command.

#### Note:

This issue exists only when `cdc cli` is v5.0.0-rc. `cdc cli` tool of other v5.0.x versions is compatible with v4.0.x clusters.

### Compatibility notes for `sort-dir` and `data-dir`

The `sort-dir` configuration is used to specify the temporary file directory for the TiCDC sorter. Its functionalities might vary in different versions. The following table lists `sort-dir`'s compatibility changes across versions.

### Compatibility with temporary tables

Since v5.3.0, TiCDC supports **global temporary tables**. Replicating global temporary tables to the downstream using TiCDC of a version earlier than v5.3.0 causes table definition error.

If the upstream cluster contains a global temporary table, the downstream TiDB cluster

is expected to be v5.3.0 or a later version. Otherwise, an error occurs during the replication process.

### 13.9.5 Troubleshoot TiCDC

This document introduces the common errors you might encounter when using TiCDC, and the corresponding maintenance and troubleshooting methods.

#### Note:

In this document, the server address specified in `cdc cli` commands is `server` ↪ `=http://127.0.0.1:8300`. When you use the command, replace the address with your actual PD address.

#### 13.9.5.1 TiCDC replication interruptions

##### 13.9.5.1.1 How do I know whether a TiCDC replication task is interrupted?

- Check the `changefeed checkpoint` monitoring metric of the replication task (choose the right `changefeed id`) in the Grafana dashboard. If the metric value stays unchanged, or the `checkpoint lag` metric keeps increasing, the replication task might be interrupted.
- Check the `exit error count` monitoring metric. If the metric value is greater than 0, an error has occurred in the replication task.
- Execute `cdc cli changefeed list` and `cdc cli changefeed query` to check the status of the replication task. `stopped` means the task has stopped, and the `error` item provides the detailed error message. After the error occurs, you can search `error` ↪ `on running processor` in the TiCDC server log to see the error stack for troubleshooting.
- In some extreme cases, the TiCDC service is restarted. You can search the `FATAL` level log in the TiCDC server log for troubleshooting.

##### 13.9.5.1.2 How do I know whether the replication task is stopped manually?

You can know whether the replication task is stopped manually by executing `cdc cli`. For example:

```
cdc cli changefeed query --server=http://127.0.0.1:8300 --changefeed-id 28
↪ c43ffc-2316-4f4f-a70b-d1a7c59ba79f
```

In the output of the above command, `admin-job-type` shows the state of this replication task:

- 0: In progress, which means that the task is not stopped manually.
- 1: Paused. When the task is paused, all replicated `processors` exit. The configuration and the replication status of the task are retained, so you can resume the task from `checkpoint-ts`.
- 2: Resumed. The replication task resumes from `checkpoint-ts`.
- 3: Removed. When the task is removed, all replicated `processors` are ended, and the configuration information of the replication task is cleared up. The replication status is retained only for later queries.

### 13.9.5.1.3 How do I handle replication interruptions?

A replication task might be interrupted in the following known scenarios:

- The downstream continues to be abnormal, and TiCDC still fails after many retries.
  - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
  - Handling method: You can resume the replication task via the HTTP interface after the downstream is back to normal.
- Replication cannot continue because of incompatible SQL statement(s) in the downstream.
  - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
  - Handling procedures:
    1. Query the status information of the replication task using the `cdc cli` ↪ `changefeed query` command and record the value of `checkpoint-ts`.
    2. Use the new task configuration file and add the `ignore-txn-start-ts` parameter to skip the transaction corresponding to the specified `start-ts`.
    3. Stop the old replication task via HTTP API. Execute `cdc cli changefeed` ↪ `create` to create a new task and specify the new task configuration file. Specify `checkpoint-ts` recorded in step 1 as the `start-ts` and start a new task to resume the replication.
- In TiCDC v4.0.13 and earlier versions, when TiCDC replicates the partitioned table, it might encounter an error that leads to replication interruption.
  - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.

– Handling procedures:

1. Pause the replication task by executing `cdc cli changefeed pause -c <changefeed-id>`.
2. Wait for about one minute, and then resume the replication task by executing `cdc cli changefeed resume -c <changefeed-id>`.

#### 13.9.5.1.4 What should I do to handle the OOM that occurs after TiCDC is restarted after a task interruption?

- Update your TiDB cluster and TiCDC cluster to the latest versions. The OOM problem has already been resolved in **v4.0.14 and later v4.0 versions, v5.0.2 and later v5.0 versions, and the latest versions.**

#### 13.9.5.2 How do I handle the Error 1298: Unknown or incorrect time zone: 'UTC' error when creating the replication task or replicating data to MySQL?

This error is returned when the downstream MySQL does not load the time zone. You can load the time zone by running `mysql_tzinfo_to_sql`. After loading the time zone, you can create tasks and replicate data normally.

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql -p
```

If the output of the command above is similar to the following one, the import is successful:

```
Enter password:
Warning: Unable to load '/usr/share/zoneinfo/iso3166.tab' as time zone.
↳ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/leap-seconds.list' as time zone
↳ . Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone.tab' as time zone.
↳ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone1970.tab' as time zone.
↳ Skipping it.
```

If the downstream is a special MySQL environment (a public cloud RDS or some MySQL derivative versions) and importing the time zone using the above method fails, you need to specify the MySQL time zone of the downstream using the `time-zone` parameter in `sink-  
↳ uri`. You can first query the time zone used by MySQL:

1. Query the time zone used by MySQL:

```
show variables like '%time_zone%';
```

```

+-----+-----+
| Variable_name | Value |
+-----+-----+
| system_time_zone | CST |
| time_zone | SYSTEM |
+-----+-----+

```

2. Specify the time zone when you create the replication task and create the TiCDC service:

```

cdc cli changefeed create --sink-uri="mysql://root@127.0.0.1:3306/?time
↪ -zone=CST" --server=http://127.0.0.1:8300

```

**Note:**

CST might be an abbreviation for the following four different time zones:

- Central Standard Time (USA) UT-6:00
- Central Standard Time (Australia) UT+9:30
- China Standard Time UT+8:00
- Cuba Standard Time UT-4:00

In China, CST usually stands for China Standard Time.

### 13.9.5.3 How do I handle the incompatibility issue of configuration files caused by TiCDC upgrade?

Refer to [Notes for compatibility](#).

### 13.9.5.4 The `start-ts` timestamp of the TiCDC task is quite different from the current time. During the execution of this task, replication is interrupted and an error `[CDC:ErrBufferReachLimit]` occurs. What should I do?

Since v4.0.9, you can try to enable the unified sorter feature in your replication task, or use the BR tool for an incremental backup and restore, and then start the TiCDC replication task from a new time.

### 13.9.5.5 When the downstream of a changefeed is a database similar to MySQL and TiCDC executes a time-consuming DDL statement, all other changefeeds are blocked. What should I do?

1. Pause the execution of the changefeed that contains the time-consuming DDL statement. Then you can see that other changefeeds are no longer blocked.

2. Search for the `apply job` field in the TiCDC log and confirm the `start-ts` of the time-consuming DDL statement.
3. Manually execute the DDL statement in the downstream. After the execution finishes, go on performing the following operations.
4. Modify the changefeed configuration and add the above `start-ts` to the `ignore-txn`  $\hookrightarrow$  `-start-ts` configuration item.
5. Resume the paused changefeed.

### 13.9.5.6 After I upgrade the TiCDC cluster to v4.0.8, the `[CDC:ErrKafkaInvalidConfig] Canal requires old value to be enabled` error is reported when I execute a changefeed. What should I do?

Since v4.0.8, if the `canal-json`, `canal` or `maxwell` protocol is used for output in a changefeed, TiCDC enables the old value feature automatically. However, if you have upgraded TiCDC from an earlier version to v4.0.8 or later, when the changefeed uses the `canal-json`, `canal` or `maxwell` protocol and the old value feature is disabled, this error is reported.

To fix the error, take the following steps:

1. Set the value of `enable-old-value` in the changefeed configuration file to `true`.
2. Execute `cdc cli changefeed pause` to pause the replication task.

```
cdc cli changefeed pause -c test-cf --server=http://127.0.0.1:8300
```

3. Execute `cdc cli changefeed update` to update the original changefeed configuration.

```
cdc cli changefeed update -c test-cf --server=http://127.0.0.1:8300 --
 \hookrightarrow sink-uri="mysql://127.0.0.1:3306/?max-txn-row=20&worker-number=8"
 \hookrightarrow --config=changefeed.toml
```

4. Execute `cdc cli changefeed resume` to resume the replication task.

```
cdc cli changefeed resume -c test-cf --server=http://127.0.0.1:8300
```

### 13.9.5.7 The `[tikv:9006]GC life time is shorter than transaction duration, transaction starts at xx, GC safe point is yy` error is reported when I use TiCDC to create a changefeed. What should I do?

You need to run the `pd-ctl service-gc-safepoint --pd <pd-addr>` command to query the current GC safepoint and service GC safepoint. If the GC safepoint is smaller than the `start-ts` of the TiCDC replication task (changefeed), you can directly add the `-- $\hookrightarrow$  disable-gc-check` option to the `cdc cli create changefeed` command to create a changefeed.

If the result of `pd-ctl service-gc-safepoint --pd <pd-addr>` does not have `gc_worker service_id`:

- If your PD version is v4.0.8 or earlier, refer to [PD issue #3128](#) for details.
- If your PD is upgraded from v4.0.8 or an earlier version to a later version, refer to [PD issue #3366](#) for details.

### 13.9.5.8 When I use TiCDC to replicate messages to Kafka, Kafka returns the Message was too large error. Why?

For TiCDC v4.0.8 or earlier versions, you cannot effectively control the size of the message output to Kafka only by configuring the `max-message-bytes` setting for Kafka in the Sink URI. To control the message size, you also need to increase the limit on the bytes of messages to be received by Kafka. To add such a limit, add the following configuration to the Kafka server configuration.

```
The maximum byte number of a message that the broker receives
message.max.bytes=2147483648
The maximum byte number of a message that the broker copies
replica.fetch.max.bytes=2147483648
The maximum message byte number that the consumer side reads
fetch.message.max.bytes=2147483648
```

### 13.9.5.9 How can I find out whether a DDL statement fails to execute in downstream during TiCDC replication? How to resume the replication?

If a DDL statement fails to execute, the replication task (change feed) automatically stops. The `checkpoint-ts` is the DDL statement's `finish-ts` minus one. If you want TiCDC to retry executing this statement in the downstream, use `cdc cli changefeed resume` to resume the replication task. For example:

```
cdc cli changefeed resume -c test-cf --server=http://127.0.0.1:8300
```

If you want to skip this DDL statement that goes wrong, set the `start-ts` of the change feed to the `checkpoint-ts` (the timestamp at which the DDL statement goes wrong) plus one, and then run the `cdc cli changefeed create` command to create a new change feed task. For example, if the `checkpoint-ts` at which the DDL statement goes wrong is `415241823337054209`, run the following commands to skip this DDL statement:

```
cdc cli changefeed remove --server=http://127.0.0.1:8300 --changefeed-id
↳ simple-replication-task
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri="mysql
↳ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
↳ task" --sort-engine="unified" --start-ts 415241823337054210
```

## 13.9.6 TiCDC FAQs

This document introduces the common questions that you might encounter when using TiCDC.

**Note:**

In this document, the server address specified in `cdc cli` commands is `--server=http://127.0.0.1:8300`. When you use the command, replace the address with your actual PD address.

### 13.9.6.1 How do I choose `start-ts` when creating a task in TiCDC?

The `start-ts` of a replication task corresponds to a Timestamp Oracle (TSO) in the upstream TiDB cluster. TiCDC requests data from this TSO in a replication task. Therefore, the `start-ts` of the replication task must meet the following requirements:

- The value of `start-ts` is larger than the `tikv_gc_safe_point` value of the current TiDB cluster. Otherwise, an error occurs when you create a task.
- Before starting a task, ensure that the downstream has all data before `start-ts`. For scenarios such as replicating data to message queues, if the data consistency between upstream and downstream is not required, you can relax this requirement according to your application need.

If you do not specify `start-ts`, or specify `start-ts` as 0, when a replication task is started, TiCDC gets a current TSO and starts the task from this TSO.

### 13.9.6.2 Why can't some tables be replicated when I create a task in TiCDC?

When you execute `cdc cli changefeed create` to create a replication task, TiCDC checks whether the upstream tables meet the **replication requirements**. If some tables do not meet the requirements, `some tables are not eligible to replicate` is returned with a list of ineligible tables. You can choose Y or y to continue creating the task, and all updates on these tables are automatically ignored during the replication. If you choose an input other than Y or y, the replication task is not created.

### 13.9.6.3 How do I view the state of TiCDC replication tasks?

To view the status of TiCDC replication tasks, use `cdc cli`. For example:

```
cdc cli changefeed list --server=http://127.0.0.1:8300
```

The expected output is as follows:

```
[{
 "id": "4e24dde6-53c1-40b6-badf-63620e4940dc",
 "summary": {
```

```
"state": "normal",
"tso": 417886179132964865,
"checkpoint": "2020-07-07 16:07:44.881",
"error": null
}
}]
```

- **checkpoint**: TiCDC has replicated all data before this timestamp to downstream.
- **state**: The state of this replication task:
  - **normal**: The task runs normally.
  - **stopped**: The task is stopped manually or encounters an error.
  - **removed**: The task is removed.

#### Note:

This feature is introduced in TiCDC 4.0.3.

#### 13.9.6.4 What is `gc-ttl` in TiCDC?

Since v4.0.0-rc.1, PD supports external services in setting the service-level GC safepoint. Any service can register and update its GC safepoint. PD ensures that the key-value data later than this GC safepoint is not cleaned by GC.

When the replication task is unavailable or interrupted, this feature ensures that the data to be consumed by TiCDC is retained in TiKV without being cleaned by GC.

When starting the TiCDC server, you can specify the Time To Live (TTL) duration of GC safepoint by configuring `gc-ttl`. You can also [use TiUP to modify `gc-ttl`](#). The default value is 24 hours. In TiCDC, this value means:

- The maximum time the GC safepoint is retained at the PD after the TiCDC service is stopped.
- The maximum time a replication task can be suspended after the task is interrupted or manually stopped. If the time for a suspended replication task is longer than the value set by `gc-ttl`, the replication task enters the **failed** status, cannot be resumed, and cannot continue to affect the progress of the GC safepoint.

The second behavior above is introduced in TiCDC v4.0.13 and later versions. The purpose is to prevent a replication task in TiCDC from suspending for too long, causing the GC safepoint of the upstream TiKV cluster not to continue for a long time and retaining too many outdated data versions, thus affecting the performance of the upstream cluster.

**Note:**

In some scenarios, for example, when you use TiCDC for incremental replication after full replication with Dumping/BR, the default 24 hours of `gc-ttl` may not be sufficient. You need to specify an appropriate value for `gc-ttl` when you start the TiCDC server.

**13.9.6.5 What is the complete behavior of TiCDC garbage collection (GC) safepoint?**

If a replication task starts after the TiCDC service starts, the TiCDC owner updates the PD service GC safepoint with the smallest value of `checkpoint-ts` among all replication tasks. The service GC safepoint ensures that TiCDC does not delete data generated at that time and after that time. If the replication task is interrupted, or manually stopped, the `checkpoint-ts` of this task does not change. Meanwhile, PD's corresponding service GC safepoint is not updated either.

If the replication task is suspended longer than the time specified by `gc-ttl`, the replication task enters the `failed` status and cannot be resumed. The PD corresponding service GC safepoint will continue.

The Time-To-Live (TTL) that TiCDC sets for a service GC safepoint is 24 hours, which means that the GC mechanism does not delete any data if the TiCDC service can be recovered within 24 hours after it is interrupted.

**13.9.6.6 How to understand the relationship between the TiCDC time zone and the time zones of the upstream/downstream databases?**

---

	Upstream	Time	Downstream
	time	time	time
	zone	zone	zone

---

Configuration	Static	Configuration	Configured
method	Time	us-	us-
	Zone	ing	ing
	Sup-	the	the
	port	--	time
		↔ tz	↔ -
		↔	↔ zone
		pa-	↔
		ram-	pa-
		e-	ram-
		ter	e-
		when	ter
		you	in
		start	sink
		the	↔ -
		TiCDC	↔ uri
		server	↔

	Upstream time zone	TiCDC time zone	Downstream time zone
Description	The time as-zone of the up-stream TiDB, which affects DML operations of the time-zone type and DDL operations of the time-zone type on columns.	The time as-zone of the up-stream MySQL, which affects DML operations of the time-zone type on columns.	The time as-zone of the down-stream MySQL, which affects DML operations of the time-zone type on columns.

**Note:**

Be careful when you set the time zone of the TiCDC server, because this time zone is used for converting the time type. Keep the upstream time zone, TiCDC time zone, and the downstream time zone consistent. The TiCDC server chooses its time zone in the following priority:

- TiCDC first uses the time zone specified using `--tz`.
- When `--tz` is not available, TiCDC tries to read the time zone set using the TZ environment variable.
- When the TZ environment variable is not available, TiCDC uses the default time zone of the machine.

### 13.9.6.7 What is the default behavior of TiCDC if I create a replication task without specifying the configuration file in `--config`?

If you use the `cdc cli changefeed create` command without specifying the `-config` parameter, TiCDC creates the replication task in the following default behaviors:

- Replicates all tables except system tables
- Enables the Old Value feature
- Only replicates tables that contain [valid indexes](#)

### 13.9.6.8 Does TiCDC support outputting data changes in the Canal format?

Yes. To enable Canal output, specify the protocol as `canal` in the `--sink-uri` parameter. For example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri="kafka
↳ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&protocol=canal" --
↳ config changefeed.toml
```

#### Note:

- This feature is introduced in TiCDC 4.0.2.
- TiCDC currently supports outputting data changes in the Canal format only to MQ sinks such as Kafka.

For more information, refer to [TiCDC changefeed configurations](#).

### 13.9.6.9 Why does the latency from TiCDC to Kafka become higher and higher?

- Check [how do I view the state of TiCDC replication tasks](#).
- Adjust the following parameters of Kafka:
  - Increase the `message.max.bytes` value in `server.properties` to 1073741824 (1 GB).
  - Increase the `replica.fetch.max.bytes` value in `server.properties` to 1073741824 (1 GB).
  - Increase the `fetch.message.max.bytes` value in `consumer.properties` to make it larger than the `message.max.bytes` value.

### 13.9.6.10 When TiCDC replicates data to Kafka, can I control the maximum size of a single message in TiDB?

When `protocol` is set to `avro` or `canal-json`, messages are sent per row change. A single Kafka message contains only one row change and is generally no larger than Kafka's limit. Therefore, there is no need to limit the size of a single message. If the size of a single Kafka message does exceed Kafka's limit, refer to [Why does the latency from TiCDC to Kafka become higher and higher?](#).

When `protocol` is set to `open-protocol`, messages are sent in batches. Therefore, one Kafka message might be excessively large. To avoid this situation, you can configure the `max-message-bytes` parameter to control the maximum size of data sent to the Kafka broker each time (optional, 10MB by default). You can also configure the `max-batch-size` parameter (optional, 16 by default) to specify the maximum number of change records in each Kafka message.

### 13.9.6.11 If I modify a row multiple times in a transaction, will TiCDC output multiple row change events?

No. When you modify the same row in one transaction multiple times, TiDB only sends the latest modification to TiKV. Therefore, TiCDC can only obtain the result of the latest modification.

### 13.9.6.12 When TiCDC replicates data to Kafka, does a message contain multiple types of data changes?

Yes. A single message might contain multiple updates or deletes, and update and delete might co-exist.

### 13.9.6.13 When TiCDC replicates data to Kafka, how do I view the timestamp, table name, and schema name in the output of TiCDC Open Protocol?

The information is included in the key of Kafka messages. For example:

```
{
 "ts":<TS>,
 "scm":<Schema Name>,
 "tbl":<Table Name>,
 "t":1
}
```

For more information, refer to [TiCDC Open Protocol event format](#).

### 13.9.6.14 When TiCDC replicates data to Kafka, how do I know the timestamp of the data changes in a message?

You can get the unix timestamp by moving `ts` in the key of the Kafka message by 18 bits to the right.

### 13.9.6.15 How does TiCDC Open Protocol represent null?

In TiCDC Open Protocol, the type code 6 represents `null`.

Type	Code	Output Example	Note
Null	6	<code>{"t":6,"v":null}</code>	

For more information, refer to [TiCDC Open Protocol column type code](#).

### 13.9.6.16 How can I tell if a Row Changed Event of TiCDC Open Protocol is an INSERT event or an UPDATE event?

If the Old Value feature is not enabled, you cannot tell whether a Row Changed Event of TiCDC Open Protocol is an `INSERT` event or an `UPDATE` event. If the feature is enabled, you can determine the event type by the fields it contains:

- `UPDATE` event contains both `"p"` and `"u"` fields
- `INSERT` event only contains the `"u"` field
- `DELETE` event only contains the `"d"` field

For more information, refer to [Open protocol Row Changed Event format](#).

### 13.9.6.17 How much PD storage does TiCDC use?

TiCDC uses etcd in PD to store and regularly update the metadata. Because the time interval between the MVCC of etcd and PD's default compaction is one hour, the amount of

PD storage that TiCDC uses is proportional to the amount of metadata versions generated within this hour. However, in v4.0.5, v4.0.6, and v4.0.7, TiCDC has a problem of frequent writing, so if there are 1000 tables created or scheduled in an hour, it then takes up all the etcd storage and returns the `etcdserver: mvcc: database space exceeded` error. You need to clean up the etcd storage after getting this error. See [etcd maintenance space-quota](#) for details. It is recommended to upgrade your cluster to v4.0.9 or later versions.

### 13.9.6.18 Does TiCDC support replicating large transactions? Is there any risk?

TiCDC provides partial support for large transactions (more than 5 GB in size). Depending on different scenarios, the following risks might exist:

- The latency of primary-secondary replication might greatly increase.
- When TiCDC's internal processing capacity is insufficient, the replication task error `ErrBufferReachLimit` might occur.
- When TiCDC's internal processing capacity is insufficient or the throughput capacity of TiCDC's downstream is insufficient, out of memory (OOM) might occur.

Since v6.2, TiCDC supports splitting a single-table transaction into multiple transactions. This can greatly reduce the latency and memory consumption of replicating large transactions. Therefore, if your application does not have a high requirement on transaction atomicity, it is recommended to enable the splitting of large transactions to avoid possible replication latency and OOM. To enable the splitting, set the value of the sink uri parameter `transaction-atomicity` to `none`.

If you still encounter an error above, it is recommended to use BR to restore the incremental data of large transactions. The detailed operations are as follows:

1. Record the `checkpoint-ts` of the changefeed that is terminated due to large transactions, use this TSO as the `--lastbackupts` of the BR incremental backup, and execute [incremental data backup](#).
2. After backing up the incremental data, you can find a log record similar to `["Full backup Failed summary : total backup ranges: 0, total success: ↪ 0, total failed: 0"] [BackupTS=421758868510212097]` in the BR log output. Record the `BackupTS` in this log.
3. [Restore the incremental data](#).
4. Create a new changefeed and start the replication task from `BackupTS`.
5. Delete the old changefeed.

### 13.9.6.19 The default value of the time type field is inconsistent when replicating a DDL statement to the downstream MySQL 5.7. What can I do?

Suppose that the `create table test (id int primary key, ts timestamp)` statement is executed in the upstream TiDB. When TiCDC replicates this statement to the downstream MySQL 5.7, MySQL uses the default configuration. The table schema after the replication is as follows. The default value of the `timestamp` field becomes `CURRENT_TIMESTAMP`:

```
mysql root@127.0.0.1:test> show create table test;
+---+
| Table | Create Table |
+---+
| test | CREATE TABLE `test` (
| | `id` int(11) NOT NULL,
| | `ts` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
| | CURRENT_TIMESTAMP, |
| | PRIMARY KEY (`id`)
| |) ENGINE=InnoDB DEFAULT CHARSET=latin1
+---+
1 row in set
```

From the result, you can see that the table schema before and after the replication is inconsistent. This is because the default value of `explicit_defaults_for_timestamp` in TiDB is different from that in MySQL. See [MySQL Compatibility](#) for details.

Since v5.0.1 or v4.0.13, for each replication to MySQL, TiCDC automatically sets `explicit_defaults_for_timestamp = ON` to ensure that the time type is consistent between the upstream and downstream. For versions earlier than v5.0.1 or v4.0.13, pay attention to the compatibility issue caused by the inconsistent `explicit_defaults_for_timestamp` value when using TiCDC to replicate the time type data.

### 13.9.6.20 Why do INSERT/UPDATE statements from the upstream become REPLACE INTO after being replicated to the downstream if I set `safe-mode` to `true` when I create a TiCDC replication task?

TiCDC guarantees that all data is replicated at least once. When there is duplicate data in the downstream, write conflicts occur. To avoid this problem, TiCDC converts `INSERT` and `UPDATE` statements into `REPLACE INTO` statements. This behavior is controlled by the `safe-mode` parameter.

In versions earlier than v6.1.3, `safe-mode` defaults to `true`, which means all `INSERT` and `UPDATE` statements are converted into `REPLACE INTO` statements. In v6.1.3 and later

versions, TiCDC can automatically determine whether the downstream has duplicate data, and the default value of `safe-mode` changes to `false`. If no duplicate data is detected, TiCDC replicates `INSERT` and `UPDATE` statements without conversion.

#### **13.9.6.21 When the sink of the replication downstream is TiDB or MySQL, what permissions do users of the downstream database need?**

When the sink is TiDB or MySQL, the users of the downstream database need the following permissions:

- `Select`
- `Index`
- `Insert`
- `Update`
- `Delete`
- `Create`
- `Drop`
- `Alter`
- `Create View`

If you need to replicate `recover table` to the downstream TiDB, you should have the `Super` permission.

#### **13.9.6.22 Why does TiCDC use disks? When does TiCDC write to disks? Does TiCDC use memory buffer to improve replication performance?**

When upstream write traffic is at peak hours, the downstream may fail to consume all data in a timely manner, resulting in data pile-up. TiCDC uses disks to process the data that is piled up. TiCDC needs to write data to disks during normal operation. However, this is not usually the bottleneck for replication throughput and replication latency, given that writing to disks only results in latency within a hundred milliseconds. TiCDC also uses memory to accelerate reading data from disks to improve replication performance.

#### **13.9.6.23 Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning and BR from upstream?**

Currently, TiCDC is not yet fully compatible with TiDB Lightning and BR. Therefore, please avoid using TiDB Lightning and BR on tables that are replicated by TiCDC.

#### **13.9.6.24 After a changefeed resumes from pause, its replication latency gets higher and higher and returns to normal only after a few minutes. Why?**

When a changefeed is resumed, TiCDC needs to scan the historical versions of data in TiKV to catch up with the incremental data logs generated during the pause. The replication process proceeds only after the scan is completed. The scan process might take several to tens of minutes.

### 13.9.6.25 How should I deploy TiCDC to replicate data between two TiDB cluster located in different regions?

It is recommended that you deploy TiCDC in the downstream TiDB cluster. If the network latency between the upstream and downstream is high, for example, more than 100 ms, the latency produced when TiCDC executes SQL statements to the downstream might increase dramatically due to the MySQL transmission protocol issues. This results in a decrease in system throughput. However, deploying TiCDC in the downstream can greatly ease this problem.

### 13.9.6.26 What is the order of executing DML and DDL statements?

The execution order is: DML -> DDL -> DML. To ensure that the table schema is correct when DML events are executed downstream during data replication, it is necessary to coordinate the execution order of DDL and DML statements. Currently, TiCDC adopts a simple approach: it replicates all DML statements before the DDL ts to downstream first, and then replicates DDL statements.

### 13.9.6.27 How should I check whether the upstream and downstream data is consistent?

If the downstream is a TiDB cluster or MySQL instance, it is recommended that you compare the data using [sync-diff-inspector](#).

### 13.9.6.28 Replication of a single table can only be run on a single TiCDC node. Will it be possible to use multiple TiCDC nodes to replicate data of multiple tables?

This feature is currently not supported, which might be supported in a future release. By then, TiCDC might replicate data change logs by TiKV Region, which means scalable processing capability.

### 13.9.6.29 Does TiCDC replication get stuck if the upstream has long-running uncommitted transactions?

TiDB has a transaction timeout mechanism. When a transaction runs for a period longer than `max-txn-ttl`, TiDB forcibly rolls it back. TiCDC waits for the transaction to be committed before proceeding with the replication, which causes replication delay.

## 13.9.7 TiCDC Glossary

This glossary provides TiCDC-related terms and definitions. These terms appears in TiCDC logs, monitoring metrics, configurations, and documents.

For TiDB-related terms and definitions, refer to [TiDB glossary](#).

### 13.9.7.1 C

#### 13.9.7.1.1 Capture

A single TiCDC instance on which the replication task of the cluster runs. Multiple captures form a TiCDC cluster.

#### 13.9.7.1.2 Changed data

The data to be written to TiCDC from the upstream TiDB cluster, including the DML-caused data changes and the DDL-caused table schema changes.

#### 13.9.7.1.3 Changefeed

An incremental replication task in TiCDC, which outputs the data change logs of several tables in a TiDB cluster to the designated downstream.

### 13.9.7.2 O

#### 13.9.7.2.1 Owner

A **capture** of a special role that manages the TiCDC cluster and schedules replication tasks of the cluster. An owner is elected by captures and there is at most one owner at any time.

### 13.9.7.3 P

#### 13.9.7.3.1 Processor

TiCDC replication tasks allocate data tables on TiCDC instances, and the processor refers to the replication processing unit of these tables. Processor tasks include pulling, sorting, restoring, and distributing changed data.

## 13.10 TiDB Binlog

### 13.10.1 TiDB Binlog Cluster Overview

This document introduces the architecture and the deployment of the cluster version of TiDB Binlog.

TiDB Binlog is a tool used to collect binlog data from TiDB and provide near real-time backup and replication to downstream platforms.

TiDB Binlog has the following features:

- **Data replication:** replicate the data in the TiDB cluster to other databases
- **Real-time backup and restoration:** back up the data in the TiDB cluster and restore the TiDB cluster when the cluster fails

**Note:**

TiDB Binlog is not compatible with some features introduced in TiDB v5.0 and they cannot be used together. For details, see [Notes](#). It is recommended to use [TiCDC](#) instead of TiDB Binlog.

### 13.10.1.1 TiDB Binlog architecture

The TiDB Binlog architecture is as follows:

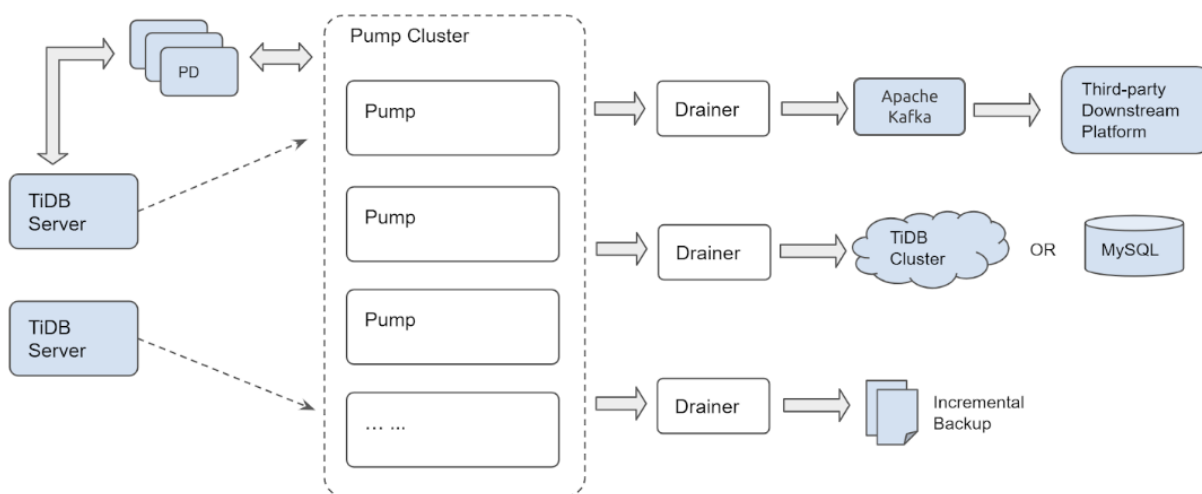

Figure 289: TiDB Binlog architecture

The TiDB Binlog cluster is composed of Pump and Drainer.

#### 13.10.1.1.1 Pump

**Pump** is used to record the binlogs generated in TiDB, sort the binlogs based on the commit time of the transaction, and send binlogs to Drainer for consumption.

#### 13.10.1.1.2 Drainer

**Drainer** collects and merges binlogs from each Pump, converts the binlog to SQL or data of a specific format, and replicates the data to a specific downstream platform.

#### 13.10.1.1.3 binlogctl guide

**binlogctl** is an operations tool for TiDB Binlog with the following features:

- Obtaining the current `tso` of TiDB cluster
- Checking the Pump/Drainer state
- Modifying the Pump/Drainer state
- Pausing or closing Pump/Drainer

### 13.10.1.2 Main features

- Multiple Pumps form a cluster which can scale out horizontally
- TiDB uses the built-in Pump Client to send the binlog to each Pump
- Pump stores binlogs and sends the binlogs to Drainer in order
- Drainer reads binlogs of each Pump, merges and sorts the binlogs, and sends the binlogs downstream
- Drainer supports **relay log**. By the relay log, Drainer ensures that the downstream clusters are in a consistent state.

### 13.10.1.3 Notes

- In v5.1, the incompatibility between the clustered index feature introduced in v5.0 and TiDB Binlog has been resolved. After you upgrade TiDB Binlog and TiDB Server to v5.1 and enable TiDB Binlog, TiDB will support creating tables with clustered indexes; data insertion, deletion, and update on the created tables with clustered indexes will be replicated to the downstream via TiDB Binlog. When you use TiDB Binlog to replicate the tables with clustered indexes, pay attention to the following:
  - If you have upgraded the cluster to v5.1 from v5.0 by manually controlling the upgrade sequence, make sure that TiDB binlog is upgraded to v5.1 before upgrading the TiDB server to v5.1.
  - It is recommended to configure the system variable `tidb_enable_clustered_index`  $\leftrightarrow$  to a same value to ensure that the structure of TiDB clustered index tables between the upstream and downstream is consistent.
- TiDB Binlog is incompatible with the following features introduced in TiDB v5.0 and they cannot be used together.
  - **TiDB Clustered Index**: After TiDB Binlog is enabled, TiDB does not allow creating clustered indexes with non-single integer columns as primary keys; data insertion, deletion, and update of the created clustered index tables will not be replicated downstream via TiDB Binlog. If you need to replicate tables with clustered indexes, upgrade your cluster to v5.1 or use **TiCDC** instead.
  - TiDB system variable `tidb_enable_async_commit`: After TiDB Binlog is enabled, performance cannot be improved by enabling this option. It is recommended to use **TiCDC** instead of TiDB Binlog.
  - TiDB system variable `tidb_enable_1pc`: After TiDB Binlog is enabled, performance cannot be improved by enabling this option. It is recommended to use **TiCDC** instead of TiDB Binlog.

- Drainer supports replicating binlogs to MySQL, TiDB, Kafka or local files. If you need to replicate binlogs to other Drainer unsupported destinations, you can set Drainer to replicate the binlog to Kafka and read the data in Kafka for customized processing according to binlog consumer protocol. See [Binlog Consumer Client User Guide](#).
- To use TiDB Binlog for recovering incremental data, set the config `db-type` to `file`  $\leftrightarrow$  (local files in the proto buffer format). Drainer converts the binlog to data in the specified [proto buffer format](#) and writes the data to local files. In this way, you can use [Reparo](#) to recover data incrementally.

Pay attention to the value of `db-type`:

- If your TiDB version is earlier than 2.1.9, set `db-type="pb"`.
  - If your TiDB version is 2.1.9 or later, set `db-type="file"` or `db-type="pb"`.
- If the downstream is MySQL, MariaDB, or another TiDB cluster, you can use [sync-diff-inspector](#) to verify the data after data replication.

### 13.10.2 TiDB Binlog Tutorial

This tutorial starts with a simple TiDB Binlog deployment with a single node of each component (Placement Driver, TiKV Server, TiDB Server, Pump, and Drainer), set up to push data into a MariaDB Server instance.

This tutorial is targeted toward users who have some familiarity with the [TiDB Architecture](#), who may have already set up a TiDB cluster (not mandatory), and who wants to gain hands-on experience with TiDB Binlog. This tutorial is a good way to “kick the tires” of TiDB Binlog and to familiarize yourself with the concepts of its architecture.

#### **Warning:**

The instructions to deploy TiDB in this tutorial should **not** be used to deploy TiDB in a production or development setting.

This tutorial assumes you’re using a modern Linux distribution on x86-64. A minimal CentOS 7 installation running in VMware is used in this tutorial for the examples. It’s recommended that you start from a clean install, so that you aren’t impacted by quirks of your existing environment. If you don’t want to use local virtualization, you can easily start a CentOS 7 VM using your cloud service.

#### 13.10.2.1 TiDB Binlog Overview

TiDB Binlog is a solution to collect binary log data from TiDB and provide real-time data backup and replication. It pushes incremental data updates from a TiDB Server cluster into downstream platforms.

You can use TiDB Binlog for incremental backups, to replicate data from one TiDB cluster to another, or to send TiDB updates through Kafka to a downstream platform of your choice.

TiDB Binlog is particularly useful when you migrate data from MySQL or MariaDB to TiDB, in which case you may use the TiDB DM (Data Migration) platform to get data from a MySQL/MariaDB cluster into TiDB, and then use TiDB Binlog to keep a separate, downstream MySQL/MariaDB instance/cluster in sync with your TiDB cluster. TiDB Binlog enables application traffic to TiDB to be pushed to a downstream MySQL or MariaDB instance/cluster, which reduces the risk of a migration to TiDB because you can easily revert the application to MySQL or MariaDB without downtime or data loss.

See [TiDB Binlog Cluster User Guide](#) for more information.

### 13.10.2.2 Architecture

TiDB Binlog comprises two components: the **Pump** and the **Drainer**. Several Pump nodes make up a pump cluster. Each Pump node connects to TiDB Server instances and receives updates made to each of the TiDB Server instances in a cluster. A Drainer connects to the Pump cluster and transforms the received updates into the correct format for a particular downstream destination, for example, Kafka, another TiDB Cluster or a MySQL/MariaDB server.

Figure 290: TiDB-Binlog architecture

The clustered architecture of Pump ensures that updates won't be lost as new TiDB Server instances join or leave the TiDB Cluster or Pump nodes join or leave the Pump cluster.

### 13.10.2.3 Installation

We're using MariaDB Server in this case instead of MySQL Server because RHEL/CentOS 7 includes MariaDB Server in their default package repositories. We'll need the client as well as the server for later use. Let's install them now:

```
sudo yum install -y mariadb-server
```

```
curl -L https://download.pingcap.org/tidb-community-server-v6.6.0-linux-
↳ amd64.tar.gz | tar xzf -
cd tidb-latest-linux-amd64
```

Expected output:

```
[kolbe@localhost ~]$ curl -LO https://download.pingcap.org/tidb-latest-linux
↳ -amd64.tar.gz | tar xzf -
% Total % Received % Xferd Average Speed Time Time Time Current
 Dload Upload Total Spent Left Speed
100 368M 100 368M 0 0 8394k 0 0:00:44 0:00:44 --:--:-- 11.1M
[kolbe@localhost ~]$ cd tidb-latest-linux-amd64
[kolbe@localhost tidb-latest-linux-amd64]$
```

#### 13.10.2.4 Configuration

Now we'll start a simple TiDB cluster, with a single instance for each of `pd-server`, `tikv-server`, and `tidb-server`.

Populate the config files using:

```
printf > pd.toml %s\n 'log-file="pd.log"' 'data-dir="pd.data"'
printf > tikv.toml %s\n 'log-file="tikv.log"' '[storage]' 'data-dir="tikv.
↳ data"' '[pd]' 'endpoints=["127.0.0.1:2379"]' '[rocksdb]' max-open-
↳ files=1024 '[raftdb]' max-open-files=1024
printf > pump.toml %s\n 'log-file="pump.log"' 'data-dir="pump.data"' 'addr
↳ ="127.0.0.1:8250"' 'advertise-addr="127.0.0.1:8250"' 'pd-urls="http
↳ ://127.0.0.1:2379"'
printf > tidb.toml %s\n 'store="tikv"' 'path="127.0.0.1:2379"' '[log.file
↳]' 'filename="tidb.log"' '[binlog]' 'enable=true'
printf > drainer.toml %s\n 'log-file="drainer.log"' '[syncer]' 'db-type="
↳ mysql"' '[syncer.to]' 'host="127.0.0.1"' 'user="root"' 'password=""'
↳ 'port=3306'
```

Use the following commands to see the configuration details:

```
for f in *.toml; do echo "$f:"; cat "$f"; echo; done
```

Expected output:

```
drainer.toml:
log-file="drainer.log"
[syncer]
db-type="mysql"
[syncer.to]
host="127.0.0.1"
user="root"
password=""
port=3306

pd.toml:
log-file="pd.log"
data-dir="pd.data"

pump.toml:
log-file="pump.log"
data-dir="pump.data"
addr="127.0.0.1:8250"
advertise-addr="127.0.0.1:8250"
pd-urls="http://127.0.0.1:2379"

tidb.toml:
store="tikv"
path="127.0.0.1:2379"
[log.file]
filename="tidb.log"
[binlog]
enable=true

tikv.toml:
log-file="tikv.log"
[storage]
data-dir="tikv.data"
[pd]
endpoints=["127.0.0.1:2379"]
[rocksdb]
max-open-files=1024
[raftdb]
max-open-files=1024
```

### 13.10.2.5 Bootstrapping

Now we can start each component. This is best done in a specific order - firstly the Placement Driver (PD), then TiKV Server, then Pump (because TiDB must connect to the

Pump service to send the binary log), and finally the TiDB Server.

Start all the services using:

```
./bin/pd-server --config=pd.toml &>pd.out &
./bin/tikv-server --config=tikv.toml &>tikv.out &
./pump --config=pump.toml &>pump.out &
sleep 3
./bin/tidb-server --config=tidb.toml &>tidb.out &
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$./bin/pd-server --config=pd.toml
↪ &>pd.out &
[1] 20935
[kolbe@localhost tidb-latest-linux-amd64]$./bin/tikv-server --config=tikv.
↪ toml &>tikv.out &
[2] 20944
[kolbe@localhost tidb-latest-linux-amd64]$./pump --config=pump.toml &>pump.
↪ out &
[3] 21050
[kolbe@localhost tidb-latest-linux-amd64]$ sleep 3
[kolbe@localhost tidb-latest-linux-amd64]$./bin/tidb-server --config=tidb.
↪ toml &>tidb.out &
[4] 21058
```

If you execute jobs, you should see a list of running daemons:

```
[kolbe@localhost tidb-latest-linux-amd64]$ jobs
[1] Running ./bin/pd-server --config=pd.toml &>pd.out &
[2] Running ./bin/tikv-server --config=tikv.toml &>tikv.out &
[3]- Running ./pump --config=pump.toml &>pump.out &
[4]+ Running ./bin/tidb-server --config=tidb.toml &>tidb.out &
```

If one of the services has failed to start (if you see “Exit 1” instead of “Running”, for example), try to restart that individual service.

### 13.10.2.6 Connecting

You should have all 4 components of our TiDB Cluster running now, and you can now connect to the TiDB Server on port 4000 using the MariaDB/MySQL command-line client:

```
mysql -h 127.0.0.1 -P 4000 -u root -e 'select tidb_version()\G'
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ mysql -h 127.0.0.1 -P 4000 -u
↪ root -e 'select tidb_version()\G'
```

```
***** 1. row *****
tidb_version(): Release Version: v3.0.0-beta.1-154-gd5afff70c
Git Commit Hash: d5afff70cdd825d5fab125c8e52e686cc5fb9a6e
Git Branch: master
UTC Build Time: 2019-04-24 03:10:00
GoVersion: go version go1.12 linux/amd64
Race Enabled: false
TiKV Min Version: 2.1.0-alpha.1-ff3dd160846b7d1aed9079c389fc188f7f5ea13e
Check Table Before Drop: false
```

At this point we have a TiDB Cluster running, and we have pump reading binary logs from the cluster and storing them as relay logs in its data directory. The next step is to start a MariaDB server that drainer can write to.

Start drainer using:

```
sudo systemctl start mariadb
./drainer --config=drainer.toml &>drainer.out &
```

If you are using an operating system that makes it easier to install MySQL server, that's also OK. Just make sure it's listening on port 3306 and that you can either connect to it as user "root" with an empty password, or adjust drainer.toml as necessary.

```
mysql -h 127.0.0.1 -P 3306 -u root
```

```
show databases;
```

Expected output:

```
[kolbe@localhost ~]$ mysql -h 127.0.0.1 -P 3306 -u root
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 20
Server version: 5.5.60-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input
 ↵ statement.

MariaDB [(none)]> show databases;
+-----+
| Database |
+-----+
| information_schema|
| mysql |
| performance_schema|
| test |
+-----+
```

```
| tidb_binlog |
+-----+
5 rows in set (0.01 sec)
```

Here we can already see the `tidb_binlog` database, which contains the `checkpoint` table used by `drainer` to record up to what point binary logs from the TiDB cluster have been applied.

```
MariaDB [tidb_binlog]> use tidb_binlog;
Database changed
MariaDB [tidb_binlog]> select * from checkpoint;
+-----+-----+
| clusterID | checkPoint |
+-----+-----+
| 6678715361817107733 | {"commitTS":407637466476445697,"ts-map":{}} |
+-----+-----+
1 row in set (0.00 sec)
```

Now, let's open another client connection to the TiDB server, so that we can create a table and insert some rows into it. (It's recommended that you do this under a GNU screen so you can keep multiple clients open at the same time.)

```
mysql -h 127.0.0.1 -P 4000 --prompt='TiDB [\d]> ' -u root
```

```
create database tidbtest;
use tidbtest;
create table t1 (id int unsigned not null AUTO_INCREMENT primary key);
insert into t1 () values (),(),(),(),();
select * from t1;
```

Expected output:

```
TiDB [(none)]> create database tidbtest;
Query OK, 0 rows affected (0.12 sec)

TiDB [(none)]> use tidbtest;
Database changed
TiDB [tidbtest]> create table t1 (id int unsigned not null AUTO_INCREMENT
↪ primary key);
Query OK, 0 rows affected (0.11 sec)

TiDB [tidbtest]> insert into t1 () values (),(),(),(),();
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

TiDB [tidbtest]> select * from t1;
```

```
+-----+
| id |
+-----+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+-----+
5 rows in set (0.00 sec)
```

Switching back to the MariaDB client, we should find the new database, new table, and the newly inserted rows:

```
use tidbtest;
show tables;
select * from t1;
```

Expected output:

```
MariaDB [(none)]> use tidbtest;
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
MariaDB [tidbtest]> show tables;
+-----+
| Tables_in_tidbtest |
+-----+
| t1 |
+-----+
1 row in set (0.00 sec)

MariaDB [tidbtest]> select * from t1;
+-----+
| id |
+-----+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+-----+
5 rows in set (0.00 sec)
```

You should see the same rows that you inserted into TiDB when querying the MariaDB server. Congratulations! You've just set up TiDB Binlog!

### 13.10.2.7 binlogctl

Information about Pumps and Drainers that have joined the cluster is stored in PD. You can use the `binlogctl` tool query and manipulate information about their states. See [binlogctl guide](#) for more information.

Use `binlogctl` to get a view of the current status of Pumps and Drainers in the cluster:

```
./binlogctl -cmd drainers
./binlogctl -cmd pumps
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$./binlogctl -cmd drainers
[2019/04/11 17:44:10.861 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
↳ drainer] [node="{NodeID: localhost.localdomain:8249, Addr:
↳ 192.168.236.128:8249, State: online, MaxCommitTS: 407638907719778305,
↳ UpdateTime: 2019-04-11 17:44:10 -0400 EDT}"]

[kolbe@localhost tidb-latest-linux-amd64]$./binlogctl -cmd pumps
[2019/04/11 17:44:13.904 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
↳ pump] [node="{NodeID: localhost.localdomain:8250, Addr:
↳ 192.168.236.128:8250, State: online, MaxCommitTS: 407638914024079361,
↳ UpdateTime: 2019-04-11 17:44:13 -0400 EDT}"]
```

If you kill a Drainer, the cluster puts it in the “paused” state, which means that the cluster expects it to rejoin:

```
pkill drainer
./binlogctl -cmd drainers
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ pkill drainer
[kolbe@localhost tidb-latest-linux-amd64]$./binlogctl -cmd drainers
[2019/04/11 17:44:22.640 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
↳ drainer] [node="{NodeID: localhost.localdomain:8249, Addr:
↳ 192.168.236.128:8249, State: paused, MaxCommitTS: 407638915597467649,
↳ UpdateTime: 2019-04-11 17:44:18 -0400 EDT}"]
```

You can use “NodeIDs” with `binlogctl` to control individual nodes. In this case, the NodeID of the drainer is “localhost.localdomain:8249” and the NodeID of the Pump is “localhost.localdomain:8250”.

The main use of `binlogctl` in this tutorial is likely to be in the event of a cluster restart. If you end all processes in the TiDB cluster and try to restart them (not including

the downstream MySQL/MariaDB server or Drainer), Pump will refuse to start because it cannot contact Drainer and believe that Drainer is still “online”.

There are 3 solutions to this issue:

- Stop Drainer using `binlogctl` instead of killing the process:

```
./binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=drainers
./binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=offline-drainer --
↳ node-id=localhost.localdomain:8249
```

- Start Drainer *before* starting Pump.
- Use `binlogctl` after starting PD (but before starting Drainer and Pump) to update the state of the paused Drainer:

```
./binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=update-drainer --node
↳ -id=localhost.localdomain:8249 --state=offline
```

### 13.10.2.8 Cleanup

To stop the TiDB cluster and TiDB Binlog processes, you can execute `kill -P $$` in the shell where you started all the processes that form the cluster (pd-server, tikv-server, pump, tidb-server, drainer). To give each component enough time to shut down cleanly, it's helpful to stop them in a particular order:

```
for p in tidb-server drainer pump tikv-server pd-server; do kill "$p";
↳ sleep 1; done
```

Expected output:

```
kolbe@localhost tidb-latest-linux-amd64]$ for p in tidb-server drainer pump
↳ tikv-server pd-server; do kill "$p"; sleep 1; done
[4]- Done ./bin/tidb-server --config=tidb.toml &>tidb.out
[5]+ Done ./drainer --config=drainer.toml &>drainer.out
[3]+ Done ./pump --config=pump.toml &>pump.out
[2]+ Done ./bin/tikv-server --config=tikv.toml &>tikv.out
[1]+ Done ./bin/pd-server --config=pd.toml &>pd.out
```

If you wish to restart the cluster after all services exit, use the same commands you ran originally to start the services. As discussed in the `binlogctl` section above, you'll need to start `drainer` before `pump`, and `pump` before `tidb-server`.

```
./bin/pd-server --config=pd.toml &>pd.out &
./bin/tikv-server --config=tikv.toml &>tikv.out &
./drainer --config=drainer.toml &>drainer.out &
sleep 3
```

```
./pump --config=pump.toml &>pump.out &
sleep 3
./bin/tidb-server --config=tidb.toml &>tidb.out &
```

If any of the components fail to start, try to restart the failed individual component(s).

### 13.10.2.9 Conclusion

In this tutorial, we've set up TiDB Binlog to replicate from a TiDB cluster to a downstream MariaDB server, using a cluster with a single Pump and a single Drainer. As we've seen, TiDB Binlog is a comprehensive platform for capturing and processing changes to a TiDB cluster.

In a more robust development, testing, or production deployment, you'd have multiple TiDB servers for high availability and scaling purposes, and you'd use multiple Pump instances to ensure that application traffic to TiDB server instances is unaffected by problems in the Pump cluster. You may also use additional Drainer instances to push updates to different downstream platforms or to implement incremental backups.

### 13.10.3 TiDB Binlog Cluster Deployment

This document describes how to [deploy TiDB Binlog using a Binary package](#).

#### 13.10.3.1 Hardware requirements

Pump and Drainer are deployed and operate on 64-bit universal hardware server platforms with Intel x86-64 architecture.

In environments of development, testing and production, the requirements on server hardware are as follows:

Service	The Number of Servers	CPU	Disk	Memory
Pump	3	8 core+	SSD, 200 GB+	16G
Drainer	1	8 core+	SAS, 100 GB+	16G

(If binlogs are output as local files, the disk size depends on how long these files are retained.)

#### 13.10.3.2 Deploy TiDB Binlog using TiUP

It is recommended to deploy TiDB Binlog using TiUP. To do that, when deploying TiDB using TiUP, you need to add the node information of drainer and pump of TiDB Binlog in [TiDB Binlog Deployment Topology](#). For detailed deployment information, refer to [Deploy a TiDB Cluster Using TiUP](#).

### 13.10.3.3 Deploy TiDB Binlog using a binary package

#### 13.10.3.3.1 Download the official binary package

The binary package of TiDB Binlog is included in the TiDB Toolkit. To download the TiDB Toolkit, see [Download TiDB Tools](#).

#### 13.10.3.3.2 The usage example

Assuming that you have three PD nodes, one TiDB node, two Pump nodes, and one Drainer node, the information of each node is as follows:

Node	IP
TiDB	192.168.0.10
PD1	192.168.0.16
PD2	192.168.0.15
PD3	192.168.0.14
Pump	192.168.0.11
Pump	192.168.0.12
Drainer	192.168.0.13

The following part shows how to use Pump and Drainer based on the nodes above.

#### 1. Deploy Pump using the binary.

- To view the command line parameters of Pump, execute `./pump -help`:

```
Usage of Pump:
-L string
 the output information level of logs: debug, info, warn, error,
 ↪ fatal ("info" by default)
-V
 the print version information
-addr string
 the RPC address through which Pump provides the service (-addr=
 ↪ "192.168.0.11:8250")
-advertise-addr string
 the RPC address through which Pump provides the external
 ↪ service (-advertise-addr="192.168.0.11:8250")
```

```
-config string
 the path of the configuration file. If you specify the
 ↪ configuration file, Pump reads the configuration in the
 ↪ configuration file first. If the corresponding
 ↪ configuration also exists in the command line parameters,
 ↪ Pump uses the configuration of the command line
 ↪ parameters to cover that of the configuration file.
-data-dir string
 the path where the Pump data is stored
-gc int
 the number of days to retain the data in Pump ("7" by default)
-heartbeat-interval int
 the interval of the heartbeats Pump sends to PD (in seconds)
-log-file string
 the file path of logs
-log-rotate string
 the switch frequency of logs (hour/day)
-metrics-addr string
 the Prometheus Pushgateway address. If not set, it is forbidden
 ↪ to report the monitoring metrics.
-metrics-interval int
 the report frequency of the monitoring metrics ("15" by default
 ↪ , in seconds)
-node-id string
 the unique ID of a Pump node. If you do not specify this ID,
 ↪ the system automatically generates an ID based on the
 ↪ host name and listening port.
-pd-urls string
 the address of the PD cluster nodes (-pd-urls="http
 ↪ ://192.168.0.16:2379,http://192.168.0.15:2379,http
 ↪ ://192.168.0.14:2379")
-fake-binlog-interval int
 the frequency at which a Pump node generates fake binlog ("3"
 ↪ by default, in seconds)
```

- Taking deploying Pump on “192.168.0.11” as an example, the Pump configuration file is as follows:

```
Pump Configuration

the bound address of Pump
addr = "192.168.0.11:8250"

the address through which Pump provides the service
advertise-addr = "192.168.0.11:8250"
```

```
the number of days to retain the data in Pump ("7" by default)
gc = 7

the directory where the Pump data is stored
data-dir = "data.pump"

the interval of the heartbeats Pump sends to PD (in seconds)
heartbeat-interval = 2

the address of the PD cluster nodes (each separated by a comma
 ↪ with no whitespace)
pd-urls = "http://192.168.0.16:2379,http://192.168.0.15:2379,http
 ↪ ://192.168.0.14:2379"

[security]
This section is generally commented out if no special security
 ↪ settings are required.
The file path containing a list of trusted SSL CAs connected to
 ↪ the cluster.
ssl-ca = "/path/to/ca.pem"
The path to the X509 certificate in PEM format that is connected
 ↪ to the cluster.
ssl-cert = "/path/to/drainner.pem"
The path to the X509 key in PEM format that is connected to the
 ↪ cluster.
ssl-key = "/path/to/drainner-key.pem"

[storage]
Set to true (by default) to guarantee reliability by ensuring
 ↪ binlog data is flushed to the disk
sync-log = true

When the available disk capacity is less than the set value, Pump
 ↪ stops writing data.
42 MB -> 42000000, 42 mib -> 44040192
default: 10 gib
stop-write-at-available-space = "10 gib"
The LSM DB settings embedded in Pump. Unless you know this part
 ↪ well, it is usually commented out.
[storage.kv]
block-cache-capacity = 8388608
block-restart-interval = 16
block-size = 4096
compaction-L0-trigger = 8
```

```
compaction-table-size = 67108864
compaction-total-size = 536870912
compaction-total-size-multiplier = 8.0
write-buffer = 67108864
write-L0-pause-trigger = 24
write-L0-slowdown-trigger = 17
```

- The example of starting Pump:

```
./pump -config pump.toml
```

If the command line parameters is the same with the configuration file parameters, the values of command line parameters are used.

## 2. Deploy Drainer using binary.

- To view the command line parameters of Drainer, execute `./drainer -help`:

```
Usage of Drainer:
-L string
 the output information level of logs: debug, info, warn, error,
 ↪ fatal ("info" by default)
-V
 the print version information
-addr string
 the address through which Drainer provides the service (-addr="
 ↪ 192.168.0.13:8249")
-c int
 the number of the concurrency of the downstream for replication
 ↪ . The bigger the value, the better throughput performance
 ↪ of the concurrency ("1" by default).
-cache-binlog-count int
 the limit on the number of binlog items in the cache ("8" by
 ↪ default)
 If a large single binlog item in the upstream causes OOM in
 ↪ Drainer, try to lower the value of this parameter to
 ↪ reduce memory usage.
-config string
 the directory of the configuration file. Drainer reads the
 ↪ configuration file first.
 If the corresponding configuration exists in the command line
 ↪ parameters, Drainer uses the configuration of the command
 ↪ line parameters to cover that of the configuration file.
-data-dir string
 the directory where the Drainer data is stored ("data.drainer"
 ↪ by default)
```

```
-dest-db-type string
 the downstream service type of Drainer
 The value can be "mysql", "tidb", "kafka", and "file". ("mysql"
 ↪ by default)
-detect-interval int
 the interval of checking the online Pump in PD ("10" by default
 ↪ , in seconds)
-disable-detect
 whether to disable the conflict monitoring
-disable-dispatch
 whether to disable the SQL feature of splitting a single binlog
 ↪ file. If it is set to "true", each binlog file is
 ↪ restored to a single transaction for replication based on
 ↪ the order of binlogs.
 It is set to "False", when the downstream is MySQL.
-ignore-schemas string
 the db filter list ("INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,
 ↪ mysql,test" by default)
 It does not support the Rename DDL operation on tables of `
 ↪ ignore schemas`.
-initial-commit-ts
 If Drainer does not have the related breakpoint information,
 ↪ you can configure the related breakpoint information
 ↪ using this parameter. ("-1" by default)
 If the value of this parameter is `-1`, Drainer automatically
 ↪ obtains the latest timestamp from PD.
-log-file string
 the path of the log file
-log-rotate string
 the switch frequency of log files, hour/day
-metrics-addr string
 the Prometheus Pushgateway address
 It it is not set, the monitoring metrics are not reported.
-metrics-interval int
 the report frequency of the monitoring metrics ("15" by default
 ↪ , in seconds)
-node-id string
 the unique ID of a Drainer node. If you do not specify this ID,
 ↪ the system automatically generates an ID based on the
 ↪ host name and listening port.
-pd-urls string
 the address of the PD cluster nodes (-pd-urls="http
 ↪ ://192.168.0.16:2379,http://192.168.0.15:2379,http
 ↪ ://192.168.0.14:2379")
-safe-mode
```

```
Whether to enable safe mode so that data can be written into
↳ the downstream MySQL/TiDB repeatedly.
This mode replaces the `INSERT` statement with the `REPLACE`
↳ statement and splits the `UPDATE` statement into `DELETE`
↳ plus `REPLACE`.
-txn-batch int
the number of SQL statements of a transaction which are output
↳ to the downstream database ("1" by default)
```

- Taking deploying Drainer on “192.168.0.13” as an example, the Drainer configuration file is as follows:

```
Drainer Configuration.

the address through which Drainer provides the service
↳ ("192.168.0.13:8249")
addr = "192.168.0.13:8249"

the address through which Drainer provides the external service
advertise-addr = "192.168.0.13:8249"

the interval of checking the online Pump in PD ("10" by default,
↳ in seconds)
detect-interval = 10

the directory where the Drainer data is stored "data.drainer" by
↳ default)
data-dir = "data.drainer"

the address of the PD cluster nodes (each separated by a comma
↳ with no whitespace)
pd-urls = "http://192.168.0.16:2379,http://192.168.0.15:2379,http
↳ ://192.168.0.14:2379"

the directory of the log file
log-file = "drainer.log"

Drainer compresses the data when it gets the binlog from Pump.
↳ The value can be "gzip". If it is not configured, it will
↳ not be compressed
compressor = "gzip"

[security]
This section is generally commented out if no special security
↳ settings are required.
```

```
The file path containing a list of trusted SSL CAs connected to
 ↳ the cluster.
ssl-ca = "/path/to/ca.pem"
The path to the X509 certificate in PEM format that is connected
 ↳ to the cluster.
ssl-cert = "/path/to/pump.pem"
The path to the X509 key in PEM format that is connected to the
 ↳ cluster.
ssl-key = "/path/to/pump-key.pem"

Syncer Configuration
[syncer]
If the item is set, the sql-mode will be used to parse the DDL
 ↳ statement.
If the downstream database is MySQL or TiDB, then the downstream
 ↳ sql-mode
is also set to this value.
sql-mode = "STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION"

the number of SQL statements of a transaction that are output to
 ↳ the downstream database ("20" by default)
txn-batch = 20

the number of the concurrency of the downstream for replication.
 ↳ The bigger the value,
the better throughput performance of the concurrency ("16" by
 ↳ default)
worker-count = 16

whether to disable the SQL feature of splitting a single binlog
 ↳ file. If it is set to "true",
each binlog file is restored to a single transaction for
 ↳ replication based on the order of binlogs.
If the downstream service is MySQL, set it to "False".
disable-dispatch = false

In safe mode, data can be written into the downstream MySQL/TiDB
 ↳ repeatedly.
This mode replaces the `INSERT` statement with the `REPLACE`
 ↳ statement and replaces the `UPDATE` statement with `DELETE`
 ↳ plus `REPLACE` statements.
safe-mode = false

the downstream service type of Drainer ("mysql" by default)
Valid value: "mysql", "tidb", "file", and "kafka".
```

```
db-type = "mysql"

If `commit ts` of the transaction is in the list, the transaction
 ↪ is filtered and not replicated to the downstream.
ignore-txn-commit-ts = []

the db filter list ("INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql,
 ↪ test" by default)
Does not support the Rename DDL operation on tables of `ignore
 ↪ schemas`.
ignore-schemas = "INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql"

`replicate-do-db` has priority over `replicate-do-table`. When
 ↪ they have the same `db` name,
regular expressions are supported for configuration.
The regular expression should start with "~".

replicate-do-db = ["~^b.*","s1"]

[syncer.relay]
It saves the directory of the relay log. The relay log is not
 ↪ enabled if the value is empty.
The configuration only comes to effect if the downstream is TiDB
 ↪ or MySQL.
log-dir = ""
the maximum size of each file
max-file-size = 10485760

[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "~^a.*"

Ignore the replication of some tables
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

the server parameters of the downstream database when `db-type`
 ↪ is set to "mysql"
[syncer.to]
host = "192.168.0.13"
```

```
user = "root"
If you do not want to set a cleartext `password` in the
 ↳ configuration file, you can create `encrypted_password`
 ↳ using `./binlogctl -cmd encrypt -text string`.
When you have created an `encrypted_password` that is not empty,
 ↳ the `password` above will be ignored, because `
 ↳ `encrypted_password` and `password` cannot take effect at the
 ↳ same time.
password = ""
encrypted_password = ""
port = 3306

[syncer.to.checkpoint]
When the checkpoint type is "mysql" or "tidb", this option can be
enabled to change the database that saves the checkpoint
schema = "tidb_binlog"
Currently only the "mysql" and "tidb" checkpoint types are
 ↳ supported
You can remove the comment tag to control where to save the
 ↳ checkpoint
The default method of saving the checkpoint for the downstream db
 ↳ -type:
mysql/tidb -> in the downstream MySQL or TiDB database
file/kafka -> file in `data-dir`
type = "mysql"
host = "127.0.0.1"
user = "root"
password = ""
`encrypted_password` is encrypted using `./binlogctl -cmd encrypt
 ↳ -text string`.
When `encrypted_password` is not empty, the `password` above will
 ↳ be ignored.
encrypted_password = ""
port = 3306

the directory where the binlog file is stored when `db-type` is
 ↳ set to `file`
[syncer.to]
dir = "data.drainer"

the Kafka configuration when `db-type` is set to "kafka"
[syncer.to]
only one of kafka-addr and zookeeper-addr is needed. If both
 ↳ are present, the program gives priority
to the kafka address in zookeeper
```

```
zookeeper-addr = "127.0.0.1:2181"
kafka-addr = "127.0.0.1:9092"
kafka-version = "0.8.2.0"
The maximum number of messages (number of binlogs) in a broker
 ↪ request. If it is left blank or a value smaller than 0 is
 ↪ configured, the default value 1024 is used.
kafka-max-messages = 1024
The maximum size of a broker request (unit: byte). The default
 ↪ value is 1 GiB and the maximum value is 2 GiB.
kafka-max-message-size = 1073741824

the topic name of the Kafka cluster that saves the binlog data.
 ↪ The default value is <cluster-id>_obinlog.
To run multiple Drainers to replicate data to the same Kafka
 ↪ cluster, you need to set different `topic-name`s for each
 ↪ Drainer.
topic-name = ""
```

- Starting Drainer:

**Note:**

If the downstream is MySQL/TiDB, to guarantee the data integrity, you need to obtain the `initial-commit-ts` value and make a full backup of the data and restore the data before the initial start of Drainer.

When Drainer is started for the first time, use the `initial-commit-ts` parameter.

```
./drainer -config drainer.toml -initial-commit-ts {initial-commit-
 ↪ ts}
```

If the command line parameter and the configuration file parameter are the same, the parameter value in the command line is used.

### 3. Starting TiDB server:

- After starting Pump and Drainer, start TiDB server with binlog enabled by adding this section to your config file for TiDB server:

```
[binlog]
enable=true
```

- TiDB server will obtain the addresses of registered Pumps from PD and will stream data to all of them. If there are no registered Pump instances, TiDB server will refuse to start or will block starting until a Pump instance comes online.

**Note:**

- When TiDB is running, you need to guarantee that at least one Pump is running normally.
- To enable the TiDB Binlog service in TiDB server, use the `-enable-binlog` startup parameter in TiDB, or add `enable=true` to the `binlog` section of the TiDB server configuration file.
- Make sure that the TiDB Binlog service is enabled in all TiDB instances in a same cluster, otherwise upstream and downstream data inconsistency might occur during data replication. If you want to temporarily run a TiDB instance where the TiDB Binlog service is not enabled, set `run_ddl=false` in the TiDB configuration file.
- Drainer does not support the `rename` DDL operation on the table of `ignore schemas` (the schemas in the filter list).
- If you want to start Drainer in an existing TiDB cluster, generally you need to make a full backup of the cluster data, obtain **snapshot timestamp**, import the data to the target database, and then start Drainer to replicate the incremental data from the corresponding **snapshot timestamp**.
- When the downstream database is TiDB or MySQL, ensure that the `sql_mode` in the upstream and downstream databases are consistent. In other words, the `sql_mode` should be the same when each SQL statement is executed in the upstream and replicated to the downstream. You can execute the `select @@sql_mode;` statement in the upstream and downstream respectively to compare `sql_mode`.
- When a DDL statement is supported in the upstream but incompatible with the downstream, Drainer fails to replicate data. An example is to replicate the `CREATE TABLE t1(a INT)ROW_FORMAT=FIXED;` statement when the downstream database MySQL uses the InnoDB engine. In this case, you can configure `skipping transactions` in Drainer, and manually execute compatible statements in the downstream database.

#### 13.10.4 TiDB Binlog Cluster Operations

This document introduces the following TiDB Binlog cluster operations:

- The state of a Pump and Drainer nodes
- Starting or exiting a Pump or Drainer process
- Managing the TiDB Binlog cluster by using the `binlogctl` tool or by directly performing SQL operations in TiDB

### 13.10.4.1 Pump or Drainer state

Pump or Drainer state description:

- **online**: running normally
- **pausing**: in the pausing process
- **paused**: has been stopped
- **closing**: in the offline process
- **offline**: has been offline

#### Note:

The state information of a Pump or Drainer node is maintained by the service itself and is regularly updated to the Placement Driver (PD).

### 13.10.4.2 Starting and exiting a Pump or Drainer process

#### 13.10.4.2.1 Pump

- **Starting**: When started, the Pump node notifies all Drainer nodes in the **online** state. If the notification is successful, the Pump node sets its state to **online**. Otherwise, the Pump node reports an error, sets its state to **paused** and exits the process.
- **Exiting**: The Pump node enters the **paused** or **offline** state before the process is exited normally; if the process is exited abnormally (caused by the `kill -9` command, process panic, crash), the node is still in the **online** state.
  - **Pause**: You can pause a Pump process by using the `kill` command (not `kill -9`  $\leftrightarrow$ ), pressing `Ctrl+C` or using the `pause-pump` command in the `binlogctl` tool. After receiving the pause instruction, the Pump node sets its state to **pausing**, stops receiving binlog write requests and stops providing binlog data to Drainer nodes. After all threads are safely exited, the Pump node updates its state to **paused** and exits the process.
  - **Offline**: You can close a Pump process only by using the `offline-pump` command in the `binlogctl` tool. After receiving the offline instruction, the Pump node sets its state to **closing** and stops receiving the binlog write requests. The Pump node continues providing binlog to Drainer nodes until all binlog data is consumed by Drainer nodes. Then, the Pump node sets its state to **offline** and exits the process.

### 13.10.4.2.2 Drainer

- Starting: When started, the Drainer node sets its state to **online** and tries to pull binlogs from all Pump nodes which are not in the **offline** state. If it fails to get the binlogs, it keeps trying.
- Exiting: The Drainer node enters the **paused** or **offline** state before the process is exited normally; if the process is exited abnormally (caused by `kill -9`, process panic, crash), the Drainer node is still in the **online** state.
  - Pause: You can pause a Drainer process by using the `kill` command (not `kill -9`), pressing `Ctrl+C` or using the `pause-drainer` command in the `binlogctl` tool. After receiving the pause instruction, the Drainer node sets its state to **pausing** and stops pulling binlogs from Pump nodes. After all threads are safely exited, the Drainer node sets its state to **paused** and exits the process.
  - Offline: You can close a Drainer process only by using the `offline-drainer` command in the `binlogctl` tool. After receiving the offline instruction, the Drainer node sets its state to **closing** and stops pulling binlogs from Pump nodes. After all threads are safely exited, the Drainer node updates its state to **offline** and exits the process.

For how to pause, close, check, and modify the state of Drainer, see the [binlogctl guide](#).

### 13.10.4.3 Use binlogctl to manage Pump/Drainer

`binlogctl` is an operations tool for TiDB Binlog with the following features:

- Checking the state of Pump or Drainer
- Pausing or closing Pump or Drainer
- Handling the abnormal state of Pump or Drainer

For detailed usage of `binlogctl`, refer to [binlogctl overview](#).

### 13.10.4.4 Use SQL statements to manage Pump or Drainer

To view or modify binlog related states, execute corresponding SQL statements in TiDB.

- Check whether binlog is enabled:

```
show variables like "log_bin";
```

```
+-----+-----+
| Variable_name | Value |
+-----+-----+
| log_bin | 0 |
+-----+-----+
```

When the Value is 0, binlog is enabled. When the Value is 1, binlog is disabled.

- Check the status of all the Pump or Drainer nodes:

```
show pump status;
```

```
+-----+-----+-----+-----+-----+
 ↪
| NodeID | Address | State | Max_Commit_Ts | Update_Time |
+-----+-----+-----+-----+-----+
 ↪
| pump1 | 127.0.0.1:8250 | Online | 408553768673342237 | 2019-05-01
 ↪ 00:00:01 |
+-----+-----+-----+-----+-----+
 ↪
| pump2 | 127.0.0.2:8250 | Online | 408553768673342335 | 2019-05-01
 ↪ 00:00:02 |
+-----+-----+-----+-----+-----+
 ↪
```

```
show drainer status;
```

```
+-----+-----+-----+-----+-----+
 ↪
| NodeID | Address | State | Max_Commit_Ts | Update_Time |
+-----+-----+-----+-----+-----+
 ↪
| drainer1 | 127.0.0.3:8249 | Online | 408553768673342532 | 2019-05-01
 ↪ 00:00:03 |
+-----+-----+-----+-----+-----+
 ↪
| drainer2 | 127.0.0.4:8249 | Online | 408553768673345531 | 2019-05-01
 ↪ 00:00:04 |
+-----+-----+-----+-----+-----+
 ↪
```

- Modify the state of a Pump or Drainer node in abnormal situations

```
change pump to node_state = 'paused' for node_id 'pump1';
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
change drainer to node_state = 'paused' for node_id 'drainer1';
```

```
Query OK, 0 rows affected (0.01 sec)
```

Executing the above SQL statements works the same as the `update-pump` or `update-drainer` commands in `binlogctl`. Use the above SQL statements **only** when the Pump or Drainer node is in abnormal situations.

**Note:**

- Checking whether binlog is enabled and the running status of Pump or Drainer is supported in TiDB v2.1.7 and later versions.
- Modifying the status of Pump or Drainer is supported in TiDB v3.0.0-rc.1 and later versions. This feature only supports modifying the status of Pump or Drainer nodes stored in PD. To pause or close the node, use the `binlogctl` tool.

### 13.10.5 TiDB Binlog Configuration File

This document introduces the configuration items of TiDB Binlog.

#### 13.10.5.1 Pump

This section introduces the configuration items of Pump. For the example of a complete Pump configuration file, see [Pump Configuration](#).

##### 13.10.5.1.1 `addr`

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8250`

##### 13.10.5.1.2 `advertise-addr`

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8250`

##### 13.10.5.1.3 `socket`

- The Unix socket address that HTTP API listens to.
- Default value: “”

#### 13.10.5.1.4 `pd-urls`

- Specifies the comma-separated list of PD URLs. If multiple addresses are specified, when the PD client fails to connect to one address, it automatically tries to connect to another address.
- Default value: `http://127.0.0.1:2379`

#### 13.10.5.1.5 `data-dir`

- Specifies the directory where binlogs and their indexes are stored locally.
- Default value: `data.pump`

#### 13.10.5.1.6 `heartbeat-interval`

- Specifies the heartbeat interval (in seconds) at which the latest status is reported to PD.
- Default value: 2

#### 13.10.5.1.7 `gen-binlog-interval`

- Specifies the interval (in seconds) at which data is written into fake binlog.
- Default value: 3

#### 13.10.5.1.8 `gc`

- Specifies the number of days (integer) that binlogs can be stored locally. Binlogs stored longer than the specified number of days are automatically deleted.
- Default value: 7

#### 13.10.5.1.9 `log-file`

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: ""

#### 13.10.5.1.10 `log-level`

- Specifies the log level.
- Default value: `info`

#### 13.10.5.1.11 node-id

- Specifies the Pump node ID. With this ID, this Pump process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8250`.

#### 13.10.5.1.12 security

This section introduces configuration items related to security.

`ssl-ca`

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: `“”`

`ssl-cert`

- Specifies the path of the X509 certificate file encoded in the Privacy Enhanced Mail (PEM) format. For example, `/path/to/pump.pem`.
- Default value: `“”`

`ssl-key`

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: `“”`

#### 13.10.5.1.13 storage

This section introduces configuration items related to storage.

`sync-log`

- Specifies whether to use `fsync` after each **batch** write to binlog to ensure data safety.
- Default value: `true`

`kv_chan_cap`

- Specifies the number of write requests that the buffer can store before Pump receives these requests.
- Default value: `1048576` (that is, 2 to the power of 20)

`slow_write_threshold`

- The threshold (in seconds). If it takes longer to write a single binlog file than this specified threshold, the write is considered slow write and "take a long time to write binlog" is output in the log.  
↪ write binlog"
- Default value: 1

stop-write-at-available-space

- Binlog write requests is no longer accepted when the available storage space is below this specified value. You can use the format such as 900 MB, 5 GB, and 12 GiB to specify the storage space. If there is more than one Pump node in the cluster, when a Pump node refuses a write request because of the insufficient space, TiDB will automatically write binlogs to other Pump nodes.
- Default value: 10 GiB

kv

Currently the storage of Pump is implemented based on [GoLevelDB](#). Under `storage` there is also a `kv` subgroup that is used to adjust the GoLevel configuration. The supported configuration items are shown as below:

- block-cache-capacity
- block-restart-interval
- block-size
- compaction-L0-trigger
- compaction-table-size
- compaction-total-size
- compaction-total-size-multiplier
- write-buffer
- write-L0-pause-trigger
- write-L0-slowdown-trigger

For the detailed description of the above items, see [GoLevelDB Document](#).

### 13.10.5.2 Drainer

This section introduces the configuration items of Drainer. For the example of a complete Drainer configuration file, see [Drainer Configuration](#)

#### 13.10.5.2.1 addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: 127.0.0.1:8249

#### 13.10.5.2.2 advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8249`

#### 13.10.5.2.3 log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: `“”`

#### 13.10.5.2.4 log-level

- Specifies the log level.
- Default value: `info`

#### 13.10.5.2.5 node-id

- Specifies the Drainer node ID. With this ID, this Drainer process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8249`.

#### 13.10.5.2.6 data-dir

- Specifies the directory used to store files that need to be saved during Drainer operation.
- Default value: `data.drainer`

#### 13.10.5.2.7 detect-interval

- Specifies the interval (in seconds) at which PD updates the Pump information.
- Default value: `5`

#### 13.10.5.2.8 pd-urls

- The comma-separated list of PD URLs. If multiple addresses are specified, the PD client will automatically attempt to connect to another address if an error occurs when connecting to one address.
- Default value: `http://127.0.0.1:2379`

### 13.10.5.2.9 initial-commit-ts

- Specifies from which commit timestamp of the transaction the replication process starts. This configuration is applicable only to the Drainer node that is in the replication process for the first time. If a checkpoint already exists in the downstream, the replication will be performed according to the time recorded in the checkpoint.
- `commit ts` (commit timestamp) is a specific point in time for **transaction** commits in TiDB. It is a globally unique and increasing timestamp from PD as the unique ID of the current transaction. You can get the `initial-commit-ts` configuration in the following typical ways:
  - If BR is used, you can get `initial-commit-ts` from the backup TS recorded in the metadata backed up by BR (`backupmeta`).
  - If Dumpling is used, you can get `initial-commit-ts` from the Pos recorded in the metadata backed up by Dumpling (`metadata`),
  - If PD Control is used, `initial-commit-ts` is in the output of the `tso` command.
- Default value: `-1`. Drainer will get a new timestamp from PD as the starting time, which means that the replication process starts from the current time.

### 13.10.5.2.10 synced-check-time

- You can access the `/status` path through the HTTP API to query the status of Drainer replication. `synced-check-time` specifies how many minutes from the last successful replication is considered as `synced`, that is, the replication is complete.
- Default value: `5`

### 13.10.5.2.11 compressor

- Specifies the compression algorithm used for data transfer between Pump and Drainer. Currently only the `gzip` algorithm is supported.
- Default value: `""`, which means no compression.

### 13.10.5.2.12 security

This section introduces configuration items related to security.

`ssl-ca`

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: `""`

`ssl-cert`

- Specifies the path of the X509 certificate file encoded in the PEM format. For example, `/path/to/drainер.pem`.
- Default value: “”

`ssl-key`

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

### 13.10.5.2.13 `syncer`

The `syncer` section includes configuration items related to the downstream.

`db-type`

Currently, the following downstream types are supported:

- `mysql`
- `tidb`
- `kafka`
- `file`

Default value: `mysql`

`sql-mode`

- Specifies the SQL mode when the downstream is the `mysql` or `tidb` type. If there is more than one mode, use commas to separate them.
- Default value: “”

`ignore-txn-commit-ts`

- Specifies the commit timestamp at which the binlog is ignored, such as `[416815754209656834, ↵ 421349811963822081]`.
- Default value: `[]`

`ignore-schemas`

- Specifies the database to be ignored during replication. If there is more than one database to be ignored, use commas to separate them. If all changes in a binlog file are filtered, the whole binlog file is ignored.
- Default value: `INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql`

### ignore-table

Ignores the specified table changes during replication. You can specify multiple tables to be ignored in the `toml` file. For example:

```
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

[[syncer.ignore-table]]
db-name = "test"
tbl-name = "audit"
```

If all changes in a binlog file are filtered, the whole binlog file is ignored.

Default value: `[]`

### replicate-do-db

- Specifies the database to be replicated. For example, `[db1, db2]`.
- Default value: `[]`

### replicate-do-table

Specifies the table to be replicated. For example:

```
[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "~^a.*"
```

Default value: `[]`

### txn-batch

- When the downstream is the `mysql` or `tidb` type, DML operations are executed in different batches. This parameter specifies how many DML operations can be included in each transaction.
- Default value: 20

### worker-count

- When the downstream is the `mysql` or `tidb` type, DML operations are executed concurrently. This parameter specifies the concurrency numbers of DML operations.
- Default value: 16

disable-dispatch

- Disables the concurrency and forcibly set `worker-count` to 1.
- Default value: `false`

safe-mode

If the safe mode is enabled, Drainer modifies the replication updates in the following way:

- `Insert` is modified to `Replace Into`
- `Update` is modified to `Delete plus Replace Into`

Default value: `false`

#### 13.10.5.2.14 `syncer.to`

The `syncer.to` section introduces different types of downstream configuration items according to configuration types.

`mysql/tidb`

The following configuration items are related to connection to downstream databases:

- `host`: If this item is not set, TiDB Binlog tries to check the `MYSQL_HOST` environment variable which is `localhost` by default.
- `port`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PORT` environment variable which is `3306` by default.
- `user`: If this item is not set, TiDB Binlog tries to check the `MYSQL_USER` environment variable which is `root` by default.
- `password`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PSWD` environment variable which is `""` by default.
- `read-timeout`: Specifies the I/O read timeout of the downstream database connection. The default value is `1m`. If Drainer keeps failing on some DDLs that take a long time, you can set this configuration to a larger value.

`file`

- `dir`: Specifies the directory where binlog files are stored. If this item is not set, `data-dir` is used.

`kafka`

When the downstream is Kafka, the valid configuration items are as follows:

- `zookeeper-addr`

- `kafka-addr`
- `kafka-version`
- `kafka-max-messages`
- `kafka-max-message-size`
- `topic-name`

#### 13.10.5.2.15 `syncer.to.checkpoint`

- **type**: Specifies in what way the replication progress is saved. Currently, the available options are `mysql`, `tidb`, and `file`.

This configuration item is the same as the downstream type by default. For example, when the downstream is `file`, the checkpoint progress is saved in the local file `<data -> -dir>/savepoint`; when the downstream is `mysql`, the progress is saved in the downstream database. If you need to explicitly specify using `mysql` or `tidb` to store the progress, make the following configuration:

- **schema**: `"tidb_binlog"` by default.

#### Note:

When deploying multiple Drainer nodes in the same TiDB cluster, you need to specify a different checkpoint schema for each node. Otherwise, the replication progress of two instances will overwrite each other.

- `host`
- `user`
- `password`
- `port`

### 13.10.5.3 TiDB Binlog Configuration File

This document introduces the configuration items of TiDB Binlog.

#### 13.10.5.3.1 Pump

This section introduces the configuration items of Pump. For the example of a complete Pump configuration file, see [Pump Configuration](#).

`addr`

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8250`

#### advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8250`

#### socket

- The Unix socket address that HTTP API listens to.
- Default value: ""

#### pd-urls

- Specifies the comma-separated list of PD URLs. If multiple addresses are specified, when the PD client fails to connect to one address, it automatically tries to connect to another address.
- Default value: `http://127.0.0.1:2379`

#### data-dir

- Specifies the directory where binlogs and their indexes are stored locally.
- Default value: `data.pump`

#### heartbeat-interval

- Specifies the heartbeat interval (in seconds) at which the latest status is reported to PD.
- Default value: `2`

#### gen-binlog-interval

- Specifies the interval (in seconds) at which data is written into fake binlog.
- Default value: `3`

#### gc

- Specifies the number of days (integer) that binlogs can be stored locally. Binlogs stored longer than the specified number of days are automatically deleted.
- Default value: `7`

#### log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

#### log-level

- Specifies the log level.
- Default value: `info`

#### node-id

- Specifies the Pump node ID. With this ID, this Pump process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8250`.

#### security

This section introduces configuration items related to security.

##### ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

##### ssl-cert

- Specifies the path of the X509 certificate file encoded in the Privacy Enhanced Mail (PEM) format. For example, `/path/to/pump.pem`.
- Default value: “”

##### ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

#### storage

This section introduces configuration items related to storage.

##### sync-log

- Specifies whether to use `fsync` after each `batch` write to binlog to ensure data safety.

- Default value: `true`

#### `kv_chan_cap`

- Specifies the number of write requests that the buffer can store before Pump receives these requests.
- Default value: 1048576 (that is, 2 to the power of 20)

#### `slow_write_threshold`

- The threshold (in seconds). If it takes longer to write a single binlog file than this specified threshold, the write is considered slow write and "take a long time to `↔ write binlog`" is output in the log.
- Default value: 1

#### `stop-write-at-available-space`

- Binlog write requests is no longer accepted when the available storage space is below this specified value. You can use the format such as 900 MB, 5 GB, and 12 GiB to specify the storage space. If there is more than one Pump node in the cluster, when a Pump node refuses a write request because of the insufficient space, TiDB will automatically write binlogs to other Pump nodes.
- Default value: 10 GiB

#### `kv`

Currently the storage of Pump is implemented based on [GoLevelDB](#). Under `storage` there is also a `kv` subgroup that is used to adjust the GoLevel configuration. The supported configuration items are shown as below:

- `block-cache-capacity`
- `block-restart-interval`
- `block-size`
- `compaction-L0-trigger`
- `compaction-table-size`
- `compaction-total-size`
- `compaction-total-size-multiplier`
- `write-buffer`
- `write-L0-pause-trigger`
- `write-L0-slowdown-trigger`

For the detailed description of the above items, see [GoLevelDB Document](#).

### 13.10.5.3.2 Drainer

This section introduces the configuration items of Drainer. For the example of a complete Drainer configuration file, see [Drainer Configuration](#)

addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8249`

advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8249`

log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: `“”`

log-level

- Specifies the log level.
- Default value: `info`

node-id

- Specifies the Drainer node ID. With this ID, this Drainer process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8249`.

data-dir

- Specifies the directory used to store files that need to be saved during Drainer operation.
- Default value: `data.drainer`

detect-interval

- Specifies the interval (in seconds) at which PD updates the Pump information.
- Default value: `5`

## pd-urls

- The comma-separated list of PD URLs. If multiple addresses are specified, the PD client will automatically attempt to connect to another address if an error occurs when connecting to one address.
- Default value: `http://127.0.0.1:2379`

## initial-commit-ts

- Specifies from which commit timestamp of the transaction the replication process starts. This configuration is applicable only to the Drainer node that is in the replication process for the first time. If a checkpoint already exists in the downstream, the replication will be performed according to the time recorded in the checkpoint.
- `commit ts` (commit timestamp) is a specific point in time for **transaction** commits in TiDB. It is a globally unique and increasing timestamp from PD as the unique ID of the current transaction. You can get the `initial-commit-ts` configuration in the following typical ways:
  - If BR is used, you can get `initial-commit-ts` from the backup TS recorded in the metadata backed up by BR (backupmeta).
  - If Dumping is used, you can get `initial-commit-ts` from the Pos recorded in the metadata backed up by Dumping (metadata),
  - If PD Control is used, `initial-commit-ts` is in the output of the `tso` command.
- Default value: `-1`. Drainer will get a new timestamp from PD as the starting time, which means that the replication process starts from the current time.

## synced-check-time

- You can access the `/status` path through the HTTP API to query the status of Drainer replication. `synced-check-time` specifies how many minutes from the last successful replication is considered as `synced`, that is, the replication is complete.
- Default value: `5`

## compressor

- Specifies the compression algorithm used for data transfer between Pump and Drainer. Currently only the `gzip` algorithm is supported.
- Default value: `""`, which means no compression.

## security

This section introduces configuration items related to security.

### ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

`ssl-cert`

- Specifies the path of the X509 certificate file encoded in the PEM format. For example, `/path/to/drainier.pem`.
- Default value: “”

`ssl-key`

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

`syncer`

The `syncer` section includes configuration items related to the downstream.

`db-type`

Currently, the following downstream types are supported:

- `mysql`
- `tidb`
- `kafka`
- `file`

Default value: `mysql`

`sql-mode`

- Specifies the SQL mode when the downstream is the `mysql` or `tidb` type. If there is more than one mode, use commas to separate them.
- Default value: “”

`ignore-txn-commit-ts`

- Specifies the commit timestamp at which the binlog is ignored, such as `[416815754209656834, ↪ 421349811963822081]`.
- Default value: `[]`

`ignore-schemas`

- Specifies the database to be ignored during replication. If there is more than one database to be ignored, use commas to separate them. If all changes in a binlog file are filtered, the whole binlog file is ignored.
- Default value: `INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql`

#### ignore-table

Ignores the specified table changes during replication. You can specify multiple tables to be ignored in the `toml` file. For example:

```
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

[[syncer.ignore-table]]
db-name = "test"
tbl-name = "audit"
```

If all changes in a binlog file are filtered, the whole binlog file is ignored.

Default value: `[]`

#### replicate-do-db

- Specifies the database to be replicated. For example, `[db1, db2]`.
- Default value: `[]`

#### replicate-do-table

Specifies the table to be replicated. For example:

```
[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "~^a.*"
```

Default value: `[]`

#### txn-batch

- When the downstream is the `mysql` or `tidb` type, DML operations are executed in different batches. This parameter specifies how many DML operations can be included in each transaction.
- Default value: `20`

#### worker-count

- When the downstream is the `mysql` or `tidb` type, DML operations are executed concurrently. This parameter specifies the concurrency numbers of DML operations.
- Default value: `16`

#### disable-dispatch

- Disables the concurrency and forcibly set `worker-count` to `1`.
- Default value: `false`

#### safe-mode

If the safe mode is enabled, Drainer modifies the replication updates in the following way:

- `Insert` is modified to `Replace Into`
- `Update` is modified to `Delete plus Replace Into`

Default value: `false`

#### syncer.to

The `syncer.to` section introduces different types of downstream configuration items according to configuration types.

#### mysql/tidb

The following configuration items are related to connection to downstream databases:

- `host`: If this item is not set, TiDB Binlog tries to check the `MYSQL_HOST` environment variable which is `localhost` by default.
- `port`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PORT` environment variable which is `3306` by default.
- `user`: If this item is not set, TiDB Binlog tries to check the `MYSQL_USER` environment variable which is `root` by default.
- `password`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PSWD` environment variable which is `""` by default.
- `read-timeout`: Specifies the I/O read timeout of the downstream database connection. The default value is `1m`. If Drainer keeps failing on some DDLs that take a long time, you can set this configuration to a larger value.

#### file

- `dir`: Specifies the directory where binlog files are stored. If this item is not set, `data-dir` is used.

kafka

When the downstream is Kafka, the valid configuration items are as follows:

- `zookeeper-addr`
- `kafka-addr`
- `kafka-version`
- `kafka-max-messages`
- `kafka-max-message-size`
- `topic-name`

`syncer.to.checkpoint`

- `type`: Specifies in what way the replication progress is saved. Currently, the available options are `mysql`, `tidb`, and `file`.

This configuration item is the same as the downstream type by default. For example, when the downstream is `file`, the checkpoint progress is saved in the local file `<data -> -dir>/savepoint`; when the downstream is `mysql`, the progress is saved in the downstream database. If you need to explicitly specify using `mysql` or `tidb` to store the progress, make the following configuration:

- `schema`: "`tidb_binlog`" by default.

#### Note:

When deploying multiple Drainer nodes in the same TiDB cluster, you need to specify a different checkpoint schema for each node. Otherwise, the replication progress of two instances will overwrite each other.

- `host`
- `user`
- `password`
- `port`

### 13.10.6 Upgrade TiDB Binlog

This document introduces how to upgrade TiDB Binlog that is deployed manually to the latest `cluster` version. There is also a section on how to upgrade TiDB Binlog from an earlier incompatible version (Kafka/Local version) to the latest version.

#### 13.10.6.1 Upgrade TiDB Binlog deployed manually

Follow the steps in this section if you deploy TiDB Binlog manually.

### 13.10.6.1.1 Upgrade Pump

First, upgrade each Pump instance in the cluster one by one. This ensures that there are always Pump instances in the cluster that can receive binlogs from TiDB. The steps are as below:

1. Replace the original file with the new version of `pump`.
2. Restart the Pump process.

### 13.10.6.1.2 Upgrade Drainer

Second, upgrade the Drainer component:

1. Replace the original file with the new version of `drainer`.
2. Restart the Drainer process.

## 13.10.6.2 Upgrade TiDB Binlog from Kafka/Local version to the cluster version

The new TiDB versions (v2.0.8-binlog, v2.1.0-rc.5 or later) are not compatible with the Kafka version or Local version of TiDB Binlog. If TiDB is upgraded to one of the new versions, it is required to use the cluster version of TiDB Binlog. If the Kafka or local version of TiDB Binlog is used before upgrading, you need to upgrade your TiDB Binlog to the cluster version.

The corresponding relationship between TiDB Binlog versions and TiDB versions is shown in the following table:

TiDB Binlog version	TiDB version	Note
Local	TiDB 1.0 or earlier	
Kafka	TiDB 1.0 ~ TiDB 2.1 RC5	TiDB 1.0 supports both the local and Kafka versions of TiDB Binlog.
Cluster	TiDB v2.0.8-binlog, TiDB 2.1 RC5 or later	TiDB v2.0.8-binlog is a special 2.0 version supporting the cluster version of TiDB Binlog.

### 13.10.6.2.1 Upgrade process

**Note:**

If importing the full data is acceptable, you can abandon the old version and deploy TiDB Binlog following [TiDB Binlog Cluster Deployment](#).

If you want to resume replication from the original checkpoint, perform the following steps to upgrade TiDB Binlog:

1. Deploy the new version of Pump.
2. Stop the TiDB cluster service.
3. Upgrade TiDB and the configuration, and write the binlog data to the new Pump cluster.
4. Reconnect the TiDB cluster to the service.
5. Make sure that the old version of Drainer has replicated the data in the old version of Pump to the downstream completely;

Query the `status` interface of Drainer, command as below:

```
curl 'http://172.16.10.49:8249/status'
```

```
{"PumpPos":{"172.16.10.49:8250":{"offset":32686}},"Synced": true ,"
 ↳ DepositWindow":{"Upper":398907800202772481,"Lower
 ↳ ":398907799455662081}}
```

If the return value of `Synced` is `True`, it means Drainer has replicated the data in the old version of Pump to the downstream completely.

6. Start the new version of Drainer.
7. Close the Pump and Drainer of the old versions and the dependent Kafka and ZooKeeper.

### 13.10.7 TiDB Binlog Monitoring

After you have deployed TiDB Binlog successfully, you can go to the Grafana Web (default address: [http://grafana\\_ip:3000](http://grafana_ip:3000), default account: admin, password: admin) to check the state of Pump and Drainer.

#### 13.10.7.1 Monitoring metrics

TiDB Binlog consists of two components: Pump and Drainer. This section shows the monitoring metrics of Pump and Drainer.

##### 13.10.7.1.1 Pump monitoring metrics

To understand the Pump monitoring metrics, check the following table:

---

Pump  
mon-  
itor-  
ing  
met-  
rics

---

Description

StorageRecords  
Size the  
to-  
tal

point”

---

	Description
Drainer monitoring metrics	
Executed Records	
Time	the time it takes to write bin-log into the downstream syncing module
95% Bin-log Size	Shows the size of the bin-log data that Drainer obtains from each Pump node

	Description
Drainer monitoring metrics	
DDL Job Count	Records the number of DDL statements handled by Drainer
Queue Size	Records the work queue size in Drainer

### 13.10.7.2 Alert rules

This section gives the alert rules for TiDB Binlog. According to the severity level, TiDB Binlog alert rules are divided into three categories (from high to low): emergency-level, critical-level and warning-level.

#### 13.10.7.2.1 Emergency-level alerts

Emergency-level alerts are often caused by a service or node failure. Manual intervention is required immediately.

`binlog_pump_storage_error_count`

- Alert rule:  
`changes(binlog_pump_storage_error_count[1m])> 0`
- Description:  
Pump fails to write the binlog data to the local storage.

- Solution:

Check whether an error exists in the `pump_storage_error` monitoring and check the Pump log to find the causes.

### 13.10.7.2.2 Critical-level alerts

For the critical-level alerts, a close watch on the abnormal metrics is required.

`binlog_drainer_checkpoint_high_delay`

- Alert rule:

```
(time()- binlog_drainer_checkpoint_tso / 1000)> 3600
```

- Description:

The delay of Drainer replication exceeds one hour.

- Solution:

- Check whether it is too slow to obtain the data from Pump:

You can check `handle tso` of Pump to get the time for the latest message of each Pump. Check whether a high latency exists for Pump and make sure the corresponding Pump is running normally.

- Check whether it is too slow to replicate data in the downstream based on Drainer `event` and Drainer `execute latency`:

- \* If Drainer `execute time` is too large, check the network bandwidth and latency between the machine with Drainer deployed and the machine with the target database deployed, and the state of the target database.

- \* If Drainer `execute time` is not too large and Drainer `event` is too small, add `work count` and `batch` and retry.

- If the two solutions above cannot work, [get support](#) from PingCAP or the community.

### 13.10.7.2.3 Warning-level alerts

Warning-level alerts are a reminder for an issue or error.

`binlog_pump_write_binlog_rpc_duration_seconds_bucket`

- Alert rule:

```
histogram_quantile(0.9, rate(binlog_pump_rpc_duration_seconds_bucket{
↔ method="WriteBinlog"}[5m]))> 1
```

- Description:

It takes too much time for Pump to handle the TiDB request of writing binlog.

- Solution:
  - Verify the disk performance pressure and check the disk performance monitoring via `node_exported`.
  - If both `disk_latency` and `util` are low, [get support](#) from PingCAP or the community.

`binlog_pump_storage_write_binlog_duration_time_bucket`

- Alert rule:

```
histogram_quantile(0.9, rate(binlog_pump_storage_write_binlog_duration_time_bucket
↪ {type="batch"}[5m])) > 1
```

- Description:

The time it takes for Pump to write the local binlog to the local disk.

- Solution:

Check the state of the local disk of Pump and fix the problem.

`binlog_pump_storage_available_size_less_than_20G`

- Alert rule:

```
binlog_pump_storage_storage_size_bytes{type="available"} < 20 * 1024 *
↪ 1024 * 1024
```

- Description:

The available disk space of Pump is less than 20 GB.

- Solution:

Check whether Pump `gc_tso` is normal. If not, adjust the GC time configuration of Pump or get the corresponding Pump offline.

`binlog_drainer_checkpoint_tso_no_change_for_1m`

- Alert rule:

```
changes(binlog_drainer_checkpoint_tso[1m]) < 1
```

- Description:

Drainer `checkpoint` has not been updated for one minute.

- Solution:

Check whether all the Pumps that are not offline are running normally.

```
binlog_drainer_execute_duration_time_more_than_10s
```

- Alert rule:

```
histogram_quantile(0.9, rate(binlog_drainer_execute_duration_time_bucket
↔ [1m])) > 10
```

- Description:

The transaction time it takes Drainer to replicate data to TiDB. If it is too large, the Drainer replication of data is affected.

- Solution:

- Check the TiDB cluster state.
- Check the Drainer log or monitor. If a DDL operation causes this problem, you can ignore it.

### 13.10.8 Reparo User Guide

Reparo is a TiDB Binlog tool, used to recover the incremental data. To back up the incremental data, you can use Drainer of TiDB Binlog to output the binlog data in the protobuf format to files. To restore the incremental data, you can use Reparo to parse the binlog data in the files and apply the binlog in TiDB/MySQL.

The Reparo installation package (`reparo`) is included in the TiDB Toolkit. To download the TiDB Toolkit, see [Download TiDB Tools](#).

#### 13.10.8.1 Reparo usage

##### 13.10.8.1.1 Description of command line parameters

Usage of Reparo:

`-L string`

The level of the output information of logs

Value: "debug"/"info"/"warn"/"error"/"fatal" ("info" by default)

`-V` Prints the version.

`-c int`

The number of concurrencies in the downstream for the replication

↔ process (`16` by default). A higher value indicates a better

↔ throughput for the replication.

`-config string`

The path of the configuration file

If the configuration file is specified, Reparo reads the configuration

↔ data in this file.

```
If the configuration data also exists in the command line parameters,
 ↪ Reparo uses the configuration data in the command line parameters
 ↪ to cover that in the configuration file.
-data-dir string
 The storage directory for the binlog file in the protobuf format that
 ↪ Drainer outputs ("data.drainer" by default)
-dest-type string
 The downstream service type
 Value: "print"/"mysql" ("print" by default)
 If it is set to "print", the data is parsed and printed to standard
 ↪ output while the SQL statement is not executed.
 If it is set to "mysql", you need to configure the "host", "port", "user"
 ↪ " and "password" information in the configuration file.
-log-file string
 The path of the log file
-log-rotate string
 The switch frequency of log files
 Value: "hour"/"day"
-start-datetime string
 Specifies the time point for starting recovery.
 Format: "2006-01-02 15:04:05"
 If it is not set, the recovery process starts from the earliest binlog
 ↪ file.
-stop-datetime string
 Specifies the time point of finishing the recovery process.
 Format: "2006-01-02 15:04:05"
 If it is not set, the recovery process ends up with the last binlog file
 ↪ .
-safe-mode bool
 Specifies whether to enable safe mode. When enabled, it supports
 ↪ repeated replication.
-txn-batch int
 The number of SQL statements in a transaction that is output to the
 ↪ downstream database (`20` by default).
```

### 13.10.8.1.2 Description of the configuration file

```
The storage directory for the binlog file in the protobuf format that
 ↪ Drainer outputs
data-dir = "./data.drainer"

The level of the output information of logs
Value: "debug"/"info"/"warn"/"error"/"fatal" ("info" by default)
log-level = "info"
```

```
Uses `start-datetime` and `stop-datetime` to specify the time range in
↳ which
the binlog files are to be recovered.
Format: "2006-01-02 15:04:05"
start-datetime = ""
stop-datetime = ""

Correspond to `start-datetime` and `stop-datetime` respectively.
They are used to specify the time range in which the binlog files are to
↳ be recovered.
If `start-datetime` and `stop-datetime` are set, there is no need to set
↳ `start-tso` and `stop-tso`.
When you perform a full recovery or resume an incremental recovery, set
↳ start-tso to tso + 1 or stop-tso + 1, respectively.
start-tso = 0
stop-tso = 0

The downstream service type
Value: "print"/"mysql" ("print" by default)
If it is set to "print", the data is parsed and printed to standard
↳ output
while the SQL statement is not executed.
If it is set to "mysql", you need to configure `host`, `port`, `user`
↳ and `password` in [dest-db].
dest-type = "mysql"

The number of SQL statements in a transaction that is output to the
↳ downstream database (`20` by default).
txn-batch = 20

The number of concurrencies in the downstream for the replication
↳ process (`16` by default). A higher value indicates a better
↳ throughput for the replication.
worker-count = 16

Safe-mode configuration
Value: "true"/"false" ("false" by default)
If it is set to "true", Reparo splits the `UPDATE` statement into a `
↳ DELETE` statement plus a `REPLACE` statement.
safe-mode = false

`replicate-do-db` and `replicate-do-table` specify the database and
↳ table to be recovered.
`replicate-do-db` has priority over `replicate-do-table`.
```

```
You can use a regular expression for configuration. The regular
 ↪ expression should start with "~".
The configuration method for `replicate-do-db` and `replicate-do-table`
 ↪ is
the same with that for `replicate-do-db` and `replicate-do-table` of
 ↪ Drainer.
replicate-do-db = ["~^b.*","s1"]
[[replicate-do-table]]
db-name = "test"
tbl-name = "log"
[[replicate-do-table]]
db-name = "test"
tbl-name = "~^a.*"

If `dest-type` is set to `mysql`, `dest-db` needs to be configured.
[dest-db]
host = "127.0.0.1"
port = 3309
user = "root"
password = ""
```

### 13.10.8.1.3 Start example

```
./reparo -config reparo.toml
```

#### Note:

- `data-dir` specifies the directory for the binlog file that Drainer outputs.
- Both `start-datetime` and `start-tso` are used to specify the time point for starting recovery, but they are different in the time format. If they are not set, the recovery process starts from the earliest binlog file by default.
- Both `stop-datetime` and `stop-tso` are used to specify the time point for finishing recovery, but they are different in the time format. If they are not set, the recovery process ends up with the last binlog file by default.
- `dest-type` specifies the destination type. Its value can be “mysql” and “print.”
  - When it is set to `mysql`, the data can be recovered to MySQL or TiDB that uses or is compatible with the MySQL protocol. In this

case, you need to specify the database information in `[dest-db]` of the configuration information.

- When it is set to `print`, only the binlog information is printed. It is generally used for debugging and checking the binlog information. In this case, there is no need to specify `[dest-db]`.

- `replicate-do-db` specifies the database for recovery. If it is not set, all the databases are to be recovered.
- `replicate-do-table` specifies the table for recovery. If it is not set, all the tables are to be recovered.

### 13.10.9 binlogctl

[Binlog Control](#) (`binlogctl` for short) is a command line tool for TiDB Binlog. You can use `binlogctl` to manage TiDB Binlog clusters.

You can use `binlogctl` to:

- Check the state of Pump or Drainer
- Pause or close Pump or Drainer
- Handle the abnormal state of Pump or Drainer

The following are its usage scenarios:

- An error occurs during data replication or you need to check the running state of Pump or Drainer.
- You need to pause or close Pump or Drainer when maintaining the cluster.
- A Pump or Drainer process exits abnormally, while the node state is not updated or is unexpected. This affects the data replication task.

#### 13.10.9.1 Download binlogctl

`binlogctl` is included in the TiDB Toolkit. To download the TiDB Toolkit, see [Download TiDB Tools](#).

#### 13.10.9.2 Descriptions

Command line parameters:

```
Usage of binlogctl:
-V prints version and exit
-cmd string
```

```
operator: "generate_meta", "pumps", "drainers", "update-pump", "
 ↪ update-drainer", "pause-pump", "pause-drainer", "offline-pump
 ↪ ", "offline-drainer", "encrypt" (default "pumps")
-data-dir string
 meta directory path (default "binlog_position")
-node-id string
 id of node, used to update some nodes with operations update-pump,
 ↪ update-drainer, pause-pump, pause-drainer, offline-pump and
 ↪ offline-drainer
-pd-urls string
 a comma separated list of PD endpoints (default "http
 ↪ ://127.0.0.1:2379")
-show-offline-nodes
 include offline nodes when querying pumps/drainers
-ssl-ca string
 Path of file that contains list of trusted SSL CAs for connection
 ↪ with cluster components.
-ssl-cert string
 Path of file that contains X509 certificate in PEM format for
 ↪ connection with cluster components.
-ssl-key string
 Path of file that contains X509 key in PEM format for connection with
 ↪ cluster components.
-state string
 set node's state, can be set to online, pausing, paused, closing or
 ↪ offline.
-text string
 text to be encrypted when using encrypt command
-time-zone Asia/Shanghai
 set time zone if you want to save time info in savepoint file; for
 ↪ example, Asia/Shanghai for CST time, `Local` for local time
```

Command examples:

- Check the state of all the Pump or Drainer nodes.

Set cmd to pumps or drainers. For example:

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd pumps
```

```
[2019/04/28 09:29:59.016 +00:00] [INFO] [nodes.go:48] ["query node"] [
 ↪ type=pump] [node="{NodeID: 1.1.1.1:8250, Addr: pump:8250, State: [
 ↪ online, MaxCommitTS: 408012403141509121, UpdateTime: 2019-04-28
 ↪ 09:29:57 +0000 UTC}"]
```

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd drainers
```

```
[2019/04/28 09:29:59.016 +00:00] [INFO] [nodes.go:48] ["query node"] [
 ↪ type=drainer] [node="{NodeID: 1.1.1.1:8249, Addr: 1.1.1.1:8249,
 ↪ State: online, MaxCommitTS: 408012403141509121, UpdateTime:
 ↪ 2019-04-28 09:29:57 +0000 UTC}"]
```

- Pause or close Pump or Drainer.

You can use the following commands to pause or close services:

Command	Description	Example
pause-pump	Pause Pump	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ pause-pump -node-id ip-127-0-0-1:8250</code>
pause-drainer	Pause Drainer	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ pause-drainer -node-id ip-127-0-0-1:8249</code>
offline-pump	Close Pump	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ offline-pump -node-id ip-127-0-0-1:8250</code>
offline-drainer	Close Drainer	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ offline-drainer -node-id ip-127-0-0-1:8249</code>

`binlogctl` sends the HTTP request to the Pump or Drainer node. After receiving the request, the node executes the exiting procedures accordingly.

- Modify the state of a Pump or Drainer node in abnormal states.

When a Pump or Drainer node runs normally or when it is paused or closed in the normal process, it is in the normal state. In abnormal states, the Pump or Drainer node cannot correctly maintain its state. This affects data replication tasks. In this case, use `binlogctl` to repair the state information.

To update the state of a Pump or Drainer node, set `cmd` to `update-pump` or `update-drainer`. The state can be `paused` or `offline`. For example:

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd update-pump -node-id
 ↪ ip-127-0-0-1:8250 -state paused
```

#### Note:

When a Pump or Drainer node runs normally, it regularly updates its state to PD. The above command directly modifies the Pump or Drainer state saved in PD; therefore, do not use the command when the Pump or Drainer node runs normally. For more information, refer to [TiDB Binlog FAQ](#).

### 13.10.10 Binlog Consumer Client User Guide

Binlog Consumer Client is used to consume TiDB secondary binlog data from Kafka and output the data in a specific format. Currently, Drainer supports multiple kinds of down streaming, including MySQL, TiDB, file and Kafka. But sometimes users have customized requirements for outputting data to other formats, for example, Elasticsearch and Hive, so this feature is introduced.

#### 13.10.10.1 Configure Drainer

Modify the configuration file of Drainer and set it to output the data to Kafka:

```
[syncer]
db-type = "kafka"

[syncer.to]
the Kafka address
kafka-addr = "127.0.0.1:9092"
the Kafka version
kafka-version = "2.4.0"
```

#### 13.10.10.2 Customized development

##### 13.10.10.2.1 Data format

Firstly, you need to obtain the format information of the data which is output to Kafka by Drainer:

```
// `Column` stores the column data in the corresponding variable based on
↳ the data type.
message Column {
 // Indicates whether the data is null
 optional bool is_null = 1 [default = false];
 // Stores `int` data
 optional int64 int64_value = 2;
 // Stores `uint`, `enum`, and `set` data
 optional uint64 uint64_value = 3;
 // Stores `float` and `double` data
 optional double double_value = 4;
 // Stores `bit`, `blob`, `binary` and `json` data
 optional bytes bytes_value = 5;
 // Stores `date`, `time`, `decimal`, `text`, `char` data
 optional string string_value = 6;
}
```

```
// `ColumnInfo` stores the column information, including the column name,
 ↪ type, and whether it is the primary key.
message ColumnInfo {
 optional string name = 1 [(gogoproto.nullable) = false];
 // the lower case column field type in MySQL
 // https://dev.mysql.com/doc/refman/8.0/en/data-types.html
 // for the `numeric` type: int bigint smallint tinyint float double
 ↪ decimal bit
 // for the `string` type: text longtext mediumtext char tinytext varchar
 // blob longblob mediumblob binary tinyblob varbinary
 // enum set
 // for the `json` type: json
 optional string mysql_type = 2 [(gogoproto.nullable) = false];
 optional bool is_primary_key = 3 [(gogoproto.nullable) = false];
}

// `Row` stores the actual data of a row.
message Row { repeated Column columns = 1; }

// `MutationType` indicates the DML type.
enum MutationType {
 Insert = 0;
 Update = 1;
 Delete = 2;
}

// `Table` contains mutations in a table.
message Table {
 optional string schema_name = 1;
 optional string table_name = 2;
 repeated ColumnInfo column_info = 3;
 repeated TableMutation mutations = 4;
}

// `TableMutation` stores mutations of a row.
message TableMutation {
 required MutationType type = 1;
 // data after modification
 required Row row = 2;
 // data before modification. It only takes effect for `Update MutationType`
 ↪ `.`
 optional Row change_row = 3;
}

// `DMLData` stores all the mutations caused by DML in a transaction.
```

```
message DMLData {
 // `tables` contains all the table changes in the transaction.
 repeated Table tables = 1;
}

// `DDLData` stores the DDL information.
message DDLData {
 // the database used currently
 optional string schema_name = 1;
 // the relates table
 optional string table_name = 2;
 // `ddl_query` is the original DDL statement query.
 optional bytes ddl_query = 3;
}

// `BinlogType` indicates the binlog type, including DML and DDL.
enum BinlogType {
 DML = 0; // Has `dml_data`
 DDL = 1; // Has `ddl_query`
}

// `Binlog` stores all the changes in a transaction. Kafka stores the
 ↪ serialized result of the structure data.
message Binlog {
 optional BinlogType type = 1 [(gogoproto.nullable) = false];
 optional int64 commit_ts = 2 [(gogoproto.nullable) = false];
 optional DMLData dml_data = 3;
 optional DDLData ddl_data = 4;
}
```

For the definition of the data format, see [secondary\\_binlog.proto](#)

### 13.10.10.2.2 Driver

The [TiDB-Tools](#) project provides [Driver](#), which is used to read the binlog data in Kafka. It has the following features:

- Read the Kafka data.
- Locate the binlog stored in Kafka based on `commit ts`.

You need to configure the following information when using Driver:

- `KafkaAddr`: the address of the Kafka cluster
- `CommitTS`: from which `commit ts` to start reading the binlog

- **Offset:** from which Kafka `offset` to start reading data. If `CommitTS` is set, you needn't configure this parameter.
- **ClusterID:** the cluster ID of the TiDB cluster
- **Topic:** the topic name of Kafka. If `Topic` is empty, use the default name in Drainer `<ClusterID>_obinlog`.

You can use `Driver` by quoting the `Driver` code in package and refer to the example code provided by `Driver` to learn how to use `Driver` and parse the binlog data.

Currently, two examples are provided:

- Using `Driver` to replicate data to MySQL. This example shows how to convert a binlog to SQL
- Using `Driver` to print data

#### Note:

- The example code only shows how to use `Driver`. If you want to use `Driver` in the production environment, you need to optimize the code.
- Currently, only the Golang version of `Driver` and example code are available. If you want to use other languages, you need to generate the code file in the corresponding language based on the binlog proto file and develop an application to read the binlog data in Kafka, parse the data, and output the data to the downstream. You are also welcome to optimize the example code and submit the example code of other languages to [TiDB-Tools](#).

### 13.10.11 TiDB Binlog Relay Log

When replicating binlogs, Drainer splits transactions from the upstream and replicates the split transactions concurrently to the downstream.

In extreme cases where the upstream clusters are not available and Drainer exits abnormally, the downstream clusters (MySQL or TiDB) might be in the intermediate states with inconsistent data. In such cases, Drainer can use the relay log to ensure that the downstream clusters are in a consistent state.

#### 13.10.11.1 Consistent state during Drainer replication

The downstream clusters reaching a consistent state means the data of the downstream clusters are the same as the snapshot of the upstream which sets `tidb_snapshot = ts`.

The checkpoint consistency means Drainer checkpoint saves the consistent state of replication in `consistent`. When Drainer runs, `consistent` is `false`. After Drainer exits normally, `consistent` is set to `true`.

You can query the downstream checkpoint table as follows:

```
select * from tidb_binlog.checkpoint;
```

clusterID	checkPoint
6791641053252586769	{"consistent":false,"commitTS":414529105591271429,"ts-map":{}}

### 13.10.11.2 Implementation principles

After Drainer enables the relay log, it first writes the binlog events to the disks and then replicates the events to the downstream clusters.

If the upstream clusters are not available, Drainer can restore the downstream clusters to a consistent state by reading the relay log.

#### Note:

If the relay log data is lost at the same time, this method does not work, but its incidence is very low. In addition, you can use the Network File System to ensure data safety of the relay log.

#### 13.10.11.2.1 Trigger scenarios where Drainer consumes binlogs from the relay log

When Drainer is started, if it fails to connect to the Placement Driver (PD) of the upstream clusters, and it detects that `consistent = false` in the checkpoint, Drainer will try to read the relay log, and restore the downstream clusters to a consistent state. After that, the Drainer process sets the checkpoint `consistent` to `true` and then exits.

#### 13.10.11.2.2 GC mechanism of relay log

Before data is replicated to the downstream, Drainer writes data to the relay log file. If the size of a relay log file reaches 10 MB (by default) and the binlog data of the current transaction is completely written, Drainer starts to write data to the next relay log file. After Drainer successfully replicates data to the downstream, it automatically cleans up the relay log files whose data has been replicated. The relay log into which data is currently being written will not be cleaned up.

### 13.10.11.3 Configuration

To enable the relay log, add the following configuration in Drainer:

```
[syncer.relay]
It saves the directory of the relay log. The relay log is not enabled if
 ↳ the value is empty.
The configuration only comes to effect if the downstream is TiDB or
 ↳ MySQL.
log-dir = "/dir/to/save/log"
The size limit of a single relay log file (unit: byte).
When the size of a relay log file reaches this limit, data is written to
 ↳ the next relay log file.
max-file-size = 10485760
```

### 13.10.12 Bidirectional Replication between TiDB Clusters

#### **Warning:**

Currently, bidirectional replication is still an experimental feature. It is **NOT** recommended to use it in the production environment.

This document describes the bidirectional replication between two TiDB clusters, how the replication works, how to enable it, and how to replicate DDL operations.

#### 13.10.12.1 User scenario

If you want two TiDB clusters to exchange data changes with each other, TiDB Binlog allows you to do that. For example, you want cluster A and cluster B to replicate data with each other.

**Note:**

The data written to these two clusters must be conflict-free, that is, in the two clusters, the same primary key or the rows with the unique index of the tables must not be modified.

The user scenario is shown as below:

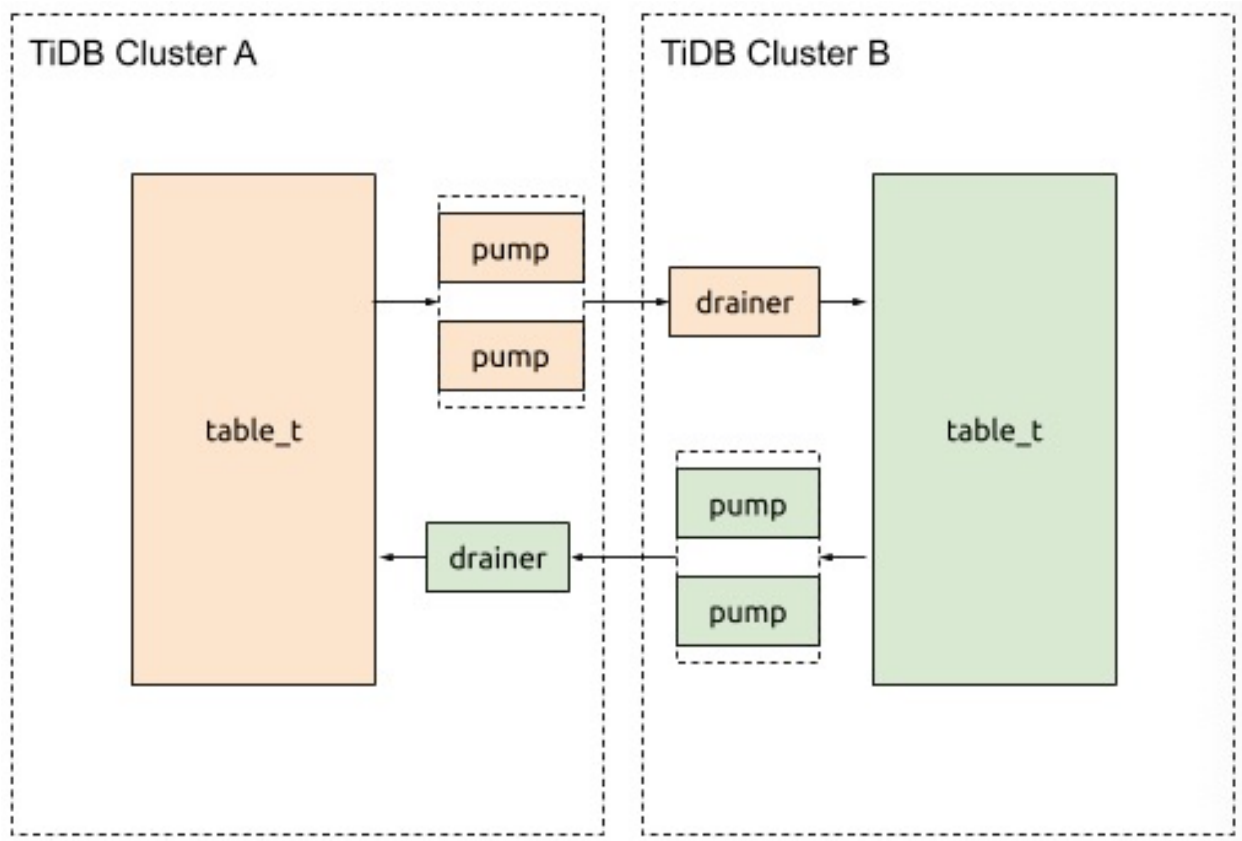

Figure 291: Architect

### 13.10.12.2 Implementation details

Figure 292: Mark Table

If the bidirectional replication is enabled between cluster A and cluster B, the data written to cluster A will be replicated to cluster B, and then these data changes will be replicated back to cluster A, which causes an infinite loop of replication. From the figure above, you can see that during the data replication, Drainer marks the binlog events, and filters out the marked events to avoid such a replication loop.

The detailed implementation is described as follows:

1. Start the TiDB Binlog replication program for each of the two clusters.
2. When the transaction to be replicated passes through the Drainer of cluster A, this Drainer adds the `_drainer_repl_mark` table to the transaction, writes this DML event update to the mark table, and replicate this transaction to cluster B.
3. Cluster B returns binlog events with the `_drainer_repl_mark` mark table to cluster A. The Drainer of cluster B identifies the mark table with the DML event when parsing the binlog event, and gives up replicating this binlog event to cluster A.

The replication process from cluster B to cluster A is the same as above. The two clusters can be upstream and downstream of each other.

#### Note:

- When updating the `_drainer_repl_mark` mark table, data changes are required to generate binlogs.

- DDL operations are not transactional, so you need to use the one-way replication method to replicate DDL operations. See [Replicate DDL operations](#) for details.

Drainer can use a unique ID for each connection to downstream to avoid conflicts. `channel_id` is used to indicate a channel for bidirectional replication. The two clusters should have the same `channel_id` configuration (with the same value).

If you add or delete columns in the upstream, there might be extra or missing columns of the data to be replicated to the downstream. Drainer allows this situation by ignoring the extra columns or by inserting default values to the missing columns.

### 13.10.12.3 Mark table

The `_drainer_repl_mark` mark table has the following structure:

```
CREATE TABLE `_drainer_repl_mark` (
 `id` bigint(20) NOT NULL,
 `channel_id` bigint(20) NOT NULL DEFAULT '0',
 `val` bigint(20) DEFAULT '0',
 `channel_info` varchar(64) DEFAULT NULL,
 PRIMARY KEY (`id`,`channel_id`)
);
```

Drainer uses the following SQL statement to update `_drainer_repl_mark`, which ensures data change and the generation of binlog:

```
update drainer_repl_mark set val = val + 1 where id = ? && channel_id = ?;
```

### 13.10.12.4 Replicate DDL operations

Because Drainer cannot add the mark table to DDL operations, you can only use the one-way replication method to replicate DDL operations.

For example, if DDL replication is enabled from cluster A to cluster B, then the replication is disabled from cluster B to cluster A. This means that all DDL operations are performed on cluster A.

#### Note:

DDL operations cannot be executed on two clusters at the same time. When a DDL operation is executed, if any DML operation is being executed at the same time or any DML binlog is being replicated, the upstream and downstream table structures of the DML replication might be inconsistent.

### 13.10.12.5 Configure and enable bidirectional replication

For bidirectional replication between cluster A and cluster B, assume that all DDL operations are executed on cluster A. On the replication path from cluster A to cluster B, add the following configuration to Drainer:

```
[syncer]
loopback-control = true
channel-id = 1 # Configures the same ID for both clusters to be replicated.
sync-ddl = true # Enables it if you need to perform DDL replication.

[syncer.to]
1 means SyncFullColumn and 2 means SyncPartialColumn.
If set to SyncPartialColumn, Drainer allows the downstream table
structure to have more or fewer columns than the data to be replicated
And remove the STRICT_TRANS_TABLES of the SQL mode to allow fewer
 ↪ columns, and insert zero values to the downstream.
sync-mode = 2

Ignores the checkpoint table.
[[syncer.ignore-table]]
db-name = "tidb_binlog"
tbl-name = "checkpoint"
```

On the replication path from cluster B to cluster A, add the following configuration to Drainer:

```
[syncer]
loopback-control = true
channel-id = 1 # Configures the same ID for both clusters to be replicated.
sync-ddl = false # Disables it if you do not need to perform DDL replication
 ↪ .

[syncer.to]
1 means SyncFullColumn and 2 means SyncPartialColumn.
If set to SyncPartialColumn, Drainer allows the downstream table
structure to have more or fewer columns than the data to be replicated
And remove the STRICT_TRANS_TABLES of the SQL mode to allow fewer
 ↪ columns, and insert zero values to the downstream.
sync-mode = 2

Ignores the checkpoint table.
[[syncer.ignore-table]]
db-name = "tidb_binlog"
tbl-name = "checkpoint"
```

### 13.10.13 TiDB Binlog Glossary

This document lists the terms used in the logs, monitoring, configurations, and documentation of TiDB Binlog.

#### 13.10.13.1 Binlog

In TiDB Binlog, binlogs refer to the binary log data from TiDB. They also refer to the binary log data that Drainer writes to Kafka or files. The former and the latter are in different formats. In addition, binlogs in TiDB and binlogs in MySQL are also in different formats.

#### 13.10.13.2 Binlog event

The DML binlogs from TiDB have three types of event: `INSERT`, `UPDATE`, and `DELETE`. In the monitoring dashboard of Drainer, you can see the number of different events that correspond to the replication data.

#### 13.10.13.3 Checkpoint

A checkpoint indicates the position from which a replication task is paused and resumed, or is stopped and restarted. It records the commit-ts that Drainer replicates to the downstream. When restarted, Drainer reads the checkpoint and starts replicating data from the corresponding commit-ts.

#### 13.10.13.4 Safe mode

Safe mode refers to the mode that supports the idempotent import of DML when a primary key or unique index exists in the table schema in the incremental replication task.

In this mode, the `INSERT` statement is re-written as `REPLACE`, and the `UPDATE` statement is re-written as `DELETE` and `REPLACE`. Then the re-written statement is executed to the downstream. Safe mode is automatically enabled within 5 minutes after Drainer is started. You can manually enable the mode by modifying the `safe-mode` parameter in the configuration file, but this configuration is valid only when the downstream is MySQL or TiDB.

### 13.10.14 Troubleshoot

#### 13.10.14.1 TiDB Binlog Troubleshooting

This document describes how to troubleshoot TiDB Binlog to find the problem.

If you encounter errors while running TiDB Binlog, take the following steps to troubleshoot:

1. Check whether each monitoring metric is normal or not. Refer to [TiDB Binlog Monitoring](#) for details.

2. Use the `binlogctl` tool to check whether the state of each Pump or Drainer node is normal or not.
3. Check whether `ERROR` or `WARN` exists in the Pump log or Drainer log.

After finding out the problem by the above steps, refer to [FAQ](#) and [TiDB Binlog Error Handling](#) for the solution. If you fail to find the solution or the solution provided does not help, submit an [issue](#) for help.

### 13.10.14.2 TiDB Binlog Error Handling

This document introduces common errors that you might encounter and solutions to these errors when you use TiDB Binlog.

#### 13.10.14.2.1 `kafka server: Message was too large, server rejected it to avoid allocation error is returned when Drainer replicates data to Kafka`

Cause: Executing a large transaction in TiDB generates binlog data of a large size, which might exceed Kafka's limit on the message size.

Solution: Adjust the configuration parameters of Kafka as shown below:

```
message.max.bytes=1073741824
replica.fetch.max.bytes=1073741824
fetch.message.max.bytes=1073741824
```

#### 13.10.14.2.2 `Pump returns no space left on device error`

Cause: The local disk space is insufficient for Pump to write binlog data normally.

Solution: Clean up the disk space and then restart Pump.

#### 13.10.14.2.3 `fail to notify all living drainer is returned when Pump is started`

Cause: When Pump is started, it notifies all Drainer nodes that are in the `online` state. If it fails to notify Drainer, this error log is printed.

Solution: Use the `binlogctl` tool to check whether each Drainer node is normal or not. This is to ensure that all Drainer nodes that are in the `online` state are working normally. If the state of a Drainer node is not consistent with its actual working status, use the `binlogctl` tool to change its state and then restart Pump.

#### 13.10.14.2.4 `Data loss occurs during the TiDB Binlog replication`

You need to confirm that TiDB Binlog is enabled on all TiDB instances and runs normally. If the cluster version is later than v3.0, use the `curl {TiDB_IP}:{STATUS_PORT}/↵ info/all` command to confirm the TiDB Binlog status on all TiDB instances.

**13.10.14.2.5** When the upstream transaction is large, Pump reports an error `rpc error: code = ResourceExhausted desc = trying to send message larger than max (2191430008 vs. 2147483647)`

This error occurs because the gRPC message sent by TiDB to Pump exceeds the size limit. You can adjust the maximum size of a gRPC message that Pump allows by specifying `max-message-size` when starting Pump.

**13.10.14.2.6** Is there any cleaning mechanism for the incremental data of the file format output by Drainer? Will the data be deleted?

- In Drainer v3.0.x, there is no cleaning mechanism for incremental data of the file format.
- In the v4.0.x version, there is a time-based data cleaning mechanism. For details, refer to [Drainer's retention-time configuration item](#).

## 13.10.15 TiDB Binlog FAQs

This document collects the frequently asked questions (FAQs) about TiDB Binlog.

**13.10.15.1** What is the impact of enabling TiDB Binlog on the performance of TiDB?

- There is no impact on the query.
- There is a slight performance impact on `INSERT`, `DELETE` and `UPDATE` transactions. In latency, a p-binlog is written concurrently in the TiKV prewrite stage before the transactions are committed. Generally, writing binlog is faster than TiKV prewrite, so it does not increase latency. You can check the response time of writing binlog in Pump's monitoring panel.

**13.10.15.2** How high is the replication latency of TiDB Binlog?

The latency of TiDB Binlog replication is measured in seconds, which is generally about 3 seconds during off-peak hours.

**13.10.15.3** What privileges does Drainer need to replicate data to the downstream MySQL or TiDB cluster?

To replicate data to the downstream MySQL or TiDB cluster, Drainer must have the following privileges:

- Insert
- Update

- Delete
- Create
- Drop
- Alter
- Execute
- Index
- Select
- Create View

#### 13.10.15.4 What can I do if the Pump disk is almost full?

1. Check whether Pump's GC works well:
  - Check whether the `gc_tso` time in Pump's monitoring panel is identical with that of the configuration file.
2. If GC works well, perform the following steps to reduce the amount of space required for a single Pump:
  - Modify the `GC` parameter of Pump to reduce the number of days to retain data.
  - Add pump instances.

#### 13.10.15.5 What can I do if Drainer replication is interrupted?

Execute the following command to check whether the status of Pump is normal and whether all the Pump instances that are not in the `offline` state are running.

```
binlogctl -cmd pumps
```

Then, check whether the Drainer monitor or log outputs corresponding errors. If so, resolve them accordingly.

#### 13.10.15.6 What can I do if Drainer is slow to replicate data to the downstream MySQL or TiDB cluster?

Check the following monitoring items:

- For the **Drainer Event** monitoring metric, check the speed of Drainer replicating INSERT, UPDATE and DELETE transactions to the downstream per second.
- For the **SQL Query Time** monitoring metric, check the time Drainer takes to execute SQL statements in the downstream.

Possible causes and solutions for slow replication:

- If the replicated database contains a table without a primary key or unique index, add a primary key to the table.
- If the latency between Drainer and the downstream is high, increase the value of the `worker-count` parameter of Drainer. For cross-datacenter replication, it is recommended to deploy Drainer in the downstream.
- If the load in the downstream is not high, increase the value of the `worker-count` parameter of Drainer.

### 13.10.15.7 What can I do if a Pump instance crashes?

If a Pump instance crashes, Drainer cannot replicate data to the downstream because it cannot obtain the data of this instance. If this Pump instance can recover to the normal state, Drainer resumes replication; if not, perform the following steps:

1. Use `binlogctl` to change the state of this Pump instance to `offline` to discard the data of this Pump instance.
2. Because Drainer cannot obtain the data of this pump instance, the data in the downstream and upstream is inconsistent. In this situation, perform full and incremental backups again. The steps are as follows:
  1. Stop the Drainer.
  2. Perform a full backup in the upstream.
  3. Clear the data in the downstream including the `tidb_binlog.checkpoint` table.
  4. Restore the full backup to the downstream.
  5. Deploy Drainer and use `initialCommitTs` (set `initialCommitTs` as the snapshot timestamp of the full backup) as the start point of initial replication.

### 13.10.15.8 What is checkpoint?

Checkpoint records the `commit-ts` that Drainer replicates to the downstream. When Drainer restarts, it reads the checkpoint and then replicates data to the downstream starting from the corresponding `commit-ts`. The `["write save point"] [ts ↪ =411222863322546177]` Drainer log means saving the checkpoint with the corresponding timestamp.

Checkpoint is saved in different ways for different types of downstream platforms:

- For MySQL/TiDB, it is saved in the `tidb_binlog.checkpoint` table.
- For Kafka/file, it is saved in the file of the corresponding configuration directory.

The data of kafka/file contains `commit-ts`, so if the checkpoint is lost, you can check the latest `commit-ts` of the downstream data by consuming the latest data in the downstream .

Drainer reads the checkpoint when it starts. If Drainer cannot read the checkpoint, it uses the configured `initialCommitTs` as the start point of the initial replication.

### 13.10.15.9 How to redeploy Drainer on the new machine when Drainer fails and the data in the downstream remains?

If the data in the downstream is not affected, you can redeploy Drainer on the new machine as long as the data can be replicated from the corresponding checkpoint.

- If the checkpoint is not lost, perform the following steps:
  1. Deploy and start a new Drainer (Drainer can read checkpoint and resumes replication).
  2. Use `binlogctl` to change the state of the old Drainer to offline.
- If the checkpoint is lost, perform the following steps:
  1. To deploy a new Drainer, obtain the `commit-ts` of the old Drainer as the `initialCommitTs` of the new Drainer.
  2. Use `binlogctl` to change the state of the old Drainer to offline.

### 13.10.15.10 How to restore the data of a cluster using a full backup and a binlog backup file?

1. Clean up the cluster and restore a full backup.
2. To restore the latest data of the backup file, use Reparo to set `start-tso = {snapshot timestamp of the full backup + 1}` and `end-ts = 0` (or you can specify a point in time).

### 13.10.15.11 How to redeploy Drainer when enabling `ignore-error` in Primary-Secondary replication triggers a critical error?

If a critical error is triggered when TiDB fails to write binlog after enabling `ignore-error`, TiDB stops writing binlog and binlog data loss occurs. To resume replication, perform the following steps:

1. Stop the Drainer instance.
2. Restart the `tibd-server` instance that triggers critical error and resume writing binlog (TiDB does not write binlog to Pump after critical error is triggered).
3. Perform a full backup in the upstream.
4. Clear the data in the downstream including the `tibd_binlog.checkpoint` table.
5. Restore the full backup to the downstream.
6. Deploy Drainer and use `initialCommitTs` (set `initialCommitTs` as the snapshot timestamp of the full backup) as the start point of initial replication.

### 13.10.15.12 When can I pause or close a Pump or Drainer node?

Refer to [TiDB Binlog Cluster Operations](#) to learn the description of the Pump or Drainer state and how to start and exit the process.

Pause a Pump or Drainer node when you need to temporarily stop the service. For example:

- Version upgrade

Use the new binary to restart the service after the process is stopped.

- Server maintenance

When the server needs a downtime maintenance, exit the process and restart the service after the maintenance is finished.

Close a Pump or Drainer node when you no longer need the service. For example:

- Pump scale-in

If you do not need too many Pump services, close some of them.

- Cancelling replication tasks

If you no longer need to replicate data to a downstream database, close the corresponding Drainer node.

- Service migration

If you need to migrate the service to another server, close the service and re-deploy it on the new server.

### 13.10.15.13 How can I pause a Pump or Drainer process?

- Directly kill the process.

**Note:**

Do not use the `kill -9` command. Otherwise, the Pump or Drainer node cannot process signals.

- If the Pump or Drainer node runs in the foreground, pause it by pressing `Ctrl+C`.
- Use the `pause-pump` or `pause-drainer` command in `binlogctl`.

#### 13.10.15.14 Can I use the `update-pump` or `update-drainer` command in `binlogctl` to pause the Pump or Drainer service?

No. The `update-pump` or `update-drainer` command directly modifies the state information saved in PD without notifying Pump or Drainer to perform the corresponding operation. Misusing the two commands can interrupt data replication and might even cause data loss.

#### 13.10.15.15 Can I use the `update-pump` or `update-drainer` command in `binlogctl` to close the Pump or Drainer service?

No. The `update-pump` or `update-drainer` command directly modifies the state information saved in PD without notifying Pump or Drainer to perform the corresponding operation. Misusing the two commands interrupts data replication and might even cause data inconsistency. For example:

- When a Pump node runs normally or is in the `paused` state, if you use the `update-pump` command to set the Pump state to `offline`, the Drainer node stops pulling the binlog data from the `offline` Pump. In this situation, the newest binlog cannot be replicated to the Drainer node, causing data inconsistency between upstream and downstream.
- When a Drainer node runs normally, if you use the `update-drainer` command to set the Drainer state to `offline`, the newly started Pump node only notifies Drainer nodes in the `online` state. In this situation, the `offline` Drainer fails to pull the binlog data from the Pump node in time, causing data inconsistency between upstream and downstream.

#### 13.10.15.16 When can I use the `update-pump` command in `binlogctl` to set the Pump state to `paused`?

In some abnormal situations, Pump fails to correctly maintain its state. Then, use the `update-pump` command to modify the state.

For example, when a Pump process is exited abnormally (caused by directly exiting the process when a panic occurs or mistakenly using the `kill -9` command to kill the process), the Pump state information saved in PD is still `online`. In this situation, if you do not need to restart Pump to recover the service at the moment, use the `update-pump` command to update the Pump state to `paused`. Then, interruptions can be avoided when TiDB writes binlogs and Drainer pulls binlogs.

#### 13.10.15.17 When can I use the `update-drainer` command in `binlogctl` to set the Drainer state to `paused`?

In some abnormal situations, the Drainer node fails to correctly maintain its state, which has influenced the replication task. Then, use the `update-drainer` command to modify the state.

For example, when a Drainer process is exited abnormally (caused by directly exiting the process when a panic occurs or mistakenly using the `kill -9` command to kill the process), the Drainer state information saved in PD is still `online`. When a Pump node is started, it fails to notify the exited Drainer node (the `notify drainer ... error`), which cause the Pump node failure. In this situation, use the `update-drainer` command to update the Drainer state to `paused` and restart the Pump node.

#### 13.10.15.18 How can I close a Pump or Drainer node?

Currently, you can only use the `offline-pump` or `offline-drainer` command in `binlogctl` to close a Pump or Drainer node.

#### 13.10.15.19 When can I use the `update-pump` command in `binlogctl` to set the Pump state to `offline`?

You can use the `update-pump` command to set the Pump state to `offline` in the following situations:

- When a Pump process is exited abnormally and the service cannot be recovered, the replication task is interrupted. If you want to recover the replication and accept some losses of binlog data, use the `update-pump` command to set the Pump state to `offline`  $\leftrightarrow$  . Then, the Drainer node stops pulling binlog from the Pump node and continues replicating data.
- Some stale Pump nodes are left over from historical tasks. Their processes have been exited and their services are no longer needed. Then, use the `update-pump` command to set their state to `offline`.

For other situations, use the `offline-pump` command to close the Pump service, which is the regular process.

#### **Warning:**

Do not use the `update-pump` command unless you can tolerate binlog data loss and data inconsistency between upstream and downstream, or you no longer need the binlog data stored in the Pump node.

#### 13.10.15.20 Can I use the `update-pump` command in `binlogctl` to set the Pump state to `offline` if I want to close a Pump node that is exited and set to `paused`?

When a Pump process is exited and the node is in the `paused` state, not all the binlog data in the node is consumed in its downstream Drainer node. Therefore, doing so might risk data inconsistency between upstream and downstream. In this situation, restart the Pump and use the `offline-pump` command to close the Pump node.

#### 13.10.15.21 When can I use the `update-drainer` command in `binlogctl` to set the Drainer state to `offline`?

Some stale Drainer nodes are left over from historical tasks. Their processes have been exited and their services are no longer needed. Then, use the `update-drainer` command to set their state to `offline`.

#### 13.10.15.22 Can I use SQL operations such as `change pump` and `change drainer` to pause or close the Pump or Drainer service?

No. For more details on these SQL operations, refer to [Use SQL statements to manage Pump or Drainer](#).

These SQL operations directly modifies the state information saved in PD and are functionally equivalent to the `update-pump` and `update-drainer` commands in `binlogctl`. To pause or close the Pump or Drainer service, use the `binlogctl` tool.

#### 13.10.15.23 What can I do when some DDL statements supported by the upstream database cause error when executed in the downstream database?

To solve the problem, follow these steps:

1. Check `drainer.log`. Search `exec failed` for the last failed DDL operation before the Drainer process is exited.
2. Change the DDL version to the one compatible to the downstream. Perform this step manually in the downstream database.
3. Check `drainer.log`. Search for the failed DDL operation and find the `commit-ts` of this operation. For example:

```
[2020/05/21 09:51:58.019 +08:00] [INFO] [syncer.go:398] ["add ddl item
 ↳ to syncer, you can add this commit ts to `ignore-txn-commit-ts`
 ↳ to skip this ddl if needed"] [sql="ALTER TABLE `test` ADD INDEX
 ↳ (`index1`)"] ["commit ts"]=416815754209656834].
```

4. Modify the `drainer.toml` configuration file. Add the `commit-ts` in the `ignore-txn-`  
↳ `commit-ts` item and restart the Drainer node.

#### 13.10.15.24 TiDB fails to write to binlog and gets stuck, and listener stopped, waiting for manual stop appears in the log

In TiDB v3.0.12 and earlier versions, the binlog write failure causes TiDB to report the fatal error. TiDB does not automatically exit but only stops the service, which seems like getting stuck. You can see the `listener stopped, waiting for manual stop` error in the log.

You need to determine the specific causes of the binlog write failure. If the failure occurs because binlog is slowly written into the downstream, you can consider scaling out Pump or increasing the timeout time for writing binlog.

Since v3.0.13, the error-reporting logic is optimized. The binlog write failure causes transaction execution to fail and TiDB Binlog will return an error but will not get TiDB stuck.

#### 13.10.15.25 TiDB writes duplicate binlogs to Pump

This issue does not affect the downstream and replication logic.

When the binlog write fails or becomes timeout, TiDB retries writing binlog to the next available Pump node until the write succeeds. Therefore, if the binlog write to a Pump node is slow and causes TiDB timeout (default 15s), then TiDB determines that the write fails and tries to write to the next Pump node. If binlog is actually successfully written to the timeout-causing Pump node, the same binlog is written to multiple Pump nodes. When Drainer processes the binlog, it automatically de-duplicates binlogs with the same TSO, so this duplicate write does not affect the downstream and replication logic.

#### 13.10.15.26 Reparo is interrupted during the full and incremental restore process. Can I use the last TSO in the log to resume replication?

Yes. Reparo does not automatically enable the safe-mode when you start it. You need to perform the following steps manually:

1. After Reparo is interrupted, record the last TSO in the log as `checkpoint-tso`.
2. Modify the Reparo configuration file, set the configuration item `start-tso` to `checkpoint-tso + 1`, set `stop-tso` to `checkpoint-tso + 80,000,000,000` (approximately five minutes after the `checkpoint-tso`), and set `safe-mode` to `true`. Start Reparo, and Reparo replicates data to `stop-tso` and then stops automatically.
3. After Reparo stops automatically, set `start-tso` to `checkpoint tso + 80,000,000,001` ↪ , set `stop-tso` to 0, and set `safe-mode` to `false`. Start Reparo to resume replication.

## 13.11 PingCAP Clinic Diagnostic Service

### 13.11.1 PingCAP Clinic Overview

PingCAP Clinic Diagnostic Service (PingCAP Clinic) is a diagnostic service provided by PingCAP for TiDB clusters that are deployed using either TiUP or TiDB Operator. This service helps to troubleshoot cluster problems remotely and provides a quick check of cluster status locally. With PingCAP Clinic, you can ensure the stable operation of your TiDB cluster for its full life-cycle, predict potential problems, reduce the probability of problems, troubleshoot cluster problems quickly, and fix cluster problems.

PingCAP Clinic provides the following two components to diagnose cluster problems:

- [Diag client](#):

Diag client (Diag) is an open-source diagnostic tool deployed on the cluster side. Diag is used to collect cluster diagnostic data, upload diagnostic data to the Clinic Server, and perform a quick health check locally on your cluster. For a full list of diagnostic data that can be collected by Diag, see [PingCAP Clinic Diagnostic Data](#).

**Note:**

Diag supports TiDB v4.0 and later versions, but **does not support** collecting data from clusters deployed using TiDB Ansible.

- [Clinic Server](#):

Clinic Server is a cloud service deployed in the cloud. By providing diagnostic services in the SaaS model, the Clinic Server can not only receive uploaded diagnostic data but also work as an online diagnostic environment to store data, view data, and provide cluster diagnostic reports. Clinic Server provides two independent services depending on the storage location:

- [Clinic Server for international users](#): Data is stored in AWS in US.
- [Clinic Server for users in the Chinese mainland](#): Data is stored in AWS in China (Beijing) regions.

#### 13.11.1.1 User scenarios

- [Troubleshoot cluster problems remotely](#)

When your cluster has some problems that cannot be fixed quickly, you can [get support](#) from PingCAP or the community. When contacting technical support for remote assistance, you need to save various diagnostic data from the cluster and forward the data to the support staff. In this case, you can use Diag to collect diagnostic data with one click. Diag helps you to collect complete diagnostic data quickly, which can avoid

complex manual data collection operations. After collecting data, you can upload the data to the Clinic Server for PingCAP technical support staff to troubleshoot cluster problems. The Clinic Server provides secure storage for uploaded diagnostic data and supports the online diagnosis, which greatly improves the troubleshooting efficiency.

- Quickly check cluster status

Even if your cluster is running stably for now, it is necessary to periodically check the cluster to detect potential stability risks. You can identify potential health risks of a cluster using the local and server-side quick check feature provided by PingCAP Clinic.

### 13.11.1.2 Implementation principles

This section introduces the implementation principles about how Diag collects diagnostic data from a cluster.

First, Diag gets cluster topology information from the deployment tool TiUP (tiup-cluster) or TiDB Operator (tidb-operator). Then, Diag collects different types of diagnostic data through various data collection methods as follows:

- Transfer server files through SCP

For clusters deployed using TiUP, Diag can collect log files and configuration files directly from the nodes of the target component through the Secure copy protocol (SCP).

- Collect data by running commands remotely through SSH

For clusters deployed using TiUP, Diag can connect to the target component system through SSH (Secure Shell) and run commands (such as Insight) to obtain system information, including kernel logs, kernel parameters, and basic information of the system and hardware.

- Collect data through HTTP call

- By calling the HTTP interface of TiDB components, Diag can get the real-time configuration sampling information and the real-time performance sampling information of TiDB, TiKV, PD, and other components.
- By calling the HTTP interface of Prometheus, Diag can get alert information and monitoring metrics data.

- Query database parameters through SQL statements

Using SQL statements, Diag can query system variables and other information of TiDB. To use this method, you need to **additionally provide** the username and password to access TiDB when collecting data.

### 13.11.1.3 The limitations of Clinic Server

**Note:**

- Clinic Server is free from July 15, 2022 to July 14, 2023. You will be notified through email before July 14, 2023 if the service starts charging fee afterwards.
- If you want to adjust the usage limitations, [get support](#) from PingCAP.

Service Type	Limitation
Number of clusters	10/organization
Storage capacity	50 GB/cluster
Storage duration	180 days
Data size	3 GB/package
Saving duration of the data rebuild environment	3 days

### 13.11.1.4 Next step

- Use PingCAP Clinic in a self-hosted environment
  - [Quick Start with PingCAP Clinic](#)
  - [Troubleshoot Clusters using PingCAP Clinic](#)
  - [PingCAP Clinic Diagnostic Data](#)
- Use PingCAP Clinic on Kubernetes
  - [Troubleshoot TiDB Cluster using PingCAP Clinic](#)
  - [PingCAP Clinic Diagnostic Data](#)

### 13.11.2 Quick Start Guide for PingCAP Clinic

This document describes how to use PingCAP Clinic diagnosis service (PingCAP Clinic) to collect, upload, and view cluster diagnosis data quickly.

PingCAP Clinic consists of two components: [Diag client](#) (shorten as Diag) and Clinic Server cloud service (shorten as Clinic Server). For details of these two components, refer to [PingCAP Clinic Overview](#).

#### 13.11.2.1 User scenarios

- To accurately identify and quickly resolve problems in your cluster when seeking help remotely from PingCAP technical support, you can collect diagnostic data with Diag, upload the collected data to the Clinic Server, and provide the data access link to the technical support.
- When the cluster is running properly and you need to check the status of the cluster, you can use Diag to collect diagnostic data, upload the data to Clinic Server, and view the results of Health Report.

**Note:**

- The following methods to collect and upload data are **only** applicable to **clusters deployed using TiUP**. For clusters deployed using TiDB Operator on Kubernetes, see [PingCAP Clinic for TiDB Operator environments](#).
- The diagnostic data collected by PingCAP Clinic is **only** used for troubleshooting cluster problems.

### 13.11.2.2 Prerequisites

Before using PingCAP Clinic, you need to install Diag and prepare an environment for uploading data.

1. On your control machine with TiUP installed, run the following command to install Diag:

```
tiup install diag
```

2. Log in to Clinic Server.

Go to the [Clinic Server for international users](#) and select **Sign in with TiDB Account** to enter the TiDB Cloud login page. If you do not have a TiDB Cloud account, create one on that page.

**Note:**

A TiDB Cloud account is only used for logging in to Clinic Server in SSO mode and is not mandatory for accessing the TiDB Cloud service.

Go to the [Clinic Server for users in the Chinese mainland](#) and select **Sign in with AskTUG** to enter the AskTUG community login page. If you do not have an AskTUG account, create one on that page

3. Create an organization on the Clinic Server. Organization is a collection of TiDB clusters. You can upload diagnostic data on the created organization.
4. Get an access token to upload data. When uploading collected data through Diag, you need a token for user authentication to ensure the data is isolated securely. If you already get a token from the Clinic Server, you can reuse the token.

To get a token, click the icon in the lower-right corner of the Cluster page, select **Get Access Token For Diag Tool**, and click + in the pop-up window. Make sure that you have copied and saved the token that is displayed.

Figure 293: An example of a token

**Note:**

- For data security, TiDB only displays the token information when it is created. If you lost the information, you can delete the old token and create a new one.
- A token is only used for uploading data.

5. Set the token and region in Diag.

- Run the following command to set the `clinic.token`:

```
tiup diag config clinic.token ${token-value}
```

- Run the following command to set the `clinic.region`:

`region` determines the encryption certificate used for packing data and the target service when uploading the data. For example:

**Note:**

- Diag v0.9.0 and later versions support setting `region`.
- For versions earlier than Diag v0.9.0, data is uploaded to Clinic Server in the Chinese region by default. To set `region` in these versions, run the `tiup update diag` command to upgrade Diag to the latest version and then set `region` in Diag.

When using Clinic Server for international users, set `region` to `US` using the following command:

```
tiup diag config clinic.region US
```

When using Clinic Server for users in the Chinese mainland, set `region` to `CN` using the following command:

```
tiup diag config clinic.region CN
```

6. (Optional) Enable log redaction.

When TiDB provides detailed log information, it might print sensitive information (for example, user data) in the log. If you want to avoid leaking sensitive information in the local log and Clinic Server, you can enable log redaction in the TiDB side. For more information, see [log redaction](#).

### 13.11.2.3 Steps

1. Run Diag to collect diagnostic data.

For example, to collect the diagnostic data from 4 hours ago to 2 hours ago based on the current time, run the following command:

```
tiup diag collect ${cluster-name} -f="-4h" -t="-2h"
```

After you run the command, Diag does not start collecting data immediately. Instead, Diag provides the estimated data size and the target data storage path in the output for you to confirm whether to continue. To confirm that you want to start collecting data, enter `Y`.

After the collection is complete, Diag provides the folder path where the collected data is located.

2. Upload the collected data to Clinic Server.

**Note:**

The size of data (the compressed file with collected data) to be uploaded should be **no larger than 3 GB**. Otherwise, the data upload fails.

- If the network where your cluster is located can access the internet, you can directly upload the folder with collected data using the following command:

```
tiup diag upload ${filepath}
```

After the upload is completed, the **Download URL** is displayed in the output.

**Note:**

When uploading data using this method, you need to use Diag v0.9.0 or a later version. You can get the Diag version when you run it. If the Diag version is earlier than 0.9.0, you can use the `tiup update diag` command to upgrade Diag to the latest version.

- If the network where your cluster is located cannot access the internet, you need to pack the collected data and upload the package. For details, see [Method 2. Pack and upload data](#).
3. After the upload is complete, get the data access link from **Download URL** in the command output.

By default, the diagnostic data includes the cluster name, cluster topology information, log content in the collected diagnostic data, and Grafana Dashboard information reorganized based on the metrics in the collected data.

You can use the data to troubleshoot cluster problems by yourself, or you can provide the data access link to PingCAP technical support staff to facilitate the remote troubleshooting.

4. View the results of Health Report

After data is uploaded, Clinic Server processes the data automatically in the background. The Health Report is generated in approximately 5 to 15 minutes. You can view the report by opening the diagnostic data link and click the “Health Report”.

#### 13.11.2.4 What’s next

- [PingCAP Clinic Overview](#)
- [Troubleshoot Clusters Using PingCAP Clinic](#)
- [PingCAP Clinic Diagnostic Data](#)

### 13.11.3 Troubleshoot Clusters Using PingCAP Clinic

For TiDB clusters and DM clusters deployed using TiUP, you can use PingCAP Clinic Diagnostic Service (PingCAP Clinic) to troubleshoot cluster problems remotely and perform a quick check on cluster status locally using [Diag client \(Diag\)](#) and Clinic Server.

#### Note:

- This document **only** applies to clusters deployed using TiUP in a self-hosted environment. For clusters deployed using TiDB Operator on Kubernetes, see [PingCAP Clinic for TiDB Operator environments](#).
- PingCAP Clinic **does not support** collecting data from clusters deployed using TiDB Ansible.

#### 13.11.3.1 User scenarios

- **Troubleshoot cluster problems remotely**
  - When your cluster has some problems, if you need to **get support** from PingCAP, you can perform the following operations to facilitate the remote troubleshooting: collect diagnostic data with Diag, upload the collected data to the Clinic Server, and provide the data access link to the technical support staff.
  - When your cluster has some problems, if you cannot analyze the problems immediately, you can use Diag to collect and save the data for later analysis.

- **Perform a quick check on the cluster status locally**

Even if your cluster is running stably for now, it is necessary to periodically check the cluster to detect potential stability risks. You can identify potential health risks of a cluster using the local quick check feature provided by PingCAP Clinic. The local check only checks configuration. To check more items, such as metrics and logs, it is recommended to upload the diagnostic data to the Clinic Server and use the Health Report feature.

#### 13.11.3.2 Prerequisites

Before using PingCAP Clinic, you need to install Diag (a component to collect data provided by PingCAP Clinic) and prepare the environment to upload data.

1. Install Diag.

- If you have installed TiUP on your control machine, run the following command to install Diag:

```
```bash
tiup install diag
```
```

- If you have installed Diag, you can use the following command to upgrade Diag to the latest version:

```
tiup update diag
```

**Note:**

- For clusters without an internet connection, you need to deploy Diag offline. For details, refer to [Deploy TiUP offline: Method 2](#).
- Diag is **only** provided in the TiDB Server offline mirror package of v5.4.0 or later.

2. Get and set an access token (token) to upload data.

When uploading collected data through Diag, you need a token for user authentication. If you already set a token Diag, you can reuse the token and skip this step.

To get a token, perform the following steps:

- Log in to the Clinic Server.  
[Clinic Server for international users](#): Data is stored in AWS in US.  
[Clinic Server for users in the Chinese mainland](#): Data is stored in AWS in China (Beijing) regions.
- Click the icon in the lower-right corner of the Cluster page, select **Get Access Token For Diag Tool**, and click + in the pop-up window. Make sure that you have copied and saved the token that is displayed.

Figure 294: Get the Token

**Note:**

- When accessing Clinic Server for the first time, before getting a token, you need to prepare the environment by referring to [Quick Start with PingCAP Clinic](#).
- For data security, TiDB only displays the token upon the token creation. If you have lost the token, delete the old token and create a new one.
- A token is only used for uploading data.

- Then, set the token in Diag. For example:

```
tiup diag config clinic.token ${token-value}
```

3. Set the **region** in Diag.

**region** determines the encryption certificate used for packing data and the target service when uploading the data. For example:

**Note:**

- Diag v0.9.0 and later versions support setting **region**.
- For versions earlier than Diag v0.9.0, data is uploaded to Clinic Server in the Chinese region by default. To set **region** in these

versions, run the `tiup update diag` command to upgrade Diag to the latest version and then set `region` in Diag.

When using Clinic Server for international users, set `region` to `US` using the following command:

```
tiup diag config clinic.region US
```

When using Clinic Server for users in the Chinese mainland, set `region` to `CN` using the following command:

```
tiup diag config clinic.region CN
```

#### 4. (Optional) Enable log redaction.

When TiDB provides detailed log information, it might print sensitive information (for example, user data) in the log. If you want to avoid leaking sensitive information in the local log and Clinic Server, you can enable log redaction in the TiDB side. For more information, see [log redaction](#).

### 13.11.3.3 Troubleshoot cluster problems remotely

You can use Diag to quickly collect diagnostic data from TiDB clusters and DM clusters, including monitoring data and configuration information.

#### 13.11.3.3.1 Step 1. Check the data to be collected

For a full list of data that can be collected by Diag, see [PingCAP Clinic Diagnostic Data](#).

To improve the efficiency of the later diagnosis, you are recommended to collect full diagnostic data including monitoring data and configuration information. For details, see [Collect data from clusters](#).

#### 13.11.3.3.2 Step 2. Collect data

With Diag, you can collect data from the TiDB clusters and the DM clusters deployed using TiUP.

##### 1. Run the data collection command of Diag.

For example, to collect the diagnostic data from 4 hours ago to 2 hours ago based on the current time, run the following command:

```
tiup diag collect ${cluster-name} -f="-4h" -t="-2h"
```

```
tiup diag collectdm ${dm-cluster-name} -f="-4h" -t="-2h"
```

Descriptions of the parameters for data collection:

- `-f/--from`: specifies the start time of the data collection. If you do not specify this parameter, the default start time is 2 hours before the current time. To modify the time zone, use the `-f="12:30 +0800"` syntax. If you do not specify the time zone information in this parameter, such as `+0800`, the time zone is UTC by default.
- `-t/--to`: specifies the end time of the data collection. If you do not specify this parameter, the default end time is the current moment. To modify the time zone, use the `-f="12:30 +0800"` syntax. If you do not specify the time zone information in this parameter, such as `+0800`, the time zone is UTC by default.

Parameter usage tips:

In addition to specifying the data collection time, you can use `Diag` to specify more parameters. To get all parameters, run the `tiup diag collect -h` or `tiup diag ↵ collectdm -h` command.

#### Note:

- `Diag` does not collect system variables data (`db_vars`) by default. To collect this data, you need to additionally provide a username and password that can access the database. Note that the reading access to system variables should be enabled in this database.
- `Diag` does not collect performance data (`perf`) and debug data (`debug`) by default.
- To collect full diagnostic data including system variables, use the command `tiup diag collect <cluster-name> --include=" ↵ system,monitor,log,config,db_vars,perf,debug"`.

- `-l`: the bandwidth limit for transferring files, the unit is Kbit/s, and the default value is 100000 (the `-l` parameter of `scp`).
- `-N/--node`: only collects data from a specified node. The format is `ip:port`.
- `--include`: only collects specific types of data. The optional values are `system`, `monitor`, `log`, `config`, and `db_vars`. To include two or more types, you can use `,` as a separator between the types.
- `--exclude`: does not collect specific types of data. The optional values are `system` ↵ `,` `monitor`, `log`, `config`, and `db_vars`. To exclude two or more types, you can use `,` as a separator between the types.

After you run the command, `Diag` does not start collecting data immediately. Instead, `Diag` provides the estimated data size and the target data storage path in the output for you to confirm whether to continue. For example:

```
Estimated size of data to collect:
Host Size Target

172.16.7.129:9090 43.57 MB 1775 metrics, compressed
172.16.7.87 0 B /tidb-deploy/tidb-4000/log/tidb_stderr.log
... ..
172.16.7.179 325 B /tidb-deploy/tikv-20160/conf/tikv.toml
Total 2.01 GB (inaccurate)
These data will be stored in /home/user/diag-fNTnz5MGhr6
Do you want to continue? [y/N]: (default=N)
```

2. Enter Y to confirm that you want to start collecting data.

Collecting data takes a certain amount of time. The time varies according to the volume of data to be collected. For example, in a test environment, collecting 1 GB of data takes about 10 minutes.

After the collection is complete, Diag provides the folder path where the collected data is located. For example:

```
Collected data are stored in /home/user/diag-fNTnz5MGhr6
```

### 13.11.3.3.3 Step 3. View data locally (optional)

The collected data is stored in separate subdirectories based on its data source. These subdirectories are named after machine names and port numbers. The storage locations of the configuration, logs, and other files of each node are the same as their relative storage paths in the real server of your TiDB cluster:

- Basic information of the system and hardware: in `insight.json`
- Contents in the system `/etc/security/limits.conf`: in `limits.conf`
- List of kernel parameters: in `sysctl.conf`
- Kernel logs: in `dmesg.log`
- Network connection during data collection: in `ss.txt`
- Configuration data: in the `config.json` directory of each node
- Meta-information for the cluster itself: in `meta.yaml` (this file is located at the top level of the directory that stores collected data)
- Monitoring data: in the `/monitor` file directory. The monitoring data is compressed by default and cannot be viewed directly. To directly view the JSON files with monitoring data, disable compression with the `--compress-metrics=false` parameter when collecting data.

### 13.11.3.3.4 Step 4. Upload data

To provide cluster diagnostic data to PingCAP technical support staff, you need to upload the data to the Clinic Server first, and then send the obtained data access link to the staff. The Clinic Server is a cloud service that stores and shares diagnostic data securely.

Depending on the network connection of the cluster, you can choose one of the following methods to upload data:

- Methods 1: if the network where the cluster is located can access the internet, you can [directly upload data using the upload command](#).
- Methods 2: if the network where the cluster is located cannot access the internet, you need to [pack the data and then upload it](#).

**Note:**

If you did not set a token or `region` in `Diag` before uploading data, `Diag` reports the upload failure and reminds you to set a token or `region`. To set a token, see [the second step in Prerequisites](#).

#### Method 1. Upload directly

If the network where the cluster is located can access the internet, you can directly upload the folder with collected data obtained in [Step 2: Collect data](#) using the following command:

```
tiup diag upload
```

After the upload is completed, the `Download URL` is displayed in the output. You can open the link of `Download URL` to see the uploaded data or send the link to the PingCAP technical support staff you contacted before.

#### Method 2. Pack and upload data

If the network where your cluster is located cannot access the internet, you need to pack the data on your intranet and upload the data package to the Clinic Server using a device with internet access. The detailed operations are as follows:

1. Pack the collected data obtained in [Step 2. Collect data](#) by running the following command:

```
tiup diag package ${filepath}
```

During packaging, `Diag` encrypts and compresses the data at the same time. In the test environment, 800 MB of data was compressed to 57 MB. The following is an example output:

```
tiup diag check ${subdir-in-output-data}
```

`${subdir-in-output-data}` in the above command is the path that stores the collected data, and this path has the `meta.yaml` file.

### 3. View the diagnostic result:

The diagnostic result is returned on the command line. For example:

```
Starting component `diag`: /root/.tiup/components/diag/v0.7.0/diag
 ↳ check diag-fNTnz5MGhr6

Diagnostic result
lili 2022-01-24T09:33:57+08:00

1. Cluster basic information
- Cluster ID: 7047403704292855808
- Cluster Name: lili
- Cluster Version: v5.3.0

2. Sampling information
- Sample ID: fNTnz5MGhr6
- Sampling Date: 2022-01-24T09:33:57+08:00
- Sample Content:: [system monitor log config]

3. Diagnostic result, including potential configuration problems
In this inspection, 22 rules were executed.

The results of **1** rules were abnormal and needed to be further
 ↳ discussed with support team.

The following is the details of the abnormalities.

Diagnostic result summary
The configuration rules are all derived from PingCAP's OnCall Service.

If the results of the configuration rules are found to be abnormal,
 ↳ they may cause the cluster to fail.

There were **1** abnormal results.

Path to save the diagnostic result file

Rule Name: tidb-max-days
- RuleID: 100
- Variation: TidbConfig.log.file.max-days
```

```
- For more information, please visit: https://s.tidb.io/msmo6awg
- Check Result:
 TidbConfig_172.16.7.87:4000 TidbConfig.log.file.max-days:0 warning
 TidbConfig_172.16.7.86:4000 TidbConfig.log.file.max-days:0 warning
 TidbConfig_172.16.7.179:4000 TidbConfig.log.file.max-days:0 warning

Result report and record are saved at diag-fNTnz5MGhr6/report
↳ -220125153215
```

In the last section of the diagnostic result (under `#### Path to save the`  
↳ `diagnostic result file` in the above example output), for each configuration potential risk found, Diag provides a corresponding knowledge base link with detailed configuration suggestions. In the example above, the relevant link is `https://s.tidb`  
↳ `.io/msmo6awg`.

### 13.11.3.5 FAQ

1. If the data upload fails, can I re-upload it?

Yes. Data upload supports breakpoint upload. If the upload fails, you can upload it again directly.

2. After uploading data, I cannot open the returned data access link. What should I do?

Log in to Clinic Server first. If you still cannot open the link after login success, check whether you have access to data. If not, contact the data owner for permission. After getting the permission, log in to Clinic Server and open the link again.

3. How long will the uploaded data be kept on the Clinic Server?

The longest time is 180 days. You can delete the data you uploaded on the Clinic Server page at any time.

### 13.11.4 PingCAP Clinic Diagnostic Data

This document provides the types of diagnostic data that can be collected by PingCAP Clinic Diagnostic Service (PingCAP Clinic) from the TiDB and DM clusters deployed using TiUP. Also, the document lists the parameters for data collection corresponding to each data type. When running a command to **collect data using Diag client (Diag)**, you can add the required parameters to the command according to the types of the data to be collected.

The diagnostic data collected by PingCAP Clinic is **only** used for troubleshooting cluster problems.

A diagnostic service deployed in the cloud, Clinic Server provides two independent services depending on the data storage location:

- [Clinic Server for international users](#): If you upload the collected data to Clinic Server for international users, the data will be stored in the Amazon S3 service deployed by PingCAP in AWS US regions. PingCAP uses strict data access policies and only authorized technical support can access the data.
- [Clinic Server for users in the Chinese mainland](#): If you upload the collected data to Clinic Server for users in the Chinese mainland, the data will be stored in the Amazon S3 service deployed by PingCAP in China (Beijing) regions. PingCAP uses strict data access policies and only authorized technical support can access the data.

### 13.11.4.1 TiDB clusters

This section lists the types of diagnostic data that can be collected by [Diag](#) from the TiDB clusters deployed using TiUP.

#### 13.11.4.1.1 TiDB cluster information

| Data type                                                  | Exported file                                                        | Parameter for data collection by PingCAP Clinic |
|------------------------------------------------------------|----------------------------------------------------------------------|-------------------------------------------------|
| Basic information of the cluster, including the cluster ID | <code>cluster</code><br>↔ <code>.</code><br>↔ <code>json</code><br>↔ | The data is collected per run by default.       |
| Detailed information of the cluster                        | <code>meta.</code><br>↔ <code>yaml</code><br>↔                       | The data is collected per run by default.       |

#### 13.11.4.1.2 TiDB diagnostic data

| Data type | Exported file                | Parameter for data collection by PingCAP Clinic |
|-----------|------------------------------|-------------------------------------------------|
| Log       | <code>tidb.log</code>        | <code>--include=log</code>                      |
| Error log | <code>tidb_stderr.log</code> | <code>--include=log</code>                      |

| Data type               | Exported file                    | Parameter for data collection by PingCAP Clinic |
|-------------------------|----------------------------------|-------------------------------------------------|
| Slow log                | <code>tidb_slow_query.log</code> | <code>--include=log</code>                      |
| Configuration file      | <code>tidb.toml</code>           | <code>--include=config</code>                   |
| Real-time configuration | <code>config.json</code>         | <code>--include=config</code>                   |

### 13.11.4.1.3 TiKV diagnostic data

| Data type               | Exported file                | Parameter for data collection by PingCAP Clinic |
|-------------------------|------------------------------|-------------------------------------------------|
| Log                     | <code>tikv.log</code>        | <code>--include=log</code>                      |
| Error log               | <code>tikv_stderr.log</code> | <code>--include=log</code>                      |
| Configuration file      | <code>tikv.toml</code>       | <code>--include=config</code>                   |
| Real-time configuration | <code>config.json</code>     | <code>--include=config</code>                   |

### 13.11.4.1.4 PD diagnostic data

| Data type               | Exported file              | Parameter for data collection by PingCAP Clinic |
|-------------------------|----------------------------|-------------------------------------------------|
| Log                     | <code>pd.log</code>        | <code>--include=log</code>                      |
| Error log               | <code>pd_stderr.log</code> | <code>--include=log</code>                      |
| Configuration file      | <code>pd.toml</code>       | <code>--include=config</code>                   |
| Real-time configuration | <code>config.json</code>   | <code>--include=config</code>                   |

| Data type                   | Exported file                  | Parameter for data collection by PingCAP Clinic |
|-----------------------------|--------------------------------|-------------------------------------------------|
| Outputs of the command tiup | <code>store.</code>            | <code>--</code>                                 |
|                             | <code>↪ json</code>            | <code>↪ include</code>                          |
|                             | <code>↪</code>                 | <code>↪ =</code>                                |
|                             |                                | <code>↪ config</code>                           |
|                             | <code>↪ ctl</code>             | <code>↪</code>                                  |
|                             | <code>↪ :v&lt;</code>          |                                                 |
|                             | <code>↪ CLUSTER_VERSION</code> |                                                 |
|                             | <code>↪ &gt;</code>            |                                                 |
|                             | <code>↪ pd</code>              |                                                 |
|                             | <code>↪ -u</code>              |                                                 |
|                             | <code>↪ http</code>            |                                                 |
|                             | <code>↪ ://</code>             |                                                 |
|                             | <code>↪ \${</code>             |                                                 |
|                             | <code>↪ pd</code>              |                                                 |
|                             | <code>↪ IP</code>              |                                                 |
|                             | <code>↪ }:\$</code>            |                                                 |
|                             | <code>↪ {</code>               |                                                 |
|                             | <code>↪ PORT</code>            |                                                 |
|                             | <code>↪ }</code>               |                                                 |
|                             | <code>↪ store</code>           |                                                 |
|                             | <code>↪</code>                 |                                                 |

| Data type                   | Exported file     | Parameter for data collection by PingCAP Clinic |
|-----------------------------|-------------------|-------------------------------------------------|
| Outputs of the command tiup | placement--       |                                                 |
|                             | ↪ -               | ↪ include                                       |

### 13.11.4.2 DM clusters

This section lists the types of diagnostic data that can be collected by Diag from the DM clusters deployed using TiUP.

#### 13.11.4.2.1 DM cluster information

| Data type                                                  | Exported file                                                        | Parameter for data collection by PingCAP Clinic |
|------------------------------------------------------------|----------------------------------------------------------------------|-------------------------------------------------|
| Basic information of the cluster, including the cluster ID | <code>cluster</code><br>↔ <code>.</code><br>↔ <code>json</code><br>↔ | The data is collected per run by default.       |
| Detailed information of the cluster                        | <code>meta.</code><br>↔ <code>yaml</code><br>↔                       | The data is collected per run by default.       |

#### 13.11.4.2.2 dm-master diagnostic data

| Data type          | Exported file                     | Parameter for data collection by PingCAP Clinic |
|--------------------|-----------------------------------|-------------------------------------------------|
| Log                | <code>m-master.log</code>         | <code>--include=log</code>                      |
| Error log          | <code>dm-master_stderr.log</code> | <code>--include=log</code>                      |
| Configuration file | <code>dm-master.toml</code>       | <code>--include=config</code>                   |

#### 13.11.4.2.3 dm-worker diagnostic data

| Data type          | Exported file                     | Parameter for data collection by PingCAP Clinic |
|--------------------|-----------------------------------|-------------------------------------------------|
| Log                | <code>dm-worker.log</code>        | <code>--include=log</code>                      |
| Error log          | <code>dm-worker_stderr.log</code> | <code>--include=log</code>                      |
| Configuration file | <code>dm-work.toml</code>         | <code>--include=config</code>                   |

#### 13.11.4.2.4 Prometheus monitoring data

| Data type        | Exported file      | Parameter for data collection by PingCAP Clinic |
|------------------|--------------------|-------------------------------------------------|
| All metrics data | {metric_name}.json | --include=monitor                               |
| All alerts data  | alerts.json        | --include=monitor                               |

#### 13.11.4.2.5 System information of the cluster node

| Data type                                    | Exported file                                                                  | Parameter for data collection by PingCAP Clinic |
|----------------------------------------------|--------------------------------------------------------------------------------|-------------------------------------------------|
| Kernel log                                   | dmesg.<br>↪ log                                                                | --<br>↪ include<br>↪ =<br>↪ system<br>↪         |
| Basic information of the system and hardware | insight<br>↪ .<br>↪ json<br>↪                                                  | --<br>↪ include<br>↪ =<br>↪ system<br>↪         |

## 13.12 TiSpark

### 13.12.1 TiSpark User Guide

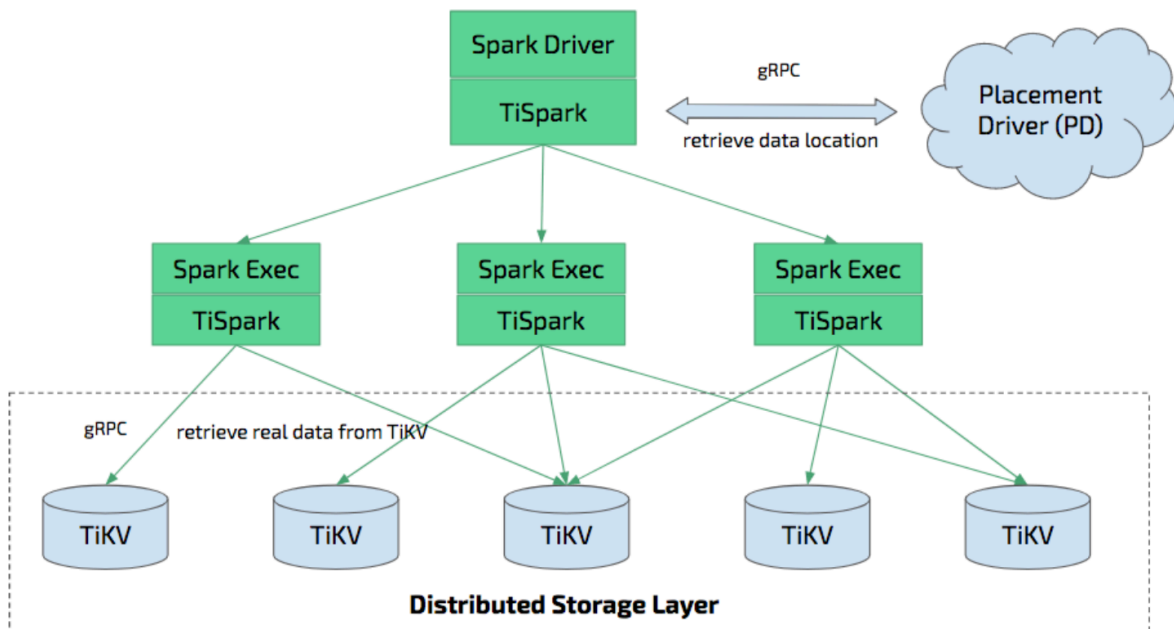

Figure 295: TiSpark architecture

### 13.12.1.1 TiSpark vs TiFlash

**TiSpark** is a thin layer built for running Apache Spark on top of TiDB/TiKV to answer the complex OLAP queries. It takes advantages of both the Spark platform and the distributed TiKV cluster and seamlessly glues to TiDB, the distributed OLTP database, to provide a Hybrid Transactional/Analytical Processing (HTAP) solution to serve as a one-stop solution for both online transactions and analysis.

**TiFlash** is another tool that enables HTAP. Both TiFlash and TiSpark allow the use of multiple hosts to execute OLAP queries on OLTP data. TiFlash stores data in a columnar format, which allows more efficient analytical queries. TiFlash and TiSpark can be used together.

### 13.12.1.2 What is TiSpark

TiSpark depends on the TiKV cluster and the PD cluster. You also need to set up a Spark cluster. This document provides a brief introduction to how to setup and use TiSpark. It requires some basic knowledge of Apache Spark. For more information, see [Apache Spark website](#).

Deeply integrating with Spark Catalyst Engine, TiSpark provides precise control on computing. This allows Spark to read data from TiKV efficiently. TiSpark also supports index seek, which enables high-speed point query. TiSpark accelerates data queries by pushing computing to TiKV so as to reduce the volume of data to be processed by Spark SQL. Meanwhile, TiSpark can use TiDB built-in statistics to select the best query plan.

With TiSpark and TiDB, you can run both transaction and analysis tasks on the same platform without building and maintaining ETLs. This simplifies the system architecture and reduces the cost of maintenance.

You can use tools of the Spark ecosystem for data processing on TiDB:

- TiSpark: Data analysis and ETLs
- TiKV: Data retrieval
- Scheduling system: Report generation

Also, TiSpark supports distributed writes to TiKV. Compared with writes to TiDB by using Spark and JDBC, distributed writes to TiKV can implement transactions (either all data are written successfully or all writes fail), and the writes are faster.

#### **Warning:**

Because TiSpark accesses TiKV directly, the access control mechanisms used by TiDB Server are not applicable to TiSpark. Since TiSpark v2.5.0, TiSpark supports user authentication and authorization, for more information, see [Security](#).

### 13.12.1.3 Requirements

- TiSpark supports Spark  $\geq$  2.3.
- TiSpark requires JDK 1.8 and Scala 2.11/2.12.
- TiSpark runs in any Spark mode such as YARN, Mesos, and Standalone.

### 13.12.1.4 Recommended deployment configurations of Spark

#### **Warning:**

Deploying TiSpark using TiUP as described in this [doc](#) has been deprecated.

Since TiSpark is a TiDB connector of Spark, to use it, a running Spark cluster is required.

This document provides basic advice on deploying Spark. Please turn to the [Spark official website](#) for detailed hardware recommendations.

For independent deployment of Spark cluster:

- It is recommended to allocate 32 GB memory for Spark. Reserve at least 25% of the memory for the operating system and the buffer cache.
- It is recommended to provision at least 8 to 16 cores per machine for Spark. First, you must assign all the CPU cores to Spark.

The following is an example based on the `spark-env.sh` configuration:

```
SPARK_EXECUTOR_MEMORY = 32g
SPARK_WORKER_MEMORY = 32g
SPARK_WORKER_CORES = 8
```

### 13.12.1.5 Get TiSpark

TiSpark is a third-party jar package for Spark that provides the ability to read and write TiKV.

#### 13.12.1.5.1 Get `mysql-connector-j`

The `mysql-connector-java` dependency is no longer provided because of the limit of the GPL license.

The following versions of TiSpark's jar will no longer include `mysql-connector-java`.

- TiSpark  $>$  3.0.1

- TiSpark > 2.5.1 for TiSpark 2.5.x
- TiSpark > 2.4.3 for TiSpark 2.4.x

However, TiSpark needs `mysql-connector-java` for writing and authentication. In such cases, you need to import `mysql-connector-java` manually using either of the following methods:

- Put `mysql-connector-java` into spark jars file.
- Import `mysql-connector-java` when you submit a spark job. See the following example:

```
spark-submit --jars tispark-assembly-3.0_2.12-3.1.0-SNAPSHOT.jar,mysql-connector-java-8.0.29.jar
```

### 13.12.1.5.2 Choose TiSpark version

You can choose TiSpark version according to your TiDB and Spark version.

| TiSpark version  | TiDB, TiKV, PD version | Spark version              | Scala version |
|------------------|------------------------|----------------------------|---------------|
| 2.4.x-scala_2.11 | 5.x, 4.x               | 2.3.x, 2.4.x               | 2.11          |
| 2.4.x-scala_2.12 | 5.x, 4.x               | 2.4.x                      | 2.12          |
| 2.5.x            | 5.x, 4.x               | 3.0.x, 3.1.x               | 2.12          |
| 3.0.x            | 5.x, 4.x               | 3.0.x, 3.1.x, 3.2.x        | 2.12          |
| 3.1.x            | 6.x, 5.x, 4.x          | 3.0.x, 3.1.x, 3.2.x, 3.3.x | 2.12          |

TiSpark 2.4.4, 2.5.2, 3.0.2 and 3.1.1 are the latest stable versions and are highly recommended.

### 13.12.1.5.3 Get TiSpark jar

You can get the TiSpark jar using one of the following methods:

- Get from [maven central](#) and search for [pingcap](#)
- Get from [TiSpark releases](#)
- Build from source with the steps below

#### Note:

Currently, java8 is the only choice to build TiSpark, run `mvn -version` to check.

```
git clone https://github.com/pingcap/tispark.git
```

Run the following command under the TiSpark root directory.

```
// add -Dmaven.test.skip=true to skip the tests
mvn clean install -Dmaven.test.skip=true
// or you can add properties to specify spark version
mvn clean install -Dmaven.test.skip=true -Pspark3.2.1
```

#### 13.12.1.5.4 TiSpark jar's artifact ID

The Artifact ID of TiSpark varies with TiSpark versions.

| TiSpark version                            | Artifact ID                                                                 |
|--------------------------------------------|-----------------------------------------------------------------------------|
| 2.4.x- $\{\text{scala\_version}\}$ , 2.5.0 | tispark-assembly                                                            |
| 2.5.1                                      | tispark-assembly- $\{\text{spark\_version}\}$                               |
| 3.0.x, 3.1.x                               | tispark-assembly- $\{\text{spark\_version}\}$ - $\{\text{scala\_version}\}$ |

#### 13.12.1.6 Getting started

This document describes how to use TiSpark in spark-shell.

##### 13.12.1.6.1 Start spark-shell

To use TiSpark in spark-shell:

Add the following configuration in `spark-defaults.conf`:

```
spark.sql.extensions org.apache.spark.sql.TiExtensions
spark.tispark.pd.addresses ${your_pd_address}
spark.sql.catalog.tidb_catalog org.apache.spark.sql.catalyst.catalog.
↪ TiCatalog
spark.sql.catalog.tidb_catalog.pd.addresses ${your_pd_address}
```

Start spark-shell with the `--jars` option.

```
spark-shell --jars tispark-assembly-{version}.jar
```

##### 13.12.1.6.2 Get TiSpark version
