`tidb_ddl_reorg_worker_cnt` to increase the concurrency. If no obvious jitter is observed in the monitor, increase the value of `tidb_ddl_reorg_batch_size`. If the columns involved in the index creation are frequently updated, the many resulting conflicts will cause the index creation to fail and be retried.

In addition, you can also set the value of `tidb_ddl_reorg_priority` to `PRIORITY_HIGH` to prioritize the index creation and speed up the process. But in the general OLTP system, it is recommended to keep its default value.

10.2.4.2.4 High GC pressure

The transaction of TiDB adopts the Multi-Version Concurrency Control (MVCC) mechanism. When the newly written data overwrites the old data, the old data is not replaced, and both versions of data are stored. Timestamps are used to mark different versions. The task of GC is to clear the obsolete data.

- In the phase of Resolve Locks, a large amount of `scan_lock` requests are created in TiKV, which can be observed in the gRPC-related metrics. These `scan_lock` requests call all Regions.
- In the phase of Delete Ranges, a few (or no) `unsafe_destroy_range` requests are sent to TiKV, which can be observed in the gRPC-related metrics and the **GC tasks** panel.
- In the phase of Do GC, each TiKV by default scans the leader Regions on the machine and performs GC to each leader, which can be observed in the **GC tasks** panel.

10.2.5 Troubleshoot Write Conflicts in Optimistic Transactions

This document introduces the reason of and solutions to write conflicts in optimistic transactions.

Before TiDB v3.0.8, TiDB uses the optimistic transaction model by default. In this model, TiDB does not check conflicts during transaction execution. Instead, while the transaction is finally committed, the two-phase commit (2PC) is triggered and TiDB checks write conflicts. If a write conflict exists and the auto-retry mechanism is enabled, then TiDB retries the transaction within limited times. If the retry succeeds or has reached the upper limit on retry times, TiDB returns the result of transaction execution to the client. Therefore, if a lot of write conflicts exist in the TiDB cluster, the duration can be longer.

10.2.5.1 The reason of write conflicts

TiDB implements its transactions by using the Percolator transaction model. `percolator` is generally an implementation of 2PC. For the detailed 2PC process, see TiDB Optimistic Transaction Model.

After the client sends a `COMMIT` request to TiDB, TiDB starts the 2PC process:

1. TiDB chooses one key from all keys in the transaction as the primary key of the transaction.

2. TiDB sends the `prewrite` request to all the TiKV Regions involved in this commit. TiKV judges whether all keys can preview successfully.
3. TiDB receives the result that all `prewrite` requests are successful.
4. TiDB gets the `commit_ts` from PD.
5. TiDB sends the `commit` request to the TiKV Region that contains the primary key of the transaction. After TiKV receives the `commit` request, it checks the validity of the data and clears the locks left in the `prewrite` stage.
6. After the `commit` request returns successfully, TiDB returns success to the client.

The write conflict occurs in the `prewrite` stage. When the transaction finds that another transaction is writing the current key (`data.commit_ts` > `txn.start_ts`), a write conflict occurs.

10.2.5.2 Detect write conflicts

In the TiDB Grafana panel, check the following monitoring metrics under **KV Errors**:

- **KV Backoff OPS** indicates the count of error messages per second returned by TiKV.

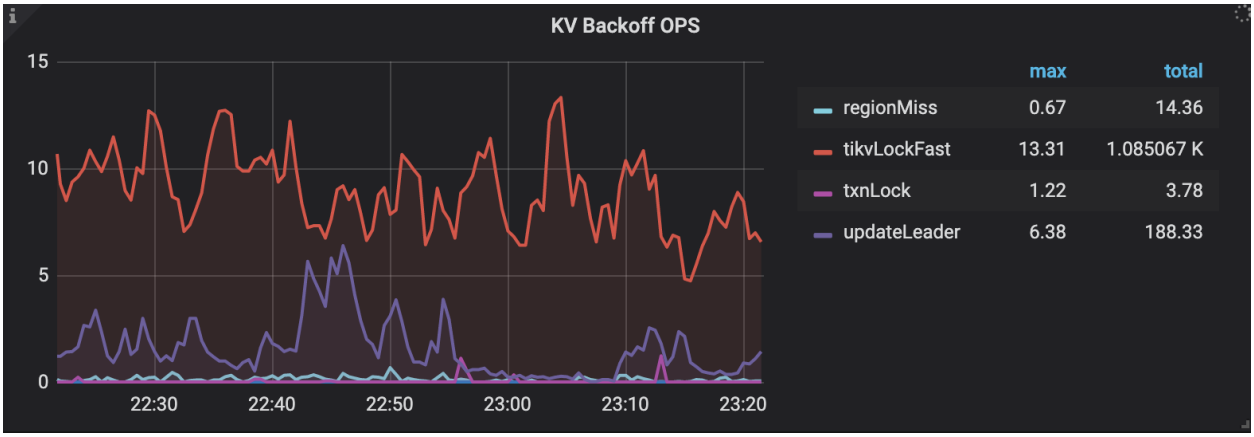

Figure 296: kv-backoff-ops

The `txnlock` metric indicates the write-write conflict. The `txnLockFast` metric indicates the read-write conflict.

- **Lock Resolve OPS** indicates the count of items related to transaction conflicts per second:

Figure 297: lock-resolve-ops

- `not_expired` indicates the TTL of the lock was not expired. The conflict transaction cannot resolve locks until the TTL is expired.
- `wait_expired` indicates that the transaction needs to wait the lock to expire.
- `expired` indicates the TTL of the lock was expired. Then the conflict transaction can resolve this lock.

- **KV Retry Duration** indicates the duration of re-sends the KV request:

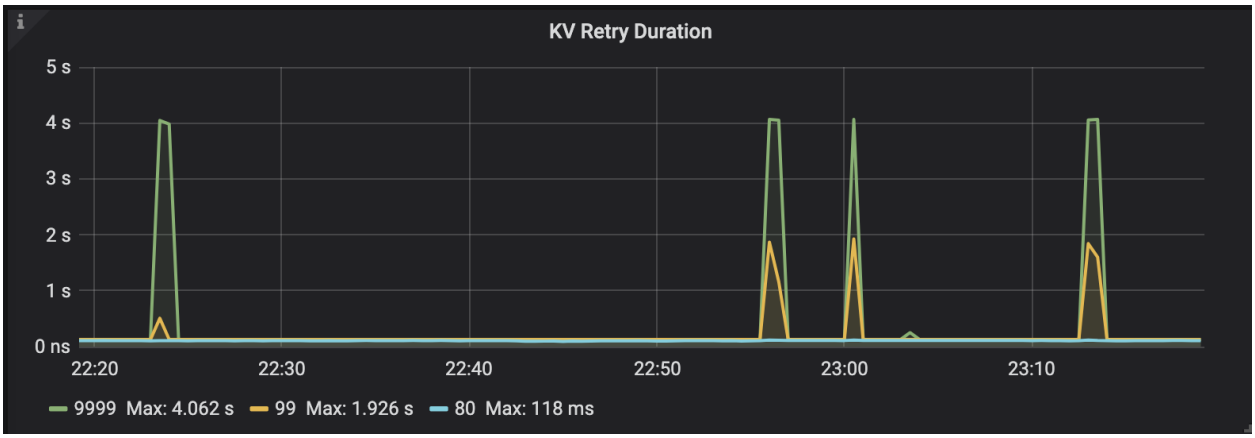

Figure 298: kv-retry-duration

You can also use `[kv:9007]Write conflict` as the keywords to search in the TiDB log. The keywords also indicate the write conflict exists in the cluster.

10.2.5.3 Resolve write conflicts

If many write conflicts exist in the cluster, it is recommended to find out the write conflict key and the reason, and then try to change the application logic to avoid write conflicts.

When the write conflict exists in the cluster, you can see the log similar to the following one in the TiDB log file:

```
[2020/05/12 15:17:01.568 +08:00] [WARN] [session.go:446] ["commit failed"] [
    ↪ conn=3] ["finished txn"="Txn{state=invalid}"] [error="[kv:9007]Write
    ↪ conflict, txnStartTS=416617006551793665, conflictStartTS
    ↪ =416617018650001409, conflictCommitTS=416617023093080065, key={
    ↪ tableID=47, indexID=1, indexValues={string, }} primary={tableID=47,
    ↪ indexID=1, indexValues={string, }} [try again later]"]
```

The explanation of the log above is as follows:

- `[kv:9007]Write conflict`: indicates the write-write conflict.
- `txnStartTS=416617006551793665`: indicates the `start_ts` of the current transaction. You can use the `pd-ctl` tool to convert `start_ts` to physical time.
- `conflictStartTS=416617018650001409`: indicates the `start_ts` of the write conflict transaction.
- `conflictCommitTS=416617023093080065`: indicates the `commit_ts` of the write conflict transaction.
- `key={tableID=47, indexID=1, indexValues={string, }}`: indicates the write conflict key. `tableID` indicates the ID of the write conflict table. `indexID` indicates the ID of write conflict index. If the write conflict key is a record key, the log prints `handle=x`, indicating which record(row) has a conflict. `indexValues` indicates the value of the index that has a conflict.
- `primary={tableID=47, indexID=1, indexValues={string, }}`: indicates the primary key information of the current transaction.

You can use the `pd-ctl` tool to convert the timestamp to readable time:

```
tiup ctl:v<CLUSTER_VERSION> pd -u https://127.0.0.1:2379 tso {TIMESTAMP}
```

You can use `tableID` to find the name of the related table:

```
curl http://{TiDBIP}:10080/db-table/{tableID}
```

You can use `indexID` and the table name to find the name of the related index:

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE TABLE_SCHEMA='{db_name}
    ↪ ' AND TABLE_NAME='{table_name}' AND INDEX_ID={indexID};
```

In addition, in TiDB v3.0.8 and later versions, the pessimistic transaction becomes the default mode. The pessimistic transaction mode can avoid write conflicts during the transaction prewrite stage, so you do not need to modify the application any more. In the pessimistic transaction mode, each DML statement writes a pessimistic lock to the related keys during execution. This pessimistic lock can prevent other transactions from modifying the same keys, thus ensuring no write conflicts exist in the `prewrite` stage of the transaction 2PC.

10.2.6 Troubleshoot High Disk I/O Usage in TiDB

This document introduces how to locate and address the issue of high disk I/O usage in TiDB.

10.2.6.1 Check the current I/O metrics

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck.

10.2.6.1.1 Locate I/O issues from monitor

The quickest way to locate I/O issues is to view the overall I/O status from the monitor, such as the Grafana dashboard which is deployed by default by TiUP. The dashboard panels related to I/O include **Overview**, **Node_exporter**, and **Disk-Performance**.

The first type of monitoring panels

In **Overview> System Info> IO Util**, you can see the I/O status of each machine in the cluster. This metric is similar to `util` in the Linux `iostat` monitor. The higher percentage represents higher disk I/O usage:

- If there is only one machine with high I/O usage in the monitor, currently there might be read and write hotspots on this machine.
- If the I/O usage of most machines in the monitor is high, the cluster now has high I/O loads.

For the first situation above (only one machine with high I/O usage), you can further observe I/O metrics from the **Disk-Performance Dashboard** such as `Disk Latency` and `Disk Load` to determine whether any anomaly exists. If necessary, use the fio tool to check the disk.

The second type of monitoring panels

The main storage component of the TiDB cluster is TiKV. One TiKV instance contains two RocksDB instances: one for storing Raft logs, located in `data/raft`, and the other for storing real data, located in `data/db`.

In **TiKV-Details > Raft IO**, you can see the metrics related to disk writes of these two instances:

- `Append log duration`: This metric indicates the response time of writes into RockDB that stores Raft logs. The `.99` response time should be within 50 ms.
- `Apply log duration`: This metric indicates the response time of writes into RockDB that stores real data. The `.99` response should be within 100 ms.

These two metrics also have the **.. per server** monitoring panel to help you view the write hotspots.

The third type of monitoring panels

In **TiKV-Details** > **Storage**, there are monitoring metrics related to storage:

- `Storage command total`: Indicates the number of different commands received.
- `Storage async write duration`: Includes monitoring metrics such as `disk sync duration`, which might be related to Raft I/O. If you encounter an abnormal situation, check the working statuses of related components by checking logs.

Other panels

In addition, some other panel metrics might help you determine whether the bottleneck is I/O, and you can try to set some parameters. By checking the prewrite/commit/raw-put (for raw key-value clusters only) of TiKV gRPC duration, you can determine that the bottleneck is indeed the slow TiKV write. The common situations of slow TiKV writes are as follows:

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which is often due to slow disk writes. You can check the value of `WAL Sync Duration max` in **RocksDB-raft** to determine the cause of slow `append log`. Otherwise, you might need to report a bug.
- The `raftstore` thread is busy. In TiKV Grafana, `Raft Propose/propose wait duration` is significantly higher than `append log duration`. Check the following aspects for troubleshooting:
  - Whether the value of `store-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1,5]` and not too large.
  - Whether the CPU resource of the machine is insufficient.
- `apply log` is slow. TiKV Grafana's `Raft I/O` and `apply log duration` metrics are relatively high, which might usually occur along with relatively high `Raft Propose /apply wait duration`. The possible causes are as follows:
  - The value of `apply-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1, 5]` and not too large. The value of `Thread CPU /apply cpu` is also relatively high.
  - Insufficient CPU resources on the machine.
  - Write hotspot issue of a single Region (Currently, the solution to this issue is still on the way). The CPU usage of a single `apply` thread is high (which can be viewed by modifying the Grafana expression, appended with `by (instance, name)`).
  - Slow write into RocksDB, and `RocksDB kv/max write duration` is high. A single Raft log might contain multiple key-value pairs (kv). 128 kvs are written to RocksDB in a batch, so one `apply` log might involve multiple RocksDB writes.

    - For other causes, report them as bugs.

- `raft commit log` is slow. In TiKV Grafana, `Raft I/O` and `commit log duration` (only available in Grafana 4.x) metrics are relatively high. Each Region corresponds to an independent Raft group. Raft has a flow control mechanism similar to the sliding window mechanism of TCP. To control the size of a sliding window, adjust the `[raftstore] raft-max-inflight-msgs` parameter. If there is a write hotspot and `commit log duration` is high, you can properly set this parameter to a larger value, such as `1024`.

10.2.6.1.2 Locate I/O issues from log

- If the client reports errors such as `server is busy` or especially `raftstore is busy`, the errors might be related to I/O issues.

  You can check the monitoring panel (**Grafana** -> **TiKV** -> **errors**) to confirm the specific cause of the `busy` error. `server is busy` is TiKV's flow control mechanism. In this way, TiKV informs `tidb/ti-client` that the current pressure of TiKV is too high, and the client should try later.

- `Write stall` appears in TiKV RocksDB logs.

  It might be that too many level-0 SST files cause the write stall. To address the issue, you can add the `[rocksdb] max-sub-compactions = 2 (or 3)` parameter to speed up the compaction of level-0 SST files. This parameter means that the compaction tasks of level-0 to level-1 can be divided into `max-sub-compactions` subtasks for multi-threaded concurrent execution.

  If the disk's I/O capability fails to keep up with the write, it is recommended to scale up the disk. If the throughput of the disk reaches the upper limit (for example, the throughput of SATA SSD is much lower than that of NVMe SSD), which results in write stall, but the CPU resource is relatively sufficient, you can try to use a compression algorithm of higher compression ratio to relieve the pressure on the disk, that is, use CPU resources to make up for disk resources.

  For example, when the pressure of `default cf compaction` is relatively high, you can change the parameter `[rocksdb.defaultcf] compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `compression-per-level = ["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

10.2.6.1.3 I/O issues found in alerts

The cluster deployment tool (TiUP) deploys the cluster with alert components by default that have built-in alert items and thresholds. The following alert items are related to I/O:

- TiKV_write_stall
- TiKV_raft_log_lag

- TiKV_async_request_snapshot_duration_seconds
- TiKV_async_request_write_duration_seconds
- TiKV_raft_append_log_duration_secs
- TiKV_raft_apply_log_duration_secs

10.2.6.2 Handle I/O issues

- When an I/O hotspot issue is confirmed to occur, you need to refer to Handle TiDB Hotspot Issues to eliminate the I/O hotspots.
- When it is confirmed that the overall I/O performance has become the bottleneck, and you can determine that the I/O performance will keep falling behind in the application side, then you can take advantage of the distributed database's capability of scaling and increase the number of TiKV nodes to have greater overall I/O throughput.
- Adjust some of the parameters as described above, and use computing/memory resources to make up for disk storage resources.

10.2.7 Troubleshoot Lock Conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. This document describes how to use Lock View to troubleshoot lock issues and how to deal with common lock conflict issues in optimistic and pessimistic transactions.

10.2.7.1 Use Lock View to troubleshoot lock issues

Since v5.1, TiDB supports the Lock View feature. This feature has several system tables built in `information_schema` that provide more information about the lock conflicts and lock waitings.

> **Note:**
>
> Currently, the Lock View feature provides conflict and waiting information for pessimistic locks only.

For the detailed introduction of these tables, see the following documents:

- `TIDB_TRX` and `CLUSTER_TIDB_TRX`: Provides information of all running transactions on the current TiDB node or in the entire cluster, including whether the transaction is in the lock-waiting state, the lock-waiting time, and the digests of statements that have been executed in the transaction.

- DATA_LOCK_WAITS: Provides the pessimistic lock-waiting information in TiKV, including the `start_ts` of the blocking and blocked transaction, the digest of the blocked SQL statement, and the key on which the waiting occurs.
- DEADLOCKS and CLUSTER_DEADLOCKS: Provides the information of several deadlock events that have recently occurred on the current TiDB node or in the entire cluster, including the waiting relationship among transactions in the deadlock loops, the digest of the statement currently being executed in the transaction, and the key on which the waiting occurs.

> **Note:**
>
> The SQL statements shown in the Lock View-related system tables are normalized SQL statements (that is, SQL statements without formats and arguments), which are obtained by internal queries according to SQL digests, so the tables cannot obtain the complete statements that include the format and arguments. For the detailed description of SQL digests and normalized SQL statement, see Statement Summary Tables.

The following sections show the examples of troubleshooting some issues using these tables.

10.2.7.1.1 Deadlock errors

To get the information of the recent deadlock errors, you can query the `DEADLOCKS` or `CLUSTER_DEADLOCKS` table.

For example, to query the `DEADLOCKS` table, you can execute the following SQL statement:

```
select * from information_schema.deadlocks;
```

The following is an example output:

```
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
| DEADLOCK_ID | OCCUR_TIME                 | RETRYABLE | TRY_LOCK_TRX_ID |
    ↪ CURRENT_SQL_DIGEST                                                 |
    ↪ CURRENT_SQL_DIGEST_TEXT              | KEY
    ↪                                    | KEY_INFO
    ↪
    ↪ | TRX_HOLDING_LOCK |
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
```

```
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406216 |
   ↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
   ↪ update `t` set `v` = ? where `id` = ? ; | 7480000000000000355
   ↪ F728000000000000002 | {"db_id":1,"db_name":"test","table_id":53,"
   ↪ table_name":"t","handle_type":"int","handle_value":"2"} |
   ↪ 426812829645406217 |
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406217 |
   ↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
   ↪ update `t` set `v` = ? where `id` = ? ; | 7480000000000000355
   ↪ F728000000000000001 | {"db_id":1,"db_name":"test","table_id":53,"
   ↪ table_name":"t","handle_type":"int","handle_value":"1"} |
   ↪ 426812829645406216 |
+--
   ↪ ----------+--------------------------+----------+------------------+------
   ↪
```

The query result above shows the waiting relationship among multiple transactions in the deadlock error, the normalized form of the SQL statements currently being executed in each transaction (statements without formats and arguments), the key on which the conflict occurs, and the information of the key.

For example, in the above example, the first row means that the transaction with the ID of `426812829645406216` is executing a statement like `update `t` set `v` =? Where `id ↪ ` =? ;` but is blocked by another transaction with the ID of `426812829645406217`. The transaction with the ID of `426812829645406217` is also executing a statement that is in the form of `update `t` set `v` =? Where `id` =? ;` but is blocked by the transaction with the ID of `426812829645406216`. The two transactions thus form a deadlock.

10.2.7.1.2 A few hot keys cause queueing locks

The `DATA_LOCK_WAITS` system table provides the lock-waiting status on the TiKV nodes. When you query this table, TiDB automatically obtains the real-time lock-waiting information from all TiKV nodes. If a few hot keys are frequently locked and block many transactions, you can query the `DATA_LOCK_WAITS` table and aggregate the results by key to try to find the keys on which issues frequently occur:

```
select `key`, count(*) as `count` from information_schema.data_lock_waits
   ↪ group by `key` order by `count` desc;
```

The following is an example output:

```
+----------------------------------------+-------+
| key                                    | count |
+----------------------------------------+-------+
| 748000000000000415F728000000000000001 | 2 |
| 748000000000000415F728000000000000002 | 1 |
+----------------------------------------+-------+
```

To avoid contingency, you might need to make multiple queries.

If you know the key that frequently has issues occurred, you can try to get the information of the transaction that tries to lock the key from the `TIDB_TRX` or `CLUSTER_TIDB_TRX` table.

Note that the information displayed in the `TIDB_TRX` and `CLUSTER_TIDB_TRX` tables is also the information of the transactions that are running at the time the query is performed. These tables do not display the information of the completed transactions. If there is a large number of concurrent transactions, the result set of the query might also be large. You can use the `limit` clause or the `where` clause to filter transactions with a long lock-waiting time. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

For example, to filter transactions with a long lock-waiting time using the `where` clause, you can execute the following SQL statement:

```
select trx.* from information_schema.data_lock_waits as l left join
    ↪ information_schema.tidb_trx as trx on l.trx_id = trx.id where l.key =
    ↪  "748000000000000415F728000000000000001"\G
```

The following is an example output:

```

10.2.7.1.3 A transaction is blocked for a long time

If a transaction is known to be blocked by another transaction (or multiple transactions) and the `start_ts` (transaction ID) of the current transaction is known, you can use the following method to obtain the information of the blocking transaction. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```
select l.key, trx.*, tidb_decode_sql_digests(trx.all_sql_digests) as sqls
   ↪ from information_schema.data_lock_waits as l join information_schema.
   ↪ cluster_tidb_trx as trx on l.current_holding_trx_id = trx.id where l.
   ↪ trx_id = 426831965449355272\G
```

The following is an example output:

```
*************************** 1. row ***************************
                  key: 74800000000000004D5F728000000000000001
             INSTANCE: 127.0.0.1:10080

          ↪ "]
                sqls: ["begin ;","select * from `t` where `id` = ? for
                   ↪ update ;","update `t` set `v` = `v` + ? where `id` =
                   ↪ ? ;"]
1 row in set (0.01 sec)
```

In the above query, the TIDB_DECODE_SQL_DIGESTS function is used on the ALL_SQL_DIGESTS column of the CLUSTER_TIDB_TRX table. This function tries to convert this column (the value is a set of SQL digests) to the normalized SQL statements, which improves readability.

If the start_ts of the current transaction is unknown, you can try to find it out from the information in the TIDB_TRX / CLUSTER_TIDB_TRX table or in the PROCESSLIST / CLUSTER_PROCESSLIST table.

10.2.7.2 Troubleshoot optimistic lock conflicts

This section provides the solutions of common lock conflict issues in the optimistic transaction mode.

10.2.7.2.1 Read-write conflicts

As the TiDB server receives a read request from a client, it gets a globally unique and increasing timestamp at the physical time as the start_ts of the current transaction. The transaction needs to read the latest data before start_ts, that is, the target key of the latest commit_ts that is smaller than start_ts. When the transaction finds that the target key is locked by another transaction, and it cannot know which phase the other transaction is in, a read-write conflict happens. The diagram is as follows:

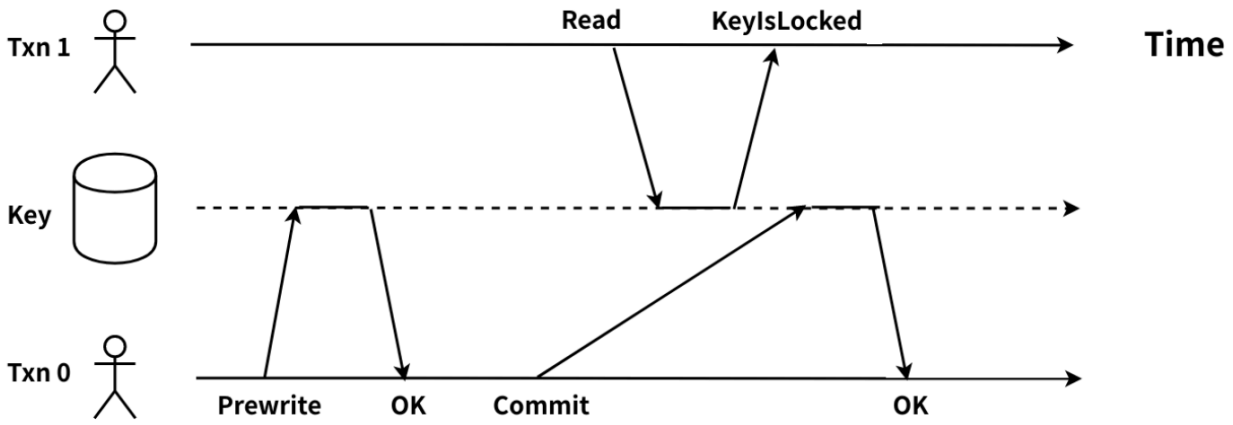

Figure 299: read-write conflict

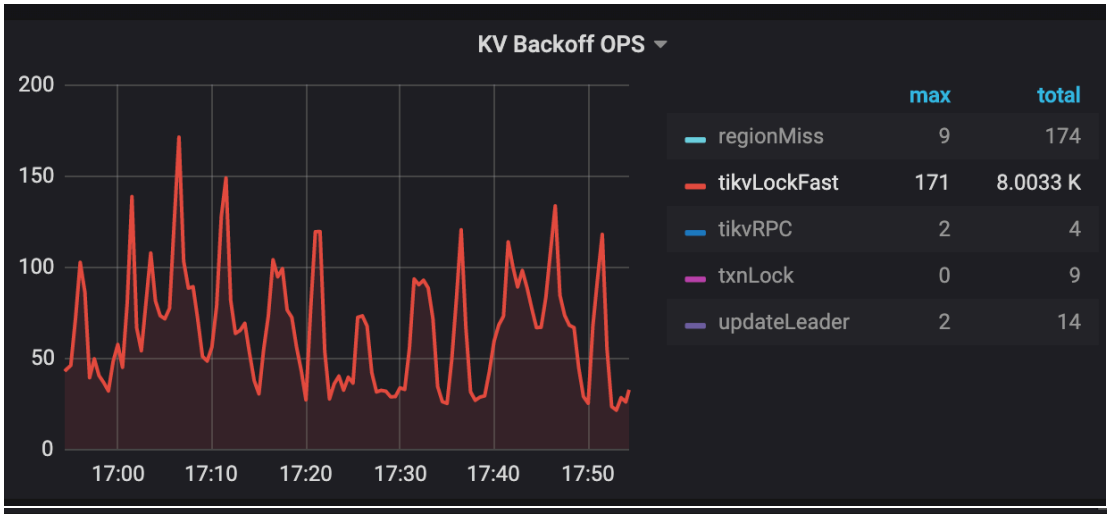
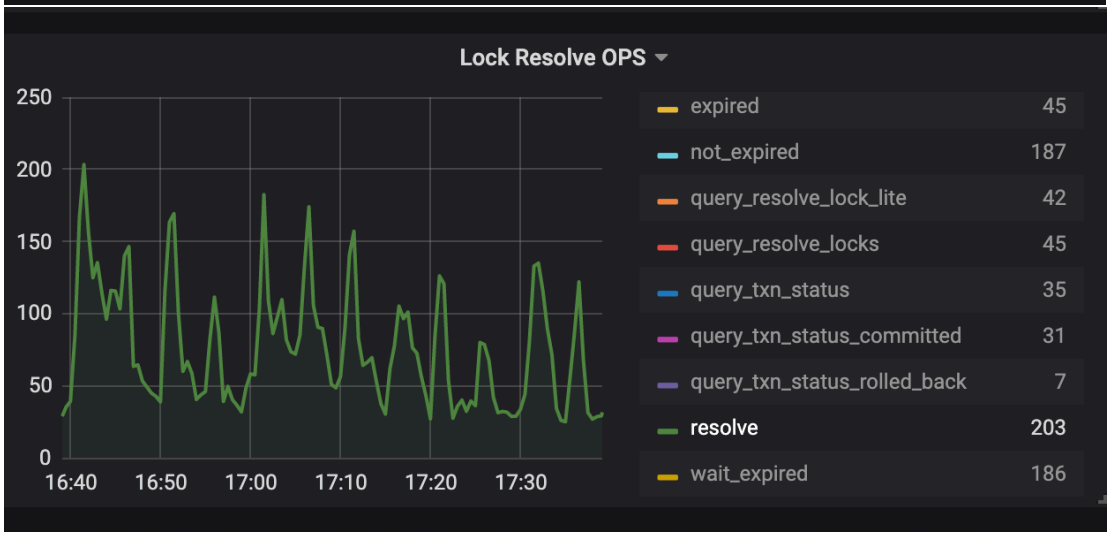


Txn0 completes the Prewrite phase and enters the Commit phase. At this time, Txn1 requests to read the same target key. Txn1 needs to read the target key of the latest commit_ts that is smaller than its start_ts. Because Txn1's start_ts is larger than Txn0's lock_ts, Txn1 must wait for the target key's lock to be cleared, but it hasn't been done. As a result, Txn1 cannot confirm whether Txn0 has been committed or not. Thus, a read-write conflict between Txn1 and Txn0 happens.



You can detect the read-write conflict in your TiDB cluster by the following ways:

1. Monitoring metrics and logs of the TiDB server

    - Monitoring data through Grafana

      In the `KV Errors` panel in the TiDB dashboard, `not_expired/resolve` in `Lock Resolve OPS` and `tikvLockFast` in `KV Backoff OPS` are monitoring metrics that can be used to check read-write conflicts in transactions. If the values of all the metrics increase, there might be many read-write conflicts. The `not_expired` item means that the transaction's lock has not timed out. The `resolve` item means that the other transaction tries to clean up the locks. The `tikvLockFast` item means that read-write conflicts occur.

- Logs of the TiDB server

  If there is any read-write conflict, you can see the following message in the TiDB log:

```
[INFO] [coprocessor.go:743] ["[TIME_COP_PROCESS] resp_time
    ↪ :406.038899ms txnStartTS:416643508703592451 region_id:8297
    ↪ store_addr:10.8.1.208:20160 backoff_ms:255 backoff_types:[
    ↪ txnLockFast,txnLockFast] kv_process_ms:333 scan_total_write
    ↪ :0 scan_processed_write:0 scan_total_data:0
    ↪ scan_processed_data:0 scan_total_lock:0 scan_processed_lock
    ↪ :0"]
```

  - txnStartTS: The start_ts of the transaction that is sending the read request. In the above log, `416643508703592451` is the start_ts.
  - backoff_types: If a read-write conflict happens, and the read request performs backoff and retry, the type of retry is `TxnLockFast`.
  - backoff_ms: The time that the read request spends in the backoff and retry, and the unit is milliseconds. In the above log, the read request spends 255 milliseconds in the backoff and retry.
  - region_id: Region ID corresponding to the target key of the read request.

2. Logs of the TiKV server

   If there is any read-write conflict, you can see the following message in the TiKV log:

```
[ERROR] [endpoint.rs:454] [error-response] [err=""locked primary_lock
    ↪ :7480000000000004
    ↪ D35F698000000000000010380000000004C788E0380000000004C0748
    ↪ lock_version: 411402933858205712 key: 7480000000000004
    ↪ D35F7280000000004C0748 lock_ttl: 3008 txn_size: 1""]
```

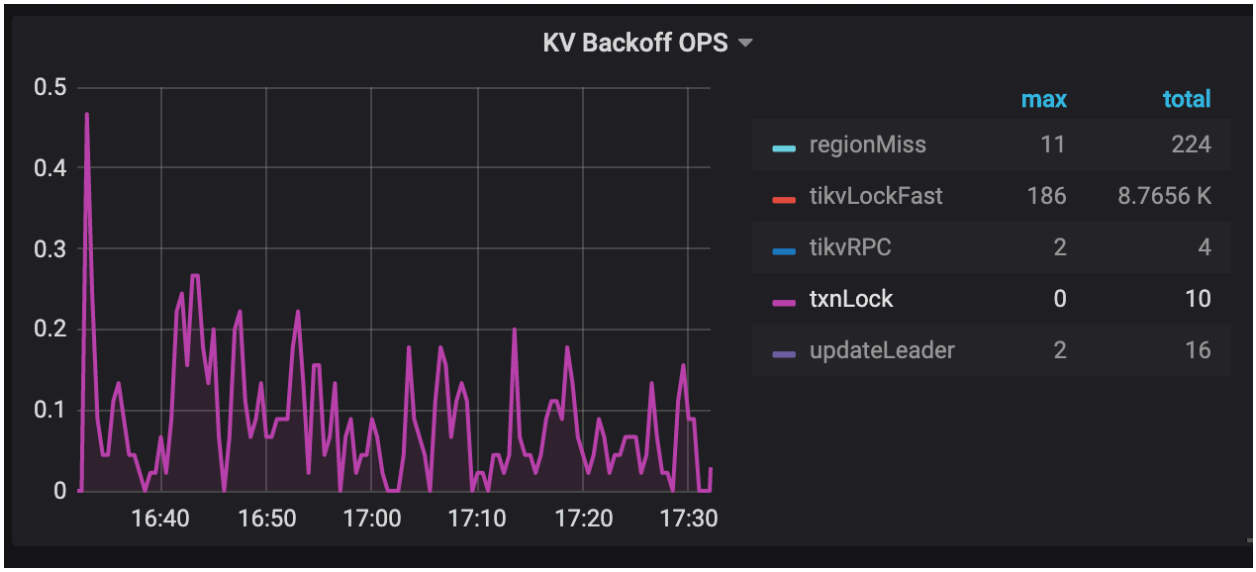
   This message indicates that a read-write conflict occurs in TiDB. The target key of the read request has been locked by another transaction. The locks are from the uncommitted optimistic transaction and the uncommitted pessimistic transaction after the prewrite phase.

   - primary_lock: Indicates that the target key is locked by the primary lock.
   - lock_version: The start_ts of the transaction that owns the lock.
   - key: The target key that is locked.
   - lock_ttl: The lock's TTL (Time To Live)
   - txn_size: The number of keys that are in the Region of the transaction that owns the lock.

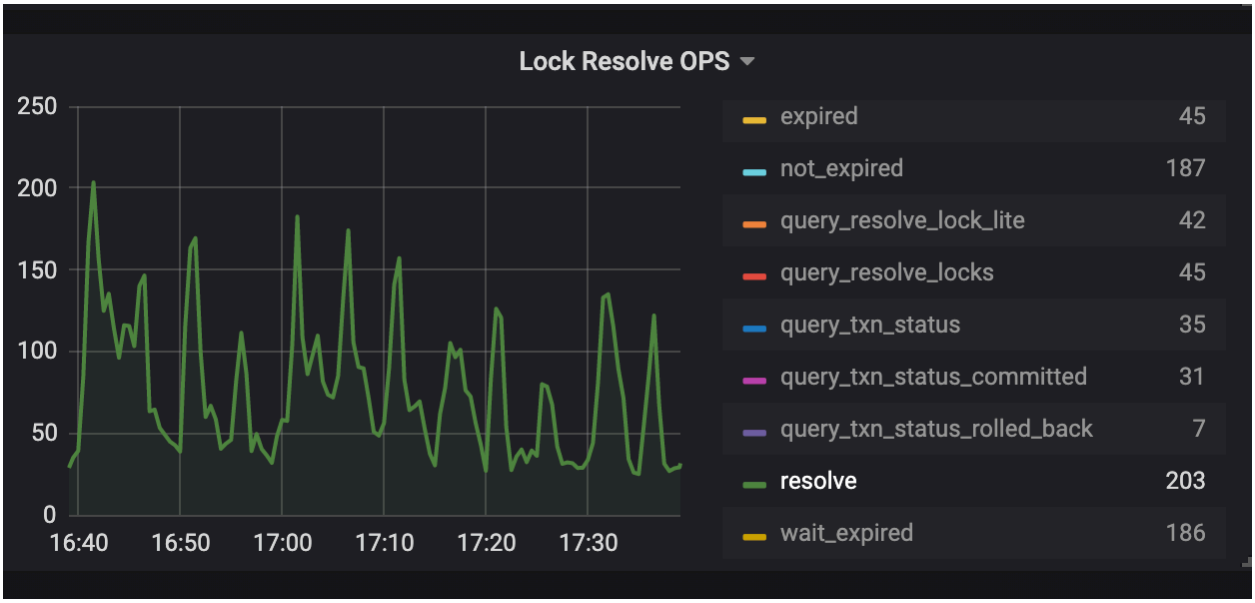
Solutions:

- A read-write conflict triggers an automatic backoff and retry. As in the above example, Txn1 has a backoff and retry. The first time of the retry is 10 ms, the longest retry is 3000 ms, and the total time is 20000 ms at maximum.

- You can use the sub-command `decoder` of TiDB Control to view the table id and rowid of the row corresponding to the specified key:



```
./tidb-ctl decoder "t\x00\x00\x00\x00\x00\x00\x1c_r\x00\x00\x00\x00
    ↪ \x00\x00\x00\xfa"
format: table_row
table_id: -9223372036854775780
row_id: -9223372036854775558
```



10.2.7.2.2 KeyIsLocked error

In the Prewrite phase of a transaction, TiDB checks whether there is any write-write conflict, and then checks whether the target key has been locked by another transaction. If the key is locked, the TiKV server outputs a "KeyIsLocked" error. At present, the error message is not printed in the logs of TiDB and TiKV. Same as read-write conflicts, when "KeyIsLocked" occurs, TiDB automatically performs backoff and retry for the transaction.

You can check whether there's any "KeyIsLocked" error in the TiDB monitoring on Grafana:

The `KV Errors` panel in the TiDB dashboard has two monitoring metrics `Lock Resolve OPS` and `KV Backoff OPS` which can be used to check write-write conflicts caused by a transaction. If the `resolve` item under `Lock Resolve OPS` and the `txnLock` item under `KV Backoff OPS` have a clear upward trend, a "KeyIsLocked" error occurs. `resolve` refers to the operation that attempts to clear the lock, and `txnLock` represents a write conflict.

Solutions:

- If there is a small amount of txnLock in the monitoring, no need to pay too much attention. The backoff and retry is automatically performed in the background. The first time of the retry is 100 ms and the maximum time is 3000 ms for a single retry.
- If there are too many "txnLock" operations in the `KV Backoff OPS`, it is recommended that you analyze the reasons to the write conflicts from the application side.
- If your application is a write-write conflict scenario, it is strongly recommended to use the pessimistic transaction mode.

10.2.7.2.3 LockNotFound error

The error log of "TxnLockNotFound" means that transaction commit time is longer than the TTL time, and when the transaction is going to commit, its lock has been rolled back by other transactions. If the TiDB server enables transaction commit retry, this transaction is re-executed according to tidb_retry_limit. (Note about the difference between explicit and implicit transactions.)

You can check whether there is any "LockNotFound" error in the following ways:

1. View the logs of the TiDB server

   If a "TxnLockNotFound" error occurs, the TiDB log message is like this:

```
[WARN] [session.go:446] ["commit failed"] [conn=149370] ["finished txn
    ↪ "="Txn{state=invalid}"] [error="[kv:6]Error: KV error safe to
    ↪ retry tikv restarts txn: Txn(Mvcc(TxnLockNotFound{ start_ts:
    ↪ 412720515987275779, commit_ts: 412720519984971777, key: [116,
    ↪ 128, 0, 0, 0, 0, 1, 111, 16, 95, 114, 128, 0, 0, 0, 0, 0, 0, 2]
    ↪ })) [try again later]"]
```

- start_ts: The start_ts of the transaction that outputs the `TxnLockNotFound` error because its lock has been rolled back by other transactions. In the above log, `412720515987275779` is the start_ts.
- commit_ts: The commit_ts of the transaction that outputs the `TxnLockNotFound` error. In the above log, `412720519984971777` is the commit_ts.

2. View the logs of the TiKV server

   If a "TxnLockNotFound" error occurs, the TiKV log message is like this:

```
Error: KV error safe to retry restarts txn: Txn(Mvcc(TxnLockNotFound))
    ↪ [ERROR [Kv.rs:708] ["KvService::batch_raft send response fail"] [
    ↪ err=RemoteStoped]
```

Solutions:

- By checking the time interval between start_ts and commit_ts, you can confirm whether the commit time exceeds the TTL time.

  Checking the time interval using the PD control tool:

```
tiup ctl:v<CLUSTER_VERSION> pd tso [start_ts]
tiup ctl:v<CLUSTER_VERSION> pd tso [commit_ts]
```

- It is recommended to check whether the write performance is slow, which might cause that the efficiency of transaction commit is poor, and thus the lock is cleared.
- In the case of disabling the TiDB transaction retry, you need to catch the exception on the application side and try again.

10.2.7.3 Troubleshoot pessimistic lock conflicts

This section provides the solutions of common lock conflict issues in the pessimistic transaction mode.

> **Note:**
>
> Even if the pessimistic transaction mode is set, autocommit transactions still try to commit using the optimistic mode first. If a conflict occurs, the transactions will switch to the pessimistic transaction mode during automatic retry.

10.2.7.3.1 Read-write conflicts

The error messages and solutions are the same as Read-write conflict for optimistic lock conflict.

10.2.7.3.2 Pessimistic lock retry limit reached

When the transaction conflict is very serious or a write conflict occurs, the optimistic transaction will be terminated directly, and the pessimistic transaction will retry the statement with the latest data from storage until there is no write conflict.

Because TiDB's locking operation is a write operation, and the process of the operation is to read first and then write, there are two RPC requests. If a write conflict occurs in the middle of a transaction, TiDB will try again to lock the target keys, and each retry will be printed to the TiDB log. The number of retries is determined by pessimistic-txn.max-retry-count.

In the pessimistic transaction mode, if a write conflict occurs and the number of retries reaches the upper limit, an error message containing the following keywords appears in the TiDB log:

```
err="pessimistic lock retry limit reached"
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust from the application side.
- If your business contains high concurrent locking on the same row (the same key) and encounters frequent conflicts, you can try to enable the system variable `tidb_pessimistic_txn_fair_locking`. Note that enabling this variable might bring some cost of throughput reduction (average latency increase) for transactions with lock conflicts. For newly deployed clusters, this variable is enabled (`ON`) by default.

10.2.7.3.3 Lock wait timeout exceeded

In the pessimistic transaction mode, transactions wait for locks of each other. The timeout for waiting a lock is defined by the innodb_lock_wait_timeout parameter of TiDB. This is the maximum wait lock time at the SQL statement level, which is the expectation of a SQL statement Locking, but the lock has never been acquired. After this time, TiDB will not try to lock again and will return the corresponding error message to the client.

When a wait lock timeout occurs, the following error message will be returned to the client:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust the application logic.

10.2.7.3.4 TTL manager has timed out

The transaction execution time cannot exceed the GC time limit. In addition, the TTL time of pessimistic transactions has an upper limit, whose default value is 1 hour. Therefore, a pessimistic transaction executed for more than 1 hour will fail to commit. This timeout threshold is controlled by the TiDB parameter `performance.max-txn-ttl`.

When the execution time of a pessimistic transaction exceeds the TTL time, the following error message occurs in the TiDB log:

```
TTL manager has timed out, pessimistic locks may expire, please commit or
    ↪ rollback this transaction
```

Solutions:

- First, confirm whether the application logic can be optimized. For example, large transactions may trigger TiDB's transaction size limit, which can be split into multiple small transactions.
- Also, you can adjust the related parameters properly to meet the application transaction logic.

10.2.7.3.5 Deadlock found when trying to get lock

Due to resource competition between two or more transactions, a deadlock occurs. If you do not handle it manually, transactions that block each other cannot be executed successfully and will wait for each other forever. To resolve dead locks, you need to manually terminate one of the transactions to resume other transaction requests.

When a pessimistic transaction has a deadlock, one of the transactions must be terminated to unlock the deadlock. The client will return the same `Error 1213` error as in MySQL, for example:

```
[err="[executor:1213]Deadlock found when trying to get lock; try restarting
    ↪ transaction"]
```

Solutions:

- If it is difficult to confirm the cause of the deadlock, for v5.1 and later versions, you are recommended to try to query the `INFORMATION_SCHEMA.DEADLOCKS` or `INFORMATION_SCHEMA.CLUSTER_DEADLOCKS` system table to get the information of deadlock waiting chain. For details, see the Deadlock errors section and the `DEADLOCKS` table document.
- If the deadlock occurs frequently, you need to adjust the transaction query logic in your application to reduce such occurrences.

10.2.8 Troubleshoot Inconsistency Between Data and Indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

This document describes the meanings of data inconsistency errors and provides some methods to bypass the consistency check. If a data consistency error occurs, you can get support from PingCAP or the community.

10.2.8.1 Error explanation

When inconsistency between data and indexes occurs, you can check TiDB error messages to know which item is inconsistent between row data and index data, or check the related error logs for further investigation.

10.2.8.1.1 Errors reported during transaction execution

This section lists the data inconsistency errors reported when TiDB executes transactions and explains the meanings of these errors with examples.

Error 8133

```
ERROR 8133 (HY000): data inconsistency in table: t, index: k2, index-
↪ count:1 != record-count:0
```

This error indicates that for the `k2` index in table `t`, the number of indexes in the table is 1 and the number of row records is 0. The number is inconsistent.

Error 8138

```
ERROR 8138 (HY000): writing inconsistent data in table: t, expected-
↪ values:{KindString green} != record-values:{KindString GREEN}
```

This error indicates that the transaction was attempting to write an incorrect row value. For the data to be written, the encoded row data does not match the original data before encoding.

Error 8139

```
ERROR 8139 (HY000): writing inconsistent data in table: t, index: i1,
↪ index-handle:4 != record-handle:3, index: tables.mutation{key:kv.Key{0
↪ x74, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x69, 0x80, 0x0, 0
↪ x0, 0x0, 0x0, 0x0, 0x0, 0x1, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0,
↪  0x0, 0xfc, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0, 0x0, 0xfc, 0x3,
↪  0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x4}, flags:0x0, value:[]uint8{0x30
↪ }, indexID:1}, record: tables.mutation{key:kv.Key{0x74, 0x80, 0x0, 0x0,
↪ 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x72, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0
```

```
↪ , 0x3}, flags:0xd, value:[]uint8{0x80, 0x0, 0x2, 0x0, 0x0, 0x0, 0x1, 0x2
↪ , 0x5, 0x0, 0xa, 0x0, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x68, 0x65, 0x6c, 0
↪ x6c, 0x6f}, indexID:0}
```

This error indicates that the handle (that is, the key of the row data) of the data to be written is inconsistent. For index `i1` in table `t`, the row to be written by the transaction has a handle of 4 in the index key-value pair and a handle of 3 in the row record key-value pair. The data of this row will not be written.

Error 8140

```
ERROR 8140 (HY000): writing inconsistent data in table: t, index: i2,
↪ col: c1, indexed-value:{KindString hellp} != record-value:{KindString
↪ hello}
```

This error indicates that the data in a row to be written by the transaction does not match the data in the index. For index `i2` in table `t`, a row to be written by the transaction has data `hellp` in the index key-value pair and data `hello` in the record key-value pair. The data of this row will not be written.

Error 8141

```
ERROR 8141 (HY000): assertion failed: key: 748000000000000405f7201330000000000000000f8
↪ , assertion: NotExist, start_ts: 430590532931813377, existing start ts:
↪ 430590532931551233, existing commit ts: 430590532931551234
```

This error indicates that the assertion failed when a transaction was being committed. Assuming that data and indexes are consistent, TiDB asserted that the key `748000000000000405f7201330000000000000000f8` did not exist. When the transaction was being committed, TiDB found the key did exist, written by the transaction with the `start ts` `430590532931551233`. TiDB will print the Multi-Version Concurrency Control (MVCC) history of this key to logs.

10.2.8.1.2 Errors reported in admin check

This section lists the data inconsistency errors that might occur in TiDB when you execute the `ADMIN CHECK [TABLE|INDEX]` statement, and explains the meanings of these errors with examples.

Error 8003

```
ERROR 8003 (HY000): table count 3 != index(idx)count 2
```

This error indicates that the table on which the `ADMIN CHECK` statement is executed has 3 row key-value pairs but only 2 index key-value pairs.

Error 8134

```
ERROR 8134 (HY000): data inconsistency in table: t, index: c2, col: c2
↪ , handle: "2", index-values:"KindInt64 13" != record-values:"KindInt64
↪ 12", compare err:<nil>
```

This error indicates that for index `c2` in table `t`, the value of column `c2` has the following inconsistency:

- In the index key-value pair of the row whose handle is `2`, the value of column `c2` is `13`.
- In the row record key-value pair, the value of column `c2` is `12`.

Error 8223

```
ERROR 8223 (HY000): data inconsistency in table: t2, index: i1, handle:
↪  {hello, hello}, index-values:"" != record-values:"handle: {hello, hello
↪ }, values: [KindString hello KindString hello]"
```

This error indicates that `index-values` are null and `record-values` are not null, meaning that there is no corresponding index for the row.

10.2.8.2 Solutions

If you encounter a data inconsistency error, get support from PingCAP for troubleshooting immediately instead of dealing with the error by yourself. If your application needs to skip such errors urgently, you can use the following methods to bypass the check.

10.2.8.2.1 Rewrite SQL

If the data inconsistency error occurs in a particular SQL statement only, you can bypass this error by rewriting the SQL statement to another equivalent form using different execution operators.

10.2.8.2.2 Disable error checks

For the following errors reported in transaction execution, you can bypass the corresponding checks:

- To bypass the checks of errors 8138, 8139, and 8140, configure `set @@tidb_enable_mutation_checke` ↪ `=0`.
- To bypass the checks of error 8141, configure `set @@tidb_txn_assertion_level=OFF`.

> **Note:**
>
> Disabling `tidb_enable_mutation_checker` and `tidb_txn_assertion_level` will bypass the corresponding checks of all SQL statements.

For other errors reported in transaction execution and all errors reported during the execution of the `ADMIN CHECK [TABLE|INDEX]` statement, you cannot bypass the corresponding check, because the data is already inconsistent.

10.3 Diagnostic Methods

10.3.1 SQL Diagnostics

SQL diagnostics is a feature introduced in TiDB v4.0. You can use this feature to locate problems in TiDB with higher efficiency. Before TiDB v4.0, you need to use different tools to obtain different information.

The SQL diagnostic system has the following advantages:

- It integrates information from all components of the system as a whole.
- It provides a consistent interface to the upper layer through system tables.
- It provides monitoring summaries and automatic diagnostics.
- You will find it easier to query cluster information.

10.3.1.1 Overview

The SQL diagnostic system consists of three major parts:

- **Cluster information table**: The SQL diagnostics system introduces cluster information tables that provide a unified way to get the discrete information of each instance. This system fully integrates the cluster topology, hardware information, software information, kernel parameters, monitoring, system information, slow queries, statements, and logs of the entire cluster into the table. So you can query these information using SQL statements.
- **Cluster monitoring table**: The SQL diagnostic system introduces cluster monitoring tables. All of these tables are in `metrics_schema`, and you can query monitoring information using SQL statements. Compared to the visualized monitoring before v4.0, you can use this SQL-based method to perform correlated queries on all the monitoring information of the entire cluster, and compare the results of different time periods to quickly identify performance bottlenecks. Because the TiDB cluster has many monitoring metrics, the SQL diagnostic system also provides monitoring summary tables, so you can find abnormal monitoring items more easily.

Automatic diagnostics: Although you can manually execute SQL statements to query cluster information tables, cluster monitoring tables, and summary tables to locate issues, the automatic diagnostics allows you to quickly locate common issues. The SQL diagnostic system performs automatic diagnostics based on the existing cluster information tables and monitoring tables, and provides relevant diagnostic result tables and diagnostic summary tables.

10.3.1.2 Cluster information tables

The cluster information tables bring together the information of all instances and instances in a cluster. With these tables, you can query all cluster information using only one SQL statement. The following is a list of cluster information tables:

- From the cluster topology table `information_schema.cluster_info`, you can get the current topology information of the cluster, the version of each instance, the Git Hash corresponding to the version, the starting time of each instance, and the running time of each instance.
- From the cluster configuration table `information_schema.cluster_config`, you can get the configuration of all instances in the cluster. For versions earlier than 4.0, you need to access the HTTP API of each instance one by one to get these configuration information.
- On the cluster hardware table `information_schema.cluster_hardware`, you can quickly query the cluster hardware information.
- On the cluster load table `information_schema.cluster_load`, you can query the load information of different instances and hardware types of the cluster.
- On the kernel parameter table `information_schema.cluster_systeminfo`, you can query the kernel configuration information of different instances in the cluster. Currently, TiDB supports querying the sysctl information.
- On the cluster log table `information_schema.cluster_log`, you can query cluster logs. By pushing down query conditions to each instance, the impact of the query on cluster performance is less than that of the `grep` command.

On the system tables earlier than TiDB v4.0, you can only view the current instance. TiDB v4.0 introduces the corresponding cluster tables and you can have a global view of the entire cluster on a single TiDB instance. These tables are currently in `information_schema`, and the query method is the same as other `information_schema` system tables.

10.3.1.3 Cluster monitoring tables

To dynamically observe and compare cluster conditions in different time periods, the SQL diagnostic system introduces cluster monitoring system tables. All monitoring tables are in `metrics_schema`, and you can query the monitoring information using SQL statements. Using this method, you can perform correlated queries on all monitoring information of the entire cluster and compare the results of different time periods to quickly identify performance bottlenecks.

- `information_schema.metrics_tables`: Because many system tables exist now, you can query meta-information of these monitoring tables on the `information_schema.metrics_tables` table.

Because the TiDB cluster has many monitoring metrics, TiDB provides the following monitoring summary tables in v4.0:

- The monitoring summary table `information_schema.metrics_summary` summarizes all monitoring data to for you to check each monitoring metric with higher efficiency.
- `information_schema.metrics_summary_by_label` also summarizes all monitoring data. Particularly, this table aggregates statistics using different labels of each monitoring metric.

10.3.1.4 Automatic diagnostics

On the cluster information tables and cluster monitoring tables above, you need to manually execute SQL statements to troubleshoot the cluster. TiDB v4.0 supports the automatic diagnostics. You can use diagnostic-related system tables based on the existing basic information tables, so that the diagnostics is automatically executed. The following are the system tables related to the automatic diagnostics:

- The diagnostic result table `information_schema.inspection_result` displays the diagnostic result of the system. The diagnostics is passively triggered. Executing `select * from inspection_result` triggers all diagnostic rules to diagnose the system, and the faults or risks in the system are displayed in the results.
- The diagnostic summary table `information_schema.inspection_summary` summarizes the monitoring information of a specific link or module. You can troubleshoot and locate problems based on the context of the entire module or link.

10.3.2 Statement Summary Tables

To better handle SQL performance issues, MySQL has provided statement summary tables in `performance_schema` to monitor SQL with statistics. Among these tables, `events_statements_summary_by_digest` is very useful in locating SQL problems with its abundant fields such as latency, execution times, rows scanned, and full table scans.

Therefore, starting from v4.0.0-rc.1, TiDB provides system tables in `information_schema` (*not* `performance_schema`) that are similar to `events_statements_summary_by_digest` in terms of features.

- `statements_summary`
- `statements_summary_history`
- `cluster_statements_summary`
- `cluster_statements_summary_history`
- `statements_summary_evicted`

> **Note:**
>
> The preceding tables are not available on TiDB Serverless clusters.

This document details these tables and introduces how to use them to troubleshoot SQL performance issues.

10.3.2.1 `statements_summary`

`statements_summary` is a system table in `information_schema`. `statements_summary` groups the SQL statements by the SQL digest and the plan digest, and provides statistics for each SQL category.

The "SQL digest" here means the same as used in slow logs, which is a unique identifier calculated through normalized SQL statements. The normalization process ignores constant, blank characters, and is case insensitive. Therefore, statements with consistent syntaxes have the same digest. For example:

```
SELECT * FROM employee WHERE id IN (1, 2, 3) AND salary BETWEEN 1000 AND
    ↪ 2000;
select * from EMPLOYEE where ID in (4, 5) and SALARY between 3000 and 4000;
```

After normalization, they are both of the following category:

```
select * from employee where id in (...) and salary between ? and ?;
```

The "plan digest" here refers to the unique identifier calculated through normalized execution plan. The normalization process ignores constants. The same SQL statements might be grouped into different categories because the same statements might have different execution plans. SQL statements of the same category have the same execution plan.

`statements_summary` stores the aggregated results of SQL monitoring metrics. In general, each of the monitoring metrics includes the maximum value and average value. For example, the execution latency metric corresponds to two fields: `AVG_LATENCY` (average latency) and `MAX_LATENCY` (maximum latency).

To make sure that the monitoring metrics are up to date, data in the `statements_summary` ↪ table is periodically cleared, and only recent aggregated results are retained and displayed. The periodical data clearing is controlled by the `tidb_stmt_summary_refresh_interval` ↪ system variable. If you happen to make a query right after the clearing, the data displayed might be very little.

The following is a sample output of querying `statements_summary`:

```
  SUMMARY_BEGIN_TIME: 2020-01-02 11:00:00
    SUMMARY_END_TIME: 2020-01-02 11:30:00
          STMT_TYPE: Select
        SCHEMA_NAME: test
             DIGEST: 0611
                 ↪ cc2fe792f8c146cc97d39b31d9562014cf15f8d41f23a4938ca341f54182
                 ↪
        DIGEST_TEXT: select * from employee where id = ?
        TABLE_NAMES: test.employee
```

```
        INDEX_NAMES: NULL
        SAMPLE_USER: root
         EXEC_COUNT: 3
        SUM_LATENCY: 1035161
        MAX_LATENCY: 399594
        MIN_LATENCY: 301353
        AVG_LATENCY: 345053
  AVG_PARSE_LATENCY: 57000
  MAX_PARSE_LATENCY: 57000
AVG_COMPILE_LATENCY: 175458
MAX_COMPILE_LATENCY: 175458
...........
           AVG_MEM: 103
           MAX_MEM: 103
          AVG_DISK: 65535
          MAX_DISK: 65535
  AVG_AFFECTED_ROWS: 0
        FIRST_SEEN: 2020-01-02 11:12:54
         LAST_SEEN: 2020-01-02 11:25:24
  QUERY_SAMPLE_TEXT: select * from employee where id=3100
   PREV_SAMPLE_TEXT:
        PLAN_DIGEST:
           ↪ f415b8d52640b535b9b12a9c148a8630d2c6d59e419aad29397842e32e8e5de3
           ↪
              PLAN: Point_Get_1   root   1      table:employee, handle:3100
```

Note:

In TiDB, the time unit of fields in statement summary tables is nanosecond (ns), whereas in MySQL the time unit is picosecond (ps).

10.3.2.2 `statements_summary_history`

The table schema of `statements_summary_history` is identical to that of `statements_summary` ↪ . `statements_summary_history` saves the history data of a time range. By checking history data, you can troubleshoot anomalies and compare monitoring metrics of different time ranges.

The fields `SUMMARY_BEGIN_TIME` and `SUMMARY_END_TIME` represent the start time and the end time of the historical time range.

10.3.2.3 `statements_summary_evicted`

The `tidb_stmt_summary_max_stmt_count` variable controls the maximum number of statements that the `statement_summary` table stores in memory. The `statement_summary` table uses the LRU algorithm. Once the number of SQL statements exceeds the `tidb_stmt_summary_max_stmt_count` value, the longest unused record is evicted from the table. The number of evicted SQL statements during each period is recorded in the `statements_summary_evicted` table.

The `statements_summary_evicted` table is updated only when a SQL record is evicted from the `statement_summary` table. The `statements_summary_evicted` only records the period during which the eviction occurs and the number of evicted SQL statements.

10.3.2.4 The `cluster` tables for statement summary

The `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` tables only show the statement summary of a single TiDB server. To query the data of the entire cluster, you need to query the `cluster_statements_summary`, `cluster_statements_summary_history`, or `cluster_statements_summary_evicted` tables.

`cluster_statements_summary` displays the `statements_summary` data of each TiDB server. `cluster_statements_summary_history` displays the `statements_summary_history` data of each TiDB server. `cluster_statements_summary_evicted` displays the `statements_summary_evicted` data of each TiDB server. These tables use the `INSTANCE` field to represent the address of the TiDB server. The other fields are the same as those in `statements_summary`, `statements_summary_history`, and `statements_summary_evicted`.

10.3.2.5 Parameter configuration

The following system variables are used to control the statement summary:

- `tidb_enable_stmt_summary`: Determines whether to enable the statement summary feature. `1` represents `enable`, and `0` means `disable`. The feature is enabled by default. The statistics in the system table are cleared if this feature is disabled. The statistics are re-calculated next time this feature is enabled. Tests have shown that enabling this feature has little impact on performance.
- `tidb_stmt_summary_refresh_interval`: The interval at which the `statements_summary` table is refreshed. The time unit is second (s). The default value is `1800`.
- `tidb_stmt_summary_history_size`: The size of each SQL statement category stored in the `statements_summary_history` table, which is also the maximum number of records in the `statements_summary_evicted` table. The default value is `24`.

- `tidb_stmt_summary_max_stmt_count`: Limits the number of SQL statements that can be stored in statement summary tables. The default value is `3000`. If the limit is exceeded, TiDB clears the SQL statements that recently remain unused. These cleared SQL statements are represented as rows with `DIGEST` set to `NULL` and recorded

in the `statements_summary_evicted` table. On the SQL statements page of TiDB Dashboard, the information of these rows is displayed as `Others`.

- `tidb_stmt_summary_max_sql_length`: Specifies the longest display length of `DIGEST_TEXT` and `QUERY_SAMPLE_TEXT`. The default value is `4096`.
- `tidb_stmt_summary_internal_query`: Determines whether to count the TiDB SQL statements. `1` means to count, and `0` means not to count. The default value is `0`.

Note:

When a category of SQL statement needs to be removed because the `tidb_stmt_summary_max_stmt_count` limit is exceeded, TiDB removes the data of that SQL statement category of all time ranges from the `statement_summary_history` table. Therefore, even if the number of SQL statement categories in a certain time range does not reach the limit, the number of SQL statements stored in the `statement_summary_history` table is less than the actual number of SQL statements. If this situation occurs and affects performance, you are recommended to increase the value of `tidb_stmt_summary_max_stmt_count`.

An example of the statement summary configuration is shown as follows:

```
set global tidb_stmt_summary_max_stmt_count = 3000;
set global tidb_enable_stmt_summary = true;
set global tidb_stmt_summary_refresh_interval = 1800;
set global tidb_stmt_summary_history_size = 24;
```

After the preceding configuration takes effect, the `statements_summary` table is cleared every 30 minutes and the `statements_summary_history` table stores up to 3000 types of SQL statements. For each type, the `statements_summary_history` table stores data for the recent 24 periods. The `statements_summary_evicted` table records the recent 24 periods during which SQL statements are evicted from the statement summary. The `statements_summary_evicted` table is updated every 30 minutes.

Note:

- If a SQL type appears every minute, the `statements_summary_history` stores data for the most recent 12 hours. If a SQL type only appears from 00:00 to 00:30 every day, the `statements_summary_history` stores data for the most recent 24 periods, with each period being 1 day. Therefore, the `statements_summary_history` stores the most recent 24 days of data for this SQL type.

- The `tidb_stmt_summary_history_size` ↪ , `tidb_stmt_summary_max_stmt_count`, and `tidb_stmt_summary_max_sql_length` configuration items affect memory usage. It is recommended that you adjust these configurations based on your needs, the SQL size, SQL count, and machine configuration. It is not recommended to set them too large values. You can calculate the memory usage using `tidb_stmt_summary_history_size` ↪ * `tidb_stmt_summary_max_stmt_count` * `tidb_stmt_summary_max_sql_length` * 3.

10.3.2.5.1 Set a proper size for statement summary

After the system has run for a period of time (depending on the system load), you can check the `statement_summary` table to see whether SQL eviction has occurred. For example:

```
select @@global.tidb_stmt_summary_max_stmt_count;
select count(*) from information_schema.statements_summary;
```

```
+-----------------------------------------+
| @@global.tidb_stmt_summary_max_stmt_count |
+-----------------------------------------+
| 3000                                    |
+-----------------------------------------+
1 row in set (0.001 sec)

+----------+
| count(*) |
+----------+
|     3001 |
+----------+
1 row in set (0.001 sec)
```

You can see that the `statements_summary` table is full of records. Then check the evicted data from the `statements_summary_evicted` table:

```
select * from information_schema.statements_summary_evicted;
```

```
+---------------------+---------------------+---------------+
| BEGIN_TIME          | END_TIME            | EVICTED_COUNT |
+---------------------+---------------------+---------------+
| 2020-01-02 16:30:00 | 2020-01-02 17:00:00 |            59 |
+---------------------+---------------------+---------------+
| 2020-01-02 16:00:00 | 2020-01-02 16:30:00 |            45 |
```

```
+--------------------+--------------------+--------------+
2 row in set (0.001 sec)
```

From the preceding result, you can see that a maximum of 59 SQL categories are evicted. In this case, it is recommended that you increase the size of the `statement_summary` table by at least 59 records, which means increasing the size to at least 3059 records.

10.3.2.6 Limitation

By default, statements summary tables are saved in memory. When a TiDB server restarts, all data will be lost.

To address this issue, TiDB v6.6.0 experimentally introduces the statement summary persistence feature, which is disabled by default. After this feature is enabled, the history data is no longer saved in memory, but directly written to disks. In this way, the history data is still available if a TiDB server restarts.

10.3.2.7 Persist statements summary

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

As described in the Limitation section, statements summary tables are saved in memory by default. Once a TiDB server restarts, all the statements summary will be lost. Starting from v6.6.0, TiDB experimentally provides the configuration item `tidb_stmt_summary_enable_persistent` to allow users to enable or disable statements summary persistence.

To enable statements summary persistence, you can add the following configuration items to the TiDB configuration file:

```
[instance]
tidb_stmt_summary_enable_persistent = true
### The following entries use the default values, which can be modified as
    ↪ needed.
### tidb_stmt_summary_filename = "tidb-statements.log"
### tidb_stmt_summary_file_max_days = 3
### tidb_stmt_summary_file_max_size = 64 # MiB
### tidb_stmt_summary_file_max_backups = 0
```

After statements summary persistence is enabled, the memory keeps only the current real-time data and no history data. Once the real-time data is refreshed as history data, the history data is written to the disk at an interval of `tidb_stmt_summary_refresh_interval` described in the Parameter configuration section. Queries on the `statements_summary_history` ↪ or `cluster_statements_summary_history` table will return results combining both in-memory and on-disk data.

Note:

- When statements summary persistence is enabled, the `tidb_stmt_summary_history_size` configuration described in the Parameter configuration section will no longer take effect because the memory does not keep the history data. Instead, the following three configurations will be used to control the retention period and size of history data for persistence: `tidb_stmt_summary_file_max_days` ↪ , `tidb_stmt_summary_file_max_size`, and `tidb_stmt_summary_file_max_backups`.
- The smaller the value of `tidb_stmt_summary_refresh_interval`, the more immediate data is written to the disk. However, this also means more redundant data is written to the disk.

10.3.2.8 Troubleshooting examples

This section provides two examples to show how to use the statement summary feature to troubleshoot SQL performance issues.

10.3.2.8.1 Could high SQL latency be caused by the server end?

In this example, the client shows slow performance with point queries on the `employee` table. You can perform a fuzzy search on SQL texts:

```
SELECT avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary
    WHERE digest_text LIKE 'select * from employee%';
```

`1ms` and `0.3ms` are considered within the normal range of `avg_latency`. Therefore, it can be concluded that the server end is not the cause. You can troubleshoot with the client or the network.

```
+-------------+-----------+-----------------------------------------+
| avg_latency | exec_count | query_sample_text                      |
+-------------+-----------+-----------------------------------------+
|     1042040 |         2 | select * from employee where name='eric' |
```

```
|     345053 |        3 | select * from employee where id=3100 |
+------------+----------+---------------------------------------+
2 rows in set (0.00 sec)
```

10.3.2.8.2 Which categories of SQL statements consume the longest total time?

If the QPS decrease significantly from 10:00 to 10:30, you can find out the three categories of SQL statements with the longest time consumption from the history table:

```
SELECT sum_latency, avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary_history
    WHERE summary_begin_time='2020-01-02 10:00:00'
    ORDER BY sum_latency DESC LIMIT 3;
```

The result shows that the following three categories of SQL statements consume the longest time in total, which need to be optimized with high priority.

```
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
| sum_latency | avg_latency | exec_count | query_sample_text
    ↪                                       |
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
|    7855660 |   1122237 |        7 | select avg(salary) from employee
    ↪ where company_id=2013       |
|    7241960 |   1448392 |        5 | select * from employee join company
    ↪ on employee.company_id=company.id |
|    2084081 |   1042040 |        2 | select * from employee where name='
    ↪ eric'                     |
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
3 rows in set (0.00 sec)
```

10.3.2.9 Fields description

10.3.2.9.1 `statements_summary` fields description

The following are descriptions of fields in the `statements_summary` table.

Basic fields:

- `STMT_TYPE`: SQL statement type.
- `SCHEMA_NAME`: The current schema in which SQL statements of this category are executed.
- `DIGEST`: The digest of SQL statements of this category.
- `DIGEST_TEXT`: The normalized SQL statement.
- `QUERY_SAMPLE_TEXT`: The original SQL statements of the SQL category. Only one original statement is taken.
- `TABLE_NAMES`: All tables involved in SQL statements. If there is more than one table, each is separated by a comma.
- `INDEX_NAMES`: All SQL indexes used in SQL statements. If there is more than one index, each is separated by a comma.
- `SAMPLE_USER`: The users who execute SQL statements of this category. Only one user is taken.
- `PLAN_DIGEST`: The digest of the execution plan.
- `PLAN`: The original execution plan. If there are multiple statements, the plan of only one statement is taken.
- `BINARY_PLAN`: The original execution plan encoded in binary format. If there are multiple statements, the plan of only one statement is taken. Execute the `SELECT` ↪ `tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan.
- `PLAN_CACHE_HITS`: The total number of times that SQL statements of this category hit the plan cache.
- `PLAN_IN_CACHE`: Indicates whether the previous execution of SQL statements of this category hit the plan cache.

Fields related to execution time:

- `SUMMARY_BEGIN_TIME`: The beginning time of the current summary period.
- `SUMMARY_END_TIME`: The ending time of the current summary period.
- `FIRST_SEEN`: The time when SQL statements of this category are seen for the first time.
- `LAST_SEEN`: The time when SQL statements of this category are seen for the last time.

Fields related to TiDB server:

- `EXEC_COUNT`: Total execution times of SQL statements of this category.
- `SUM_ERRORS`: The sum of errors occurred during execution.
- `SUM_WARNINGS`: The sum of warnings occurred during execution.
- `SUM_LATENCY`: The total execution latency of SQL statements of this category.
- `MAX_LATENCY`: The maximum execution latency of SQL statements of this category.
- `MIN_LATENCY`: The minimum execution latency of SQL statements of this category.
- `AVG_LATENCY`: The average execution latency of SQL statements of this category.
- `AVG_PARSE_LATENCY`: The average latency of the parser.
- `MAX_PARSE_LATENCY`: The maximum latency of the parser.

- `AVG_COMPILE_LATENCY`: The average latency of the compiler.
- `MAX_COMPILE_LATENCY`: The maximum latency of the compiler.
- `AVG_MEM`: The average memory (byte) used.
- `MAX_MEM`: The maximum memory (byte) used.
- `AVG_DISK`: The average disk space (byte) used.
- `MAX_DISK`: The maximum disk space (byte) used.

Fields related to TiKV Coprocessor task:

- `SUM_COP_TASK_NUM`: The total number of Coprocessor requests sent.
- `MAX_COP_PROCESS_TIME`: The maximum execution time of Coprocessor tasks.
- `MAX_COP_PROCESS_ADDRESS`: The address of the Coprocessor task with the maximum execution time.
- `MAX_COP_WAIT_TIME`: The maximum waiting time of Coprocessor tasks.
- `MAX_COP_WAIT_ADDRESS`: The address of the Coprocessor task with the maximum waiting time.
- `AVG_PROCESS_TIME`: The average processing time of SQL statements in TiKV.
- `MAX_PROCESS_TIME`: The maximum processing time of SQL statements in TiKV.
- `AVG_WAIT_TIME`: The average waiting time of SQL statements in TiKV.
- `MAX_WAIT_TIME`: The maximum waiting time of SQL statements in TiKV.
- `AVG_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry.
- `MAX_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry.
- `AVG_TOTAL_KEYS`: The average number of keys that Coprocessor has scanned.
- `MAX_TOTAL_KEYS`: The maximum number of keys that Coprocessor has scanned.
- `AVG_PROCESSED_KEYS`: The average number of keys that Coprocessor has processed. Compared with `avg_total_keys`, `avg_processed_keys` does not include the old versions of MVCC. A great difference between `avg_total_keys` and `avg_processed_keys` indicates that many old versions exist.
- `MAX_PROCESSED_KEYS`: The maximum number of keys that Coprocessor has processed.

Transaction-related fields:

- `AVG_PREWRITE_TIME`: The average time of the prewrite phase.
- `MAX_PREWRITE_TIME`: The longest time of the prewrite phase.
- `AVG_COMMIT_TIME`: The average time of the commit phase.
- `MAX_COMMIT_TIME`: The longest time of the commit phase.
- `AVG_GET_COMMIT_TS_TIME`: The average time of getting `commit_ts`.
- `MAX_GET_COMMIT_TS_TIME`: The longest time of getting `commit_ts`.
- `AVG_COMMIT_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `MAX_COMMIT_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.

- `AVG_RESOLVE_LOCK_TIME`: The average time for resolving lock conflicts occurred between transactions.
- `MAX_RESOLVE_LOCK_TIME`: The longest time for resolving lock conflicts occurred between transactions.
- `AVG_LOCAL_LATCH_WAIT_TIME`: The average waiting time of the local transaction.
- `MAX_LOCAL_LATCH_WAIT_TIME`: The maximum waiting time of the local transaction.
- `AVG_WRITE_KEYS`: The average count of written keys.
- `MAX_WRITE_KEYS`: The maximum count of written keys.
- `AVG_WRITE_SIZE`: The average amount of written data (in byte).
- `MAX_WRITE_SIZE`: The maximum amount of written data (in byte).
- `AVG_PREWRITE_REGIONS`: The average number of Regions involved in the prewrite phase.
- `MAX_PREWRITE_REGIONS`: The maximum number of Regions during the prewrite phase.
- `AVG_TXN_RETRY`: The average number of transaction retries.
- `MAX_TXN_RETRY`: The maximum number of transaction retries.
- `SUM_BACKOFF_TIMES`: The sum of retries when SQL statements of this category encounter errors that require a retry.
- `BACKOFF_TYPES`: All types of errors that require retries and the number of retries for each type. The format of the field is `type:number`. If there is more than one error type, each is separated by a comma, like `txnLock:2,pdRPC:1`.
- `AVG_AFFECTED_ROWS`: The average number of rows affected.
- `PREV_SAMPLE_TEXT`: When the current SQL statement is `COMMIT`, `PREV_SAMPLE_TEXT` is the previous statement to `COMMIT`. In this case, SQL statements are grouped by the digest and `prev_sample_text`. This means that `COMMIT` statements with different `prev_sample_text` are grouped to different rows. When the current SQL statement is not `COMMIT`, the `PREV_SAMPLE_TEXT` field is an empty string.

10.3.2.9.2 `statements_summary_evicted` fields description

- `BEGIN_TIME`: Records the starting time.
- `END_TIME`: Records the ending time.
- `EVICTED_COUNT`: The number of SQL categories that are evicted during the record period.

10.3.3 Identify Expensive Queries

TiDB allows you to identify expensive queries during SQL execution, so you can diagnose and improve the performance of SQL execution. Specifically, TiDB prints the information about statements whose execution time exceeds `tidb_expensive_query_time_threshold` (60 seconds by default) or memory usage exceeds `tidb_mem_quota_query` (1 GB by default) to the tidb-server log file ("tidb.log" by default).

Note:

The expensive query log differs from the slow query log in this way: TiDB prints statement information to the expensive query log **as soon as** the statement exceeds the threshold of resource usage (execution time or memory usage); while TiDB prints statement information to the slow query log **after** the statement execution.

10.3.3.1 Expensive query log example

```
[2020/02/05 15:32:25.096 +08:00] [WARN] [expensivequery.go:167] [
    ↪ expensive_query] [cost_time=60.008338935s] [wait_time=0s] [
    ↪ request_count=1] [total_keys=70] [process_keys=65] [num_cop_tasks=1]
    ↪ [process_avg_time=0s] [process_p90_time=0s] [process_max_time=0s] [
    ↪ process_max_addr=10.0.1.9:20160] [wait_avg_time=0.002s] [
    ↪ wait_p90_time=0.002s] [wait_max_time=0.002s] [wait_max_addr
    ↪ =10.0.1.9:20160] [stats=t:pseudo] [conn_id=60026] [user=root] [
    ↪ database=test] [table_ids="[122]"] [txn_start_ts=414420273735139329]
    ↪ [mem_max="1035 Bytes (1.0107421875 KB)"] [sql="insert into t select
    ↪ sleep(1) from t"]
```

10.3.3.2 Fields description

Basic fields:

- `cost_time`: The execution time of a statement when the log is printed.
- `stats`: The version of statistics used by the tables or indexes involved in a statement. If the value is `pseudo`, it means that there are no available statistics. In this case, you need to analyze the tables or indexes.
- `table_ids`: The IDs of the tables involved in a statement.
- `txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `sql`: The sql statement.

Memory usage related fields:

- `mem_max`: Memory usage of a statement when the log is printed. This field has two kinds of units to measure memory usage: byte and other readable and adaptable units (such as MB and GB).

User related fields:

- `user`: The name of the user who executes the statement.
- `conn_id`: The connection ID (session ID). For example, you can use the keyword `con:60026` to search for the log whose session ID is `60026`.
- `database`: The database where the statement is executed.

TiKV Coprocessor task related fields:

- `wait_time`: The total waiting time of all Coprocessor requests of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `request_count`: The number of Coprocessor requests that a statement sends.
- `total_keys`: The number of keys that Coprocessor has scanned.
- `processed_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `num_cop_tasks`: The number of Coprocessor requests that a statement sends.
- `process_avg_time`: The average execution time of Coprocessor tasks.
- `process_p90_time`: The P90 execution time of Coprocessor tasks.
- `process_max_time`: The maximum execution time of Coprocessor tasks.
- `process_max_addr`: The address of the Coprocessor task with the longest execution time.
- `wait_avg_time`: The average waiting time of Coprocessor tasks.
- `wait_p90_time`: The P90 waiting time of Coprocessor tasks.
- `wait_max_time`: The maximum waiting time of Coprocessor tasks.
- `wait_max_addr`: The address of the Coprocessor task with the longest waiting time.

10.3.4 Use PLAN REPLAYER to Save and Restore the On-Site Information of a Cluster

When you locate and troubleshoot the issues of a TiDB cluster, you often need to provide information on the system and the execution plan. To help you get the information and troubleshoot cluster issues in a more convenient and efficient way, the `PLAN REPLAYER` ↪ command is introduced in TiDB v5.3.0. This command enables you to easily save and restore the on-site information of a cluster, improves the efficiency of troubleshooting, and helps you more easily archive the issue for management.

The features of `PLAN REPLAYER` are as follows:

- Exports the information of a TiDB cluster at an on-site troubleshooting to a ZIP-formatted file for storage.
- Imports into a cluster the ZIP-formatted file exported from another TiDB cluster. This file contains the information of the latter TiDB cluster at an on-site troubleshooting.

10.3.4.1 Use `PLAN REPLAYER` to export cluster information

You can use `PLAN REPLAYER` to save the on-site information of a TiDB cluster. The export interface is as follows:

```
PLAN REPLAYER DUMP EXPLAIN [ANALYZE] sql-statement;
```

Based on `sql-statement`, TiDB sorts out and exports the following on-site information:

- TiDB version
- TiDB configuration
- TiDB session variables
- TiDB SQL bindings
- The table schema in `sql-statement`
- The statistics of the table in `sql-statement`
- The result of `EXPLAIN [ANALYZE] sql-statement`
- Some internal procudures of query optimization

> **Note:**
>
> `PLAN REPLAYER` **DOES NOT** export any table data.

10.3.4.1.1 Examples of exporting cluster information

```
use test;
create table t(a int, b int);
insert into t values(1,1), (2, 2), (3, 3);
analyze table t;

plan replayer dump explain select * from t;
```

`PLAN REPLAYER DUMP` packages the table information above into a `ZIP` file and returns the file identifier as the execution result.

> **Note:**
>
> The `ZIP` file is stored in a TiDB cluster for at most one hour. After one hour, TiDB will delete it.

```
MySQL [test]> plan replayer dump explain select * from t;
```

```
+-------------------------------------------------------------------+
| Dump_link                                                         |
+-------------------------------------------------------------------+
| replayer_JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip |
+-------------------------------------------------------------------+
1 row in set (0.015 sec)
```

Alternatively, you can use the session variable `tidb_last_plan_replayer_token` to obtain the result of the last `PLAN REPLAYER DUMP` execution.

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_Fdamsm3C7ZiPJ-LQqgVjkA==_1663304195885090000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

When there are multiple SQL statements, you can obtain the result of the `PLAN REPLAYER DUMP` execution using a file. The results of multiple SQL statements are separated by `;` in this file.

```
plan replayer dump explain 'sqls.txt';
```

```
Query OK, 0 rows affected (0.03 sec)
```

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_LEDKg8sb-K0u24QesiH8ig==_1663226556509182000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Because the file cannot be downloaded on MySQL Client, you need to use the TiDB HTTP interface and the file identifier to download the file:

```
http://${tidb-server-ip}:${tidb-server-status-port}/plan_replayer/dump/${
    ↪ file_token}
```

`${tidb-server-ip}:${tidb-server-status-port}` is the address of any TiDB server in the cluster. For example:

```
curl http://127.0.0.1:10080/plan_replayer/dump/
    ↪ replayer_JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip >
    ↪ plan_replayer.zip
```

10.3.4.2 Use PLAN REPLAYER to import cluster information

> **Warning:**
>
> When you import the on-site information of a TiDB cluster to another cluster, the TiDB session variables, SQL bindings, table schemas and statistics of the latter cluster are modified.

With an existing ZIP file exported using PLAN REPLAYER, you can use the PLAN REPLAYER import interface to restore the on-site information of a cluster to any other TiDB cluster. The syntax is as follows:

```
PLAN REPLAYER LOAD 'file_name';
```

In the statement above, file_name is the name of the ZIP file to be exported.

For example:

```
PLAN REPLAYER LOAD 'plan_replayer.zip';
```

After the cluster information is imported, the TiDB cluster is loaded with the required table schema, statistics and other information that affects the construction of the execution plan. You can view the execution plan and verify statistics in the following way:

```
mysql> desc t;
+-------+---------+------+------+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+------+---------+-------+
| a     | int(11) | YES |     | NULL    |       |
| b     | int(11) | YES |     | NULL    |       |
+-------+---------+------+------+---------+-------+
2 rows in set (0.01 sec)

mysql> explain select * from t where a = 1 or b =1;
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| id                   | estRows | task    | access object | operator info
    ↪                  |
```

```
+--
    ↪ ----------------------+---------+-----------+--------------+-----------------
    ↪
| TableReader_7         | 0.01    | root      |              | data:Selection_6
    ↪                |
|  ─Selection_6         | 0.01    | cop[tikv] |              | or(eq(test.t.a,
    ↪ 1), eq(test.t.b, 1)) |
|    ─TableFullScan_5   | 6.00    | cop[tikv] | table:t      | keep order:false,
    ↪  stats:pseudo  |
+--
    ↪ ----------------------+---------+-----------+--------------+-----------------
    ↪
3 rows in set (0.00 sec)

mysql> show stats_meta;
+--
    ↪ -------+-----------+---------------+--------------------+-------------+-----
    ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count |
    ↪ Row_count |
+--
    ↪ -------+-----------+---------------+--------------------+-------------+-----
    ↪
| test    | t         |               | 2022-08-26 15:52:07 |        3 |
    ↪        6 |
+--
    ↪ -------+-----------+---------------+--------------------+-------------+-----
    ↪
1 row in set (0.04 sec)
```

After the scene is loaded and restored, you can diagnose and improve the execution plan for the cluster.

10.3.4.3 Use `PLAN REPLAYER CAPTURE` to capture target plans

When you locate the execution plan of TiDB in some scenarios, the target SQL statement and the target execution plan might only appear occasionally in the query, so you cannot directly capture the statement and the plan using `PLAN REPLAYER`. In such cases, you can use `PLAN REPLAYER CAPTURE` to help you capture the optimizer information of the target SQL statement and the target plan.

`PLAN REPLAYER CAPTURE` has the following main features:

- Registers the target SQL statement and the digest of the target execution plan in the TiDB cluster in advance, and starts matching the target query.

- When the target query is matched successfully, directly captures its optimizer-related information and exports it as a ZIP file.
- For each matched SQL and execution plan, the information is only captured once.
- Displays the ongoing matching tasks and generated files through the system table.
- Periodically cleans up historical files.

10.3.4.3.1 Enable `PLAN REPLAYER CAPTURE`

`PLAN REPLAYER CAPTURE` is controlled by the system variable `tidb_enable_plan_replayer_capture` ↪ . To enable `PLAN REPLAYER CAPTURE`, set the value of the system variable to `ON`.

10.3.4.3.2 Use `PLAN REPLAYER CAPTURE`

You can register the digest of the target SQL statement and execution plan in the TiDB cluster using the following statement:

```
PLAN REPLAYER CAPTURE 'sql_digest' 'plan_digest';
```

If the target SQL statement has multiple execution plans and you want to capture all execution plans, you can register all the execution plans at once using the following statement:

```
PLAN REPLAYER CAPTURE 'sql_digest' '*';
```

10.3.4.3.3 View the capture tasks

You can view the ongoing capture tasks of `PLAN REPLAYER CAPTURE` in the TiDB cluster using the following statement:

```
mysql> PLAN REPLAYER CAPTURE 'example_sql' 'example_plan';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
+------------+-------------+--------------------+
| sql_digest | plan_digest | update_time        |
+------------+-------------+--------------------+
| example_sql | example_plan | 2023-01-28 11:58:22 |
+------------+-------------+--------------------+
1 row in set (0.01 sec)
```

10.3.4.3.4 View the capture results

After `PLAN REPLAYER CAPTURE` successfully captures the result, you can view the token used for file download using the following SQL statement:

```
mysql> SELECT * FROM mysql.plan_replayer_status;
```

```
+--
    ↪ ------------------------------------------------------------------+--------------
    ↪
| sql_digest                                                          | plan_digest
    ↪                                                                 | origin_sql | token
    ↪                                                                 | update_time      |
    ↪ fail_reason | instance    |
+--
    ↪ ------------------------------------------------------------------+--------------

    ↪ replayer_RZcRHJB7BaCccxFfOIAhWg==_1668746293578282450.zip |
    ↪ 2022-11-18 12:38:13 | NULL | 172.16.4.4:4022 |
+--
    ↪ ------------------------------------------------------------------+--------------
    ↪
3 rows in set (0.00 sec)
```

The method of downloading the file of `PLAN REPLAYER CAPTURE` is the same as that of `PLAN REPLAYER`. For details, see Examples of exporting cluster information.

> **Note:**
>
> The result file of `PLAN REPLAYER CAPTURE` is kept in the TiDB cluster for up to one week. After one week, TiDB deletes the file.

10.3.4.3.5 Remove the capture tasks

If a capture task is no longer needed, you can remove it using the `PLAN REPLAYER ↪ CAPTURE REMOVE` statement. For example:

```
mysql> PLAN REPLAYER CAPTURE '077
    ↪ a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0' '4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce';
```

```
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
| sql_digest                                                       | plan_digest
    ↪                                                  | update_time       |
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
| 077a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0 | 4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce |
    ↪ 2024-05-21 11:26:10 |
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
1 row in set (0.01 sec)

mysql> PLAN REPLAYER CAPTURE REMOVE '077
    ↪ a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0' '4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
Empty set (0.01 sec)
```

10.3.4.4 Use `PLAN REPLAYER CONTINUOUS CAPTURE`

After `PLAN REPLAYER CONTINUOUS CAPTURE` is enabled, TiDB asynchronously records the applications' SQL statements with the `PLAN REPLAYER` method according to their `SQL ↪ DIGEST` and `PLAN DIGEST`. For SQL statements and execution plans that share the same DIGEST, `PLAN REPLAYER CONTINUOUS CAPTURE` does not record them repeatedly.

10.3.4.4.1 Enable `PLAN REPLAYER CONTINUOUS CAPTURE`

`PLAN REPLAYER CONTINUOUS CAPTURE` is controlled by the system variable `tidb_enable_plan_replay ↪` . To enable `PLAN REPLAYER CONTINUOUS CAPTURE`, set the value of the system variable to `ON`.

10.3.4.4.2 View the capture results

The method of viewing the capture results of `PLAN REPLAYER CONTINUOUS CAPTURE` is the same as that of Viewing the capture results of `PLAN REPLAYER CAPTURE`.

10.3.5 Understanding Stale Read and safe-ts in TiKV

In this guide, you can learn about Stale Read and safe-ts in TiKV and how to diagnose common issues related to Stale Read.

10.3.5.1 Overview of Stale Read and safe-ts

Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. In TiKV, Stale Read relies on safe-ts. If a read request on a Region peer has a timestamp (ts) that is less than or equal to the Region's safe-ts, TiDB can safely read the data from the peer. TiKV implements this safety guarantee by ensuring that safe-ts is always less than or equal to resolved-ts.

10.3.5.2 Understand safe-ts and resolved-ts

This section explains the concepts and maintenance of safe-ts and resolved-ts.

10.3.5.2.1 What is safe-ts?

The safe-ts is a timestamp that each peer in a Region maintains. It ensures that all transactions with a timestamp less than this value have been applied locally, which enables local Stale Read.

10.3.5.2.2 What is resolved-ts?

The resolved-ts is a timestamp that guarantees all transactions with a timestamp less than this value have been applied by the leader. Unlike safe-ts, which is a peer concept, resolved-ts is only maintained by the Region leader. Followers might have a smaller apply index than the leader, so resolved-ts cannot be directly treated as safe-ts in followers.

10.3.5.2.3 The maintenance of safe-ts

The `RegionReadProgress` module maintains safe-ts. The Region leader maintains resolved-ts and periodically sends its resolved-ts, the minimum required apply index (which validates this resolved-ts), and the Region itself to the `RegionReadProgerss` modules of all replicas via the CheckLeader RPC.

When a peer applies data, it updates the apply index and checks if any pending resolved-ts can become the new safe-ts.

10.3.5.2.4 The maintenance of resolved-ts

The Region leader uses a resolver to manage resolved-ts. This resolver tracks locks in the LOCK CF (Column Family) by receiving change logs when Raft applies. When initialized, the resolver scans the entire Region to track locks.

10.3.5.3 Diagnose Stale Read issues

This section introduces how to diagnose Stale Read issues using Grafana, `tikv-ctl`, and logs.

10.3.5.3.1 Identify issues

In the Grafana > TiDB dashboard > **KV Request** dashboard, the following panels show the hit rate, OPS, and traffic of Stale Read:

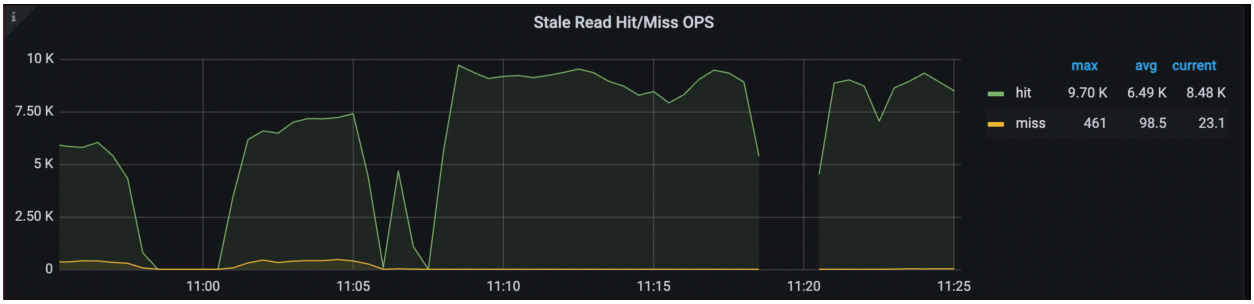

Figure 300: Stale Read Hit/Miss OPS

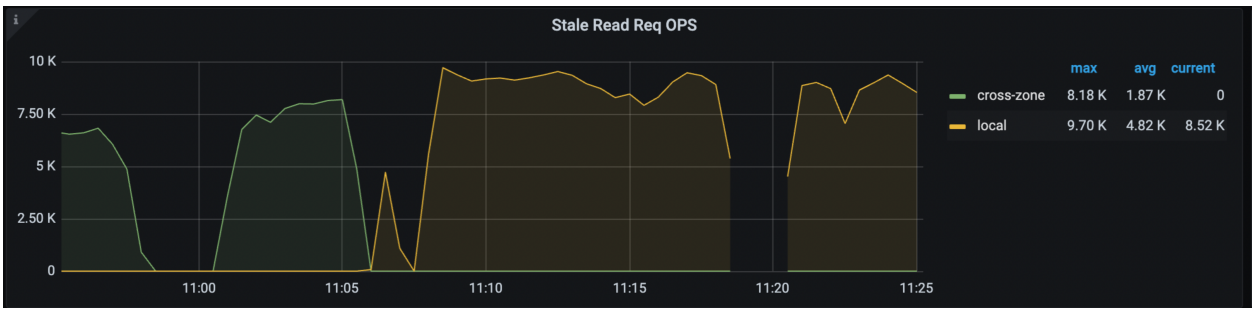

Figure 301: Stale Read Req OPS

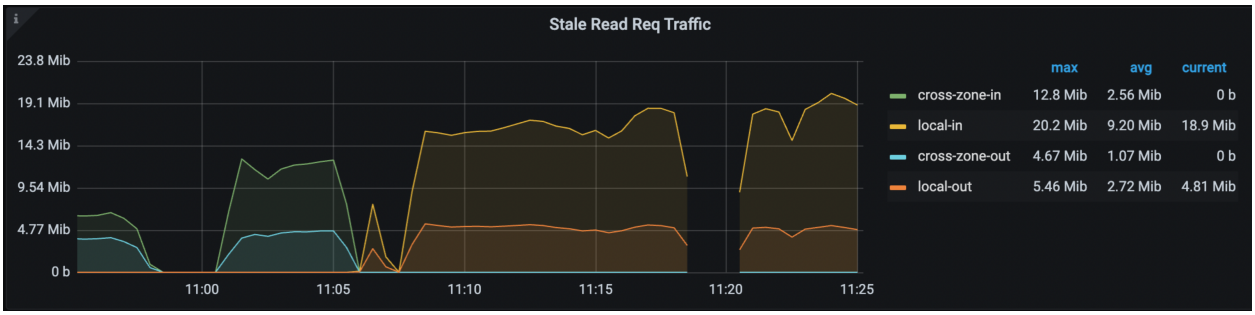

Figure 302: Stale Read Req Traffic

For more information about the preceding metrics, see TiDB monitoring metrics.

When Stale Read issues occur, you might notice changes in the preceding metrics. The most direct indicator is a WARN log from TiDB, which reports `DataIsNotReady` with a Region ID and the `safe-ts` it encounters.

10.3.5.3.2 Common causes

The most common causes that can impact the effectiveness of Stale Read are as follows:

- Transactions that take long time to commit.
- Transactions live too long before they commit.
- Delays in pushing the information of CheckLeader from the leader to the follower.

10.3.5.3.3 Use Grafana to diagnose

In the **TiKV-Details > Resolved-TS** dashboard, you can identify the Region with the smallest resolved-ts and safe-ts for each TiKV. If these timestamps are significantly behind real-time, you need to check the details of these Regions using `tikv-ctl`.

10.3.5.3.4 Use `tikv-ctl` to diagnose

`tikv-ctl` provides up-to-date details of the resolver and `RegionReadProgress`. For more details, see Get the state of a Region's `RegionReadProgress`.

The following is an example:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 14 --log --
    ↪ min-start-ts 0
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 0,
    applied_index: 92,
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
    pending back item (latest) applied index: 0,
    paused: false,
Resolver:
    exist: true,
    resolved_ts: 0,
    tracked index: 92,
    number of locks: 0,
    number of transactions: 0,
    stopped: false,
```

The preceding output helps you determine:

- Whether locks are blocking resolved-ts.
- Whether the apply index is too small to update safe-ts.
- Whether the leader is sending a sufficiently updated resolved-ts when a follower peer exists.

10.3.5.3.5 Use logs to diagnose

Every 10 seconds, TiKV checks the following metrics:

- The Region leader whose resolved-ts is the minimal
- The Region follower whose safe-ts is the minimal
- The Region follower whose resolved-ts is the minimal

If any of these timestamps is abnormally small, TiKV prints a log.

These logs are especially useful when you want to diagnose a historical problem that is no longer present.

The following shows an example of the logs:

```
[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:505] ["the max gap of
   ↪ leader resolved-ts is large"] [last_resolve_attempt="Some(LastAttempt
   ↪  { success: false, ts: TimeStamp(443888082736381953), reason: \"lock
   ↪ \", lock: Some(748000000000000625F728000000002512B5C) })"] [
   ↪ duration_to_last_update_safe_ts=10648ms] [min_memory_lock=None] [
   ↪ txn_num=0] [lock_num=0] [min_lock=None] [safe_ts=443888117326544897]
   ↪ [gap=110705ms] [region_id=291]

[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:526] ["the max gap of
   ↪ follower safe-ts is large"] [oldest_candidate=None] [latest_candidate
   ↪ =None] [applied_index=3276] [duration_to_last_consume_leader=11460ms]
   ↪  [resolved_ts=443888117117353985] [safe_ts=443888117117353985] [gap
   ↪ =111503ms] [region_id=273]

[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:547] ["the max gap of
   ↪ follower resolved-ts is large; it's the same region that has the min
   ↪ safe-ts"]
```

10.3.5.4 Troubleshooting tips

10.3.5.4.1 Handle slow transaction commit

A transaction that takes a long time to commit is often a large transaction. The prewrite phase of this slow transaction leaves some locks, but it takes too long before the commit phase clean the locks. To troubleshoot this issue, you can try to identify the transaction to which the locks belong and try to pinpoint the reason they exist, such as using logs.

The following list some actions you can take:

- Specify the `--log` option in the `tikv-ctl` command and check TiKV logs to find the specific locks with their start_ts.
- Search the start_ts in both TiDB and TiKV logs to identify issues with the transaction.

  If a query takes over 60 seconds, an `expensive_query` log is printed with the SQL statement. You can use the start_ts value to match the log. The following is an example:

```
[2023/07/17 19:32:09.403 +08:00] [WARN] [expensivequery.go:145] [
    ↪ expensive_query] [cost_time=60.025022732s] [cop_time=0.00346666s]
    ↪  [process_time=8.358409508s] [wait_time=0.013582596s] [
    ↪ request_count=278] [total_keys=9943616] [process_keys=9943360] [
    ↪ num_cop_tasks=278] [process_avg_time=0.030066221s] [
    ↪ process_p90_time=0.045296042s] [process_max_time=0.052828934s] [
    ↪ process_max_addr=192.168.31.244:20160] [wait_avg_time=0.000048858
    ↪ s] [wait_p90_time=0.00006057s] [wait_max_time=0.00040991s] [
    ↪ wait_max_addr=192.168.31.244:20160] [stats=t:442916666913587201]
    ↪ [conn=2826881778407440457] [user=root] [database=test] [table_ids
    ↪ ="[100]"] [**txn_start_ts**=442916790435840001] [mem_max
    ↪ ="2514229289 Bytes (2.34 GB)"] [sql="update t set b = b + 1"]
```

- Use the `CLUSTER_TIDB_TRX` table to find active transactions if you cannot get enough information about the locks from logs.
- Execute `SHOW PROCESSLIST` to view the current sessions connected to the same TiDB server and their time spent on the current statement. But it does not show start_ts.

If the locks exist due to ongoing large transactions, consider modifying your application logic as these locks can hinder the progress of resolve-ts.

If the locks do not belong to any ongoing transactions, it might be due to a coordinator (TiDB) crashing after it prewrites the locks. In this case, TiDB will automatically resolve the locks. No action is required unless the problem persists.

10.3.5.4.2 Handle long-lived transactions

Transactions that remain active for a long time could possibly block the advance of resolved-ts, even if they eventually commit quickly. This is because it is the start-ts of these long-lived transactions that are used to calculate the resolved-ts.

To address this issue:

- Identify the Transaction: Begin by pinpointing the transaction associated with the locks. It is crucial to understand the reason behind their existence. Leveraging logs can be particularly helpful.
- Examine Application Logic: If the prolonged transaction duration is a result of your application's logic, consider revising it to prevent such occurrences.
- Address Slow Queries: If the transaction's duration is extended due to slow queries, prioritize resolving these queries to alleviate the issue.

10.3.5.4.3 Address CheckLeader issues

To address CheckLeader issues, you can check the network and the **Check Leader Duration** metric in **TiKV-Details > Resolved-TS** dashboard.

10.3.5.5 Example

If you observe an increasing miss rate of **Stale Read OPS** as follows:

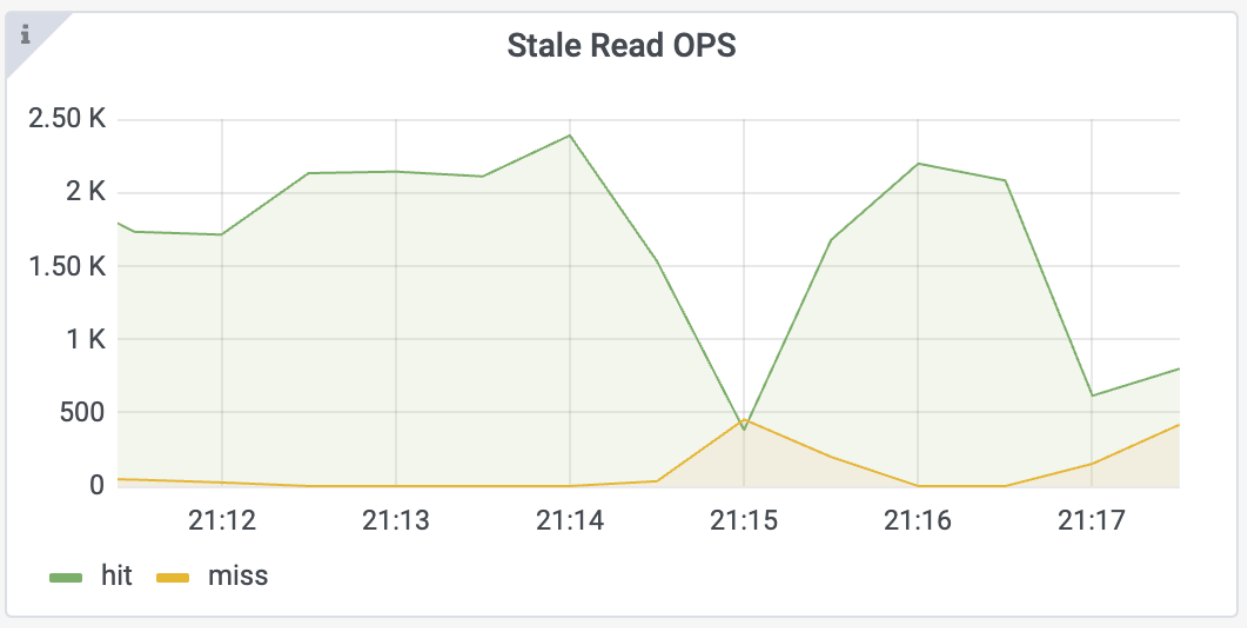

Figure 303: Example: Stale Read OPS

You can first check the **Max Resolved TS gap** and **Min Resolved TS Region** metrics in the **TiKV-Details > Resolved-TS** dashboard:

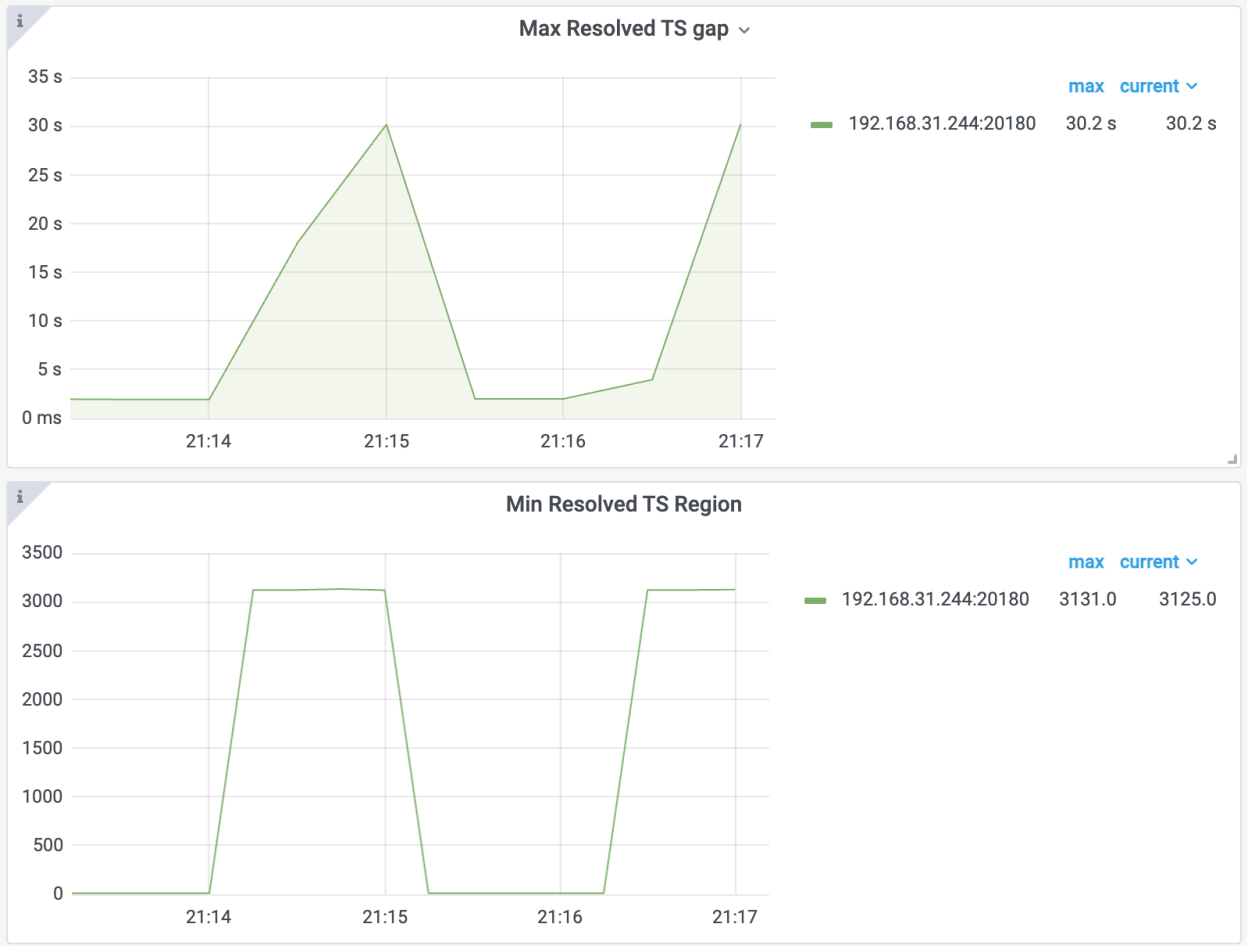

Figure 304: Example: Max Resolved TS gap

From the preceding metrics, you can find that Region `3121` and some other Regions have not updated their resolved-ts in time.

To get more details about the state of Region `3121`, you can run the following command:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 3121 --log
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 442918444145049601,
    applied_index: 2477,
    read_state.ts: 442918444145049601,
    read_state.apply_index: 1532,
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
```

```
    pending back item (latest) applied index: 0,
    paused: false,
    discarding: false,
Resolver:
    exist: true,
    resolved_ts: 442918444145049601,
    tracked index: 2477,
    number of locks: 480000,
    number of transactions: 1,
    stopped: false,
```

A notable observation here is that the `applied_index` equals to the `tracked index` in resolver. Therefore, the resolver appears to be the root of this issue. You can also see that there is 1 transaction that leaves 480000 locks in this Region, which might be the cause.

To get the exact transaction and the keys of some of the locks, you can check TiKV logs and grep `locks with`. The output is as follows:

```
[2023/07/17 21:16:44.257 +08:00] [INFO] [resolver.rs:213] ["locks with the
    ↪ minimum start_ts in resolver"] [keys="[74800000000000006
    ↪ A5F7280000000000405F6, ... , 748000000000000006A5F72800000000000EFF6,
    ↪ 748000000000000006A5F7280000000000721D9, 74800000000000006
    ↪ A5F72800000000002F691]"] [start_ts=442918429687808001] [region_id
    ↪ =3121]
```

From the TiKV log, you can get the start_ts of the transaction, that is `442918429687808001` ↪ . To get more information about the statement and transaction, you can grep this timestamp in TiDB logs. The output is as follows:

```
[2023/07/17 21:16:18.287 +08:00] [INFO] [2pc.go:685] ["[BIG_TXN]"] [session
    ↪ =2826881778407440457] ["key sample"=74800000000000006
    ↪ a5f728000000000000000] [size=319967171] [keys=10000000] [puts
    ↪ =10000000] [dels=0] [locks=0] [checks=0] [txnStartTS
    ↪ =442918429687808001]

[2023/07/17 21:16:22.703 +08:00] [WARN] [expensivequery.go:145] [
    ↪ expensive_query] [cost_time=60.047172498s] [cop_time=0.004575113s] [
    ↪ process_time=15.356963423s] [wait_time=0.017093811s] [request_count
    ↪ =397] [total_keys=20000398] [process_keys=10000000] [num_cop_tasks
    ↪ =397] [process_avg_time=0.038682527s] [process_p90_time=0.082608262s]
    ↪  [process_max_time=0.116321331s] [process_max_addr
    ↪ =192.168.31.244:20160] [wait_avg_time=0.000043057s] [wait_p90_time
    ↪ =0.00004007s] [wait_max_time=0.00075014s] [wait_max_addr
    ↪ =192.168.31.244:20160] [stats=t:442918428521267201] [conn
    ↪ =2826881778407440457] [user=root] [database=test] [table_ids="[106]"]
    ↪  [txn_start_ts=442918429687808001] [mem_max="2513773983 Bytes (2.34
    ↪ GB)"] [sql="update t set b = b + 1"]
```

Then, you can basically locate the statement that caused the problem. To further check it, you can execute the `SHOW PROCESSLIST` statement. The output is as follows:

```
+--
    ↪ ------------------+------+--------------------+--------+---------+------+-----
    ↪
| Id                  | User | Host               | db     | Command | Time |
    ↪ State   | Info                    |
+--
    ↪ ------------------+------+--------------------+--------+---------+------+-----
    ↪
| 2826881778407440457 | root | 192.168.31.43:58641 | test | Query | 48 |
    ↪ autocommit | update t set b = b + 1 |
| 2826881778407440613 | root | 127.0.0.1:45952 | test | Execute | 0 |
    ↪ autocommit | select * from t where a=? |
| 2826881778407440619 | root | 192.168.31.43:60428 | <null> | Query | 0 |
    ↪ autocommit | show processlist |
+--
    ↪ ------------------+------+--------------------+--------+---------+------+-----
    ↪
```

The output shows that someone is executing an unexpected `UPDATE` statement (`update t set b = b + 1`), which results in a large transaction and hinders Stale Read.

To resolve this issue, you can stop the application that is running this `UPDATE` statement.

10.4 Support Resources

If you encounter a problem when you use TiDB, you can reach out for support from PingCAP or the TiDB community via the following methods:

- Get support from PingCAP for TiDB Enterprise Edition:
    - Submit a request
- Get support from PingCAP for TiDB Cloud:
    - Report an issue directly from the TiDB Cloud console
    - Documentation for TiDB Cloud support
- Seek help from the TiDB community:
    - TiDB Community
    - Discord channels

    - Slack channels: #everyone (English), #tidb-japan (Japanese)
    - Stack Overflow (questions tagged with #tidb)

- Report a bug

    - Submit an issue on GitHub

- Learn TiDB's implementation and design

    - TiDB development guide
    - Discussions on GitHub

11 Performance Tuning

11.1 Tuning Guide

11.1.1 TiDB Performance Tuning Overview

This document introduces the basic concepts of performance tuning, such as user response time, throughput, and database time, and also provides a general process for performance tuning.

11.1.1.1 User response time and database time

11.1.1.1.1 User response time

User response time indicates how long an application takes to return the results of a request to users. As you can see from the following sequential timing diagram, the time of a typical user request contains the following:

- The network latency between the user and the application
- The processing time of the application
- The network latency during the interaction between the application and the database
- The service time of the database

The user response time is affected by various subsystems on the request chain, such as network latency and bandwidth, number and request types of concurrent users, and resource usage of server CPU and I/O. To optimize the entire system effectively, you need to first identify the bottlenecks in user response time.

To get a total user response time within a specified time range (`ΔT`), you can use the following formula:

Total user response time in `ΔT` = Average TPS (Transactions Per Second) x Average user response time x `ΔT`.

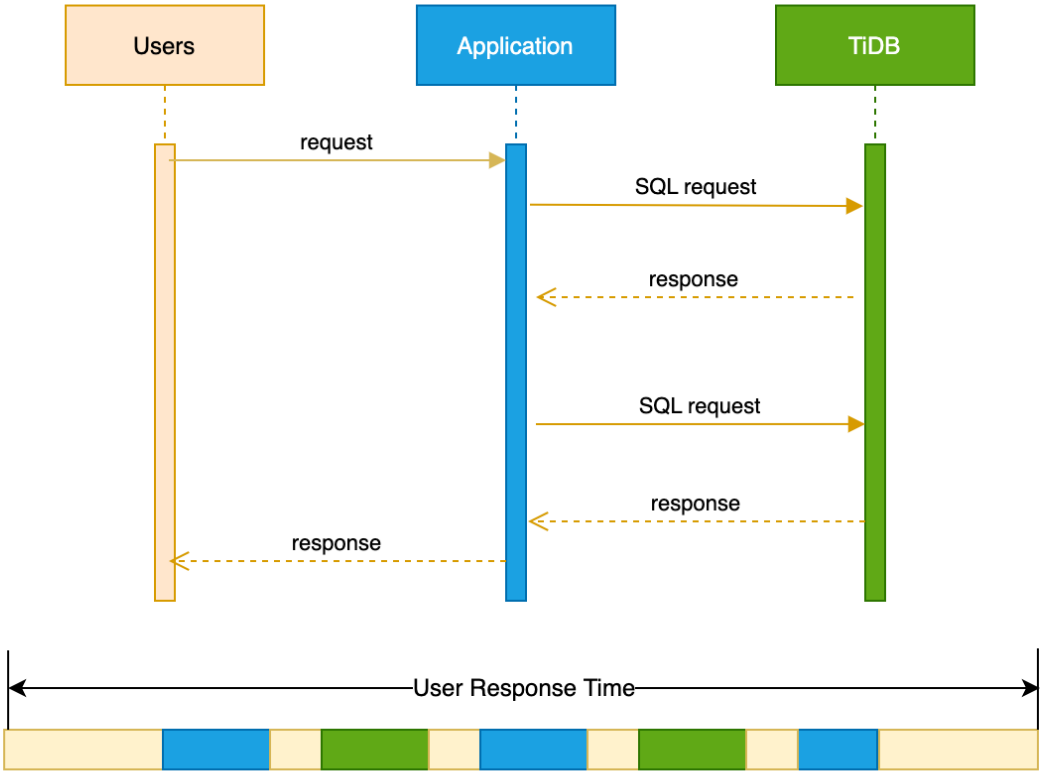

Figure 305: user_response_time

11.1.1.1.2 Database time

Database time indicates the total service time provided by a database. The database time in ΔT is the sum of the time that a database takes to process all application requests concurrently.

To get the database time, you can use any of the following methods:

- Method 1: Multiply the average query latency by QPS and by ΔT, that is, `DB Time in ΔT = QPS × avg latency × ΔT`
- Method 2: Multiply the average number of active sessions by ΔT, that is, `DB Time in ΔT = avg active connections × ΔT`
- Method 3: Calculate the time based on the TiDB internal Prometheus metric `tidb_server_tokens`, that is. `ΔT DB Time = rate(tidb_server_tokens)× ΔT`

11.1.1.2 Relationship between user response time and system throughput

User response time consists of service time, queuing time, and concurrent waiting time to complete a user request.

```
User Response time = Service time + Queuing delay + Coherency delay
```

- Service time: the time a system consumes on certain resources when processing a request, for example, the CPU time that a database consumes to complete a SQL request.
- Queuing delay: the time a system waits in a queue for service of certain resources when processing a request.
- Coherency delay: the time a system communicates and collaborates with other concurrent tasks, so that it can access shared resources when processing a request.

System throughput indicates the number of requests that can be completed by a system per second. User response time and throughput are usually inverse of each other. When the throughput increases, the system resource utilization and the queuing latency for a requested service increase accordingly. Once resource utilization exceeds a certain inflection point, the queuing latency will increase dramatically.

For example, for a database system running OLTP loads, after its CPU utilization exceeds 65%, the CPU queueing scheduling latency increases significantly. This is because concurrent requests of a system are not completely independent, which means that these requests can collaborate and compete for shared resources. For example, requests from different users might perform mutually exclusive locking operations on the same data. When the resource utilization increases, the queuing and scheduling latency increases too, which causes that the shared resources cannot be released in time and in turn prolongs the waiting time for shared resources by other tasks.

11.1.1.3 Performance tuning process

The performance tuning process consists of the following 6 steps:

1. Define a tuning objective.
2. Establish a performance baseline.
3. Identify bottlenecks in user response time.
4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution.
5. Implement tuning solutions.
6. Evaluate tuning results.

To achieve the tuning objective of a performance tuning project, you usually need to repeat Step 2 to Step 6 multiple times.

11.1.1.3.1 Step 1. Define a tuning objective

For different types of systems, tuning objectives are different too. For example, for a financial core OLTP system, the tuning objective might be to reduce the long-tail latency of

transactions; for a financial settlement system, the tuning objective might be to make better use of hardware resources and reduce the time of batch settlement tasks.

A good tuning objective should be easily quantifiable. For example:

- Good tuning objective: The p99 latency for transfer transactions needs to be less than 200 ms during peak business hours of 9 am to 10 am.
- Poor tuning objective: The system is too slow to respond so it needs to be optimized.

Defining a clear tuning objective helps guide the subsequent performance tuning steps.

11.1.1.3.2 Step 2. Establish a performance baseline

To tune performance efficiently, you need to capture the current performance data to establish a performance baseline. The performance data to be captured typically includes the following:

- Mean and long-tail values of user response time, and throughput of your application
- Database performance data such as database time, query latency, and QPS

  TiDB measures and stores performance data thoroughly in different dimensions, such as slow query logs, Top SQL, Continuous Performance Profiling, and traffic visualizer. In addition, you can perform historical backtracking and comparison of the timing metrics data stored in Prometheus.
- Resource utilization, including resources such as CPU, IO, and network
- Configuration information, such as application configurations, database configurations, and operating system configurations

11.1.1.3.3 Step 3. Identify bottlenecks in user response time

Identify or speculate on bottlenecks in user response times based on data from the performance baseline.

Applications usually do not measure and record the full chain of user requests, so you cannot effectively break down user response time from top to bottom through the application.

In contrast, databases have a complete record of performance metrics such as query latency and throughput. Based on database time, you can determine if the bottleneck in user response time is in a database.

- If the bottleneck is not in databases, you need to rely on the resource utilization collected outside databases or profile the application to identify the bottleneck outside databases. Common scenarios include insufficient resources of an application or proxy server, and insufficient usage of hardware resources caused by serial points in an application.

- If bottlenecks are in databases, you can analyze and diagnose the database performances using comprehensive tuning tools. Common scenarios include the presence of slow SQL, unreasonable usage of a database by an application, and the presence of read and write hotspots in databases.

For more information about the analysis and diagnostic methods and tools, see Performance Analysis and Tuning.

11.1.1.3.4 Step 4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution

After identifying the bottleneck of a system through performance analysis, you can propose a tuning solution that is cost-effective, has low risks, and provides the maximum benefit based on the actual situation.

According to Amdahl's Law, the maximum gain from performance tuning depends on the percentage of the optimized part in the overall system. Therefore, you need to identify the system bottlenecks and the corresponding percentage based on the performance data, and then predict the gains after the bottleneck is resolved or optimized.

Note that even if a solution can bring the greatest potential benefits by tunning the largest bottleneck, you still need to evaluate the risks and costs of this solution. For example:

- The most straightforward tuning objective solution for a resource-overloaded system is to expand its capacity, but in practice, the expansion solution might be too costly to be adopted.
- When a slow query in a business module causes a slow response of the entire module, upgrading to a new version of the database can solve the slow query issue, but it might also affect modules that did not have this issue. Therefore, this solution might have a potentially high risk. A low-risk solution is to skip the database version upgrade and rewrite the existing slow queries for the current database version.

11.1.1.3.5 Step 5. Implement tuning solutions

Considering the benefits, risks, and costs, choose one or more tuning solutions for implementation. In the implementation process, you need to make thorough preparation for changes to the production system and record the changes in detail.

To mitigate risks and validate the benefits of a tuning solution, it is recommended that you perform validation and complete regression of changes in both test and staging environments. For example, if the selected tuning solution of a slow query is to create a new index to optimize the query access path, you need to ensure that the new index does not introduce any obvious write hotspots to the existing data insertion workload and slows down other modules.

11.1.1.3.6 Step 6. Evaluate tuning results

After applying the tuning solution, you need to evaluate the results:

- If the tuning objective is reached, the entire tuning project is completed successfully.
- If the tuning objective is not reached, you need to repeat Step 2 to Step 6 in this document until the tuning objective is reached.

After reaching your tuning objectives, you might need to further plan your system capacity to meet your business growth.

11.1.2 Performance Analysis and Tuning

This document describes a tuning approach by database time, and illustrates how to use the TiDB Performance Overview dashboard for performance analysis and tuning.

With the methods described in this document, you can analyze user response time and database time from a global and top-down perspective, to confirm whether the bottleneck in user response time is caused by database issues. If the bottleneck is in the database, you can use the database time overview and SQL latency breakdowns to identify the bottleneck and tune performance.

11.1.2.1 Performance tuning based on database time

TiDB is constantly measuring and collecting SQL processing paths and database time. Therefore, it is easy to identify database performance bottlenecks in TiDB. Based on database time metrics, you can achieve the following two goals even without data on user response time:

- Determine whether the bottleneck is in TiDB by comparing the average SQL processing latency with the idle time of a TiDB connection in a transaction.
- If the bottleneck is in TiDB, further identify the exact module in the distributed system based on database time overview, color-based performance data, key metrics, resource utilization, and top-down latency breakdowns.

11.1.2.1.1 Is TiDB the bottleneck?

- If the average idle time of TiDB connections in transactions is higher than the average SQL processing latency, the database is not to blame for the transaction latency of applications. The database time takes only a small part of the user response time, indicating that the bottleneck is outside the database.

  In this case, check the external components of the database. For example, determine whether there are sufficient hardware resources in the application server, and whether the network latency from the application to the database is excessively high.

- If the average SQL processing latency is higher than the average idle time of TiDB connections in transactions, the bottleneck in transactions is in TiDB, and the database time takes a large percentage of the user response time.

11.1.2.1.2 If the bottleneck is in TiDB, how to identify it?

The following figure shows a typical SQL process. You can see that most SQL processing paths are covered in TiDB performance metrics. The database time is broken down into different dimensions, which are colored accordingly. You can quickly understand the workload characteristics and catch the bottlenecks inside the database if any.

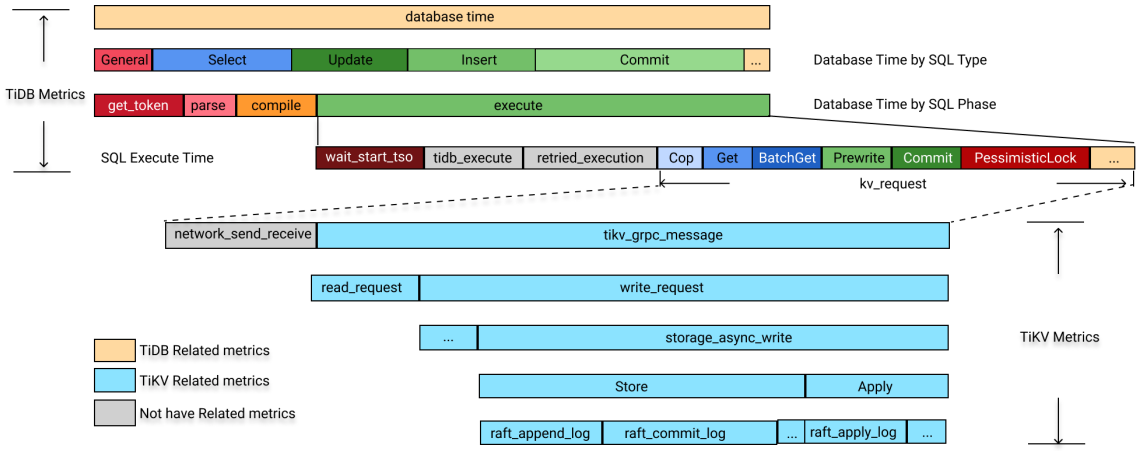

Figure 306: database time decomposition chart

Database time is the sum of all SQL processing time. A breakdown of the database time into the following three dimensions helps you quickly identify bottlenecks in TiDB:

- By SQL processing type: Determine which type of SQL statements consumes the most database time. The formula is:

  ```
  DB Time = Select Time + Insert Time + Update Time + Delete Time +
  ↪ Commit Time + ...
  ```

- By the 4 steps of SQL processing (get_token/parse/compile/execute): Determine which step consumes the most time. The formula is:

  ```
  DB Time = Get Token Time + Parse Time + Compile Time + Execute Time
  ```

- By executor time, TSO wait time, KV request time, and execution retry time: Determine which execution step constitutes the bottleneck. The formula is:

  ```
  Execute Time ~= TiDB Executor Time + KV Request Time + PD TSO Wait Time
  ↪  + Retried execution time
  ```

11.1.2.2 Performance analysis and tuning using the Performance Overview dashboard

This section describes how to perform performance analysis and tuning based on database time using the Performance Overview dashboard in Grafana.

The Performance Overview dashboard orchestrates the metrics of TiDB, PD, and TiKV, and presents each of them in the following sections:

- Database time and SQL execution time overview: Color-coded SQL types, database time by SQL execution phase, and database time of different requests help you quickly identify database workload characteristics and performance bottlenecks.
- Key metrics and resource utilization: Contains database QPS, connection information, request command types between the applications and the database, database internal TSO and KV request OPS, and TiDB/TiKV resource usage.
- Top-down latency breakdown: Contains a comparison of query latency and connection idle time, breakdown of query latency, latency of TSO requests and KV requests in SQL execution, and breakdown of TiKV internal write latency.

11.1.2.2.1 Database time and SQL execution time overview

The database time metric is the sum of the latency that TiDB processes SQL per second, which is also the total time that TiDB concurrently processes application SQL requests per second (equal to the number of active connections).

The Performance Overview dashboard provides the following three stacked area graphs. They help you understand database workload profile and quickly identify the bottleneck causes in terms of statements, sql phase, and TiKV or PD request type during SQL execution.

- Database Time By SQL Type
- Database Time By SQL Phase
- SQL Execute Time Overview

Tune by color

The diagrams of database time breakdown and execution time overview present both expected and unexpected time consumption intuitively. Therefore, you can quickly identify performance bottleneck and learn the workload profile. Green and blue areas stand for normal time consumption and requests. If non-green or non-blue areas occupy a significant proportion in these two diagrams, the database time distribution is inappropriate.

- Database Time By SQL Type:
    - Blue: `Select` statement
    - Green: `Update`, `Insert`, `Commit` and other DML statements
    - Red: General SQL types, including `StmtPrepare`, `StmtReset`, `StmtFetch`, and `StmtClose`

- Database Time By SQL Phase: The SQL execution phase is in green and other phases are in red on general. If non-green areas are large, it means much database time is consumed in other phases than the execution phase and further cause analysis is required. A common scenario is that the compile phase shown in orange takes a large area due to unavailability of prepared plan cache.

- SQL Execute Time Overview: Green metrics stand for common KV write requests (such as `Prewrite` and `Commit`), blue metrics stand for common KV read requests (such as Cop and Get), purple metrics stand for TiFlash MPP requests, and metrics in other colors stand for unexpected situations which you need to pay attention. For example, pessimistic lock KV requests are marked red and TSO waiting is marked dark brown. If non-blue or non-green areas are large, it means there is bottleneck during SQL execution. For example:

    - If serious lock conflicts occur, the red area will take a large proportion.
    - If excessive time is consumed in waiting TSO, the dark brown area will take a large proportion.

Example 1: TPC-C workload

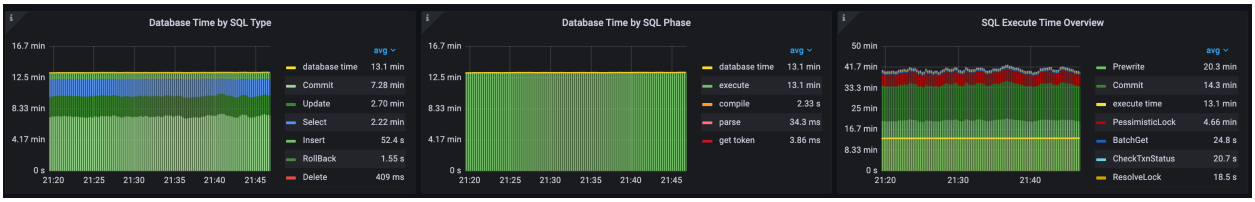

Figure 307: TPC-C

- Database Time by SQL Type: Most time-consuming statements are `commit`, `update`, `select`, and `insert` statements.

- Database Time by SQL Phase: The most time-consuming phase is SQL execution in green.

- SQL Execute Time Overview: The most time-consuming KV requests in SQL execution are `Prewrite` and `Commit` in green.

> **Note:**
>
> It is normal that the total KV request time is greater than the execute time. Because the TiDB executor may send KV requests to multiple TiKVs concurrently, causing the total KV request wait time to be greater than the execute time. In the preceding TPC-C workload, TiDB sends `Prewrite` and `Commit` requests concurrently to multiple TiKVs when a

transaction is committed. Therefore, the total time for `Prewrite`, `Commit` ↪ , and `PessimisticsLock` requests in this example is obviously longer than the execute time.

- The `execute` time may also be significantly greater than the total time of the KV request plus the `tso_wait` time. This means that the SQL execution time is spent mostly inside the TiDB executor. Here are two common examples:

```
> - Example 1: After TiDB executor reads a large amount of data from
    ↪ TiKV, it needs to do complex join and aggregation inside TiDB,
    ↪ which consumes a lot of time.
> - Example 2: The application experiences serious write statement lock
    ↪  conflicts. Frequent lock retries result in long `Retried
    ↪ execution time`.
```

Example 2: OLTP read-heavy workload

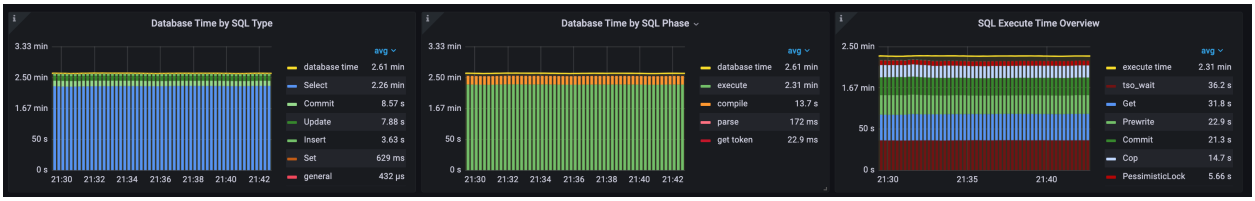

Figure 308: OLTP

- Database Time by SQL Type: Major time-consuming statements are `SELECT`, `COMMIT`, `UPDATE`, and `INSERT`, among which `SELECT` consumes most database time.
- Database Time by SQL Phase: Most time is consumed in the `execute` phase in green.
- SQL Execute Time Overview: In SQL execution phase, `pd tso_wait` in dark brown, `KV Get` in blue, and `Prewrite` and `Commit` in green are time-consuming.

Example 3: Read-only OLTP workload

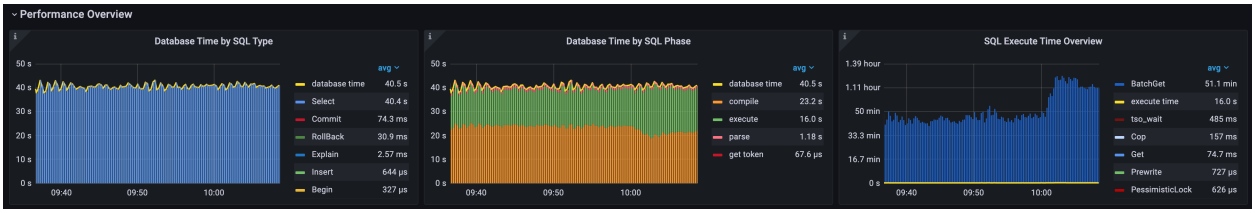

Figure 309: OLTP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Major time-consuming phases are `compile` in orange and `execute` in green. Latency in the `compile` phase is the highest, indicating that TiDB is taking too long to generate execution plans and the root cause needs to be further determined based on the subsequent performance data.
- SQL Execute Time Overview: The KV BatchGet requests in blue consume the most time during SQL execution.

> **Note:**
>
> In example 3, `SELECT` statements need to read thousands of rows concurrently from multiple TiKVs. Therefore, the total time of the `BatchGet` request is much longer than the execution time.

Example 4: Lock contention workload

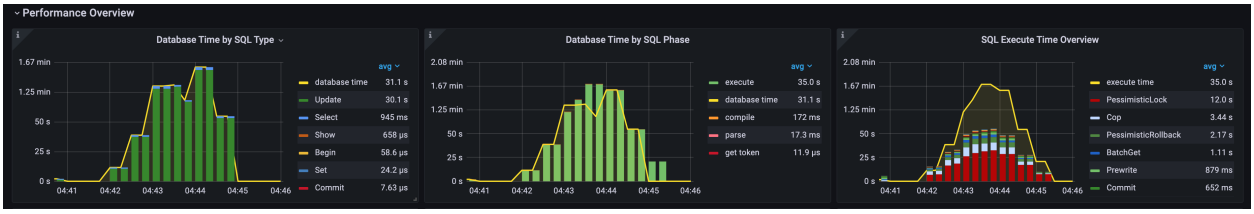

Figure 310: OLTP

- Database Time by SQL Type: Mainly are `UPDATE` statements.
- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The KV request PessimisticLock shown in red consumes the most time during SQL execution, and the execution time is obviously longer than the total time of KV requests. This is caused by serious lock conflicts in write statements and frequent lock retries prolong `Retried execution time`. Currently, TiDB does not measure `Retried execution time`.

Example 5: HTAP CH-Benchmark workload

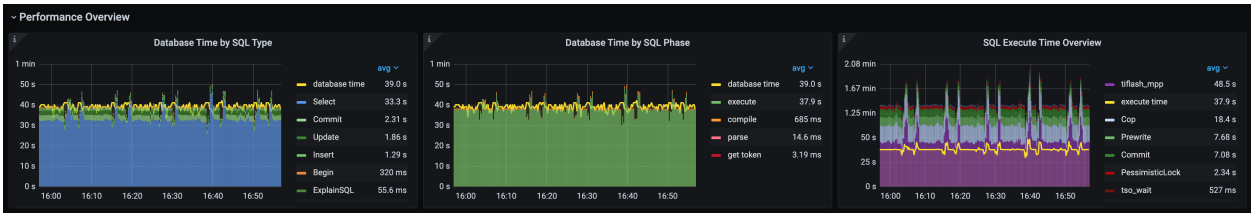

Figure 311: HTAP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The `tiflash_mpp` requests shown in purple consume the most time during SQL execution, followed by the KV requests, including the `Cop` requests in blue, and the `Prewrite` and `Commit` requests in green.

11.1.2.2.2 TiDB key metrics and cluster resource utilization

Query Per Second, Command Per Second, and Prepared-Plan-Cache

By checking the following three panels in Performance Overview, you can learn the application workload type, how the application interacts with TiDB, and whether the application fully utilizes TiDB prepared plan cache.

- QPS: Short for Query Per Second. It shows the count of SQL statements executed by the application.
- CPS By Type: Short for Command Per Second. Command indicates MySQL protocol-specific commands. A query statement can be sent to TiDB either by a query command or a prepared statement.
- Queries Using Plan Cache OPS: `avg-hit` is the number of queries using the execution plan cache per second in a TiDB cluster, and `avg-miss` is the number of queries not using the execution plan cache per second in a TiDB cluster.

  `avg-hit + avg-miss` is equal to `StmtExecute`, which is the number of all queries executed per second. When prepared plan cache is enabled in TiDB, the following three scenarios will occur:

  - No prepared plan cache is hit: `avg-hit` (the number of hits per second) is 0, and `avg-miss` is equal to the number of `StmtExecute` commands per second. The possible reasons include:
    - The application is using the query interface.
    - The cached plans are cleaned up because the application calls the `StmtClose` command after each `StmtExecute` execution.
    - All statements executed by `StmtExecute` do not meet the cache conditions so the execution plan cache cannot be hit.
  - All prepared plan cache is hit: `avg-hit` (the number of hits per second) is equal to the number of `StmtExecute` commands per second, and `avg-miss` (the number without hits per second) is 0.
  - Some prepared plan cache is hit: `avg-hit` (the number of hits per second) is fewer than the number of `StmtExecute` commands per second. Prepared plan cache has known limitations. For example, it does not support subqueries, so SQL statements with subqueries cannot use prepared plan cache.

Example 1: TPC-C workload

The TPC-C workload are mainly `UPDATE`, `SELECT`, and `INSERT` statements. The total QPS is equal to the number of `StmtExecute` commands per second and the latter is almost equal to `avg-hit` on the Queries Using Plan Cache OPS panel. Ideally, the client caches the object of the prepared statement. In this way, the cached statement is called directly when a SQL statement is executed. All SQL executions hit the prepared plan cache, and there is no need to recompile to generate execution plans.

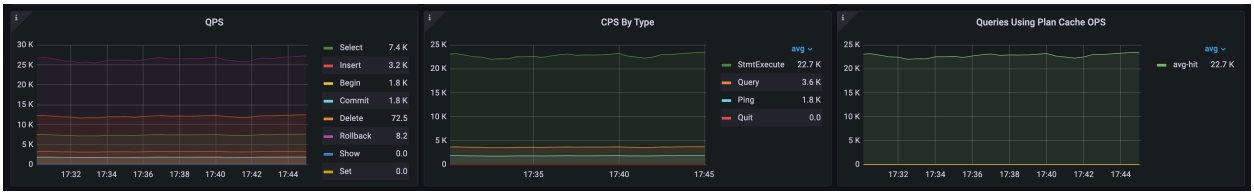

Figure 312: TPC-C

Example 2: Prepared plan cache unavailable for query commands in read-only OLTP workload

In this workload, `Commit QPS` = `Rollback QPS` = `Select QPS`. The application has enabled auto-commit concurrency, and rollback is performed every time a connection is fetched from the connection pool. As a result, these three statements are executed the same number of times.

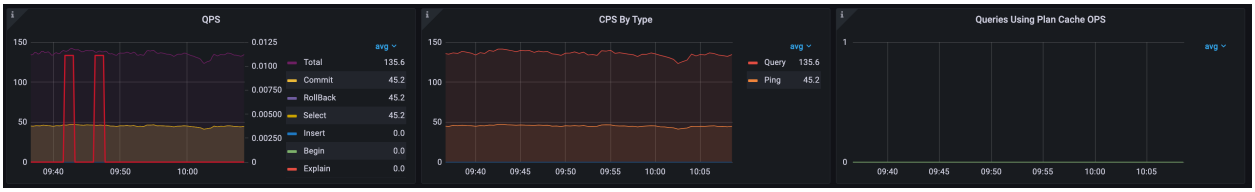

Figure 313: OLTP-Query

- The red bold line in the QPS panel stands for failed queries, and the Y-axis on the right shows the number of failed queries. A value other than 0 means the presence of failed queries.
- The total QPS is equal to the number of queries in the CPS By Type panel, the query command has been used by the application.
- The Queries Using Plan Cache OPS panel has no data, because prepared plan cache is unavailable for query command. This means that TiDB needs to parse and generate an execution plan for every query execution. As a result, the compile time is longer with increasing CPU consumption by TiDB.

Example 3: Prepared plan cache unavailable with prepared statement enabled for OLTP workload

`StmtPreare` times = `StmtExecute` times = `StmtClose` times ~= `StmtFetch` times. The application uses the prepare > execute > fetch > close loop. To prevent prepared statement object leak, many application frameworks call `close` after the `execute` phase. This creates two problems.

- A SQL execution requires four commands and four network round trips.
- Queries Using Plan Cache OPS is 0, indicating zero hit of prepared plan cache. The `StmtClose` command clears cached execution plans by default and the next `StmtPreare` command needs to generate the execution plan again.

> **Note:**
>
> Starting from TiDB v6.0.0, you can prevent the `StmtClose` command from clearing cached execution plans via the global variable (`set global tidb_ignore_prepared_cache_close_stmt=on;`). In this way, subsequent executions can hit the prepared plan cache.

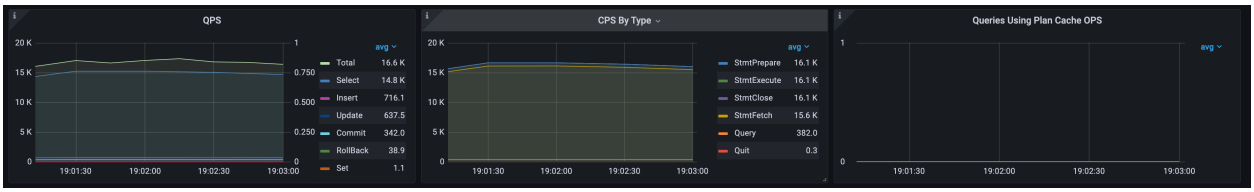

Figure 314: OLTP-Prepared

Example 4: Prepared statements have a resource leak

The number of `StmtPrepare` commands per second is much greater than that of `StmtClose` per second, which indicates that the application has an object leak for prepared statements.

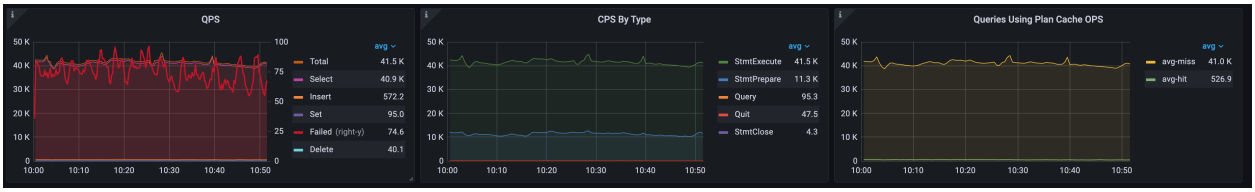

Figure 315: OLTP-Query

- In the QPS panel, the red bold line indicates the number of failed queries, and the Y axis on the right indicates the coordinate value of the number. In this example, the number of failed quries per second is 74.6.

- In the CPS By Type panel, the number of `StmtPrepare` commands per second is much greater than that of `StmtClose` per second, which indicates that an object leak occurs in the application for prepared statements.
- In the Queries Using Plan Cache OPS panel, `avg-miss` is almost equal to `StmtExecute` in the CPS By Type panel, which indicates that almost all SQL executions miss the execution plan cache.

KV/TSO Request OPS and KV Request Time By Source

- In the KV/TSO Request OPS panel, you can view the statistics of KV and TSO requests per second. Among the statistics, `kv request total` represents the sum of all requests from TiDB to TiKV. By observing the types of requests from TiDB to PD and TiKV, you can get an idea of the workload profile within the cluster.
- In the KV Request Time By Source panel, you can view the time ratio of each KV request type and all request sources.
    - kv request total time: The total time of processing KV and TiFlash requests per second.
    - Each KV request and the corresponding request source form a stacked bar chart, in which `external` identifies normal business requests and `internal` identifies internal activity requests (such as DDL and auto analyze requests).

Example 1: Busy workload

Figure 316: TPC-C

In this TPC-C workload:

- The total number of KV requests per second is 79,700. The top request types are `Prewrite`, `Commit`, `PessimisticsLock`, and `BatchGet` in order of number of requests.
- Most of the KV processing time is spent on `Commit-external_Commit` and `Prewrite-external_Commit`, which indicates that the most time-consuming KV requests are `Commit` and `Prewrite` from external commit statements.

Example 2: Analyze workload

Figure 317: OLTP

In this workload, only `ANALYZE` statements are running in the cluster:

- The total number of KV requests per second is 35.5 and the number of Cop requests per second is 9.3.
- Most of the KV processing time is spent on `Cop-internal_stats`, which indicates that the most time-consuming KV request is `Cop` from internal `ANALYZE` operations.

TiDB CPU, TiKV CPU, and IO usage

In the TiDB CPU and TiKV CPU/IO MBps panels, you can observe the logical CPU usage and IO throughput of TiDB and TiKV, including average, maximum, and delta (maximum CPU usage minus minimum CPU usage), based on which you can determine the overall CPU usage of TiDB and TiKV.

- Based on the `delta` value, you can determine if CPU usage in TiDB is unbalanced (usually accompanied by unbalanced application connections) and if there are read/write hot spots among the cluster.
- With an overview of TiDB and TiKV resource usage, you can quickly determine if there are resource bottlenecks in your cluster and whether TiKV or TiDB needs scale-out.

Example 1: High TiDB resource usage

In this workload, each TiDB and TiKV is configured with 8 CPUs.

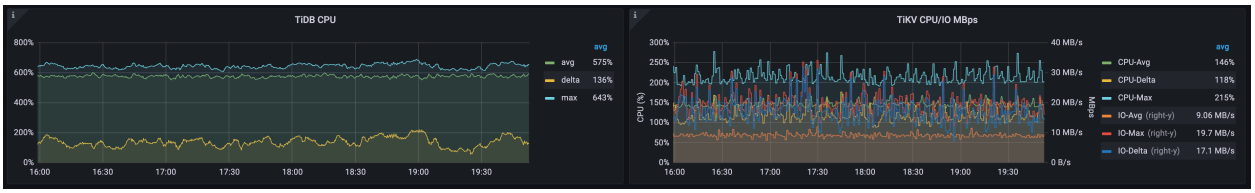

Figure 318: TPC-C

- The average, maximum, and delta CPU usage of TiDB are 575%, 643%, and 136%, respectively.

- The average, maximum, and delta CPU usage of TiKV are 146%, 215%, and 118%, respectively. The average, maximum, and delta I/O throughput of TiKV are 9.06 MB/s, 19.7 MB/s, and 17.1 MB/s, respectively.

Obviously, TiDB consumes more CPU, which is near the bottleneck threshold of 8 CPUs. It is recommended that you scale out the TiDB.

Example 2: High TiKV resource usage

In the TPC-C workload below, each TiDB and TiKV is configured with 16 CPUs.

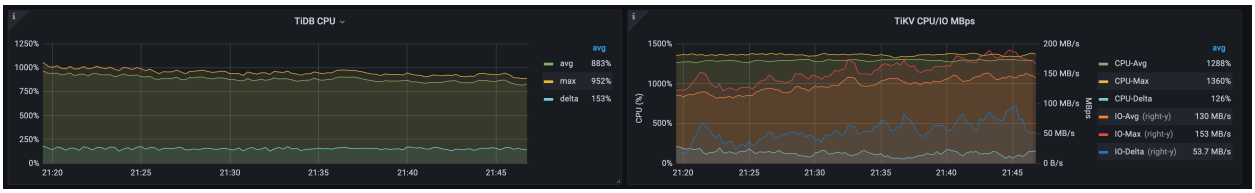

Figure 319: TPC-C

- The average, maximum, and delta CPU usage of TiDB are 883%, 962%, and 153%, respectively.
- The average, maximum, and delta CPU usage of TiKV are 1288%, 1360%, and 126%, respectively. The average, maximum, and delta I/O throughput of TiKV are 130 MB/s, 153 MB/s, and 53.7 MB/s, respectively.

Obviously, TiKV consumes more CPU, which is expected because TPC-C is a write-heavy scenario. It is recommended that you scale out the TiKV to improve performance.

11.1.2.2.3 Query latency breakdown and key latency metrics

The latency panel provides average values and 99th percentile. The average values help identify the overall bottleneck, while the 99th or 999th percentile or 999th helps determine whether there is a significant latency jitter.

Duration, Connection Idle Duration, and Connection Count

The Duration panel contains the average and P99 latency of all statements, and the average latency of each SQL type. The Connection Idle Duration panel contains the average and the P99 connection idle duration. Connection idle duration includes the following two states:

- in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is within a transaction.
- not-in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is not within a transaction.

An applications perform transactions with the same database connction. By comparing the average query latency with the connection idle duration, you can determine if TiDB is the bottleneck for overall system, or if user response time jitter is caused by TiDB.

- If the application workload is not read-only and contains transactions, by comparing the average query latency with `avg-in-txn`, you can determine the proportion in processing transactions inside and outside the database, and identify the bottleneck in user response time.
- If the application workload is read-only or autocommit mode is on, you can compare the average query latency with `avg-not-in-txn`.

In real customer scenarios, it is not rare that the bottleneck is outside the database, for example:

- The client server configuration is too low and the CPU resources are exhausted.
- HAProxy is used as a TiDB cluster proxy, and the HAProxy CPU resource is exhausted.
- HAProxy is used as a TiDB cluster proxy, and the network bandwidth of the HAProxy server is used up under high workload.
- The network latency from the application server to the database is high. For example, the network latency is high because in public-cloud deployments the applications and the TiDB cluster are not in the same region, or the dns workload balancer and the TiDB cluster are not in the same region.
- The bottleneck is in client applications. The application server's CPU cores and Numa resources cannot be fully utilized. For example, only one JVM is used to establish thousands of JDBC connections to TiDB.

In the Connection Count panel, you can check the total number of connections and also the number of connections on each TiDB node, which helps you determine whether the total number of connections is normal and whether the number of connections on each TiDB node is unbalanced. `active connections` indicates the number of active connections, which is equal to the database time per second. The Y axis on the right (`disconnection/s`) indicates the number of disconnections per second in a cluster, which can be used to determine whether the application uses short connections.

Example 1: The number of disconnection/s is too high

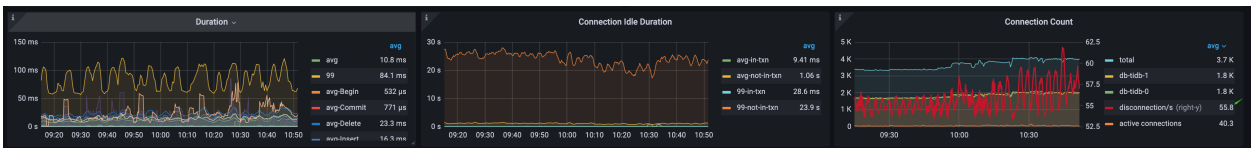

Figure 320: high disconnection/s

In this workload:

- The average latency and P99 latency of all SQL statements are 10.8 ms and 84.1 ms, respectively.
- The average connection idle time in transactions `avg-in-txn` is 9.4 ms.
- The total number of connections to the cluster is 3,700, and the number of connections to each TiDB node is 1,800. The average number of active connections is 40.3, which indicates that most of the connections are idle. The average number of `disonnnection /s` is 55.8, which indicates that the application is connecting and disconnecting frequently. The behavior of short connections will have a certain impact on TiDB resources and response time.

Example 2: TiDB is the bottleneck of user response time

Figure 321: TiDB is the Bottleneck

In this TPC-C workload:

- The average latency and P99 latency of all SQL statements are 477 us and 3.13 ms, respectively. The average latencies of the commit statement, insert statement, and query statement are 2.02 ms, 609 us, and 468 us, respectively.
- The average connection idle time in transactions `avg-in-txn` is 171 us.

The average query latency is significantly greater than `avg-in-txn`, which means the main bottleneck in transactions is inside the database.

Example 3: TiDB is not the bottleneck of user response time

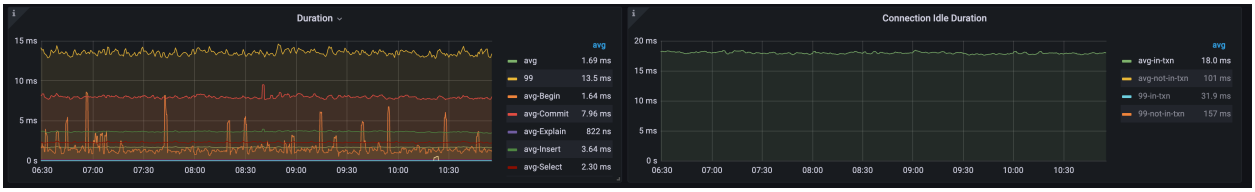

Figure 322: TiDB is not Bottleneck

In this workload, the average query latency is 1.69 ms and `avg-in-txn` is 18 ms, indicating that TiDB spends 1.69 ms on average to process a SQL statement in transactions, and then needs to wait for 18 ms to receive the next statement.

The average query latency is significantly lower than `avg-in-txn`. The bottleneck of user response time is not in TiDB. This example is in a public cloud environment, where high network latency between the application and the database results in extremely high connection idle time, because the application and the database are not in the same region.

Parse, Compile, and Execute Duration

In TiDB, there is a typical processing flow from sending query statements to returning results.

SQL processing in TiDB consists of four phases, `get token`, `parse`, `compile`, and `execute`.

- `get token`: Usually only a few microseconds and can be ignored. The token is limited only when the number of connections to a single TiDB instance reaches the token-limit limit.
- `parse`: The query statements are parsed into abstract syntax tree (AST).
- `compile`: Execution plans are compiled based on the AST from the `parse` phase and statistics. The `compile` phase contains logical optimization and physical optimization. Logical optimization optimizes query plans by rules, such as column pruning based on relational algebra. Physical optimization estimates the cost of the execution plans by statistics by a cost-based optimizer and selects a physical execution plan with the lowest cost.
- `execute`: The time consumption to execute a SQL statement. TiDB first waits for the globally unique timestamp TSO. Then the executor constructs the TiKV API request based on the Key range of the operator in the execution plan and distributes it to TiKV. `execute` time includes the TSO wait time, the KV request time, and the time spent by TiDB executor in processing data.

If an application uses the `query` or `StmtExecute` MySQL command interface only, you can use the following formula to identify the bottleneck in average latency.

```
avg Query Duration = avg Get Token + avg Parse Duration + avg Compile
    ↪ Duration + avg Execute Duration
```

Usually, the `execute` phase accounts for the most of the `query` latency. However, the `parse` and `compile` phases can also take a large part in the following cases:

- Long latency in the `parse` phase: For example, when the `query` statement is long, much CPU will be consumed to parse the SQL text.
- Long latency in the `compile` phase: If the prepared plan cache is not hit, TiDB needs to compile an execution plan for every SQL execution. The latency in the `compile` phase can be several or tens of milliseconds or even higher. If prepared plan cache is not hit, logical and physical optimization are done in the `compile` phase, which consumes a lot of CPU and memory, makes Go Runtime (TiDB is written in Go) under pressure, and affects the performance of other TiDB components. Prepared plan cache is important for efficient processing of OLTP workload in TiDB.

Example 1: Database bottleneck in the `compile` phase

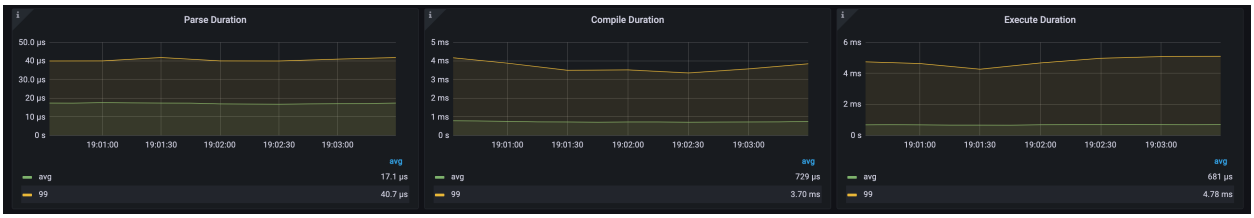

Figure 323: Compile

In the preceding figure, the average time of the `parse`, `compile`, and `execute` phases are 17.1 us, 729 us, and 681 us, respectively. The `compile` latency is high because the application uses the `query` command interface and cannot use prepared plan cache.

Example 2: Database bottleneck in the `execute` phase

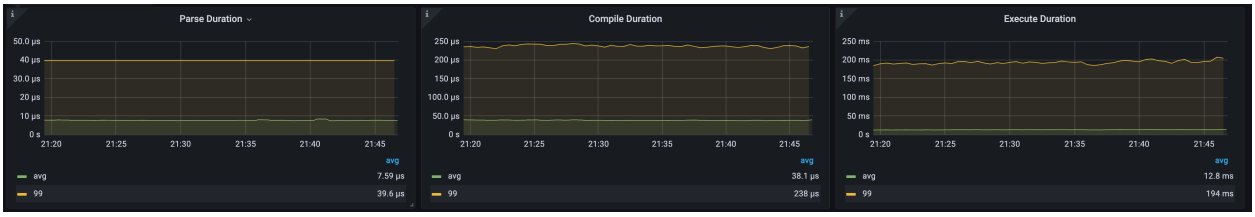

Figure 324: Execute

In this TPC-C workload, the average time of `parse`, `compile` and `execute` phases are 7.39 us, 38.1 us, and 12.8 ms, respectively. The `execute` phase is the bottleneck of the `query` latency.

KV and TSO Request Duration

TiDB interacts with PD and TiKV in the `execute` phase. As shown in the following figure, when processing SQL request, TiDB requests TSOs before entering the `parse` and `compile` phases. The PD Client does not block the caller, but returns a `TSFuture` and asynchronously sends and receives the TSO requests in the background. Once the PD client finishes handling the TSO requests, it returns `TSFuture`. The holder of the `TSFuture` needs to call the Wait method to get the final TSOs. After TiDB finishes the `parse` and `compile` phases, it enters the `execute` phase, where two situations might occur:

- If the TSO request has completed, the Wait method immediately returns an available TSO or an error
- If the TSO request has not yet completed, the Wait method is blocked until a TSO is available or an error appears (the gRPC request has been sent but no result is returned, and the network latency is high)

The TSO wait time is recorded as `TSO WAIT` and the network time of the TSO request is recorded as `TSO RPC`. After the TSO wait is complete, TiDB executor usually sends read or write requests to TiKV.

- Common KV read requests: `Get`, `BatchGet`, and `Cop`
- Common KV write requests: `PessimisticLock`, `Prewrite` and `Commit` for two-phase commits

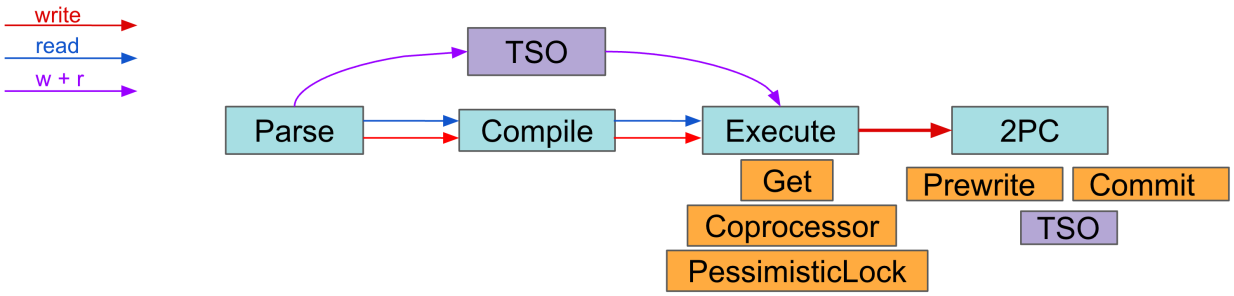

Figure 325: Execute

The indicators in this section correspond to the following three panels.

- Avg TiDB KV Request Duration: The average latency of KV requests measured by TiDB
- Avg TiKV GRPC Duration: The average latency in processing gPRC messages in TiKV
- PD TSO Wait/RPC Duration: TiDB executor TSO wait time and network latency for TSO requests (RPC)

The relationship between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is as follows:

```
Avg TiDB KV Request Duration = Avg TiKV GRPC Duration + Network latency
    ↪ between TiDB and TiKV + TiKV gRPC processing time + TiDB gRPC
    ↪ processing time and scheduling latency
```

The difference between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is closely related to the network traffic, network latency, and resource usage by TiDB and TiKV.

- In the same data center: The difference is generally less than 2 ms.
- In different availability zones in the same region: The difference is generally less than 5 ms.

Example 1: Low workload of clusters deployed on the same data center

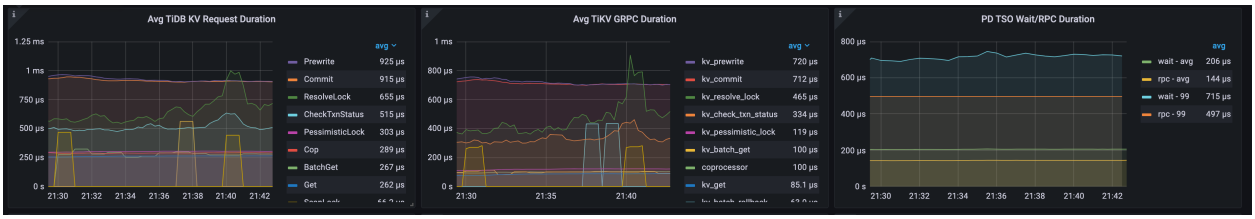

Figure 326: Same Data Center

In this workload, the average `Prewrite` latency on TiDB is 925 us, and the average `kv_prewrite` processing latency inside TiKV is 720 us. The difference is about 200 us, which is normal in the same data center. The average TSO wait latency is 206 us, and the RPC time is 144 us.

Example 2: Normal workload on public cloud clusters

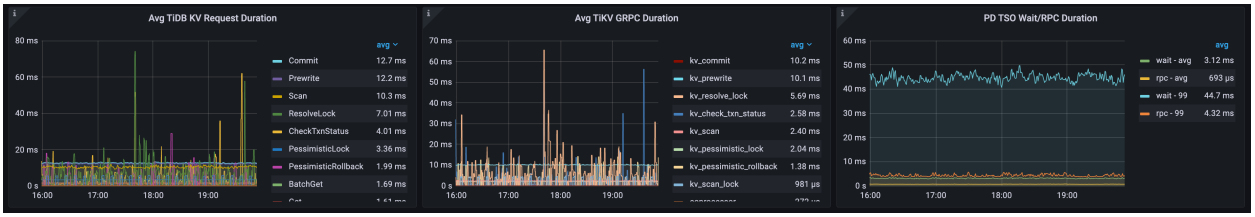

Figure 327: Cloud Env

In this example, TiDB clusters are deployed in different data centers in the same region. The average `commit` latency on TiDB is 12.7 ms, and the average `kv_commit` processing latency inside TiKV is 10.2 ms, a difference of about 2.5 ms. The average TSO wait latency is 3.12 ms, and the RPC time is 693 us.

Example 3: Resource overloaded on public cloud clusters

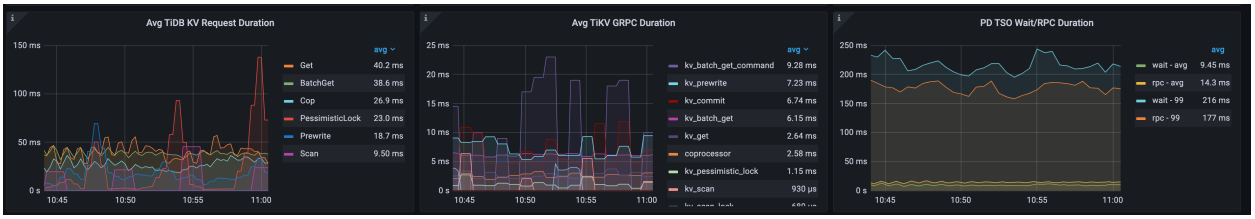

Figure 328: Cloud Env, TiDB Overloaded

In this example, the TiDB clusters are deployed in different data centers in the same region, and TiDB network and CPU resources are severely overloaded. The average `BatchGet`

latency on TiDB is 38.6 ms, and the average `kv_batch_get` processing latency inside TiKV is 6.15 ms. The difference is more than 32 ms, which is much higher than the normal value. The average TSO wait latency is 9.45 ms and the RPC time is 14.3 ms.

Storage Async Write Duration, Store Duration, and Apply Duration

TiKV processes a write request in the following procedure:

- `scheduler worker` processes the write request, performs a transaction consistency check, and converts the write request into a key-value pair to be sent to the `raftstore` module.
- The TiKV consensus module `raftstore` applies the Raft consensus algorithm to make the storage layer (composed of multiple TiKVs) fault-tolerant.

  Raftstore consists of a `Store` thread and an `Apply` thread:

  - The `Store` thread processes Raft messages and new `proposals`. When a new `proposals` is received, the `Store` thread of the leader node writes to the local Raft DB and copies the message to multiple follower nodes. When this `proposals` is successfully persisted in most instances, the `proposals` is successfully committed.
  - The `Apply` thread writes the committed `proposals` to the KV DB. When the content is successfully written to the KV DB, the `Apply` thread notifies externally that the write request has completed.

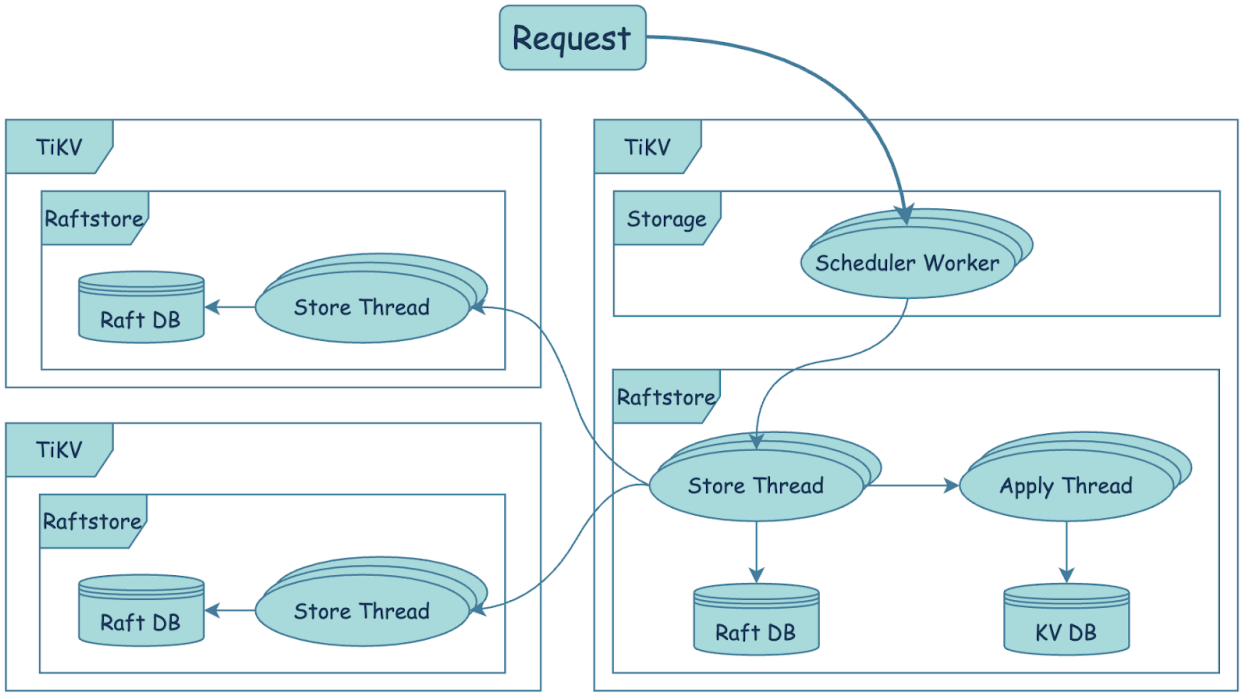

Figure 329: TiKV Write

The `Storage Async Write Duration` metric records the latency after a write request enters raftstore. The data is collected on a basis of per request.

The `Storage Async Write Duration` metric contains two parts, `Store Duration` and `Apply Duration`. You can use the following formula to determine whether the bottleneck for write requests is in the `Store` or `Apply` step.

```
avg Storage Async Write Duration = avg Store Duration + avg Apply Duration
```

> **Note:**
>
> `Store Duration` and `Apply Duration` are supported since v5.3.0.

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

According to the preceding formula, the QPS of a write-heavy OLTP workload in v5.4.0 is 14% higher than that in v5.3.0:

- v5.3.0: 24.4 ms ~= 17.7 ms + 6.59 ms
- v5.4.0: 21.4 ms ~= 14.0 ms + 7.33 ms

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Store Duration` compared with v5.3.0.

v5.3.0:

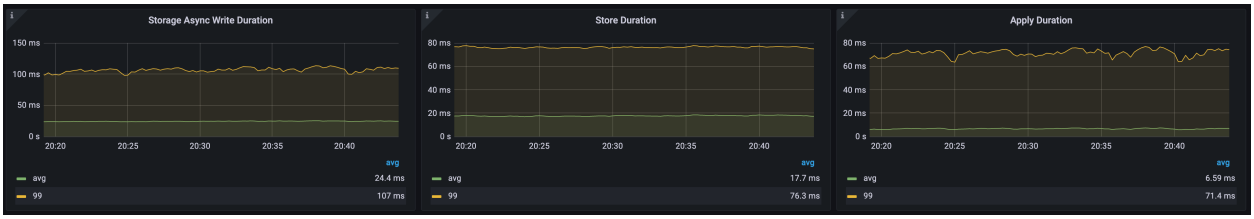

Figure 330: v5.3.0

v5.4.0:

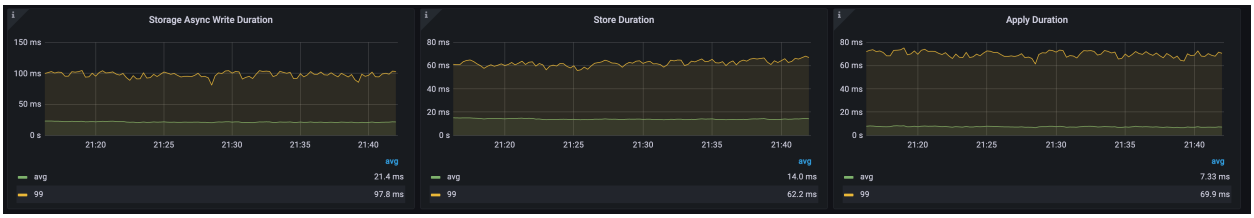

Figure 331: v5.4.0

Example 2: Store Duration is a bottleneck

Apply the preceding formula: 10.1 ms ~= 9.81 ms + 0.304 ms. The result indicates that the latency bottleneck for write requests is in `Store Duration`.

Figure 332: Store

Commit Log Duration, Append Log Duration, and Apply Log Duration

`Commit Log Duration`, `Append Log Duration`, and `Apply Log Duration` are latency metrics for key operations within raftstore. These latencies are captured at the batch operation level, with each operation combining multiple write requests. Therefore, the latencies do not directly correspond to the `Store Duration` and `Apply Duration` mentioned above.

- `Commit Log Duration` and `Append Log Duration` record time of operations performed in the `Store` thread. `Commit Log Duration` includes the time of copying Raft logs to other TiKV nodes (to ensure raft-log persistence). `Commit Log Duration` usually contains two `Append Log Duration` operations, one for the leader and the other for the follower. `Commit Log Duration` is usually significantly higher than `Append Log Duration`, because the former includes the time of copying Raft logs to other TiKV nodes through network.
- `Apply Log Duration` records the latency of `apply` Raft logs by the `Apply` thread.

Common scenarios where `Commit Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.store-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high, resulting in high `Append Log Duration` latency
- The network latency between TiKV nodes is high
- The number of the gRPC threads are too small, CPU usage is uneven among the GRPC threads.

Common scenarios where `Apply Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high

- `raftstore.apply-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

The QPS of a write-heavy OLTP workload in v5.4.0 is improved by 14% compared with that in v5.3.0. The following table compares the three key latencies.

Avg Duration	v5.3.0 (ms)	v5.4.0 (ms)
Append Log Duration	0.27	0.303
Commit Log Duration	13	8.68
Apply Log Duration	0.457	0.514

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Commit Log Duration` and `Store Duration` compared with v5.3.0.

v5.3.0:

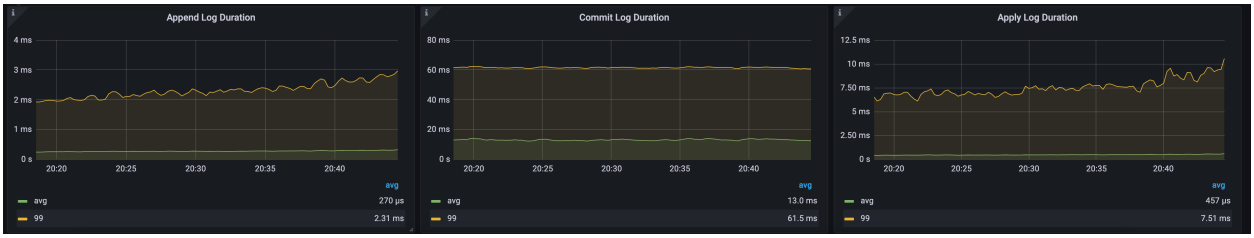

Figure 333: v5.3.0

v5.4.0:

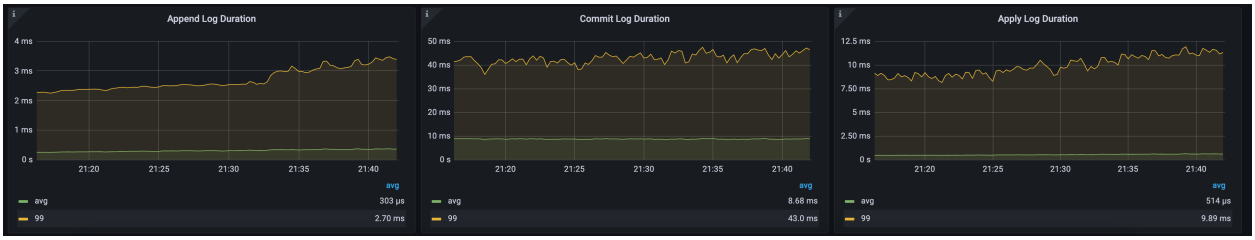

Figure 334: v5.4.0

Example 2: Commit Log Duration is a bottleneck

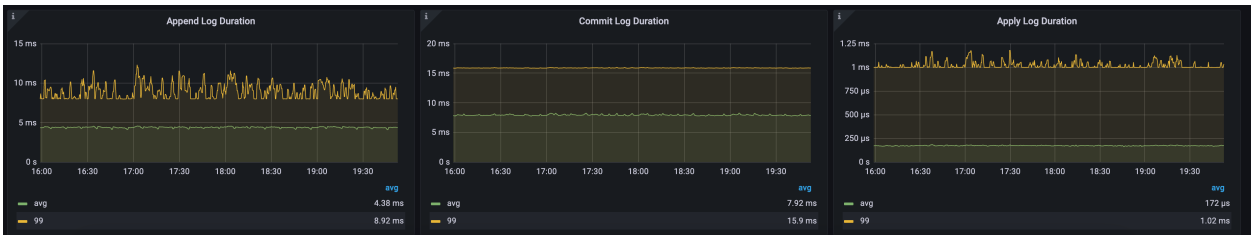

Figure 335: Store

- Average `Append Log Duration` = 4.38 ms
- Average `Commit Log Duration` = 7.92 ms
- Average `Apply Log Duration` = 172 us

For the `Store` thread, `Commit Log Duration` is obviously higher than `Apply Log Duration`. Meanwhile, `Append Log Duration` is significantly higher than `Apply Log Duration`, indicating that the `Store` thread might suffer from bottlenecks in both CPU and I/O. Possible ways to reduce `Commit Log Duration` and `Append Log Duration` are as follows:

- If TiKV CPU resources are sufficient, consider adding `Store` threads by increasing the value of `raftstore.store-pool-size`.
- If TiDB is v5.4.0 or later, consider enabling `Raft Engine` by setting `raft-engine.enable: true`. Raft Engine has a light execution path. This helps reduce I/O writes and long-tail latency of writes in some scenarios.
- If TiKV CPU resources are sufficient and TiDB is v5.3.0 or later, consider enabling `StoreWriter` by setting `raftstore.store-io-pool-size: 1`.

11.1.2.3 If my TiDB version is earlier than v6.1.0, what should I do to use the Performance Overview dashboard?

Starting from v6.1.0, Grafana has a built-in Performance Overview dashboard by default. This dashboard is compatible with TiDB v4.x and v5.x versions. If your TiDB is earlier than v6.1.0, you need to manually import `performance_overview.json`, as shown in the following figure:

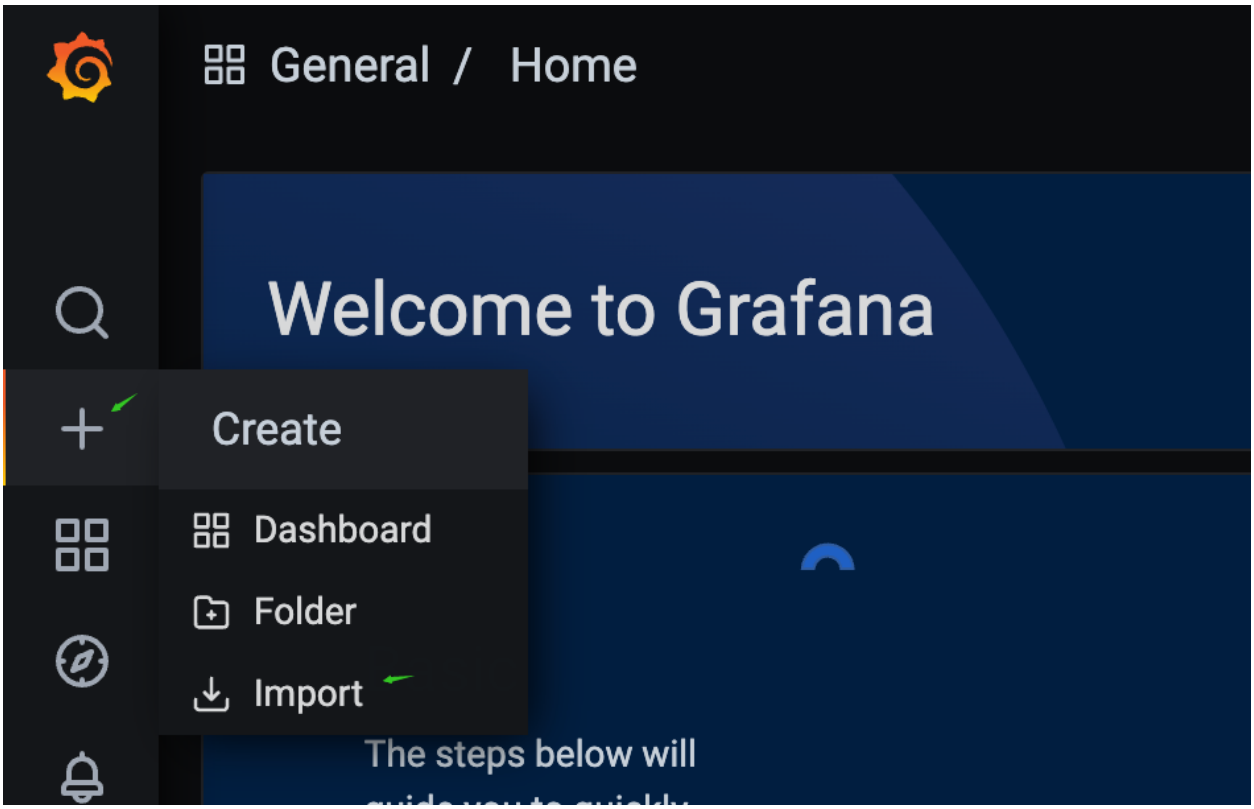

Figure 336: Store

11.1.3 Performance Tuning Practices for OLTP Scenarios

TiDB provides comprehensive performance diagnostics and analysis features, such as Top SQL and Continuous Profiling features on the TiDB Dashboard, and TiDB Performance Overview Dashboard.

This document describes how to use these features together to analyze and compare the performance of the same OLTP workload in seven different runtime scenarios, which demonstrates a performance tuning process to help you analyze and tune TiDB performance efficiently.

> **Note:**
>
> Top SQL and Continuous Profiling are not enabled by default. You need to enable them in advance.

By running the same application with different JDBC configurations in these scenarios, this document shows you how the overall system performance is affected by different

interactions between applications and databases, so that you can apply Best Practices for Developing Java Applications with TiDB for better performance.

11.1.3.1 Environment description

This document takes a core banking OLTP workload for demonstration. The configurations of the simulation environment are as follows:

- Application development language for the workload: JAVA
- SQL statements used in business: 200 statements in total, 90% of which are SELECT statements. It is a typical read-heavy OLTP workload.
- Tables used in transactions: 60 tables in total. 12 tables involve update operations, and the rest 48 tables are read-only.
- Isolation level used by the application: `read committed`.
- TiDB cluster configuration: 3 TiDB nodes and 3 TiKV nodes, with 16 CPUs allocated to each node.
- Client server configuration: 36 CPUs.

11.1.3.2 Scenario 1. Use the Query interface

11.1.3.2.1 Application configuration

The application uses the following JDBC configuration to connect to the database through the Query interface.

```
useServerPrepStmts=false
```

11.1.3.2.2 Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that the non-business SQL type `SELECT @@session.tx_isolation` consumes the most resources. Although TiDB processes these types of SQL statements quickly, these types of SQL statements have the highest number of executions that result in the highest overall CPU time consumption.

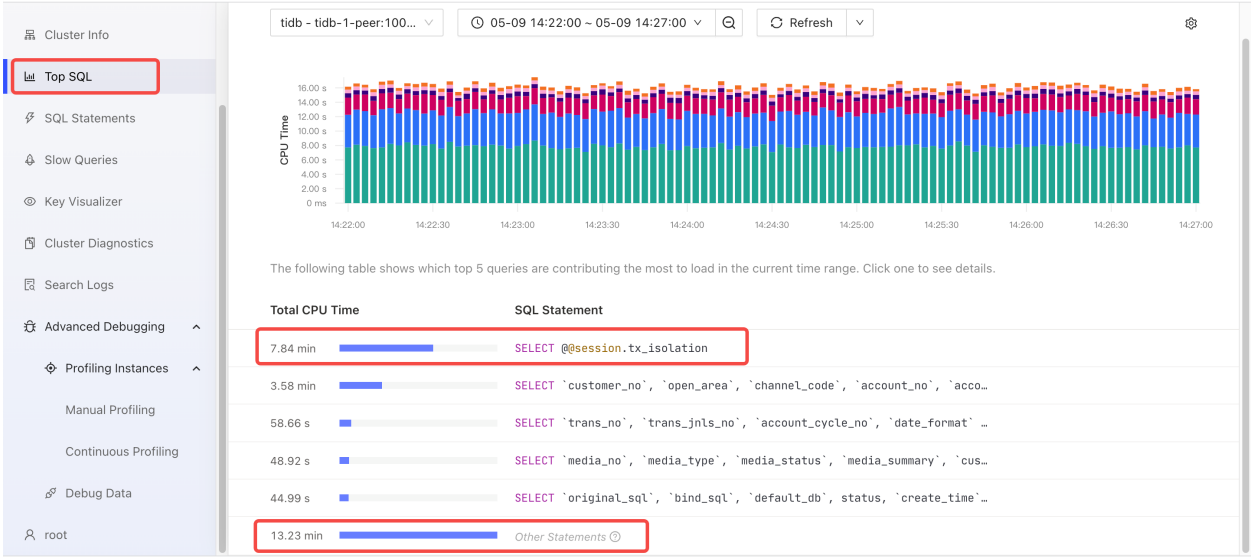

Figure 337: dashboard-for-query-interface

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is significant during the SQL execution. Because the application uses the Query interface, TiDB cannot use the execution plan cache. TiDB needs to compile and generate an execution plan for each SQL statement.

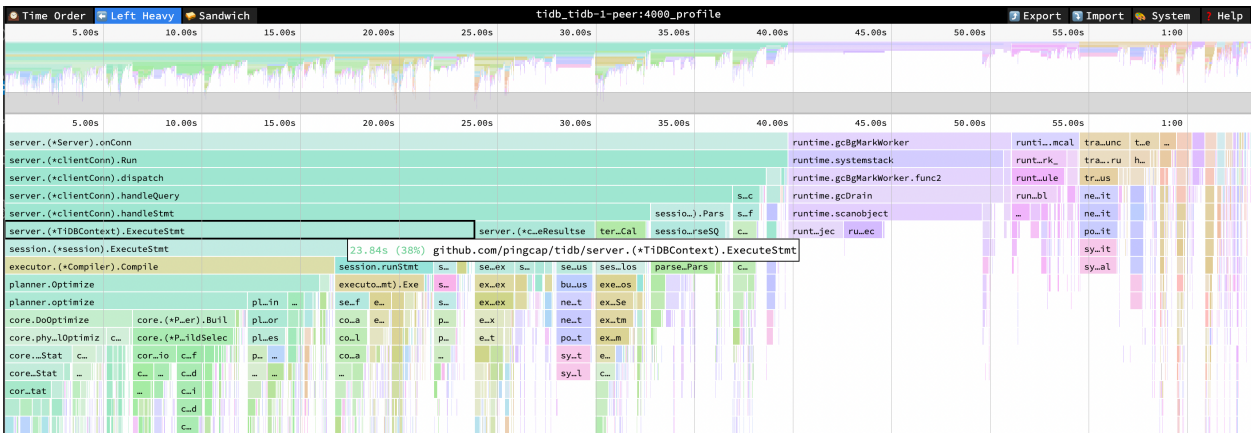

Figure 338: flame-graph-for-query-interface

- ExecuteStmt cpu = 38% cpu time = 23.84s
- Compile cpu = 27% cpu time = 17.17s
- Optimize cpu = 26% cpu time = 16.41s

Performance Overview dashboard

Check the database time overview and QPS in the following Performance Overview dashboard.

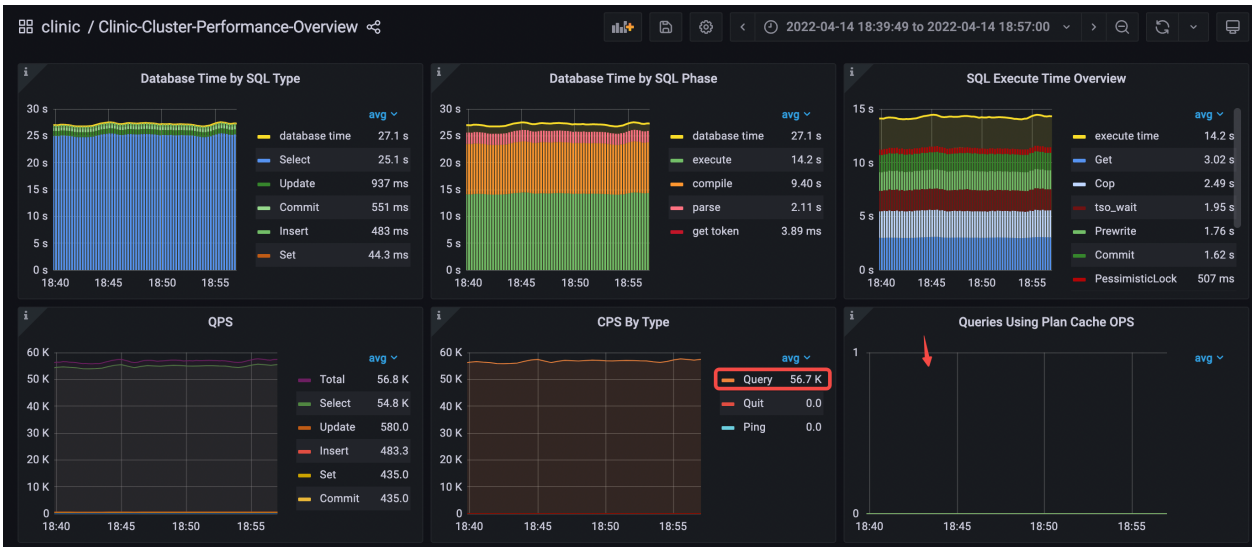

Figure 339: performance-overview-1-for-query-interface

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `tso wait` take most of the time.
- CPS By Type: only the `Query` command is used.
- Queries Using Plan Cache OPS: no data indicates that the execution plan cache is not hit.
- In the query duration, the latency of `execute` and `compile` takes the highest percentage.
- avg QPS = 56.8k

Check the resource consumption of the cluster: the average utilization of TiDB CPU is 925%, the average utilization of TiKV CPU is 201%, and the average throughput of TiKV IO is 18.7 MB/s. The resource consumption of TiDB is significantly higher.

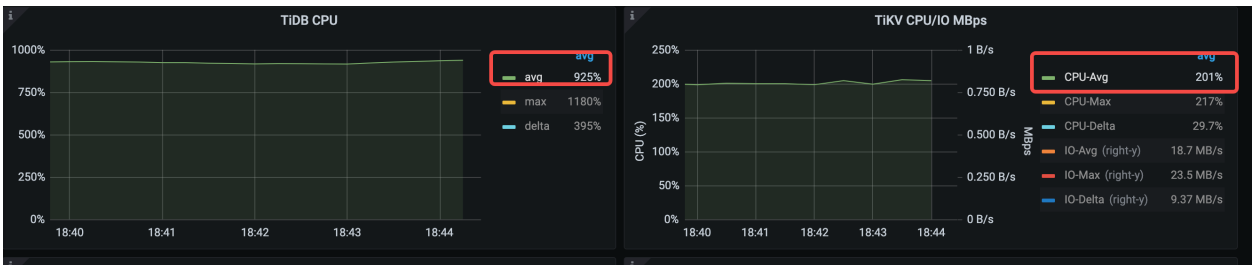

Figure 340: performance-overview-2-for-query-interface

11.1.3.2.3 Analysis conclusion

We need to eliminate these useless non-business SQL statements, which have a large number of executions and contribute to the high TiDB CPU usage.

11.1.3.3 Scenario 2. Use the maxPerformance configuration

11.1.3.3.1 Application configuration

The application adds a new parameter `useConfigs=maxPerformance` to the JDBC connection string in Scenario 1. This parameter can be used to eliminate the SQL statements sent from JDBC to the database (for example, `select @@session.transaction_read_only` ↪). The full configuration is as follows:

```
useServerPrepStmts=false&useConfigs=maxPerformance
```

11.1.3.3.2 Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that `SELECT` ↪ `@@session.tx_isolation`, which consumed the most resources, has disappeared.

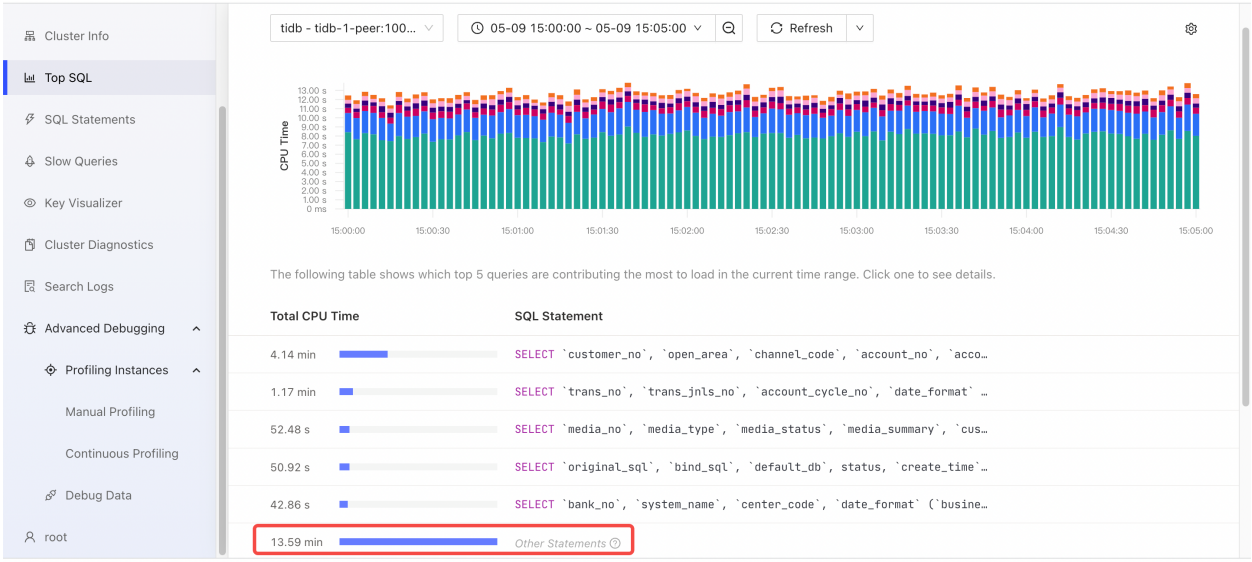

Figure 341: dashboard-for-maxPerformance

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is still significant during the SQL execution.

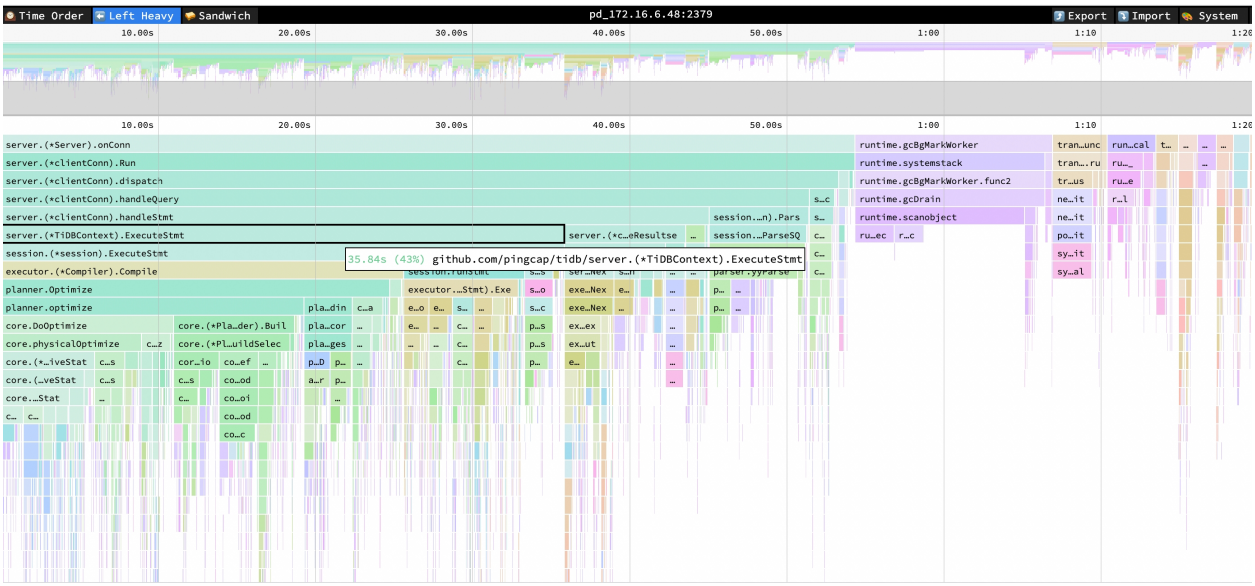

Figure 342: flame-graph-for-maxPerformance

- ExecuteStmt cpu = 43% cpu time =35.84s
- Compile cpu = 31% cpu time =25.61s
- Optimize cpu = 30% cpu time = 24.74s

Performance Overview dashboard

The data of the database time overview and QPS is as follows:

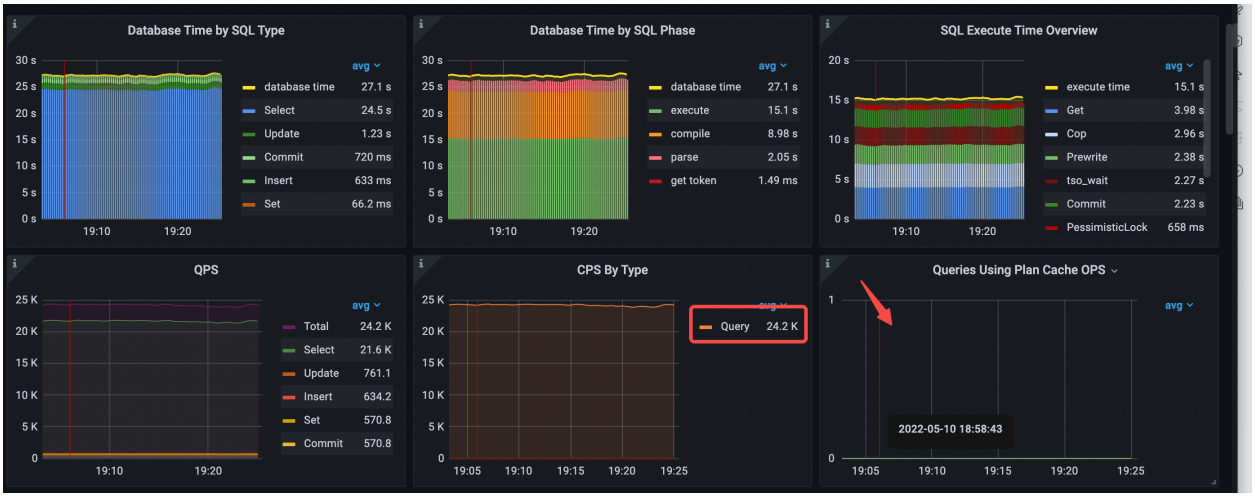

Figure 343: performance-overview-1-for-maxPerformance

- Database Time by SQL Type: the `Select` statement type takes most of the time.

- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- In the database time, the latency of `execute` and `compile` takes the highest percentage.
- CPS By Type: only the `Query` command is used.
- avg QPS = 24.2k (from 56.3k to 24.2k)
- The execution plan cache is not hit.

From Scenario 1 to Scenario 2, the average TiDB CPU utilization drops from 925% to 874%, and the average TiKV CPU utilization increases from 201% to about 250%.

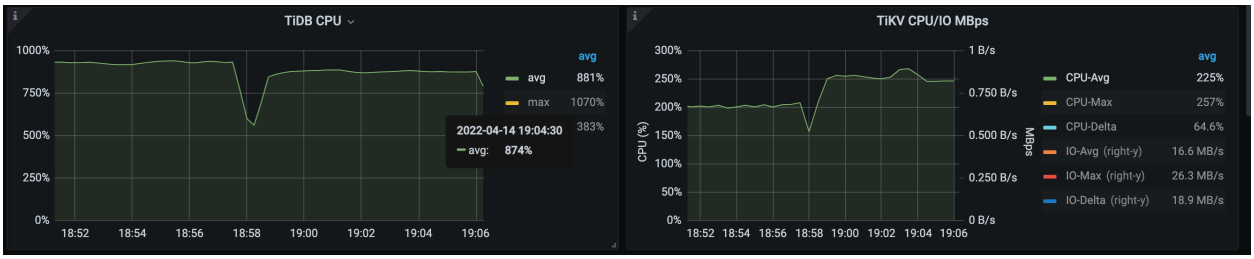

Figure 344: performance-overview-2-for-maxPerformance

The changes in key latency metrics are as follows:

Figure 345: performance-overview-3-for-maxPerformance

- avg query duration = 1.12ms (from 479 s to 1.12ms)
- avg parse duration = 84.7 s (from 37.2 s to 84.7 s)

- avg compile duration = 370 s (from 166 s to 370 s)
- avg execution duration = 626 s (from 251 s to 626 s)

11.1.3.3.3 Analysis conclusion

Compared with Scenario 1, the QPS of Scenario 2 has significantly decreased. The average query duration and average `parse`, `compile`, and `execute` durations have significantly increased. This is because SQL statements such as `select @@session.transaction_read_only` in Scenario 1, which are executed many times and have fast processing time, lower the average performance data. After Scenario 2 blocks such statements, only business-related SQL statements remain, so the average duration increases.

When the application uses the Query interface, TiDB cannot use the execution plan cache, which results in TiDB consuming high resources to compile execution plans. In this case, it is recommended that you use the Prepared Statement interface, which uses the execution plan cache of TiDB to reduce the TiDB CPU consumption caused by execution plan compiling and decrease the latency.

11.1.3.4 Scenario 3. Use the Prepared Statement interface with execution plan caching not enabled

11.1.3.4.1 Application configuration

The application uses the following connection configuration. Compared with Scenario 2, the value of the JDBC parameter `useServerPrepStmts` is modified to `true`, indicating that the Prepared Statement interface is enabled.

```
useServerPrepStmts=true&useConfigs=maxPerformance"
```

11.1.3.4.2 Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the CPU consumption of `CompileExecutePreparedStmt` and `Optimize` is still significant after the Prepared Statement interface is enabled.

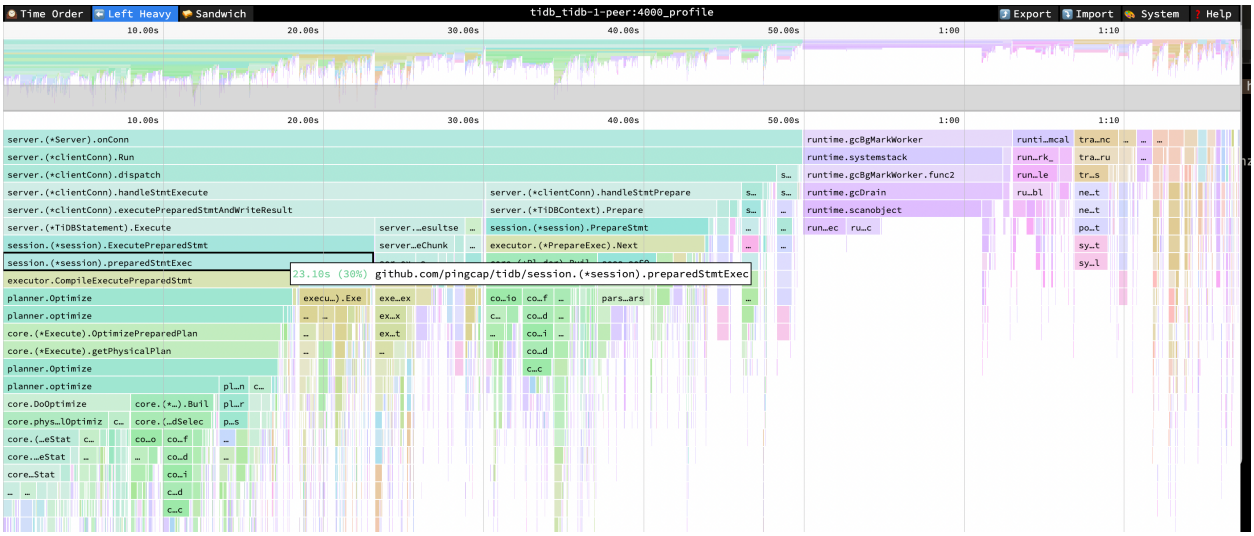

Figure 346: flame-graph-for-PrepStmts

- ExecutePreparedStmt cpu = 31% cpu time = 23.10s
- preparedStmtExec cpu = 30% cpu time = 22.92s
- CompileExecutePreparedStmt cpu = 24% cpu time = 17.83s
- Optimize cpu = 23% cpu time = 17.29s

Performance Overview dashboard

After the Prepared Statement interface is used, the data of database time overview and QPS is as follows:

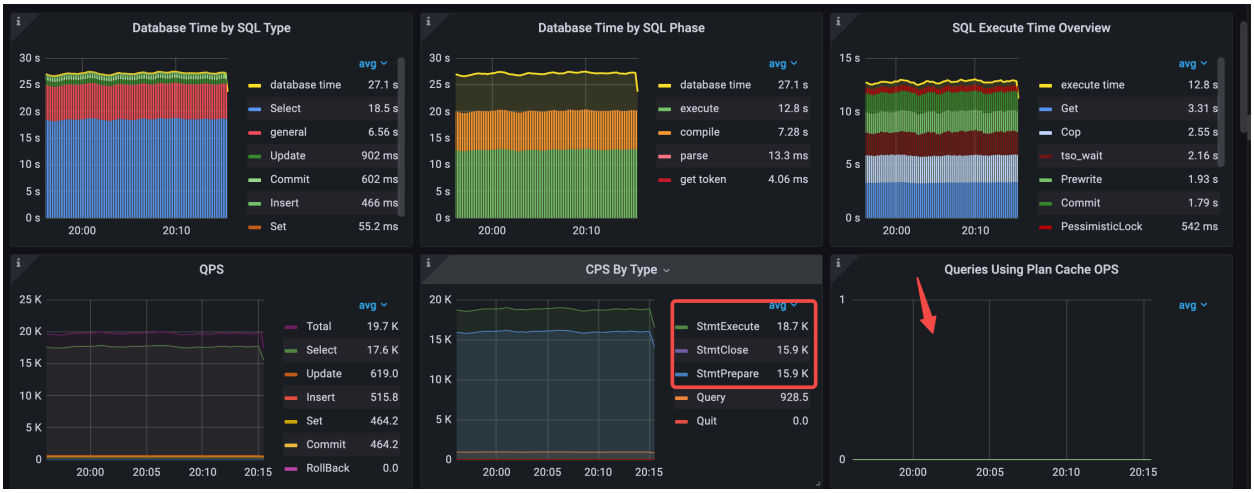

Figure 347: performance-overview-1-for-PrepStmts

The QPS drops from 24.4k to 19.7k. From the Database Time Overview, you can see that the application uses three types of Prepared commands, and the `general` statement

type (which includes the execution time of commands such as `StmtPrepare` and `StmtClose`) takes the second place in Database Time by SQL Type. This indicates that even when the Prepared Statement interface is used, the execution plan cache is not hit. The reason is that, when the `StmtClose` command is executed, TiDB clears the execution plan cache of SQL statements in the internal processing.

- Database Time by SQL Type: the `Select` statement type takes most of the time, followed by `general` statements.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- CPS By Type: 3 types of commands (`StmtPrepare`, `StmtExecute`, `StmtClose`) are used.
- avg QPS = 19.7k (from 24.4k to 19.7k)
- The execution plan cache is not hit.

The TiDB average CPU utilization increases from 874% to 936%.

Figure 348: performance-overview-1-for-PrepStmts

The key latency metrics are as follows:

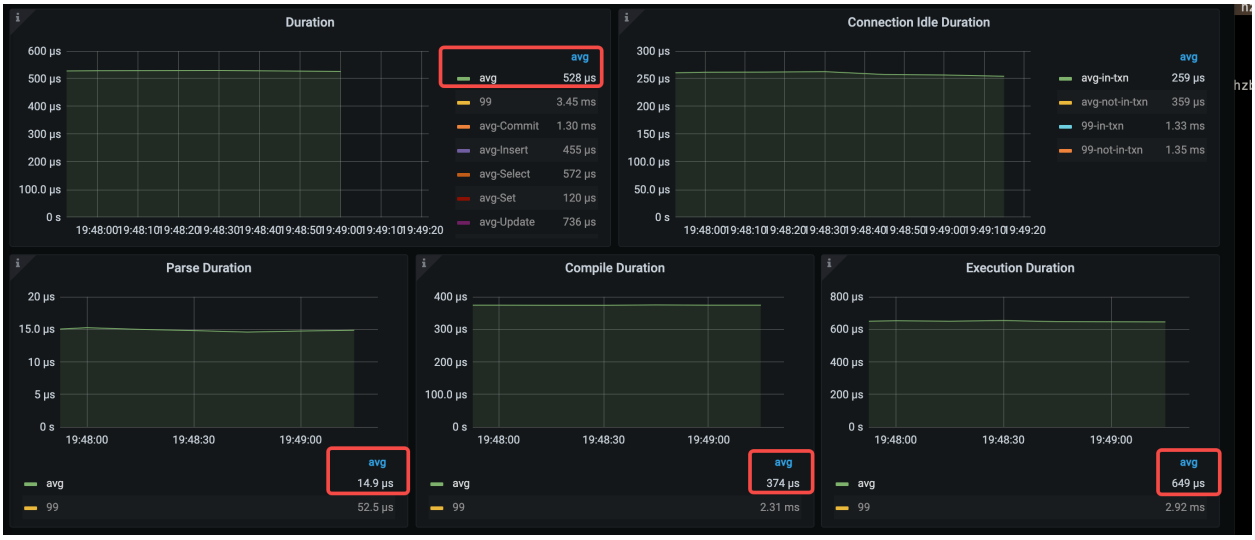

Figure 349: performance-overview-2-for-PrepStmts

- avg query duration = 528 s (from 1.12ms to 528 s)
- avg parse duration = 14.9 s (from 84.7 s to 14.9 s)
- avg compile duration = 374 s (from 370 s to 374 s)
- avg execution duration = 649 s (from 626 s to 649 s)

11.1.3.4.3 Analysis conclusion

Unlike Scenario 2, the application in Scenario 3 enables the Prepared Statement interface but still fails to hit the cache. In addition, Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). Compared with Scenario 2, Scenario 3 has two more network round-trip delays.

- Analysis for the decrease in QPS: From the **CPS By Type** pane, you can see that Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). `StmtPrepare` and `StmtClose` are non-conventional commands that are not counted by QPS, so QPS is reduced. The non-conventional commands `StmtPrepare` and `StmtClose` are counted in the `general` SQL type, so `general` time is displayed in the database overview of Scenario 3, and it accounts for more than a quarter of the database time.
- Analysis for the significant decrease in average query duration: for the `StmtPrepare` and `StmtClose` command types newly added in Scenario 3, their query duration is calculated separately in the TiDB internal processing. TiDB executes these two types of commands very quickly, so the average query duration is significantly reduced.

Although Scenario 3 uses the Prepared Statement interface, the execution plan cache is still not hit, because many application frameworks call the `StmtClose` method after

`StmtExecute` to prevent memory leaks. Starting from v6.0.0, you can set the global variable `tidb_ignore_prepared_cache_close_stmt=on;`. After that, TiDB will not clear the cached execution plans even if the application calls the `StmtClose` method, so the next SQL execution can reuse the existing execution plan and avoid compiling the execution plan repeatedly.

11.1.3.5 Scenario 4. Use the Prepared Statement interface and enable execution plan caching

11.1.3.5.1 Application configuration

The application configuration remains the same as that of Scenario 3. To resolve the issue of not hitting the cache even if the application triggers `StmtClose`, the following parameters are configured.

- Set the TiDB global variable `set global tidb_ignore_prepared_cache_close_stmt =on;` (introduced since TiDB v6.0.0, `off` by default).
- Set the TiDB configuration item `prepared-plan-cache: {enabled: true}` to enable the plan cache feature.

11.1.3.5.2 Performance analysis

TiDB Dashboard

From the flame chart of the TiDB CPU usage, you can see that `CompileExecutePreparedStmt` and `Optimize` have no significant CPU consumption. 25% of the CPU is consumed by the `Prepare` command, which contains parsing-related functions of Prepare such as `PlanBuilder` and `parseSQL`.

PreparseStmt cpu = 25% cpu time = 12.75s

Figure 350: flame-graph-for-3-commands

Performance Overview dashboard

In the Performance Overview dashboard, the most significant change is the average time of the `compile` phase, which is reduced from 8.95 seconds per second in Scenario 3 to 1.18 seconds per second. The number of queries using the execution plan cache is roughly equal to the value of `StmtExecute`. With the increase in QPS, the database time consumed by `Select` statements per second decreases, and the database time consumed by `general` statements per second type increases.

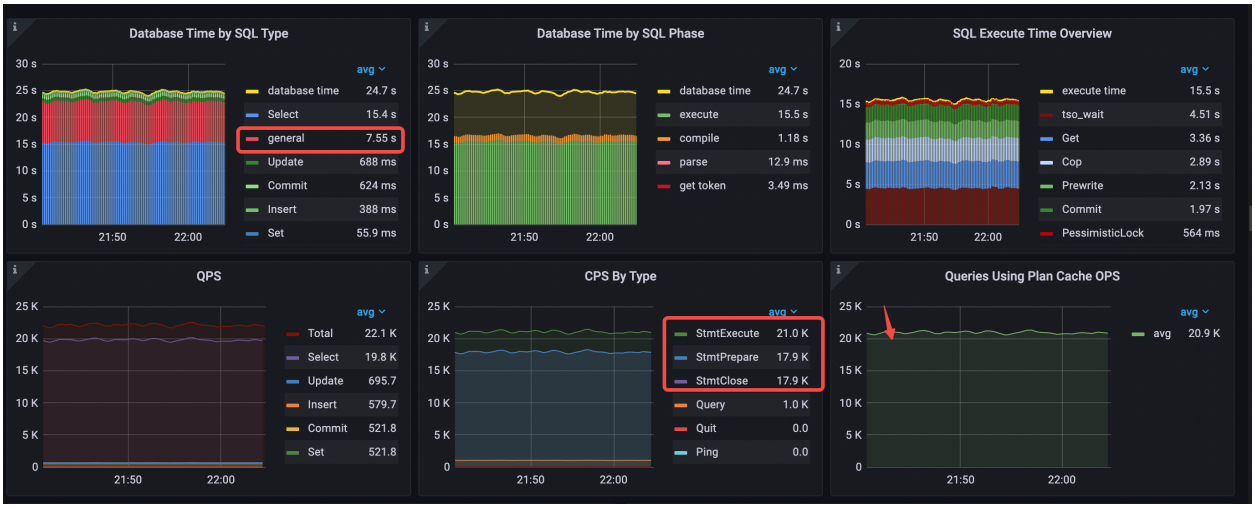

Figure 351: performance-overview-1-for-3-commands

- Database Time by SQL Type: the `Select` statement type takes the most time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: 3 types of commands (same as Scenario 3)
- Compared with scenario 3, the time consumed by `general` statements is longer because the QPS is increased.
- avg QPS = 22.1k (from 19.7k to 22.1k)

The average TiDB CPU utilization drops from 936% to 827%.

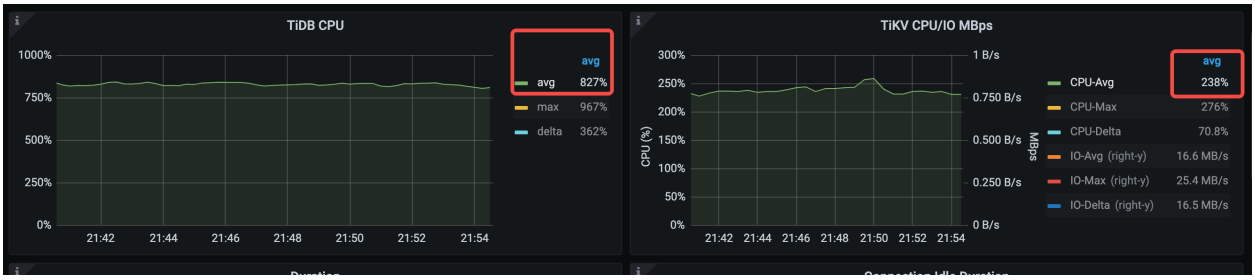

Figure 352: performance-overview-2-for-3-commands

The average `compile` time drops significantly, from 374 us to 53.3 us. Because the QPS increases, the average `execute` time increases too.

Figure 353: performance-overview-3-for-3-commands

- avg query duration = 426 s (from 528 s to 426 s)
- avg parse duration = 12.3 s (from 14.8 s to 12.3 s)
- avg compile duration = 53.3 s (from 374 s to 53.3 s)
- avg execution duration = 699 s (from 649 s to 699us)

11.1.3.5.3 Analysis conclusion

Compared with Scenario 3, Scenario 4 also uses 3 command types. The difference is that Scenario 4 hits the execution plan cache, which reduces compile duration greatly, reduces the query duration, and improves QPS.

Because the `StmtPrepare` and `StmtClose` commands consume significant database time and increase the number of interactions between the application and TiDB each time the

application executes a SQL statement. The next scenario will further tune the performance by eliminating the calls of these two commands through JDBC configurations.

11.1.3.6 Scenario 5. Cache prepared objects on the client side

11.1.3.6.1 Application configuration

Compared with Scenario 4, 3 new JDBC parameters `cachePrepStmts=true&prepStmtCacheSize=1000&prepStmtCacheSqlLimit=20480` are configured, as explained below.

- `cachePrepStmts = true`: caches Prepared Statement objects on the client side, which eliminates the calls of StmtPrepare and StmtClose.
- `prepStmtCacheSize`: the value must be greater than 0.
- `prepStmtCacheSqlLimit`: the value must be greater than the length of the SQL text.

In Scenario 5, the complete JDBC configurations are as follows.

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

11.1.3.6.2 Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the high CPU consumption of the `Prepare` command is no longer present.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

Figure 354: flame-graph-for-1-command

Performance Overview dashboard

In the Performance Overview dashboard, the most notable changes are that the three Stmt command types in the **CPS By Type** pane drop to one type, the `general` statement type in the **Database Time by SQL Type** pane is disappeared, and the QPS in the **QPS** pane increases to 30.9k.

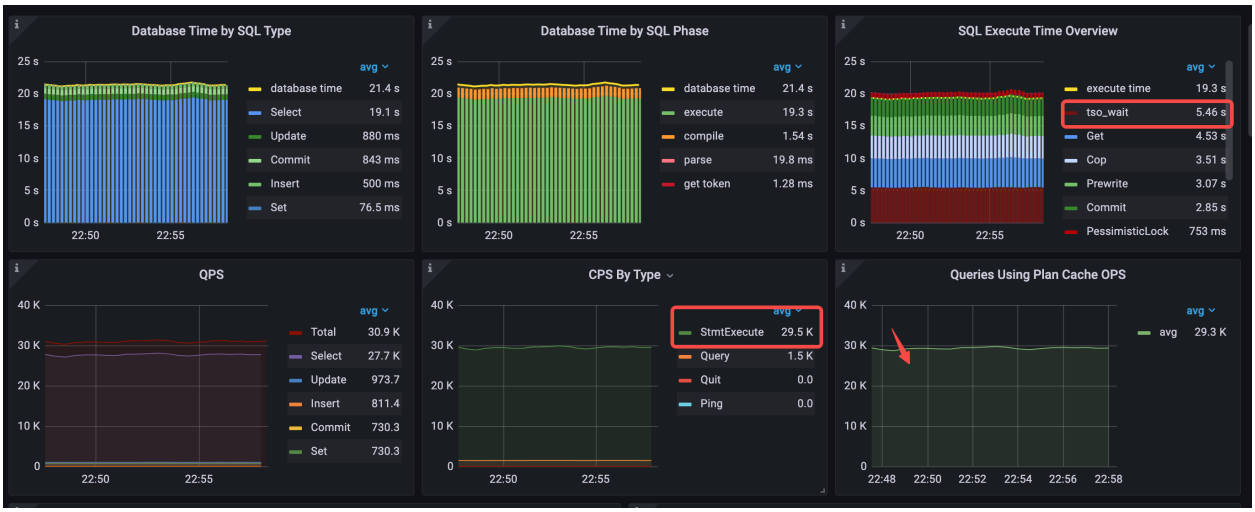

Figure 355: performance-overview-for-1-command

- Database Time by SQL Type: the `Select` statement type takes most of the time and the `general` statement type disappears.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 30.9k (from 22.1k to 30.9k)

The average TiDB CPU utilization drops from 827% to 577%. As the QPS increases, the average TiKV CPU utilization increases to 313%.

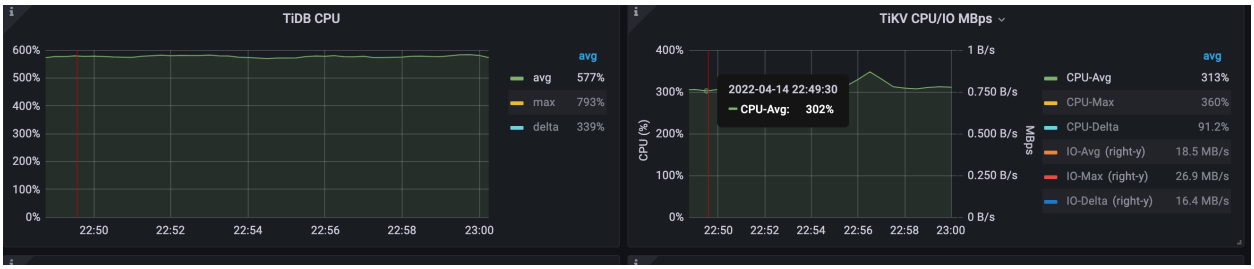

Figure 356: performance-overview-for-2-command

The key latency metrics are as follows:

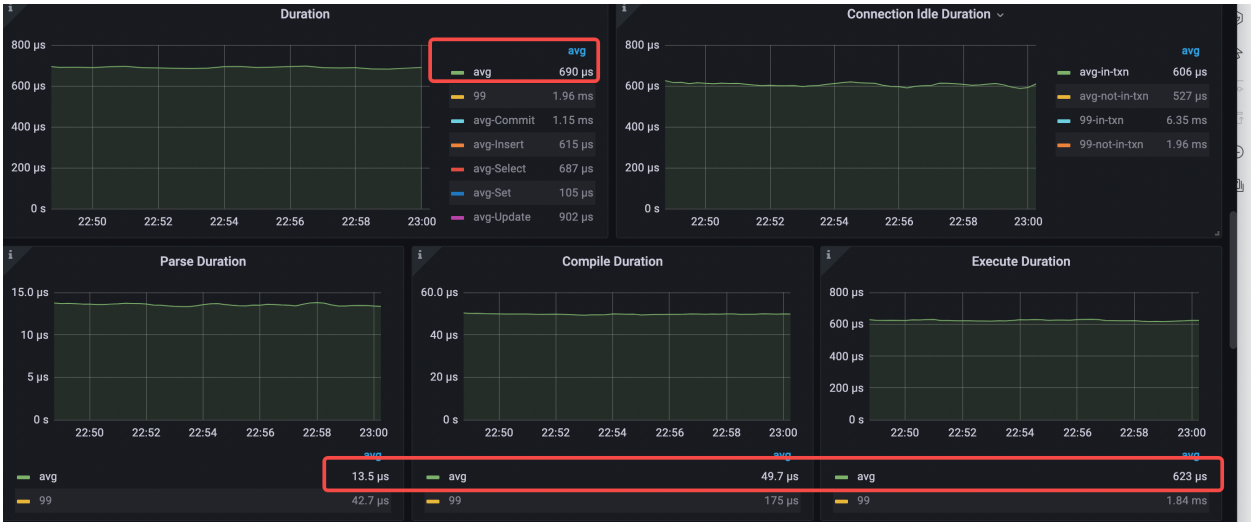

Figure 357: performance-overview-for-3-command

- avg query duration = 690 s (from 426 s to 690 s)
- avg parse duration = 13.5 s (from 12.3 s to 13.5 s)
- avg compile duration = 49.7 s (from 53.3 s to 49.7 s)
- avg execution duration = 623 s (from 699us to 623 s)
- avg pd tso wait duration = 196 s (from 224 s to 196 s)
- connection idle duration avg-in-txn = 608 s (from 250 s to 608 s)

11.1.3.6.3 Analysis conclusion

- Compared with Scenario 4, the **CPS By Type** pane in Scenario 5 has the `StmtExecute` command only, which avoids two network round trips and increases the overall system QPS.
- In the case of QPS increase, the latency decreases in terms of parse duration, compile duration, and execution duration, but the query duration increases instead. This is because TiDB processes `StmtPrepare` and `StmtClose` very quickly, and eliminating these two command types increases the average query duration.
- In Database Time by SQL Phase, `execute` takes the most time and is close to the database time. While in SQL Execute Time Overview, `tso wait` takes most of the time, and more than a quarter of `execute` time is taken to wait for TSO.
- The total `tso wait` time per second is 5.46s. The average `tso wait` time is 196 us, and the number of `tso cmd` times per second is 28k, which is very close to the QPS of 30.9k. This is because according to the implementation of the `read committed` isolation level in TiDB, every SQL statement in a transaction needs to request TSO from PD.

TiDB v6.0 provides `rc read`, which optimizes the `read committed` isolation level by reducing `tso cmd`. This feature is controlled by the global variable `set global ↪ tidb_rc_read_check_ts=on;`. When this variable is enabled, the default behavior of TiDB acts the same as the `repeatable-read` isolation level, at which only `start-ts` and `commit-ts` need to be obtained from the PD. The statements in a transaction use the `start-ts` to read data from TiKV first. If the data read from TiKV is earlier than `start-ts`, the data is returned directly. If the data read from TiKV is later than `start-ts`, the data is discarded. TiDB requests TSO from PD, and then retries the read. The `for update ts` of subsequent statements uses the latest PD TSO.

11.1.3.7 Scenario 6: Enable the `tidb_rc_read_check_ts` variable to reduce TSO requests

11.1.3.7.1 Application configuration

Compared with Scenario 5, the application configuration remains the same. The only difference is that the `set global tidb_rc_read_check_ts=on;` variable is configured to reduce TSO requests.

11.1.3.7.2 Performance analysis

Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

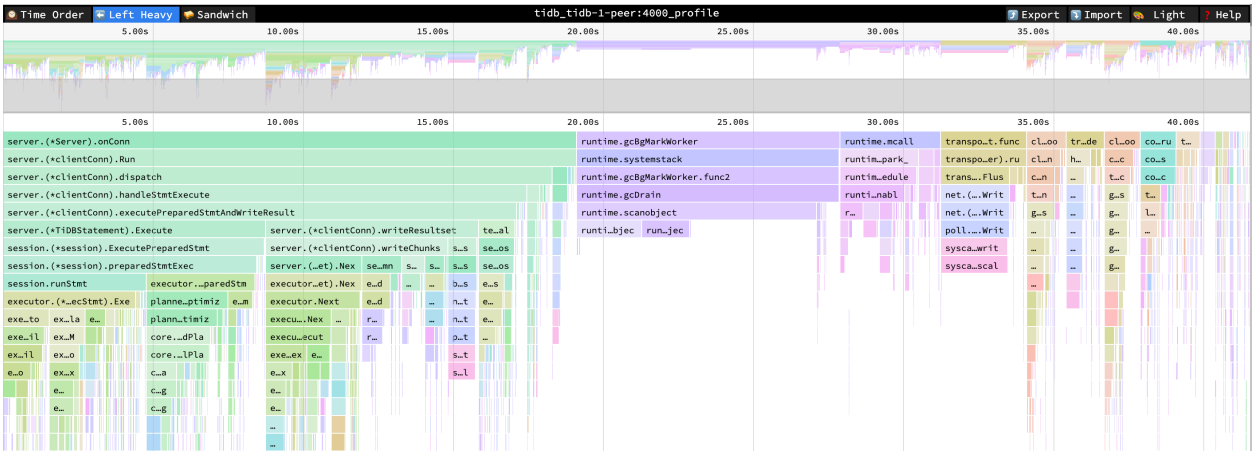

Figure 358: flame-graph-for-rc-read

Performance Overview dashboard

After using RC read, QPS increases from 30.9k to 34.9k, and the `tso wait` time consumed per second decreases from 5.46 s to 456 ms.

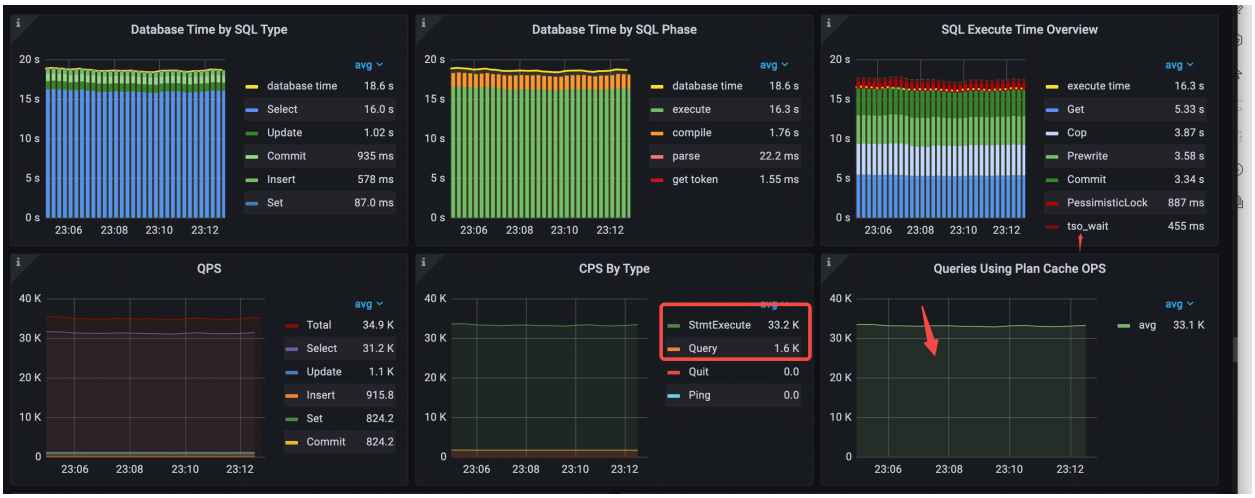

Figure 359: performance-overview-1-for-rc-read

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `Prewrite` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 34.9k (from 30.9k to 34.9k)

The `tso cmd` per second drops from 28.3k to 2.7k.

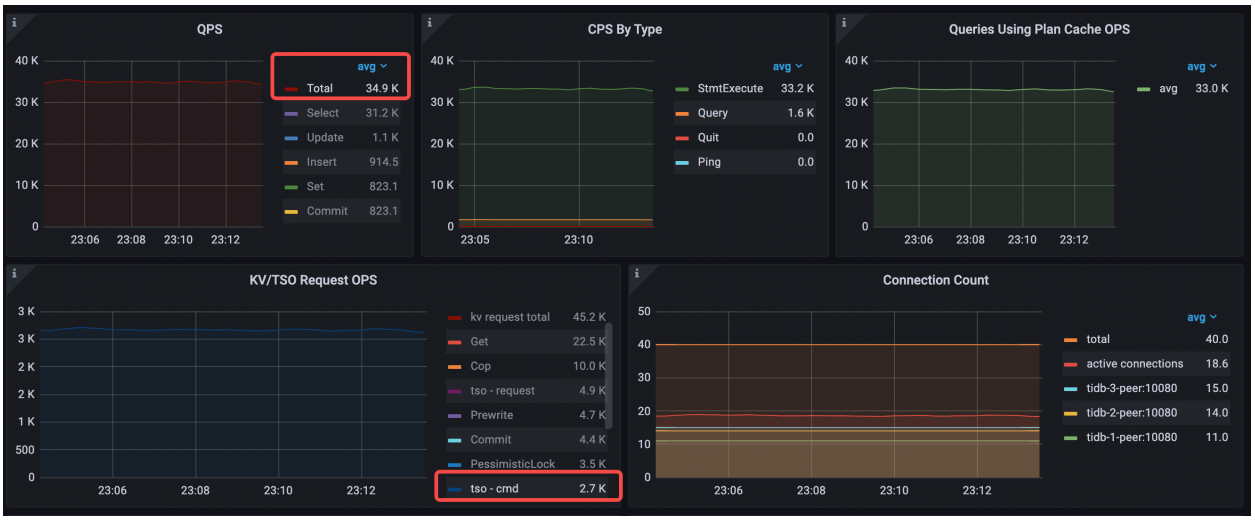

Figure 360: performance-overview-2-for-rc-read

The average TiDB CPU increases to 603% (from 577% to 603%).

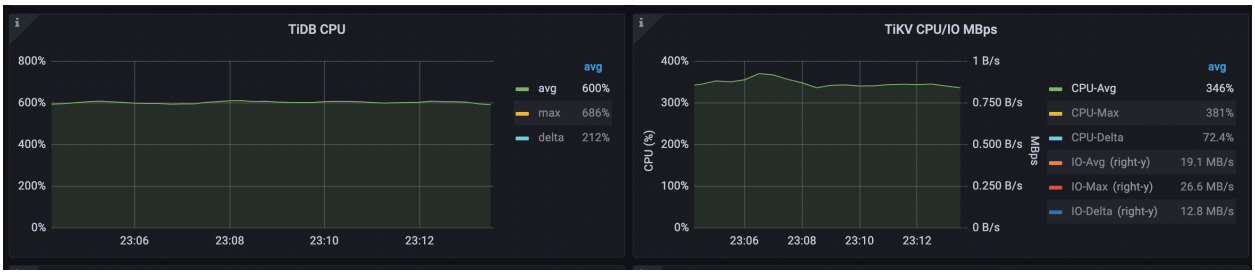

Figure 361: performance-overview-3-for-rc-read

The key latency metrics are as follows:

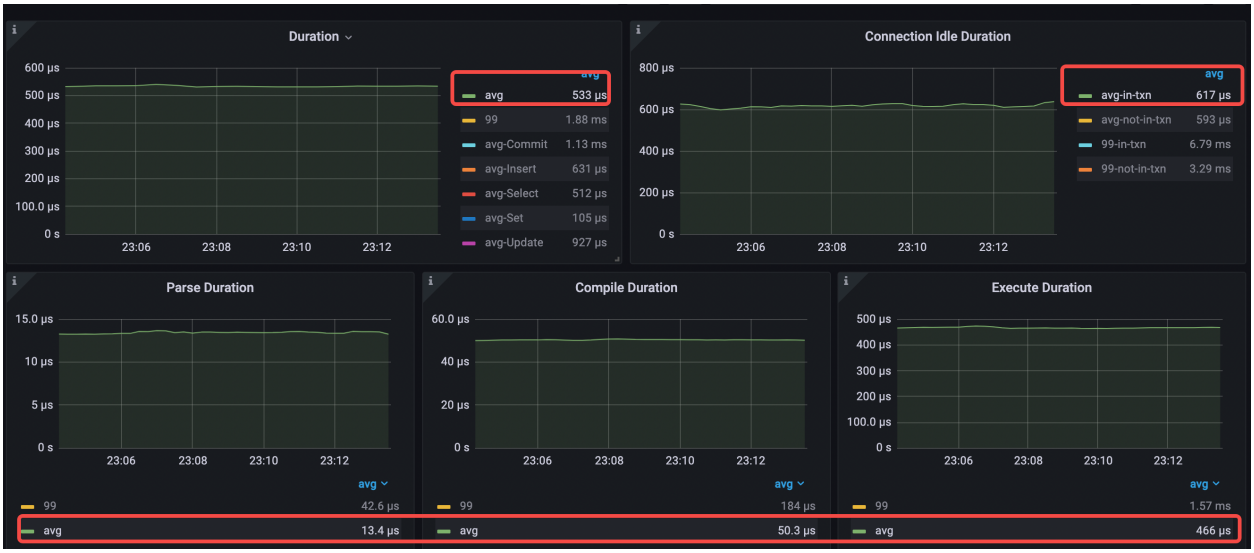

Figure 362: performance-overview-4-for-rc-read

- avg query duration = 533 s (from 690 s to 533 s)
- avg parse duration = 13.4 s (from 13.5 s to 13.4 s)
- avg compile duration = 50.3 s (from 49.7 s to 50.3 s)
- avg execution duration = 466 s (from 623 s to 466 s)
- avg pd tso wait duration = 171 s (from 196 s to 171 s)

11.1.3.7.3 Analysis conclusion

After enabling RC Read by `set global tidb_rc_read_check_ts=on;`, RC Read significantly reduces the times of `tso cmd`, thus reducing `tso wait` and average query duration, and improving QPS.

The bottlenecks of both current database time and latency are in the `execute` phase, in which the `Get` and `Cop` read requests take the highest percentage. Most of the tables in this workload are read-only or rarely modified, so you can use the small table caching feature supported since TiDB v6.0.0 to cache the data of these small tables and reduce the waiting time and resource consumption of KV read requests.

11.1.3.8 Scenario 7: Use the small table cache

11.1.3.8.1 Application configuration

Compared with Scenario 6, the application configuration remains the same. The only difference is that Scenario 7 uses SQL statements such as `alter table t1 cache;` to cache those read-only tables for the business.

11.1.3.8.2 Performance analysis

TiDB Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

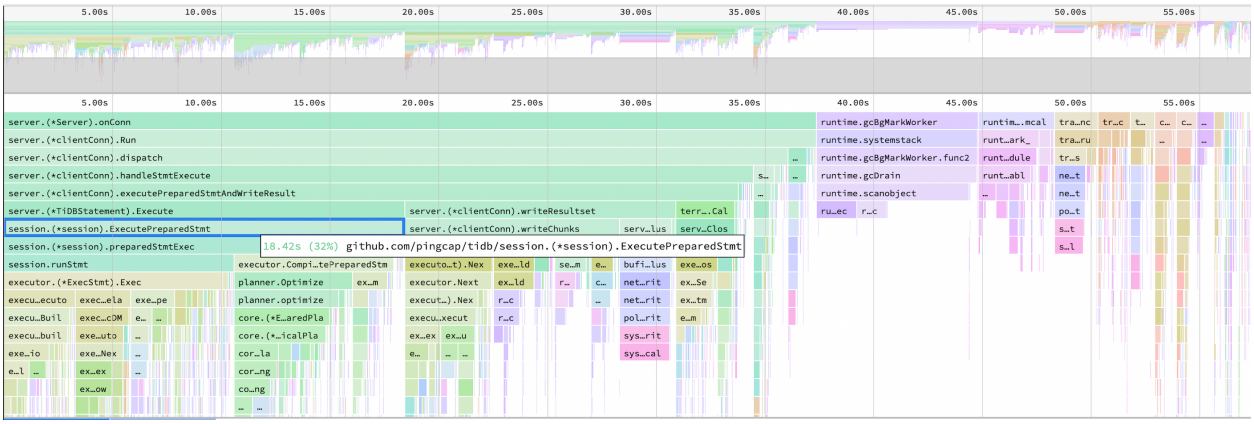

Figure 363: flame-graph-for-table-cache

Performance Overview dashboard

The QPS increases from 34.9k to 40.9k, and the KV request types take the most time in the `execute` phase change to `Prewrite` and `Commit`. The database time consumed by `Get` per second decreases from 5.33 seconds to 1.75 seconds, and the database time consumed by `Cop` per second decreases from 3.87 seconds to 1.09 seconds.

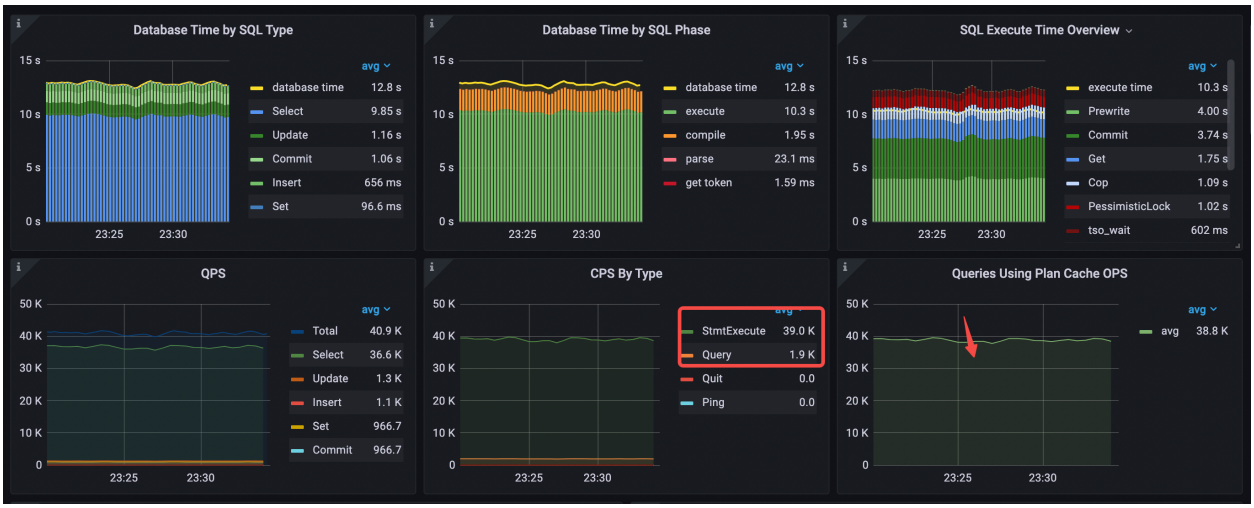

Figure 364: performance-overview-1-for-table-cache

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Prewrite`, `Commit`, and `Get` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 40.9k (from 34.9k to 40.9k)

The average TiDB CPU utilization drops from 603% to 478% and the average TiKV CPU utilization drops from 346% to 256%.

Figure 365: performance-overview-2-for-table-cache

The average query latency drops from 533 us to 313 us. The average `execute` latency drops from 466 us to 250 us.

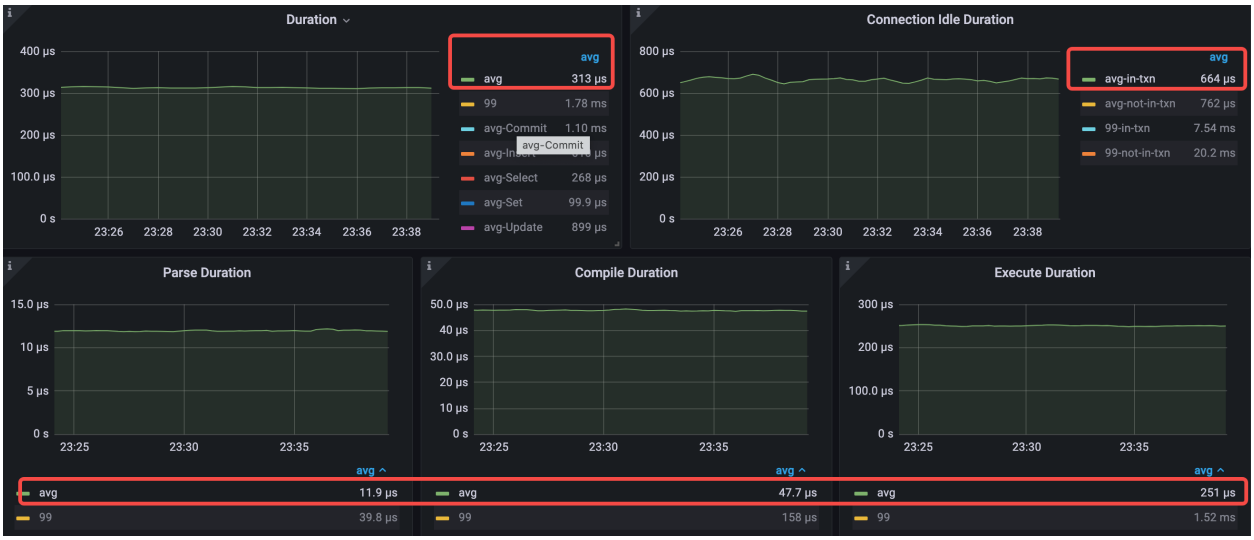

Figure 366: performance-overview-3-for-table-cache

- avg query duration = 313 s (from 533 s to 313 s)
- avg parse duration = 11.9 s (from 13.4 s to 11.9 s)
- avg compile duration = 47.7 s (from 50.3 s to 47.7 s)
- avg execution duration = 251 s (from 466 s to 251 s)

11.1.3.8.3 Analysis conclusion

After caching all read-only tables, the `Execute Duration` drops significantly because all read-only tables are cached in TiDB and there is no need to query data in TiKV for those tables, so the query duration drops and the QPS increases.

This is an optimistic result because data of read-only tables in actual business might be too large for TiDB to cache them all. Another limitation is that although the small table caching feature supports write operations, the write operation requires a default wait of 3 seconds to ensure that the cache of all TiDB nodes is invalidated first, which might not be feasible to applications with strict latency requirements.

11.1.3.9 Summary

The following table lists the performance of seven different scenarios.

Metrics	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6	Scenario 7	Comparing Scenario 5 with Scenario 2 (%)	Comparing Scenario 7 with Scenario 3 (%)
query duration	479 s	1120 s	528 s	426 s	690 s	533 s	313 s	-38%	-41%
QPS	56.3k	24.2k	19.7k	22.1k	30.9k	34.9k	40.9k	+28%	+108%

In these scenarios, Scenario 2 is a common scenario where applications use the Query interface, and Scenario 5 is an ideal scenario where applications use the Prepared Statement interface.

- Comparing Scenario 5 with Scenario 2, you can see that by using best practices for Java application development and caching Prepared Statement objects on the client side, each SQL statement requires only one command and database interaction to hit the execution plan cache, which results in a 38% drop in query latency and a 28% increase in QPS, while the average TiDB CPU utilization drops from 936% to 577%.
- Comparing Scenario 7 with Scenario 3, you can see that with the latest TiDB optimization features such as RC Read and small table cache on top of Scenario 5, latency is reduced by 41% and QPS is increased by 108%, while the average TiDB CPU utilization drops from 936% to 478%.

By comparing the performance of each scenario, we can draw the following conclusions:

- The execution plan cache of TiDB plays a critical role in the OLTP performance tuning. The RC Read and small table cache features introduced from v6.0.0 also play an important role in the further performance tuning of this workload.
- TiDB is compatible with different commands of the MySQL protocol. When using the Prepared Statement interface and setting the following JDBC connection parameters, the application can achieve its best performance:

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

- It is recommended that you use TiDB Dashboard (for example, the Top SQL feature and Continuous Profiling feature) and Performance Overview dashboard for performance analysis and tuning.

- With the Top SQL feature, you can visually monitor and explore the CPU consumption of each SQL statement in your database during execution to troubleshoot database performance issues.
- With Continuous Profiling, you can continuously collect performance data from each instance of TiDB, TiKV, and PD. When applications use different interfaces to interact with TiDB, the difference in the CPU consumption of TiDB is huge.
- With Performance Overview Dashboard, you can get an overview of database time and SQL execution time breakdown information. You can analyze and diagnose performance based on database time to determine whether the performance bottleneck of the entire system is in TiDB or not. If the bottleneck is in TiDB, you can use the database time and latency breakdowns, along with load profile and resource usage, to identify performance bottlenecks within TiDB and tune the performance accordingly.

With a combination usage of these features, you can analyze and tune performance for real-world applications efficiently.

11.1.4 TiFlash Performance Analysis and Tuning Methods

This document introduces TiFlash resource utilization and key performance metrics. You can monitor and evaluate the TiFlash cluster performance through the TiFlash panel on the Performance Overview dashboard.

11.1.4.1 Resource utilization of a TiFlash cluster

With the following three metrics, you can quickly get the resource utilization of a TiFlash cluster:

- CPU: the CPU utilization per TiFlash instance.
- Memory: the memory usage per TiFlash instance.
- IO utilization: the IO utilization per TiFlash instance.

Example: Resource utilization during CH-benCHmark workload

This TiFlash cluster consists of two nodes, each node configured with 16 cores and 48 GB of memory. During the CH-benCHmark workload, CPU utilization can reach up to 1500%, memory usage can reach up to 20 GB, and IO utilization can reach up to 91%. These metrics indicate that TiFlash node resources are approaching saturation.

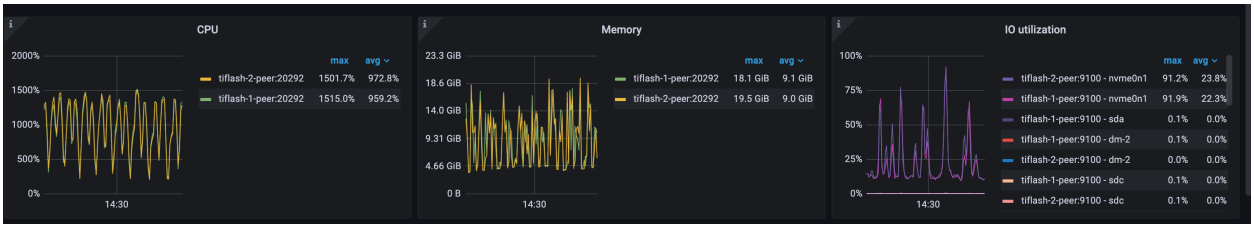

Figure 367: CH-TiFlash-MPP

11.1.4.2 Key metrics for TiFlash performance

11.1.4.2.1 Throughput metrics

With the following metrics, you can get the throughput of TiFlash:

- MPP Query count: the instant value of MPP query count for each TiFlash instance, reflecting the current number of MPP queries that need to be processed by the TiFlash instance (including those being processed and those awaiting scheduling).
- Request QPS: the number of coprocessor requests received by all TiFlash instances.
  - `run_mpp_task`, `dispatch_mpp_task`, and `mpp_establish_conn` are MPP requests.
  - `batch`: the number of batch requests.
  - `cop`: the number of coprocessor requests that are sent directly via the coprocessor interface.
  - `cop_execution`: the number of coprocessor requests currently being executed.
  - `remote_read`, `remote_read_constructed`, and `remote_read_sent` are remote read-related metrics. An increase in remote reads usually indicates an issue in the system.
- Executor QPS: the number of each type of dag operators in the requests received by all TiFlash instances, where `table_scan` is the table scan operator, `selection` is the selection operator, `aggregation` is the aggregation operator, `top_n` is the TopN operator, `limit` is the limit operator, `join` is a join operator, `exchange_sender` is a data sending operator, and `exchange_receiver` is a data receiving operator.

11.1.4.2.2 Latency metrics

With the following metrics, you can get the latency of TiFlash:

- Request Duration Overview: provides a stacked chart of the total processing duration for all request types in all TiFlash instances per second.
  - If the type of a request is `run_mpp_task`, `dispatch_mpp_task`, or `mpp_establish_conn` ↪ , it indicates that the SQL statement execution has been partially or fully

pushed down to TiFlash, typically involving join and data distribution operations. This is the most common request type in TiFlash.

- If the type of a request is `cop`, it indicates that the statement related to this request has not been fully pushed down to TiFlash. Typically, TiDB pushes down the table full scan operator to TiFlash for data access and filtering. If `cop` becomes the most common request type in the stacked chart, you need to check if it is reasonable.
    - If the amount of data queried by a SQL statement is large, the optimizer might estimate that TiFlash full table scans are more cost-effective according to the cost model.
    - If the schema of a queried table lacks suitable indexes, the optimizer can only push the query down to TiFlash for a full table scan, even if the amount of data to be queried is small. In this case, it is more efficient to create proper indexes and access the data through TiKV.

- Request Duration: the total processing duration for each MPP and coprocessor request type in all TiFlash instances, which includes the average latency and p99 latency.

- Request Handle Duration: the time from the start of executing the `cop` and `batch cop` ↪ requests to the completion of the execution, excluding waiting time. This metric is only applicable to the `cop` and `batch cop` types of requests, including average and P99 latency.

Example 1: Processing duration overview of TiFlash MPP requests

In the workload of the following diagram, `run_mpp_task` and `mpp_establish_conn` requests constitute the majority of the total processing duration, indicating that most of the requests are MPP tasks that are fully pushed down to TiFlash for execution.

The processing duration of `cop` requests is relatively small, indicating that some of the requests are pushed down to TiFlash for data access and filtering through the coprocessor.

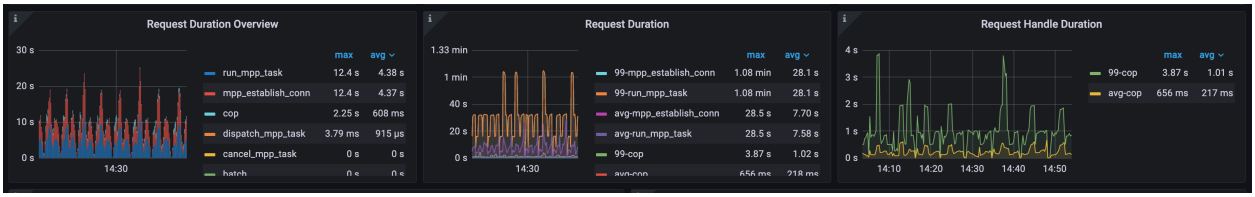

Figure 368: CH-TiFlash-MPP

Example 2: TiFlash `cop` requests constitute the majority of the total processing duration

In the workload of the following diagram, `cop` requests constitute the majority of the total processing duration. In this case, you can check the SQL execution plan to see why these `cop` requests are generated.

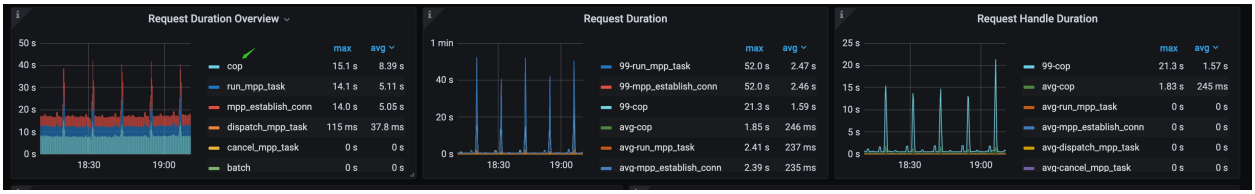

Figure 369: Cop

11.1.4.2.3 Raft-related metrics

With the following metrics, you can get the Raft replication status of TiFlash:

- Raft Wait Index Duration: the duration of waiting until the local Region index >= `read_index` for all TiFlash instances, which represents the latency of the `wait_index` operation. If this metric is too high, it indicates that data replication from TiKV to TiFlash has a significant latency. Possible reasons include the following:
    - TiKV resource is overloaded.
    - TiFlash resource is overloaded, especially IO resources.
    - There is a network bottleneck between TiKV and TiFlash.
- Raft Batch Read Index Duration: the latency of `read_index` for all TiFlash instances. If this metric is too high, it indicates that the interaction between TiFlash and TiKV is slow. Possible reasons include the following:
    - TiFlash resource is overloaded.
    - TiKV resource is overloaded.
    - There is a network bottleneck between TiFlash and TiKV.

11.1.4.2.4 IO throughput metrics

With the following metrics, you can get the IO throughput of TiFlash:

- Write Throughput By Instance: the throughput of data written by each TiFlash instance. It includes the throughput by applying the Raft data logs and Raft snapshots.
- Write flow: the traffic of disk writes by all TiFlash instances.
    - File Descriptor: the stable layer of the DeltaTree storage engine used by TiFlash.
    - Page: refers to Pagestore, the Delta change layer of the DeltaTree storage engine used by TiFlash.
- Read flow: traffic of disk read operations for all TiFlash instances.
    - File Descriptor: the stable layer of the DeltaTree storage engine used by TiFlash.

- Page: refers to Pagestore, the Delta change layer of the DeltaTree storage engine used by TiFlash.

You can calculate the write amplification factor of the entire TiFlash cluster using the `(Read flow + Write flow)÷ total Write Throughput By Instance` formula.

Example 1: Raft and IO metrics of the CH-benCHmark workload in a self-hosted environment

As shown in the following diagram, the `Raft Wait Index Duration` and the 99th percentile of `Raft Batch Read Index Duration` for this TiFlash cluster are relatively high, at 3.24 seconds and 753 milliseconds respectively. This is because the TiFlash workload in this cluster is high and latency occurs in data replication.

In this cluster, there are two TiFlash nodes. The incremental data replication speed from TiKV to TiFlash is approximately 28 MB per second. The maximum write throughput of the stable layer (File Descriptor) is 939 MB/s, and the maximum read throughput is 1.1 GiB/s. Meanwhile, the maximum write throughput of the Delta layer (Page) is 74 MB/s, and the maximum read throughput is 111 MB/s. In this environment, TiFlash uses dedicated NVME disks, which have strong IO throughput capabilities.

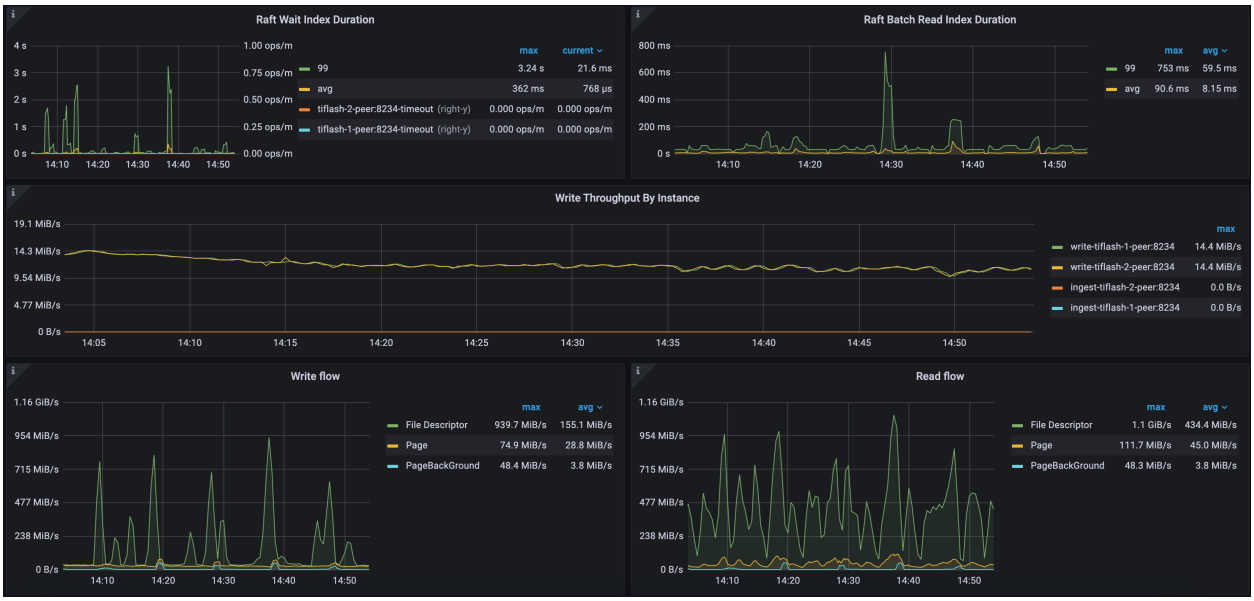

Figure 370: CH-2TiFlash-OP

Example 2: Raft and IO metrics of the CH-benCHmark workload in a public cloud deployment environment

As shown in the following diagram, the 99th percentile of `Raft Wait Index Duration` is up to 438 milliseconds, and 99th percentile of the `Raft Batch Read Index Duration` is up to 125 milliseconds. This cluster has only one TiFlash node. TiKV replicates about 5 MB

of incremental data to TiFlash per second. The maximum write traffic of the stable layer (File Descriptor) is 78 MB/s and the maximum read traffic is 221 MB/s. In the meantime, the maximum write traffic of the Delta layer (Page) is 8 MB/s and the maximum read traffic is 18 MB/s. In this environment, TiFlash uses an AWS EBS cloud disk, which has relatively weak IO throughput.

Figure 371: CH-TiFlash-MPP

11.1.5 TiCDC Performance Analysis and Tuning Methods

This document introduces TiCDC resource utilization and key performance metrics. You can monitor and evaluate TiCDC performance on data replication through the CDC panel on the Performance Overview dashboard.

11.1.5.1 Resource utilization of a TiCDC cluster

With the following three metrics, you can quickly get the resource utilization of a TiCDC cluster:

- CPU usage: the CPU usage per TiCDC node.
- Memory usage: the memory usage per TiCDC node.
- Goroutine count: the number of goroutines per TiCDC node.

11.1.5.2 Key metrics for TiCDC data replication

11.1.5.2.1 TiCDC overall metrics

With the following metrics, you can get an overview of TiCDC data replication:

- Changefeed checkpoint lag: the progress lag of data replication between the upstream and the downstream, measured in seconds.

  If the speed at which TiCDC consumes data and writes downstream keeps up with upstream data changes, this metric remains within a small latency range, typically within 10 seconds. Otherwise, this metric will continue to increase.

  When this metric (that is, `Changefeed checkpoint lag`) increases, common reasons are as follows:

  - Insufficient system resources: if the CPU, memory, or disk space of TiCDC is insufficient, it might cause data processing to be too slow, which results in a long checkpoint of the TiCDC changefeed.
  - Network issues: if network interruptions, lags, or insufficient bandwidth occur in TiCDC, it might affect data transfer speed, which results in a long checkpoint of the TiCDC changefeed.
  - High QPS in the upstream: if the data to be processed by TiCDC is excessively large, it might cause data processing timeouts, which results in an increased checkpoint of the TiCDC changefeed. Typically, a single TiCDC node can handle a maximum QPS of around 60K.
  - Database issues:
    - The gap between the `min resolved ts` of the upstream TiKV cluster and the latest PD TSO is significant. This issue usually occurs because TiKV fails to advance the resolved ts in time when the write workload of the upstream is excessively heavy.
    - The write latency in downstream databases is high, blocking TiCDC from replicating data to the downstream timely.

- Changefeed resolved ts lag: the progress lag between the internal replication status of a TiCDC node and the upstream, measured in seconds. If this metric is high, it indicates that the data processing capability of the TiCDC Puller or Sorter module might be insufficient, or there might be network latency or slow disk read/write speed issues. In such cases, to ensure the efficient and stable operation of TiCDC, you need to take appropriate measures, such as increasing the number of TiCDC nodes or optimizing the network configuration.

- The status of changefeeds: for status explanations of changefeeds, see Changefeed state transfer.

Example 1: High checkpoint lag due to high upstream QPS in the case of a single TiCDC node

As shown in the following diagram, because the upstream QPS is excessively high and there is only a single TiCDC node in the cluster, the TiCDC node is overloaded, the CPU

usage is high, and both `Changefeed checkpoint lag` and `Changefeed resolved ts lag` keep increasing. The changefeed status intermittently transitions from `0` to `1`, indicating that the changefeed keeps getting errors. You can try resolving this issue by adding more resources as follows:

- Add more TiCDC nodes: scale out the TiCDC cluster to multiple nodes to increase processing capacity.
- Optimize TiCDC node resources: increase CPU and memory configurations of the TiCDC node to improve performance.

Figure 372: TiCDC overview

11.1.5.2.2 Data flow throughput metrics and downstream latency

With the following metrics, you can learn the data flow throughput and downstream latency of TiCDC:

- Puller output events/s: the number of rows that the Puller module of TiCDC nodes sends to the Sorter module per second.
- Sorter output events/s: the number of rows that the Sorter module of TiCDC nodes sends to the Mounter module per second.
- Mounter output events/s: the number of rows that the Mounter module of TiCDC nodes sends to the Sink module per second.
- Table sink output events/s: the number of rows that the Table Sorter module of the TiCDC nodes sends to the Sink module per second.
- SinkV2 - Sink flush rows/s: the number of rows that the Sink module in the TiCDC node sends to the downstream per second.
- Transaction Sink Full Flush Duration: the average latency and p999 latency of writing downstream transactions by the MySQL Sink of TiCDC nodes.
- MQ Worker Send Message Duration Percentile: the latency of sending messages by MQ worker when the downstream is Kafka.
- Kafka Outgoing Bytes: the traffic of writing downstream transactions in MQ Workload.

Example 2: Impact of downstream database write speed on TiCDC data replication performance

As shown in the following diagram, both upstream and downstream are TiDB clusters. The TiCDC `Puller output events/s` metric indicates the QPS of the upstream database. The `Transaction Sink Full Flush Duration` metric indicates the average write latency of the downstream database, which is high during the first workload and low during the second workload.

- During the first workload, because the downstream TiDB cluster writes data slowly, TiCDC consumes data at a speed that falls behind the upstream QPS, leading to a continuous increase in `Changefeed checkpoint lag`. However, `Changefeed resolved ts lag` remains within 300 milliseconds, indicating that replication lag and throughput bottlenecks are not caused by the puller and sorter modules but caused by the downstream sink module.
- During the second workload, because the downstream TiDB cluster writes data faster, TiCDC replicates data at a speed that completely catches up with the upstream, the `Changefeed checkpoint lag` and `Changefeed resolved ts lag` remain within 500 milliseconds, which is a relatively ideal replication speed for TiCDC.

Figure 373: TiCDC overview

Figure 374: data flow and txn latency

11.1.6 Latency Breakdown

This document breaks down the latency into metrics and then analyzes it from the user's perspective from the following aspects:

- General SQL layer
- Read queries
- Write queries
- Batch client
- TiKV snapshot
- Async write

These analyses provide you with a deep insight into time cost during TiDB SQL queries. This is a guide to TiDB's critical path diagnosis. Besides, the Diagnosis use cases section introduces how to analyze latency in real use cases.

It's better to read Performance Analysis and Tuning before this document. Note that when breaking down latency into metrics, the average value of duration or latency is calculated instead of some specific slow queries. Many metrics are shown as histogram, which is a distribution of the duration or latency. To calculate the average latency, you need to use the following sum and count counter.

```
avg = ${metric_name}_sum / ${metric_name}_count
```

Metrics described in this document can be read directly from the Prometheus dashboard of TiDB.

11.1.6.1 General SQL layer

This general SQL layer latency exists on the top level of TiDB and is shared by all SQL queries. The following is the time cost diagram of general SQL layer operation:

```
Diagram(
    NonTerminal("Token wait duration"),
    Choice(
        0,
        Comment("Prepared statement"),
        NonTerminal("Parse duration"),
    ),
    OneOrMore(
        Sequence(
        Choice(
            0,
            NonTerminal("Optimize prepared plan duration"),
            Sequence(
            Comment("Plan cache miss"),
            NonTerminal("Compile duration"),
            ),
        ),
        NonTerminal("TSO wait duration"),
        NonTerminal("Execution duration"),
        ),
        Comment("Retry"),
    ),
)
```

The general SQL layer latency can be observed as the `e2e duration` metric and is calculated as:

```
e2e duration =
    tidb_server_get_token_duration_seconds +
    tidb_session_parse_duration_seconds +
    tidb_session_compile_duration_seconds +
    tidb_session_execute_duration_seconds{type="general"}
```

- `tidb_server_get_token_duration_seconds` records the duration of Token waiting. This is usually less than 1 millisecond and is small enough to be ignored.
- `tidb_session_parse_duration_seconds` records the duration of parsing SQL queries to an Abstract Syntax Tree (AST), which can be skipped by `PREPARE/EXECUTE` statements.
- `tidb_session_compile_duration_seconds` records the duration of compiling an AST to an execution plan, which can be skipped by SQL prepared execution plan cache.

- `tidb_session_execute_duration_seconds{type="general"}` records the duration of execution, which mixes all types of user queries. This needs to be broken down into fine-grained durations for analyzing performance issues or bottlenecks.

Generally, OLTP (Online Transactional Processing) workload can be divided into read and write queries, which share some critical code. The following sections describe latency in read queries and write queries, which are executed differently.

11.1.6.2 Read queries

Read queries have only a single process form.

11.1.6.2.1 Point get

The following is the time cost diagram of point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Resolve TSO"),
        Comment("Read by clustered PK in auto-commit-txn mode or snapshot
            ↪ read"),
    ),
    Choice(
        0,
        NonTerminal("Read handle by index key"),
        Comment("Read by clustered PK, encode handle by key"),
    ),
    NonTerminal("Read value by handle"),
)
```

During point get, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handle duration +
    read value duration
```

`pd_client_cmd_handle_cmds_duration_seconds{type="wait"}` records the duration of fetching TSO (Timestamp Oracle) from PD. When reading in an auto-commit transaction mode with a clustered primary index or from a snapshot, the value will be zero.

The `read handle duration` and `read value duration` are calculated as:

```
read handle duration = read value duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="get"} =
```

```
    send request duration =
    tidb_tikvclient_request_seconds{type="Get"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

The `tidb_tikvclient_request_seconds{type="Get"}` records a duration of get requests which are sent directly to TiKV via a batched gRPC wrapper. For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration`, `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    tikv_engine_seek_micro_seconds{type="seek_average"} +
    read value duration +
    read value duration(non-short value)
```

At this time, requests are in TiKV. TiKV processes get requests by one seek and one or two read actions (short values are encoded in a write column family, and reading it once is enough). TiKV gets a snapshot before processing the read request. For more details about the TiKV snapshot duration, refer to the TiKV snapshot section.

The `read value duration(from disk)` is calculated as:

```
read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="get/
        ↪ batch_get_command"})) / sum(rate(tikv_storage_rocksdb_perf{metric
        ↪ ="block_read_count",req="get/batch_get_command"}))
```

TiKV uses RocksDB as its storage engine. When the required value is missing from the block cache, TiKV needs to load the value from the disk. For `tikv_storage_rocksdb_perf`, the get request can be either `get` or `batch_get_command`.

11.1.6.2.2 Batch point get

The following is the time cost diagram of batch point get operations:

```
Diagram(
  NonTerminal("Resolve TSO"),
  Choice(
    0,
    NonTerminal("Read all handles by index keys"),
    Comment("Read by clustered PK, encode handle by keys"),
  ),
```

```
  NonTerminal("Read values by handles"),
)
```

During batch point get, the `tidb_session_execute_duration_seconds{type="general"}` is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handles duration +
    read values duration
```

The process of batch point get is almost the same as Point get except that batch point get reads multiple values at the same time.

The `read handles duration` and `read values duration` are calculated as:

```
read handles duration = read values duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} =
    send request duration =
    tidb_tikvclient_request_seconds{type="BatchGet"} =
    tidb_tikvclient_batch_wait_duration(transaction) +
    tidb_tikvclient_batch_send_latency(transaction) +
    tikv_grpc_msg_duration_seconds{type="kv_batch_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}(transaction)
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_dur` ↪ `(transaction)`, `tidb_tikvclient_batch_send_latency(transaction)`, and `tidb_tikvclient_rpc` ↪ `{store="?"}(transaction)`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_batch_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_batch_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    n * (
        tikv_engine_seek_micro_seconds{type="seek_max"} +
        read value duration +
        read value duration(non-short value)
    )

read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ batch_get"})) / sum(rate(tikv_storage_rocksdb_perf{metric="
        ↪ block_read_count",req="batch_get"}))
```

After getting a snapshot, TiKV reads multiple values from the same snapshot. The read duration is the same as Point get. When TiKV loads data from disk, the average duration can be calculated by `tikv_storage_rocksdb_perf` with `req="batch_get"`.

11.1.6.2.3 Table scan & Index scan

The following is the time cost diagram of table scan and index scan operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related table/index ranges"),
        OneOrMore(
            NonTerminal("Wait for result"),
            Comment("Next loop: drain the result"),
        ),
    ),
)
```

During table scan and index scan, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )
    tidb_distsql_handle_query_duration_seconds{sql_type="general"} <= send
        ↪ request duration
```

Table scan and index scan are processed in the same way. `req_per_copr` is the distributed task count. Because coprocessor execution and data responding to client are in different threads, `tidb_distsql_handle_query_duration_seconds{sql_type="general"}` is the wait time and it is less than the `send request duration`.

The `send request duration` and `req_per_copr` are calculated as:

```
send request duration =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="coprocessor"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tikv_grpc_msg_duration_seconds{type="coprocessor"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} +
    tikv_coprocessor_request_wait_seconds{type="schedule"} +
    tikv_coprocessor_request_handler_build_seconds{type="index/select"} +
    tikv_coprocessor_request_handle_seconds{type="index/select"}

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    ↪ (tidb_distsql_scan_keys_partial_num_count)
```

In TiKV, the table scan type is `select` and the index scan type is `index`. The details of `select` and `index` type duration are the same.

11.1.6.2.4 Index look up

The following is the time cost diagram of index look up operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related index ranges"),
        OneOrMore(
            Sequence(
                NonTerminal("Wait for index scan result"),
                NonTerminal("Wait for table scan result"),
            ),
        Comment("Next loop: drain the result"),
        ),
    ),
)
```

During index look up, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    ) +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    (tidb_distsql_scan_keys_partial_num_count)
```

An index look up combines index scan and table scan, which are processed in a pipeline.

11.1.6.3 Write queries

Write queries are much more complex than read queries. There are some variants of write queries. The following is the time cost diagram of write queries operations:

```
Diagram(
    NonTerminal("Execute write query"),
    Choice(
        0,
```

```
        NonTerminal("Pessimistic lock keys"),
        Comment("bypass in optimistic transaction"),
    ),
    Choice(
        0,
        NonTerminal("Auto Commit Transaction"),
        Comment("bypass in non-auto-commit or explicit transaction"),
    ),
)
```

	Pessimistic transaction	Optimistic transaction
Auto-commit	execute + lock + commit	execute + commit
Non-auto-commit	execute + lock	execute

A write query is divided into the following three phases:

- execute phase: execute and write mutation into the memory of TiDB.
- lock phase: acquire pessimistic locks for the execution result.
- commit phase: commit the transaction via the two-phase commit protocol (2PC).

In the execute phase, TiDB manipulates data in memory and the main latency comes from reading the required data. For update and delete queries, TiDB reads data from TiKV first, and then updates or deletes the row in memory.

The exception is lock-time read operations (`SELECT FOR UPDATE`) with point get and batch point get, which perform read and lock in a single Remote Procedure Call (RPC).

11.1.6.3.1 Lock-time point get

The following is the time cost diagram of lock-time point get operations:

```
Diagram(
    Choice(
        0,
        Sequence(
            NonTerminal("Read handle key by index key"),
            NonTerminal("Lock index key"),
        ),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock handle key"),
    NonTerminal("Read value from pessimistic lock cache"),
)
```

During lock-time point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    2 * tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

Lock-time point get locks the key and returns its value. Compared with the lock phase after execution, this saves 1 round trip. The duration of the lock-time point get can be treated the same as Lock duration.

11.1.6.3.2 Lock-time batch point get

The following is the time cost diagram of lock-time batch point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Read handle keys by index keys"),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock index and handle keys"),
    NonTerminal("Read values from pessimistic lock cache"),
)
```

During lock-time batch point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} +
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

The execution of the lock-time batch point get is similar to the Lock-time point get except that the lock-time batch point get reads multiple values in a single RPC. For more details about the `tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"}` duration, refer to the Batch point get section.

11.1.6.3.3 Lock

This section describes the lock duration.

```
round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_pessimistic_lock
        ↪ "})) /
```

```
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2
        ↪ pc_pessimistic_lock"})) /
    committer-concurrency
)

lock = tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"} =
    round * tidb_tikvclient_request_seconds{type="PessimisticLock"}
```

Locks are acquired through the 2PC structure, which has a flow control mechanism. The flow control limits concurrent on-the-fly requests by `committer-concurrency` (default value is 128). For simplicity, the flow control can be treated as an amplification of request latency (`round`).

The `tidb_tikvclient_request_seconds{type="PessimisticLock"}` is calculated as:

```
tidb_tikvclient_request_seconds{type="PessimisticLock"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_dur` ↪ , `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds` ↪ `{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} =
    tikv_scheduler_latch_wait_duration_seconds{type="
        ↪ acquire_pessimistic_lock"} +
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    (lock in-mem key count + lock on-disk key count) * lock read duration +
    lock on-disk key count / (lock in-mem key count + lock on-disk key count
        ↪ ) *
    lock write duration
```

- Since TiDB v6.0, TiKV uses in-memory pessimistic lock by default. In-memory pessimistic lock bypass the async write process.
- `tikv_storage_engine_async_request_duration_seconds{type="snapshot"}` is a snapshot type duration. For more details, refer to the TiKV Snapshot section.
- The `lock in-mem key count` and `lock on-disk key count` are calculated as:

```
lock in-mem key count =
    sum(rate(tikv_in_memory_pessimistic_locking{result="success"})) /
```

```
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="
        ↪ kv_pessimistic_lock"}}))

lock on-disk key count =
    sum(rate(tikv_in_memory_pessimistic_locking{result="full"})) /
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="
        ↪ kv_pessimistic_lock"}}))
```

The count of in-memory and on-disk locked keys can be calculated by the in-memory lock counter. TiKV reads the keys' values before acquiring locks, and the read duration can be calculated by RocksDB performance context.

```
lock read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ acquire_pessimistic_lock"})) / sum(rate(
        ↪ tikv_storage_rocksdb_perf{metric="block_read_count",req="
        ↪ acquire_pessimistic_lock"}))
```

- `lock write duration` is the duration of writing on-disk lock. For more details, refer to the Async write section.

11.1.6.3.4 Commit

This section describes the commit duration. The following is the time cost diagram of commit operations:

```
Diagram(
    Stack(
        Sequence(
            Choice(
                0,
                Comment("use 2pc or causal consistency"),
                NonTerminal("Get min-commit-ts"),
            ),
            Optional("Async prewrite binlog"),
            NonTerminal("Prewrite mutations"),
            Optional("Wait prewrite binlog result"),
        ),
        Sequence(
            Choice(
                1,
                Comment("1pc"),
                Sequence(
                    Comment("2pc"),
                    NonTerminal("Get commit-ts"),
                    NonTerminal("Check schema"),
```

```
                NonTerminal("Commit PK mutation"),
            ),
            Sequence(
                Comment("async-commit"),
                NonTerminal("Commit mutations asynchronously"),
            ),
        ),
        Choice(
            0,
            Comment("committed"),
            NonTerminal("Async cleanup"),
        ),
        Optional("Commit binlog"),
    ),
),
)
```

The duration of the commit phase is calculated as:

```
commit =
    Get_latest_ts_time +
    Prewrite_time +
    Get_commit_ts_time +
    Commit_time

Get_latest_ts_time = Get_commit_ts_time =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"}

prewrite_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_prewrite"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_prewrite"})) /
    committer-concurrency
)

commit_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_commit"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_commit"})) /
    committer-concurrency
)

Prewrite_time =
    prewrite_round * tidb_tikvclient_request_seconds{type="Prewrite"}

Commit_time =
    commit_round * tidb_tikvclient_request_seconds{type="Commit"}
```

The commit duration can be broken down into four metrics:

- `Get_latest_ts_time` records the duration of getting latest TSO in async-commit or single-phase commit (1PC) transaction.
- `Prewrite_time` records the duration of the prewrite phase.
- `Get_commit_ts_time` records the duration of common 2PC transaction.
- `Commit_time` records the duration of the commit phase. Note that an async-commit or 1PC transaction does not have this phase.

Like pessimistic lock, flow control acts as an amplification of latency (`prewrite_round` and `commit_round` in the preceding formula).

The `tidb_tikvclient_request_seconds{type="Prewrite"}` and `tidb_tikvclient_request_secon` ↪ `{type="Commit"}` duration are calculated as:

```
tidb_tikvclient_request_seconds{type="Prewrite"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_prewrite"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tidb_tikvclient_request_seconds{type="Commit"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_commit"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_dur` ↪ , `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds` ↪ `{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_prewrite"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_prewrite"} =
    prewrite key count * prewrite read duration +
    prewrite write duration

prewrite key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="prewrite"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="prewrite"}))

prewrite read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ prewrite"})) / sum(rate(tikv_storage_rocksdb_perf{metric="
        ↪ block_read_count",req="prewrite"}))
```

Like locks in TiKV, prewrite is processed in read and write phases. The read duration can be calculated from the RocksDB performance context. For more details about the write duration, refer to the Async write section.

The `tikv_grpc_msg_duration_seconds{type="kv_commit"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_commit"} =
    commit key count * commit read duration +
    commit write duration

commit key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="commit"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="commit"}))

commit read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="commit
        ↪ "})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_read_count
        ↪ ",req="commit"})) (storage)
```

The duration of `kv_commit` is almost the same as `kv_prewrite`. For more details about the write duration, refer to the Async write section.

11.1.6.4 Batch client

The following is the time cost diagram of the batch client:

```
Diagram(
    NonTerminal("Get conn pool to the target store"),
    Choice(
        0,
        Sequence(
            Comment("Batch enabled"),
                NonTerminal("Push request to channel"),
                NonTerminal("Wait response"),
            ),
            Sequence(
            NonTerminal("Get conn from pool"),
            NonTerminal("Call RPC"),
            Choice(
                0,
                Comment("Unary call"),
                NonTerminal("Recv first"),
            ),
        ),
    ),
)
```

- The overall duration of sending a request is observed as `tidb_tikvclient_request_seconds` ↪ .
- RPC client maintains connection pools (named ConnArray) to each store, and each pool has a BatchConn with a batch request (send) channel.
- Batch is enabled when the store is TiKV and batch size is positive, which is true in most cases.
- The size of batch request channel is `tikv-client.max-batch-size` (default is `128`), the duration of enqueue is observed as `tidb_tikvclient_batch_wait_duration`.
- There are three kinds of stream requests: `CmdBatchCop`, `CmdCopStream`, and `CmdMPPConn`, which involve an additional `recv()` call to fetch the first response from the stream.

Though there is still some latency missed observed, the `tidb_tikvclient_request_seconds` ↪ can be calculated approximately as:

```
tidb_tikvclient_request_seconds{type="?"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_?"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

- `tidb_tikvclient_batch_wait_duration` records the waiting duration in the batch system.
- `tidb_tikvclient_batch_send_latency` records the encode duration in the batch system.
- `tikv_grpc_msg_duration_seconds{type="kv_?"}` is the TiKV processing duration.
- `tidb_tikvclient_rpc_net_latency_seconds` records the network latency.

11.1.6.5 TiKV snapshot

The following is the time cost diagram of TiKV snapshot operations:

```
Diagram(
    Choice(
        0,
        Comment("Local Read"),
        Sequence(
            NonTerminal("Propose Wait"),
            NonTerminal("Read index Read Wait"),
        ),
    ),
    NonTerminal("Fetch A Snapshot From KV Engine"),
)
```

The overall duration of a TiKV snapshot is observed as `tikv_storage_engine_async_request_durati` ↪ `{type="snapshot"}` and is calculated as:

```
tikv_storage_engine_async_request_duration_seconds{type="snapshot"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} =
    tikv_raftstore_request_wait_time_duration_secs +
    tikv_raftstore_commit_log_duration_seconds +
    get snapshot from rocksdb duration
```

When leader lease is expired, TiKV proposes a read index command before getting a snapshot from RocksDB. `tikv_raftstore_request_wait_time_duration_secs` and `tikv_raftstore_commit_log_duration_seconds` are the duration of committing read index command.

Since getting a snapshot from RocksDB is usually a fast operation, the `get snapshot from rocksdb duration` is ignored.

11.1.6.6 Async write

Async write is the process that TiKV writes data into the Raft-based replicated state machine asynchronously with a callback.

- The following is the time cost diagram of async write operations when the asynchronous IO is disabled:

```
Diagram(
    NonTerminal("Propose Wait"),
    NonTerminal("Process Command"),
    Choice(
        0,
        Sequence(
            NonTerminal("Wait Current Batch"),
            NonTerminal("Write to Log Engine"),
        ),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

- The following is the time cost diagram of async write operations when the asynchronous IO is enabled:

```
Diagram(
    NonTerminal("Propose Wait"),
```

```
    NonTerminal("Process Command"),
    Choice(
        0,
        NonTerminal("Wait Until Persisted by Write Worker"),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

The async write duration is calculated as:

```
async write duration(async io disabled) =
    propose +
    async io disabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds

async write duration(async io enabled) =
    propose +
    async io enabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds
```

Async write can be broken down into the following three phases:

- Propose
- Commit
- Apply: `tikv_raftstore_apply_wait_time_duration_secs + tikv_raftstore_apply_log_durat`
  ↪ in the preceding formula

The duration of the propose phase is calculated as:

```
propose =
    propose wait duration +
    propose duration

propose wait duration =
    tikv_raftstore_store_wf_batch_wait_duration_seconds

propose duration =
    tikv_raftstore_store_wf_send_to_queue_duration_seconds -
    tikv_raftstore_store_wf_batch_wait_duration_seconds
```

The Raft process is recorded in a waterfall manner. So the propose duration is calculated from the difference between the two metrics.

The duration of the commit phase is calculated as:

```
async io disabled commit = max(
    persist log locally duration,
    replicate log duration
)

async io enabled commit = max(
    wait by write worker duration,
    replicate log duration
)
```

Since v5.3.0, TiKV supports Async IO Raft (write Raft log by a StoreWriter thread pool). The Async IO Raft is only enabled when the `store-io-pool-size` is set to a positive value, which changes the process of commit. The `persist log locally duration` and `wait by write worker duration` are calculated as:

```
persist log locally duration =
    batch wait duration +
    write to raft db duration

batch wait duration =
    tikv_raftstore_store_wf_before_write_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

write to raft db duration =
    tikv_raftstore_store_wf_write_end_duration_seconds -
    tikv_raftstore_store_wf_before_write_duration_seconds

wait by write worker duration =
    tikv_raftstore_store_wf_persist_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds
```

The difference between with and without Async IO is the duration of persisting logs locally. With Async IO, the duration of persisting log locally can be calculated from the waterfall metrics directly (skip the batch wait duration).

The replicate log duration records the duration of log persisted in quorum peers, which contains an RPC duration and the duration of log persisting in the majority. The `replicate log duration` is calculated as:

```
replicate log duration =
    raftmsg send wait duration +
    commit log wait duration
```

```
raftmsg send wait duration =
    tikv_raftstore_store_wf_send_proposal_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

commit log wait duration =
    tikv_raftstore_store_wf_commit_log_duration -
    tikv_raftstore_store_wf_send_proposal_duration_seconds
```

11.1.6.6.1 Raft DB

The following is the time cost diagram of Raft DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
    NonTerminal("Write and Sync Log"),
    NonTerminal("Apply Log to Memtable"),
)
```

```
write to raft db duration = raft db write duration
commit log wait duration >= raft db write duration

raft db write duration(raft engine enabled) =
    raft_engine_write_preprocess_duration_seconds +
    raft_engine_write_leader_duration_seconds +
    raft_engine_write_apply_duration_seconds

raft db write duration(raft engine disabled) =
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_thread_wait"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_scheduling_flushes_compactions_time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_wal_time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="
        ↪ write_memtable_time"}
```

Because `commit log wait duration` is the longest duration of quorum peers, it might be larger than `raft db write duration`.

Since v6.1.0, TiKV uses Raft Engine as its default log storage engine, which changes the process of writing log.

11.1.6.6.2 KV DB

The following is the time cost diagram of KV DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
    NonTerminal("Preprocess"),
    Choice(
        0,
        Comment("No Need to Switch"),
        NonTerminal("Switch WAL or Memtable"),
    ),
    NonTerminal("Write and Sync WAL"),
    NonTerminal("Apply to Memtable"),
)
```

```
tikv_raftstore_apply_log_duration_seconds =
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_thread_wait"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_scheduling_flushes_compactions_time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_wal_time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="
        ↪ write_memtable_time"}
```

In the async write process, committed logs need to be applied to the KV DB. The applying duration can be calculated from the RocksDB performance context.

11.1.6.7 Diagnosis use cases

The preceding sections explain the details about time cost metrics during querying. This section introduces common procedures of metrics analysis when you encounter slow read or write queries. All metrics can be checked in the Database Time panel of Performance Overview Dashboard.

11.1.6.7.1 Slow read queries

If `SELECT` statements account for a significant portion of the database time, you can assume that TiDB is slow at read queries.

The execution plans of slow queries can be found in the Top SQL statements panel of TiDB Dashboard. To investigate the time costs of slow read queries, you can analyze Point get, Batch point get and some simple coprocessor queries according to the preceding descriptions.

11.1.6.7.2 Slow write queries

Before investigating slow writes, you need to troubleshoot the cause of the conflicts by checking `tikv_scheduler_latch_wait_duration_seconds_sum{type="acquire_pessimistic_lock"} by (instance)`:

- If this metric is high in some specific TiKV instances, there might be conflicts in hot Regions.
- If this metric is high across all instances, there might be conflicts in the application.

After confirming the cause of conflicts from the application, you can investigate slow write queries by analyzing the duration of Lock and Commit.

11.1.7 TiDB Best Practices on Public Cloud

Public cloud infrastructure has become an increasingly popular choice for deploying and managing TiDB. However, deploying TiDB on public cloud requires careful consideration of several critical factors, including performance tuning, cost optimization, reliability, and scalability.

This document covers various essential best practices for deploying TiDB on public cloud, such as reducing compaction I/O flow in KV RocksDB, using a dedicated disk for Raft Engine, optimizing costs for cross-AZ traffic, mitigating Google Cloud live migration events, and fine-tuning the PD server in large clusters. By following these best practices, you can maximize the performance, cost efficiency, reliability, and scalability of your TiDB deployment on public cloud.

11.1.7.1 Reduce compaction I/O flow in KV RocksDB

As the storage engine of TiKV, RocksDB is used to store user data. Because the provisioned IO throughput on cloud EBS is usually limited due to cost considerations, RocksDB might exhibit high write amplification, and the disk throughput might become the bottleneck for the workload. As a result, the total number of pending compaction bytes grows over time and triggers flow control, which indicates that TiKV lacks sufficient disk bandwidth to keep up with the foreground write flow.

To alleviate the bottleneck caused by limited disk throughput, you can improve performance by enabling Titan. If your average row size is smaller than 512 bytes, Titan is not applicable. In this case, you can improve performance by increasing all the compression levels.

11.1.7.1.1 Enable Titan

Titan is a high-performance RocksDB plugin for key-value separation, which can reduce write amplification in RocksDB when large values are used.

If your average row size is larger than 512 bytes, you can enable Titan to reduce the compaction I/O flow as follows, with `min-blob-size` set to `"512B"` or `"1KB"` and `blob-file-compression` set to `"zstd"`:

```
[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"
```

> **Note:**
>
> When Titan is enabled, there might be a slight performance degradation for range scans on the primary key. For more information, see Impact of `min-blob-size` on performance.

11.1.7.1.2 Increase all the compression levels

If your average row size is smaller than 512 bytes, you can increase all the compression levels of the default column family to `"zstd"` as follows:

```
[rocksdb.defaultcf]
compression-per-level = ["zstd", "zstd", "zstd", "zstd", "zstd", "zstd", "
    ↪ zstd"]
```

11.1.7.2 Use a dedicated disk for Raft Engine

The Raft Engine in TiKV plays a critical role similar to that of a write-ahead log (WAL) in traditional databases. To achieve optimal performance and stability, it is crucial to allocate a dedicated disk for the Raft Engine when you deploy TiDB on public cloud. The following `iostat` shows the I/O characteristics on a TiKV node with a write-heavy workload.

```
Device            r/s     rkB/s       w/s     wkB/s     f/s  aqu-sz %util
sdb          1649.00 209030.67 1293.33 304644.00 13.33   5.09 48.37
sdd          1033.00  4132.00  1141.33 31685.33  571.00   0.94 100.00
```

The device `sdb` is used for KV RocksDB, while `sdd` is used to restore Raft Engine logs. Note that `sdd` has a significantly higher `f/s` value, which represents the number of flush requests completed per second for the device. In Raft Engine, when a write in a batch is marked synchronous, the batch leader will call `fdatasync()` after writing, guaranteeing that buffered data is flushed to the storage. By using a dedicated disk for Raft Engine, TiKV reduces the average queue length of requests, thereby ensuring optimal and stable write latency.

Different cloud providers offer various disk types with different performance characteristics, such as IOPS and MBPS. Therefore, it is important to choose an appropriate cloud provider, disk type, and disk size based on your workload.

11.1.7.2.1 Choose appropriate disks for Raft Engine on public clouds

This section outlines best practices for choosing appropriate disks for Raft Engine on different public clouds. Depending on performance requirements, two types of recommended disks are available.

Middle-range disk

The following are recommended middle-range disks for different public clouds:

- On AWS, gp3 is recommended. The gp3 volume offers a free allocation of 3000 IOPS and 125 MB/s throughput, regardless of the volume size, which is usually sufficient for the Raft Engine.
- On Google Cloud, pd-ssd is recommended. The IOPS and MBPS vary depending on the allocated disk size. To meet performance requirements, it is recommended to allocate 200 GB for Raft Engine. Although Raft Engine does not require such a large space, it ensures optimal performance.
- On Azure, Premium SSD v2 is recommended. Similar to AWS gp3, Premium SSD v2 provides a free allocation of 3000 IOPS and 125 MB/s throughput, regardless of the volume size, which is usually sufficient for Raft Engine.

High-end disk

If you expect an even lower latency for Raft Engine, consider using high-end disks. The following are recommended high-end disks for different public clouds:

- On AWS, io2 is recommended. Disk size and IOPS can be provisioned according to your specific requirements.
- On Google Cloud, pd-extreme is recommended. Disk size, IOPS, and MBPS can be provisioned, but it is only available on instances with more than 64 CPU cores.
- On Azure, ultra disk is recommended. Disk size, IOPS, and MBPS can be provisioned according to your specific requirements.

11.1.7.2.2 Example 1: Run a social network workload on AWS

AWS offers 3000 IOPS and 125 MBPS/s for a 20 GB gp3 volume.

By using a dedicated 20 GB gp3 Raft Engine disk on AWS for a write-intensive social network application workload, the following improvements are observed but the estimated cost only increases by 0.4%:

- a 17.5% increase in QPS (queries per second)
- an 18.7% decrease in average latency for insert statements
- a 45.6% decrease in p99 latency for insert statements.

Metric	Shared Raft Engine disk	Dedicated Raft Engine disk	Difference (%)
QPS (K/s)	8.0	9.4	17.5
AVG Insert Latency (ms)	11.3	9.2	-18.7
P99 Insert Latency (ms)	29.4	16.0	-45.6

11.1.7.2.3 Example 2: Run TPC-C/Sysbench workload on Azure

By using a dedicated 32 GB ultra disk for Raft Engine on Azure, the following improvements are observed:

- Sysbench `oltp_read_write` workload: a 17.8% increase in QPS and a 15.6% decrease in average latency.
- TPC-C workload: a 27.6% increase in QPS and a 23.1% decrease in average latency.

Metric	Workload	Shared Raft Engine disk	Dedicated Raft Engine disk
QPS (K/s)	Sysbench `oltp_read_write`	60.7	71.5
QPS (K/s)	TPC-C	23.9	30.5
AVG Latency (ms)	Sysbench `oltp_read_write`	4.5	3.8
AVG Latency (ms)	TPC-C	3.9	3.0

11.1.7.2.4 Example 3: Attach a dedicated pd-ssd disk on Google Cloud for Raft Engine on TiKV manifest

The following TiKV configuration example shows how to attach an additional 512 GB pd-ssd disk to a cluster on Google Cloud deployed by TiDB Operator, with `raft-engine.dir` configured to store Raft Engine logs to this specific disk.

```
tikv:
    config: |
      [raft-engine]
        dir = "/var/lib/raft-pv-ssd/raft-engine"
        enable = true
        enable-log-recycle = true
    requests:
      storage: 4Ti
    storageClassName: pd-ssd
    storageVolumes:
    - mountPath: /var/lib/raft-pv-ssd
      name: raft-pv-ssd
      storageSize: 512Gi
```

11.1.7.3 Optimize cost for cross-AZ network traffic

Deploying TiDB across multiple availability zones (AZs) can lead to increased costs due to cross-AZ data transfer fees. To optimize costs, it is important to reduce cross-AZ network traffic.

To reduce cross-AZ read traffic, you can enable the Follower Read feature, which allows TiDB to prioritize selecting replicas in the same availability zone. To enable this feature, set the `tidb_replica_read` variable to `closest-replicas` or `closest-adaptive`.

To reduce cross-AZ write traffic in TiKV instances, you can enable the gRPC compression feature, which compresses data before transmitting it over the network. The following configuration example shows how to enable gzip gRPC compression for TiKV.

```
server_configs:
  tikv:
    server.grpc-compression-type: gzip
```

To reduce network traffic caused by the data shuffle of TiFlash MPP tasks, it is recommended to deploy multiple TiFlash instances in the same availability zones (AZs). Starting from v6.6.0, compression exchange is enabled by default, which reduces the network traffic caused by MPP data shuffle.

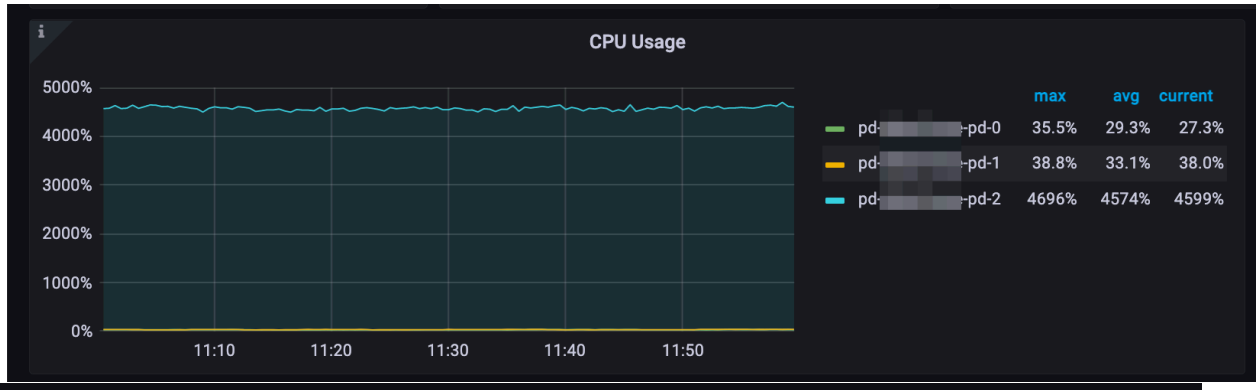
11.1.7.4 Mitigate live migration maintenance events on Google Cloud

The Live Migration feature of Google Cloud enables VMs to be seamlessly migrated between hosts without causing downtime. However, these migration events, although infrequent, can significantly impact the performance of VMs, including those running in a TiDB cluster. During such events, affected VMs might experience reduced performance, leading to longer query processing times in the TiDB cluster.

To detect live migration events initiated by Google Cloud and mitigate the performance impact of these events, TiDB provides a watching script based on Google's metadata example. You can deploy this script on TiDB, TiKV, and PD nodes to detect maintenance events. When a maintenance event is detected, appropriate actions can be taken automatically as follows to minimize disruption and optimize the cluster behavior:

- TiDB: Takes the TiDB node offline by cordoning it and deleting the TiDB pod. This assumes that the node pool of the TiDB instance is set to auto-scale and dedicated to TiDB. Other pods running on the node might experience interruptions, and the cordoned node is expected to be reclaimed by the auto-scaler.
- TiKV: Evicts leaders on the affected TiKV store during maintenance.
- PD: Resigns a leader if the current PD instance is the PD leader.

It is important to note that this watching script is specifically designed for TiDB clusters deployed using TiDB Operator, which offers enhanced management functionalities for TiDB in Kubernetes environments.



By utilizing the watching script and taking necessary actions during maintenance events, TiDB clusters can better handle live migration events on Google Cloud and ensure smoother operations with minimal impact on query processing and response times.

11.1.7.5 Tune PD for a large-scale TiDB cluster with high QPS

In a TiDB cluster, a single active Placement Driver (PD) server is used to handle crucial tasks such as serving the TSO (Timestamp Oracle) and processing requests. However, relying on a single active PD server can limit the scalability of TiDB clusters.

11.1.7.5.1 Symptoms of PD limitation

The following diagrams show the symptoms of a large-scale TiDB cluster consisting of three PD servers, each equipped with 56 CPUs. From these diagrams, it is observed that when the query per second (QPS) exceeds 1 million and the TSO (Timestamp Oracle) requests per second exceed 162,000, the CPU utilization reaches approximately 4,600%. This high CPU utilization indicates that the PD leader is experiencing a significant load and is running out of available CPU resources.

11.1.7.5.2 Tune PD performance

To address the high CPU utilization issue in the PD server, you can make the following tuning adjustments:

Adjust PD configuration

`tso-update-physical-interval`: This parameter controls the interval at which the PD server updates the physical TSO batch. By reducing the interval, the PD server can allocate

TSO batches more frequently, thereby reducing the waiting time for the next allocation.

```
tso-update-physical-interval = "10ms" # default: 50ms
```

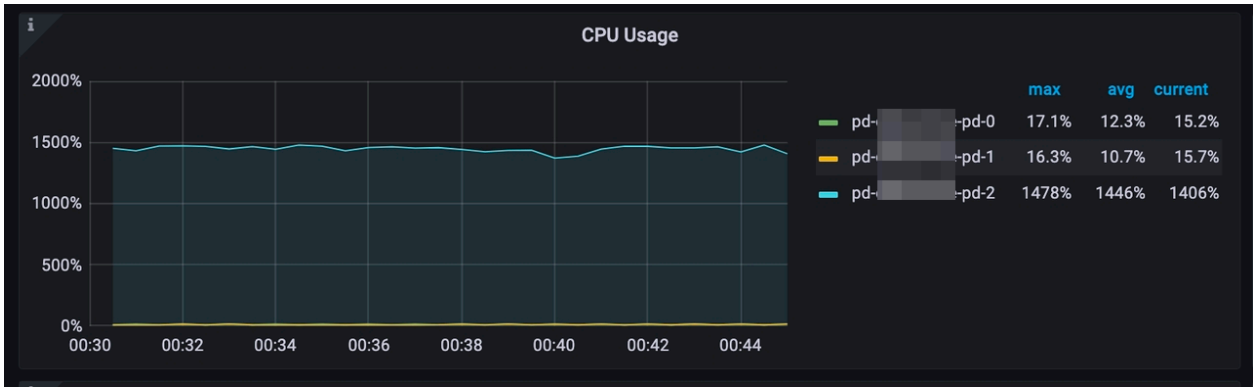
Adjust a TiDB global variable

In addition to the PD configuration, enabling the TSO client batch wait feature can further optimize the TSO client's behavior. To enable this feature, you can set the global variable `tidb_tso_client_batch_max_wait_time` to a non-zero value.

```
set global tidb_tso_client_batch_max_wait_time = 2; # default: 0
```

Adjust TiKV configuration

To reduce the number of Regions and alleviate the heartbeat overhead on the system, it is recommended to increase the Region size in the TiKV configuration from `96MB` to `256MB`.



```
[coprocessor]
  region-split-size = "256MB"
```

11.1.7.6 After tuning

After the tunning, the following effects can be observed:

- The TSO requests per second are decreased to 64,800.
- The CPU utilization is significantly reduced from approximately 4,600% to 1,400%.
- The P999 value of `PD server TSO handle time` is decreased from 2ms to 0.5ms.

These improvements indicate that the tuning adjustments have successfully reduced the CPU utilization of the PD server while maintaining stable TSO handling performance.

11.2 Configuration Tuning

11.2.1 Tune Operating System Performance

This document introduces how to tune each subsystem of CentOS 7.

Note:

- The default configuration of the CentOS 7 operating system is suitable for most services running under moderate workloads. Adjusting the performance of a particular subsystem might negatively affects other subsystems. Therefore, before tuning the system, back up all the user data and configuration information.
- Fully test all the changes in the test environment before applying them to the production environment.

11.2.1.1 Performance analysis methods

System tuning must be based on the results of system performance analysis. This section lists common methods for performance analysis.

11.2.1.1.1 In 60 seconds

Linux Performance Analysis in 60,000 Milliseconds is published by the author Brendan Gregg and the Netflix Performance Engineering team. All tools used can be obtained from the official release of Linux. You can analyze outputs of the following list items to troubleshoot most common performance issues.

- `uptime`
- `dmesg | tail`
- `vmstat 1`
- `mpstat -P ALL 1`
- `pidstat 1`
- `iostat -xz 1`
- `free -m`
- `sar -n DEV 1`
- `sar -n TCP,ETCP 1`
- `top`

For detailed usage, see the corresponding `man` instructions.

11.2.1.1.2 perf

perf is an important performance analysis tool provided by the Linux kernel, which covers hardware level (CPU/PMU, performance monitoring unit) features and software features (software counters, trace points). For detailed usage, see perf Examples.

11.2.1.1.3 BCC/bpftrace

Starting from CentOS 7.6, the Linux kernel has supported Berkeley Packet Filter (BPF). Therefore, you can choose proper tools to conduct an in-depth analysis based on the results in In 60 seconds. Compared with perf/ftrace, BPF provides programmability and smaller performance overhead. Compared with kprobe, BPF provides higher security and is more suitable for the production environments. For detailed usage of the BCC toolkit, see BPF Compiler Collection (BCC).

11.2.1.2 Performance tuning

This section introduces performance tuning based on the classified kernel subsystems.

11.2.1.2.1 CPU—frequency scaling

cpufreq is a module that dynamically adjusts the CPU frequency. It supports five modes. To ensure service performance, select the performance mode and fix the CPU frequency at the highest supported operating frequency without dynamic adjustment. The command for this operation is `cpupower frequency-set --governor performance`.

11.2.1.2.2 CPU—interrupt affinity

- Automatic balance can be implemented through the `irqbalance` service.
- Manual balance:

- Identify the devices that need to balance interrupts. Starting from CentOS 7.5, the system automatically configures the best interrupt affinity for certain devices and their drivers, such as devices that use the `be2iscsi` driver and NVMe settings. You can no longer manually configure interrupt affinity for such devices.
- For other devices, check the chip manual to see whether these devices support distributing interrupts.
  - If they do not, all interrupts of these devices are routed to the same CPU and cannot be modified.
  - If they do, calculate the `smp_affinity` mask and set the corresponding configuration file. For details, see the kernel document.

11.2.1.2.3 NUMA CPU binding

To avoid accessing memory across Non-Uniform Memory Access (NUMA) nodes as much as possible, you can bind a thread/process to certain CPU cores by setting the CPU affinity of the thread. For ordinary programs, you can use the `numactl` command for the CPU binding. For detailed usage, see the Linux manual pages. For network interface card (NIC) interrupts, see tune network.

11.2.1.2.4 Memory—transparent huge page (THP)

It is **NOT** recommended to use THP for database applications, because databases often have sparse rather than continuous memory access patterns. If high-level memory fragmentation is serious, a higher latency will occur when THP pages are allocated. If the direct compaction is enabled for THP, the CPU usage will surge. Therefore, it is recommended to disable THP.

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

11.2.1.2.5 Memory—virtual memory parameters

- `dirty_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to use the `pdflush` operation to write the dirty page caches to disk. The default value of `dirty_ratio` is 20% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, lowering this value helps improve the efficiency of memory reclamation.
- `dirty_background_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to write the dirty page caches to the disk in the background. The default value of `dirty_background_ratio` is 10% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, setting a lower value helps improve the efficiency of memory reclamation.

11.2.1.2.6 Storage and file system

The core I/O stack link is long, including the file system layer, the block device layer, and the driver layer.

I/O scheduler

The I/O scheduler determines when and how long I/O operations run on the storage device. It is also called I/O elevator. For SSD devices, it is recommended to set the I/O scheduling policy to `noop`.

```
echo noop > /sys/block/${SSD_DEV_NAME}/queue/scheduler
```

Formatting parameters—block size

Blocks are the working units of the file system. The block size determines how much data can be stored in a single block, and thus determines the minimum amount of data to be written or read each time.

The default block size is suitable for most scenarios. However, if the block size (or the size of multiple blocks) is the same or slightly larger than the amount of data normally read or written each time, the file system performs better and the data storage efficiency is higher. Small files still use the entire block. Files can be distributed among multiple blocks, but this will increase runtime overhead.

When using the `mkfs` command to format a device, specify the block size as a part of the file system options. The parameters that specify the block size vary with the file system. For details, see the corresponding `mkfs` manual pages, such as using `man mkfs.ext4`.

`mount` parameters

If the `noatime` option is enabled in the `mount` command, the update of metadata is disabled when files are read. If the `nodiratime` behavior is enabled, the update of metadata is disabled when the directory is read.

11.2.1.2.7 Network tuning

The network subsystem consists of many different parts with sensitive connections. The CentOS 7 network subsystem is designed to provide the best performance for most workloads and automatically optimizes the performance of these workloads. Therefore, usually you do not need to manually adjust network performance.

Network issues are usually caused by issues of hardware or related devices. So before tuning the protocol stack, rule out hardware issues.

Although the network stack is largely self-optimizing, the following aspects in the network packet processing might become the bottleneck and affect performance:

- NIC hardware cache: To correctly observe the packet loss at the hardware level, use the `ethtool -S ${NIC_DEV_NAME}` command to observe the `drops` field. When packet loss occurs, it might be that the processing speed of the hard/soft interrupts cannot

catch up with the receiving speed of NIC. If the received buffer size is less than the upper limit, you can also try to increase the RX buffer to avoid packet loss. The query command is: `ethtool -g ${NIC_DEV_NAME}`, and the modification command is `ethtool -G ${NIC_DEV_NAME}`.

- Hardware interrupts: If the NIC supports the Receive-Side Scaling (RSS, also called multi-NIC receiving) feature, observe the `/proc/interrupts` NIC interrupts. If the interrupts are uneven, see CPU—frequency scaling, CPU—interrupt affinity, and NUMA CPU binding. If the NIC does not support RSS or the number of RSS is much smaller than the number of physical CPU cores, configure Receive Packet Steering (RPS, which can be regarded as the software implementation of RSS), and the RPS extension Receive Flow Steering (RFS). For detailed configuration, see the kernel document.

- Software interrupts: Observe the monitoring of `/proc/net/softnet_stat`. If the values of the other columns except the third column are increasing, properly adjust the value of `net.core.netdev_budget` or `net.core.dev_weight` for `softirq` to get more CPU time. In addition, you also need to check the CPU usage to determine which tasks are frequently using the CPU and whether they can be optimized.

- Receive queue of application sockets: Monitor the `Resv-q` column of `ss -nmp`. If the queue is full, consider increasing the size of the application socket cache or use the automatic cache adjustment method. In addition, consider whether you can optimize the architecture of the application layer and reduce the interval between reading sockets.

- Ethernet flow control: If the NIC and switch support the flow control feature, you can use this feature to leave some time for the kernel to process the data in the NIC queue, to avoid the issue of NIC buffer overflow.

- Interrupts coalescing: Too frequent hardware interrupts reduces system performance, and too late hardware interrupts causes packet loss. Newer NICs support the interrupt coalescing feature and allow the driver to automatically adjust the number of hardware interrupts. You can execute `ethtool -c ${NIC_DEV_NAME}` to check and `ethtool -C ${NIC_DEV_NAME}` to enable this feature. The adaptive mode allows the NIC to automatically adjust the interrupt coalescing. In this mode, the driver checks the traffic mode and kernel receiving mode, and evaluates the coalescing settings in real time to prevent packet loss. NICs of different brands have different features and default configurations. For details, see the NIC manuals.

- Adapter queue: Before processing the protocol stack, the kernel uses this queue to buffer the data received by the NIC, and each CPU has its own backlog queue. The maximum number of packets that can be cached in this queue is `netdev_max_backlog`. Observe the second column of `/proc/net/softnet_stat`. When the second column of a row continues to increase, it means that the CPU [row-1] queue is full and the data packet is lost. To resolve this problem, continue to double the `net.core.netdev_max_backlog` value.

- Send queue: The length value of a send queue determines the number of packets that can be queued before sending. The default value is `1000`, which is sufficient for 10 Gbps. But if you have observed the value of TX errors from the output of `ip -s link`, you can try to double it: `ip link set dev ${NIC_DEV_NAME} txqueuelen 2000`.
- Driver: NIC drivers usually provide tuning parameters. See the device hardware manual and its driver documentation.

11.2.2 TiDB Memory Control

Currently, TiDB can track the memory quota of a single SQL query and take actions to prevent OOM (out of memory) or troubleshoot OOM when the memory usage exceeds a specific threshold value. The system variable `tidb_mem_oom_action` specifies the action to take when a query reaches the memory limit:

- A value of `LOG` means that queries will continue to execute when the `tidb_mem_quota_query` ↪ limit is reached, but TiDB will print an entry to the log.
- A value of `CANCEL` means TiDB stops executing the SQL query immediately after the `tidb_mem_quota_query` limit is reached, and returns an error to the client. The error information clearly shows the memory usage of each physical execution operator that consumes memory in the SQL execution process.

11.2.2.1 Configure the memory quota of a query

The system variable `tidb_mem_quota_query` sets the limit for a query in bytes. Some usage examples:

```
-- Set the threshold value of memory quota for a single SQL query to 8GB:
SET tidb_mem_quota_query = 8 << 30;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8MB:
SET tidb_mem_quota_query = 8 << 20;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8KB:
SET tidb_mem_quota_query = 8 << 10;
```

11.2.2.2 Configure the memory usage threshold of a tidb-server instance

Since v6.5.0, you can use the system variable `tidb_server_memory_limit` to set the threshold for the memory usage of a tidb-server instance.

For example, set the total memory usage of a tidb-server instance to 32 GB:

```
SET GLOBAL tidb_server_memory_limit = "32GB";
```

After you set this variable, when the memory usage of a tidb-server instance reaches 32 GB, TiDB will terminate the SQL operation with the largest memory usage among all running SQL operations in order, until the memory usage of the instance drops below 32 GB. The forcibly terminated SQL operation will return the `Out Of Memory Quota!` error to the client.

Currently, the memory limit set by `tidb_server_memory_limit` **DOES NOT** terminate the following SQL operations:

- DDL operations
- SQL operations that contain window functions and common table expressions

> **Warning:**
>
> - During the startup process, TiDB does not guarantee that the `tidb_server_memory_limit` limit is enforced. If the free memory of the operating system is insufficient, TiDB might still encounter OOM. You need to ensure that the TiDB instance has enough available memory.
> - In the process of memory control, the total memory usage of TiDB might slightly exceed the limit set by `tidb_server_memory_limit`.
> - Since v6.5.0, the configruation item `server-memory-quota` is deprecated. To ensure compatibility, after you upgrade your cluster to v6.5.0 or a later version, `tidb_server_memory_limit` will inherit the value of `server-memory-quota`. If you have not configured `server-memory-quota` before the upgrade, the default value of `tidb_server_memory_limit` is used, which is `80%`.

When the memory usage of a tidb-server instance reaches a certain proportion of the total memory (the proportion is controlled by the system variable `tidb_server_memory_limit_gc_trigger` ↪), tidb-server will try to trigger a Golang GC to relieve memory stress. To avoid frequent GCs that cause performance issues due to the instance memory fluctuating around the threshold, this GC method will trigger GC at most once every minute.

> **Note:**
>
> In a hybrid deployment scenario, `tidb_server_memory_limit` is the memory usage threshold for a single tidb-server instance, instead of the total memory threshold for the whole physical machine.

11.2.2.3 View the memory usage of the current tidb-server instance using the INFORMATION_SCHEMA system table

To view the memory usage of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE`.

To view the memory-related operations and execution basis of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE_OPS_HISTORY`. For each instance, this table retains the latest 50 records.

11.2.2.4 Trigger the alarm of excessive memory usage

When the memory usage of a tidb-server instance exceeds its memory threshold (70% of its total memory by default) and any of the following conditions is met, TiDB records the related status files and prints an alarm log.

- It is the first time the memory usage exceeds the memory threshold.
- The memory usage exceeds the memory threshold and it has been more than 60 seconds since the last alarm.
- The memory usage exceeds the memory threshold and `(Current memory usage - Memory usage at the last alarm)/ Total memory > 10%`.

You can control the memory threshold that triggers the alarm by modifying the memory usage ratio via the system variable `tidb_memory_usage_alarm_ratio`.

When the alarm of excessive memory usage is triggered, TiDB takes the following actions:

- TiDB records the following information in the directory where the TiDB log file `filename` is located.
    - The information about the top 10 SQL statements with the highest memory usage and the top 10 SQL statements with the longest running time among all SQL statements currently being executed
    - The goroutine stack information
    - The usage status of heap memory
- TiDB prints an alarm log containing the keyword `tidb-server has the risk of OOM` and the values of the following memory-related system variables.
    - `tidb_mem_oom_action`
    - `tidb_mem_quota_query`
    - `tidb_server_memory_limit`
    - `tidb_analyze_version`
    - `tidb_enable_rate_limit_action`

To avoid accumulating too many status files for alarms, TiDB only retains the status files generated during the recent five alarms by default. You can adjust this number by configuring the system variable tidb_memory_usage_alarm_keep_record_num.

The following example constructs a memory-intensive SQL statement that triggers the alarm:

1. Set tidb_memory_usage_alarm_ratio to 0.85:

```
SET GLOBAL tidb_memory_usage_alarm_ratio = 0.85;
```

2. Execute CREATE TABLE t(a int); and insert 1000 rows of data.

3. Execute select * from t t1 join t t2 join t t3 order by t1.a. This SQL statement outputs one billion records, which consumes a large amount of memory and therefore triggers the alarm.

4. Check the tidb.log file which records the total system memory, current system memory usage, memory usage of the tidb-server instance, and the directory of status files.

```
[2022/10/11 16:39:02.281 +08:00] [WARN] [memoryusagealarm.go:212] ["
    ↪ tidb-server has the risk of OOM because of memory usage exceeds
    ↪ alarm ratio. Running SQLs and heap profile will be recorded in
    ↪ record path"] ["is tidb_server_memory_limit set"=false] ["system
    ↪ memory total"=33682427904] ["system memory usage"=22120655360] ["
    ↪ tidb-server memory usage"=21468556992] [memory-usage-alarm-ratio
    ↪ =0.85] ["record path"=/tiup/deploy/tidb-4000/log/oom_record]
```

   The fields of the example log file above are described as follows:

   - is tidb_server_memory_limit set indicates whether tidb_server_memory_limit is set.
   - system memory total indicates the total memory of the current system.
   - system memory usage indicates the current system memory usage.
   - tidb-server memory usage indicates the memory usage of the tidb-server instance.
   - memory-usage-alarm-ratio indicates the value of the system variable tidb_memory_usage_alarm_ratio.
   - record path indicates the directory of status files.

5. By checking the directory of status files (In the preceding example, the directory is /tiup/deploy/tidb-4000/log/oom_record), you can see a record directory with the corresponding timestamp (for example, record2022-10-09T17:18:38+08:00). The record directory includes three files: goroutinue, heap, and running_sql. These three files are suffixed with the time when status files are logged. They respectively record goroutine stack information, the usage status of heap memory, and the running SQL information when the alarm is triggered. For the content in running_sql, refer to expensive-queries.

11.2.2.5 Other memory control behaviors of tidb-server

11.2.2.5.1 Flow control

- TiDB supports dynamic memory control for the operator that reads data. By default, this operator uses the maximum number of threads that `tidb_distsql_scan_concurrency` ↪ allows to read data. When the memory usage of a single SQL execution exceeds `tidb_mem_quota_query` each time, the operator that reads data stops one thread.
- This flow control behavior is controlled by the system variable `tidb_enable_rate_limit_action` ↪ .
- When the flow control behavior is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, destroy one token now`.

11.2.2.5.2 Disk spill

TiDB supports disk spill for execution operators. When the memory usage of a SQL execution exceeds the memory quota, tidb-server can spill the intermediate data of execution operators to the disk to relieve memory pressure. Operators supporting disk spill include Sort, MergeJoin, HashJoin, and HashAgg.

- The disk spill behavior is jointly controlled by the following parameters: `tidb_mem_quota_query` ↪ , `tidb_enable_tmp_storage_on_oom`, `tmp-storage-path`, and `tmp-storage-` ↪ `quota`.
- When the disk spill is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, spill to disk now` or `memory exceeds quota, set` ↪ `aggregate mode to spill-mode`.
- Disk spill for the Sort, MergeJoin, and HashJoin operator is introduced in v4.0.0; disk spill for the HashAgg operator is introduced in v5.2.0.
- When the SQL executions containing Sort, MergeJoin, or HashJoin cause OOM, TiDB triggers disk spill by default. When SQL executions containing HashAgg cause OOM, TiDB does not trigger disk spill by default. You can configure the system variable `tidb_executor_concurrency = 1` to trigger disk spill for HashAgg.

> **Note:**
>
> The disk spill for HashAgg does not support SQL executions containing the `DISTINCT` aggregate function. When a SQL execution containing a `DISTINCT` aggregate function uses too much memory, the disk spill does not apply.

The following example uses a memory-consuming SQL statement to demonstrate the disk spill feature for HashAgg:

1. Configure the memory quota of a SQL statement to 1GB (1 GB by default):

```
SET tidb_mem_quota_query = 1 << 30;
```

2. Create a single table `CREATE TABLE t(a int);` and insert 256 rows of different data.

3. Execute the following SQL statement:

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

Because executing this SQL statement occupies too much memory, the following "Out of Memory Quota" error message is returned:

```
ERROR 1105 (HY000): Out Of Memory Quota![conn_id=3]
```

4. Configure the system variable `tidb_executor_concurrency` to 1. With this configuration, when out of memory, HashAgg automatically tries to trigger disk spill.

```
SET tidb_executor_concurrency = 1;
```

5. Execute the same SQL statement. You can find that this time, the statement is successfully executed and no error message is returned. From the following detailed execution plan, you can see that HashAgg has used 600 MB of hard disk space.

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

```

11.2.2.6 Others

11.2.2.6.1 Mitigate OOM issues by configuring `GOMEMLIMIT`

GO 1.19 introduces an environment variable `GOMEMLIMIT` to set the memory limit that triggers GC.

For v6.1.3 <= TiDB < v6.5.0, you can mitigate a typical category of OOM issues by manually setting `GOMEMLIMIT`. The typical category of OOM issues is: before OOM occurs, the estimated memory in use on Grafana occupies only half of the entire memory (TiDB-Runtime > Memory Usage > estimate-inuse), as shown in the following figure:

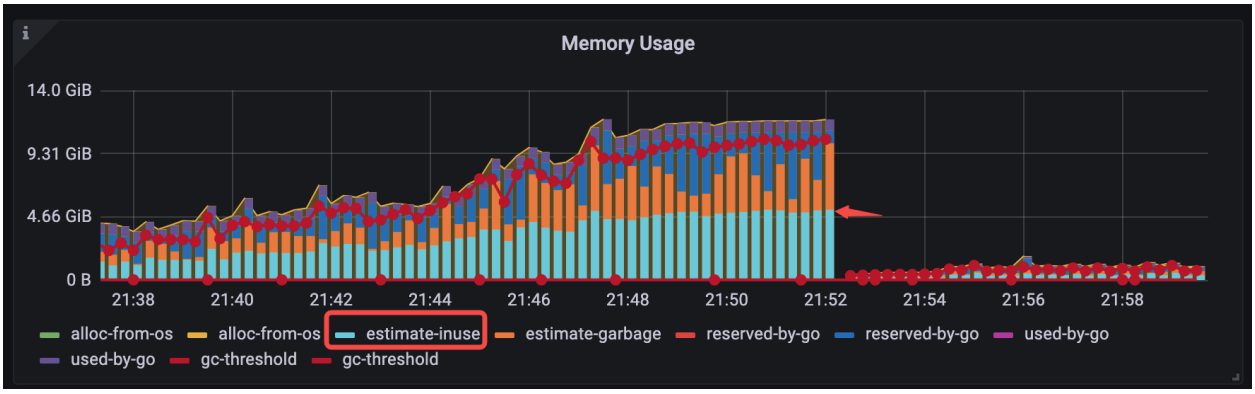

Figure 375: normal OOM case example

To verify the performance of `GOMEMLIMIT`, a test is performed to compare the specific memory usage with and without `GOMEMLIMIT` configuration.

- In TiDB v6.1.2, the TiDB server encounters OOM (system memory: about 48 GiB) after the simulated workload runs for several minutes:

Figure 376: v6.1.2 workload oom

- In TiDB v6.1.3, `GOMEMLIMIT` is set to 40000 MiB. It is found that the simulated workload runs stably for a long time, OOM does not occur in the TiDB server, and the maximum memory usage of the process is stable at around 40.8 GiB:

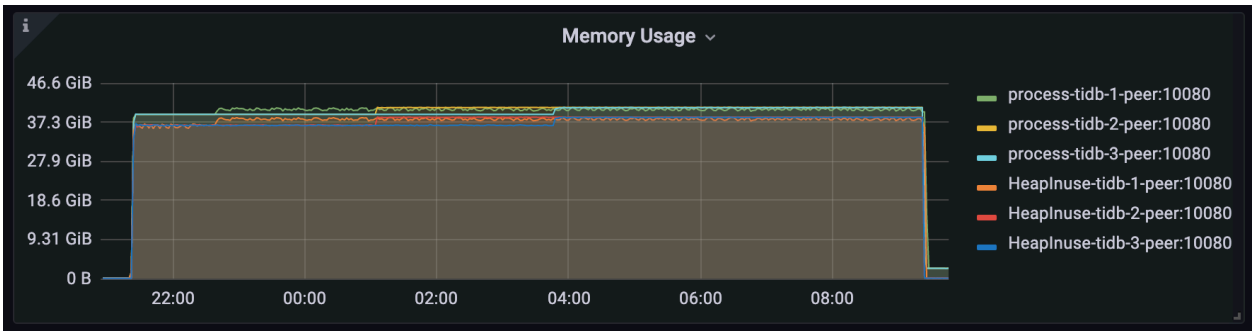

Figure 377: v6.1.3 workload no oom with GOMEMLIMIT

11.2.3 Tune TiKV Thread Pool Performance

This document introduces TiKV internal thread pools and how to tune their performance.

11.2.3.1 Thread pool introduction

The TiKV thread pool is mainly composed of gRPC, Scheduler, UnifyReadPool, Raftstore, StoreWriter, Apply, RocksDB, and some scheduled tasks and detection components that do not consume much CPU. This document mainly introduces a few CPU-intensive thread pools that affect the performance of read and write requests.

- The gRPC thread pool: it handles all network requests and forwards requests of different task types to different thread pools.

- The Scheduler thread pool: it detects write transaction conflicts, converts requests like the two-phase commit, pessimistic locking, and transaction rollbacks into key-value pair arrays, and then sends them to the Raftstore thread for Raft log replication.
- The Raftstore thread pool:
    - It processes all Raft messages and the proposal to add a new log.
    - It writes Raft logs to the disk. If the value of `store-io-pool-size` is `0`, the Raftstore thread writes the logs to the disk; if the value is not `0`, the Raftstore thread sends the logs to the StoreWriter thread.
    - When Raft logs in the majority of replicas are consistent, the Raftstore thread sends the logs to the Apply thread.
- The StoreWriter thread pool: it writes all Raft logs to the disk and returns the result to the Raftstore thread.
- The Apply thread pool: it receives the submitted log sent from the Raftstore thread pool, parses it as a key-value request, then writes it to RocksDB, calls the callback function to notify the gRPC thread pool that the write request is complete, and returns the result to the client.
- The RocksDB thread pool: it is a thread pool for RocksDB to compact and flush tasks. For RocksDB's architecture and `Compact` operation, refer to RocksDB: A Persistent Key-Value Store for Flash and RAM Storage.
- The UnifyReadPool thread pool: it is a combination of the Coprocessor thread pool and Storage Read Pool. All read requests such as kv get, kv batch get, raw kv get, and coprocessor are executed in this thread pool.

11.2.3.2 TiKV read-only requests

TiKV's read requests are divided into the following types:

- Simple queries that specify a certain row or several rows, running in the Storage Read Pool.
- Complex aggregate calculation and range queries, running in the Coprocessor Read Pool.

Starting from TiKV v5.0, all read requests use the unified thread pool for queries by default. If your TiKV cluster is upgraded from TiKV v4.0 and the `use-unified-pool` configuration of `readpool.storage` was set to `false` before the upgrade, all read requests continue using different thread pools after the upgrade. In this scenario, to make all read requests use the unified thread pool for queries, you can set the value of `readpool.storage` ↪ `.use-unified-pool` to `true`.

11.2.3.3 Performance tuning for TiKV thread pools

- The gRPC thread pool.

  The default size (configured by `server.grpc-concurrency`) of the gRPC thread pool is `5`. This thread pool has almost no computing overhead and is mainly responsible for network I/O and deserialization requests, so generally you do not need to adjust the default configuration.

  - If the machine deployed with TiKV has a small number (less than or equal to 8) of CPU cores, consider setting the `server.grpc-concurrency` configuration item to `2`.
  - If the machine deployed with TiKV has very high configuration, TiKV undertakes a large number of read and write requests, and the value of `gRPC poll CPU` that monitors Thread CPU on Grafana exceeds 80% of `server.grpc-concurrency` ↪ , then consider increasing the value of `server.grpc-concurrency` to keep the thread pool usage rate below 80% (that is, the metric on Grafana is lower than `80% * server.grpc-concurrency`).

- The Scheduler thread pool.

  When TiKV detects that the number of machine CPU cores is larger than or equal to 16, the default size (configured by `storage.scheduler-worker-pool-size`) of the Scheduler thread pool is `8`; when TiKV detects that the number of machine CPU cores is smaller than 16, the default size is `4`.

  This thread pool is mainly used to convert complex transaction requests into simple key-value read and write requests. However, **the Scheduler thread pool itself does not perform any write operation**.

  - If it detects a transaction conflict, then this thread pool returns the conflict result to the client in advance.
  - If no conflict is detected, then this thread pool merges the key-value requests that perform write operations into a Raft log and sends it to the Raftstore thread for Raft log replication.

  Generally speaking, to avoid excessive thread switching, it is best to ensure that the utilization rate of the Scheduler thread pool is between 50% and 75%. If the thread pool size is `8`, then it is recommended to keep `TiKV-Details.Thread CPU.scheduler` ↪ `worker CPU` on Grafana between 400% and 600%.

- The Raftstore thread pool.

  The Raftstore thread pool is the most complex thread pool in TiKV. The default size (configured by `raftstore.store-pool-size`) of this thread pool is `2`. For the StoreWriter thread pool, the default size (configured by `raftstore.store-io-pool-` ↪ `size`) is `0`.

- When the size of the StoreWriter thread pool is 0, all write requests are written into RocksDB in the way of `fsync` by the Raftstore thread. In this case, it is recommended to tune the performance as follows:
  - Keep the overall CPU usage of the Raftstore thread below 60%. When the number of Raftstore threads is 2, keep the **TiKV-Details**, **Thread CPU**, **Raft store CPU** on Grafana below 120%. Due to I/O requests, the CPU usage of Raftstore threads in theory is always lower than 100%.
  - Do not increase the size of the Raftstore thread pool to improve write performance without careful consideration, because this might increase the disk burden and degrade performance.
- When the size of the StoreWriter thread pool is not 0, all write requests are written into RocksDB in the way of `fsync` by the StoreWriter thread. In this case, it is recommended to tune the performance as follows:
  - Enable the StoreWriter thread pool ONLY when the overall CPU resources are sufficient. When the StoreWriter thread pool is enabled, keep the CPU usage of the StoreWriter thread and the Raftstore thread below 80%.

  Compared with the case that the write requests are processed by the Raftstore thread, in theory, when the write requests are processed by the StoreWriter thread, write latency and the tail latency of data read are significantly reduced. However, as the write speed grows faster, the number of Raft logs increases accordingly. This can cause the CPU overhead of the Raftstore threads, the Apply threads, and the gRPC threads to increase. In this case, insufficient CPU resources might offset the tuning effect, and as a result, the write speed might become slower than before. Therefore, if the CPU resources are not sufficient, it is not recommended to enable the StoreWriter thread. Because the Raftstore thread sends most of the I/O requests to the StoreWriter thread, you need to keep the CPU usage of the Raftstore thread below 80%.
- In most cases, set the size of the StoreWriter thread pool to 1 or 2. This is because the size of the StoreWriter thread pool affects the number of Raft logs, so the value of the thread pool size should not be too large. If the CPU usage is higher than 80%, consider increasing the thread pool size.
- Pay attention to the impact of increasing Raft logs on the CPU overhead of other thread pools. If necessary, you need to increase the number of Raftstore threads, Apply threads, and gRPC threads accordingly.

- The UnifyReadPool thread pool.

  The UnifyReadPool is responsible for handling all read requests. The default size (configured by `readpool.unified.max-thread-count`) is 80% of the number of the machine's CPU cores. For example, if the machine CPU has 16 cores, the default thread pool size is 12. It is recommended to adjust the CPU usage rate according to the application workloads and keep it between 60% and 90% of the thread pool size.

If the peak value of the `TiKV-Details.Thread CPU.Unified read pool CPU` on Grafana does not exceed 800%, then it is recommended to set `readpool.unified.max-thread-count` to `10`. Too many threads can cause more frequent thread switching, and take up resources of other thread pools.

Since v6.3.0, TiKV supports automatically adjusting the UnifyReadPool thread pool size based on the current CPU usage. To enable this feature, you can set the `readpool.unified.auto-adjust-pool-size = true`. It is recommended to automatically adjust the thread pool size for clusters that are reread and whose maximum CPU usage exceeds 80%.

- The RocksDB thread pool.

  The RocksDB thread pool is a thread pool for RocksDB to compact and flush tasks. Usually, you do not need to configure it.

  - If the machine has a small number of CPU cores, set both `rocksdb.max-background-jobs` and `raftdb.max-background-jobs` to `4`.
  - If you encounter write stall, go to Write Stall Reason in **RocksDB-kv** on Grafana and check on the metrics that are not `0`.
    - If it is caused by reasons related to pending compaction bytes, set `rocksdb.max-sub-compactions` to `2` or `3`. This configuration item indicates the number of sub-threads allowed for a single compaction job. Its default value is `3` in TiKV 4.0 and `1` in TiKV 3.0.
    - If the reason is related to memtable count, it is recommended to increase the `max-write-buffer-number` of all columns (`5` by default).
    - If the reason is related to the level0 file limit, it is recommended to increase values of the following parameters to `64` or a larger number:

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

11.2.4 Tune TiKV Memory Parameter Performance

This document describes how to tune the TiKV parameters for optimal performance. You can find the default configuration file in etc/config-template.toml. To modify the configuration, you can use TiUP or modify TiKV dynamically for a limited set of configuration items. For the complete configuration, see TiKV configuration file.

TiKV uses RocksDB for persistent storage at the bottom level of the TiKV architecture. Therefore, many of the performance parameters are related to RocksDB. TiKV uses

two RocksDB instances: the default RocksDB instance stores KV data, the Raft RocksDB instance (RaftDB) stores Raft logs.

TiKV implements `Column Families` (CF) from RocksDB.

- The default RocksDB instance stores KV data in the `default`, `write` and `lock` CFs.
    - The `default` CF stores the actual data. The corresponding parameters are in `[rocksdb.defaultcf]`.
    - The `write` CF stores the version information in Multi-Version Concurrency Control (MVCC) and index-related data. The corresponding parameters are in `[rocksdb.writecf]`.
    - The `lock` CF stores the lock information. The system uses the default parameters.
- The Raft RocksDB (RaftDB) instance stores Raft logs.
    - The `default` CF stores the Raft log. The corresponding parameters are in `[raftdb.defaultcf]`.

After TiKV 3.0, by default, all CFs share one block cache instance. You can configure the size of the cache by setting the `capacity` parameter under `[storage.block-cache]`. The bigger the block cache, the more hot data can be cached, and the easier to read data, in the meantime, the more system memory is occupied.

Before TiKV 3.0, shared block cache is not supported, and you need to configure block cache for each CF individually.

Each CF also has a separate `write buffer`. You can configure the size by setting the `write-buffer-size` parameter.

11.2.4.1 Parameter specification

```
### Log level: trace, debug, warn, error, info, off.
log-level = "info"

[server]
### Set listening address
### addr = "127.0.0.1:20160"

### Size of thread pool for gRPC
### grpc-concurrency = 4
### The number of gRPC connections between each TiKV instance
### grpc-raft-conn-num = 10

### Most read requests from TiDB are sent to the coprocessor of TiKV. This
   ↪ parameter is used to set the number of threads
```

```
### of the coprocessor. If many read requests exist, add the number of
   ↪ threads and keep the number within that of the
### system CPU cores. For example, for a 32-core machine deployed with TiKV,
   ↪  you can even set this parameter to 30 in
### repeatable read scenarios. If this parameter is not set, TiKV
   ↪ automatically sets it to CPU cores * 0.8.
### end-point-concurrency = 8

### Tag the TiKV instances to schedule replicas.
### labels = {zone = "cn-east-1", host = "118", disk = "ssd"}

[storage]
### The data directory
### data-dir = "/tmp/tikv/store"

### In most cases, you can use the default value. When importing data, it is
   ↪  recommended to set the parameter to 1024000.
### scheduler-concurrency = 102400
### This parameter controls the number of write threads. When write
   ↪ operations occur frequently, set this parameter value
### higher. Run `top -H -p tikv-pid` and if the threads named `sched-worker-
   ↪ pool` are busy, set the value of parameter
### `scheduler-worker-pool-size` higher and increase the number of write
   ↪ threads.
### scheduler-worker-pool-size = 4

[storage.block-cache]
#### Whether to create a shared block cache for all RocksDB column families.
#### ## Block cache is used by RocksDB to cache uncompressed blocks. Big
   ↪ block cache can speed up read.
#### It is recommended to turn on shared block cache. Since only the total
   ↪ cache size need to be
#### set, it is easier to configure. In most cases, it should be able to
   ↪ auto-balance cache usage
#### between column families with standard LRU algorithm.
#### ## The rest of config in the storage.block-cache session is effective
   ↪ only when shared block cache
#### is on.
#### Starting from v6.6.0, the `shared` option is always enabled and cannot
   ↪ be disabled.
### shared = true

#### Size of the shared block cache. Normally it should be tuned to 30%-50%
   ↪ of system's total memory.
#### When the config is not set, it is decided by the sum of the following
```

```
   ↪ fields or their default
#### value:
####  * rocksdb.defaultcf.block-cache-size or 25% of system's total memory
####  * rocksdb.writecf.block-cache-size or 15% of system's total memory
####  * rocksdb.lockcf.block-cache-size or 2% of system's total memory
####  * raftdb.defaultcf.block-cache-size or 2% of system's total memory
#### ## To deploy multiple TiKV nodes on a single physical machine,
   ↪ configure this parameter explicitly.
#### Otherwise, the OOM problem might occur in TiKV.
### capacity = "1GB"

[pd]
### PD address
### endpoints = ["127.0.0.1:2379","127.0.0.2:2379","127.0.0.3:2379"]

[metric]
### The interval of pushing metrics to Prometheus Pushgateway
interval = "15s"
### Prometheus Pushgateway address
address = ""
job = "tikv"

[raftstore]
### Raft RocksDB directory. The default value is Raft subdirectory of [
   ↪ storage.data-dir].
### If there are multiple disks on the machine, store the data of Raft
   ↪ RocksDB on different disks to improve TiKV performance.
### raftdb-path = "/tmp/tikv/store/raft"

### When the data size change in a Region is larger than the threshold value
   ↪ , TiKV checks whether this Region needs split.
### To reduce the costs of scanning data in the checking process, set the
   ↪ value to 32 MB during the data import process. In the normal
   ↪ operation status, set it to the default value.
region-split-check-diff = "32MB"

[coprocessor]
#### If the size of a Region with the range of [a,e) is larger than the
   ↪ value of `region_max_size`, TiKV trys to split the Region to several
   ↪ Regions, for example, the Regions with the ranges of [a,b), [b,c), [c
   ↪ ,d), and [d,e).
#### After the Region split, the size of the split Regions is equal to the
   ↪ value of `region_split_size` (or slightly larger than the value of `
   ↪ region_split_size`).
### region-max-size = "144MB"
```

```
### region-split-size = "96MB"

[rocksdb]
### The maximum number of threads of RocksDB background tasks. The
   ↪ background tasks include compaction and flush.
### For detailed information why RocksDB needs to implement compaction, see
   ↪ RocksDB-related materials. When write
### traffic (like the importing data size) is big, it is recommended to
   ↪ enable more threads. But set the number of the enabled
### threads smaller than that of CPU cores. For example, when importing data
   ↪ , for a machine with a 32-core CPU,
### set the value to 28.
### max-background-jobs = 8

### The maximum number of file handles RocksDB can open
### max-open-files = 40960

### The file size limit of RocksDB MANIFEST. For more details, see https://
   ↪ github.com/facebook/rocksdb/wiki/MANIFEST
max-manifest-file-size = "20MB"

### The directory of RocksDB write-ahead logs. If there are two disks on the
   ↪  machine, store the RocksDB data and WAL logs
### on different disks to improve TiKV performance.
### wal-dir = "/tmp/tikv/store"

### Use the following two parameters to deal with RocksDB archiving WAL.
### For more details, see https://github.com/facebook/rocksdb/wiki/How-to-
   ↪ persist-in-memory-RocksDB-database%3F
### wal-ttl-seconds = 0
### wal-size-limit = 0

### In most cases, set the maximum total size of RocksDB WAL logs to the
   ↪ default value.
### max-total-wal-size = "4GB"

### Use this parameter to enable the readahead feature during RocksDB
   ↪ compaction. If you are using mechanical disks, it is recommended to
   ↪ set the value to 2MB at least.
### compaction-readahead-size = "2MB"

[rocksdb.defaultcf]
### The data block size. RocksDB compresses data based on the unit of block.
### Similar to page in other databases, block is the smallest unit cached in
   ↪  block-cache.
```

```
block-size = "64KB"

### The compaction mode of each layer of RocksDB data. The optional values
    ↪ include no, snappy, zlib,
### bzip2, lz4, lz4hc, and zstd. Note that the Snappy compressed file must
    ↪ be in the [official Snappy format](https://github.com/google/snappy).
    ↪  Other variants of Snappy compression are not supported.
### "no:no:lz4:lz4:lz4:zstd:zstd" indicates there is no compaction of level0
    ↪  and level1; lz4 compaction algorithm is used
### from level2 to level4; zstd compaction algorithm is used from level5 to
    ↪ level6.
### "no" means no compaction. "lz4" is a compaction algorithm with moderate
    ↪ speed and compaction ratio. The
### compaction ratio of zlib is high. It is friendly to the storage space,
    ↪ but its compaction speed is slow. This
### compaction occupies many CPU resources. Different machines deploy
    ↪ compaction modes according to CPU and I/O resources.
### For example, if you use the compaction mode of "no:no:lz4:lz4:lz4:zstd:
    ↪ zstd" and find much I/O pressure of the
### system (run the iostat command to find %util lasts 100%, or run the top
    ↪ command to find many iowaits) when writing
### (importing) a lot of data while the CPU resources are adequate, you can
    ↪ compress level0 and level1 and exchange CPU
### resources for I/O resources. If you use the compaction mode of "no:no:
    ↪ lz4:lz4:lz4:zstd:zstd" and you find the I/O
### pressure of the system is not big when writing a lot of data, but CPU
    ↪ resources are inadequate. Then run the top
### command and choose the -H option. If you find a lot of bg threads (
    ↪ namely the compaction thread of RocksDB) are
### running, you can exchange I/O resources for CPU resources and change the
    ↪  compaction mode to "no:no:no:lz4:lz4:zstd:zstd".
### In a word, it aims at making full use of the existing resources of the
    ↪ system and improving TiKV performance
### in terms of the current resources.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### The RocksDB memtable size
write-buffer-size = "128MB"

### The maximum number of the memtables. The data written into RocksDB is
    ↪ first recorded in the WAL log, and then inserted
### into memtables. When the memtable reaches the size limit of `write-
    ↪ buffer-size`, it turns into read only and generates
### a new memtable receiving new write operations. The flush threads of
    ↪ RocksDB will flush the read only memtable to the
```

```
### disks to become an sst file of level0. `max-background-flushes` controls
    ↪  the maximum number of flush threads. When the
### flush threads are busy, resulting in the number of the memtables waiting
    ↪  to be flushed to the disks reaching the limit
### of `max-write-buffer-number`, RocksDB stalls the new operation.
### "Stall" is a flow control mechanism of RocksDB. When importing data, you
    ↪  can set the `max-write-buffer-number` value
### higher, like 10.
max-write-buffer-number = 5

### When the number of sst files of level0 reaches the limit of `level0-
    ↪ slowdown-writes-trigger`, RocksDB
### tries to slow down the write operation, because too many sst files of
    ↪ level0 can cause higher read pressure of
### RocksDB. `level0-slowdown-writes-trigger` and `level0-stop-writes-
    ↪ trigger` are for the flow control of RocksDB.
### When the number of sst files of level0 reaches 4 (the default value),
    ↪ the sst files of level0 and the sst files
### of level1 which overlap those of level0 implement compaction to relieve
    ↪ the read pressure.
level0-slowdown-writes-trigger = 20

### When the number of sst files of level0 reaches the limit of `level0-stop
    ↪ -writes-trigger`, RocksDB stalls the new
### write operation.
level0-stop-writes-trigger = 36

### When the level1 data size reaches the limit value of `max-bytes-for-
    ↪ level-base`, the sst files of level1
### and their overlap sst files of level2 implement compaction. The golden
    ↪ rule: the first reference principle
### of setting `max-bytes-for-level-base` is guaranteeing that the `max-
    ↪ bytes-for-level-base` value is roughly equal to the
### data volume of level0. Thus unnecessary compaction is reduced. For
    ↪ example, if the compaction mode is
### "no:no:lz4:lz4:lz4:lz4:lz4", the `max-bytes-for-level-base` value is
    ↪ write-buffer-size * 4, because there is no
### compaction of level0 and level1 and the trigger condition of compaction
    ↪ for level0 is that the number of the
### sst files reaches 4 (the default value). When both level0 and level1
    ↪ adopt compaction, it is necessary to analyze
### RocksDB logs to know the size of an sst file compressed from an mentable
    ↪ . For example, if the file size is 32MB,
### the proposed value of `max-bytes-for-level-base` is 32MB * 4 = 128MB.
max-bytes-for-level-base = "512MB"
```

```
### The sst file size. The sst file size of level0 is influenced by the
    ↪ compaction algorithm of `write-buffer-size`
### and level0. `target-file-size-base` is used to control the size of a
    ↪ single sst file of level1-level6.
target-file-size-base = "32MB"

[rocksdb.writecf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"

[raftdb]
### The maximum number of the file handles RaftDB can open
### max-open-files = 40960

### Enable the readahead feature in RaftDB compaction. If you are using
    ↪ mechanical disks, it is recommended to set
### this value to 2MB at least.
### compaction-readahead-size = "2MB"

[raftdb.defaultcf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"
```

11.2.4.2 TiKV memory usage

Besides `block cache` and `write buffer` which occupy the system memory, the system memory is occupied in the following scenarios:

- Some of the memory is reserved as the system's page cache.
- When TiKV processes large queries such as `select * from ...`, it reads data, generates the corresponding data structure in the memory, and returns this structure to TiDB. During this process, TiKV occupies some of the memory.

11.2.4.3 Recommended configuration of TiKV

- In production environments, it is not recommended to deploy TiKV on the machine whose CPU cores are less than 8 or the memory is less than 32GB.
- If you demand a high write throughput, it is recommended to use a disk with good throughput capacity.
- If you demand a very low read-write latency, it is recommended to use SSD with high IOPS.

11.2.5 Follower Read

When a read hotspot appears in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader, and improve the throughput of the whole system by balancing the load among multiple followers. This document introduces the use and implementation mechanism of Follower Read.

11.2.5.1 Overview

The Follower Read feature refers to using any follower replica of a Region to serve a read request under the premise of strongly consistent reads. This feature improves the throughput of the TiDB cluster and reduces the load of the leader. It contains a series of load balancing mechanisms that offload TiKV read loads from the leader replica to the follower replica in a Region. TiKV's Follower Read implementation provides users with strongly consistent reads.

> **Note:**
>
> To achieve strongly consistent reads, the follower node currently needs to request the current execution progress from the leader node (that is `ReadIndex`), which causes an additional network request overhead. Therefore, the main benefits of Follower Read are to isolate read requests from write requests in the cluster and to increase overall read throughput.

11.2.5.2 Usage

To enable TiDB's Follower Read feature, modify the value of the `tidb_replica_read` variable as follows:

```
set [session | global] tidb_replica_read = '<target value>';
```

Scope: SESSION | GLOBAL

Default: leader

This variable is used to set the expected data read mode.

- When the value of `tidb_replica_read` is set to `leader` or an empty string, TiDB maintains its default behavior and sends all read operations to the leader replica to perform.
- When the value of `tidb_replica_read` is set to `follower`, TiDB selects a follower replica of the Region to perform all read operations.
- When the value of `tidb_replica_read` is set to `leader-and-follower`, TiDB can select any replicas to perform read operations. In this mode, read requests are load balanced between the leader and follower.
- When the value of `tidb_replica_read` is set to `prefer-leader`, TiDB prefers to select the leader replica to perform read operations. If the leader replica is obviously slow in processing read operations (such as caused by disk or network performance jitter), TiDB will select other available follower replicas to perform read operations.
- When the value of `tidb_replica_read` is set to `closest-replicas`, TiDB prefers to select a replica in the same availability zone to perform read operations, which can be a leader or a follower. If there is no replica in the same availability zone, TiDB reads from the leader replica.
- When the value of `tidb_replica_read` is set to `closest-adaptive`:
    - If the estimated result of a read request is greater than or equal to the value of `tidb_adaptive_closest_read_threshold`, TiDB prefers to select a replica in the same availability zone for read operations. To avoid unbalanced distribution of read traffic across availability zones, TiDB dynamically detects the distribution of availability zones for all online TiDB and TiKV nodes. In each availability zone, the number of TiDB nodes whose `closest-adaptive` configuration takes effect is limited, which is always the same as the number of TiDB nodes in the availability zone with the fewest TiDB nodes, and the other TiDB nodes automatically read from the leader replica. For example, if TiDB nodes are distributed across 3 availability zones (A, B, and C), where A and B each contains 3 TiDB nodes and C contains only 2 TiDB nodes, the number of TiDB nodes whose `closest-adaptive` configuration takes effect in each availability zone is 2, and the other TiDB node in each of the A and B availability zones automatically selects the leader replica for read operations.

- If the estimated result of a read request is less than the value of `tidb_adaptive_closest_read_t` ↪ , TiDB can only select the leader replica for read operations.

- When the value of `tidb_replica_read` is set to `learner`, TiDB reads data from the learner replica. If there is no learner replica in the Region, TiDB returns an error.

> **Note:**
>
> When the value of `tidb_replica_read` is set to `closest-replicas` or `closest-adaptive`, you need to configure the cluster to ensure that replicas are distributed across availability zones according to the specified configuration. To configure `location-labels` for PD and set the correct `labels` for TiDB and TiKV, refer to Schedule replicas by topology labels. TiDB depends on the `zone` label to match TiKV nodes in the same availability zone, so you need to make sure that the `zone` label is included in the `location-labels` of PD and `zone` is included in the configuration of each TiDB and TiKV node. If your cluster is deployed using TiDB Operator, refer to High availability of data.

11.2.5.3 Implementation mechanism

Before the Follower Read feature was introduced, TiDB applied the strong leader principle and submitted all read and write requests to the leader node of a Region to handle. Although TiKV can distribute Regions evenly on multiple physical nodes, for each Region, only the leader can provide external services. The other followers can do nothing to handle read requests but receive the data replicated from the leader at all times and prepare for voting to elect a leader in case of a failover.

To allow data reading in the follower node without violating linearizability or affecting Snapshot Isolation in TiDB, the follower node needs to use `ReadIndex` of the Raft protocol to ensure that the read request can read the latest data that has been committed on the leader. At the TiDB level, the Follower Read feature simply needs to send the read request of a Region to a follower replica based on the load balancing policy.

11.2.5.3.1 Strongly consistent reads

When the follower node processes a read request, it first uses `ReadIndex` of the Raft protocol to interact with the leader of the Region, to obtain the latest commit index of the current Raft group. After the latest commit index of the leader is applied locally to the follower, the processing of a read request starts.

11.2.5.3.2 Follower replica selection strategy

Because the Follower Read feature does not affect TiDB's Snapshot Isolation transaction isolation level, TiDB adopts the round-robin strategy to select the follower replica. Currently, for the coprocessor requests, the granularity of the Follower Read load balancing policy is at the connection level. For a TiDB client connected to a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

However, for the non-coprocessor requests, such as a point query, the granularity of the Follower Read load balancing policy is at the transaction level. For a TiDB transaction on a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

11.2.6 Tune Region Performance

This document introduces how to tune Region performance by adjusting the Region size and how to use bucket to optimize concurrent queries when the Region size is large.

11.2.6.1 Overview

TiKV automatically shards bottom-layered data. Data is split into multiple Regions based on the key ranges. When the size of a Region exceeds a threshold, TiKV splits it into two or more Regions.

In scenarios involving large datasets, if the Region size is relatively small, TiKV might have too many Regions, which causes more resource consumption and performance regression. Since v6.1.0, TiDB supports customizing Region size. The default size of a Region is 96 MiB. To reduce the number of Regions, you can adjust Regions to a larger size.

To reduce the performance overhead of many Regions, you can also enable Hibernate Region or `Region Merge`.

11.2.6.2 Use `region-split-size` to adjust Region size

Note:

The recommended range for the Region size is [48 MiB, 256 MiB]. Commonly used sizes include 96 MiB, 128 MiB, and 256 MiB. It is NOT recommended to set the Region size beyond 1 GiB. Avoid setting the size to more than 10 GiB. An excessively large Region size might result in the following side effects:

- Performance jitters
- Decreased query performance, especially for queries that deal with a large range of data
- Slower Region scheduling

To adjust the Region size, you can use the `coprocessor.region-split-size` configuration item. When TiFlash or the Dumpling tool is used, the Region size should not exceed 1 GiB. After increasing the Region size, you need to reduce the concurrency if the Dumpling tool is used; otherwise, TiDB might run out of memory.

11.2.6.3 Use bucket to increase concurrency

> **Warning:**
>
> Currently, this is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

After Regions are set to a larger size, if you want to further improve the query concurrency, you can set `coprocessor.enable-region-bucket` to `true` to increase the query concurrency. When you use this configuration, Regions are divided into buckets. Buckets are smaller ranges within a Region and are used as the unit of concurrent query to improve the scan concurrency. You can control the bucket size using `coprocessor.region-bucket-size`. The default value is `96MiB`.

11.2.7 Tune TiFlash Performance

This document introduces how to tune the performance of TiFlash by properly planning machine resources and tuning TiDB parameters. By following these methods, your TiFlash cluster can achieve optimal performance.

11.2.7.1 Plan resources

If you want to save machine resources and have no requirement on isolation, you can use the method that combines the deployment of both TiKV and TiFlash. It is recommended that you save enough resources for TiKV and TiFlash respectively, and do not share disks.

11.2.7.2 Tune TiDB parameters

This section describes how to improve TiFlash performance by tuning TiDB parameters, including:

- Forcibly enable the MPP mode
- Push down aggregate functions to a position before `Join` or `Union`
- Enable `Distinct` optimization
- Compact data using the `ALTER TABLE ... COMPACT` statement
- Replace Shuffled Hash Join with Broadcast Hash Join
- Set a greater execution concurrency
- Configure `tiflash_fine_grained_shuffle_stream_count`

11.2.7.2.1 Forcibly enable the MPP mode

MPP execution plans can fully utilize distributed computing resources, thereby significantly improving the efficiency of batch data queries. When the optimizer does not generate an MPP execution plan for a query, you can forcibly enable the MPP mode:

The variable `tidb_enforce_mpp` controls whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution. To enable MPP mode forcibly, run the following command:

```
set @@tidb_enforce_mpp = ON;
```

The following example shows the query result before and after `tidb_enforce_mpp` is enabled. Before this variable is enabled, TiDB needs to read data from TiKV and execute `Join` and `Aggregation` in TiDB. After `tidb_enforce_mpp` is enabled, `Join` and `Aggregation` are pushed down to TiFlash. In addition, because the optimizer does not necessarily generate MPP execution plans, by enabling `tidb_enforce_mpp`, you can force the optimizer to generate MPP execution plans.

Before MPP mode is enabled:

```

11.2.7.2.2 Push down aggregate functions to a position before `Join` or `Union`

By pushing down aggregate operations to the position before `Join` or `Union`, you can reduce the data to be processed in the `Join` or `Union` operation, thereby improving performance.

The variable `tidb_opt_agg_push_down` controls whether the optimizer executes the optimization operation of pushing down the aggregate function to the position before `Join` or `Union`. When the aggregate operations are quite slow in the query, you can set this variable to `ON`.

```
set @@tidb_opt_agg_push_down = ON;
```

The following example shows the query result before and after the `tidb_opt_agg_push_down` variable is enabled. Before this variable is enabled, the `HashAgg_58` operation is executed following the `HashJoin_41` operation. After this variable is enabled, newly generated `HashAgg_21` and `HashAgg_32` operations are executed before the `HashJoin_76` operation. This significantly reduces the data to be processed by the `Join` operation.

Before `tidb_opt_agg_push_down` is enabled:

```

11.2.7.2.3 Enable `Distinct` optimization

TiFlash does not support some aggregate functions that accept the `Distinct` column, such as `Sum`. By default, the entire aggregate function is calculated in TiDB. By enabling the `Distinct` optimization, some operations can be pushed down to TiFlash, thereby improving query performance.

If the aggregate function with the `distinct` operation is slow in a query, you can enable the optimization operation of pushing down the aggregate function with `Distinct` (such as `select sum(distinct a)from t`) to Coprocessor by setting the value of the `tidb_opt_distinct_agg_push_down` variable to `ON`.

```
set @@tidb_opt_distinct_agg_push_down = ON;
```

The following example shows the query result before and after the `tidb_opt_distinct_agg_push_down` variable is enabled. Before this variable is enabled, TiDB needs to read all data from TiFlash and execute `distinct` in TiDB. After this variable is enabled, `distinct a` is pushed down to TiFlash, and a new `group by` column `test.t.a` is added in `HashAgg_6`. The two warnings in the query result indicate that the aggregate function cannot be fully pushed down to TiFlash.

Before `tidb_opt_distinct_agg_push_down` is enabled:

```
mysql> explain analyze select count(distinct a) from test.t;

11.2.7.2.4 Compact data using the `ALTER TABLE ... COMPACT` statement

Executing the `ALTER TABLE ... COMPACT` statement can initiate compaction for a specific table or partition on a TiFlash node. During the compaction, the physical data on the node is rewritten, including cleaning up deleted rows and merging multiple versions of data caused by updates. This helps enhance access performance and reduce disk usage. The following are examples:

```
ALTER TABLE employees COMPACT TIFLASH REPLICA;
```

```
ALTER TABLE employees COMPACT PARTITION pNorth, pEast TIFLASH REPLICA;
```

11.2.7.2.5 Replace Shuffled Hash Join with Broadcast Hash Join

For `Join` operations with small tables, the Broadcast Hash Join algorithm can avoid transfering large tables, thereby improving the computing performance.

- The `tidb_broadcast_join_threshold_size` variable controls whether to use the Broadcast Hash Join algorithm. If the table size (unit: byte) is smaller than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

```
set @@tidb_broadcast_join_threshold_size = 2000000;
```

- The `tidb_broadcast_join_threshold_count` variable also controls whether to use the Broadcast Hash Join algorithm. If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set. In this situation, the size is determined by the number of rows in the result set. If the estimated number of rows for the subquery is fewer than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

```
set @@tidb_broadcast_join_threshold_count = 100000;
```

The following example shows the query result before and after `tidb_broadcast_join_threshold_size` is re-configured. Before the re-configuration, the `ExchangeType` of `ExchangeSender_29` is `HashPartition`. After the value of this variable chages to `10000000`, the `ExchangeType` of `ExchangeSender_29` changes to `Broadcast`.

Before `tidb_broadcast_join_threshold_size` is re-configured:

```
mysql> explain analyze select max(l_shipdate), max(l_commitdate), max(
    ↪ l_receiptdate) from supplier,lineitem where s_suppkey = l_suppkey;

11.2.7.2.6 Set a greater execution concurrency

A greater execution concurrency allows TiFlash to occupy more CPU resources of the system, thereby improving query performance.

The `tidb_max_tiflash_threads` variable is used to set the maximum concurrency for TiFlash to execute a request. The unit is threads.

```
set @@tidb_max_tiflash_threads = 20;
```

The following example shows the query result before and after `tidb_max_tiflash_threads` is re-configured. Before the re-configuration, the execution concurrency of all TiFlash operators is 24. After the value of this variable changes to 20, the concurrency becomes 60.

Before `tidb_max_tiflash_threads` is re-configured:

```
mysql> explain analyze select a, count(*) from t group by a;

11.2.7.2.7 Configure `tiflash_fine_grained_shuffle_stream_count`

You can increase the concurrency for executing window functions by configuring `tiflash_fine_grained_shuffle_stream_count` of the Fine Grained Shuffle feature. In this way, the execution of window functions can occupy more system resources, which improves query performance.

When a window function is pushed down to TiFlash for execution, you can use this variable to control the concurrency level of the window function execution. The unit is threads.

```
set @@tiflash_fine_grained_shuffle_stream_count = 20;
```

The following example shows the query result before and after the `tiflash_fine_grained_shuffle_st` ↪ variable is re-configured. Before the re-configuration, the `stream_count` of `[` ↪ `ExchangeSender_11, ExchangeReceiver_12, Sort_13, Window_22]` is 8. After the re-configuration, the `stream_count` becomes 20.

Before `tiflash_fine_grained_shuffle_stream_count` is re-configured:

```
mysql> explain analyze select *, row_number() over (partition by a) from t;

11.2.8 Coprocessor Cache

Starting from v4.0, the TiDB instance supports caching the results of the calculation that is pushed down to TiKV (the Coprocessor Cache feature), which can accelerate the calculation process in some scenarios.

11.2.8.1 Configuration

You can configure Coprocessor Cache via the `tikv-client.copr-cache` configuration items in the TiDB configuration file. For details about how to enable and configure Coprocessor Cache, see TiDB Configuration File.

11.2.8.2 Feature description

- When a SQL statement is executed on a single TiDB instance for the first time, the execution result is not cached.
- Calculation results are cached in the memory of TiDB. If the TiDB instance is restarted, the cache becomes invalid.
- The cache is not shared among TiDB instances.
- Only push-down calculation result is cached. Even if cache is hit, TiDB still need to perform subsequent calculation.

- The cache is in the unit of Region. Writing data to a Region causes the Region cache to be invalid. For this reason, the Coprocessor Cache feature mainly takes effect on the data that rarely changes.
- When push-down calculation requests are the same, the cache is hit. Usually in the following scenarios, the push-down calculation requests are the same or partially the same:
    - The SQL statements are the same. For example, the same SQL statement is executed repeatedly.

      In this scenario, all the push-down calculation requests are consistent, and all requests can use the push-down calculation cache.
    - The SQL statements contain a changing condition, and the other parts are consistent. The changing condition is the primary key of the table or the partition.

      In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
    - The SQL statements contain multiple changing conditions and the other parts are consistent. The changing conditions exactly match a compound index column.

      In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
- This feature is transparent to users. Enabling or disabling this feature does not affect the calculation result and only affects the SQL execution time.

11.2.8.3 Check the cache effect

You can check the cache effect of Coprocessor by executing `EXPLAIN ANALYZE` or viewing the Grafana monitoring panel.

11.2.8.3.1 Use `EXPLAIN ANALYZE`

You can view the cache hit rate in Operators for accessing tables by using the `EXPLAIN ANALYZE` statement. See the following example:

```
EXPLAIN ANALYZE SELECT * FROM t USE INDEX(a);
+--
    ↪ ----------------------------+----------+---------+-----------+---------------

   ↪ 4, max: 5.530817ms, min: 1.51829ms, avg: 2.70883ms, p95: 5.530817ms,
   ↪ max_proc_keys: 2480, p95_proc_keys: 2480, tot_proc: 1ms, tot_wait: 1
   ↪ ms, rpc_num: 4, rpc_time: 10.816328ms, copr_cache_hit_rate: 0.75} | |
   ↪  6.685169219970703 MB | N/A |
|  ─IndexFullScan_4(Build)   | 262400.00 | 262400 | cop[tikv] | table:t,
   ↪ index:a(a, c) | proc max:93ms, min:1ms, p80:93ms, p95:93ms, iters
   ↪ :275, tasks:4
   ↪
   ↪ | keep order:false, stats:pseudo | 1.7549400329589844 MB | N/A |
|  ─TableRowIDScan_5(Probe)  | 262400.00 | 0      | cop[tikv] | table:t
   ↪             | time:0ns, loops:0
   ↪
   ↪ | keep order:false, stats:pseudo | N/A              | N/A |
+--
   ↪ ----------------------------+----------+---------+-----------+---------------
   ↪
3 rows in set (0.62 sec)
```

The column `execution info` of the execution result gives the `copr_cache_hit_ratio` information, which indicates the hit rate of the Coprocessor Cache. The `0.75` in the above example means that the hit rate is about 75%.

11.2.8.3.2 View the Grafana monitoring panel

In Grafana, you can see the **copr-cache** panel in the `distsql` subsystem under the `tidb` namespace. This panel monitors the number of hits, misses, and cache discards of the Coprocessor Cache in the entire cluster.

11.2.9 Garbage Collection (GC)

11.2.9.1 GC Overview

TiDB uses MVCC to control transaction concurrency. When you update the data, the original data is not deleted immediately but is kept together with the new data, with a timestamp to distinguish the version. The goal of Garbage Collection (GC) is to clear the obsolete data.

11.2.9.1.1 GC process

Each TiDB cluster contains a TiDB instance that is selected as the GC leader, which controls the GC process.

GC runs periodically on TiDB. For each GC, TiDB firstly calculates a timestamp called "safe point". Then, TiDB clears the obsolete data under the premise that all the snapshots

after the safe point retain the integrity of the data. Specifically, there are three steps involved in each GC process:

1. Resolve Locks. During this step, TiDB scans locks before the safe point on all Regions and clears these locks.
2. Delete Ranges. During this step, the obsolete data of the entire range generated from the `DROP TABLE/DROP INDEX` operation is quickly cleared.
3. Do GC. During this step, each TiKV node scans data on it and deletes unneeded old versions of each key.

In the default configuration, GC is triggered every 10 minutes. Each GC retains data of the recent 10 minutes, which means that the GC life time is 10 minutes by default (safe point = the current time - GC life time). If one round of GC has been running for too long, before this round of GC is completed, the next round of GC will not start even if it is time to trigger the next GC. In addition, for long-duration transactions to run properly after exceeding the GC life time, the safe point does not exceed the start time (start_ts) of the ongoing transactions.

11.2.9.1.2 Implementation details

Resolve Locks

The TiDB transaction model is implemented based on Google's Percolator. It's mainly a two-phase commit protocol with some practical optimizations. When the first phase is finished, all the related keys are locked. Among these locks, one is the primary lock and the others are secondary locks which contain a pointer to the primary lock; in the second phase, the key with the primary lock gets a write record and its lock is removed. The write record indicates the write or delete operation in the history or the transactional rollback record of this key. The type of write record that replaces the primary lock indicates whether the corresponding transaction is committed successfully. Then all the secondary locks are replaced successively. If, for some reason such as failure, these secondary locks are retained and not replaced, you can still find the primary key based on the information in the secondary locks and determines whether the entire transaction is committed based on whether the primary key is committed. However, if the primary key information is cleared by GC and this transaction has uncommitted secondary locks, you will never learn whether these locks can be committed. As a result, data integrity cannot be guaranteed.

The Resolve Locks step clears the locks before the safe point. This means that if the primary key of a lock is committed, this lock needs to be committed; otherwise, it needs to be rolled back. If the primary key is still locked (not committed or rolled back), this transaction is seen as timing out and rolled back.

The Resolve Locks step is implemented in either of the following two ways, which can be configured using the system variable `tidb_gc_scan_lock_mode`:

Warning:

Currently, `PHYSICAL` (Green GC) is an experimental feature. It is not recommended that you use it in the production environment.

- `LEGACY` (default): The GC leader sends requests to all Regions to scan obsolete locks, checks the primary key statuses of scanned locks, and sends requests to commit or roll back the corresponding transaction.
- `PHYSICAL`: TiDB bypasses the Raft layer and directly scans data on each TiKV node.

Delete Ranges

A great amount of data with consecutive keys is removed during operations such as `DROP TABLE/INDEX`. Removing each key and performing GC later for them can result in low execution efficiency on storage reclaiming. In such scenarios, TiDB actually does not delete each key. Instead, it only records the range to be removed and the timestamp of the deletion. Then the Delete Ranges step performs a fast physical deletion on the ranges whose timestamp is before the safe point.

Do GC

The Do GC step clears the outdated versions for all keys. To guarantee that all timestamps after the safe point have consistent snapshots, this step deletes the data committed before the safe point, but retains the last write for each key before the safe point as long as it is not a deletion.

In this step, TiDB only needs to send the safe point to PD, and then the whole round of GC is completed. TiKV automatically detects the change of safe point and performs GC for all Region leaders on the current node. At the same time, the GC leader can continue to trigger the next round of GC.

Note:

Starting with TiDB 5.0, the Do GC step will always use the `DISTRIBUTED` gc mode. This replaces the earlier `CENTRAL` gc mode, which was implemented by TiDB servers sending GC requests to each Region.

11.2.9.2 Garbage Collection Configuration

You can configure garbage collection (GC) using the following system variables:

- tidb_gc_enable: controls whether to enable garbage collection for TiKV.
- tidb_gc_run_interval: specifies the GC interval.
- tidb_gc_life_time: specifies the time limit during which data is retained for each GC.
- tidb_gc_concurrency: specifies the number of threads in the Resolve Locks step of GC.
- tidb_gc_scan_lock_mode: specifies the way of scanning locks in the Resolve Locks step of GC.
- tidb_gc_max_wait_time: specifies the maximum time that active transactions block the GC safe point.

For more information about how to modify the value of a system variable, see System variables.

11.2.9.2.1 GC I/O limit

TiKV supports the GC I/O limit. You can configure `gc.max-write-bytes-per-sec` to limit writes of a GC worker per second, and thus to reduce the impact on normal requests.

`0` indicates disabling this feature.

You can dynamically modify this configuration using tikv-ctl:

```
tikv-ctl --host=ip:port modify-tikv-config -n gc.max-write-bytes-per-sec -v
    ↪ 10MB
```

11.2.9.2.2 Changes in TiDB 5.0

In previous releases of TiDB, garbage collection was configured via the `mysql.tidb` system table. While changes to this table continue to be supported, it is recommended to use the system variables provided. This helps ensure that any changes to configuration can be validated, and prevent unexpected behavior (#20655).

The `CENTRAL` garbage collection mode is no longer supported. The `DISTRIBUTED` GC mode (which has been the default since TiDB 3.0) will automatically be used in its place. This mode is more efficient, since TiDB no longer needs to send requests to each TiKV region to trigger garbage collection.

For information on changes in previous releases, refer to earlier versions of this document using the *TIDB version selector* in the left hand menu.

11.2.9.2.3 Changes in TiDB 6.1.0

Before TiDB v6.1.0, the transaction in TiDB does not affect the GC safe point. Starting from v6.1.0, TiDB considers the startTS of the transaction when calculating the GC safe point, to resolve the problem that the data to be accessed has been cleared. If the transaction is too long, the safe point will be blocked for a long time, which affects the application performance.

In TiDB v6.1.0, the system variable `tidb_gc_max_wait_time` is introduced to control the maximum time that active transactions block the GC safe point. After the value is exceeded, the GC safe point is forwarded forcefully.

GC in Compaction Filter

Based on the `DISTRIBUTED` GC mode, the mechanism of GC in Compaction Filter uses the compaction process of RocksDB, instead of a separate GC worker thread, to run GC. This new GC mechanism helps to avoid extra disk read caused by GC. Also, after clearing the obsolete data, it avoids a large number of left tombstone marks which degrade the sequential scan performance.

The following example shows how to enable the mechanism in the TiKV configuration file:

```
[gc]
enable-compaction-filter = true
```

You can also enable this GC mechanism by modifying the configuration dynamically. See the following example:

```
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | false |
+------+------------------+-----------------------------+-------+
```

```
set config tikv gc.enable-compaction-filter = true;
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | true |
+------+------------------+-----------------------------+-------+
```

11.3 SQL Tuning

11.3.1 SQL Tuning Overview

SQL is a declarative language. That is, an SQL statement describes *what the final result should look like* and not a set of steps to execute in sequence. TiDB will optimize the

execution, and is semantically permitted to execute parts of the query in any order provided that it correctly returns the final result as described.

A useful comparison to SQL optimization, is to describe what happens when you use GPS navigation. From your provided address, *2955 Campus Drive San Mateo CA 94403*, the GPS software plans the most time-efficient way to route you. It may make use of various statistics such as previous trips, meta data such as speed limits, and in modern cases, a live feed of traffic information. Several of these analogies translate to TiDB.

This section introduces several concepts about query execution:

- Understanding the Query Execution Plan introduces how to use the `EXPLAIN` statement to understand how TiDB has decided to execute a statement.
- SQL Optimization Process introduces what optimizations TiDB is capable of using to improve query execution performance.
- Control Execution Plans introduces ways to control the generation of the execution plan. This can be useful in cases where the execution plan decided by TiDB is suboptimal.

11.3.2 Understanding the Query Execution Plan

11.3.2.1 TiDB Query Execution Plan Overview

> **Note:**
>
> When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less -S` command. Then, after the `EXPLAIN` result is output, you can press the right arrow → button on your keyboard to horizontally scroll through the output.

SQL is a declarative language. It describes what the results of a query should look like, **not the methodology** to actually retrieve those results. TiDB considers all the possible ways in which a query could be executed, including using what order to join tables and whether any potential indexes can be used. The process of *considering query execution plans* is known as SQL optimization.

The `EXPLAIN` statement shows the selected execution plan for a given statement. That is, after considering hundreds or thousands of ways in which the query could be executed, TiDB believes that this *plan* will consume the least resources and execute in the shortest amount of time:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a INT NOT NULL,
    ↪ pad1 VARCHAR(255), INDEX(a));
```

```
INSERT INTO t VALUES (1, 1, 'aaa'),(2,2, 'bbb');
EXPLAIN SELECT * FROM t WHERE a = 1;
```

```
Query OK, 0 rows affected (0.96 sec)

Query OK, 2 rows affected (0.02 sec)
Records: 2 Duplicates: 0 Warnings: 0

+--
   ↪ ----------------------------+---------+----------+-------------------+------
   ↪
| id                          | estRows | task     | access object     |
   ↪ operator info                              |
+--
   ↪ ----------------------------+---------+----------+-------------------+------
   ↪
| IndexLookUp_10              | 10.00   | root     |                   |
   ↪                                          |
|  ─IndexRangeScan_8(Build)   | 10.00   | cop[tikv] | table:t, index:a(a) |
   ↪ range:[1,1], keep order:false, stats:pseudo |
|  ─TableRowIDScan_9(Probe)   | 10.00   | cop[tikv] | table:t          | keep
   ↪ order:false, stats:pseudo          |
+--
   ↪ ----------------------------+---------+----------+-------------------+------
   ↪
3 rows in set (0.00 sec)
```

`EXPLAIN` does not execute the actual query. `EXPLAIN ANALYZE` can be used to execute the query and show `EXPLAIN` information. This can be useful in diagnosing cases where the execution plan selected is suboptimal. For additional examples of using `EXPLAIN`, see the following documents:

- Indexes
- Joins
- Subqueries
- Aggregation
- Views
- Partitions

11.3.2.1.1 Understand EXPLAIN output

The following describes the output of the `EXPLAIN` statement above:

- `id` describes the name of an operator, or sub-task that is required to execute the SQL statement. See Operator overview for additional details.

- `estRows` shows an estimate of the number of rows TiDB expects to process. This number might be based on dictionary information, such as when the access method is based on a primary or unique key, or it could be based on statistics such as a CMSketch or histogram.
- `task` shows where an operator is performing the work. See Task overview for additional details.
- `access object` shows the table, partition and index that is being accessed. The parts of the index are also shown, as in the case above that the column `a` from the index was used. This can be useful in cases where you have composite indexes.
- `operator info` shows additional details about the access. See Operator info overview for additional details.

Note:

In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0.

Before v6.4.0, `estRows` means the number of estimated rows to be processed by the probe side operators for each row from the build side operators. Since v6.4.0, `estRows` means the **total number** of estimated rows to be processed by the probe side operators. The actual number of rows displayed (indicated by the `actRows` column) in the result of `EXPLAIN ANALYZE` means the total row count, so since v6.4.0 the meanings of `estRows` and `actRows` for the probe side child nodes of `IndexJoin` and `Apply` operators are consistent.

For example:

```
CREATE TABLE t1(a INT, b INT);
CREATE TABLE t2(a INT, b INT, INDEX ia(a));
EXPLAIN SELECT /*+ INL_JOIN(t2) */ * FROM t1 JOIN t2 ON t1.a =
    ↪  t2.a;
EXPLAIN SELECT (SELECT a FROM t2 WHERE t2.a = t1.b LIMIT 1)
    ↪ FROM t1;
```

```

Operator overview

An operator is a particular step that is executed as part of returning query results. The operators that perform table scans (of the disk or the TiKV Block Cache) are listed as follows:

- **TableFullScan**: Full table scan

- **TableRangeScan**: Table scans with the specified range
- **TableRowIDScan**: Scans the table data based on the RowID. Usually follows an index read operation to retrieve the matching data rows.
- **IndexFullScan**: Similar to a "full table scan", except that an index is scanned, rather than the table data.
- **IndexRangeScan**: Index scans with the specified range.

TiDB aggregates the data or calculation results scanned from TiKV/TiFlash. The data aggregation operators can be divided into the following categories:

- **TableReader**: Aggregates the data obtained by the underlying operators like `TableFullScan` or `TableRangeScan` in TiKV.
- **IndexReader**: Aggregates the data obtained by the underlying operators like `IndexFullScan` or `IndexRangeScan` in TiKV.
- **IndexLookUp**: First aggregates the RowID (in TiKV) scanned by the `Build` side. Then at the `Probe` side, accurately reads the data from TiKV based on these RowIDs. At the `Build` side, there are operators like `IndexFullScan` or `IndexRangeScan`; at the `Probe` side, there is the `TableRowIDScan` operator.
- **IndexMerge**: Similar to `IndexLookUp`. `IndexMerge` can be seen as an extension of `IndexLookupReader`. `IndexMerge` supports reading multiple indexes at the same time. There are many `Build`s and one `Probe`. The execution process of `IndexMerge` the same as that of `IndexLookUp`.

While the structure appears as a tree, executing the query does not strictly require the child nodes to be completed before the parent nodes. TiDB supports intra-query parallelism, so a more accurate way to describe the execution is that the child nodes *flow into* their parent nodes. Parent, child and sibling operators *might* potentially be executing parts of the query in parallel.

In the previous example, the `└─IndexRangeScan_8(Build)` operator finds the internal `RowID` for rows that match the `a(a)` index. The `└─TableRowIDScan_9(Probe)` operator then retrieves these rows from the table.

Range query

In the `WHERE`/`HAVING`/`ON` conditions, the TiDB optimizer analyzes the result returned by the primary key query or the index key query. For example, these conditions might include comparison operators of the numeric and date type, such as `>`, `<`, `=`, `>=`, `<=`, and the character type such as `LIKE`.

Note:

- In order to use an index, the condition must be *sargable*. For example, the condition `YEAR(date_column)< 1992` cannot use an index, but `date_column < '1992-01-01` can.

- It is recommended to compare data of the same type and character set and collation. Mixing types may require additional `cast` operations, or prevent indexes from being used.
- You can also use `AND` (intersection) and `OR` (union) to combine the range query conditions of one column. For a multi-dimensional composite index, you can use conditions in multiple columns. For example, regarding the composite index `(a, b, c)`:
  - When `a` is an equivalent query, continue to figure out the query range of `b`; when `b` is also an equivalent query, continue to figure out the query range of `c`.
  - Otherwise, if `a` is a non-equivalent query, you can only figure out the range of `a`.

Task overview

Currently, calculation tasks of TiDB can be divided into two categories: cop tasks and root tasks. A `cop[tikv]` task indicates that the operator is performed inside the TiKV coprocessor. A `root` task indicates that it will be completed inside of TiDB.

One of the goals of SQL optimization is to push the calculation down to TiKV as much as possible. The Coprocessor in TiKV supports most of the built-in SQL functions (including the aggregate functions and the scalar functions), SQL `LIMIT` operations, index scans, and table scans.

Operator info overview

The `operator info` can show useful information such as which conditions were able to be pushed down:

- `range: [1,1]` shows that the predicate from the where clause of the query (`a = 1`) was pushed right down to TiKV (the task is of `cop[tikv]`).
- `keep order:false` shows that the semantics of this query did not require TiKV to return the results in order. If the query were to be modified to require an order (such as `SELECT * FROM t WHERE a = 1 ORDER BY id`), then this condition would be `keep order:true`.
- `stats:pseudo` shows that the estimates shown in `estRows` might not be accurate. TiDB periodically updates statistics as part of a background operation. A manual update can also be performed by running `ANALYZE TABLE t`.

Different operators output different information after the `EXPLAIN` statement is executed. You can use optimizer hints to control the behavior of the optimizer, and thereby controlling the selection of the physical operators. For example, `/*+ HASH_JOIN(t1, t2)*/` means that the optimizer uses the `Hash Join` algorithm. For more details, see Optimizer Hints.

11.3.2.2 `EXPLAIN` Walkthrough

Because SQL is a declarative language, you cannot automatically tell whether a query is executed efficiently. You must first use the `EXPLAIN` statement to learn the current execution plan.

The following statement from the bikeshare example database counts how many trips were taken on July 1, 2017:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ----------------------------+----------+----------+---------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪
    ↪ |
+--
    ↪ ----------------------------+----------+----------+---------------+-----------
    ↪
| StreamAgg_20                | 1.00    | root     |               | funcs:count(
    ↪ Column#13)->Column#11
    ↪
    ↪ |
| └─TableReader_21            | 1.00    | root     |               | data:
    ↪ StreamAgg_9
    ↪
    ↪ |
|   └─StreamAgg_9             | 1.00    | cop[tikv] |              | funcs:count
    ↪ (1)->Column#13
    ↪
    ↪ |
|     └─Selection_19          | 250.00  | cop[tikv] |              | ge(
    ↪ bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(bikeshare
    ↪ .trips.start_date, 2017-07-01 23:59:59.000000) |
|       └─TableFullScan_18    | 10000.00 | cop[tikv] | table:trips | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ----------------------------+----------+----------+---------------+-----------
    ↪
5 rows in set (0.00 sec)
```

From the child operator `└─TableFullScan_18` back, you can see its execution process as follows, which is currently suboptimal:

1. The coprocessor (TiKV) reads the entire `trips` table as a `TableFullScan` operation. It then passes the rows that it reads to the `Selection_19` operator, which is still within TiKV.
2. The `WHERE start_date BETWEEN ..` predicate is then filtered in the `Selection_19` operator. Approximately `250` rows are estimated to meet this selection. Note that this number is estimated according to the statistics and the operator's logic. The `└─TableFullScan_18` operator shows `stats:pseudo`, which means that the table does not have the actual statistical information. After running `ANALYZE TABLE trips` to collect statistical information, the statistics are expected to be more accurate.
3. The rows that meet the selection criteria then have a `count` function applied to them. This is also completed inside the `StreamAgg_9` operator, which is still inside TiKV (`cop[tikv]`). The TiKV coprocessor can execute a number of MySQL built-in functions, `count` being one of them.
4. The results from `StreamAgg_9` are then sent to the `TableReader_21` operator which is now inside the TiDB server (the task of `root`). The `estRows` column value for this operator is `1`, which means that the operator will receive one row from each of the TiKV Regions to be accessed. For more information about these requests, see `EXPLAIN ANALYZE`.
5. The `StreamAgg_20` operator then applies a `count` function to each of the rows from the `└─TableReader_21` operator, which you can see from `SHOW TABLE REGIONS` and will be about 56 rows. Because this is the root operator, it then returns results to the client.

> **Note:**
>
> For a general view of the Regions that a table contains, execute `SHOW TABLE REGIONS`.

11.3.2.2.1 Assess the current performance

`EXPLAIN` only returns the query execution plan but does not execute the query. To get the actual execution time, you can either execute the query or use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ----------------------------+----------+----------+-----------+---------------+-
    ↪
```

```
| id                          | estRows | actRows | task     | access object |
    ↪ execution info
    ↪

    ↪
    ↪ | ge(bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(
    ↪ bikeshare.trips.start_date, 2017-07-01 23:59:59.000000) | N/A | N/A |
|       ─TableFullScan_18     | 10000.00 | 19117643 | cop[tikv] | table:trips
    ↪  | proc max:612ms, min:8ms, p80:248ms, p95:460ms, iters:18695, tasks
    ↪ :56
    ↪
    ↪ | keep order:false, stats:pseudo
    ↪
    ↪ | N/A      | N/A |
+--
    ↪ ----------------------------+---------+---------+----------+---------------+-
    ↪
5 rows in set (1.03 sec)
```

The example query above takes `1.03` seconds to execute, which is an ideal performance.

From the result of `EXPLAIN ANALYZE` above, `actRows` indicates that some of the estimates (`estRows`) are inaccurate (expecting 10 thousand rows but finding 19 million rows), which is already indicated in the `operator info` (`stats:pseudo`) of `−TableFullScan_18`. If you run `ANALYZE TABLE` first and then `EXPLAIN ANALYZE` again, you can see that the estimates are much closer:

```
ANALYZE TABLE trips;
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
Query OK, 0 rows affected (10.22 sec)

+--
    ↪ ---------------------------+-------------+---------+-----------+--------------
    ↪
5 rows in set (0.93 sec)
```

After `ANALYZE TABLE` is executed, you can see that the estimated rows for the `−↪ TableFullScan_18` operator is accurate and the estimate for `−Selection_19` is now also much closer. In the two cases above, although the execution plan (the set of operators TiDB uses to execute this query) has not changed, quite frequently sub-optimal plans are caused by outdated statistics.

In addition to `ANALYZE TABLE`, TiDB automatically regenerates statistics as a background operation after the threshold of `tidb_auto_analyze_ratio` is reached. You can see how close TiDB is to this threshold (how healthy TiDB considers the statistics to be) by executing the `SHOW STATS_HEALTHY` statement:

```
SHOW STATS_HEALTHY;
```

```
+----------+------------+----------------+---------+
| Db_name  | Table_name | Partition_name | Healthy |
+----------+------------+----------------+---------+
| bikeshare | trips   |                |     100 |
+----------+------------+----------------+---------+
1 row in set (0.00 sec)
```

11.3.2.2.2 Identify optimizations

The current execution plan is efficient in the following aspects:

- Most of the work is handled inside the TiKV coprocessor. Only 56 rows need to be sent across the network back to TiDB for processing. Each of these rows is short and contains only the count that matches the selection.

- Aggregating the count of rows both in TiDB (`StreamAgg_20`) and in TiKV (`StreamAgg_9`) uses the stream aggregation, which is very efficient in its memory usage.

The biggest issue with the current execution plan is that the predicate `start_date BETWEEN '2017-07-01 00:00:00' AND '2017-07-01 23:59:59'` does not apply immediately. All rows are read first with a `TableFullScan` operator, and then a selection is applied afterwards. You can find out the cause from the output of `SHOW CREATE TABLE trips`:

```
SHOW CREATE TABLE trips\G
```

```
*************************** 1. row ***************************
       Table: trips
Create Table: CREATE TABLE `trips` (
  `trip_id` bigint(20) NOT NULL AUTO_INCREMENT,
  `duration` int(11) NOT NULL,
  `start_date` datetime DEFAULT NULL,
  `end_date` datetime DEFAULT NULL,
  `start_station_number` int(11) DEFAULT NULL,
  `start_station` varchar(255) DEFAULT NULL,
  `end_station_number` int(11) DEFAULT NULL,
  `end_station` varchar(255) DEFAULT NULL,
  `bike_number` varchar(255) DEFAULT NULL,
  `member_type` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`trip_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =20477318
1 row in set (0.00 sec)
```

There is **NO** index on `start_date`. You would need an index in order to push this predicate into an index reader operator. Add an index as follows:

```
ALTER TABLE trips ADD INDEX (start_date);
```

```
Query OK, 0 rows affected (2 min 10.23 sec)
```

Note:

You can monitor the progress of DDL jobs using the `ADMIN SHOW DDL JOBS` command. The defaults in TiDB are carefully chosen so that adding an index does not impact production workloads too much. For testing environments, consider increasing the `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` values. On a reference system, a batch size of 10240 and worker count of 32 can achieve a 10x performance improvement over the defaults.

After adding an index, you can then repeat the query in `EXPLAIN`. In the following output, you can see that a new execution plan is chosen, and the `TableFullScan` and `Selection` operators have been eliminated:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ -------------------------+---------+-----------+-------------------------
    ↪
| id                        | estRows | task    | access object
    ↪                         | operator info
    ↪                                                |
+--
    ↪ -------------------------+---------+-----------+-------------------------
    ↪
| StreamAgg_17              | 1.00    | root      |
    ↪                                               | funcs:count(Column#13)->Column
    ↪ #11                           |
|  ─IndexReader_18          | 1.00    | root      |
    ↪                                               | index:StreamAgg_9
    ↪                                                 |
|    ─StreamAgg_9           | 1.00    | cop[tikv] |
    ↪                                                   | funcs:count(1)->Column#13
    ↪                                     |
|      ─IndexRangeScan_16   | 8471.88 | cop[tikv] | table:trips, index:
    ↪ start_date(start_date) | range:[2017-07-01 00:00:00,2017-07-01
    ↪ 23:59:59], keep order:false |
+--
    ↪ -------------------------+---------+-----------+-------------------------
    ↪
4 rows in set (0.00 sec)
```

To compare the actual execution time, you can again use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ -------------------------+---------+---------+-----------+-----------------
    ↪
| id                        | estRows | actRows | task    | access object
    ↪                         | execution info
    ↪
    ↪ | operator info                                                | memory
    ↪   | disk |
```

```
+--
   ↪ -------------------------+---------+---------+----------+-------------------
   ↪
| StreamAgg_17              | 1.00    | 1       | root     |
   ↪                                     | time:4.516728ms, loops:2
   ↪
   ↪ | funcs:count(Column#13)->Column#11                          | 372
   ↪ Bytes | N/A |
|  ─IndexReader_18          | 1.00    | 1       | root     |
   ↪                                     | time:4.514278ms, loops:2,
   ↪ cop_task: {num: 1, max:4.462288ms, proc_keys: 11409, rpc_num: 1,
   ↪ rpc_time: 4.457148ms} | index:StreamAgg_9                        |
   ↪ 238 Bytes | N/A |
|    ─StreamAgg_9           | 1.00    | 1       | cop[tikv] |
   ↪                                   | time:4ms, loops:12
   ↪
   ↪ | funcs:count(1)->Column#13                                  | N/A
   ↪      | N/A |
|      ─IndexRangeScan_16   | 8471.88 | 11409 | cop[tikv] | table:trips,
   ↪ index:start_date(start_date) | time:4ms, loops:12
   ↪
   ↪ | range:[2017-07-01 00:00:00,2017-07-01 23:59:59], keep order:false |
   ↪  N/A | N/A |
+--
   ↪ -------------------------+---------+---------+----------+-------------------
   ↪
4 rows in set (0.00 sec)
```

From the result above, the query time has reduced from 1.03 seconds to 0.0 seconds.

> **Note:**
>
> Another optimization that applies here is the coprocessor cache. If you are unable to add indexes, consider enabling the coprocessor cache. When it is enabled, as long as the Region has not been modified since the operator is last executed, TiKV will return the value from the cache. This will also help reduce much of the cost of the expensive `TableFullScan` and `Selection` operators.

11.3.2.3 Explain Statements That Use Indexes

TiDB supports several operators which make use of indexes to speed up query execution:

- IndexLookup
- IndexReader
- Point_Get and Batch_Point_Get
- IndexFullScan

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 intkey INT NOT NULL,
 pad1 VARBINARY(1024),
 INDEX (intkey)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM
    ↪ dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
```

11.3.2.3.1 IndexLookup

TiDB uses the `IndexLookup` operator when retrieving data from a secondary index. In this case, the following queries will all use the `IndexLookup` operator on the `intkey` index:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT * FROM t1 WHERE intkey < 10;
EXPLAIN SELECT * FROM t1 WHERE intkey BETWEEN 300 AND 310;
EXPLAIN SELECT * FROM t1 WHERE intkey IN (123,29,98);
EXPLAIN SELECT * FROM t1 WHERE intkey >= 99 AND intkey <= 103;
```

```

+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator has two child nodes:

- The `─IndexRangeScan_8(Build)` operator performs a range scan on the `intkey` index and retrieves the values of the internal `RowID` (for this table, the primary key).
- The `─TableRowIDScan_9(Probe)` operator then retrieves the full row from the table data.

Because an `IndexLookup` task requires two steps, the SQL Optimizer might choose the `TableFullScan` operator based on statistics in scenarios where a large number of rows match. In the following example, a large number of rows match the condition of `intkey > 100`, and a `TableFullScan` is chosen:

```
EXPLAIN SELECT * FROM t1 WHERE intkey > 100;
```

```
+--
   ↪ ---------------------+---------+----------+--------------+-----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪      |
+--
   ↪ ---------------------+---------+----------+--------------+-----------------
   ↪
| TableReader_7         | 898.50 | root     |               | data:Selection_6
   ↪     |
|  ─Selection_6         | 898.50 | cop[tikv] |              | gt(test.t1.intkey
   ↪ , 100) |
|    ─TableFullScan_5   | 1010.00 | cop[tikv] | table:t1 | keep order:false
   ↪     |
+--
   ↪ ---------------------+---------+----------+--------------+-----------------
   ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator can also be used to efficiently optimize `LIMIT` on an indexed column:

```
EXPLAIN SELECT * FROM t1 ORDER BY intkey DESC LIMIT 10;
```

```
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| id                           | estRows | task     | access object
   ↪              | operator info                    |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| IndexLookUp_21               | 10.00   | root     |
   ↪                              | limit embedded(offset:0, count:10) |
|  ─Limit_20(Build)            | 10.00   | cop[tikv] |
   ↪                               | offset:0, count:10             |
|    ─IndexFullScan_18         | 10.00   | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true, desc    |
```

```
|  └─TableRowIDScan_19(Probe)  | 10.00  | cop[tikv] | table:t1
   ↪                  | keep order:false, stats:pseudo |
+--
   ↪ ----------------------------+--------+----------+-----------------------
   ↪
4 rows in set (0.00 sec)
```

In the above example, the last 10 rows are read from the index `intkey`. These `RowID` values are then retrieved from the table data.

11.3.2.3.2 IndexReader

TiDB supports the *covering index optimization*. If all rows can be retrieved from an index, TiDB will skip the second step that is usually required in an `IndexLookup`. Consider the following two examples:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT id FROM t1 WHERE intkey = 123;
```

```
+--
   ↪ ----------------------------+--------+----------+-----------------------
   ↪
| id                          | estRows | task    | access object
   ↪              | operator info                  |
+--
   ↪ ----------------------------+--------+----------+-----------------------
   ↪
| IndexLookUp_10              | 1.00    | root     |
   ↪                             |                                |
|  └─IndexRangeScan_8(Build)  | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[123,123], keep order:false |
|  └─TableRowIDScan_9(Probe)  | 1.00    | cop[tikv] | table:t1
   ↪                  | keep order:false               |
+--
   ↪ ----------------------------+--------+----------+-----------------------
   ↪
3 rows in set (0.00 sec)

+--
   ↪ ----------------------+--------+----------+-----------------------------+
   ↪
| id                     | estRows | task    | access object               |
   ↪ operator info                 |
+--
   ↪ ----------------------+--------+----------+-----------------------------+
   ↪
```

```
| Projection_4          | 1.00   | root     |                                 |
   ↪ test.t1.id                    |
|  ─IndexReader_6       | 1.00   | root     |                                 |
   ↪ index:IndexRangeScan_5        |
|    ─IndexRangeScan_5  | 1.00   | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[123,123], keep order:false |
+--
   ↪ ----------------------+--------+----------+-----------------------------+
   ↪
3 rows in set (0.00 sec)
```

Because `id` is also the internal `RowID`, it is stored in the `intkey` index. After using the `intkey` index as part of `─IndexRangeScan_5`, the value of the `RowID` can be returned directly.

11.3.2.3.3 Point_Get and Batch_Point_Get

TiDB uses the `Point_Get` or `Batch_Point_Get` operator when retrieving data directly from a primary key or unique key. These operators are more efficient than `IndexLookup`. For example:

```
EXPLAIN SELECT * FROM t1 WHERE id = 1234;
EXPLAIN SELECT * FROM t1 WHERE id IN (1234,123);

ALTER TABLE t1 ADD unique_key INT;
UPDATE t1 SET unique_key = id;
ALTER TABLE t1 ADD UNIQUE KEY (unique_key);

EXPLAIN SELECT * FROM t1 WHERE unique_key = 1234;
EXPLAIN SELECT * FROM t1 WHERE unique_key IN (1234, 123);
```

```
+-------------+---------+------+--------------+---------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+--------------+---------------+
| Point_Get_1 | 1.00 | root | table:t1    | handle:1234 |
+-------------+---------+------+--------------+---------------+
1 row in set (0.00 sec)

+--
   ↪ ----------------+---------+------+--------------+-------------------------
   ↪
| id                | estRows | task | access object | operator info
   ↪                           |
+--
   ↪ ----------------+---------+------+--------------+-------------------------
   ↪
```

```

    ↪ | keep order:false, desc:false |
+--
    ↪ ----------------+---------+------+-------------------------------------------+----
    ↪
1 row in set (0.00 sec)
```

11.3.2.3.4 IndexFullScan

Because indexes are ordered, the `IndexFullScan` operator can be used to optimize common queries such as the `MIN` or `MAX` values for an indexed value:

```
EXPLAIN SELECT MIN(intkey) FROM t1;
EXPLAIN SELECT MAX(intkey) FROM t1;
```

```
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task     | access object

+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| StreamAgg_12                | 1.00    | root     |
   ↪ | funcs:min(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
   ↪                               | offset:0, count:1                |
|    ─IndexReader_29          | 1.00    | root     |
   ↪                               | index:Limit_28                   |
|      ─Limit_28              | 1.00    | cop[tikv] |
   ↪                              | offset:0, count:1                |
|        ─IndexFullScan_27    | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true           |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
5 rows in set (0.00 sec)

+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task     | access object
   ↪ | operator info                    |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| StreamAgg_12                | 1.00    | root     |
   ↪ | funcs:max(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
   ↪                               | offset:0, count:1                |
|    ─IndexReader_29          | 1.00    | root     |
   ↪                               | index:Limit_28                   |
|      ─Limit_28              | 1.00    | cop[tikv] |
```

```
    ↪                              | offset:0, count:1                |
|       └─IndexFullScan_27   | 1.00    | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:true, desc     |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
5 rows in set (0.00 sec)
```

In the above statements, an `IndexFullScan` task is performed on each TiKV Region. Despite the name `FullScan`, only the first row needs to be read (`└─Limit_28`). Each TiKV Region returns its `MIN` or `MAX` value to TiDB, which then performs Stream Aggregation to filter for a single row. Stream Aggregation with the aggregation function `MAX` or `MIN` also ensures that `NULL` is returned if the table is empty.

By contrast, executing the `MIN` function on an unindexed value will result in `TableFullScan`. The query will require all rows to be scanned in TiKV, but a `TopN` calculation is performed to ensure each TiKV Region only returns one row to TiDB. Although `TopN` prevents excessive rows from being transferred between TiKV and TiDB, this statement is still considered far less efficient than the above example where `MIN` is able to make use of an index.

```
EXPLAIN SELECT MIN(pad1) FROM t1;
```

```
+--
    ↪ ----------------------------+---------+----------+--------------+----------
    ↪
| id                          | estRows | task     | access object | operator

```

```
    ↪ intkey) | keep order:false                                                    |
+--
    ↪ -------------------------+---------+-----------+-------------------------------
    ↪
4 rows in set (0.00 sec)
```

In the above examples, `IndexFullScan` is more efficient than `TableFullScan` because the width of the value in the `(intkey + RowID)` index is less than the width of the full row.

The following statement does not support using an `IndexFullScan` operator because additional columns are required from the table:

```
EXPLAIN SELECT AVG(intkey), ANY_VALUE(pad1) FROM t1;
```

11.3.2.4 Explain Statements That Use Joins

In TiDB, the SQL Optimizer needs to decide in which order tables should be joined and what is the most efficient join algorithm for a particular SQL statement. The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
   ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
   ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
SELECT SLEEP(1);
ANALYZE TABLE t1, t2;
```

11.3.2.4.1 Index Join

If the number of estimated rows that need to be joined is small (typically less than 10000 rows), it is preferable to use the index join method. This method of join works similar to the primary method of join used in MySQL. In the following example, the operator `TableReader_29(Build)` first reads the table `t1`. For each row that matches, TiDB will probe the table `t2`:

> **Note:**
>
> In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0. For more details, see TiDB Query Execution Plan Overview.

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.id =
    ↪ t2.t1_id;
```

```

   ↪
   ↪ |
+--
   ↪ ------------------------------+----------+-----------+-------------------------
   ↪
```

Index join is efficient in memory usage, but might be slower to execute than other join methods when a large number of probe operations are required. Consider also the following query:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id=t2.t1_id WHERE t1.pad1 = 'value'
   ↪ and t2.pad1='value';
```

In an inner join operation, TiDB implements join reordering and might access either `t1` or `t2` first. Assume that TiDB selects `t1` as the first table to apply the `build` step, and then TiDB is able to filter on the predicate `t1.pad1 = 'value'` before probing the table `t2`. The filter for the predicate `t2.pad1='value'` will be applied on each probe of table `t2`, which might be less efficient than other join methods.

Index join is effective if the build side is small and the probe side is pre-indexed and large. Consider the following query where an index join performs worse than a hash join and is not chosen by the SQL Optimizer:

```
-- DROP previously added index
ALTER TABLE t2 DROP INDEX t1_id;

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
```

```
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```

```

In the above example, the index join operation is missing an index on `t1.int_col`. Once this index is added, the performance of the operation improves from `0.3 sec` to `0.06 sec`, as the following result shows:

```
-- Re-add index
ALTER TABLE t2 ADD INDEX (t1_id);

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
```

```
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```

Note:

> In the above example, the SQL Optimizer selects the hash join plan which performs worse than the index join. Query optimization is an NP-complete problem, and less-than-optimal plans might be chosen. If this is a frequent query, it is recommended to use SQL Plan Management to bind a hint to a query, which can be easier to manage than inserting hints into queries that your application sends to TiDB.

Variations of Index Join

An index join operation using the hint `INL_JOIN` creates a hash table of the intermediate results before joining on the outer table. TiDB also supports creating a hash table on the outer table using the hint `INL_HASH_JOIN`. Each of these variations of index join is automatically selected by the SQL Optimizer.

Configuration

Index join performance is influenced by the following system variables:

- `tidb_index_join_batch_size` (default value: `25000`) - the batch size of `index lookup join` operations.
- `tidb_index_lookup_join_concurrency` (default value: `4`) - the number of concurrent index lookup tasks.

11.3.2.4.2 Hash Join

In a hash join operation, TiDB reads and caches the data on the `Build` side of the join in a hash table, and then reads the data on the `Probe` side of the join, probing the hash table to access required rows. Hash joins require more memory to execute than index joins but execute much faster when there are a lot of rows that need to be joined. The hash join operator is multi-threaded in TiDB and executes in parallel.

An example of hash join is as follows:

```
EXPLAIN SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```

For the execution process of `HashJoin_27`, TiDB performs the following operations in order:

1. Cache the data of the `Build` side in memory.
2. Construct a Hash Table on the `Build` side based on the cached data.
3. Read the data at the `Probe` side.
4. Use the data of the `Probe` side to probe the Hash Table.
5. Return qualified data to the user.

The `operator info` column in the `EXPLAIN` result table also records other information about `HashJoin_27`, including whether the query is Inner Join or Outer Join, and what are the conditions of Join. In the above example, the query is an Inner Join, where the Join condition `equal:[eq(test.t1.id, test.t2.id)]` partly corresponds with the query condition `WHERE t1.id = t2.id`. The operator info of the other Join operators in the following examples is similar to this one.

Runtime Statistics

If `tidb_mem_quota_query` (default value: 1 GB) is exceeded, and the `tidb_enable_tmp_storage_on_o` ↪ value is `ON` (default), TiDB will attempt to use temporary storage, and might create the `Build` operator (used as part of the hash join) on disk. Runtime statistics such as memory usage are recorded in the `execution info` of the `EXPLAIN ANALYZE` result table. The following example shows the output of `EXPLAIN ANALYZE` with a 1 GB (default) and a 500 MB quota for `tidb_mem_quota_query`. At 500 MB, disk is used for temporary storage:

```
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
   ↪ t2.id;
SET tidb_mem_quota_query=500 * 1024 * 1024;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
   ↪ t2.id;
```

Configuration

Hash join performance is influenced by the following system variables:

- `tidb_mem_quota_query` (default value: 1GB) - if the memory quota for a query is exceeded, TiDB will attempt to spill the `Build` operator of a hash join to disk to save memory.
- `tidb_hash_join_concurrency` (default value: `5`) - the number of concurrent hash join tasks.

11.3.2.4.3 Merge Join

Merge join is a special sort of join that applies when both sides of the join are read in sorted order. It can be described as similar to an *efficient zipper merge*: as data is read on both the `Build` and the `Probe` sides of the join, the join operation works like a streaming operation. Merge joins require far less memory than hash join but do not execute in parallel.

The following is an example:

```
EXPLAIN SELECT /*+ MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--

|    ─TableFullScan_9      | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ true                                      |
+--
   ↪ ---------------------------+----------+----------+---------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of the merge join operator, TiDB performs the following operations:

1. Read all the data of a Join Group from the `Build` side into the memory.
2. Read the data of the `Probe` side.

3. Compare whether each row of data on the `Probe` side matches a complete Join Group on the `Build` side. Apart from equivalent conditions, there are non-equivalent conditions. Here "match" mainly refers to checking whether non-equivalent conditions are met. Join Group refers to the data with the same value among all Join Keys.

11.3.2.5 Explain Statements in the MPP Mode

TiDB supports using the MPP mode to execute queries. In the MPP mode, the TiDB optimizer generates execution plans for MPP. Note that the MPP mode is only available for tables that have replicas on TiFlash.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id int, value int);
INSERT INTO t1 values(1,2),(2,3),(1,3);
ALTER TABLE t1 set tiflash replica 1;
ANALYZE TABLE t1;
SET tidb_allow_mpp = 1;
```

11.3.2.5.1 MPP query fragments and MPP tasks

In the MPP mode, a query is logically sliced into multiple query fragments. Take the following statement as an example:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

This query is divided into two fragments in the MPP mode. One for the first-stage aggregation and the other for the second-stage aggregation, also the final aggregation. When this query is executed, each query fragment is instantiated into one or more MPP tasks.

11.3.2.5.2 Exchange operators

`ExchangeReceiver` and `ExchangeSender`are two exchange operators specific for MPP execution plans. The `ExchangeReceiver` operator reads data from downstream query fragments and the `ExchangeSender` operator sends data from downstream query fragments to upstream query fragments. In the MPP mode, the root operator of each MPP query fragment is `ExchangeSender`, meaning that query fragments are delimited by the `ExchangeSender` operator.

The following is a simple MPP execution plan:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ---------------------------------+---------+------------------+--------------
   ↪

|    ─Projection_26               | 2.00    | batchCop[tiflash] |              |
   ↪ Column#4                                        |
|      ─HashAgg_27                | 2.00    | batchCop[tiflash] |              |
   ↪ group by:test.t1.id, funcs:sum(Column#7)->Column#4 |
|        ─ExchangeReceiver_29     | 2.00    | batchCop[tiflash] |              |
   ↪                                                 |
|          ─ExchangeSender_28     | 2.00    | batchCop[tiflash] |              |
   ↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
|            ─HashAgg_9           | 2.00    | batchCop[tiflash] |              |
   ↪ group by:test.t1.id, funcs:count(1)->Column#7 |
|              ─TableFullScan_25  | 3.00    | batchCop[tiflash] | table:t1     |
   ↪ keep order:false                                |
+--
   ↪ ---------------------------------+---------+------------------+--------------
   ↪
```

The above execution plan contains two query fragments:

- The first is `[TableFullScan_25, HashAgg_9, ExchangeSender_28]`, which is mainly responsible for the first-stage aggregation.
- The second is `[ExchangeReceiver_29, HashAgg_27, Projection_26, ExchangeSender_30 ↪ ]`, which is mainly responsible for the second-stage aggregation.

The `operator info` column of the `ExchangeSender` operator shows the exchange type information. Currently, there are three exchange types. See the following:

- HashPartition: The `ExchangeSender` operator firstly partitions data according to the Hash values and then distributes data to the `ExchangeReceiver` operator of upstream MPP tasks. This exchange type is often used for Hash Aggregation and Shuffle Hash Join algorithms.
- Broadcast: The `ExchangeSender` operator distributes data to upstream MPP tasks through broadcast. This exchange type is often used for Broadcast Join.
- PassThrough: The `ExchangeSender` operator sends data to the only upstream MPP task, which is different from the Broadcast type. This exchange type is often used when returning data to TiDB.

In the example execution plan, the exchange type of the operator `ExchangeSender_28` is HashPartition, meaning that it performs the Hash Aggregation algorithm. The exchange

type of the operator `ExchangeSender_30` is PassThrough, meaning that it is used to return data to TiDB.

MPP is also often applied to join operations. The MPP mode in TiDB supports the following two join algorithms:

- Shuffle Hash Join: Shuffle the data input from the join operation using the HashPartition exchange type. Then, upstream MPP tasks join data within the same partition.
- Broadcast Join: Broadcast data of the small table in the join operation to each node, after which each node joins the data separately.

The following is a typical execution plan for Shuffle Hash Join:

```
SET tidb_broadcast_join_threshold_count=0;
SET tidb_broadcast_join_threshold_size=0;
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

   ↪                                              |
|          ─ExchangeSender_22       | 6.00    | cop[tiflash] |              |
   ↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
```

```
|           └─Selection_21            | 6.00   | cop[tiflash] |           |
   ↪ not(isnull(test.t1.id))                    |
|             └─TableFullScan_20      | 6.00   | cop[tiflash] | table:b   |
   ↪ keep order:false                           |
+--
   ↪ ------------------------------------+--------+--------------+---------------+
   ↪
12 rows in set (0.00 sec)
```

In the above execution plan:

- The query fragment `[TableFullScan_20, Selection_21, ExchangeSender_22]` reads data from table b and shuffles data to upstream MPP tasks.
- The query fragment `[TableFullScan_16, Selection_17, ExchangeSender_18]` reads data from table a and shuffles data to upstream MPP tasks.
- The query fragment `[ExchangeReceiver_19, ExchangeReceiver_23, HashJoin_44 ↪ , ExchangeSender_47]` joins all data and returns it to TiDB.

A typical execution plan for Broadcast Join is as follows:

```
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

|      └─HashJoin_43                  | 9.00   | cop[tiflash] |               |
   ↪ inner join, equal:[eq(test.t1.id, test.t1.id)] |
|        └─ExchangeReceiver_20(Build) | 6.00   | cop[tiflash] |               |
   ↪                                           |
|          └─ExchangeSender_19        | 6.00   | cop[tiflash] |               |
   ↪ ExchangeType: Broadcast                   |
|            └─Selection_18           | 6.00   | cop[tiflash] |               |
   ↪ not(isnull(test.t1.id))                   |
```

```
|            └─TableFullScan_17      | 6.00   | cop[tiflash] | table:a   |
   ↪ keep order:false                              |
|       └─Selection_22(Probe)        | 6.00   | cop[tiflash] |           |
   ↪ not(isnull(test.t1.id))                       |
|         └─TableFullScan_21         | 6.00   | cop[tiflash] | table:b   |
   ↪ keep order:false                              |
+--
   ↪ ------------------------------------+--------+-------------+---------------+
   ↪
```

In the above execution plan:

- The query fragment `[TableFullScan_17, Selection_18, ExchangeSender_19]` reads data from the small table (table a) and broadcasts the data to each node that contains data from the large table (table b).
- The query fragment `[TableFullScan_21, Selection_22, ExchangeReceiver_20, ↪ HashJoin_43, ExchangeSender_46]` joins all data and returns it to TiDB.

11.3.2.5.3 `EXPLAIN ANALYZE` statements in the MPP mode

The `EXPLAIN ANALYZE` statement is similar to `EXPLAIN`, but it also outputs some runtime information.

The following is the output of a simple `EXPLAIN ANALYZE` example:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ---------------------------------+---------+---------+------------------+-----
   ↪
| id                              | estRows | actRows | task         | access
   ↪  object | execution info
   ↪                                                                          |
   ↪  operator info                                          | memory |

    ↪ tiflash_scan:{dtfile:{total_scanned_packs:1,...}} | keep order:false
    ↪                            | N/A    | N/A |
+--
    ↪ ---------------------------------+---------+---------+-------------------+-----
    ↪
```

Compared to the output of `EXPLAIN`, the `operator info` column of the operator `ExchangeSender` also shows `tasks`, which records the id of the MPP task that the query fragment instantiates into. In addition, each MPP operator has a `threads` field in the `execution info` column, which records the concurrency of operations when TiDB executes this operator. If the cluster consists of multiple nodes, this concurrency is the result of adding up the concurrency of all nodes.

11.3.2.5.4 MPP version and exchange data compression

Starting from v6.6.0, the new fields `MPPVersion` and `Compression` are added to the MPP execution plan.

- `MppVersion`: The version number of the MPP execution plan, which can be set through the system variable `mpp_version`.
- `Compression`: The data compression mode of the `Exchange` operator, which can be set through the system variable `mpp_exchange_compression_mode`. If data compression

is not enabled, this field is not displayed in the execution plan.

See the following example:

```
mysql > EXPLAIN SELECT COUNT(*) AS count_order FROM lineitem GROUP BY
    ↪ l_returnflag, l_linestatus ORDER BY l_returnflag, l_linestatus;

+--

   ↪
   ↪ |
+--
   ↪ ------------------------------------+--------------+--------------+-----------
   ↪
```

In the preceding execution plan result, TiDB uses an MPP execution plan of version 1 to build `TableReader`. The `ExchangeSender` operator of the `HashPartition` type uses the `FAST` data compression mode. Data compression is not enabled for the `ExchangeSender` operator of the `PassThrough` type.

11.3.2.6 Explain Statements That Use Subqueries

TiDB performs several optimizations to improve the performance of subqueries. This document describes some of these optimizations for common subqueries and how to interpret the output of `EXPLAIN`.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
   ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
   ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
CREATE TABLE t3 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 t1_id INT NOT NULL,
 UNIQUE (t1_id)
);
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
INSERT INTO t3 SELECT NULL, id FROM t1 WHERE id < 1000;

SELECT SLEEP(1);
```

```
ANALYZE TABLE t1, t2, t3;
```

11.3.2.6.1 Inner join (non-unique subquery)

In the following example, the `IN` subquery searches for a list of IDs from the table `t2` ↪ . For semantic correctness, TiDB needs to guarantee that the column `t1_id` is unique. Using `EXPLAIN`, you can see the execution plan used to remove duplicates and perform an `INNER JOIN` operation:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2);
```

```
+--
   ↪ ------------------------------+---------+-----------+-----------------------
   ↪

   ↪
   ↪ |
|  ─TableReader_12(Probe)       | 21.11   | root      |
   ↪                               | data:TableRangeScan_11
   ↪
   ↪ |
```

```
|   └─TableRangeScan_11       | 21.11   | cop[tikv] | table:t1
   ↪                 | range: decided by [test.t2.t1_id], keep order:false
   ↪                                                              |
+--
   ↪ ------------------------------+---------+-----------+-----------------------
   ↪
```

From the query results above, you can see that TiDB uses the index join operation `IndexJoin_15` to join and transform the subquery. In the execution plan, the execution process is as follows:

1. The index scanning operator `└─IndexFullScan_26` at the TiKV side reads the values of the `t2.t1_id` column.
2. Some tasks of the `└─StreamAgg_34` operator deduplicate the values of `t1_id` in TiKV.
3. Some tasks of the `└─StreamAgg_44(Build)` operator deduplicate the values of `t1_id` in TiDB. The deduplication is performed by the aggregate function `firstrow(test.` ↪ `t2.t1_id)`.
4. The operation results are joined with the primary key of the `t1` table. The join condition is `eq(test.t1.id, test.t2.t1_id)`.

11.3.2.6.2 Inner join (unique subquery)

In the previous example, aggregation is required to ensure that the values of `t1_id` are unique before joining against the table `t1`. But in the following example, `t3.t1_id` is already guaranteed unique because of a `UNIQUE` constraint:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t3);
```

```

+--
   ↪ --------------------------+---------+-----------+--------------------------
   ↪
```

Semantically because `t3.t1_id` is guaranteed unique, it can be executed directly as an `INNER JOIN`.

11.3.2.6.3 Semi join (correlated subquery)

In the previous two examples, TiDB is able to perform an `INNER JOIN` operation after the data inside the subquery is made unique (via `StreamAgg`) or guaranteed unique. Both joins are performed using an Index Join.

In this example, TiDB chooses a different execution plan:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2 WHERE t1_id !=
   ↪ t1.int_col);
```

```

    ↪                                                                |
|     └─TableFullScan_20    | 71010.00 | cop[tikv] | table:t1             |
    ↪  keep order:true
    ↪
    ↪ |
+--
    ↪ --------------------------+----------+-----------+-------------------------
    ↪
```

From the result above, you can see that TiDB uses a `Semi Join` algorithm. Semi-join differs from inner join: semi-join only permits the first value on the right key (`t2.t1_id`), which means that the duplicates are eliminated as a part of the join operator task. The join algorithm is also Merge Join, which is like an efficient zipper-merge as the operator reads data from both the left and the right side in sorted order.

The original statement is considered a *correlated subquery*, because the subquery refers to a column (`t1.int_col`) that exists outside of the subquery. However, the output of `EXPLAIN` shows the execution plan after the subquery decorrelation optimization has been applied. The condition `t1_id != t1.int_col` is rewritten to `t1.id != t1.int_col`. TiDB can perform this in `└─Selection_21` as it is reading data from the table `t1`, so this decorrelation and rewriting make the execution a lot more efficient.

11.3.2.6.4 Anti semi join (`NOT IN` subquery)

In the following example, the query semantically returns all rows from the table `t3` *unless* `t3.t1_id` is in the subquery:

```
EXPLAIN SELECT * FROM t3 WHERE t1_id NOT IN (SELECT id FROM t1 WHERE
    ↪ int_col < 100);
```

```

+--
   ↪ -------------------------+---------+-----------+---------------+-------------
   ↪
```

This query starts by reading the table `t3` and then probes the table `t1` based on the `PRIMARY KEY`. The join type is an *anti semi join*; anti because this example is for the non-existence of the value (`NOT IN`) and semi-join because only the first row needs to match before the join is rejected.

11.3.2.6.5 Null-aware semi join (`IN` and `= ANY` subqueries)

The value of the `IN` or `= ANY` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `IN` and `= ANY` operators are converted to semi join and left outer semi join respectively. In the preceding example of Semi join, since columns `test.t1.id` ↪ and `test.t2.t1_id` on both sides of the join key are `not NULL`, the semi join does not need to be considered as null-aware (`NULL` is not processed specially). TiDB processes the null-aware semi join based on the Cartesian product and filter without special optimization. The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a,b) IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a,b) IN (SELECT * FROM s);
```

    ↪ ---------------------------+---------+-----------+---------------+------------
    ↪
8 rows in set (0.01 sec)
```

In the first query statement `EXPLAIN SELECT (a,b)IN (SELECT * FROM s)FROM t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by the `IN` subquery is null-aware. Specifically, the Cartesian product is calculated first, then the column connected by `IN` or `= ANY` is put into other conditions as a normal equality query for filtering.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a,b)IN (SELECT * ↪ FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the `IN` subquery should have been converted to a null-aware semi join. But TiDB optimizes it by converting semi join to inner join and aggregate. This is because `NULL` and `false` are equivalent in `IN` subqueries for non-scalar output. The `NULL` rows in the push-down filter results in the negative semantics of the `WHERE` clause. Therefore, these rows can be ignored beforehand.

Note:

The `Exists` operator is also converted to semi join, but it is not null-aware.

11.3.2.6.6 Null-aware anti semi join (`NOT IN` and `!= ALL` subqueries)

The value of the `NOT IN` or `!= ALL` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `NOT IN` and `! = ALL` operators are converted to anti semi join and anti left outer semi join respectively. In the preceding example of Anti semi join, since columns `test.t3.t1_id` and `test.t1.id` on both sides of the join key are `not NULL`, the anti semi join does not need to be considered as null-aware (`NULL` is not processed specially).

TiDB v6.3.0 optimizes null-aware anti join (NAAJ) as follows:

- Build hash join using the null-aware equality condition (NA-EQ)

  Set operators introduce the equality condition, which requires a special process for the `NULL` value of operators on both sides of the condition. The equality condition that requires null-aware is called NA-EQ. Different from earlier versions, TiDB v6.3.0 no longer processes NA-EQ as before, but places it in other conditions after join, and then determines the legitimacy of the result set after matching the Cartesian product.

  Since TiDB v6.3.0, NA-EQ, a weakened equality condition, is still used to build hash join. This reduces the matching amount of data that needs to be traversed and speeds up the matching process. The acceleration is more significant when the percentage of total `DISTINCT()` values of the build table is almost 100%.

- Speed up the return of matching results using the special property of `NULL`

  Since anti semi join is a conjunctive normal form (CNF), a `NULL` on either side of the join leads to a definite result. This property can be used to speed up the return of the entire matching process.

The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a, b) NOT IN (SELECT * FROM s);
```

```
tidb> EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;

    ↪
5 rows in set (0.00 sec)
```

In the first query statement `EXPLAIN SELECT (a, b)NOT IN (SELECT * FROM s)FROM ↪ t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a, b)NOT IN ( ↪ SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the anti semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

Currently, TiDB can only be null-aware of anti semi join and anti left outer semi join. Only the hash join type is supported and its build table should be fixed to the right table.

> **Note:**
>
> The `Not Exists` operator is also converted to the anti semi join, but it is not null-aware.

11.3.2.6.7 Explain statements using other types of subqueries

- Explain Statements in the MPP Mode
- Explain Statements That Use Indexes

- Explain Statements That Use Aggregation
- Explain Statements Using Views
- Explain Statements Using Partitions
- Explain Statements Using Index Merge

11.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB);
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
SELECT SLEEP(1);
ANALYZE TABLE t1;
```

From the output of `SHOW TABLE REGIONS`, you can see that this table is split into multiple Regions:

```
SHOW TABLE t1 REGIONS;
```

```
+--
    ↪ ---------+--------------+--------------+-----------+-----------------+-------+--
    ↪
| REGION_ID | START_KEY | END_KEY    | LEADER_ID | LEADER_STORE_ID | PEERS |
    ↪  SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB) |
```

```
    ↪ APPROXIMATE_KEYS |
+--
    ↪ --------+-------------+-------------+----------+-----------------+-------+--
    ↪
|       64 | t_64_       | t_64_r_31766 |     65 |              1 | 65    |
    ↪         0 |         1325 | 102033520 |                98 |
    ↪ 52797 |
|       66 | t_64_r_31766 | t_64_r_63531 |   67 |              1 | 67    |
    ↪         0 |         1325 |  72522521 |               104 |
    ↪ 78495 |
|       68 | t_64_r_63531 | t_64_r_95296 |   69 |              1 | 69    |
    ↪         0 |         1325 |         0 |               104 |
    ↪ 95433 |
|        2 | t_64_r_95296 |          |        3 |              1 | 3     |
    ↪         0 |         1501 |         0 |                81 |
    ↪ 63211 |
+--
    ↪ --------+-------------+-------------+----------+-----------------+-------+--
    ↪
4 rows in set (0.00 sec)
```

Using `EXPLAIN` with the following aggregation statement, you can see that `StreamAgg_8` is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in `StreamAgg_16`:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
| id                         | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
| StreamAgg_16               | 1.00     | root     |               | funcs:count(
    ↪ Column#7)->Column#5 |
| └─TableReader_17           | 1.00     | root     |               | data:
    ↪ StreamAgg_8              |
|   └─StreamAgg_8            | 1.00     | cop[tikv] |              | funcs:count
    ↪ (1)->Column#7    |
|     └─TableFullScan_15     | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
```

```
    ↪ ------------------------+----------+----------+--------------+-----------
    ↪
4 rows in set (0.00 sec)
```

This is easiest to observe in `EXPLAIN ANALYZE`, where the `actRows` matches the number of Regions from `SHOW TABLE REGIONS` because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ ------------------------+----------+---------+----------+---------------+---
    ↪
| id                        | estRows  | actRows | task     | access object |
    ↪ execution info
    ↪
    ↪ | operator info               | memory   | disk |
+--
    ↪ ------------------------+----------+---------+----------+---------------+---
    ↪

    ↪
4 rows in set (0.01 sec)
```

11.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the `HashAgg` operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```
+--
   ↪ ------------------------+----------+----------+--------------+-------------
   ↪
| id                        | estRows  | task     | access object | operator
   ↪ info             |
+--
   ↪ ------------------------+----------+----------+--------------+-------------
   ↪
| HashAgg_9                 | 1.00     | root     |               | funcs:count(
   ↪ Column#6)->Column#5 |
| ─TableReader_10           | 1.00     | root     |               | data:
   ↪ HashAgg_5               |
|   ─HashAgg_5              | 1.00     | cop[tikv] |              | funcs:count
   ↪ (1)->Column#6    |
|     ─TableFullScan_8      | 242020.00 | cop[tikv] | table:t1 | keep order:
   ↪ false            |
+--
   ↪ ------------------------+----------+----------+--------------+-------------
   ↪
4 rows in set (0.00 sec)
```

The `operator info` shows that the hashing function used to aggregate the data is `funcs
↪ :count(1)->Column#6`.

11.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```
CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 5 rows affected (0.01 sec)
```

```
Records: 5 Duplicates: 0 Warnings: 0

+--
    ↪ ---------------------------+---------+----------+--------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪ |
+--
    ↪ ---------------------------+---------+----------+--------------+-----------
    ↪
| Projection_4                | 8000.00 | root     |               | test.t2.col1
    ↪ , Column#3                                                                 |
|  ─StreamAgg_8               | 8000.00 | root     |               | group by:
    ↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
    ↪ ->test.t2.col1 |
|    ─Sort_13                 | 10000.00 | root    |               | test.t2.
    ↪ col1
    ↪                                                                          |
|      ─TableReader_12        | 10000.00 | root    |               | data:
    ↪ TableFullScan_11
    ↪                                                                  |
|        ─TableFullScan_11    | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo
    ↪ |
+--
    ↪ ---------------------------+---------+----------+--------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In this example, the `─Sort_13` operator can be eliminated by adding an index on `col1` ↪ . Once the index is added, the data can be read in order and the `─Sort_13` operator is eliminated:

```
ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.28 sec)

+--

    ↪ ) | keep order:true, stats:pseudo
    ↪                                                    |
+--
    ↪ ---------------------------+---------+----------+-------------------------+
    ↪
5 rows in set (0.00 sec)
```

11.3.2.8 EXPLAIN Statements Using Views

`EXPLAIN` displays the tables and indexes that a view references, not the name of the view itself. This is because views are only virtual tables and do not store any data themselves. The definition of the view and the rest of the statement are merged together during SQL optimization.

From the bikeshare example database, you can see that the following two queries are executed in a similar manner:

```
ALTER TABLE trips ADD INDEX (duration);
CREATE OR REPLACE VIEW long_trips AS SELECT * FROM trips WHERE duration >
    ↪ 3600;
EXPLAIN SELECT * FROM long_trips;
EXPLAIN SELECT * FROM trips WHERE duration > 3600;
```

```
Query OK, 0 rows affected (2 min 10.11 sec)

Query OK, 0 rows affected (0.13 sec)

+--
    ↪ ---------------------------+----------+----------+-----------------------
```

```
    ↪
| id                          | estRows   | task     | access object
    ↪                      | operator info                    |
+--
    ↪ ----------------------------+-----------+----------+----------------------
    ↪
| IndexLookUp_12              | 6372547.67 | root    |
    ↪                                    |                                  |
|  ─IndexRangeScan_10(Build)  | 6372547.67 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_11(Probe)  | 6372547.67 | cop[tikv] | table:trips
    ↪                     | keep order:false                 |
+--
    ↪ ----------------------------+-----------+----------+----------------------
    ↪
3 rows in set (0.00 sec)

+--
    ↪ ----------------------------+----------+----------+----------------------
    ↪
| id                          | estRows  | task     | access object
    ↪                      | operator info                    |
+--
    ↪ ----------------------------+----------+----------+----------------------
    ↪
| IndexLookUp_10              | 833219.37 | root    |
    ↪                                   |                                  |
|  ─IndexRangeScan_8(Build)  | 833219.37 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 833219.37 | cop[tikv] | table:trips
    ↪                     | keep order:false                 |
+--
    ↪ ----------------------------+-----------+----------+----------------------
    ↪
3 rows in set (0.00 sec)
```

Similarly, predicates from the view are pushed down to the base table:

```
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
+--
    ↪ ----------------------------+---------+----------+----------------------
    ↪
| id                          | estRows | task    | access object
```

```
    ↪                      | operator info                                  |
+--
    ↪ ------------------------------+---------+-----------+-------------------------
    ↪
| IndexLookUp_14              | 3.33    | root      |
    ↪                                 |
    ↪                                                |
|  ─IndexRangeScan_11(Build) | 3333.33 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false, stats:
    ↪ pseudo |
|  ─Selection_13(Probe)       | 3.33    | cop[tikv] |
    ↪                                   | eq(bikeshare.trips.bike_number, "
    ↪ W00950")   |
|    ─TableRowIDScan_12       | 3333.33 | cop[tikv] | table:trips
    ↪                     | keep order:false, stats:pseudo              |
+--
    ↪ ------------------------------+---------+-----------+-------------------------
    ↪
4 rows in set (0.00 sec)

+--
    ↪ ----------------------+------------+-----------+--------------+-------------
    ↪
| id                    | estRows    | task      | access object | operator
    ↪ info                          |
+--
    ↪ ----------------------+------------+-----------+--------------+-------------
    ↪
| TableReader_7         | 43.00      | root      |               | data:
    ↪ Selection_6                     |
|  ─Selection_6         | 43.00      | cop[tikv] |               | eq(bikeshare.
    ↪ trips.bike_number, "W00950") |
|    ─TableFullScan_5   | 19117643.00 | cop[tikv] | table:trips | keep order
    ↪ :false                  |
+--
    ↪ ----------------------+------------+-----------+--------------+-------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself.

Consider the following composite index:

```
ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
Query OK, 0 rows affected (2 min 31.20 sec)

+--

| IndexLookUp_10              | 19117.64 | root    |
   ↪                                                 |
   ↪                                               |
|  ─IndexRangeScan_8(Build)  | 19117.64 | cop[tikv] | table:trips, index:
   ↪ bike_number(bike_number, duration) | range:["W00950","W00950"], keep
```

```
    ↪ order:false |
|  └─TableRowIDScan_9(Probe)  | 19117.64 | cop[tikv] | table:trips
    ↪                                     | keep order:false
    ↪                         |
+--
    ↪ ----------------------------+----------+-----------+-------------------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement, TiDB is able to use both parts of the composite index (`bike_number, duration`). In the second statement, only the first part which is `bike_number` of the index (`bike_number, duration`) is used.

11.3.2.9 Explain Statements Using Partitions

The `EXPLAIN` statement displays the partitions that TiDB needs to access in order to execute a query. Because of partition pruning, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of `EXPLAIN`.

The sample data used in this document:

```
CREATE TABLE t1 (
 id BIGINT NOT NULL auto_increment,
 d date NOT NULL,
 pad1 BLOB,
 pad2 BLOB,
 pad3 BLOB,
 PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
 PARTITION p2016 VALUES LESS THAN (2017),
 PARTITION p2017 VALUES LESS THAN (2018),
 PARTITION p2018 VALUES LESS THAN (2019),
 PARTITION p2019 VALUES LESS THAN (2020),
 PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES
 ('2016-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
```

```
 ('2018-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024));

INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

SELECT SLEEP(1);
ANALYZE TABLE t1;
```

The following example shows a statement against the newly created partitioned table:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE d = '2017-06-01';
```

```

+--
    ↪ ---------------------------+---------+----------+-------------------------+-
    ↪
```

```
5 rows in set (0.01 sec)
```

Starting from the inner-most (`└─TableFullScan_19`) operator and working back towards the root operator (`StreamAgg_21`):

- TiDB successfully identified that only one partition (`p2017`) needed to be accessed. This is noted under `access object`.
- The partition itself was scanned in the operator `└─TableFullScan_19` and then `└─Selection_20` was applied to filter for rows that have a start date of `2017-06-01 00:00:00.000000`.
- The rows that match `└─Selection_20` are then stream aggregated in the coprocessor, which natively understands the `count` function.
- Each coprocessor request then sends back one row to `└─TableReader_22` inside TiDB, which is then stream aggregated under `StreamAgg_21` and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

27 rows in set (0.00 sec)
```

From the output above:

- TiDB believes that it needs to access all of the partitions `(p2016..pMax)`. This is because the predicate `YEAR(d)= 2017` is considered non-sargable. This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.
- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `—PartitionUnion_21` unions the results from accessing each partition.

11.3.2.10 Explain Statements Using Index Merge

Index merge is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

Index merge in TiDB has two types: the intersection type and the union type. The former applies to the `AND` expression, while the latter applies to the `OR` expression. The union-type index merge is introduced in TiDB v4.0 as an experimental feature and has become GA in v5.4.0. The intersection type is introduced in TiDB v6.5.0, and can be used only when the `USE_INDEX_MERGE` hint is specified.

11.3.2.10.1 Enable index merge

In v5.4.0 or a later TiDB version, index merge is enabled by default. In other situations, if index merge is not enabled, you need to set the variable `tidb_enable_index_merge` to `ON` to enable this feature.

```
SET session tidb_enable_index_merge = ON;
```

11.3.2.10.2 Examples

```
CREATE TABLE t(a int, b int, c int, d int, INDEX idx_a(a), INDEX idx_b(b),
    ↪ INDEX idx_c(c), INDEX idx_d(d));
```

```
EXPLAIN SELECT /*+ NO_INDEX_MERGE() */ * FROM t WHERE a = 1 OR b = 1;

+--
    ↪ ---------------------------+---------+----------+----------------------+--
    ↪
```

In the preceding query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without index merge, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, index merge is introduced in TiDB to access tables.

For the preceding query, the optimizer chooses the union-type index merge to access the table. Index merge allows the optimizer to use multiple indexes per table, to merge the results returned by each index, and to generate the latter execution plan in the preceding output.

In the output, the `type: union` information in `operator info` of the `IndexMerge_8` ↪ operator indicates that this operator is a union-type index merge. It has three child nodes. `IndexRangeScan_5` and `IndexRangeScan_6` scan the `RowID`s that meet the condition according to the range, and then the `TableRowIDScan_7` operator accurately reads all the data that meets the condition according to these `RowID`s.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan`/`TableRangeScan`, the `operator info` column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan` /`TableFullScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_5` operator indicates that the operator scans the data from 1 to positive infinity.

```

   ↪
```

From the preceding example, you can see that the filter condition is a `WHERE` clause that uses `AND` as the connector. Before index merge is enabled, the optimizer can only choose one of the three indexes (`idx_a`, `idx_b`, or `idx_c`).

If one of the filter conditions has a low selectivity, the optimizer directly chooses the corresponding index to achieve the ideal execution efficiency. However, if the data distribution meets all of the following three conditions, you can consider using the intersection-type index merge:

- The data size of the whole table is large, and directly reading the whole table is inefficient.
- For each one of the three filter conditions, the respective selectivity is very high, so the execution efficiency of `IndexLookUp` using a single index is not ideal.
- The overall selectivity of the three filter conditions is low.

When using the intersection-type index merge to access tables, the optimizer can choose to use multiple indexes on a table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the preceding example output. The `type: intersection` information in the `operator info` of the `IndexMerge_9` operator indicates that this operator is an intersection-type index merge. The other parts of the execution plan are similar to the preceding union-type index merge example.

Note:

- The Index Merge feature is enabled by default from v5.4.0. That is, `tidb_enable_index_merge` is `ON`.
- You can use the SQL hint `USE_INDEX_MERGE` to force the optimizer to apply Index Merge, regardless of the setting of `tidb_enable_index_merge` ↪ . To enable Index Merge when the filtering conditions contain expressions that cannot be pushed down, you must use the SQL hint `USE_INDEX_MERGE`.
- If the optimizer can choose the single index scan method (other than full table scan) for a query plan, the optimizer will not automatically use index merge. For the optimizer to use index merge, you need to use the optimizer hint.

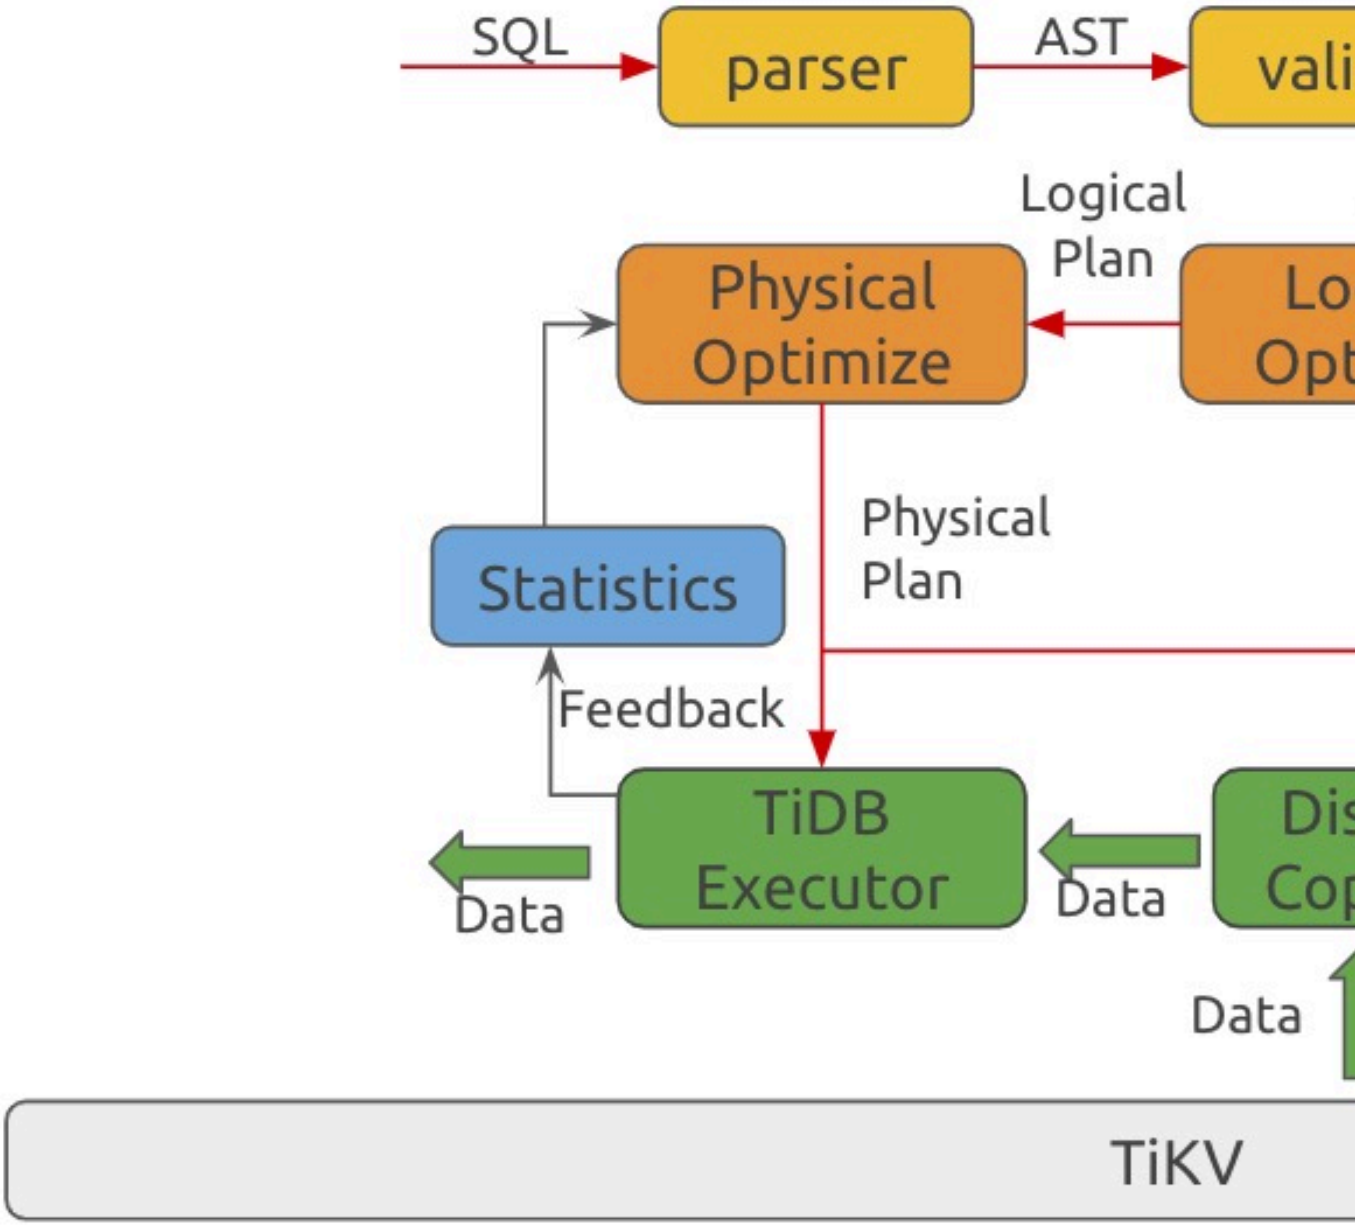

Figure 378: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see SQL Logical Optimization.

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see SQL Physical Optimization.

At the same time, when TiDB executes the `PREPARE` statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see Execution Plan Cache.

11.3.3.2 Logic Optimization

11.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the `IN` sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- Subquery Related Optimizations
- Column Pruning
- Decorrelation of Correlated Subquery
- Eliminate Max/Min
- Predicates Push Down
- Partition Pruning
- TopN and Limit Operator Push Down
- Join Reorder
- Derive TopN or Limit from Window Functions

11.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`
- `IN (SELECT ... FROM ..)`
- `EXISTS (SELECT ... FROM ...)`
- `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

Sometimes a subquery contains non-subquery columns, such as `select * from t where t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of subquery is usually called a "correlated subquery", and the externally introduced column is called a "correlated column". For optimizations about correlated subquery, see Decorrelation of correlated subquery. This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in Understanding TiDB Execution Plan as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

`... < ALL (SELECT ... FROM ...)` or `... > ANY (SELECT ... FROM ...)`

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is NULL. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id)and if(sum(s.id is null)!= 0, null, true)`
- `t.id < any (select s.id from s)` is rewritten as `t.id < max(s.id)or if(sum(s.id is null)!= 0, null, false)`

`... != ANY (SELECT ... FROM ...)`

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s)where (t.id != s.id or cnt_distinct > 1)`

`... = ALL (SELECT ... FROM ...)`

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s )where (t.id = s.id and cnt_distinct <= 1)`

`... IN (SELECT ... FROM ...)`

In this case, the subquery of `IN` is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of `JOIN`.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2.The form of a`. The `DISTINCT` attribute here can be eliminated automatically if `t2.a` has the `UNIQUE` attribute.

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```

   ↪ ---------------------------+---------+----------+----------------------+----
   ↪
```

This rewrite gets better performance when the `IN` subquery is relatively small and the external query is relatively large, because without rewriting, using `index join` with t2 as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the `t2` table is relatively large, this rewrite affects the performance of the query. Currently, the variable tidb_opt_insubq_to_join_and_agg is used to control this optimization. When this optimization is not suitable, you can manually disable it.

`EXISTS` subquery and `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the `EXISTS` subquery is evaluated to `TRUE` in the optimization stage in advance, so it does not show in the final execution result.

```
create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);
```

```

   ↪ --------------------+---------+----------+--------------+-----------------
   ↪
```

In the preceding optimization, the optimizer automatically optimizes the statement execution. In addition, you can also add the SEMI_JOIN_REWRITE hint to further rewrite the statement.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

11.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b> 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the `Selection` operator uses column b. Then the `DataSource` operator uses columns a and column b. Columns c and column d can be pruned because the `DataSource` operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called "Column Pruning", corresponding to the `columnPruner` rule. If you want to disable this rule, refer to The Blocklist of Optimization Rules and Expression Pushdown.

11.3.3.2.4 Decorrelation of Correlated Subquery

Subquery related optimizations describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

Introduction

Take `select * from t1 where t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition `t2.b=t1.b`, this condition happens to be an equivalent condition, so the query can be rewritten as `select t1.* from t1, (select b, sum(a)sum_a from t2 group by b)t2 where t1.b = t2.b and t1.a < t2.sum_a;`. In this way, a correlated subquery is rewritten into `JOIN`.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, which might bring better execution performance. In this case, you can disable this optimization by using the `NO_DECORRELATE` optimizer hint or by disabling the "subquery decorrelation" optimization rule in the blocklist of optimization rules and expression pushdown. In most cases, it is recommended to use the optimizer hint along with SQL Plan Management to disable the decorrelation.

Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

|        ─Selection_22         | 9990.00 | cop[tikv] |             | not(
   ↪ isnull(test.t2.b))
   ↪                                                        |
|          ─TableFullScan_21   | 10000.00 | cop[tikv] | table:t2 | keep
   ↪ order:false, stats:pseudo
   ↪                                                    |
|  ─TableReader_15(Probe)      | 9990.00 | root     |              | data:
   ↪ Selection_14
   ↪                                                               |
|    ─Selection_14             | 9990.00 | cop[tikv] |             | not(
   ↪ isnull(test.t1.b))
   ↪                                                        |
|      ─TableFullScan_13       | 10000.00 | cop[tikv] | table:t1 | keep
   ↪ order:false, stats:pseudo
   ↪                                                    |
+--
   ↪ ------------------------------+---------+----------+--------------+--------
   ↪
```

The above is an example where the optimization takes effect. `HashJoin_11` is a normal `inner join`.

Then, you can use the `NO_DECORRELATE` optimizer hint to tell the optimizer not to perform decorrelation for the subquery:

```
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);
```

```

|      ─StreamAgg_20                    | 10000.00 | root     |
    ↪                       | funcs:sum(Column#14)->Column#7
    ↪                                                |
|        ─Projection_45                 | 100000.00 | root    |
    ↪                       | cast(test.t2.a, decimal(10,0) BINARY)->Column
    ↪ #14                             |
|          ─IndexLookUp_44              | 100000.00 | root    |
    ↪                       |
    ↪
    ↪ |
```

```
|           └─IndexRangeScan_42(Build)  | 100000.00 | cop[tikv] | table:t2,
    ↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
    ↪ order:false, stats:pseudo |
|           └─TableRowIDScan_43(Probe)  | 100000.00 | cop[tikv] | table:t2
    ↪          | keep order:false, stats:pseudo
    ↪                                                |
+--
    ↪ ----------------------------------------+----------+----------+--------------
    ↪
```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(` ↪ `test.t2.b, test.t1.b)]` in `operator info` of `IndexRangeScan_42(Build)`. It means that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

11.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max/min` functions, the query optimizer tries to convert the `max/min` aggregate functions to the TopN operator by applying the `max/min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max/min` functions in the `select` statement:

- The statement with only one `max/min` function
- The statement with multiple `max/min` functions

One `max/min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
    ↪ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+--
    ↪ ---------------------------+---------+----------+-----------------------+---
    ↪
| id                        | estRows | task    | access object         |
    ↪ operator info                    |
+--
    ↪ ---------------------------+---------+----------+-----------------------+---
    ↪
| StreamAgg_13              | 1.00    | root     |                       |
    ↪ funcs:max(test.t.a)->Column#4   |
|  ─Limit_17                 | 1.00    | root     |                        |
    ↪ offset:0, count:1                |
|    ─IndexReader_27         | 1.00    | root     |                        |
    ↪ index:Limit_26                   |
|      ─Limit_26             | 1.00    | cop[tikv] |                       |
    ↪ offset:0, count:1                |
|        ─IndexFullScan_25   | 1.00    | cop[tikv] | table:t, index:idx_a(a) |
    ↪  keep order:true, desc, stats:pseudo |
+--
    ↪ ---------------------------+---------+----------+-----------------------+---
    ↪
5 rows in set (0.00 sec)
```

Multiple `max`/`min` functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max`/`min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
    (select max(a) as max_a from t) t1,
    (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max /min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
    (select max(a) as max_a from (select a from t where a is not null order
        ↪  by a desc limit 1) t) t1,
    (select min(a) as min_a from (select a from t where a is not null order
        ↪  by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+--
    ↪ ----------------------------------+---------+----------+-----------------------
    ↪
| id                                | estRows | task     | access object         |
    ↪  operator info                      |
+--
    ↪ ----------------------------------+---------+----------+-----------------------
    ↪
| Projection_17                     | 1.00    | root     |                       |
    ↪  minus(Column#4, Column#5)->Column#6 |
|  ─HashJoin_18                     | 1.00    | root     |
    ↪ | CARTESIAN inner join              |
|    ─StreamAgg_45(Build)           | 1.00    | root     |
    ↪ | funcs:min(test.t.a)->Column#5   |
|      ─Limit_49                    | 1.00    | root     |
    ↪ | offset:0, count:1                 |
|        ─IndexReader_59            | 1.00    | root     |
    ↪ | index:Limit_58                    |
|          ─Limit_58                | 1.00    | cop[tikv] |
    ↪ | offset:0, count:1                 |
|            ─IndexFullScan_57      | 1.00    | cop[tikv] | table:t, index:

|    ─StreamAgg_24(Probe)           | 1.00    | root     |
    ↪ | funcs:max(test.t.a)->Column#4   |
|      ─Limit_28                    | 1.00    | root     |
    ↪ | offset:0, count:1                 |
```

```
|       └─IndexReader_38          | 1.00   | root     |
   ↪ | index:Limit_37                  |
|         └─Limit_37              | 1.00   | cop[tikv] |
   ↪ | offset:0, count:1               |
|           └─IndexFullScan_36    | 1.00   | cop[tikv] | table:t, index:
   ↪ idx_a(a) | keep order:true, desc, stats:pseudo |
+--
   ↪ ---------------------------------+---------+----------+-------------------
   ↪
12 rows in set (0.01 sec)
```

11.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```
create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
   ↪ ----------------------+----------+-----------+--------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪           |
+--
   ↪ ----------------------+----------+-----------+--------------+----------------
   ↪
| TableReader_7         | 3323.33 | root    |               | data:Selection_6
   ↪           |
| └─Selection_6         | 3323.33 | cop[tikv] |             | lt(test.t.a, 1)
   ↪            |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+----------+-----------+--------------+----------------
   ↪
```

```
3 rows in set (0.00 sec)
```

In this query, pushing down the predicate `a < 1` to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```
create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪            |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| TableReader_7         | 3323.33 | root    |               | data:Selection_6
   ↪           |
| ─Selection_6          | 3323.33 | cop[tikv] |             | lt(test.t.a, 1)
   ↪             |
|   ─TableFullScan_5    | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate `a < substring('123', 1, 1)` are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate `a < 1`. After that, TiDB can push `a < 1` down to TiKV.

Case 3: push predicates below join operator

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+--
   ↪ ---------------------------+----------+-----------+---------------+-----------
   ↪
| id                          | estRows | task    | access object | operator
   ↪ info                          |
+--
   ↪ ---------------------------+----------+-----------+---------------+-----------
   ↪
| HashJoin_8                  | 4154.17 | root    |               | inner join,
   ↪ equal:[eq(test.t.a, test.s.a)] |
```

```
|  └─TableReader_15(Build)   | 3323.33 | root     |              | data:
   ↪ Selection_14                      |
|    └─Selection_14          | 3323.33 | cop[tikv] |              | lt(test.s.a
   ↪ , 1)                          |
|      └─TableFullScan_13    | 10000.00 | cop[tikv] | table:s   | keep order:
   ↪ false, stats:pseudo          |
|  └─TableReader_12(Probe)   | 3323.33 | root     |              | data:
   ↪ Selection_11                      |
|    └─Selection_11          | 3323.33 | cop[tikv] |              | lt(test.t.a
   ↪ , 1)                          |
|      └─TableFullScan_10    | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo          |
+--
   ↪ --------------------------+---------+----------+--------------+-----------
   ↪
7 rows in set (0.00 sec)
```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the `ON` condition is `t.a = s.a`. The predicate `s.a <1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```
create table t(id int primary key, a varchar(10) not null);
desc select * from t where truncate(a, " ") = '1';
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪                            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |              | eq(truncate(cast(
   ↪ test.t.a, double BINARY), 0), 1) |
|  └─TableReader_7       | 10000.00 | root    |              | data:
   ↪ TableFullScan_6                        |
|    └─TableFullScan_6   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo               |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
```

In this query, there is a predicate `truncate(a, " ")= '1'`.

From the `explain` results, you can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `truncate`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
| id                          | estRows | task      | access object | operator
   ↪ info                             |
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
| Selection_7                 | 10000.00 | root      |               | isnull(test
   ↪ .s.a)                            |
|  ─HashJoin_8                | 12500.00 | root      |               | left outer
   ↪  join, equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_13(Build)   | 10000.00 | root      |               | data:
   ↪ TableFullScan_12                   |
|      ─TableFullScan_12      | 10000.00 | cop[tikv] | table:s       | keep order:
   ↪ false, stats:pseudo              |
|    ─TableReader_11(Probe)   | 10000.00 | root      |               | data:
   ↪ TableFullScan_10                   |
|      ─TableFullScan_10      | 10000.00 | cop[tikv] | table:t       | keep order:
   ↪ false, stats:pseudo              |
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
6 rows in set (0.00 sec)
```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with `NULL` values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```
create table t(id int primary key, a char);
set @a = 1;
```

```
explain select * from t where a < @a;
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |               | lt(test.t.a,
   ↪ getvar("a"))  |
| └─TableReader_7       | 10000.00 | root    |               | data:
   ↪ TableFullScan_6       |
|   └─TableFullScan_6   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with `1`, and does not push down it to TiKV.

An example to help you understand is as follows:

```
create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+----+------+----------+
| id | a    | @a:=@a+1 |
+----+------+----------+
|  1 |    1 | 2        |
|  2 |    2 | 3        |
+----+------+----------+
2 rows in set (0.00 sec)
```

As you can see from this query, the value of `@a` will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

11.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (200),
 PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO t1 VALUES (1, 'test1'),(101, 'test2'), (201, 'test3');
EXPLAIN SELECT * FROM t1 WHERE id BETWEEN 80 AND 120;
```

```
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
| id                        | estRows | task    | access object       |
   ↪ operator info                                |
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
| PartitionUnion_8          | 80.00   | root      |                      |
   ↪                                             |
|  ─TableReader_10          | 40.00   | root      |                      | data:
   ↪ TableRangeScan_9                          |
|    ─TableRangeScan_9      | 40.00   | cop[tikv] | table:t1, partition:p0 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
|  ─TableReader_12          | 40.00   | root      |                      | data:
   ↪ TableRangeScan_11                         |

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
   ↪ ----------------------+----------+-----------+----------------------+--------
   ↪
| id                    | estRows | task     | access object       | operator
   ↪ info               |
+--
   ↪ ----------------------+----------+-----------+----------------------+--------
   ↪
| TableReader_8         | 10.00   | root     |                      | data:
   ↪ Selection_7            |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
   ↪ .x, 1)              |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ----------------------+----------+-----------+----------------------+--------
   ↪
```

In the SQL statement above, it can be known from the condition `x = 1` that all results fall in one partition. The value `1` can be confirmed to be in the `p1` partition after passing through the Hash partition. Therefore, only the `p1` partition needs to be scanned, and there is no need to access the `p2`, `p3`, and `p4` partitions that will not have matching results. From the execution plan, only one `TableFullScan` operator appears and the `p1` partition is specified in `access object`, so it can be confirmed that `partition pruning` takes effect.

Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
   ↪ ---------------------------+---------+----------+--------------------+---
   ↪
| id                          | estRows | task     | access object      |
   ↪ operator info              |
+--
   ↪ ---------------------------+---------+----------+--------------------+---
   ↪
| Union_10                    | 13333.33 | root    |                    |
   ↪                             |
|  ─TableReader_13            | 3333.33 | root     |                    | data
   ↪ :Selection_12             |
|    ─Selection_12            | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_11      | 10000.00 | cop[tikv] | table:t, partition:p0
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_16            | 3333.33 | root     |                    | data
   ↪ :Selection_15             |
|    ─Selection_15            | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_14      | 10000.00 | cop[tikv] | table:t, partition:p1
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_19            | 3333.33 | root     |                    | data
   ↪ :Selection_18             |
|    ─Selection_18            | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_17      | 10000.00 | cop[tikv] | table:t, partition:p2
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_22            | 3333.33 | root     |                    | data
   ↪ :Selection_21             |
|    ─Selection_21            | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_20      | 10000.00 | cop[tikv] | table:t, partition:p3
   ↪ | keep order:false, stats:pseudo |
+--
   ↪ ---------------------------+---------+----------+--------------------+---
   ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the `x > 2` condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
    ↪ t2.x < 2);
```

```
+--

|  ─Apply_15                        | 9990.00 | root     |
    ↪                     | inner join, equal:[eq(test.t2.x, test.t1.x)] |
|    ─TableReader_18(Build)         | 9990.00 | root     |
    ↪                     | data:Selection_17                             |
|      ─Selection_17                | 9990.00 | cop[tikv] |
    ↪                   | not(isnull(test.t2.x))                        |
|        ─TableFullScan_16          | 10000.00 | cop[tikv] | table:t2
    ↪         | keep order:false, stats:pseudo                |
|    ─Selection_19(Probe)           | 0.80    | root     |
    ↪                     | not(isnull(test.t1.x))                        |
|      ─MaxOneRow_20                | 1.00    | root     |
    ↪                     |                                               |
|        ─Union_21                  | 2.00    | root     |
    ↪                     |                                               |
|          ─TableReader_24          | 2.00    | root     |
    ↪                     | data:Selection_23                             |
|            ─Selection_23          | 2.00    | cop[tikv] |
    ↪                   | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
|              ─TableFullScan_22    | 2500.00 | cop[tikv] | table:t1,
    ↪ partition:p0 | keep order:false, stats:pseudo    |
|          ─TableReader_27          | 2.00    | root     |
    ↪                     | data:Selection_26                             |
|            ─Selection_26          | 2.00    | cop[tikv] |
    ↪                   | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
|              ─TableFullScan_25    | 2500.00 | cop[tikv] | table:t1,
    ↪ partition:p1 | keep order:false, stats:pseudo    |
+--
```

```
    ↪ ----------------------------------+---------+----------+-------------------
    ↪
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x = 3;
```

```
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| id                    | estRows | task     | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| TableReader_8         | 10.00   | root     |                      | data:
    ↪ Selection_7           |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
    ↪ .x, 3)             |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x in(1,13);
```

```
+--
    ↪ --------------------------+----------+----------+----------------------+-----
    ↪
| id                          | estRows | task     | access object        |
    ↪ operator info               |
+--
    ↪ --------------------------+----------+----------+----------------------+-----
    ↪
| Union_8                     | 40.00   | root     |                      |
    ↪                               |
|  ─TableReader_11            | 20.00   | root     |                      | data:
    ↪ Selection_10              |
|    ─Selection_10            | 20.00   | cop[tikv] |                     | in(
    ↪ test.t.x, 1, 13)          |
|      ─TableFullScan_9       | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪  keep order:false, stats:pseudo |
|  ─TableReader_14            | 20.00   | root     |                      | data:
    ↪ Selection_13              |
|    ─Selection_13            | 20.00   | cop[tikv] |                     | in(
    ↪ test.t.x, 1, 13)          |
|      ─TableFullScan_12      | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ --------------------------+----------+----------+----------------------+-----
    ↪
```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
```

```
    partition p2 values less than (15)
    );
explain select * from t where x between 7 and 14;
```

```

    ↪
| id                        | estRows | task     | access object      |
    ↪ operator info                 |
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
| Union_8                   | 500.00  | root     |                    |
    ↪                                 |
|  ─TableReader_11          | 250.00  | root     |                    | data:
    ↪ Selection_10              |
|    ─Selection_10          | 250.00  | cop[tikv] |                   | ge(
    ↪ test.t.x, 7), le(test.t.x, 14) |
|      ─TableFullScan_9     | 10000.00 | cop[tikv] | table:t, partition:p1 |
    ↪  keep order:false, stats:pseudo |
|  ─TableReader_14          | 250.00  | root     |                    | data:
    ↪ Selection_13              |
|    ─Selection_13          | 250.00  | cop[tikv] |                   | ge(
    ↪ test.t.x, 7), le(test.t.x, 14) |
|      ─TableFullScan_12    | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
```

Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of `fn(col)`, the query condition is one of `>`, `<`, `=`, `>=`, and `<=`, and the `fn` function is monotonous.

If the `fn` function is monotonous, for any `x` and `y`, if `x > y`, then `fn(x) > fn(y)`. Then this `fn` function can be called strictly monotonous. For any `x` and `y`, if `x > y`, then `fn` ↪ `(x) >= fn(y)`. In this case, `fn` could also be called "monotonous". Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

- `UNIX_TIMESTAMP()`
- `TO_DAYS()`

For example, partition pruning takes effect when the partition expression is in the form of `fn(col)`, where the `fn` is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
   partition p0 values less than (to_days('2020-04-01')),
   partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```

   ↪ info                          |
+--
   ↪ ----------------------+---------+----------+----------------------+---------
   ↪
| TableReader_8         | 3333.33 | root     |                      | data:
   ↪ Selection_7                     |
|  ─Selection_7         | 3333.33 | cop[tikv] |                      | gt(test.t
   ↪ .id, 2020-04-18 00:00:00.000000) |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ----------------------+---------+----------+----------------------+---------
   ↪
```

Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
   partition p0 values less than (5),
   partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
   ↪ t2.x < 2);
```

```

|            ─Selection_26         | 2.00    | cop[tikv] |
   ↪                   | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|              ─TableFullScan_25   | 2.50    | cop[tikv] | table:t1,
   ↪ partition:p1 | keep order:false, stats:pseudo                |
+--
   ↪ ----------------------------------+----------+-----------+-------------------
   ↪
14 rows in set (0.00 sec)
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table.

Theoretically, the `t1.x> val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

11.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to Optimization Rules and Blocklist for Expression Pushdown.

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```
+-------------------------+---------+-----------+--------------+--------------------
   ↪
| id                      | estRows | task      | access object | operator
   ↪ info            |
+-------------------------+---------+-----------+--------------+--------------------
   ↪
| TopN_7                  | 10.00   | root      |              | test.t.a,
   ↪ offset:0, count:10 |
|  ─TableReader_15        | 10.00   | root      |              | data:TopN_14
   ↪                |
|    ─TopN_14             | 10.00   | cop[tikv] |              | test.t.a,
   ↪ offset:0, count:10 |
|      ─TableFullScan_13  | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo |
+-------------------------+---------+-----------+--------------+--------------------
   ↪
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| id                              | estRows | task      | access object |
   ↪ operator info                                |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| TopN_12                         | 10.00    | root      |               | test.t.a,
   ↪  offset:0, count:10                  |
|  ─HashJoin_17                   | 12.50    | root      |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    ─TopN_18(Build)              | 10.00    | root      |               | test.t.a
   ↪ , offset:0, count:10                 |
|      ─TableReader_26            | 10.00    | root      |               | data:
   ↪ TopN_25                                |
|        ─TopN_25                 | 10.00    | cop[tikv] |               | test.t.a
   ↪ , offset:0, count:10                 |
|          ─TableFullScan_24      | 10000.00 | cop[tikv] | table:t       | keep
   ↪ order:false, stats:pseudo              |
|    ─TableReader_30(Probe)       | 10000.00 | root      |               | data:
   ↪ TableFullScan_29                       |
|      ─TableFullScan_29          | 10000.00 | cop[tikv] | table:s       | keep
   ↪ order:false, stats:pseudo              |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+-------------------------------+----------+-----------+---------------+---------------
   ↪
```

```
| id                           | estRows | task    | access object | operator
   ↪ info                        |
+------------------------------+---------+---------+---------------+---------------
   ↪
| TopN_12                      | 10.00   | root    |               | test.t.id,
   ↪ offset:0, count:10         |
|  ─HashJoin_16                | 12500.00 | root   |               | inner join,
   ↪  equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_21(Build)    | 10000.00 | root   |               | data:
   ↪ TableFullScan_20                 |
|      ─TableFullScan_20       | 10000.00 | cop[tikv] | table:s     | keep order:
   ↪ false, stats:pseudo        |
|    ─TableReader_19(Probe)    | 10000.00 | root   |               | data:
   ↪ TableFullScan_18                 |
|      ─TableFullScan_18       | 10000.00 | cop[tikv] | table:t     | keep order:
   ↪ false, stats:pseudo        |
+------------------------------+---------+---------+---------------+---------------
   ↪
6 rows in set (0.00 sec)
```

TopN cannot be pushed down before `Inner Join`. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;
```

```
+---------------------------------+---------+----------+--------------+-------------
   ↪
| id                              | estRows | task     | access object |
   ↪ operator info                           |
+---------------------------------+---------+----------+--------------+-------------
   ↪
| TopN_12                         | 10.00   | root     |               | test.t.id
   ↪ , offset:0, count:10                |
|  ─HashJoin_17                   | 12.50   | root     |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
```

```
|   └─Limit_21(Build)           | 10.00   | root     |              | offset
   ↪ :0, count:10                          |
|     └─TableReader_31          | 10.00   | root     |              | data:
   ↪ Limit_30                              |
|       └─Limit_30              | 10.00   | cop[tikv] |             | offset
   ↪ :0, count:10                          |
|         └─TableFullScan_29    | 10.00   | cop[tikv] | table:t     | keep
   ↪ order:true, stats:pseudo              |
|   └─TableReader_35(Probe)     | 10000.00 | root    |              | data:
   ↪ TableFullScan_34                      |
|     └─TableFullScan_34        | 10000.00 | cop[tikv] | table:s   | keep
   ↪ order:false, stats:pseudo             |
+-------------------------------+----------+-----------+--------------+-------------
   ↪
8 rows in set (0.00 sec)
```

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t ↪ .id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

11.3.3.2.9 Introduction to Join Reorder

In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1

As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, the following two Join Reorder algorithms are used in TiDB:

- The greedy algorithm: among all nodes participating in the join, TiDB selects the table with the least rows to estimate its join result with each of the other tables respectively, and then selects the pair with the smallest join result. After that, TiDB continues the similar process to select and join other nodes for the next round, until all the nodes have completed the join.

- The dynamic programming algorithm: among all nodes participating in the join, TiDB enumerates all possible join orders and selects the optimal join order.

Example: the greedy algorithm of Join Reorder

Take the preceding three tables (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

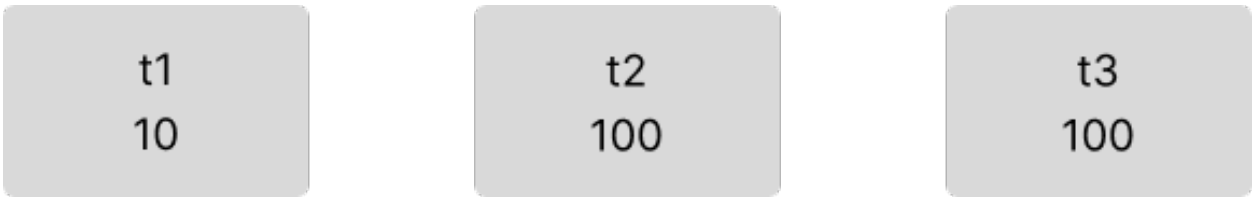

Figure 379: join-reorder-1

After that, the table with the least rows is selected and joined with other two tables respectively. By comparing the sizes of the output result sets, TiDB selects the pair with a smaller result set.

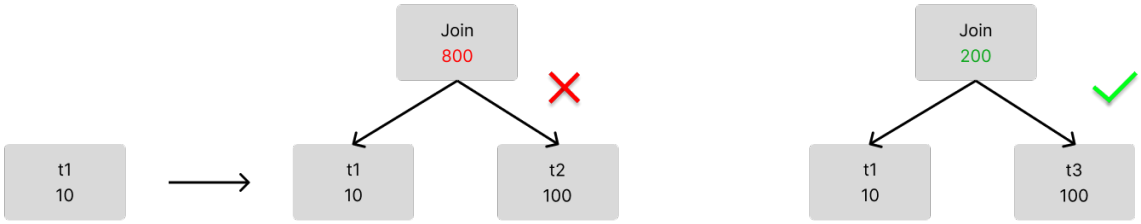

Figure 380: join-reorder-2

Then TiDB enters the next round of selection. If you try to join four tables, TiDB continues to compare the sizes of the output result sets and selects the pair with a smaller result set.

In this case only three tables are joined, so TiDB gets the final join result.

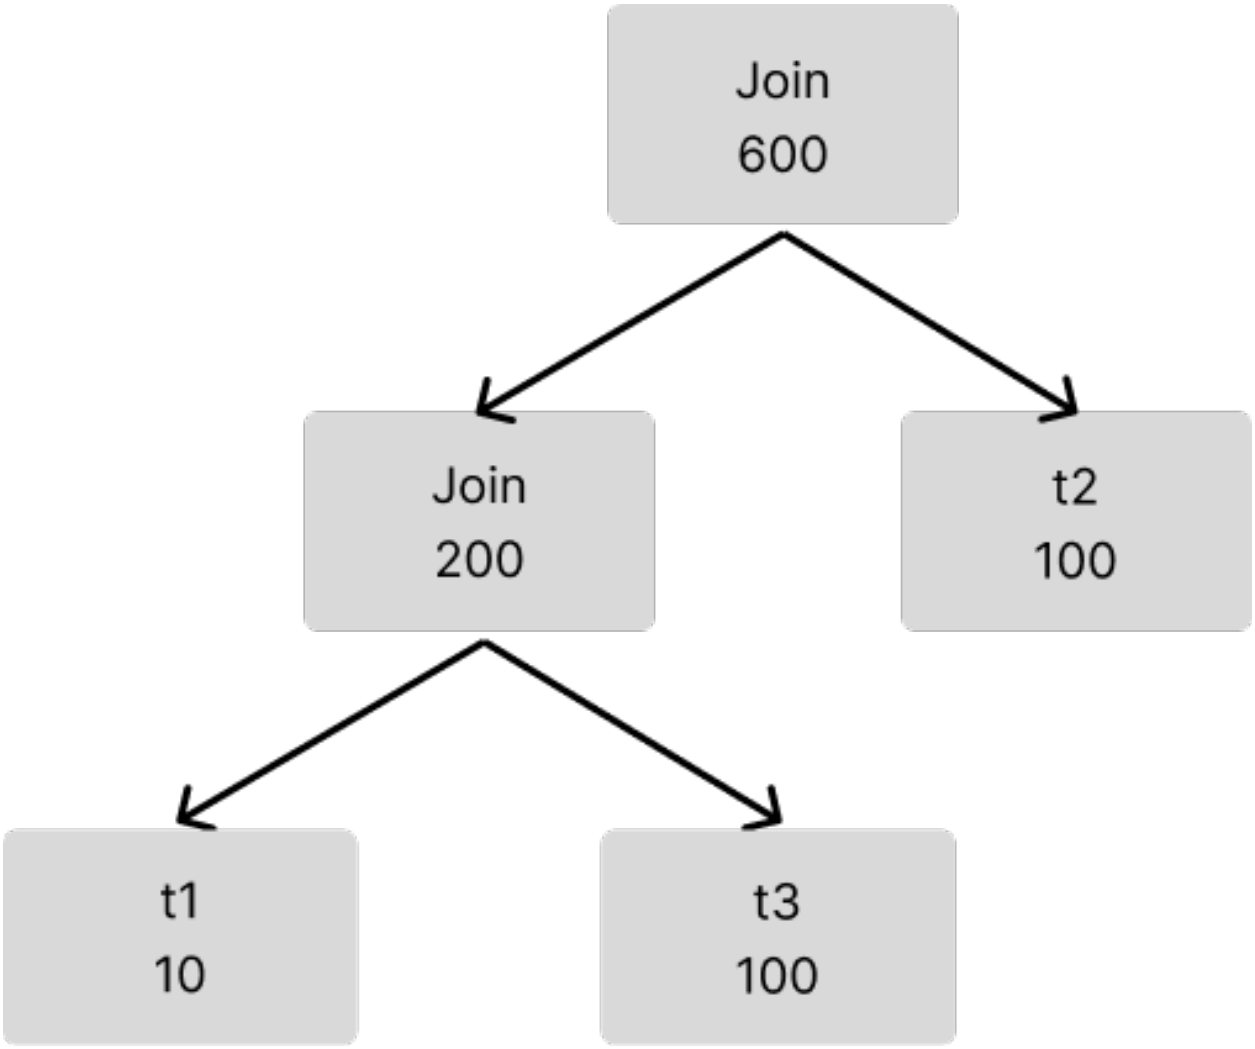

Figure 381: join-reorder-3

Example: the dynamic programming algorithm of Join Reorder

Taking the preceding three tables (t1, t2, and t3) as an example again, the dynamic programming algorithm can enumerate all possibilities. Therefore, comparing with the greedy algorithm, which must start with the `t1` table (the table with the least rows), the dynamic programming algorithm can enumerate a join order as follows:

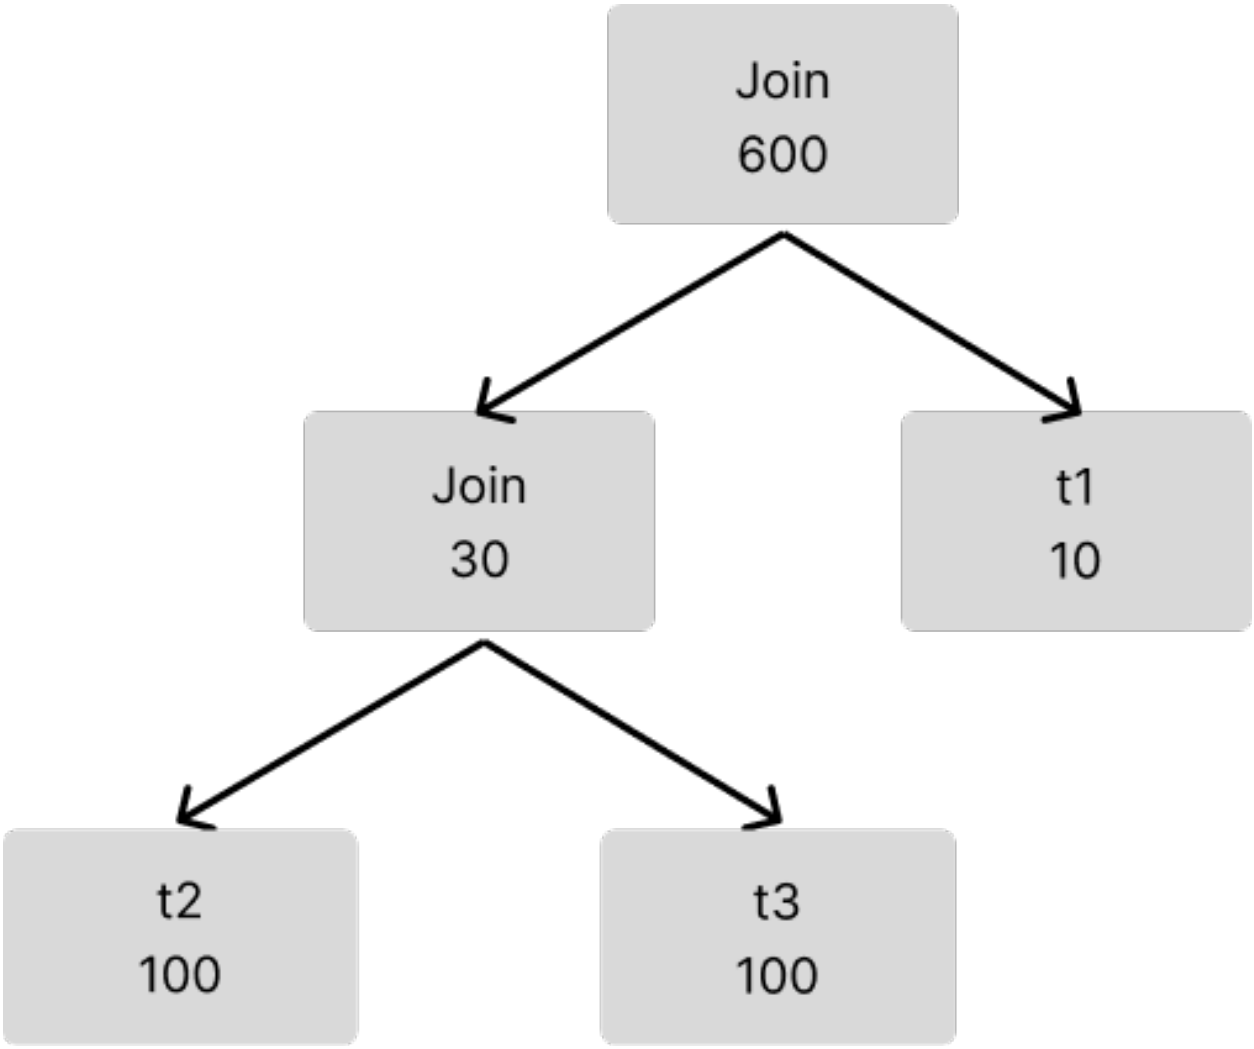

Figure 382: join-reorder-4

When this choice is better than the greedy algorithm, the dynamic programming algorithm can choose a better join order.

Because all possibilities are enumerated, the dynamic programming algorithm consumes more time and is more susceptible to statistics.

Selection of the Join Reorder algorithms

The selection of the TiDB Join Reorder algorithms is controlled by the `tidb_opt_join_reorder_thres`
↪ variable. If the number of nodes participating in Join Reorder is greater than this threshold, TiDB uses the greedy algorithm. Otherwise, TiDB uses the dynamic programming algorithm.

Limitations of Join Reorder algorithms

The current Join Reorder algorithms have the following limitations:

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.
- The Join Reorder algorithm's support for Outer Join is controlled by the `tidb_enable_outer_join_reorder` system variable.
- Currently, the dynamic programming algorithm cannot perform Join Reorder for outer join.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to Description of the syntax elements.

11.3.3.2.10 Derive TopN or Limit from Window Functions

Window Functions are a common type of SQL function. When you use a window function for row numbering, such as `ROW_NUMBER()` or `RANK()`, it is common to filter the results after the window function is evaluated. For example:

```
SELECT * FROM (SELECT ROW_NUMBER() OVER (ORDER BY a) AS rownumber FROM t)
    ↪ dt WHERE rownumber <= 3
```

In a typical SQL execution process, TiDB first sorts all data in the table `t`, then calculates the `ROW_NUMBER()` result for each row, and finally filters with `rownumber <= 3`.

Starting from v7.0.0, TiDB supports deriving the TopN or Limit operator from window functions. With this optimization rule, TiDB can rewrite the original SQL into an equivalent form as follows:

```
WITH t_topN AS (SELECT a FROM t1 ORDER BY a LIMIT 3) SELECT * FROM (SELECT
    ↪ ROW_NUMBER() OVER (ORDER BY a) AS rownumber FROM t_topN) dt WHERE
    ↪ rownumber <= 3
```

After rewriting, TiDB can derive a TopN operator from the window function and the subsequent filter condition. Compared with the Sort operator in the original SQL (`ORDER BY` ↪), the TopN operator has a much higher execution efficiency. In addition, both TiKV and TiFlash support pushing down the TopN operator, which further improves the performance of the rewritten SQL.

Deriving TopN or Limit from window functions is disabled by default. To enable this feature, you can set the session variable tidb_opt_derive_topn to `ON`.

After enabling this feature, you can disable it by performing one of the following operations:

- Set the session variable tidb_opt_derive_topn to `OFF`.
- Follow the steps described in The blocklist of optimization rules and expression pushdown.

Limitations

- Only the `ROW_NUMBER()` window function is supported for SQL rewriting.
- TiDB can only rewrite SQL when filtering on the `ROW_NUMBER()` results and the filter condition is `<` or `<=`.

Usage examples

The following examples demonstrate how to use the optimization rule.

Window functions without PARTITION BY

Example 1: window functions without ORDER BY

```
CREATE TABLE t(id int, value int);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER () AS rownumber FROM t) dt
    ↪ WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+---------+-----------+---------------+--------------
    ↪
| id                              | estRows | task      | access object | operator
    ↪  info                                                |
+---------------------------------+---------+-----------+---------------+--------------
    ↪
| Projection_9                    | 2.40    | root      |               | Column#5
    ↪                                                    |
|  ─Selection_10                   | 2.40    | root      |               | le(Column
    ↪ #5, 3)                                             |
|    ─Window_11                    | 3.00    | root      |               |
    ↪ row_number()->Column#5 over(rows between current row and current row)
    ↪  |
|      ─Limit_15                   | 3.00    | root      |               | offset:0,
    ↪  count:3                                           |
|        ─TableReader_26           | 3.00    | root      |               | data:
    ↪ Limit_25                                                 |
|          ─Limit_25               | 3.00    | cop[tikv] |               | offset:0,
    ↪  count:3                                           |
|            ─TableFullScan_24     | 3.00    | cop[tikv] | table:t       | keep
    ↪ order:false, stats:pseudo                                |
+---------------------------------+---------+-----------+---------------+--------------
    ↪
```

In this query, the optimizer derives the Limit operator from the window function and pushes it down to TiKV.

Example 2: window functions with ORDER BY

```
CREATE TABLE t(id int, value int);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (ORDER BY value) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+---------+----------+--------------+------------
    ↪
| id                              | estRows | task     | access object |
    ↪ operator info
    ↪                                                                  |
+---------------------------------+---------+----------+--------------+------------
    ↪
| Projection_10                   | 2.40    | root     |              | Column#5
    ↪
    ↪ |
| └─Selection_11                  | 2.40    | root     |              | le(
    ↪ Column#5, 3)
    ↪                                                                  |
|   └─Window_12                   | 3.00    | root     |              |
    ↪ row_number()->Column#5 over(order by test.t.value rows between
    ↪ current row and current row) |
|     └─TopN_13                   | 3.00    | root     |              | test.t.
    ↪ value, offset:0, count:3
    ↪                                                    |
|       └─TableReader_25          | 3.00    | root     |              | data:
    ↪ TopN_24
    ↪                                                                       |
|         └─TopN_24               | 3.00    | cop[tikv] |             | test.t.
    ↪ value, offset:0, count:3
    ↪                                                  |
|           └─TableFullScan_23    | 10000.00 | cop[tikv] | table:t    | keep
    ↪ order:false, stats:pseudo

    ↪
```

In this query, the optimizer derives the TopN operator from the window function and pushes it down to TiKV.

Window functions with PARTITION BY

> **Note:**
>
> For a window function containing `PARTITION BY`, the optimization rule only takes effect when the partition column is a prefix of the primary key and the primary key is a clustered index.

Example 3: window functions without ORDER BY

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+-----------------------------------+---------+-----------+---------------+------------
    ↪
| id                                | estRows | task      | access object |
    ↪ operator info
    ↪                                                                                  |
+-----------------------------------+---------+-----------+---------------+------------

    ↪ |
|  └─Selection_10                  | 8000.00 | root     |               | le(
    ↪ Column#6, 3)
    ↪                                                                      |
|    └─Shuffle_15                  | 10000.00 | root    |               |
    ↪ execution info: concurrency:5, data sources:[TableReader_13]
    ↪                             |
```

```
|     └─Window_11               | 10000.00 | root    |             |
    ↪ row_number()->Column#6 over(partition by test.t.value1 rows between
    ↪ current row and current row) |
|       └─Sort_14               | 10000.00 | root    |             | test.t.
    ↪ value1
    ↪
    ↪ |
|         └─TableReader_13      | 10000.00 | root    |             | data:
    ↪ TableFullScan_12
    ↪                                                                  |
|           └─TableFullScan_12  | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪                                                        |
+-------------------------------+----------+-----------+--------------+------------
    ↪
```

In this query, the SQL is not rewritten because the `PARTITION BY` column is not a prefix of the primary key.

Example 6: PARTITION BY column is a prefix of the primary key but not a clustered index

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) nonclustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1) AS
    ↪ rownumber FROM t use index()) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+-------------------------------+----------+-----------+--------------+------------
    ↪
| id                            | estRows | task     | access object |
    ↪ operator info
    ↪                                                                 |
+-------------------------------+----------+-----------+--------------+------------
    ↪
| Projection_9                  | 8000.00 | root     |              | Column#7
    ↪
    ↪ |
|  └─Selection_10               | 8000.00 | root     |              | le(
    ↪ Column#7, 3)
    ↪                                                                    |
|    └─Shuffle_15               | 10000.00 | root    |              |
    ↪ execution info: concurrency:5, data sources:[TableReader_13]
    ↪                        |
```

```
|     └─Window_11               | 10000.00 | root    |             |
    ↪ row_number()->Column#7 over(partition by test.t.id1 rows between
    ↪ current row and current row) |
|       └─Sort_14               | 10000.00 | root    |             | test.t.
    ↪ id1

    ↪ |
|         └─TableReader_13      | 10000.00 | root    |             | data:
    ↪ TableFullScan_12
    ↪                                                                |
|           └─TableFullScan_12  | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪                                                    |
+-------------------------------+----------+-----------+-------------+------------
    ↪
```

In this query, although the `PARTITION BY` column is a prefix of the primary key, the SQL is not rewritten because the primary key is not a clustered index.

11.3.3.3 Physical Optimization

11.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

Understand the Query Execution Plan has introduced some physical operators. This chapter focuses on the following aspects:

- In Index Selection, you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In Introduction to Statistics, you will learn what statistics TiDB collects to obtain the data distribution of a table.
- Wrong Index Solution introduces how to use the right index when you find the index is selected wrongly.
- Distinct Optimization introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.
- Cost Model introduces how to choose a optimal execution plan based on the cost model during physical optimization.

11.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / BatchPointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	This TableReader operator is for TiKV. It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the `_tidb_rowid` column, or if there are no other opera-

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	This TableReader operator is for TiFlash. TiFlash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookUpReader	A table has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as IndexReader.	Since the index does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the IndexReader operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexMerge	A table has multiple indexes or a multi-valued index.	When a multi-valued index or multiple indexes are used.	To use the operator, you can specify the optimizer hints, or let the optimizer to automatically select this operator based on cost estimation. For details, see Explain Statements Using Index Merge.

Note:

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection of an operator for accessing tables.

Index selection rules

TiDB selects indexes based on rules or cost. The based rules include pre-rules and skyline-pruning. When selecting an index, TiDB tries the pre-rule first. If an index satisfies a pre-rule, TiDB directly selects this index. Otherwise, TiDB uses skyline-pruning to exclude unsuitable indexes, and then selects the index with the lowest cost based on the cost estimation of each operator that accesses tables.

Rule-based selection

Pre-rules

TiDB uses the following heuristic pre-rules to select indexes:

- Rule 1: If an index satisfies "unique index with full match + no need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)", TiDB directly selects this index.
- Rule 2: If an index satisfies "unique index with full match + the need to retrieve rows from a table (which means that the plan generated by the index is the IndexLookupReader operator)", TiDB selects the index with the smallest number of rows to be retrieved from a table as a candidate index.
- Rule 3: If an index satisfies "ordinary index + no need to retrieve rows from a table + the number of rows to be read is less than the value of a certain threshold", TiDB selects the index with the smallest number of rows to be read as a candidate index.
- Rule 4: If only one candidate index is selected based on rule 2 and 3, select this candidate index. If two candidate indexes are respectively selected based on rule 2 and 3, select the index with the smaller number of rows to be read (the number of rows with index + the number of rows to be retrieved from a table).

The "index with full match" in the above rules means each indexed column has the equal condition. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if the pre-rules match an index, TiDB outputs a NOTE-level warning indicating that the index matches the pre-rule.

In the following example, because the index `idx_b` meets the condition "unique index with full match + the need to retrieve rows from a table" in rule 2, TiDB selects the index `idx_b` as the access path, and `SHOW WARNING` returns a note indicating that the index `idx_b` matches the pre-rule.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, UNIQUE INDEX idx_b(b
    ↪ ));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT b, c FROM t WHERE b = 3 OR b = 6;

```

Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes, which can reduce the probability of wrong index selection caused by wrong estimation. To judge an index, the following three dimensions are needed:

- How many access conditions are covered by the indexed columns. An "access condition" is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.

- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or IndexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do. If both indexes need TiDB to retrieve rows from the table, compare how many filtering conditions are covered by the indexed columns. Filtering conditions mean the `where` condition that can be judged based on the index. If the column set of an index covers more access conditions, the smaller the number of retrieved rows from a table, and the better the index is in this dimension.
- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.

For these three dimensions above, if the index `idx_a` performs no worse than the index `idx_b` in all three dimensions and performs better than `idx_b` in one dimension, then `idx_a` is preferred. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if skyline-pruning excludes some indexes, TiDB outputs a NOTE-level warning listing the remaining indexes after the skyline-pruning exclusion.

In the following example, the indexes `idx_b` and `idx_e` are both inferior to `idx_b_c`, so they are excluded by skyline-pruning. The returned result of `SHOW WARNING` displays the remaining indexes after skyline-pruning.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, d INT, e INT, INDEX
    ↪ idx_b(b), INDEX idx_b_c(b, c), INDEX idx_e(e));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT * FROM t WHERE b = 2 AND c > 4;

Cost estimation-based selection

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

   This is usually due to stale or inaccurate statistics. You can re-execute the `analyze table` statement or modify the parameters of the `analyze table` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

   At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

3. The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

   In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

Control index selection

The index selection can be controlled by a single query through Optimizer Hints.

- `USE_INDEX` / `IGNORE_INDEX` can force the optimizer to use / not use certain indexes. `FORCE_INDEX` and `USE_INDEX` have the same effect.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

Use multi-valued indexes

Multi-valued indexes are different from normal indexes. TiDB currently only uses IndexMerge to access multi-valued indexes. Therefore, to use multi-valued indexes for data access, make sure that the value of the system variable `tidb_enable_index_merge` is set to `ON`.

For the limitations of multi-valued indexes, refer to `CREATE INDEX`.

Supported scenarios

Currently, TiDB supports accessing multi-valued indexes using IndexMerge that is automatically converted from `json_member_of`, `json_contains`, and `json_overlaps` conditions. You can either rely on the optimizer to automatically select IndexMerge based on cost, or specify the selection of multi-valued indexes through the optimizer hint `use_index_merge` or `use_index`. See the following examples:

```
mysql> CREATE TABLE t1 (j JSON, INDEX idx((CAST(j->'$.path' AS SIGNED ARRAY
    ↪ ))));  -- Uses '$.path' as the path to create a multi-valued index
Query OK, 0 rows affected (0.04 sec)

mysql> EXPLAIN SELECT /*+ use_index_merge(t1, idx) */ * FROM t1 WHERE (1
    ↪ MEMBER OF (j->'$.path'));

    ↪ json_memberof(cast(1, json BINARY), json_extract(test.t.j1, "$.path")
    ↪ ), json_memberof(cast(2, json BINARY), json_extract(test.t.j2, "$.
    ↪ path")) |
| └─IndexMerge_9                 | 0.01    | root      |
    ↪                                                                        |
    ↪ type: union
    ↪
    ↪ |
|    └─IndexRangeScan_6(Build)  | 10.00   | cop[tikv] | table:t, index:k1(cast
    ↪ (json_extract(`j1`, _utf8'$.path') as signed array)) | range:[1,1],
    ↪ keep order:false, stats:pseudo
```

```
    ↪
    ↪ |
|    └─Selection_8(Probe)       | 0.01   | cop[tikv] |
    ↪                                                                | eq(
    ↪ test.t.a, 3)
    ↪
    ↪ |
|      └─TableRowIDScan_7       | 10.00  | cop[tikv] | table:t
    ↪                                                        | keep order:
    ↪ false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ------------------------------+--------+----------+-----------------------
    ↪
5 rows in set, 6 warnings (0.01 sec)
```

Currently, TiDB only supports using one index to access instead of generating the following plan that uses multiple indexes to access at the same time:

```
Selection
 └─IndexMerge
   ├─IndexRangeScan(k1)
   ├─IndexRangeScan(k2)
   ├─IndexRangeScan(ka)
   └─Selection
     └─TableRowIDScan
```

Unsupported scenarios

For `OR` conditions composed of multiple expressions that correspond to multiple different indexes, multi-valued indexes cannot be used:

```
mysql> create table t(j1 json, j2 json, a int, INDEX k1((CAST(j1->'$.path'
    ↪ AS SIGNED ARRAY))), INDEX k2((CAST(j2->'$.path' AS SIGNED ARRAY))),
    ↪ INDEX ka(a));
Query OK, 0 rows affected (0.03 sec)

mysql> explain select /*+ use_index_merge(t, k1, k2, ka) */ * from t where
    ↪ (1 member of (j1->'$.path')) or (2 member of (j2->'$.path'));
+--
    ↪ ----------------------+----------+-----------+--------------+---------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪
    ↪ |
```

```
+--
    ↪ ---------------------+---------+----------+--------------+----------------
    ↪
| Selection_5          | 8000.00 | root     |              | or(json_memberof(
    ↪ cast(1, json BINARY), json_extract(test.t.j1, "$.path")),
    ↪ json_memberof(cast(2, json BINARY), json_extract(test.t.j2, "$.path")
    ↪ )) |
| └─TableReader_7      | 10000.00 | root     |              | data:
    ↪ TableFullScan_6
    ↪
    ↪ |
|   └─TableFullScan_6  | 10000.00 | cop[tikv] | table:t  | keep order:false
    ↪ , stats:pseudo
    ↪
    ↪ |
+--
    ↪ ---------------------+---------+----------+--------------+----------------
    ↪
3 rows in set, 3 warnings (0.00 sec)

mysql> explain select /*+ use_index_merge(t, k1, k2, ka) */ * from t where
    ↪ (1 member of (j1->'$.path')) or (a = 3);
+--
    ↪ ---------------------+---------+----------+--------------+----------------
    ↪
| id                   | estRows | task     | access object | operator info
    ↪                                                                  |
+--
    ↪ ---------------------+---------+----------+--------------+----------------
    ↪
| Selection_5          | 8000.00 | root     |              | or(json_memberof(
    ↪ cast(1, json BINARY), json_extract(test.t.j1, "$.path")), eq(test.t.a
    ↪ , 3)) |
| └─TableReader_7      | 10000.00 | root     |              | data:
    ↪ TableFullScan_6
    ↪                                                                  |
|   └─TableFullScan_6  | 10000.00 | cop[tikv] | table:t  | keep order:false
    ↪ , stats:pseudo                                                   |
+--
    ↪ ---------------------+---------+----------+--------------+----------------
    ↪
3 rows in set, 3 warnings (0.00 sec)
```

A workaround for the preceding scenario is to rewrite the query using `Union All`:

The following are some more complex scenarios that are not yet supported.

```
mysql> CREATE TABLE t4 (j JSON, INDEX idx((CAST(j AS SIGNED ARRAY))));
Query OK, 0 rows affected (0.04 sec)

-- If a query contains the OR condition composed of multiple json_contains
   ↪  expressions, the index cannot be accessed using IndexMerge.
mysql> EXPLAIN SELECT /*+ use_index_merge(t3, idx) */ * FROM t3 WHERE (
   ↪ json_contains(j, '[1, 2]')) OR (json_contains(j, '[3, 4]'));
+--
   ↪ ----------------------+----------+-----------+--------------+----------------
   ↪

11.3.3.3.3 Introduction to Statistics

TiDB uses statistics to decide which index to choose.

Versions of statistics

The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`.

- For TiDB Self-Hosted, the default value of this variable changes from `1` to `2` starting from v5.3.0.
- For TiDB Cloud, the default value of this variable changes from `1` to `2` starting from v6.5.0.
- If your cluster is upgraded from an earlier version, the default value of `tidb_analyze_version` does not change after the upgrade.

Compared to Version 1, Version 2 statistics avoids the potential inaccuracy caused by hash collision when the data volume is huge. It also maintains the estimate precision in most scenarios.

These two versions include different information in TiDB:

Information	Version 1	Version 2
The total number of rows in the table	√	√
Column Count-Min Sketch	√	×
Index Count-Min Sketch	√	×

Information	Version 1	Version 2
Column Top-N	√	√ (Maintenance methods and precision are improved)
Index Top-N	√ (Insufficient maintenance precision might cause inaccuracy)	√ (Maintenance methods and precision are improved)
Column histogram	√	√ (The histogram does not include Top-N values.)

Information	Version 1	Version 2
Index histogram	√	√ (The histogram buckets record the number of different values in each bucket, and the histogram does not include Top-N values.)
The number of `NULL` ↪ s in the column	√	√

Information	Version 1	Version 2
The number of NULLs in the index	√	√
The average length of columns	√	√
The average length of indexes	√	√

When `tidb_analyze_version = 2`, if memory overflow occurs after `ANALYZE` is executed, you need to set `tidb_analyze_version = 1` to fall back to Version 1, and perform one of the following operations:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
sql   SELECT DISTINCT(CONCAT('ANALYZE TABLE ', table_schema, '.', table_name
↪ , ';'))FROM information_schema.tables, mysql.stats_histograms WHERE
↪ stats_ver = 2 AND table_id = tidb_table_id;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
sql   SELECT DISTINCT(CONCAT('DROP STATS ', table_schema, '.', table_name
↪ , ';'))FROM information_schema.tables, mysql.stats_histograms WHERE
↪ stats_ver = 2 AND table_id = tidb_table_id;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
sql   SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt'; mysql -h ${TiDB_IP
↪ } -u user -P ${TIDB_PORT} ... < '/tmp/sql.txt'
```

This document briefly introduces the histogram, Count-Min Sketch, and Top-N, and details the collection and maintenance of statistics.

Histogram

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here "equal-depth" means that the number of values falling into each bucket is as equal as possible. For example, for a given set {1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5}, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

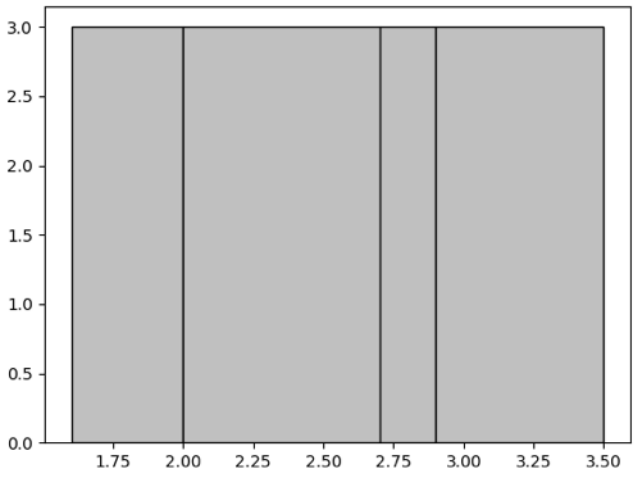

Figure 383: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to Manual Collection. When the number of buckets is larger, the accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage

of memory resources. You can adjust this number appropriately according to the actual scenario.

Count-Min Sketch

Count-Min Sketch is a hash structure. When an equivalence query contains `a = 1` or `IN` query (for example, `a in (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see Full Collection.
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see Full Collection.

Top-N values

Top-N values are values with the top N occurrences in a column or index. TiDB records the values and occurrences of Top-N values.

Collect statistics

Manual collection

You can run the `ANALYZE` statement to collect statistics.

> **Note:**
>
> The execution time of `ANALYZE TABLE` in TiDB is longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while in TiDB a comprehensive set of statistics is completely rebuilt. Scripts that were written for MySQL may naively expect `ANALYZE TABLE` will be a short-lived operation.
>
> For quicker analysis, you can set `tidb_enable_fast_analyze` to `1` to enable the Quick Analysis feature. The default value for this parameter is `0`.

After Quick Analysis is enabled, TiDB randomly samples approximately 10,000 rows of data to build statistics. Therefore, in the case of uneven data distribution or a relatively small amount of data, the accuracy of statistical information is relatively poor. It might lead to poor execution plans, such as choosing the wrong index. If the execution time of the normal `ANALYZE` statement is acceptable, it is recommended to disable the Quick Analysis feature.

`tidb_enable_fast_analyze` is an experimental feature, which currently **does not match exactly** with the statistical information of `tidb_analyze_version=2`. Therefore, you need to set the value of `tidb_analyze_version` to `1` when `tidb_enable_fast_analyze` is enabled.

Full collection

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|
    ↪ CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated `TOPN`s.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- `WITH FLOAT_NUM SAMPLERATE` specifies the sampling rate.

`WITH NUM SAMPLES` and `WITH FLOAT_NUM SAMPLERATE` correspond to two different algorithms of collecting samples.

- `WITH NUM SAMPLES` specifies the size of the sampling set, which is implemented in the reservoir sampling method in TiDB. When a table is large, it is not recommended to use this method to collect statistics. Because the intermediate result set of the reservoir sampling contains redundant results, it causes additional pressure on resources such as memory.

- `WITH FLOAT_NUM SAMPLERATE` is a sampling method introduced in v5.3.0. With the value range `(0, 1]`, this parameter specifies the sampling rate. It is implemented in the way of Bernoulli sampling in TiDB, which is more suitable for sampling larger tables and performs better in collection efficiency and resource usage.

Before v5.3.0, TiDB uses the reservoir sampling method to collect statistics. Since v5.3.0, the TiDB Version 2 statistics uses the Bernoulli sampling method to collect statistics by default. To re-use the reservoir sampling method, you can use the `WITH NUM SAMPLES` statement.

The current sampling rate is calculated based on an adaptive algorithm. When you can observe the number of rows in a table using `SHOW STATS_META`, you can use this number of rows to calculate the sampling rate corresponding to 100,000 rows. If you cannot observe this number, you can use the sum of all the values in the `APPROXIMATE_KEYS` column in the results of `SHOW TABLE REGIONS` of the table as another reference to calculate the sampling rate.

> **Note:**
>
> Normally, `STATS_META` is more credible than `APPROXIMATE_KEYS`. However, after importing data through the methods like TiDB Lightning physical import mode, the result of `STATS_META` is `0`. To handle this situation, you can use `APPROXIMATE_KEYS` to calculate the sampling rate when the result of `STATS_META` is much smaller than the result of `APPROXIMATE_KEYS`.

Collect statistics on some columns

In most cases, when executing SQL statements, the optimizer only uses statistics on some columns (such as columns in the `WHERE`, `JOIN`, `ORDER BY`, and `GROUP BY` statements). These columns are called `PREDICATE COLUMNS`.

If a table has many columns, collecting statistics on all the columns can cause a large overhead. To reduce the overhead, you can collect statistics on only specific columns or `PREDICATE COLUMNS` to be used by the optimizer.

> **Note:**
>
> Collecting statistics on some columns is only applicable for `tidb_analyze_version = 2`.

- To collect statistics on specific columns, use the following syntax:

```
ANALYZE TABLE TableName COLUMNS ColumnNameList [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

In the syntax, `ColumnNameList` specifies the name list of the target columns. If you need to specify more than one column, use comma `,` to separate the column names. For example, `ANALYZE table t columns a, b`. Besides collecting statistics on the specific columns in a specific table, this syntax collects statistics on the indexed columns and all indexes in that table at the same time.

> **Note:**
>
> The syntax above is a full collection. For example, after collecting statistics on columns `a` and `b` using this syntax, if you also want to collect statistics on column `c`, you need to specify all three columns using `ANALYZE table t columns a, b, c`, rather than only specifying the additional column `c` using `ANALYZE TABLE t COLUMNS c`.

- To collect statistics on `PREDICATE COLUMNS`, do the following:

> **Warning:**
>
> Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

1. Set the value of the `tidb_enable_column_tracking` system variable to `ON` to enable TiDB to collect `PREDICATE COLUMNS`.

   After the setting, TiDB writes the `PREDICATE COLUMNS` information to the `mysql.column_stats_usage` system table every 100 * `stats-lease`.

2. After the query pattern of your business is relatively stable, collect statistics on `PREDICATE COLUMNS` by using the following syntax:

   ```
   ANALYZE TABLE TableName PREDICATE COLUMNS [WITH NUM BUCKETS|TOPN|
       ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
       ↪ FLOATNUM SAMPLERATE];
   ```

   Besides collecting statistics on `PREDICATE COLUMNS` in a specific table, this syntax collects statistics on indexed columns and all indexes in that table at the same time.

Note:

- If the `mysql.column_stats_usage` system table does not contain any `PREDICATE COLUMNS` record for that table, the preceding syntax collects statistics on all columns and all indexes in that table.
- After using this syntax to collect statistics, when executing a new type of SQL query, the optimizer might temporarily use the old or pseudo column statistics for this time, and TiDB will collect the statistics on the used columns from the next time.

- To collect statistics on all columns and indexes, use the following syntax:

```
ANALYZE TABLE TableName ALL COLUMNS [WITH NUM BUCKETS|TOPN|CMSKETCH
    ↪ DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE
    ↪ ];
```

If you want to persist the column configuration in the `ANALYZE` statement (including `COLUMNS ColumnNameList`, `PREDICATE COLUMNS`, and `ALL COLUMNS`), set the value of the `tidb_persist_analyze_options` system variable to `ON` to enable the ANALYZE configuration persistence feature. After enabling the ANALYZE configuration persistence feature:

- When TiDB collects statistics automatically or when you manually collect statistics by executing the `ANALYZE` statement without specifying the column configuration, TiDB continues using the previously persisted configuration for statistics collection.
- When you manually execute the `ANALYZE` statement multiple times with column configuration specified, TiDB overwrites the previously recorded persistent configuration using the new configuration specified by the latest `ANALYZE` statement.

To locate `PREDICATE COLUMNS` and columns on which statistics have been collected, use the following syntax:

```
SHOW COLUMN_STATS_USAGE [ShowLikeOrWhere];
```

The `SHOW COLUMN_STATS_USAGE` statement returns the following 6 columns:

Column name	Description
`Db_name`	The database name
`Table_name` ↪	The table name
`Partition_name` ↪	The partition name

Column name	Description
`Column_name`	The column name
`Last_used_at`	The last time when the column statistics were used in the query optimization
`Last_analyzed_at`	The last time when the column statistics were collected

In the following example, after executing `ANALYZE TABLE t PREDICATE COLUMNS;`, TiDB collects statistics on columns `b`, `c`, and `d`, where column `b` is a `PREDICATE COLUMN` and columns `c` and `d` are index columns.

```
SET GLOBAL tidb_enable_column_tracking = ON;
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE t (a INT, b INT, c INT, d INT, INDEX idx_c_d(c, d));
Query OK, 0 rows affected (0.00 sec)

-- The optimizer uses the statistics on column b in this query.
SELECT * FROM t WHERE b > 1;
Empty set (0.00 sec)

-- After waiting for a period of time (100 * stats-lease), TiDB writes the
   ↪  collected `PREDICATE COLUMNS` to mysql.column_stats_usage.
-- Specify `last_used_at IS NOT NULL` to show the `PREDICATE COLUMNS`
   ↪ collected by TiDB.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
   ↪ last_used_at IS NOT NULL;
+--
   ↪ -------+-----------+---------------+------------+--------------------+------
   ↪
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
   ↪ Last_analyzed_at |
+--
   ↪ -------+-----------+---------------+------------+--------------------+------
```

```
    ↪
| test   | t         |              | b          | 2022-01-05 17:21:33 | NULL
    ↪          |
+--
    ↪ -------+-----------+---------------+------------+---------------------+------
    ↪
1 row in set (0.00 sec)

ANALYZE TABLE t PREDICATE COLUMNS;
Query OK, 0 rows affected, 1 warning (0.03 sec)

-- Specify `last_analyzed_at IS NOT NULL` to show the columns for which
    ↪ statistics have been collected.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
    ↪ last_analyzed_at IS NOT NULL;
+--
    ↪ -------+-----------+---------------+------------+---------------------+------
    ↪
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
    ↪ Last_analyzed_at |

    ↪
3 rows in set (0.00 sec)
```

Collect statistics on indexes

To collect statistics on all indexes in `IndexNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

When `IndexNameList` is empty, this syntax collects statistics on all indexes in `TableName` ↪ .

Note:

To ensure that the statistical information before and after the collection is consistent, when `tidb_analyze_version` is `2`, this syntax collects statistics on the entire table (including all columns and indexes), instead of only on indexes.

Collect statistics on partitions

- To collect statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

- To collect index statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- If you only need to collect statistics on some columns of some partitions in a table, use the following syntax:

Warning:

Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

```
ANALYZE TABLE TableName PARTITION PartitionNameList [COLUMNS
    ↪ ColumnNameList|PREDICATE COLUMNS|ALL COLUMNS] [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

Collect statistics of partitioned tables in dynamic pruning mode

When accessing partitioned tables in dynamic pruning mode, TiDB collects table-level statistics, which is called GlobalStats. Currently, GlobalStats is aggregated from statistics of all partitions. In dynamic pruning mode, a statistics update of any partitioned table can trigger the GlobalStats to be updated.

Note:

- When GlobalStats update is triggered:
  - If some partitions have no statistics (such as a new partition that has never been analyzed), GlobalStats generation is interrupted and a warning message is displayed saying that no statistics are available on partitions.
  - If statistics of some columns are absent in specific partitions (different columns are specified for analyzing in these partitions), GlobalStats generation is interrupted when statistics of these columns are aggregated, and a warning message is displayed saying that statistics of some columns are absent in specific partitions.
- In dynamic pruning mode, the Analyze configurations of partitions and tables should be the same. Therefore, if you specify the `COLUMNS` ↪ configuration following the `ANALYZE TABLE TableName PARTITION` ↪ `PartitionNameList` statement or the `OPTIONS` configuration following `WITH`, TiDB will ignore them and return a warning.

Incremental collection

To improve the speed of analysis after full collection, incremental collection could be used to analyze the newly added sections in monotonically non-decreasing columns such as time columns.

Note:

- Currently, the incremental collection is only provided for index.
- When using the incremental collection, you must ensure that only `INSERT` operations exist on the table, and that the newly inserted value on the index column is monotonically non-decreasing. Otherwise, the statistical information might be inaccurate, affecting the TiDB optimizer to select an appropriate execution plan.

You can perform incremental collection using the following syntax.

- To incrementally collect statistics on index columns in all `IndexNameLists` in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName INDEX [IndexNameList] [WITH NUM
    ↪ BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|
    ↪ WITH FLOATNUM SAMPLERATE];
```

- To incrementally collect statistics on index columns for partitions in all `PartitionNameLists` ↪ in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

Automatic update

For the `INSERT`, `DELETE`, or `UPDATE` statements, TiDB automatically updates the number of rows and modified rows. TiDB persists this information regularly and the update cycle is 20 * `stats-lease`. The default value of `stats-lease` is `3s`. If you specify the value as `0`, TiDB stops updating statistics automatically.

Relevant system variables

Three system variables related to automatic update of statistics are as follows:

System Variable	Default Value	Description
`tidb_auto_analyze_ratio` ↪	0.5	The threshold value of automatic update

System Variable	Default Value	Description
tidb_auto_analyze_start_time	00:00 +0000	The start time in a day when TiDB can perform automatic update
tidb_auto_analyze_end_time	23:59 +0000	The end time in a day when TiDB can perform automatic update

System Variable	Default Value	Description
tidb_auto_analyze_partition_batch_size ↪	1	The number of partitions that TiDB automatically analyzes when analyzing a partitioned table (that is, when automatically updating statistics on a partitioned table)

System Variable	Default Value	Description

When the ratio of the number of modified rows to the total number of rows of `tbl` in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics on this table.

To avoid the situation that modifying a small amount of data on a small table frequently triggers the automatic update, when a table has less than 1000 rows, such data modifying does not trigger the automatic update in TiDB. You can use the `SHOW STATS_META` statement to view the number of rows in a table.

> **Note:**
>
> Currently, the automatic update does not record the configuration items input at manual `ANALYZE`. Therefore, when you use the `WITH` syntax to control the collecting behavior of `ANALYZE`, you need to manually set scheduled tasks to collect statistics.

Disable automatic update

If you find that automatic update of statistics consumes excessive resources and affects online application operations, you can disable it using the `tidb_enable_auto_analyze` system variable.

Terminate background `ANALYZE` tasks

Since TiDB v6.0, TiDB supports using the `KILL` statement to terminate an `ANALYZE` task running in the background. If you find that an `ANALYZE` task running in the background consumes a lot of resources and affects your application, you can terminate the `ANALYZE` task by taking the following steps:

1. Execute the following SQL statement:

   ```
   SHOW ANALYZE STATUS
   ```

   By checking the `instance` column and the `process_id` column in the result, you can get the TiDB instance address and the task `ID` of the background `ANALYZE` task.

2. Terminate the `ANALYZE` task that is running in the background.

- If enable-global-kill is true (true by default), you can execute the KILL ↪ TIDB ${id}; statement directly, where ${id} is the ID of the background ANALYZE task obtained from the previous step.
- If enable-global-kill is false, you need to use a client to connect to the TiDB instance that is executing the backend ANALYZE task, and then execute the KILL ↪ TIDB ${id}; statement. If you use a client to connect to another TiDB instance, or if there is a proxy between the client and the TiDB cluster, the KILL statement cannot terminate the background ANALYZE task.

For more information on the KILL statement, see KILL.

Control ANALYZE concurrency

When you run the ANALYZE statement, you can adjust the concurrency using the following parameters, to control its effect on the system.

tidb_build_stats_concurrency

Currently, when you run the ANALYZE statement, the task is divided into multiple small tasks. Each task only works on one column or index. You can use the tidb_build_stats_concurrency parameter to control the number of simultaneous tasks. The default value is 4.

tidb_distsql_scan_concurrency

When you analyze regular columns, you can use the tidb_distsql_scan_concurrency parameter to control the number of Region to be read at one time. The default value is 15.

tidb_index_serial_scan_concurrency

When you analyze index columns, you can use the tidb_index_serial_scan_concurrency ↪ parameter to control the number of Region to be read at one time. The default value is 1.

Persist ANALYZE configurations

Since v5.4.0, TiDB supports persisting some ANALYZE configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The following are the ANALYZE configurations that support persistence:

Configuration	Corresponding ANALYZE syntax
The number of histogram buckets	WITH NUM BUCKETS
The number of Top-N	WITH NUM TOPN
The number of samples	WITH NUM SAMPLES
The sampling rate	WITH FLOAT_NUM SAMPLERATE

Configuration	Corresponding ANALYZE syntax
The `ANALYZE` column type	AnalyzeColumnOption ::= (‘ALL COLUMNS’ | ‘PREDICATE COLUMNS’ | ‘COLUMNS’ ColumnNameList)
The `ANALYZE` column	ColumnNameList ::= Identifier (‘,’ Identifier)*

Enable ANALYZE configuration persistence

The `ANALYZE` configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is `2` and `tidb_persist_analyze_options` is `ON` by default).

You can use this feature to record the persistence configurations specified in the `ANALYZE` statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configuration, TiDB will collect statistics according to the recorded configurations.

To query the configuration persisted on a specific table used for auto analyze operations, you can use the following SQL statement:

```
SELECT sample_num, sample_rate, buckets, topn, column_choice, column_ids
    ↪ FROM mysql.analyze_options opt JOIN information_schema.tables tbl ON
```

```
    ↪ opt.table_id = tbl.tidb_table_id WHERE tbl.table_schema = '{db_name}'
    ↪  AND tbl.table_name = '{table_name}';
```

TiDB will overwrite the previously recorded persistent configuration using the new configurations specified by the latest `ANALYZE` statement. For example, if you run `ANALYZE TABLE t WITH 200 TOPN;`, it will set the top 200 values in the `ANALYZE` statement. Subsequently, executing `ANALYZE TABLE t WITH 0.1 SAMPLERATE;` will set both the top 200 values and a sampling rate of 0.1 for auto `ANALYZE` statements, similar to `ANALYZE TABLE t WITH 200 TOPN, 0.1 SAMPLERATE;`.

Disable ANALYZE configuration persistence

To disable the `ANALYZE` configuration persistence feature, set the `tidb_persist_analyze_options` system variable to `OFF`. Because the `ANALYZE` configuration persistence feature is not applicable to `tidb_analyze_version = 1`, setting `tidb_analyze_version = 1` can also disable the feature.

After disabling the `ANALYZE` configuration persistence feature, TiDB does not clear the persisted configuration records. Therefore, if you enable this feature again, TiDB continues to collect statistics using the previously recorded persistent configurations.

> **Note:**
>
> When you enable the `ANALYZE` configuration persistence feature again, if the previously recorded persistence configurations are no longer applicable to the latest data, you need to execute the `ANALYZE` statement manually and specify the new persistence configurations.

The memory quota for collecting statistics

> **Warning:**
>
> Currently, the `ANALYZE` memory quota is an experimental feature, and the memory statistics might be inaccurate in production environments.

Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the memory quota for collecting statistics in TiDB.

To set a proper value of `tidb_mem_quota_analyze`, consider the data size of the cluster. When the default sampling rate is used, the main considerations are the number of columns, the size of column values, and the memory configuration of TiDB. Consider the following suggestions when you configure the maximum and minimum values:

Note:

The following suggestions are for reference only. You need to configure the values based on the real scenario.

- Minimum value: should be greater than the maximum memory usage when TiDB collects statistics from the table with the most columns. An approximate reference: when TiDB collects statistics from a table with 20 columns using the default configuration, the maximum memory usage is about 800 MiB; when TiDB collects statistics from a table with 160 columns using the default configuration, the maximum memory usage is about 5 GiB.
- Maximum value: should be less than the available memory when TiDB is not collecting statistics.

View `ANALYZE` state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using the following SQL statement:

```
SHOW ANALYZE STATUS [ShowLikeOrWhere]
```

This statement returns the state of `ANALYZE`. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW ANALYZE STATUS` statement returns the following 11 columns:

Column name	Description
table_schema	The database name
table_name	The table name
partition_name	The partition name

Column name	Description
job_info	The task information. If an index is analyzed, this information will include the index name. When `tidb_analyze_version =2`, this information will include configuration items such as sample rate.
processed_rows	The number of rows that have been analyzed
start_time	The time at which the task starts
state	The state of a task, including `pending`, `running`, `finished`, and `failed`
fail_reason	The reason why the task fails. If the execution is successful, the value is `NULL`.
instance	The TiDB instance that executes the task
process_id	The process ID that executes the task

Starting from TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the

restart using this statement. Before TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement can only show instance-level tasks, and task records are cleared after a TiDB restart.

`SHOW ANALYZE STATUS` shows the most recent task records only. Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

When `tidb_mem_quota_analyze` is set and an automatic `ANALYZE` task running in the TiDB background uses more memory than this threshold, the task will be retried. You can see failed and retried tasks in the output of the `SHOW ANALYZE STATUS` statement.

When `tidb_max_auto_analyze_time` is greater than 0 and an automatic `ANALYZE` task running in the TiDB background takes more time than this threshold, the task will be terminated.

```
mysql> SHOW ANALYZE STATUS [ShowLikeOrWhere];
+--
   ↪ ------------+------------+----------------+-----------------------------------
   ↪
| Table_schema | Table_name | Partition_name | Job_info
   ↪                                                                    |
   ↪ Processed_rows | Start_time     | End_time          | State   |
   ↪ Fail_reason                                                          |
+--
   ↪ ------------+------------+----------------+-----------------------------------
   ↪
| test         | sbtest1   |                | retry auto analyze table all
   ↪ columns with 100 topn, 0.055 samplerate           |       2000000 |
   ↪ 2022-05-07 16:41:09 | 2022-05-07 16:41:20 | finished | NULL
   ↪                                                                  |
| test         | sbtest1   |                | auto analyze table all columns
   ↪ with 100 topn, 0.5 samplerate                    |            0 |
   ↪ 2022-05-07 16:40:50 | 2022-05-07 16:41:09 | failed | analyze panic
   ↪ due to memory quota exceeds, please try with smaller samplerate |
```

View statistics

You can view the statistics status using the following statements.

Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

```
SHOW STATS_META [ShowLikeOrWhere];
```

The syntax of `ShowLikeOrWhereOpt` is as follows:

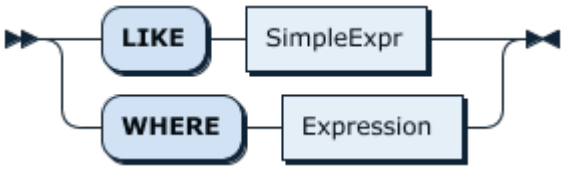

Figure 384: ShowLikeOrWhereOpt

Currently, the `SHOW STATS_META` statement returns the following 6 columns:

Column name	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`update_time`	The time of the update
`modify_count`	The number of modified rows
`row_count`	The total number of rows

Note:

When TiDB automatically updates the total number of rows and the number of modified rows according to DML statements, `update_time` is also updated. Therefore, `update_time` does not necessarily indicate the last time when the `ANALYZE` statement is executed.

Health state of tables

You can use the `SHOW STATS_HEALTHY` statement to check the health state of tables and roughly estimate the accuracy of the statistics. When `modify_count >= row_count`, the health state is 0; when `modify_count < row_count`, the health state is (1 - `modify_count` ↪ `/row_count`) * 100.

The syntax is as follows:

```
SHOW STATS_HEALTHY [ShowLikeOrWhere];
```

The synopsis of `SHOW STATS_HEALTHY` is:

Figure 385: ShowStatsHealthy

Currently, the `SHOW STATS_HEALTHY` statement returns the following 4 columns:

Column name	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`healthy`	The health state of tables

Metadata of columns

You can use the `SHOW STATS_HISTOGRAMS` statement to view the number of different values and the number of `NULL` in all the columns.

Syntax as follows:

```
SHOW STATS_HISTOGRAMS [ShowLikeOrWhere]
```

This statement returns the number of different values and the number of `NULL` in all the columns. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_HISTOGRAMS` statement returns the following 10 columns:

Column name	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`is_index`	Whether it is an index column or not
`update_time`	The time of the update
`distinct_count`	The number of different values
`null_count`	The number of `NULL`
`avg_col_size`	The average length of columns

Column name	Description
correlation	The Pearson correlation coefficient of the column and the integer primary key, which indicates the degree of association between the two columns

Buckets of histogram

You can use the `SHOW STATS_BUCKETS` statement to view each bucket of the histogram.

The syntax is as follows:

```
SHOW STATS_BUCKETS [ShowLikeOrWhere]
```

The diagram is as follows:

Figure 386: SHOW STATS_BUCKETS

This statement returns information about all the buckets. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_BUCKETS` statement returns the following 11 columns:

Column name	Description
`db_name`	The database name
`table_name` ↪	The table name
`partition_name` ↪	The partition name

Column name	Description
`column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`is_index`	Whether it is an index column or not
`bucket_id`	The ID of a bucket
`count`	The number of all the values that falls on the bucket and the previous buckets
`repeats`	The occurrence number of the maximum value
`lower_bound`	The minimum value
`upper_bound`	The maximum value
`ndv`	The number of different values in the bucket. When `tidb_analyze_version` = `1`, `ndv` is always `0`, which has no actual meaning.

Top-N information

You can use the `SHOW STATS_TOPN` statement to view the Top-N information currently collected by TiDB.

The syntax is as follows:

```
SHOW STATS_TOPN [ShowLikeOrWhere];
```

Currently, the `SHOW STATS_TOPN` statement returns the following 7 columns:

Column name	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`is_index`	Whether it is an index column or not
`value`	The value of this column

Column name	Description
`count`	How many times the value appears

Delete statistics

You can run the `DROP STATS` statement to delete statistics.

```
DROP STATS TableName
```

The preceding statement deletes all statistics of `TableName`. If a partitioned table is specified, this statement will delete statistics of all partitions in this table as well as GlobalStats generated in dynamic pruning mode.

```
DROP STATS TableName PARTITION PartitionNameList;
```

This preceding statement only deletes statistics of the specified partitions in `PartitionNameList`.

```
DROP STATS TableName GLOBAL;
```

The preceding statement only deletes GlobalStats generated in dynamic pruning mode of the specified table.

Load statistics

> **Note:**
>
> Loading statistics is not available on TiDB Serverless clusters.

By default, depending on the size of column statistics, TiDB loads statistics differently as follows:

- For statistics that consume small amounts of memory (such as count, distinctCount, and nullCount), as long as the column data is updated, TiDB automatically loads the corresponding statistics into memory for use in the SQL optimization stage.

- For statistics that consume large amounts of memory (such as histograms, TopN, and Count-Min Sketch), to ensure the performance of SQL execution, TiDB loads the statistics asynchronously on demand. Take histograms as an example. TiDB loads histogram statistics on a column into memory only when the optimizer uses the histogram statistics on that column. On-demand asynchronous statistics loading does not affect the performance of SQL execution but might provide incomplete statistics for SQL optimization.

Since v5.4.0, TiDB introduces the synchronously loading statistics feature. This feature allows TiDB to synchronously load large-sized statistics (such as histograms, TopN, and Count-Min Sketch statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

To enable this feature, set the value of the `tidb_stats_load_sync_wait` system variable to a timeout (in milliseconds) that SQL optimization can wait for at most to synchronously load complete column statistics. The default value of this variable is `100`, indicating that the feature is enabled.

After enabling the synchronously loading statistics feature, you can further configure the feature as follows:

- To control how TiDB behaves when the waiting time of SQL optimization reaches the timeout, modify the value of the `tidb_stats_load_pseudo_timeout` system variable. The default value of this variable is `ON`, indicating that after the timeout, the SQL optimization process does not use any histogram, TopN, or CMSketch statistics on any columns. If this variable is set to `OFF`, after the timeout, SQL execution fails.
- To specify the maximum number of columns that the synchronously loading statistics feature can process concurrently, modify the value of the `stats-load-concurrency` option in the TiDB configuration file. The default value is `5`.
- To specify the maximum number of column requests that the synchronously loading statistics feature can cache, modify the value of the `stats-load-queue-size` option in the TiDB configuration file. The default value is `1000`.

During TiDB startup, SQL statements executed before the initial statistics are fully loaded might have suboptimal execution plans, thus causing performance issues. To avoid such issues, TiDB v7.1.0 introduces the configuration parameter `force-init-stats`. With this option, you can control whether TiDB provides services only after statistics initialization has been finished during startup. This parameter is disabled by default.

> **Warning:**
>
> Lightweight statistics initialization is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

Starting from v7.1.0, TiDB introduces `lite-init-stats` for lightweight statistics initialization.

- When the value of `lite-init-stats` is `true`, statistics initialization does not load any histogram, TopN, or Count-Min Sketch of indexes or columns into memory.
- When the value of `lite-init-stats` is `false`, statistics initialization loads histograms, TopN, and Count-Min Sketch of indexes and primary keys into memory but does not load any histogram, TopN, or Count-Min Sketch of non-primary key columns into memory. When the optimizer needs the histogram, TopN, and Count-Min Sketch of a specific index or column, the necessary statistics are loaded into memory synchronously or asynchronously.

The default value of `lite-init-stats` is `false`, which means to disable lightweight statistics initialization. Setting `lite-init-stats` to `true` speeds up statistics initialization and reduces TiDB memory usage by avoiding unnecessary statistics loading.

Import and export statistics

Export statistics

The interface to export statistics is as follows:

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${
    ↪ db_name}/${table_name}
```

For example:

```
curl -s http://127.0.0.1:10080/stats/dump/test/t1 -o /tmp/t1.json
```

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database at specific time:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${
    ↪ db_name}/${table_name}/${yyyyMMddHHmmss}
```

Import statistics

> **Note:**
>
> When you start the MySQL client, use the `--local-infile=1` option.

Generally, the imported statistics refer to the JSON file obtained using the export interface.

Syntax:

```
LOAD STATS 'file_name'
```

`file_name` is the file name of the statistics to be imported.

Lock statistics

> **Warning:**
>
> Locking statistics is an experimental feature for the current version. It is not recommended to use it in the production environment.

Since v6.5.0, TiDB supports locking statistics. After the statistics of a table are locked, the statistics of the table cannot be modified and the `ANALYZE` statement cannot be executed on the table. For example:

Create table `t`, and insert data into it. When the statistics of table `t` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> create table t(a int, b int);
Query OK, 0 rows affected (0.03 sec)

mysql> insert into t values (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> analyze table t;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> show warnings;
+--
    ↪ -----+------+-----------------------------------------------------------+
    ↪
| Level | Code | Message                                                   |
+--
    ↪ -----+------+-----------------------------------------------------------+
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t |
+--
    ↪ -----+------+-----------------------------------------------------------+
    ↪
```

```
1 row in set (0.00 sec)
```

Lock the statistics of table `t` and execute `ANALYZE`. From the output of `SHOW STATS_LOCKED`, you can see that the statistics of table `t` have been locked. The warning message shows that the `ANALYZE` statement has skipped table `t`.

```
mysql> lock stats t;
Query OK, 0 rows affected (0.00 sec)

mysql> show stats_locked;
+---------+------------+----------------+--------+
| Db_name | Table_name | Partition_name | Status |
+---------+------------+----------------+--------+
| test    | t          |                | locked |
+---------+------------+----------------+--------+
1 row in set (0.01 sec)

mysql> analyze table t;
Query OK, 0 rows affected, 2 warnings (0.00 sec)

mysql> show warnings;
+--
   ↪ -------+------+-----------------------------------------------------------------------
   ↪
| Level   | Code | Message                                                                |
+--
   ↪ -------+------+-----------------------------------------------------------------------
   ↪
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t |
| Warning | 1105 | skip analyze locked table: t                                           |
+--
   ↪ -------+------+-----------------------------------------------------------------------
   ↪
2 rows in set (0.00 sec)
```

Unlock the statistics of table `t` and `ANALYZE` can be successfully executed again.

```
mysql> unlock stats t;
Query OK, 0 rows affected (0.01 sec)

mysql> analyze table t;
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> show warnings;
```

```
+--
    ↪ -----+------+-------------------------------------------------------------------+
    ↪
| Level | Code | Message                                                           |
+--
    ↪ -----+------+-------------------------------------------------------------------+
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t |
+--
    ↪ -----+------+-------------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

11.3.3.3.4 Introduction to Extended Statistics

TiDB can collect the following two types of statistics:

- Basic statistics: statistics such as histograms and Count-Min Sketch. See Introduction to Statistics for details.
- Extended statistics: statistics filtered by tables and columns.

> **Tip:**
>
> Before reading this document, it is recommended that you read Introduction to Statistics first.

When the `ANALYZE` statement is executed manually or automatically, TiDB by default only collects the basic statistics and does not collect the extended statistics. This is because the extended statistics are only used for optimizer estimates in specific scenarios, and collecting them requires additional overhead.

Extended statistics are disabled by default. To collect extended statistics, you need to first enable the extended statistics, and then register each individual extended statistics object.

After the registration, the next time the `ANALYZE` statement is executed, TiDB collects both the basic statistics and the registered extended statistics.

Limitations

Extended statistics are not collected in the following scenarios:

- Statistics collection on indexes only
- Statistics collection using the `ANALYZE INCREMENTAL` command
- Statistics collection when the value of the system variable `tidb_enable_fast_analyze` is set to `true`

Common operations

Enable extended statistics

To enable extended statistics, set the system variable `tidb_enable_extended_stats` to `ON`:

```
SET GLOBAL tidb_enable_extended_stats = ON;
```

The default value of this variable is `OFF`. The setting of this system variable applies to all extended statistics objects.

Register extended statistics

The registration for extended statistics is not a one-time task, and you need repeat the registration for each extended statistics object.

To register extended statistics, use the SQL statement `ALTER TABLE ADD STATS_EXTENDED` ↪ . The syntax is as follows:

```
ALTER TABLE table_name ADD STATS_EXTENDED IF NOT EXISTS stats_name
    ↪ stats_type(column_name, column_name...);
```

In the syntax, you can specify the table name, statistics name, statistics type, and column name of the extended statistics to be collected.

- `table_name` specifies the name of the table from which the extended statistics are collected.
- `stats_name` specifies the name of the statistics object, which must be unique for each table.
- `stats_type` specifies the type of the statistics. Currently, only the correlation type is supported.
- `column_name` specifies the column group, which might have multiple columns. Currently, you can only specify two column names.

How it works

To improve access performance, each TiDB node maintains a cache in the system table `mysql.stats_extended` for extended statistics. After you register the extended statistics, the next time the `ANALYZE` statement is executed, TiDB will collect the extended statistics if the system table `mysql.stats_extended` has the corresponding objects.

Each row in the `mysql.stats_extended` table has a `version` column. Once a row is updated, the value of `version` is increased. In this way, TiDB loads the table into memory incrementally, instead of fully.

TiDB loads `mysql.stats_extended` periodically to ensure that the cache is kept the same as the data in the table.

> **Warning:**
>
> It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.
>
> If you have mistakenly operated on the table, you can execute the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:
>
> ```
> ADMIN RELOAD STATS_EXTENDED;
> ```

Delete extended statistics

To delete an extended statistics object, use the following statement:

```
ALTER TABLE table_name DROP STATS_EXTENDED stats_name;
```

How it works

After you execute the statement, TiDB marks the value of the corresponding object in `mysql.stats_extended`'s column `status` to `2`, instead of deleting the object directly.

Other TiDB nodes will read this change and delete the object in their memory cache. The background garbage collection will delete the object eventually.

> **Warning:**
>
> It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can use the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

Export and import extended statistics

The way of exporting or importing extended statistics is the same as exporting or importing basic statistics. See Introduction to Statistics - Import and export statistics for details.

Usage examples for correlation-type extended statistics

Currently, TiDB only supports the correlation-type extended statistics. This type is used to estimate the number of rows in the range query and improve index selection. The following example shows how the correlation-type extended statistics are used to estimate the number of rows in a range query.

Step 1. Define the table

Define a table `t` as follows:

```
CREATE TABLE t(col1 INT, col2 INT, KEY(col1), KEY(col2));
```

Suppose that `col1` and `col2` of table `t` both obey monotonically increasing constraints in row order. This means that the values of `col1` and `col2` are strictly correlated in order, and the correlation factor is `1`.

Step 2. Execute an example query without extended statistics

Execute the following query without using extended statistics:

```
SELECT * FROM t WHERE col1 > 1 ORDER BY col2 LIMIT 1;
```

For the execution of the preceding query, the TiDB optimizer has the following options to access table `t`:

- Uses the index on `col1` to access table `t` and then sorts the result by `col2` to calculate `Top-1`.
- Uses the index on `col2` to meet the first row that satisfies `col1 > 1`. The cost of this access method mainly depends on how many rows are filtered out when TiDB scans the table in `col2`'s order.

Without extended statistics, the TiDB optimizer only supposes that `col1` and `col2` are independent, which **leads to a significant estimation error**.

Step 3. Enable extended statistics

Set `tidb_enable_extended_stats` to `ON`, and register the extended statistics object for `col1` and `col2`:

```
ALTER TABLE t ADD STATS_EXTENDED s1 correlation(col1, col2);
```

When you execute `ANALYZE` after the registration, TiDB calculates the Pearson correlation coefficient of `col` and `col2` of table `t`, and writes the object into the `mysql.stats_extended` table.

Step 4. See how extended statistics make a difference

After TiDB has the extended statistics for correlation, the optimizer can estimate how many rows to be scanned more precisely.

At this time, for the query in Stage 2. Execute an example query without extended statistics, `col1` and `col2` are strictly correlated in order. If TiDB accesses table `t` by using the index on `col2` to meet the first row that satisfies `col1 > 1`, the TiDB optimizer will equivalently translate the row count estimation into the following query:

```
SELECT * FROM t WHERE col1 <= 1 OR col1 IS NULL;
```

The preceding query result plus one will be the final estimation for the row count. In this way, you do not need to use the independent assumption and **the significant estimation error is avoided**.

If the correlation factor (`1` in this example) is less than the value of the system variable `tidb_opt_correlation_threshold`, the optimizer will use the independent assumption, but it will also increase the estimation heuristically. The larger the value of `tidb_opt_correlation_exp_factor`, the larger the estimation result. The larger the absolute value of the correlation factor, the larger the estimation result.

11.3.3.3.5 Wrong Index Solution

If you find that the execution speed of some query does not reach the expectation, the optimizer might choose the wrong index to run the query.

You can first view the health state of tables in the statistics, and then solve this issue according to the different health states.

Low health state

The low health state means TiDB has not performed the`ANALYZE` statement for a long time. You can update the statistics by running the `ANALYZE` command. After the update, if the optimizer still uses the wrong index, refer to the next section.

Near 100% health state

The near 100% health state suggests that the `ANALYZE` statement is just completed or was completed a short time ago. In this case, the wrong index issue might be related to TiDB's estimation logic for the number of rows.

For equivalence queries, the cause might be Count-Min Sketch. You can check whether Count-Min Sketch is the cause and take corresponding solutions.

If the cause above does not apply to your problem, you can force-select indexes by using the `USE_INDEX` or `use index` optimzer hint (see USE_INDEX for details). Also, you can change the query behavior by using SQL Plan Management in a non-intrusive way.

Other situations

Apart from the aforementioned situations, the wrong index issue might also be caused by data updates which renders all the indexes no longer applicable. In such cases, you need to perform analysis on the conditions and data distribution to see whether new indexes can speed up the query. If so, you can add new indexes by running the `ADD INDEX` command.

11.3.3.3.6 Distinct Optimization

This document introduces the `distinct` optimization in the TiDB query optimizer, including `SELECT DISTINCT` and `DISTINCT` in the aggregate functions.

`DISTINCT` modifier in `SELECT` statements

The `DISTINCT` modifier specifies removal of duplicate rows from the result set. `SELECT DISTINCT` is transformed to `GROUP BY`, for example:

```
mysql> explain SELECT DISTINCT a from t;
+--
   ↪ ----------------------+---------+-----------+--------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                               |
+--
   ↪ ----------------------+---------+-----------+--------------+----------------
   ↪
| HashAgg_6             | 2.40    | root      |               | group by:test.t.a
   ↪ , funcs:firstrow(test.t.a)->test.t.a |
| └─TableReader_11      | 3.00    | root      |               | data:
   ↪ TableFullScan_10                          |
|   └─TableFullScan_10  | 3.00    | cop[tikv] | table:t       | keep order:false
   ↪ , stats:pseudo                |
+--
   ↪ ----------------------+---------+-----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

`DISTINCT` option in aggregate functions

Usually, aggregate functions with the `DISTINCT` option is executed in the TiDB layer in a single-threaded execution model.

The tidb_opt_distinct_agg_push_down system variable or the distinct-agg-push-down configuration item in TiDB controls whether to rewrite the distinct aggregate queries and push them to the TiKV or TiFlash Coprocessor.

Take the following queries as an example of this optimization. tidb_opt_distinct_agg_push_down is disabled by default, which means the aggregate functions are executed in the TiDB layer. After enabling this optimization by setting its value to 1, the distinct a part of count(distinct a) is pushed to TiKV or TiFlash Coprocessor: there is a HashAgg_5 to remove the duplicated values on column a in the TiKV Coprocessor. It might reduce the computation overhead of HashAgg_8 in the TiDB layer.

```
mysql> desc select count(distinct a) from test.t;
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                     |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| StreamAgg_6           | 1.00    | root    |               | funcs:count(
   ↪ distinct test.t.a)->Column#4 |
|  ─TableReader_10      | 10000.00 | root    |               | data:
   ↪ TableFullScan_9                |
|    ─TableFullScan_9   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo      |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
3 rows in set (0.01 sec)

mysql> set session tidb_opt_distinct_agg_push_down = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> desc select count(distinct a) from test.t;
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                     |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| HashAgg_8             | 1.00    | root    |               | funcs:count(
   ↪ distinct test.t.a)->Column#3 |
|  ─TableReader_9       | 1.00    | root    |               | data:HashAgg_5
```

```
    ↪                          |
|    └─HashAgg_5           | 1.00    | cop[tikv] |              | group by:test.
    ↪ t.a,                   |
|      └─TableFullScan_7   | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo      |
+--
    ↪ ------------------------+---------+-----------+--------------+-------------
    ↪
4 rows in set (0.00 sec)
```

11.3.3.3.7 Cost Model

TiDB uses a cost model to choose an index and operator during physical optimization. The process is illustrated in the following diagram:

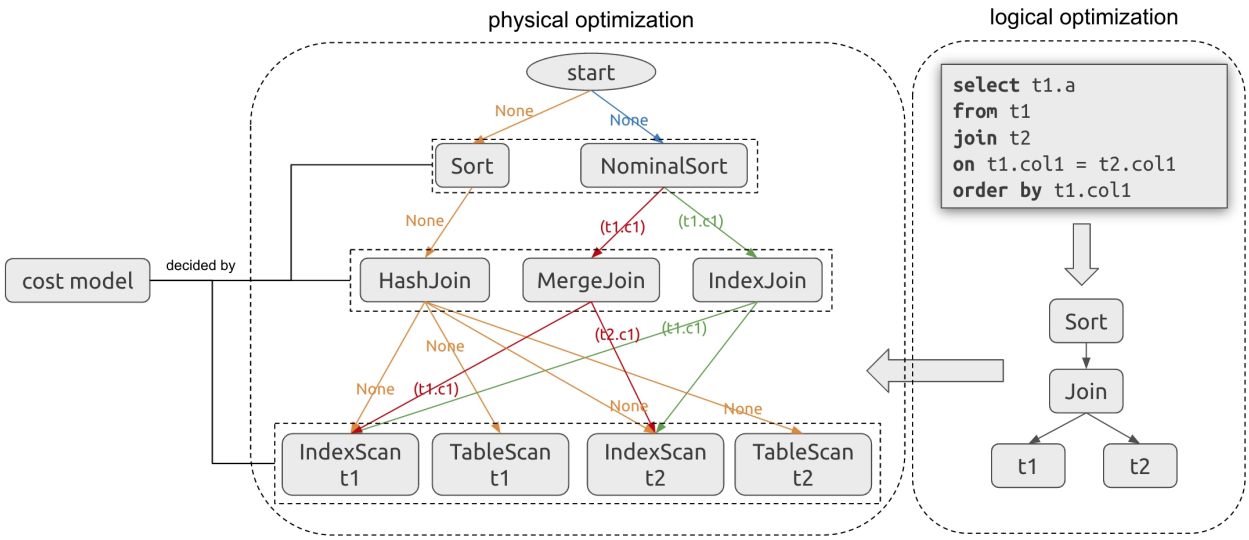

Figure 387: CostModel

TiDB calculates the access cost of each index and the execution cost of each physical operator in plans (such as HashJoin and IndexJoin) and chooses the minimum cost plan.

The following is a simplified example to explain how the cost model works. Suppose that there is a table `t`:

```
mysql> SHOW CREATE TABLE t;
+--
    ↪ -----+-----------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
```

```
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) DEFAULT NULL,
  KEY `b` (`b`),
  KEY `c` (`c`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

When executing the `SELECT * FROM t WHERE b < 100 and c < 100` statement, suppose that TiDB estimates 20 rows meet the `b < 100` condition and 500 rows meet `c < 100`, and the length of `INT` type indexes is 8. Then TiDB calculates the cost for two indexes:

- The cost of index `b` = row count of `b < 100` * length of index `b` = 20 * 8 = 160
- The cost of index `c` = row count of `c < 100` * length of index `c` = 500 * 8 = 4000

Because the cost of index `b` is lower, TiDB chooses `b` as the index.

The preceding example is simplified and only used to explain the basic principle. In real SQL executions, the TiDB cost model is more complex.

Cost Model Version 2

TiDB v6.2.0 introduces Cost Model Version 2, a new cost model.

Cost Model Version 2 provides a more accurate regression calibration of the cost formula, adjusts some of the cost formulas, and is more accurate than the previous version of the cost formula.

To switch the version of cost model, you can set the `tidb_cost_model_version` variable.

> **Note:**
>
> Switching the version of the cost model might cause changes to query plans.

11.3.3.4 SQL Prepared Execution Plan Cache

Warning:

If a cached `UPDATE` or `DELETE` statement encounters a DDL operation that modifies the relevant schema during execution, it might cause data inconsistency between tables and indexes. For more information, see Issue #51407. It is recommended to monitor the status of this issue and upgrade to the latest LTS version to resolve this issue. Before upgrading, you can try the following workarounds:

- Before executing DDL, temporarily disable the prepared plan cache, and re-enable it after the DDL is complete.
- Avoid executing DDL during business peak hours. After executing DDL, immediately run `ADMIN CHECK TABLE` to check the consistency between tables and indexes. If errors are found, rebuild the relevant indexes.

TiDB supports execution plan caching for `Prepare` and `Execute` queries. This includes both forms of prepared statements:

- Using the `COM_STMT_PREPARE` and `COM_STMT_EXECUTE` protocol features.
- Using the SQL statements `PREPARE` and `EXECUTE`.

The TiDB optimizer handles these two types of queries in the same way: when preparing, the parameterized query is parsed into an AST (Abstract Syntax Tree) and cached; in later execution, the execution plan is generated based on the stored AST and specific parameter values.

When the execution plan cache is enabled, in the first execution every `Prepare` statement checks whether the current query can use the execution plan cache, and if the query can use it, then put the generated execution plan into a cache implemented by LRU (Least Recently Used) linked list. In the subsequent `Execute` queries, the execution plan is obtained from the cache and checked for availability. If the check succeeds, the step of generating an execution plan is skipped. Otherwise, the execution plan is regenerated and saved in the cache.

TiDB also supports execution plan caching for some non-`PREPARE` statements, similar to the `Prepare`/`Execute` statements. For more details, refer to Non-prepared plan cache.

In the current version of TiDB, if a `Prepare` statement meets any of the following conditions, the query or the plan is not cached:

- The query contains SQL statements other than `SELECT`, `UPDATE`, `INSERT`, `DELETE`, `Union`, `Intersect`, and `Except`.
- The query accesses partitioned tables or temporary tables, or a table that contains generated columns.

- The query contains non-correlated sub-queries, such as `SELECT * FROM t1 WHERE t1 ↪ .a > (SELECT 1 FROM t2 WHERE t2.b < 1)`.
- The query contains correlated sub-queries with `PhysicalApply` operators in the execution plan, such as `SELECT * FROM t1 WHERE t1.a > (SELECT a FROM t2 WHERE ↪ t1.b > t2.b)`.
- The query contains the `ignore_plan_cache` hint, such as `select /*+ ignore_plan_cache ↪ ()*/ * from t`.
- The query contains variables other than `?` (including system variables or user-defined variables), such as `select * from t where a>? and b>@x`.
- The query contains the functions that cannot be cached: `database()`, `current_user ↪ `, `current_role`, `user`, `connection_id`, `last_insert_id`, `row_count`, `version`, and `like`.
- The query uses a variable as the `LIMIT` parameter (such as `LIMIT ?` and `LIMIT 10, ?`) and the variable value is greater than 10000.
- The query contains `?` after `Order By`, such as `Order By ?`. Such queries sort data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Order By a+?`, it is cached.
- The query contains `?` after `Group By`, such as `Group By?`. Such queries group data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Group By a+?`, it is cached.
- The query contains `?` in the definition of the `Window Frame` window function, such as `(partition by year order by sale rows ? preceding)`. If `?` appears elsewhere in the window function, the query is cached.
- The query contains parameters for comparing `int` and `string`, such as `c_int >= ? ↪ ` or `c_int in (?, ?)`, in which `?` indicates the string type, such as `set @x='123'`. To ensure that the query result is compatible with MySQL, parameters need to be adjusted in each query, so such queries are not cached.
- The plan attempts to access `TiFlash`.
- In most cases, the plan that contains `TableDual` is not cached, unless the current `Prepare` statement does not have parameters.

The LRU linked list is designed as a session-level cache because `Prepare`/`Execute` cannot be executed across sessions. Each element of the LRU list is a key-value pair. The value is the execution plan, and the key is composed of the following parts:

- The name of the database where `Execute` is executed
- The identifier of the `Prepare` statement, that is, the name after the `PREPARE` keyword
- The current schema version, which is updated after every successfully executed DDL statement
- The SQL mode when executing `Execute`
- The current time zone, which is the value of the `time_zone` system variable
- The value of the `sql_select_limit` system variable

Any change in the preceding information (for example, switching databases, renaming `Prepare` statement, executing DDL statements, or modifying the value of SQL mode/`time_zone`), or the LRU cache elimination mechanism causes the execution plan cache miss when executing.

After the execution plan cache is obtained from the cache, TiDB first checks whether the execution plan is still valid. If the current `Execute` statement is executed in an explicit transaction, and the referenced table is modified in the transaction pre-order statement, the cached execution plan accessing this table does not contain the `UnionScan` operator, then it cannot be executed.

After the validation test is passed, the scan range of the execution plan is adjusted according to the current parameter values, and then used to perform data querying.

There are several points worth noting about execution plan caching and query performance:

- No matter an execution plan is cached or not, it is affected by SQL bindings. For execution plans that have not been cached (the first `Execute`), these plans are affected by existing SQL bindings. For execution plans that have been cached, if new SQL Bindings are created, these plans become invalid.
- Cached plans are not affected by changes in statistics, optimization rules, and blocklist pushdown by expressions.
- Considering that the parameters of `Execute` are different, the execution plan cache prohibits some aggressive query optimization methods that are closely related to specific parameter values to ensure adaptability. This causes that the query plan may not be optimal for certain parameter values. For example, the filter condition of the query is `where a > ? And a < ?`, the parameters of the first `Execute` statement are `2` and `1` respectively. Considering that these two parameters maybe be `1` and `2` in the next execution time, the optimizer does not generate the optimal `TableDual` execution plan that is specific to current parameter values;
- If cache invalidation and elimination are not considered, an execution plan cache is applied to various parameter values, which in theory also results in non-optimal execution plans for certain values. For example, if the filter condition is `where a < ?` and the parameter value used for the first execution is `1`, then the optimizer generates the optimal `IndexScan` execution plan and puts it into the cache. In the subsequent executions, if the value becomes `10000`, the `TableScan` plan might be the better one. But due to the execution plan cache, the previously generated `IndexScan` is used for execution. Therefore, the execution plan cache is more suitable for application scenarios where the query is simple (the ratio of compilation is high) and the execution plan is relatively fixed.

Starting from v6.1.0, the execution plan cache is enabled by default. You can control prepared plan cache via the system variable `tidb_enable_prepared_plan_cache`.

> **Note:**
>
> The execution plan cache feature applies only to `Prepare`/`Execute` queries and does not take effect for normal queries.

After the execution plan cache feature is enabled, you can use the session-level system variable `last_plan_from_cache` to see whether the previous `Execute` statement used the cached execution plan, for example:

```
MySQL [test]> create table t(a int);
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> prepare stmt from 'select * from t where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)

-- The first execution generates an execution plan and saves it in the
   ↪ cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+

If you find that a certain set of `Prepare`/`Execute` has unexpected behavior due to the execution plan cache, you can use the `ignore_plan_cache()` SQL hint to skip using the execution plan cache for the current statement. Still, use the preceding statement as an example:

```
MySQL [test]> prepare stmt from 'select /*+ ignore_plan_cache() */ * from t
    ↪  where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;

1 row in set (0.00 sec)
```

11.3.3.4.1 Diagnostics of Prepared Plan Cache

Some queries or plans cannot be cached. You can use the `SHOW WARNINGS` statement to check whether the query or plan is cached. If it is not cached, you can check the reason for the failure in the result. For example:

```
mysql> PREPARE st FROM 'SELECT * FROM t WHERE a > (SELECT MAX(a) FROM t)';
    ↪ -- The query contains a subquery and cannot be cached.

Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> show warnings; -- Checks the reason why the query plan cannot be
    ↪ cached.

+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1105 | skip plan-cache: sub-queries are un-cacheable |
+---------+------+-----------------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> prepare st from 'select * from t where a<?';

Query OK, 0 rows affected (0.00 sec)

mysql> set @a='1';

Query OK, 0 rows affected (0.00 sec)

mysql> execute st using @a; -- The optimization converts a non-INT type to
    ↪  an INT type, and the execution plan might change with the change of
    ↪  the parameter, so TiDB does not cache the plan.

Empty set, 1 warning (0.01 sec)

mysql> show warnings;

+---------+------+-------------------------------------------------+
| Level   | Code | Message                                         |
+---------+------+-------------------------------------------------+
| Warning | 1105 | skip plan-cache: '1' may be converted to INT |
+---------+------+-------------------------------------------------+
1 row in set (0.00 sec)
```

11.3.3.4.2 Memory management of Prepared Plan Cache

Using Prepared Plan Cache incurs memory overhead. To view the total memory consumption by the cached execution plans of all sessions in each TiDB instance, you can use the **Plan Cache Memory Usage** monitoring panel in Grafana.

> **Note:**
>
> Because of the memory reclaim mechanism of Golang and some uncounted memory structures, the memory displayed in Grafana is not equal to the actual heap memory usage. It is tested that there is a deviation of about ±20% between the memory displayed in Grafana and the actual heap memory usage.

To view the total number of execution plans cached in each TiDB instance, you can use the **Plan Cache Plan Num** panel in Grafana.

The following is an example of the **Plan Cache Memory Usage** and **Plan Cache Plan Num** panels in Grafana:

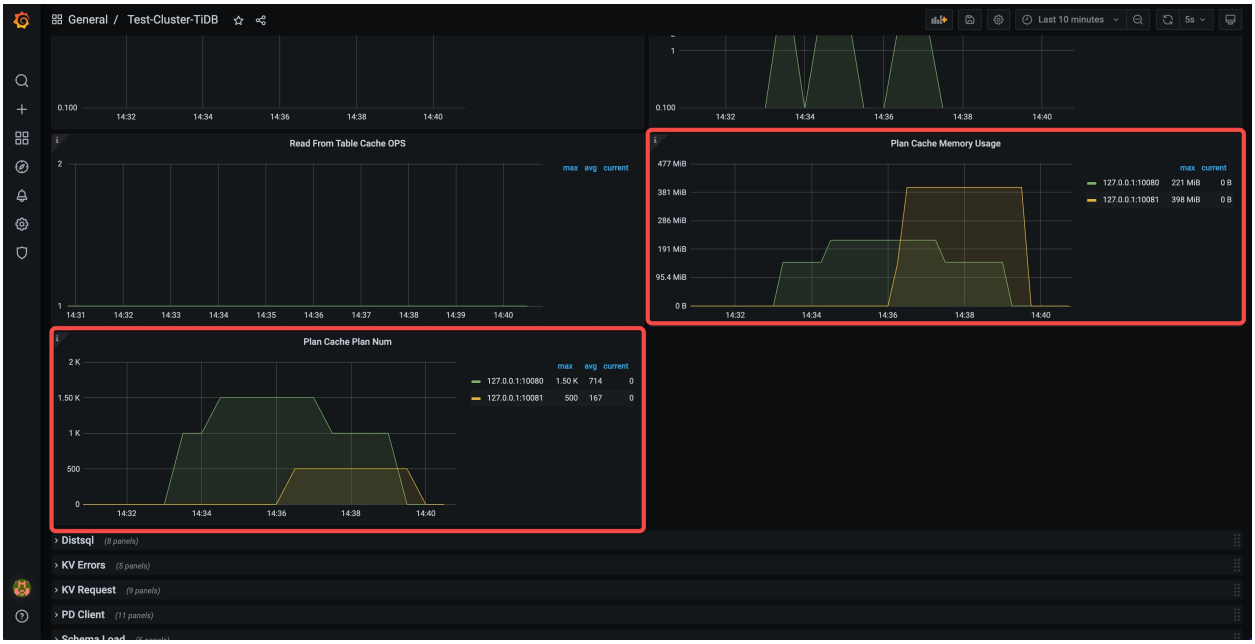

Figure 388: grafana_panels

Starting from v7.1.0, you can control the maximum number of plans that can be cached in each session by configuring the system variable `tidb_session_plan_cache_size`. For different environments, the recommended value is as follows and you can adjust it according to the monitoring panels:

- When the memory threshold of the TiDB server instance is <= 64 GiB, set `tidb_session_plan_cache_size` to `50`.
- When the memory threshold of the TiDB server instance is > 64 GiB, set `tidb_session_plan_cache_size` to `100`.

Starting from v7.1.0, you can control the maximum size of a plan that can be cached using the system variable `tidb_plan_cache_max_plan_size`. The default value is 2 MB. If the size of a plan exceeds this value, the plan will not be cached.

When the unused memory of the TiDB server is less than a certain threshold, the memory protection mechanism of plan cache is triggered, through which some cached plans will be evicted.

You can control the threshold by configuring the system variable `tidb_prepared_plan_cache_memory_` ↪ . The threshold is 0.1 by default, which means when the unused memory of the TiDB server is less than 10% of the total memory (90% of the memory is used), the memory protection mechanism is triggered.

Due to memory limit, plan cache might be missed sometimes. You can check the status by viewing the `Plan Cache Miss OPS` metric in the Grafana dashboard.

11.3.3.4.3 Clear execution plan cache

You can clear execution plan cache by executing the `ADMIN FLUSH [SESSION | INSTANCE] PLAN_CACHE` statement.

In this statement, `[SESSION | INSTANCE]` specifies whether the plan cache is cleared for the current session or the whole TiDB instance. If the scope is not specified, the preceding statement applies to the `SESSION` cache by default.

The following is an example of clearing the `SESSION` execution plan cache:

```
MySQL [test]> create table t (a int);
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> prepare stmt from 'select * from t';
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- Select the cached plan
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)

MySQL [test]> admin flush session plan_cache; -- Clear the cached plan of
    ↪ the current session
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- The cached plan cannot be
    ↪ selected again, because it has been cleared
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      0 |
+------------------------+
1 row in set (0.00 sec)
```

Currently, TiDB does not support clearing `GLOBAL` execution plan cache. That means you cannot clear the cached plan of the whole TiDB cluster. The following error is reported if you try to clear the `GLOBAL` execution plan cache:

```
MySQL [test]> admin flush global plan_cache;
ERROR 1105 (HY000): Do not support the 'admin flush global scope.'
```

11.3.3.4.4 Ignore the `COM_STMT_CLOSE` command and the `DEALLOCATE PREPARE` statement

To reduce the syntax parsing cost of SQL statements, it is recommended that you run `prepare stmt` once, then `execute stmt` multiple times before running `deallocate prepare`:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...; -- Execute once
MySQL [test]> ...
MySQL [test]> execute stmt using ...; -- Execute multiple times
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In real practice, you may be used to running `deallocate prepare` each time after running `execute stmt`, as shown below:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
MySQL [test]> prepare stmt from '...'; -- Prepare twice
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In such practice, the plan obtained by the first executed statement cannot be reused by the second executed statement.

To address the problem, you can set the system variable `tidb_ignore_prepared_cache_close_stmt` to `ON` so TiDB ignores commands to close `prepare stmt`:

```
mysql> set @@tidb_ignore_prepared_cache_close_stmt=1; -- Enable the
    ↪ variable
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare once
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt;                    -- Execute once
Empty set (0.00 sec)

mysql> deallocate prepare stmt;         -- Release after the first execute
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare twice
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt;                    -- Execute twice
Empty set (0.00 sec)

mysql> select @@last_plan_from_cache;  -- Reuse the last plan
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)
```

Monitoring

In the Grafana dashboard on the TiDB page in the **Executor** section, there are the "Queries Using Plan Cache OPS" and "Plan Cache Miss OPS" graphs. These graphs can be used to check if both TiDB and the application are configured correctly to allow the SQL Plan Cache to work correctly. The **Server** section on the same page provides the "Prepared Statement Count" graph. This graph shows a non-zero value if the application uses prepared statements, which is required for the SQL Plan Cache to function correctly.

Figure 389: `sql_plan_cache`

11.3.3.5 SQL Non-Prepared Execution Plan Cache

Warning:

> The non-prepared execution plan cache is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

TiDB supports execution plan caching for some non-`PREPARE` statements, similar to the `Prepare/Execute` statements. This feature allows these statements to skip the optimization phase and improve performance.

11.3.3.5.1 Principle

The non-prepared plan cache is a session-level feature that shares a cache with the prepared plan cache. The basic principle of the non-prepared plan cache is as follows:

1. After you enable the non-prepared plan cache, TiDB first parameterizes the query based on the abstract syntax tree (AST). For example, `SELECT * FROM t WHERE b < 10 AND a = 1` is parameterized as `SELECT * FROM t WHERE b < ? and a = ?`.
2. Then, TiDB uses the parameterized query to search the plan cache.
3. If a reusable plan is found, it is directly used and the optimization phase is skipped.
4. Otherwise, the optimizer generates a new plan and adds it back into the cache for reuse in the subsequent query.

11.3.3.5.2 Usage

To enable or disable the non-prepared plan cache, you can set the `tidb_enable_non_prepared_plan_ca` system variable. You can also control the size of the non-prepared plan cache using the `tidb_session_plan_cache_size` system variable. When the number of cached plans exceeds `tidb_session_plan_cache_size`, TiDB evicts plans using the least recently used (LRU) strategy.

Starting from v7.1.0, you can control the maximum size of a plan that can be cached using the system variable `tidb_plan_cache_max_plan_size`. The default value is 2 MB. If the size of a plan exceeds this value, the plan will not be cached.

> **Note:**
>
> The memory specified by `tidb_session_plan_cache_size` is shared between the prepared and non-prepared plan cache. If you have enabled the prepared plan cache for the current cluster, enabling the non-prepared plan cache might reduce the hit rate of the original prepared plan cache.

11.3.3.5.3 Example

The following example shows how to use the non-prepared plan cache:

1. Create a table `t` for testing:

```
CREATE TABLE t (a INT, b INT, KEY(b));
```

2. Enable the non-prepared plan cache:

```
SET tidb_enable_non_prepared_plan_cache = ON;
```

3. Execute the following two queries:

```
SELECT * FROM t WHERE b < 10 AND a = 1;
SELECT * FROM t WHERE b < 5 AND a = 2;
```

4. Check whether the second query hits the cache:

```
SELECT @@last_plan_from_cache;
```

   If the value of `last_plan_from_cache` in the output is `1`, it means that the execution plan of the second query comes from the cache:

```
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)
```

11.3.3.5.4 Restrictions

Cache suboptimal plans

TiDB only caches one plan for a parameterized query. For example, the queries `SELECT * FROM t WHERE a < 1` and `SELECT * FROM t WHERE a < 100000` share the same parameterized form, `SELECT * FROM t WHERE a < ?`, and thus share the same plan.

If this causes performance issues, you can use the `ignore_plan_cache()` hint to ignore plans in the cache, so that the optimizer generates a new execution plan for the SQL every time. If the SQL cannot be modified, you can create a binding to solve the problem. For example, `CREATE BINDING FOR SELECT ... USING SELECT /*+ ignore_plan_cache()*/ ...`.

Usage restrictions

Due to the preceding risks and the fact that the execution plan cache only provides significant benefits for simple queries (if a query is complex and takes a long time to execute, using the execution plan cache might not be very helpful), TiDB has strict restrictions on the scope of non-prepared plan cache. The restrictions are as follows:

- Queries or plans that are not supported by the Prepared plan cache are also not supported by the non-prepared plan cache.
- Queries that contain complex operators such as `Window` or `Having` are not supported.
- Queries that contain three or more `Join` tables or subqueries are not supported.
- Queries that contain numbers or expressions directly after `ORDER BY` or `GROUP BY` are not supported, such as `ORDER BY 1` and `GROUP BY a+1`. Only `ORDER BY column_name` and `GROUP BY column_name` are supported.
- Queries that filter on columns of `JSON`, `ENUM`, `SET`, or `BIT` type are not supported, such as `SELECT * FROM t WHERE json_col = '{}'`.
- Queries that filter on `NULL` values are not supported, such as `SELECT * FROM t WHERE a is NULL`.
- Queries with more than 200 parameters after parameterization are not supported by default, such as `SELECT * FROM t WHERE a in (1, 2, 3, ... 201)`. Starting from v7.1.1, you can modify this limit using the `tidb_opt_fix_control` system variable.
- Queries that access partitioned tables, virtual columns, temporary tables, views, or memory tables are not supported, such as `SELECT * FROM INFORMATION_SCHEMA.COLUMNS`, where `COLUMNS` is a TiDB memory table.
- Queries with hints or bindings are not supported.
- DML statements or `SELECT` statements with the `FOR UPDATE` clause are not supported by default. To remove this restriction, you can execute `SET tidb_enable_non_prepared_plan_cache = ON`.

After you enable this feature, the optimizer quickly evaluates the query. If it does not meet the support conditions for non-prepared plan cache, the query falls back to the regular optimization process.

11.3.3.5.5 Performance benefits

In internal tests, enabling the non-prepared plan cache feature can achieve significant performance benefits in most TP scenarios. However, it also introduces some additional performance overhead, including determining whether the query is supported and parameterizing the query. If this feature cannot support the majority of queries in your workload, enabling it might actually adversely affect performance.

In this case, you need to observe the `non-prepared` metric in the **Queries Using Plan Cache OPS** panel and the `non-prepared-unsupported` metric in the **Plan Cache Miss OPS** panel on Grafana. If most queries are not supported and only a few can hit the plan cache, you can disable this feature.

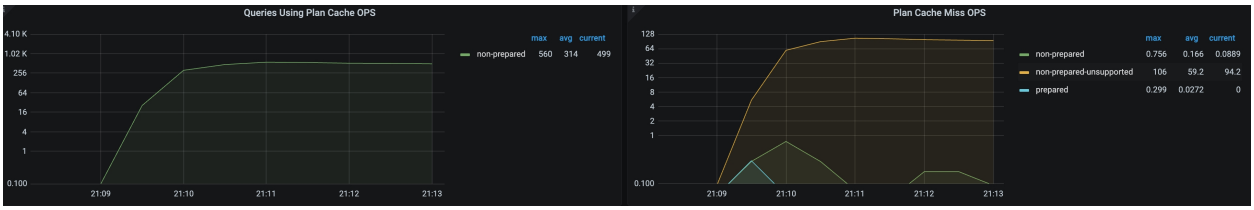

Figure 390: non-prepared-unsupported

11.3.3.5.6 Diagnostics

After enabling the non-prepared plan cache, you can execute the `EXPLAIN FORMAT='plan_cache' SELECT ...` statement to verify whether the query can hit the cache. For queries that cannot hit the cache, the system returns the reason in a warning.

Note that if you do not add `FORMAT='plan_cache'`, the `EXPLAIN` statement will never hit the cache.

To verify whether the query hits the cache, execute the following `EXPLAIN FORMAT='plan_cache'` statement:

```
EXPLAIN FORMAT='plan_cache' SELECT * FROM (SELECT a+1 FROM t) t;
```

The output is as follows:

```
3 rows in set, 1 warning (0.00 sec)
```

To view the queries that cannot hit the cache, execute `SHOW warnings;`:

```
SHOW warnings;
```

The output is as follows:

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                 |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | skip non-prepared plan-cache: queries that have sub-
    ↪ queries are not supported |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

In the preceding example, the query cannot hit the cache because the non-prepared plan cache does not support the + operation.

11.3.3.5.7 Monitoring

After enabling the non-prepared plan cache, you can monitor the memory usage, number of plans in the cache, and cache hit rate in the following panes:

Figure 391: non-prepare-plan-cache

You can also monitor the cache hit rate in the `statements_summary` table and slow query log. The following shows how to view the cache hit rate in the `statements_summary` table:

1. Create a table `t`:

```
CREATE TABLE t (a int);
```

2. Enable the non-prepared plan cache:

```
SET @@tidb_enable_non_prepared_plan_cache=ON;
```

3. Execute the following three queries:

```
SELECT * FROM t WHERE a<1;
SELECT * FROM t WHERE a<2;
SELECT * FROM t WHERE a<3;
```

4. Query the `statements_summary` table to view the cache hit rate:

```
SELECT digest_text, query_sample_text, exec_count, plan_in_cache,
    ↪ plan_cache_hits FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE
    ↪  query_sample_text LIKE '%SELECT * FROM %';
```

The output is as follows:

```
+--
    ↪ ------------------------------+------------------------------------+
    ↪
| digest_text                   | query_sample_text                    |
    ↪ exec_count | plan_in_cache | plan_cache_hits |
+--
    ↪ ------------------------------+------------------------------------+
    ↪
| SELECT * FROM `t` WHERE `a` < ? | SELECT * FROM t WHERE a<1      |
    ↪         3 |             1 |              2 |
+--
    ↪ ------------------------------+------------------------------------+
    ↪
1 row in set (0.01 sec)
```

From the output, you can see that the query was executed three times and hit the cache twice.

11.3.4 Control Execution Plans

11.3.4.1 Control Execution Plan

The first two chapters of SQL Tuning introduce how to understand TiDB's execution plan and how TiDB generates an execution plan. This chapter introduces what methods can be used to control the generation of the execution plan when you determine the problems with the execution plan. This chapter mainly includes the following three aspects:

- In Optimizer Hints, you will learn how to use hints to guide TiDB to generate an execution plan.
- But hints change the SQL statement intrusively. In some scenarios, hints cannot be simply inserted. In SQL Plan Management, you will know how TiDB uses another syntax to non-intrusively control the generation of execution plans, and the methods of automatic execution plan evolution in the background. This method helps address issues such as execution plan instability caused by version upgrades and cluster performance degradation.
- Finally, you will learn how to use the blocklist in Blocklist of Optimization Rules and Expression Pushdown.

Besides the preceding methods, the execution plan is also affected by some system variables. By modifying these variables at the system level or session level, you can control the generation of the execution plan. Starting from v6.5.3 and v7.1.0, TiDB introduces a relatively special variable `tidb_opt_fix_control`. This variable can accept multiple control items to control the behavior of the optimizer in a more fine-grained way, to prevent performance regression caused by behavior changes in the optimizer after cluster upgrade. Refer to Optimizer Fix Controls for a more detailed introduction.

11.3.4.2 Optimizer Hints

TiDB supports optimizer hints, which are based on the comment-like syntax introduced in MySQL 5.7. For example, one of the common syntaxes is `/*+ HINT_NAME([t1_name [, t2_name] ...])*/`. Use of optimizer hints is recommended in cases where the TiDB optimizer selects a less optimal query plan.

If you encounter a situation where hints do not take effect, see Troubleshoot common issues that hints do not take effect.

11.3.4.2.1 Syntax

Optimizer hints are case insensitive and specified within `/*+ ... */` comments following the `SELECT`, `UPDATE` or `DELETE` keyword in a SQL statement. Optimizer hints are not currently supported for `INSERT` statements.

Multiple hints can be specified by separating with commas. For example, the following query uses three different hints:

```
SELECT /*+ USE_INDEX(t1, idx1), HASH_AGG(), HASH_JOIN(t1) */ count(*) FROM t t1, t t2 WHERE t1.a = t2.b;
```

How optimizer hints affect query execution plans can be observed in the output of `EXPLAIN` and `EXPLAIN ANALYZE`.

An incorrect or incomplete hint will not result in a statement error. This is because hints are intended to have only a *hint* (suggestion) semantic to query execution. Similarly, TiDB will at most return a warning if a hint is not applicable.

> **Note:**
>
> If the comments do not follow behind the specified keywords, they will be treated as common MySQL comments. The comments do not take effect, and no warning is reported.

Currently, TiDB supports two categories of hints, which are different in scope. The first category of hints takes effect in the scope of query blocks, such as `/*+ HASH_AGG()*/`; the second category of hints takes effect in the whole query, such as `/*+ MEMORY_QUOTA(1024 MB)*/`.

Each query or sub-query in a statement corresponds to a different query block, and each query block has its own name. For example:

```
SELECT * FROM (SELECT * FROM t) t1, (SELECT * FROM t) t2;
```

The above query statement has three query blocks: the outermost `SELECT` corresponds to the first query block, whose name is `sel_1`; the two `SELECT` sub-queries correspond to the second and the third query block, whose names are `sel_2` and `sel_3`, respectively. The sequence of the numbers is based on the appearance of `SELECT` from left to right. If you replace the first `SELECT` with `DELETE` or `UPDATE`, then the corresponding query block names are `del_1` or `upd_1`.

11.3.4.2.2 Hints that take effect in query blocks

This category of hints can follow behind **any** `SELECT`, `UPDATE` or `DELETE` keywords. To control the effective scope of the hint, use the name of the query block in the hint. You can make the hint parameters clear by accurately identifying each table in the query (in case of duplicated table names or aliases). If no query block is specified in the hint, the hint takes effect in the current block by default.

For example:

```
SELECT /*+ HASH_JOIN(@sel_1 t1@sel_1, t3) */ * FROM (SELECT t1.a, t1.b
    ↪ FROM t t1, t t2 WHERE t1.a = t2.a) t1, t t3 WHERE t1.b = t3.b;
```

This hint takes effect in the `sel_1` query block, and its parameters are the `t1` and `t3` tables in `sel_1` (`sel_2` also contains a `t1` table).

As described above, you can specify the name of the query block in the hint in the following ways:

- Set the query block name as the first parameter of the hint, and separate it from other parameters with a space. In addition to `QB_NAME`, all the hints listed in this section also have another optional hidden parameter `@QB_NAME`. By using this parameter, you can specify the effective scope of this hint.
- Append `@QB_NAME` to a table name in the parameter to explicitly specify which query block this table belongs to.

> **Note:**
>
> You must put the hint in or before the query block where the hint takes effect. If the hint is put after the query block, it cannot take effect.

QB_NAME

If the query statement is a complicated statement that includes multiple nested queries, the ID and name of a certain query block might be mistakenly identified. The hint `QB_NAME` can help us in this regard.

`QB_NAME` means Query Block Name. You can specify a new name to a query block. The specified `QB_NAME` and the previous default name are both valid. For example:

```
SELECT /*+ QB_NAME(QB1) */ * FROM (SELECT * FROM t) t1, (SELECT * FROM t)
    ↪ t2;
```

This hint specifies the outer `SELECT` query block's name to `QB1`, which makes `QB1` and the default name `sel_1` both valid for the query block.

> **Note:**
>
> In the above example, if the hint specifies the `QB_NAME` to `sel_2` and does not specify a new `QB_NAME` for the original second `SELECT` query block, then `sel_2` becomes an invalid name for the second `SELECT` query block.

MERGE_JOIN(t1_name [, tl_name ...])

The `MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the sort-merge join algorithm for the given table(s). Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ MERGE_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_SMJ` is the alias for `MERGE_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_SMJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_SMJ` and `MERGE_JOIN` are both valid names for the hint, but `MERGE_JOIN` is recommended.

NO_MERGE_JOIN(t1_name [, tl_name ...])

The `NO_MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the sort-merge join algorithm for the given table(s). For example:

```
SELECT /*+ NO_MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

INL_JOIN(t1_name [, tl_name ...])

Note:

In some cases, the `INL_JOIN` hint might not take effect. For more information, see `INL_JOIN` hint does not take effect.

The `INL_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the index nested loop join algorithm for the given table(s). This algorithm might consume less system resources and take shorter processing time in some scenarios and might produce an opposite result in other scenarios. If the result set is less than 10,000 rows after the outer table is filtered by the `WHERE` condition, it is recommended to use this hint. For example:

```
SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id AND t2
    ↪ .id = t3.id;
```

In the preceding SQL statement, the `INL_JOIN(t1, t2)` hint tells the optimizer to use the index nested loop join algorithm for `t1` and `t2`. Note that this does not mean that the index nested loop join algorithm is used between `t1` and `t2`. Instead, the hint indicates that `t1` and `t2` each use the index nested loop join algorithm with another table (`t3`).

The parameter(s) given in `INL_JOIN()` is the candidate table for the inner table when you create the query plan. For example, `INL_JOIN(t1)` means that TiDB only considers using `t1` as the inner table to create a query plan. If the candidate table has an alias, you must use the alias as the parameter in `INL_JOIN()`; if it does not have an alias, use the table's original name as the parameter. For example, in the `select /*+ INL_JOIN(t1)*/ * from t t1, t t2 where t1.a = t2.b;` query, you must use the `t` table's alias `t1` or `t2` rather than `t` as `INL_JOIN()`'s parameter.

Note:

`TIDB_INLJ` is the alias for `INL_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_INLJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_INLJ` and `INL_JOIN` are both valid names for the hint, but `INL_JOIN` is recommended.

NO_INDEX_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop join algorithm for the given table(s). For example:

```
SELECT /*+ NO_INDEX_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

INL_HASH_JOIN

The `INL_HASH_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop hash join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm. The difference between the two algorithms is that `INL_JOIN` creates a hash table on the joined inner table, but `INL_HASH_JOIN` creates a hash table on the joined outer table. `INL_HASH_JOIN` has a fixed limit on memory usage, while the memory used by `INL_JOIN` depends on the number of rows matched in the inner table.

NO_INDEX_HASH_JOIN(t1_name [, tl_name …])

The `NO_INDEX_HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop hash join algorithm for the given table(s).

INL_MERGE_JOIN

The `INL_MERGE_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop merge join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm.

NO_INDEX_MERGE_JOIN(t1_name [, tl_name …])

The `NO_INDEX_MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop merge join algorithm for the given table(s).

HASH_JOIN(t1_name [, tl_name …])

The `HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm for the given table(s). This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_HJ` is the alias for `HASH_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_HJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_HJ` and `HASH_JOIN` are both valid names for the hint, but `HASH_JOIN` is recommended.

NO_HASH_JOIN(t1_name [, tl_name …])

The `NO_HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the hash join algorithm for the given table(s). For example:

```
SELECT /*+ NO_HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

HASH_JOIN_BUILD(t1_name [, tl_name ...])

The `HASH_JOIN_BUILD(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the build side. In this way, you can build hash tables using specific tables. For example:

```
SELECT /*+ HASH_JOIN_BUILD(t1) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

HASH_JOIN_PROBE(t1_name [, tl_name ...])

The `HASH_JOIN_PROBE(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the probe side. In this way, you can execute the hash join algorithm with specific tables as the probe side. For example:

```
SELECT /*+ HASH_JOIN_PROBE(t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

SEMI_JOIN_REWRITE()

The `SEMI_JOIN_REWRITE()` hint tells the optimizer to rewrite the semi-join query to an ordinary join query. Currently, this hint only works for `EXISTS` subqueries.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

```
-- Does not use SEMI_JOIN_REWRITE() to rewrite the query.
EXPLAIN SELECT * FROM t WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t.a);
```

```

    ↪
```

From the preceding example, you can see that when using the `SEMI_JOIN_REWRITE()` hint, TiDB can select the execution method of IndexJoin based on the driving table `t1`.

SHUFFLE_JOIN(t1_name [, tl_name ...])

The `SHUFFLE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the Shuffle Join algorithm on specified tables. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ SHUFFLE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

Note:

- Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.
- This hint can be used in combination with the `HASH_JOIN_BUILD` hint and `HASH_JOIN_PROBE` hint to control the Build side and Probe side of the Shuffle Join algorithm.

BROADCAST_JOIN(t1_name [, tl_name ...])

`BROADCAST_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the Broadcast Join algorithm on specified tables. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ BROADCAST_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

Note:

- Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

- This hint can be used in combination with the HASH_JOIN_BUILD hint and HASH_JOIN_PROBE hint to control the Build side and Probe side of the Broadcast Join algorithm.

NO_DECORRELATE()

The NO_DECORRELATE() hint tells the optimizer not to try to perform decorrelation for the correlated subquery in the specified query block. This hint is applicable to the EXISTS, IN, ANY, ALL, SOME subqueries and scalar subqueries that contain correlated columns (that is, correlated subqueries).

When this hint is used in a query block, the optimizer will not try to perform decorrelation for the correlated columns between the subquery and its outer query block, but always use the Apply operator to execute the query.

By default, TiDB tries to perform decorrelation for correlated subqueries to achieve higher execution efficiency. However, in some scenarios, decorrelation might actually reduce the execution efficiency. In this case, you can use this hint to manually tell the optimizer not to perform decorrelation. For example:

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
```

```
-- Not using NO_DECORRELATE().
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

    ↪ order:false, stats:pseudo
    ↪                                                                  |
+--
    ↪ --------------------------------+---------+----------+--------------+--------
    ↪
```

From the preceding execution plan, you can see that the optimizer has automatically performed decorrelation. The decorrelated execution plan does not have the Apply operator. Instead, the plan has join operations between the subquery and the outer query block. The original filter condition (`t2.b = t1.b`) with the correlated column becomes a regular join condition.

```
-- Using NO_DECORRELATE().
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);
```

|            ─TableRowIDScan_43(Probe)  | 100000.00 | cop[tikv] | table:t2
   ↪          | keep order:false, stats:pseudo
   ↪                                                    |
+--
   ↪ ------------------------------------+----------+----------+--------------
   ↪
```

From the preceding execution plan, you can see that the optimizer does not perform decorrelation. The execution plan still contains the Apply operator. The filter condition (`t2.b = t1.b`) with the correlated column is still the filter condition when accessing the `t2` table.

HASH_AGG()

The `HASH_AGG()` hint tells the optimizer to use the hash aggregation algorithm in all the aggregate functions in the specified query block. This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.
    ↪ id;
```

STREAM_AGG()

The `STREAM_AGG()` hint tells the optimizer to use the stream aggregation algorithm in all the aggregate functions in the specified query block. Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ STREAM_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1
    ↪ .id;
```

MPP_1PHASE_AGG()

`MPP_1PHASE_AGG()` tells the optimizer to use the one-phase aggregation algorithm for all aggregate functions in the specified query block. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ MPP_1PHASE_AGG() */ COUNT(*) FROM t1, t2 WHERE t1.a > 10 GROUP
    ↪ BY t1.id;
```

Note:

Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

MPP_2PHASE_AGG()

`MPP_2PHASE_AGG()` tells the optimizer to use the two-phase aggregation algorithm for all aggregate functions in the specified query block. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ MPP_2PHASE_AGG() */ COUNT(*) FROM t1, t2 WHERE t1.a > 10 GROUP
    ↪ BY t1.id;
```

> **Note:**
>
> Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

USE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 use index(idx1, idx2);` statement.

```
SELECT /*+ USE_INDEX(t1, idx1, idx2) */ * FROM t1;
```

> **Note:**
>
> If you specify only the table name but not index name in this hint, the execution does not consider any index but scan the entire table.

FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es).

The usage and effect of `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` are the same as the usage and effect of `USE_INDEX(t1_name, idx1_name [, idx2_name ...])`.

The following 4 queries have the same effect:

```
SELECT /*+ USE_INDEX(t, idx1) */ * FROM t;
SELECT /*+ FORCE_INDEX(t, idx1) */ * FROM t;
SELECT * FROM t use index(idx1);
SELECT * FROM t force index(idx1);
```

IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to ignore the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 ignore index(idx1, idx2);` statement.

```
select /*+ IGNORE_INDEX(t1, idx1, idx2) */ * from t t1;
```

ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])

The `ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and read the specified index in order.

> **Warning:**
>
> This hint might cause SQL statements to fail. It is recommended to test it first. If an error occurs during the test, remove the hint. If the test runs normally, you can continue using it.

This hint is usually applied in the following scenario:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```

   ↪ count:10         |
|  ─IndexReader_14          | 10.00   | root      |                    | index:
   ↪ Limit_13             |
|    ─Limit_13              | 10.00   | cop[tikv] |                    | offset:0,
   ↪  count:10         |
|      ─IndexFullScan_12    | 10.00   | cop[tikv] | table:t, index:a(a) | keep
   ↪  order:true, stats:pseudo |
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
```

The optimizer generates two types of plan for this query: `Limit + IndexScan(keep ↪ order: true)` and `TopN + IndexScan(keep order: false)`. When the `ORDER_INDEX` hint is used, the optimizer chooses the first plan that reads the index in order.

> **Note:**

- If the query itself does not need to read the index in order (that is, without a hint, the optimizer does not generate a plan that reads the index in order in any situation), when the `ORDER_INDEX` hint is used, the error `Can't find a proper physical plan for this query` occurs. In this case, you need to remove the corresponding `ORDER_INDEX` hint.
- The index on a partitioned table cannot be read in order, so do not use the `ORDER_INDEX` hint on the partitioned table and its related indexes.

NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])

The `NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and not to read the specified index in order. This hint is usually applied in the following scenario.

The following example shows that the effect of the query statement is equivalent to `SELECT * FROM t t1 use index(idx1, idx2);`:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ NO_ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
| id                        | estRows | task     | access object     | operator
   ↪ info               |
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
| TopN_7                    | 10.00   | root     |                   | test.t.a,
   ↪  offset:0, count:10 |
| ─IndexReader_14           | 10.00   | root     |                   | index:
   ↪ TopN_13                |
|   ─TopN_13                | 10.00   | cop[tikv] |                   | test.t.a
   ↪ , offset:0, count:10 |
|     ─IndexFullScan_12     | 10000.00 | cop[tikv] | table:t, index:a(a) |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
```

The same as the example of `ORDER_INDEX` hint, the optimizer generates two types of plans for this query: `Limit + IndexScan(keep order: true)` and `TopN + IndexScan(` ↪ `keep order: false)`. When the `NO_ORDER_INDEX` hint is used, the optimizer will choose the latter plan to read the index out of order.

AGG_TO_COP()

The `AGG_TO_COP()` hint tells the optimizer to push down the aggregate operation in the specified query block to the coprocessor. If the optimizer does not push down some aggregate function that is suitable for pushdown, then it is recommended to use this hint. For example:

```
select /*+ AGG_TO_COP() */ sum(t1.a) from t t1;
```

LIMIT_TO_COP()

The `LIMIT_TO_COP()` hint tells the optimizer to push down the `Limit` and `TopN` operators in the specified query block to the coprocessor. If the optimizer does not perform such an operation, it is recommended to use this hint. For example:

```
SELECT /*+ LIMIT_TO_COP() */ * FROM t WHERE a = 1 AND b > 10 ORDER BY c
    ↪ LIMIT 1;
```

READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])

The `READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])` hint tells the optimizer to read specific table(s) from specific storage engine(s). Currently, this hint supports two storage engine parameters - `TIKV` and `TIFLASH`. If a table has an alias, use the alias as the parameter of `READ_FROM_STORAGE()`; if the table does not has an alias, use the table's original name as the parameter. For example:

```
select /*+ READ_FROM_STORAGE(TIFLASH[t1], TIKV[t2]) */ t1.a from t t1, t
    ↪ t2 where t1.a = t2.a;
```

USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to access a specific table with the index merge method. Index merge has two types: intersection type and union type. For details, see Explain Statements Using Index Merge.

If you explicitly specify the list of indexes, TiDB selects indexes from the list to build index merge; if you do not specify the list of indexes, TiDB selects indexes from all available indexes to build index merge.

For the intersection-type index merge, the given list of indexes is a required parameter in the hint. For the union-type index merge, the given list of indexes is an optional parameter in the hint. See the following example.

```
SELECT /*+ USE_INDEX_MERGE(t1, idx_a, idx_b, idx_c) */ * FROM t1 WHERE t1.
    ↪ a > 10 OR t1.b > 10;
```

When multiple `USE_INDEX_MERGE` hints are made to the same table, the optimizer tries to select the index from the union of the index sets specified by these hints.

> **Note:**
>
> The parameters of `USE_INDEX_MERGE` refer to index names, rather than column names. The index name of the primary key is `primary`.

LEADING(t1_name [, tl_name ...])

The `LEADING(t1_name [, tl_name ...])` hint reminds the optimizer that, when generating the execution plan, to determine the order of multi-table joins according to the order of table names specified in the hint. For example:

```
SELECT /*+ LEADING(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id and t2.
    ↪ id = t3.id;
```

In the above query with multi-table joins, the order of joins is determined by the order of table names specified in the `LEADING()` hint. The optimizer will first join `t1` and `t2` and then join the result with `t3`. This hint is more general than `STRAIGHT_JOIN`.

The `LEADING` hint does not take effect in the following situations:

- Multiple `LEADING` hints are specified.
- The table name specified in the `LEADING` hint does not exist.
- A duplicated table name is specified in the `LEADING` hint.
- The optimizer cannot perform join operations according to the order as specified by the `LEADING` hint.
- The `straight_join()` hint already exists.
- The query contains an outer join together with the Cartesian product.

In the preceding situations, a warning is generated.

```
-- Multiple `LEADING` hints are specified.
SELECT /*+ LEADING(t1, t2) LEADING(t3) */ * FROM t1, t2, t3 WHERE t1.id =
    ↪ t2.id and t2.id = t3.id;

-- To learn why the `LEADING` hint fails to take effect, execute `show
    ↪ warnings`.
SHOW WARNINGS;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | We can only use one leading hint at most, when multiple
    ↪ leading hints are used, all leading hints will be invalid |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
```

Note:

If the query statement includes an outer join, in the hint you can specify only the tables whose join order can be swapped. If there is a table in the hint whose join order cannot be swapped, the hint will be invalid. For example, in `SELECT * FROM t1 LEFT JOIN (t2 JOIN t3 JOIN t4)ON t1.a = t2.a;`, if you want to control the join order of `t2`, `t3`, and `t4` tables, you cannot specify `t1` in the `LEADING` hint.

MERGE()

Using the `MERGE()` hint in queries with common table expressions (CTE) can disable the materialization of the subqueries and expand the subquery inlines into CTE. This hint is only applicable to non-recursive CTE. In some scenarios, using `MERGE()` brings higher execution efficiency than the default behavior of allocating a temporary space. For example, pushing down query conditions or in nesting CTE queries:

```
-- Uses the hint to push down the predicate of the outer query.
WITH CTE AS (SELECT /*+ MERGE() */ * FROM tc WHERE tc.a < 60) SELECT * FROM
    ↪  CTE WHERE CTE.a < 18;

-- Uses the hint in a nested CTE query to expand a CTE inline into the
    ↪ outer query.
WITH CTE1 AS (SELECT * FROM t1), CTE2 AS (WITH CTE3 AS (SELECT /*+ MERGE()
    ↪ */ * FROM t2), CTE4 AS (SELECT * FROM t3) SELECT * FROM CTE3, CTE4)
    ↪ SELECT * FROM CTE1, CTE2;
```

Note:

`MERGE()` is only applicable to simple CTE queries. It is not applicable in the following situations:

- Recursive CTE
- Subqueries with inlines that cannot be expanded, such as aggregate operators, window functions, and `DISTINCT`.

When the number of CTE references is too high, the query performance might be lower than the default materialization behavior.

11.3.4.2.3 Hints that take effect globally

The global hint works in views. When specified as a global hint, the hint defined in a query can take effect inside the view. To specify a global hint, first use the `QB_NAME` hint to define a query block name, and then add the target hints in the form of `ViewName@QueryBlockName`.

Step 1: Define the query block name of the view using the `QB_NAME` hint

Use the `QB_NAME` hint to define a new name for each query block of the view. The definition of the `QB_NAME` hint for views is the same as that for query blocks, but the syntax is extended from `QB_NAME(QB)` to `QB_NAME(QB, ViewName@QueryBlockName [. ViewName@QueryBlockName .ViewName@QueryBlockName ...])`.

Note:

There is a white space between `@QueryBlockName` and the immediately following `.ViewName@QueryBlockName`. Otherwise, the `.ViewName@QueryBlockName` will be treated as a part of the `QueryBlockName`. For example, `QB_NAME(v2_1, v2@SEL_1 .@SEL_1)` is valid, while `QB_NAME(v2_1, v2@SEL_1.@SEL_1)` cannot be parsed correctly.

- For a simple statement with a single view and no subqueries, the following example specifies the first query block name of view `v`:

```
SELECT /* Comment: The name of the current query block is the default
    ↪  @SEL_1 */ * FROM v;
```

For view `v`, the first view name in the list (`ViewName@QueryBlockName [. ViewName@QueryBlockName .ViewName@QueryBlockName ...]`) starting from the query statement is `v@SEL_1`. The first query block of the view `v` can be declared as `QB_NAME(v_1, v@SEL_1 .@SEL_1)`, or simply written as `QB_NAME(v_1, v)`, omitting `@SEL_1`:

```
CREATE VIEW v AS SELECT /* Comment: The name of the current query
    ↪ block is the default @SEL_1 */ * FROM t;

-- Specifies the global hint
SELECT /*+ QB_NAME(v_1, v) USE_INDEX(t@v_1, idx) */ * FROM v;
```

- For a complex statement with nested views and subqueries, the following example specifies the names for each of two query blocks of the view `v1` and `v2`:

```
SELECT /* Comment: The name of the current query block is the default
    ↪  @SEL_1 */ * FROM v2 JOIN (
    SELECT /* Comment: The name of the current query block is the
        ↪ default @SEL_2 */ * FROM v2) vv;
```

For the first view `v2`, the first view name in the list starting from the first query statement is `v2@SEL_1`. For the second view `v2`, the first view name is `v2@SEL_2`. The following example only considers the first view `v2`.

The first query block of view `v2` can be declared as `QB_NAME(v2_1, v2@SEL_1 .@SEL_1 ↪ )`, and the second query block of the view `v2` can be declared as `QB_NAME(v2_2, ↪ v2@SEL_1 .@SEL_2)`:

```
CREATE VIEW v2 AS
    SELECT * FROM t JOIN /* Comment: For view v2, the name of the
        ↪ current query block is the default @SEL_1. So, the current
        ↪ query block view list is v2@SEL_1 .@SEL_1 */
    (
        SELECT COUNT(*) FROM t1 JOIN v1 /* Comment: For view v2, the
            ↪ name of the current query block is the default @SEL_2.
            ↪ So, the current query block view list is v2@SEL_1 .
            ↪ @SEL_2 */
    ) tt;
```

For view `v1`, the first view name in the list starting from the preceding statement is `v2@SEL_1 .v1@SEL_2`. The first query block in view `v1` can be declared as `QB_NAME ↪ (v1_1, v2@SEL_1 .v1@SEL_2 .@SEL_1)`, and the second query block in view `v1` can be declared as `QB_NAME(v1_2, v2@SEL_1 .v1@SEL_2 .@SEL_2)`:

```
CREATE VIEW v1 AS SELECT * FROM t JOIN /* Comment: For view `v1`, the
    ↪ name of the current query block is the default @SEL_1. So, the
    ↪ current query block view list is v2@SEL_1 .@SEL_2 .v1@SEL_1 */
    (
        SELECT COUNT(*) FROM t1 JOIN t2 /* Comment: For view `v1`, the
            ↪ name of the current query block is the default @SEL_2.
            ↪ So, the current query block view list is v2@SEL_1 .
            ↪ @SEL_2 .v1@SEL_2 */
```

```
) tt;
```

Note:

- To use global hints with views, you must define the corresponding `QB_NAME` hints in the view. Otherwise, the global hints will not take effect.
- When using a hint to specify multiple table names in a view, you need to ensure that the table names appearing in the same hint are in the same query block of the same view.
- When you define the `QB_NAME` hint in a view for the outermost query block:
  - For the first item of the view list in the `QB_NAME`, if the `@SEL_` ↪ is not explicitly declared, the default is consistent with the query block position where the `QB_NAME` is defined. That is, the query `SELECT /*+ QB_NAME(qb1, v2)*/ * FROM v2 JOIN` ↪ `(SELECT /*+ QB_NAME(qb2, v2)*/ * FROM v2)vv;` is equivalent to `SELECT /*+ QB_NAME(qb1, v2@SEL_1)*/ * FROM v2 JOIN` ↪ `(SELECT /*+ QB_NAME(qb2, v2@SEL_2)*/ * FROM v2)vv;`.
  - For items other than the first item of the view list in the `QB_NAME` ↪ , only `@SEL_1` can be omitted. That is, if `@SEL_1` is declared in the first query block of the current view, `@SEL_1` can be omitted. Otherwise, `@SEL_` cannot be omitted. For the preceding example:
    - The first query block of the view `v2` can be declared as `QB_NAME` ↪ `(v2_1, v2)`.
    - The second query block of the view `v2` can be declared as `QB_NAME(v2_2, v2.@SEL_2)`.
    - The first query block of the view `v1` can be declared as `QB_NAME` ↪ `(v1_1, v2.v1@SEL_2)`.
    - The second query block of the view `v1` can be declared as `QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2)`.

Step 2: Add the target hints

After defining the `QB_NAME` hint for query blocks of the view, you can add required hints that take effect in query blocks in the form of `ViewName@QueryBlockName` to make them effective inside the view. For example:

- Specify the `MERGE_JOIN()` hint for the first query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_1, v2) merge_join(t@v2_1) */ * FROM v2;
```

- Specify the `MERGE_JOIN()` and `STREAM_AGG()` hints for the second query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_2, v2.@SEL_2) merge_join(t1@v2_2) stream_agg(
    ↪ @v2_2) */ * FROM v2;
```

- Specify the `HASH_JOIN()` hint for the first query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_1, v2.v1@SEL_2) hash_join(t@v1_1) */ * FROM v2;
```

- Specify the `HASH_JOIN()` and `HASH_AGG()` hints for the second query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2) hash_join(t1@v1_2)
    ↪ hash_agg(@v1_2) */ * FROM v2;
```

11.3.4.2.4 Hints that take effect in the whole query

This category of hints can only follow behind the **first** `SELECT`, `UPDATE` or `DELETE` keyword, which is equivalent to modifying the value of the specified system variable when this query is executed. The priority of the hint is higher than that of existing system variables.

> **Note:**
>
> This category of hints also has an optional hidden variable `@QB_NAME`, but the hint takes effect in the whole query even if you specify the variable.

NO_INDEX_MERGE()

The `NO_INDEX_MERGE()` hint disables the index merge feature of the optimizer.

For example, the following query will not use index merge:

```
select /*+ NO_INDEX_MERGE() */ * from t where t.a > 0 or t.b > 0;
```

In addition to this hint, setting the `tidb_enable_index_merge` system variable also controls whether to enable this feature.

> **Note:**

- `NO_INDEX_MERGE` has a higher priority over `USE_INDEX_MERGE`. When both hints are used, `USE_INDEX_MERGE` does not take effect.
- For a subquery, `NO_INDEX_MERGE` only takes effect when it is placed at the outermost level of the subquery.

USE_TOJA(boolean_value)

The `boolean_value` parameter can be `TRUE` or `FALSE`. The `USE_TOJA(TRUE)` hint enables the optimizer to convert an `in` condition (containing a sub-query) to join and aggregation operations. Comparatively, the `USE_TOJA(FALSE)` hint disables this feature.

For example, the following query will convert `in (select t2.a from t2)subq` to corresponding join and aggregation operations:

```
select /*+ USE_TOJA(TRUE) */ t1.a, t1.b from t1 where t1.a in (select t2.a
    ↪ from t2) subq;
```

In addition to this hint, setting the `tidb_opt_insubq_to_join_and_agg` system variable also controls whether to enable this feature.

MAX_EXECUTION_TIME(N)

The `MAX_EXECUTION_TIME(N)` hint places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it. In the following hint, `MAX_EXECUTION_TIME(1000)` means that the timeout is 1000 milliseconds (that is, 1 second):

```
select /*+ MAX_EXECUTION_TIME(1000) */ * from t1 inner join t2 where t1.id
    ↪  = t2.id;
```

In addition to this hint, the `global.max_execution_time` system variable can also limit the execution time of a statement.

MEMORY_QUOTA(N)

The `MEMORY_QUOTA(N)` hint places a limit `N` (a threshold value in MB or GB) on how much memory a statement is permitted to use. When a statement's memory usage exceeds this limit, TiDB produces a log message based on the statement's over-limit behavior or just terminates it.

In the following hint, `MEMORY_QUOTA(1024 MB)` means that the memory usage is limited to 1024 MB:

```
select /*+ MEMORY_QUOTA(1024 MB) */ * from t;
```

In addition to this hint, the `tidb_mem_quota_query` system variable can also limit the memory usage of a statement.

READ_CONSISTENT_REPLICA()

The `READ_CONSISTENT_REPLICA()` hint enables the feature of reading consistent data from the TiKV follower node. For example:

```
select /*+ READ_CONSISTENT_REPLICA() */ * from t;
```

In addition to this hint, setting the `tidb_replica_read` environment variable to `'follower'` or `'leader'` also controls whether to enable this feature.

IGNORE_PLAN_CACHE()

The `IGNORE_PLAN_CACHE()` hint reminds the optimizer not to use the Plan Cache when handling the current `prepare` statement.

This hint is used to temporarily disable the Plan Cache for a certain type of queries when prepare-plan-cache is enabled.

In the following example, the Plan Cache is forcibly disabled when executing the `prepare` statement.

```
prepare stmt from 'select /*+ IGNORE_PLAN_CACHE() */ * from t where t.id =
    ↪ ?';
```

STRAIGHT_JOIN()

The `STRAIGHT_JOIN()` hint reminds the optimizer to join tables in the order of table names in the `FROM` clause when generating the join plan.

```
SELECT /*+ STRAIGHT_JOIN() */ * FROM t t1, t t2 WHERE t1.a = t2.a;
```

Note:

- `STRAIGHT_JOIN` has higher priority over `LEADING`. When both hints are used, `LEADING` does not take effect.
- It is recommended to use the `LEADING` hint, which is more general than the `STRAIGHT_JOIN` hint.

NTH_PLAN(N)

The `NTH_PLAN(N)` hint reminds the optimizer to select the `N`th physical plan found during the physical optimization. `N` must be a positive integer.

If the specified `N` is beyond the search range of the physical optimization, TiDB will return a warning and select the optimal physical plan based on the strategy that ignores this hint.

This hint does not take effect when the cascades planner is enabled.

In the following example, the optimizer is forced to select the third physical plan found during the physical optimization:

```
SELECT /*+ NTH_PLAN(3) */ count(*) from t where a > 5;
```

> **Note:**
>
> `NTH_PLAN(N)` is mainly used for testing, and its compatibility is not guaranteed in later versions. Use this hint **with caution**.

RESOURCE_GROUP(resource_group_name)

`RESOURCE_GROUP(resource_group_name)` is used for Resource Control to isolate resources. This hint temporarily executes the current statement using the specified resource group. If the specified resource group does not exist, this hint will be ignored.

Example:

```
SELECT /*+ RESOURCE_GROUP(rg1) */ * FROM t limit 10;
```

11.3.4.2.5 Troubleshoot common issues that hints do not take effect

Hints do not take effect because your MySQL command-line client strips hints

MySQL command-line clients earlier than 5.7.7 strip optimizer hints by default. If you want to use the Hint syntax in these earlier versions, add the `--comments` option when starting the client. For example: `mysql -h 127.0.0.1 -P 4000 -uroot --comments`.

Hints do not take effect because the database name is not specified

If you do not specify the database name when creating a connection, hints might not take effect. For example:

When connecting to TiDB, you use the `mysql -h127.0.0.1 -P4000 -uroot` command without the `-D` option, and then execute the following SQL statements:

```
SELECT /*+ use_index(t, a) */ a FROM test.t;
SHOW WARNINGS;
```

Because TiDB cannot identify the database for table `t`, the `use_index(t, a)` hint does not take effect.

```
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                 |
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | use_index(.t, a) is inapplicable, check whether the
    ↪ table(.t) exists |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Hints do not take effect because the database name is not explicitly specified in cross-table queries

When executing cross-table queries, you need to explicitly specify database names. Otherwise, hints might not take effect. For example:

```
USE test1;
CREATE TABLE t1(a INT, KEY(a));
USE test2;
CREATE TABLE t2(a INT, KEY(a));
SELECT /*+ use_index(t1, a) */ * FROM test1.t1, t2;
SHOW WARNINGS;
```

In the preceding statements, because table `t1` is not in the current `test2` database, the `use_index(t1, a)` hint does not take effect.

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                              |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | use_index(test2.t1, a) is inapplicable, check whether
    ↪ the table(test2.t1) exists |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

In this case, you need to specify the database name explicitly by using `use_index(test1
↪ .t1, a)` instead of `use_index(t1, a)`.

Hints do not take effect because they are placed in wrong locations

Hints cannot take effect if they are not placed directly after the specific keywords. For example:

```
SELECT * /*+ use_index(t, a) */ FROM t;
SHOW WARNINGS;
```

The warning is as follows:

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1064 | You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your TiDB version for the right syntax to use [
    ↪ parser:8066]Optimizer hint can only be followed by certain keywords
    ↪ like SELECT, INSERT, etc. |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

In this case, you need to place the hint directly after the `SELECT` keyword. For more details, see the Syntax section.

`INL_JOIN` hint does not take effect

`INL_JOIN` hint does not take effect when built-in functions are used on columns for joining tables

In some cases, if you use a built-in function on a column that joins tables, the optimizer might fail to choose the `IndexJoin` plan, resulting in the `INL_JOIN` hint not taking effect either.

For example, the following query uses the built-in function `substr` on the column `tname` that joins tables:

```
CREATE TABLE t1 (id varchar(10) primary key, tname varchar(10));
CREATE TABLE t2 (id varchar(10) primary key, tname varchar(10));
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id=t2.id and
    ↪ SUBSTR(t1.tname,1,2)=SUBSTR(t2.tname,1,2);
```

The execution plan is as follows:

```
+--
    ↪ --------------------------+----------+----------+---------------+-----------
    ↪
```

```
| id                          | estRows | task     | access object | operator
    ↪ info                                                |
+--
    ↪ ----------------------------+---------+----------+---------------+-----------
    ↪
| HashJoin_12                 | 12500.00 | root    |               | inner join,
    ↪ equal:[eq(test.t1.id, test.t2.id) eq(Column#5, Column#6)] |
|  ─Projection_17(Build)      | 10000.00 | root    |               | test.t2.id,
    ↪  test.t2.tname, substr(test.t2.tname, 1, 2)->Column#6 |
|    ─TableReader_19          | 10000.00 | root    |               | data:
    ↪ TableFullScan_18                                    |
|      ─TableFullScan_18      | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo                                 |
|  ─Projection_14(Probe)      | 10000.00 | root    |               | test.t1.id,
    ↪  test.t1.tname, substr(test.t1.tname, 1, 2)->Column#5 |
|    ─TableReader_16          | 10000.00 | root    |               | data:
    ↪ TableFullScan_15                                    |
|      ─TableFullScan_15      | 10000.00 | cop[tikv] | table:t1 | keep order:
    ↪ false, stats:pseudo                                 |
+--
    ↪ ----------------------------+---------+----------+---------------+-----------
    ↪
7 rows in set, 1 warning (0.01 sec)
```

```
SHOW WARNINGS;
```

```
+---------+------+-----------------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                    |
+---------+------+-----------------------------------------------------------------------
    ↪
| Warning | 1815 | Optimizer Hint /*+ INL_JOIN(t1, t2) */ or /*+ TIDB_INLJ(
    ↪ t1, t2) */ is inapplicable |
+---------+------+-----------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

As you can see from the preceding example, the `INL_JOIN` hint does not take effect. This is due to a limitation of the optimizer that prevents using the `Projection` or `Selection` operator as the probe side of `IndexJoin`.

`INL_JOIN`, `INL_HASH_JOIN`, and `INL_MERGE_JOIN` hints do not take effect due to collation incompatibility

When the collation of the join key is incompatible between two tables, the `IndexJoin`

operator cannot be utilized to execute the query. In this case, the INL_JOIN, INL_HASH_JOIN, and INL_MERGE_JOIN hints do not take effect. For example:

```
CREATE TABLE t1 (k varchar(8), key(k)) COLLATE=utf8mb4_general_ci;
CREATE TABLE t2 (k varchar(8), key(k)) COLLATE=utf8mb4_bin;
EXPLAIN SELECT /*+ tidb_inlj(t1) */ * FROM t1, t2 WHERE t1.k=t2.k;
```

The execution plan is as follows:

```
+--
   ↪ -------------------------+---------+----------+-------------------+------
   ↪
| id                        | estRows | task     | access object     |
   ↪ operator info                              |
+--
   ↪ -------------------------+---------+----------+-------------------+------
   ↪
| HashJoin_19               | 12487.50 | root    |                   | inner
   ↪ join, equal:[eq(test.t1.k, test.t2.k)] |
| ─IndexReader_24(Build)  | 9990.00 | root     |                    | index:
   ↪ IndexFullScan_23                  |
|   ─IndexFullScan_23     | 9990.00 | cop[tikv] | table:t2, index:k(k) |
   ↪ keep order:false, stats:pseudo    |
| ─IndexReader_22(Probe)  | 9990.00 | root     |                    | index:
   ↪ IndexFullScan_21                  |
|   ─IndexFullScan_21     | 9990.00 | cop[tikv] | table:t1, index:k(k) |
   ↪ keep order:false, stats:pseudo    |
+--
   ↪ -------------------------+---------+----------+-------------------+------
   ↪
5 rows in set, 1 warning (0.00 sec)
```

In the preceding statements, the collations of `t1.k` and `t2.k` are incompatible (`utf8mb4_general_ci` and `utf8mb4_bin` respectively), which prevents the `INL_JOIN` or `TIDB_INLJ` hint from taking effect.

```

`INL_JOIN` hint does not take effect due to join order

The `INL_JOIN(t1, t2)` or `TIDB_INLJ(t1, t2)` hint semantically instructs `t1` and `t2` to act as inner tables in an `IndexJoin` operator to join with other tables, rather than directly joining them using an `IndexJoin` operator. For example:

```
EXPLAIN SELECT /*+ inl_join(t1, t3) */ * FROM t1, t2, t3 WHERE t1.id = t2.
    ↪ id AND t2.id = t3.id AND t1.id = t3.id;
+--
    ↪ ------------------------------+---------+----------+--------------+---------
    ↪
| id                            | estRows | task     | access object | operator
    ↪  info
    ↪
    ↪ |
+--
    ↪ ------------------------------+---------+----------+--------------+---------
    ↪
| IndexJoin_16                  | 15625.00 | root    |               | inner join
    ↪ , inner:TableReader_13, outer key:test.t2.id, test.t1.id, inner key:
    ↪ test.t3.id, test.t3.id, equal cond:eq(test.t1.id, test.t3.id), eq(
    ↪ test.t2.id, test.t3.id) |
| ─IndexJoin_34(Build)          | 12500.00 | root    |               | inner
    ↪ join, inner:TableReader_31, outer key:test.t2.id, inner key:test.t1.
    ↪ id, equal cond:eq(test.t2.id, test.t1.id)
    ↪                                    |
|   ─TableReader_40(Build)      | 10000.00 | root    |               | data:
    ↪ TableFullScan_39
    ↪
    ↪ |
|     ─TableFullScan_39         | 10000.00 | cop[tikv] | table:t2 | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
|   ─TableReader_31(Probe)      | 10000.00 | root    |               | data:
    ↪ TableRangeScan_30
    ↪
    ↪ |
|     ─TableRangeScan_30        | 10000.00 | cop[tikv] | table:t1 | range:
    ↪ decided by [test.t2.id], keep order:false, stats:pseudo
    ↪
```

```
    ↪ |
|  └─TableReader_13(Probe)      | 12500.00 | root    |              | data:
    ↪ TableRangeScan_12
    ↪
    ↪ |
|    └─TableRangeScan_12        | 12500.00 | cop[tikv] | table:t3 | range:
    ↪ decided by [test.t2.id test.t1.id], keep order:false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ------------------------------+---------+-----------+--------------+--------
    ↪
```

In the preceding example, `t1` and `t3` are not directly joined together by an `IndexJoin`.

To perform a direct `IndexJoin` between `t1` and `t3`, you can first use `LEADING(t1, t3)` hint to specify the join order of `t1` and `t3`, and then use the `INL_JOIN` hint to specify the join algorithm. For example:

```
EXPLAIN SELECT /*+ leading(t1, t3), inl_join(t3) */ * FROM t1, t2, t3 WHERE
    ↪  t1.id = t2.id AND t2.id = t3.id AND t1.id = t3.id;
+--
    ↪ ------------------------------+---------+-----------+--------------+--------
    ↪
| id                           | estRows | task    | access object | operator
    ↪  info
    ↪
    ↪ |
+--
    ↪ ------------------------------+---------+-----------+--------------+--------
    ↪
| Projection_12                | 15625.00 | root    |              | test.t1.id
    ↪ , test.t1.name, test.t2.id, test.t2.name, test.t3.id, test.t3.name
    ↪                            |
|  └─HashJoin_21                | 15625.00 | root    |              | inner
    ↪ join, equal:[eq(test.t1.id, test.t2.id) eq(test.t3.id, test.t2.id)]
    ↪                               |
|    └─TableReader_36(Build)    | 10000.00 | root    |              | data:
    ↪ TableFullScan_35
    ↪
    ↪ |
|      └─TableFullScan_35       | 10000.00 | cop[tikv] | table:t2 | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
|    └─IndexJoin_28(Probe)      | 12500.00 | root    |              | inner
```

```
    ↪ join, inner:TableReader_25, outer key:test.t1.id, inner key:test.t3.
    ↪ id, equal cond:eq(test.t1.id, test.t3.id) |
|     ─TableReader_34(Build)  | 10000.00 | root    |              | data:

Using hints causes the `Can't find a proper physical plan for this query` error

The `Can't find a proper physical plan for this query` error might occur in the following scenarios:

- A query itself does not require reading indexes in order. That is, for this query, the optimizer does not generate a plan to read indexes in order in any case without using hints. In this case, if the `ORDER_INDEX` hint is specified, this error occurs. To resolve this issue, remove the corresponding `ORDER_INDEX` hint.
- A query excludes all possible join methods by using the `NO_JOIN` related hints.

```
CREATE TABLE t1 (a INT);
CREATE TABLE t2 (a INT);
EXPLAIN SELECT /*+ NO_HASH_JOIN(t1), NO_MERGE_JOIN(t1) */ * FROM t1, t2
    ↪ WHERE t1.a=t2.a;
ERROR 1815 (HY000): Internal : Can't find a proper physical plan for this
    ↪ query
```

- The system variable `tidb_opt_enable_hash_join` is set to `OFF`, and all other join types are also excluded.

```
CREATE TABLE t1 (a INT);
CREATE TABLE t2 (a INT);
set tidb_opt_enable_hash_join=off;
EXPLAIN SELECT /*+ NO_MERGE_JOIN(t1) */ * FROM t1, t2 WHERE t1.a=t2.a;
ERROR 1815 (HY000): Internal : Can't find a proper physical plan for this
    ↪ query
```

11.3.4.3 SQL Plan Management (SPM)

SQL Plan Management is a set of functions that execute SQL bindings to manually interfere with SQL execution plans. These functions include SQL binding, baseline capturing, and baseline evolution.

11.3.4.3.1 SQL binding

An SQL binding is the basis of SPM. The Optimizer Hints document introduces how to select a specific execution plan using hints. However, sometimes you need to interfere with execution selection without modifying SQL statements. With SQL bindings, you can select a specified execution plan without modifying SQL statements.

> **Note:**
>
> To use SQL bindings, you need to have the `SUPER` privilege. If TiDB prompts that you do not have sufficient privileges, see Privilege Management to add the required privileges.

Create a binding

You can create a binding for a SQL statement according to a SQL statement or a historical execution plan.

Create a binding according to a SQL statement

```
CREATE [GLOBAL | SESSION] BINDING FOR BindableStmt USING BindableStmt
```

This statement binds SQL execution plans at the GLOBAL or SESSION level. Currently, supported bindable SQL statements (BindableStmt) in TiDB include `SELECT`, `DELETE`, `UPDATE`, and `INSERT` / `REPLACE` with `SELECT` subqueries.

> **Note:**
>
> Bindings have higher priority over manually added hints. Therefore, when you execute a statement containing a hint while a corresponding binding is present, the hint controlling the behavior of the optimizer does not take effect. However, other types of hints are still effective.

Specifically, two types of these statements cannot be bound to execution plans due to syntax conflicts. See the following examples:

```
-- Type one: Statements that get the Cartesian product by using the `JOIN`
   ↪  keyword and not specifying the associated columns with the `USING`
   ↪ keyword.
CREATE GLOBAL BINDING for
    SELECT * FROM t t1 JOIN t t2
USING
    SELECT * FROM t t1 JOIN t t2;

-- Type two: `DELETE` statements that contain the `USING` keyword.
CREATE GLOBAL BINDING for
    DELETE FROM t1 USING t1 JOIN t2 ON t1.a = t2.a
USING
    DELETE FROM t1 USING t1 JOIN t2 ON t1.a = t2.a;
```

You can bypass syntax conflicts by using equivalent statements. For example, you can rewrite the above statements in the following ways:

```
-- First rewrite of type one statements: Add a `USING` clause for the `
   ↪ JOIN` keyword.
CREATE GLOBAL BINDING for
    SELECT * FROM t t1 JOIN t t2 USING (a)
USING
    SELECT * FROM t t1 JOIN t t2 USING (a);

-- Second rewrite of type one statements: Delete the `JOIN` keyword.
CREATE GLOBAL BINDING for
    SELECT * FROM t t1, t t2
USING
    SELECT * FROM t t1, t t2;

-- Rewrite of type two statements: Remove the `USING` keyword from the `
   ↪ delete` statement.
CREATE GLOBAL BINDING for
    DELETE t1 FROM t1 JOIN t2 ON t1.a = t2.a
```

```
using
    DELETE t1 FROM t1 JOIN t2 ON t1.a = t2.a;
```

> **Note:**
>
> When creating execution plan bindings for `INSERT` / `REPLACE` statements with `SELECT` subqueries, you need to specify the optimizer hints you want to bind in the `SELECT` subquery, not after the `INSERT` / `REPLACE` keyword. Otherwise, the optimizer hints do not take effect as intended.

Here are two examples:

```
-- The hint takes effect in the following statement.
CREATE GLOBAL BINDING for
    INSERT INTO t1 SELECT * FROM t2 WHERE a > 1 AND b = 1
using
    INSERT INTO t1 SELECT /*+ use_index(@sel_1 t2, a) */ * FROM t2 WHERE a
        ↪ > 1 AND b = 1;

-- The hint cannot take effect in the following statement.
CREATE GLOBAL BINDING for
    INSERT INTO t1 SELECT * FROM t2 WHERE a > 1 AND b = 1
using
    INSERT /*+ use_index(@sel_1 t2, a) */ INTO t1 SELECT * FROM t2 WHERE a
        ↪ > 1 AND b = 1;
```

If you do not specify the scope when creating an execution plan binding, the default scope is SESSION. The TiDB optimizer normalizes bound SQL statements and stores them in the system table. When processing SQL queries, if a normalized statement matches one of the bound SQL statements in the system table and the system variable `tidb_use_plan_baselines` is set to `on` (the default value is `on`), TiDB then uses the corresponding optimizer hint for this statement. If there are multiple matchable execution plans, the optimizer chooses the least costly one to bind.

`Normalization` is a process that converts a constant in an SQL statement to a variable parameter and explicitly specifies the database for tables referenced in the query, with standardized processing on the spaces and line breaks in the SQL statement. See the following example:

```
SELECT * FROM t WHERE a > 1
-- After normalization, the above statement is as follows:
SELECT * FROM test . t WHERE a > ?
```

Note:

Multiple constants joined by commas `,` are normalized as `...` instead of `?`.

For example:

```
SELECT * FROM t limit 10
SELECT * FROM t limit 10, 20
SELECT * FROM t WHERE a IN (1)
SELECT * FROM t WHERE a IN (1,2,3)
-- After normalization, the above statements are as follows:
SELECT * FROM test . t limit ?
SELECT * FROM test . t limit ...
SELECT * FROM test . t WHERE a IN ( ? )
SELECT * FROM test . t WHERE a IN ( ... )
```

When bindings are created, TiDB treats SQL statements that contain a single constant and SQL statements that contain multiple constants joined by commas differently. Therefore, you need to create bindings for the two SQL types separately.

For example:

```
CREATE TABLE t(a INT, b INT, KEY idx(a));
CREATE SESSION BINDING for SELECT * FROM t WHERE a IN (?)
    ↪ USING SELECT /*+ use_index(t, idx) */ * FROM t WHERE a
    ↪ in (?);
SHOW BINDINGS;

When a SQL statement has bound execution plans in both GLOBAL and SESSION scopes, because the optimizer ignores the bound execution plan in the GLOBAL scope when it encounters the SESSION binding, the bound execution plan of this statement in the SESSION scope shields the execution plan in the GLOBAL scope.

For example:

```
-- Creates a GLOBAL binding and specifies using `sort merge join` in this
    ↪ binding.
CREATE GLOBAL BINDING for
    SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
    SELECT /*+ merge_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- The execution plan of this SQL statement uses the `sort merge join`
    ↪ specified in the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Creates another SESSION binding and specifies using `hash join` in this
    ↪  binding.
CREATE BINDING for
    SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
    SELECT /*+ hash_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- In the execution plan of this statement, `hash join` specified in the
    ↪ SESSION binding is used, instead of `sort merge join` specified in
    ↪ the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;
```

When the first `SELECT` statement is being executed, the optimizer adds the `sm_join(t1, t2)` hint to the statement through the binding in the GLOBAL scope. The top node of the execution plan in the `explain` result is MergeJoin. When the second `SELECT` statement is being executed, the optimizer uses the binding in the SESSION scope instead of the binding in the GLOBAL scope and adds the `hash_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is HashJoin.

Each standardized SQL statement can have only one binding created using `CREATE BINDING` at a time. When multiple bindings are created for the same standardized SQL statement, the last created binding is retained, and all previous bindings (created and evolved) are marked as deleted. But session bindings and global bindings can coexist and are not affected by this logic.

In addition, when you create a binding, TiDB requires that the session is in a database context, which means that a database is specified when the client is connected or `use ${database}` is executed.

The original SQL statement and the bound statement must have the same text after normalization and hint removal, or the binding will fail. Take the following examples:

- This binding can be created successfully because the texts before and after parameterization and hint removal are the same: `SELECT * FROM test . t WHERE a > ?`

  ```
  sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM t use index (idx)WHERE a > 2
  ```

- This binding will fail because the original SQL statement is processed as `SELECT * FROM test . t WHERE a > ?`, while the bound SQL statement is processed differently as `SELECT * FROM test . t WHERE b > ?`.

  ```
  sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM t use index(idx)WHERE b > 2
  ```

> **Note:**
>
> For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, you need to create execution plan bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

Create a binding according to a historical execution plan

To make the execution plan of a SQL statement fixed to a historical execution plan, you can use `plan_digest` to bind that historical execution plan to the SQL statement, which is more convenient than binding it according to a SQL statement.

Currently, this feature has the following limitations:

- The feature generates hints according to historical execution plans and uses the generated hints for binding. Because historical execution plans are stored in Statement Summary Tables, before using this feature, you need to enable the `tidb_enable_stmt_summary` system variable first.
- This feature does not support TiFlash queries, Join queries with three or more tables, or queries that contain subqueries.

The SQL statement of this binding method is as follows:

```
CREATE [GLOBAL | SESSION] BINDING FROM HISTORY USING PLAN DIGEST '
    ↪ plan_digest';
```

This statement binds an execution plan to a SQL statement using `plan_digest`. The default scope is SESSION. The applicable SQL statements, priorities, scopes, and effective conditions of the created bindings are the same as that of bindings created according to SQL statements.

To use this binding method, you need to first get the `plan_digest` corresponding to the target historical execution plan in `statements_summary`, and then create a binding using the `plan_digest`. The detailed steps are as follows:

1. Get the `plan_digest` corresponding to the target execution plan in `statements_summary` ↪ .

   For example:

   ```
   CREATE TABLE t(id INT PRIMARY KEY , a INT, KEY(a));
   SELECT /*+ IGNORE_INDEX(t, a) */ * FROM t WHERE a = 1;
   SELECT * FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE
       ↪ QUERY_SAMPLE_TEXT = 'SELECT /*+ IGNORE_INDEX(t, a) */ * FROM t
       ↪ WHERE a = 1'\G;
   ```

   The following is a part of the example query result of `statements_summary`:

   ```
   SUMMARY_BEGIN_TIME: 2022-12-01 19:00:00
   ...........
        DIGEST_TEXT: select * from `t` where `a` = ?
   ...........
        PLAN_DIGEST: 4
           ↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb
           ↪
              PLAN: id                task      estRows operator info
                 ↪                      actRows execution info
                 ↪
                 ↪ memory    disk
   ```

```
                TableReader_7     root       10     data:Selection_6
                   ↪                    0      time:4.05ms, loops:1,
                   ↪ cop_task: {num: 1, max: 598.6µs, proc_keys: 0,
                   ↪ rpc_num: 2, rpc_time: 609.8µs,
                   ↪ copr_cache_hit_ratio: 0.00, distsql_concurrency
                   ↪ : 15} 176 Bytes N/A
                 └─Selection_6     cop[tikv]  10     eq(test.t.a, 1)

                   ↪ µs, loops:0}
                   ↪
                   ↪ N/A        N/A
                   └─TableFullScan_5 cop[tikv] 10000 table:t, keep
                     ↪ order:false, stats:pseudo 0 tikv_task:{time
                     ↪ :560.8µs, loops:0}
                     ↪
                     ↪ N/A        N/A
BINARY_PLAN: 6
   ↪ QOYCuQDCg1UYWJsZVJlYWRlcl83Ev8BCgtTZWxlY3Rpb25fNhKOAQoPBSJQRnVsbFNjYW5fN
   ↪ /
   ↪ QSkAAQHwW4jDQDgCQAJKCwoJCgR0ZXN0EgF0Uh5rZWVwIG9yZGVyOmZhbHNlLCBzdGF0czpw
   ↪ ////CQMEAXgJCBD///8
   ↪ BIQFzCDhVQw19BAAkBX0QUg9lcSgBfCAudC5hLCAxKWrmYQAYHOi0gc6hBB1hJAFAAVIQZGF
   ↪ ////////////8BGAE=
```

In this example, you can see that the execution plan corresponding to `plan_digest` is `4e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb`.

2. Use `plan_digest` to create a binding:

```
CREATE BINDING FROM HISTORY USING PLAN DIGEST '4
   ↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb';
```

To verify whether the created binding takes effect, you can view bindings:

```
SHOW BINDINGS\G;
```

```
*************************** 1. row ***************************
Original_sql: select * from `test` . `t` where `a` = ?
   Bind_sql: SELECT /*+ use_index(@`sel_1` `test`.`t` ) ignore_index(`t` `a
      ↪ `)*/ * FROM `test`.`t` WHERE `a` = 1
      ...........
  Sql_digest: 6909
     ↪ a1bbce5f64ade0a532d7058dd77b6ad5d5068aee22a531304280de48349f
 Plan_digest:
1 row in set (0.01 sec)
```

```
ERROR:

```

Remove a binding

You can remove a binding according to a SQL statement or `sql_digest`.

Remove a binding according to a SQL statement

```
DROP [GLOBAL | SESSION] BINDING FOR BindableStmt;
```

This statement removes a specified execution plan binding at the GLOBAL or SESSION level. The default scope is SESSION.

Generally, the binding in the SESSION scope is mainly used for test or in special situations. For a binding to take effect in all TiDB processes, you need to use the GLOBAL binding. A created SESSION binding shields the corresponding GLOBAL binding until the end of the SESSION, even if the SESSION binding is dropped before the session closes. In this case, no binding takes effect and the plan is selected by the optimizer.

The following example is based on the example in create binding in which the SESSION binding shields the GLOBAL binding:

```
-- Drops the binding created in the SESSION scope.
drop session binding for SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Views the SQL execution plan again.
explain SELECT * FROM t1,t2 WHERE t1.id = t2.id;
```

In the example above, the dropped binding in the SESSION scope shields the corresponding binding in the GLOBAL scope. The optimizer does not add the `sm_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is not fixed to MergeJoin by this hint. Instead, the top node is independently selected by the optimizer according to the cost estimation.

Remove a binding according to `sql_digest`

In addition to removing a binding according to a SQL statement, you can also remove a binding according to `sql_digest`.

```
DROP [GLOBAL | SESSION] BINDING FOR SQL DIGEST 'sql_digest';
```

This statement removes an execution plan binding corresponding to `sql_digest` at the GLOBAL or SESSION level. The default scope is SESSION. You can get the `sql_digest` by viewing bindings.

> **Note:**
>
> Executing `DROP GLOBAL BINDING` drops the binding in the current tidb-server instance cache and changes the status of the corresponding row in the system table to 'deleted'. This statement does not directly delete the records in the system table, because other tidb-server instances need to read the 'deleted' status to drop the corresponding binding in their cache. For the records in these system tables with the status of 'deleted', at every 100 `bind-info-lease` (the default value is `3s`, and `300s` in total) interval, the background thread triggers an operation of reclaiming and clearing on the bindings of `update_time` before 10 `bind-info-lease` (to ensure that all tidb-server instances have read the 'deleted' status and updated the cache).

Change binding status

Change binding status according to a SQL statement

```
SET BINDING [ENABLED | DISABLED] FOR BindableStmt;
```

You can execute this statement to change the status of a binding. The default status is ENABLED. The effective scope is GLOBAL by default and cannot be modified.

When executing this statement, you can only change the status of a binding from `Disabled` to `Enabled` or from `Enabled` to `Disabled`. If no binding is available for status changes, a warning message is returned, saying `There are no bindings can be set the status. Please check the SQL text`. Note that a binding in `Disabled` status is not used by any query.

Change binding status according to `sql_digest`

In addition to changing the binding status according to a SQL statement, you can also change the binding status according to `sql_digest`:

```
SET BINDING [ENABLED | DISABLED] FOR SQL DIGEST 'sql_digest';
```

The binding status that can be changed by `sql_digest` and the effect is the same as those changed according to a SQL statement. If no binding is available for status changes, a warning message `can't find any binding for 'sql_digest'` is returned.

View bindings

```
SHOW [GLOBAL | SESSION] BINDINGS [ShowLikeOrWhere]
```

This statement outputs the execution plan bindings at the GLOBAL or SESSION level according to the order of binding update time from the latest to earliest. The default scope is SESSION. Currently `SHOW BINDINGS` outputs 11 columns, as shown below:

Column Name	Note
original_sql	Original SQL statement after parameterization
bind_sql	Bound SQL statement with hints
default_db	Default database
status	Status including `enabled` (replacing the `using` status from v6.0), `disabled`, `deleted`, `invalid`, `rejected`, and `pending` ↪ `verify`
create_time	Creating time
update_time	Updating time
charset	Character set
collation	Ordering rule

Column Name	Note
source	The way in which a binding is created, including `manual` (created according to a SQL statement), `history` (created according to a historical execution plan), `capture` (captured automatically by TiDB), and `evolve` (evolved automatically by TiDB)
sql_digest	Digest of a normalized SQL statement
plan_digest	Digest of an execution plan

Troubleshoot a binding

You can use either of the following methods to troubleshoot a binding:

- Use the system variable `last_plan_from_binding` to show whether the execution plan used by the last executed statement is from the binding.

```
-- Create a global binding
CREATE GLOBAL BINDING for
    SELECT * FROM t
USING
    SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

SELECT * FROM t;
SELECT @@[SESSION.]last_plan_from_binding;
```

```
+--------------------------+
| @@last_plan_from_binding |
+--------------------------+
|                        1 |
+--------------------------+
1 row in set (0.00 sec)
```

- Use the `explain format = 'verbose'` statement to view the query plan of a SQL statement. If the SQL statement uses a binding, you can run `show warnings` to check which binding is used in the SQL statement.

```
-- Create a global binding

CREATE GLOBAL BINDING for
    SELECT * FROM t
USING
    SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

-- Use explain format = 'verbose' to view the execution plan of a SQL
    ↪  statement

explain format = 'verbose' SELECT * FROM t;

-- Run `show warnings` to view the binding used in the query.

show warnings;
```

```
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
| Level | Code | Message
    ↪                                                                  |
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
| Note | 1105 | Using the bindSQL: SELECT /*+ USE_INDEX(`t` `idx_a`)*/
    ↪  * FROM `test`.`t` |
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

Cache bindings

Each TiDB instance has a least recently used (LRU) cache for bindings. The cache capacity is controlled by the system variable `tidb_mem_quota_binding_cache`. You can view bindings that are cached in the TiDB instance.

To view the cache status of bindings, run the `SHOW binding_cache status` statement. In this statement, the effective scope is GLOBAL by default and cannot be modified. This statement returns the number of available bindings in the cache, the total number of available bindings in the system, memory usage of all cached bindings, and the total memory for the cache.

```
SHOW binding_cache status;
```

```
+-------------------+-------------------+-------------+--------------+
| bindings_in_cache | bindings_in_table | memory_usage | memory_quota |
+-------------------+-------------------+-------------+--------------+
|                 1 |                 1 | 159 Bytes   | 64 MB        |
+-------------------+-------------------+-------------+--------------+
1 row in set (0.00 sec)
```

11.3.4.3.2 Baseline capturing

Used for preventing regression of execution plans during an upgrade, this feature captures queries that meet capturing conditions and creates bindings for these queries.

A plan baseline refers to a collection of accepted plans that the optimizer can use for executing a SQL statement. Generally, TiDB adds a plan into the plan baseline only after confirming that the plan performs well. A plan in this context encompasses all the necessary plan-related details (such as SQL plan identifier, hint set, bind values, and optimizer environment) that the optimizer requires to reproduce an execution plan.

Enable capturing

To enable baseline capturing, set `tidb_capture_plan_baselines` to `on`. The default value is `off`.

> **Note:**
>
> Because the automatic binding creation function relies on Statement Summary, make sure to enable Statement Summary before using automatic binding.

After automatic binding creation is enabled, the historical SQL statements in the Statement Summary are traversed every `bind-info-lease` (the default value is `3s`), and a binding

is automatically created for SQL statements that appear at least twice. For these SQL statements, TiDB automatically binds the execution plan recorded in Statement Summary.

However, TiDB does not automatically capture bindings for the following types of SQL statements:

- `EXPLAIN` and `EXPLAIN ANALYZE` statements.
- SQL statements executed internally in TiDB, such as `SELECT` queries used for automatically loading statistical information.
- Statements that contain `Enabled` or `Disabled` bindings.
- Statements that are filtered out by capturing conditions.

> **Note:**
>
> Currently, a binding generates a group of hints to fix an execution plan generated by a query statement. In this way, for the same query, the execution plan does not change. For most OLTP queries, including queries using the same index or Join algorithm (such as HashJoin and IndexJoin), TiDB guarantees plan consistency before and after the binding. However, due to the limitations of hints, TiDB cannot guarantee plan consistency for some complex queries, such as Join of more than two tables, MPP queries, and complex OLAP queries.

For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, TiDB automatically captures bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

> **Note:**
>
> Because TiDB has some embedded SQL statements to ensure the correctness of some features, baseline capturing by default automatically shields these SQL statements.

Filter out bindings

This feature allows you to configure a blocklist to filter out queries whose bindings you do not want to capture. A blocklist has three dimensions, table name, frequency, and user name.

Usage

Insert filtering conditions into the system table `mysql.capture_plan_baselines_blacklist` ↪ . Then the filtering conditions take effect in the entire cluster immediately.

```
-- Filter by table name
 INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
    ↪ filter_value) VALUES('table', 'test.t');

-- Filter by database name and table name through wildcards
 INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
    ↪ filter_value) VALUES('table', 'test.table_*');
 INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
    ↪ filter_value) VALUES('table', 'db_*.table_*');

-- Filter by frequency
 INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
    ↪ filter_value) VALUES('frequency', '2');

-- Filter by user name
 INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type,
    ↪ filter_value) VALUES('user', 'user1');
```

Dimension name	Description	Remarks
table	Filter by table name. Each filtering rule is in the `db.table` format. The supported filtering syntax includes Plain table names and Wildcards.	Case insensitive. If a table name contains illegal characters, the log returns a warning message `[sql-bind] failed to load mysql.capture_plan_baselines_blacklist .`
frequency	Filter by frequency. SQL statements executed more than once are captured by default. You can set a high frequency to capture statements that are frequently executed.	Setting frequency to a value smaller than 1 is considered illegal, and the log returns a warning message `[sql-bind] frequency threshold is less than 1, ignore it`. If multiple frequency filter rules are inserted, the value with the highest frequency prevails.
user	Filter by user name. Statements executed by blocklisted users are not captured.	If multiple users execute the same statement and their user names are all in the blocklist, this statement is not captured.

Note:

- Modifying a blocklist requires the super privilege.
- If a blocklist contains illegal filters, TiDB returns the warning message `[sql-bind] unknown capture filter type, ignore it` in the log.

Prevent regression of execution plans during an upgrade

Before upgrading a TiDB cluster, you can use baseline capturing to prevent regression of execution plans by performing the following steps:

1. Enable baseline capturing and keep it working.

> **Note:**
> Test data shows that long-term working of baseline capturing has a slight impact on the performance of the cluster load. Therefore, it is recommended to enable baseline capturing as long as possible so that important plans (appear twice or above) are captured.

2. Upgrade the TiDB cluster. After the upgrade, TiDB uses those captured bindings to ensure execution plan consistency.
3. After the upgrade, delete bindings as required.

    - Check the binding source by running the `SHOW GLOBAL BINDINGS` statement.

      In the output, check the `Source` field to see whether a binding is captured (`capture`) or manually created (`manual`).
    - Determine whether to retain the captured bindings:

```
-- View the plan with the binding enabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = true;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;

-- View the plan with the binding disabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = false;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;
```

        - If the execution plan is consistent, you can delete the binding safely.
        - If the execution plan is inconsistent, you need to identify the cause, for example, by checking statistics. In this case, you need to retain the binding to ensure plan consistency.

11.3.4.4.3.3 Baseline evolution

Baseline evolution is an important feature of SPM introduced in TiDB v4.0.

As data updates, the previously bound execution plan might no longer be optimal. The baseline evolution feature can automatically optimize the bound execution plan.

In addition, baseline evolution, to a certain extent, can also avoid the jitter brought to the execution plan caused by the change of statistical information.

Usage

Use the following statement to enable automatic binding evolution:

```
SET GLOBAL tidb_evolve_plan_baselines = ON;
```

The default value of `tidb_evolve_plan_baselines` is `off`.

> **Warning:**
>
> - Baseline evolution is an experimental feature. Unknown risks might exist. It is **NOT** recommended that you use it in the production environment.
> - This variable is forcibly set to `off` until the baseline evolution feature becomes generally available (GA). If you try to enable this feature, an error is returned. If you have already used this feature in a production environment, disable it as soon as possible. If you find that the binding status is not as expected, get support from PingCAP or the community.

After the automatic binding evolution feature is enabled, if the optimal execution plan selected by the optimizer is not among the binding execution plans, the optimizer marks the plan as an execution plan that waits for verification. At every `bind-info-lease` (the default value is `3s`) interval, an execution plan to be verified is selected and compared with the binding execution plan that has the least cost in terms of the actual execution time. If the plan to be verified has shorter execution time (the current criterion for the comparison is that the execution time of the plan to be verified is no longer than 2/3 that of the binding execution plan), this plan is marked as a usable binding. The following example describes the process above.

Assume that table `t` is defined as follows:

```
CREATE TABLE t(a INT, b INT, KEY(a), KEY(b));
```

Perform the following query on table `t`:

```
SELECT * FROM t WHERE a < 100 AND b < 100;
```

In the table defined above, few rows meet the `a < 100` condition. But for some reason, the optimizer mistakenly selects the full table scan instead of the optimal execution plan that uses index `a`. You can first use the following statement to create a binding:

```
CREATE GLOBAL BINDING for SELECT * FROM t WHERE a < 100 AND b < 100 using
    ↪ SELECT * FROM t use index(a) WHERE a < 100 AND b < 100;
```

When the query above is executed again, the optimizer selects index `a` (influenced by the binding created above) to reduce the query time.

Assuming that as insertions and deletions are performed on table `t`, an increasing number of rows meet the `a < 100` condition and a decreasing number of rows meet the `b < 100` condition. At this time, using index `a` under the binding might no longer be the optimal plan.

The binding evolution can address this kind of issues. When the optimizer recognizes data change in a table, it generates an execution plan for the query that uses index `b`. However, because the binding of the current plan exists, this query plan is not adopted and executed. Instead, this plan is stored in the backend evolution list. During the evolution process, if this plan is verified to have an obviously shorter execution time than that of the current execution plan that uses index `a`, index `b` is added into the available binding list. After this, when the query is executed again, the optimizer first generates the execution plan that uses index `b` and makes sure that this plan is in the binding list. Then the optimizer adopts and executes this plan to reduce the query time after data changes.

To reduce the impact that the automatic evolution has on clusters, use the following configurations:

- Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is `600s`. In the actual verification process, the maximum execution time is also limited to no more than twice the time of the verified execution plan.
- Set `tidb_evolve_plan_task_start_time` (`00:00 +0000` by default) and `tidb_evolve_plan_task_e`
  ↪ (`23:59 +0000` by default) to limit the time window.

Notes

Because the baseline evolution automatically creates a new binding, when the query environment changes, the automatically created binding might have multiple behavior choices. Pay attention to the following notes:

- Baseline evolution only evolves standardized SQL statements that have at least one global binding.
- Because creating a new binding deletes all previous bindings (for a standardized SQL statement), the automatically evolved binding will be deleted after manually creating a new binding.

- All hints related to the calculation process are retained during the evolution. These hints are as follows:

Hint	Description
`memory_quota` ↪	The maximum memory that can be used for a query.
`use_toja`	Whether the optimizer transforms sub-queries to Join.
`use_cascades` ↪	Whether to use the cascades optimizer.
`no_index_merge` ↪	Whether the optimizer uses Index Merge as an option for reading tables.
`read_consistent_replica` ↪	Whether to forcibly enable Follower Read when reading tables.
`max_execution_time` ↪	The longest duration for a query.

- `read_from_storage` is a special hint in that it specifies whether to read data from TiKV or from TiFlash when reading tables. Because TiDB provides isolation reads, when the isolation condition changes, this hint has a great influence on the evolved execution plan. Therefore, when this hint exists in the initially created binding, TiDB ignores all its evolved bindings.

11.3.4.3.4 Upgrade checklist

During cluster upgrade, SQL Plan Management (SPM) might cause compatibility issues and make the upgrade fail. To ensure a successful upgrade, you need to include the following list for upgrade precheck:

- When you upgrade from a version earlier than v5.2.0 (that is, v4.0, v5.0, and v5.1) to the current version, make sure that `tidb_evolve_plan_baselines` is disabled before the upgrade. To disable this variable, perform the following steps.

```
-- Check whether `tidb_evolve_plan_baselines` is disabled in the
   ↪ earlier version.
```

```
SELECT @@global.tidb_evolve_plan_baselines;

-- If `tidb_evolve_plan_baselines` is still enabled, disable it.

SET GLOBAL tidb_evolve_plan_baselines = OFF;
```

- Before you upgrade from v4.0 to the current version, you need to check whether the syntax of all queries corresponding to the available SQL bindings is correct in the new version. If any syntax errors exist, delete the corresponding SQL binding. To do that, perform the following steps.

```
-- Check the query corresponding to the available SQL binding in the
   ↪ version to be upgraded.

SELECT bind_sql FROM mysql.bind_info WHERE status = 'using';

-- Verify the result from the above SQL query in the test environment
   ↪  of the new version.

bind_sql_0;
bind_sql_1;
...

-- In the case of a syntax error (ERROR 1064 (42000): You have an
   ↪ error in your SQL syntax), delete the corresponding binding.
-- For any other errors (for example, tables are not found), it means
   ↪  that the syntax is compatible. No other operation is needed.
```

11.3.4.4 The Blocklist of Optimization Rules and Expression Pushdown

This document introduces how to use the blocklist of optimization rules and the blocklist of expression pushdown to control the behavior of TiDB.

11.3.4.4.1 The blocklist of optimization rules

The blocklist of optimization rules is one way to tune optimization rules, mainly used to manually disable some optimization rules.

Important optimization rules

Optimization Rule	Rule Name	Description
Column pruning	column_prune	Prune operator will prune the column if it is not needed by the upper executor.
Decorrelate subquery	decorrelate	Tries to rewrite the correlated subquery to non-correlated join or aggregation.

Optimization Rule	Rule Name	Description
Aggregation elimination	aggregation_eliminate	Tries to remove unnecessary aggregation operators from the execution plan.
Projection elimination	projection_eliminate	Removes unnecessary projection operators from the execution plan.

Optimization Rule	Option Name	Description
Max/Min elimination	max_min_eliminate	Remove some max/min functions in aggregation to the `order by` + `limit 1` form.
Predicate push-down	predicate_push_down	Trigger to push predicates down to the operator that is closer to the data source.

Optimization Rule	Rule Name	Description
Outer join elimination	outer_join_elimination	Tries to remove the unnecessary left join or right join from the execution plan.

Optimization Rule	Partition Name	Description
Partition pruning	partition_processor	Prunes partitions which are rejected by the predicates and rewrite partitioned table query to the `UnionAll` ↪ ↪ `+` ↪ ↪ `Partition` ↪ ↪ `Datasource` ↪ form.
Aggregation push-down	aggregation_push_down	Tries to push aggregations down to their children.

Optimization Rule	Rule Name	Description
TopN push-down	topn_push_down	This rule is to push the TopN operator to the place closer to the data source.
Join reorder	join_reorder	Decides the order of multi-table joins.
Derive TopN or Limit from window functions	derive_topn_from_window	Derives the TopN or Limit operator from window functions.

Disable optimization rules

You can use the blocklist of optimization rules to disable some of them if some rules lead to a sub-optimal execution plan for special queries.

Usage

> **Note:**
>
> All the following operations need the `super privilege` privilege of the database. Each optimization rule has a name. For example, the name of column pruning is `column_prune`. The names of all optimization rules can be found in the second column of the table Important Optimization Rules.

- If you want to disable some rules, write its name to the `mysql.opt_rule_blacklist` table. For example:

```
INSERT INTO mysql.opt_rule_blacklist VALUES("join_reorder"), ("
    ↪ topn_push_down");
```

Executing the following SQL statement can make the above operation take effect immediately. The effective range includes all old connections of the corresponding TiDB server:

```
admin reload opt_rule_blacklist;
```

> **Note:**
>
> `admin reload opt_rule_blacklist` only takes effect on the TiDB server where the above statement has been run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

- If you want to re-enable a rule, delete the corresponding data in the table, and then run the `admin reload` statement:

```
DELETE FROM mysql.opt_rule_blacklist WHERE name IN ("join_reorder", "
    ↪ topn_push_down");
```

```
admin reload opt_rule_blacklist;
```

11.3.4.4.2 The blocklist of expression pushdown

The blocklist of expression pushdown is one way to tune the expression pushdown, mainly used to manually disable some expressions of some specific data types.

Expressions that are supported to be pushed down

For more information about the expressions that are supported to be pushed down, see Supported expressions for pushdown to TiKV.

Disable the pushdown of specific expressions

When you get wrong results due to the expression pushdown, you can use the blocklist to make a quick recovery for the application. More specifically, you can add some of the supported functions or operators to the `mysql.expr_pushdown_blacklist` table to disable the pushdown of specific expressions.

The schema of `mysql.expr_pushdown_blacklist` is shown as follows:

```
DESC mysql.expr_pushdown_blacklist;
```

```
+------------+--------------+------+------+-------------------+-------+
| Field      | Type         | Null | Key | Default           | Extra |
+------------+--------------+------+------+-------------------+-------+
| name       | char(100)    | NO   |     | NULL              |       |
| store_type | char(100)  | NO   |     | tikv,tiflash,tidb |     |
| reason     | varchar(200) | YES |     | NULL              |       |
+------------+--------------+------+------+-------------------+-------+
3 rows in set (0.00 sec)
```

Here is the description of each field above:

- `name`: The name of the function that is disabled to be pushed down.
- `store_type`: To specify the component that you want to prevent the function from being pushed down to for computing. Available components are `tidb`, `tikv`, and `tiflash`. The `store_type` is case-insensitive. If you need to specify multiple components, use a comma to separate each component.
    - When `store_type` is `tidb`, it indicates whether the function can be executed in other TiDB servers while the TiDB memory table is being read.
    - When `store_type` is `tikv`, it indicates whether the function can be executed in TiKV server's Coprocessor component.
    - When `store_type` is `tiflash`, it indicates whether the function can be executed in TiFlash Server's Coprocessor component.
- `reason`: To record the reason why this function is added to the blocklist.

Usage

This section describes how to use the blocklist of expression pushdown.

Add to the blocklist

To add one or more expressions (functions or operators) to the blocklist, perform the following steps:

1. Insert the corresponding function name or operator name, and the set of components you want to disable the pushdown, to the `mysql.expr_pushdown_blacklist` table.

2. Execute `admin reload expr_pushdown_blacklist`.

Remove from the blocklist

To remove one or more expressions from the blocklist, perform the following steps:

1. Delete the corresponding function name or operator name, and the set of components you want to disable the pushdown, from the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

> **Note:**
>
> `admin reload expr_pushdown_blacklist` only takes effect on the TiDB server where this statement is run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

11.3.4.4.3 Expression blocklist usage example

In the following example, the `<` and `>` operators are added to the blocklist, and then the `>` operator is removed from the blocklist.

To judge whether the blocklist takes effect, observe the results of `EXPLAIN` (See TiDB Query Execution Plan Overview).

1. The predicates `a < 2` and `a > 2` in the `WHERE` clause of the following SQL statement can be pushed down to TiKV.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
   ↪ ----------------------+----------+-----------+---------------+-----------
   ↪
| id                    | estRows | task    | access object | operator
   ↪ info                |
+--
   ↪ ----------------------+----------+-----------+---------------+-----------
   ↪
| TableReader_7         | 0.00    | root    |               | data:
   ↪ Selection_6                |
|  ─Selection_6         | 0.00    | cop[tikv] |             | gt(ssb_1.t.
   ↪ a, 2), lt(ssb_1.t.a, 2) |
|    ─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo |
```

```
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

2. Insert the expression to the `mysql.expr_pushdown_blacklist` table and execute `admin reload expr_pushdown_blacklist`.

```
INSERT INTO mysql.expr_pushdown_blacklist VALUES('<','tikv',''), ('>',
    ↪ 'tikv','');
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

3. Observe the execution plan again and you will find that both the `<` and `>` operators are not pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 and a > 2;
```

```
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
| id                    | estRows | task     | access object | operator
    ↪ info                |
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
| Selection_7           | 10000.00 | root    |               | gt(ssb_1.t.a
    ↪ , 2), lt(ssb_1.t.a, 2) |
| └─TableReader_6       | 10000.00 | root    |               | data:
    ↪ TableFullScan_5           |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

4. Remove one expression (here is `>`) from the blocklist and execute `admin reload expr_pushdown_blacklist`.

```
DELETE FROM mysql.expr_pushdown_blacklist WHERE name = '>';
```

```
Query OK, 1 row affected (0.01 sec)
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

5. Observe the execution plan again and you will find that < is not pushed down while > is pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
| id                        | estRows | task      | access object | operator
   ↪  info            |
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
| Selection_8               | 0.00     | root      |               | lt(ssb_1.t
   ↪ .a, 2)           |
| └─TableReader_7           | 0.00     | root      |               | data:
   ↪ Selection_6           |
|   └─Selection_6           | 0.00     | cop[tikv] |               | gt(ssb_1.
   ↪ t.a, 2)           |
|     └─TableFullScan_5     | 10000.00 | cop[tikv] | table:t       | keep
   ↪ order:false, stats:pseudo |
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
4 rows in set (0.00 sec)
```

11.3.4.5 Optimizer Fix Controls

As the product evolves iteratively, the behavior of the TiDB optimizer changes, which in turn generates more reasonable execution plans. However, in some particular scenarios, the new behavior might lead to unexpected results. For example:

- The effect of some behaviors relies on a specific scenario. Changes that bring improvements to most scenarios might cause regressions to others.

- Sometimes, the relationship between changes in the behavior details and their consequences is very complicated. An improvement in a certain behavior might cause overall regression.

Therefore, TiDB provides the Optimizer Fix Controls feature that allows you to make fine-grained control of TiDB optimizer behaviors by setting values for a group of fixes. This document describes the Optimizer Fix Controls feature and how to use them, and lists all the fixes that TiDB currently supports for Optimizer Fix Controls.

11.3.4.5.1 Introduction to `tidb_opt_fix_control`

Starting from v6.5.3 and v7.1.0, TiDB provides the `tidb_opt_fix_control` system variable to control the behavior of the optimizer in a more fine-grained way.

Each fix is a control item used to adjust the behavior in the TiDB optimizer for one particular purpose. It is denoted by a number that corresponds to a GitHub Issue that contains the technical details of the behavior change. For example, for fix `44262`, you can review what it controls in Issue 44262.

The `tidb_opt_fix_control` system variable accepts multiple fixes as one value, separated by commas (`,`). The format is `"<#issue1>:<value1>,<#issue2>:<value2>,...,<#issueN>:<valueN>"`, where `<#issueN>` is the fix number. For example:

```
SET SESSION tidb_opt_fix_control = '44262:ON,44389:ON';
```

11.3.4.5.2 Optimizer Fix Controls reference

44262 New in v6.5.3 and v7.1.1

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to allow the use of Dynamic pruning mode to access the partitioned table when the GlobalStats are missing.

44389 New in v6.5.3 and v7.1.1

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- For filters such as `c = 10 and (a = 'xx' or (a = 'kk' and b = 1))`, this variable controls whether to try to build more comprehensive scan ranges for `IndexRangeScan`.

44823 New in v7.1.1

- Default value: `200`
- Possible values: `[0, 2147483647]`

- To conserve memory, Plan Cache does not cache queries that exceed a specified number of parameters.
- This variable controls the threshold for the maximum number of parameters. `0` means no limit.

44830 New in v6.5.7

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether Plan Cache is allowed to cache execution plans with the `PointGet` operator generated during physical optimization.

44855 New in v6.5.4 and v7.1.1

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- In some scenarios, when the `Probe` side of an `IndexJoin` operator contains a `Selection` operator, TiDB severely overestimates the row count of `IndexScan`. This might cause suboptimal query plans to be selected instead of `IndexJoin`.
- To mitigate this issue, TiDB has introduced an improvement. However, due to potential query plan fallback risks, this improvement is disabled by default.
- This variable controls whether to enable the preceding improvement.

46177 New in v6.5.6 and v7.1.3

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether the optimizer explores enforced plans during query optimization after finding an unenforced plan.

12 Tutorials

12.1 Multiple Availability Zones in One Region Deployment

As a distributed SQL database, TiDB combines the best features of the traditional relational database and the scalability of the NoSQL database, and is highly available across availability zones (AZs). This document introduces the deployment of multiple AZs in one region.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.1.1 Raft protocol

Raft is a distributed consensus algorithm. Using this algorithm, both PD and TiKV, among components of the TiDB cluster, achieve disaster recovery of data, which is implemented through the following mechanisms:

- The essential role of Raft members is to perform log replication and act as a state machine. Among Raft members, data replication is implemented by replicating logs. Raft members change their own states in different conditions to elect a leader to provide services.
- Raft is a voting system that follows the majority protocol. In a Raft group, if a member gets the majority of votes, its membership changes to leader. In other words, when the majority of nodes remain in the Raft group, a leader can be elected to provide services.

To take advantage of Raft's reliability, the following conditions must be met in a real deployment scenario:

- Use at least three servers in case one server fails.
- Use at least three racks in case one rack fails.
- Use at least three AZs in case one AZ fails.
- Deploy TiDB in at least three regions in case data safety issue occurs in one region.

The native Raft protocol does not have good support for an even number of replicas. Considering the impact of cross-region network latency, three AZs in the same region might be the most suitable solution to a highly available and disaster tolerant Raft deployment.

12.1.2 Three AZs in one region deployment

TiDB clusters can be deployed in three AZs in the same region. In this solution, data replication across the three AZs is implemented using the Raft protocol within the cluster. These three AZs can provide read and write services at the same time. Data consistency is not affected even if one AZ fails.

12.1.2.1 Simple architecture

TiDB, TiKV, and PD are distributed among three AZs, which is the most common deployment with the highest availability.

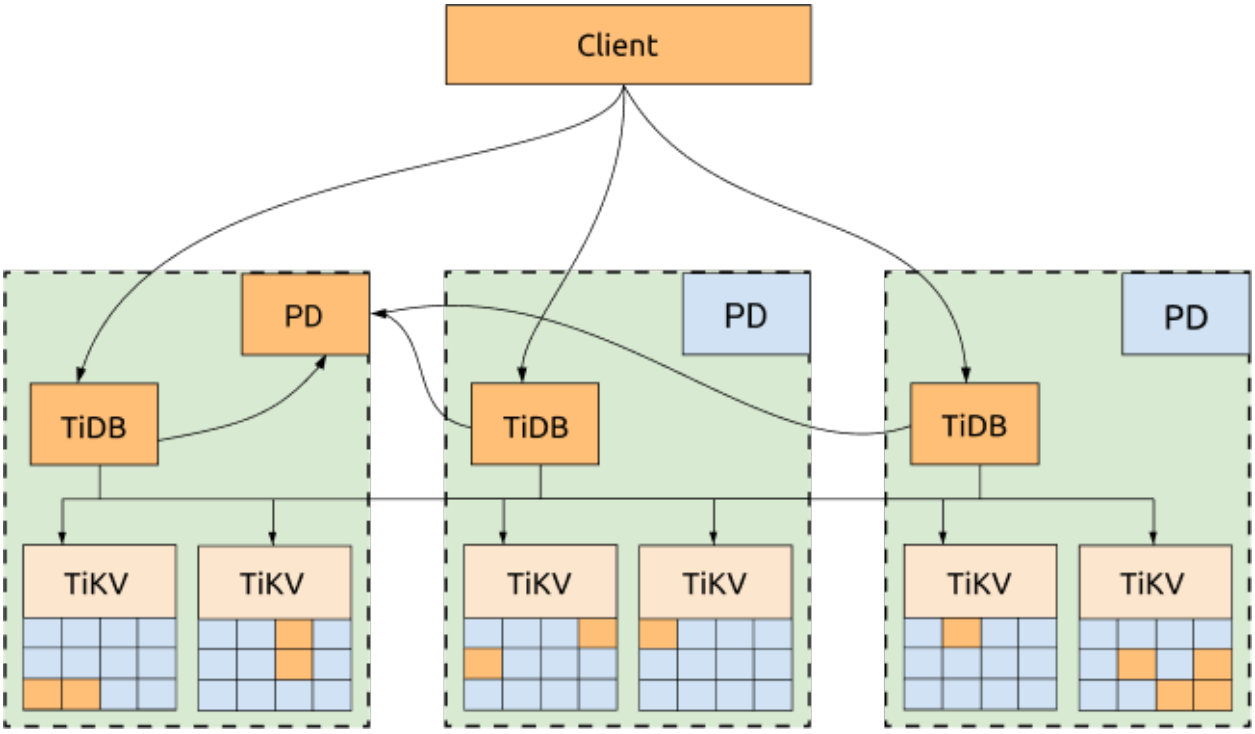

Figure 392: 3-AZ Deployment Architecture

Advantages:

- All replicas are distributed among three AZs, with high availability and disaster recovery capability.
- No data will be lost if one AZ is down (RPO = 0).
- Even if one AZ is down, the other two AZs will automatically start leader election and automatically resume services within a certain period (within 20 seconds in most cases). See the following diagram for more information:

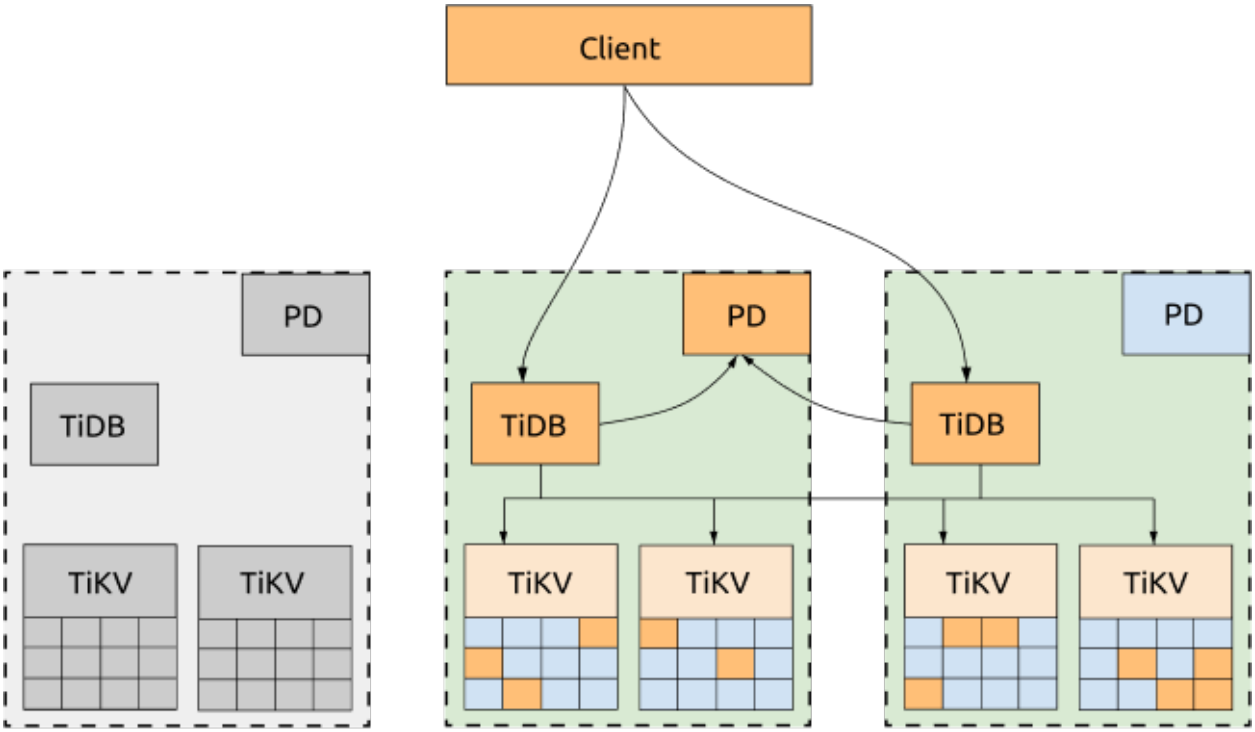

Figure 393: Disaster Recovery for 3-AZ Deployment

Disadvantages:

The performance can be affected by the network latency.

- For writes, all the data has to be replicated to at least two AZs. Because TiDB uses a two-phase commit for writes, the write latency is at least twice the latency of the network between two AZs.
- The read performance will also be affected by the network latency if the leader is not in the same AZ with the TiDB node that sends the read request.
- Each TiDB transaction needs to obtain TimeStamp Oracle (TSO) from the PD leader. So if the TiDB and PD leaders are not in the same AZ, the performance of the transactions will also be affected by the network latency because each transaction with the write request has to obtain TSO twice.

12.1.2.2 Optimized architecture

If not all of the three AZs need to provide services to the applications, you can dispatch all the requests to one AZ and configure the scheduling policy to migrate the TiKV Region leader and PD leader to the same AZ. In this way, neither obtaining TSO nor reading TiKV Regions will be impacted by the network latency across AZs. If this AZ is down, the PD leader and TiKV Region leader will be automatically elected in other surviving AZs, and you just need to switch the requests to the AZs that are still alive.

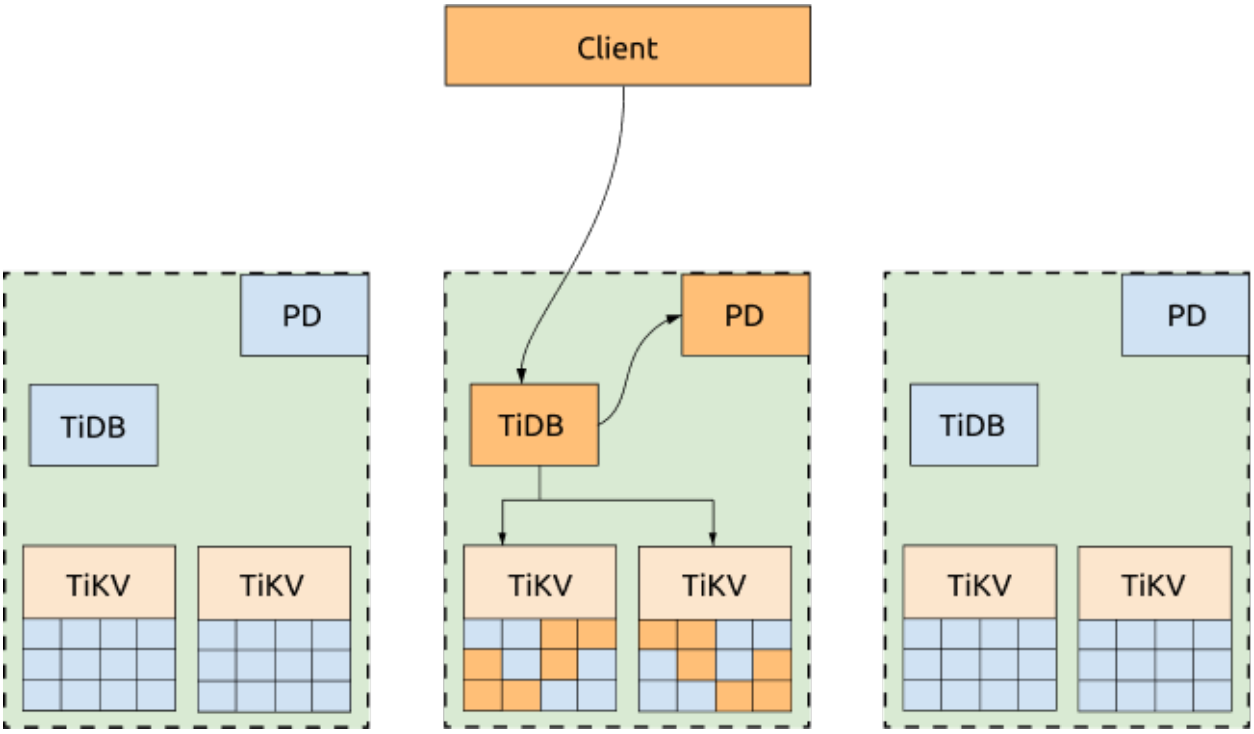

Figure 394: Read Performance Optimized 3-AZ Deployment

Advantages:

The cluster's read performance and the capability to get TSO are improved. A configuration template of scheduling policy is as follows:

```
-- Evicts all leaders of other AZs to the AZ that provides services to the
   ↪ application.
config set label-property reject-leader LabelName labelValue

-- Migrates PD leaders and sets priority.
member leader transfer pdName1
member leader_priority pdName1 5
member leader_priority pdName2 4
member leader_priority pdName3 3
```

Note:

Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

Disadvantages:

- Write scenarios are still affected by network latency across AZs. This is because Raft follows the majority protocol and all written data must be replicated to at least two AZs.
- The TiDB server that provides services is only in one AZ.
- All application traffic is processed by one AZ and the performance is limited by the network bandwidth pressure of that AZ.
- The capability to get TSO and the read performance are affected by whether the PD server and TiKV server are up in the AZ that processes application traffic. If these servers are down, the application is still affected by the cross-center network latency.

12.1.2.3 Deployment example

This section provides a topology example, and introduces TiKV labels and TiKV labels planning.

12.1.2.3.1 Topology example

The following example assumes that three AZs (AZ1, AZ2, and AZ3) are located in one region; each AZ has two sets of racks and each rack has three servers. The example ignores the hybrid deployment or the scenario where multiple instances are deployed on one machine. The deployment of a TiDB cluster (three replicas) on three AZs in one region is as follows:

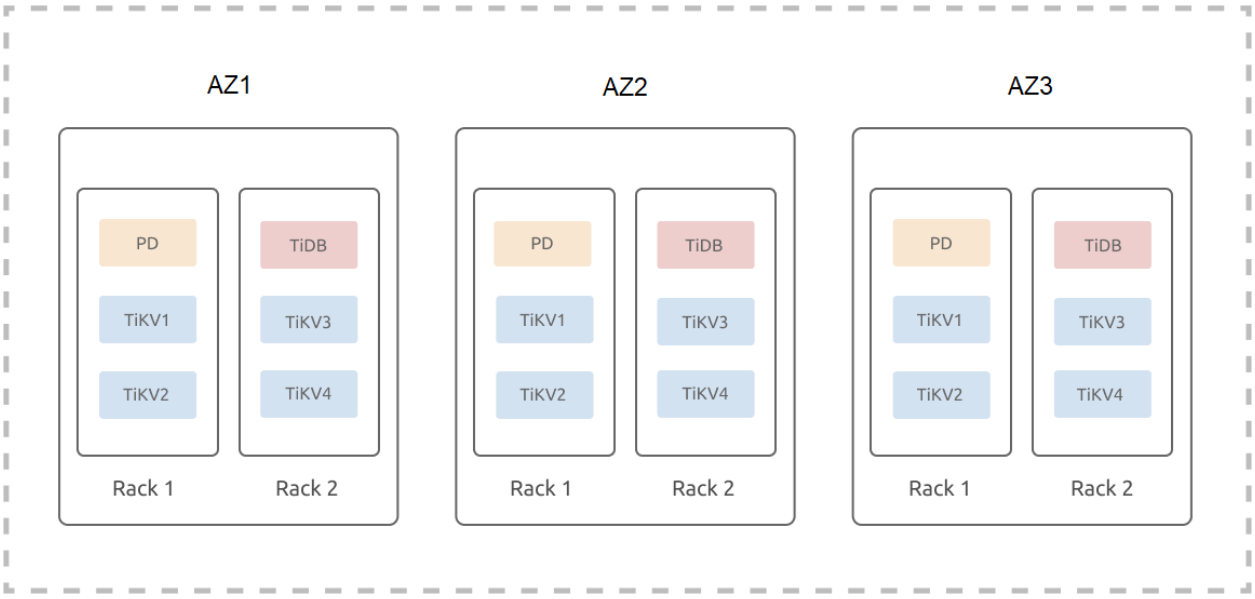

Figure 395: 3-AZ in One Region

12.1.2.3.2 TiKV labels

TiKV is a Multi-Raft system where data is divided into Regions and the size of each Region is 96 MB by default. Three replicas of each Region form a Raft group. For a TiDB cluster of three replicas, because the number of Region replicas is independent of the TiKV instance numbers, three replicas of a Region are only scheduled to three TiKV instances. This means that even if the cluster is scaled out to have N TiKV instances, it is still a cluster of three replicas.

Because a Raft group of three replicas tolerates only one replica failure, even if the cluster is scaled out to have N TiKV instances, this cluster still tolerates only one replica failure. Two failed TiKV instances might cause some Regions to lose replicas and the data in this cluster is no longer complete. SQL requests that access data from these Regions will fail. The probability of two simultaneous failures among N TiKV instances is much higher than the probability of two simultaneous failures among three TiKV instances. This means that the more TiKV instances the Multi-Raft system is scaled out to have, the less the availability of the system.

Because of the preceding limitation, `label` is used to describe the location information of TiKV. The label information is refreshed to the TiKV startup configuration file with deployment or rolling upgrade operations. The started TiKV reports its latest label information to PD. Based on the user-registered label name (the label metadata) and the TiKV topology, PD optimally schedules Region replicas and improves the system availability.

12.1.2.3.3 TiKV labels planning example

To improve the availability and disaster recovery of the system, you need to design and plan TiKV labels according to your existing physical resources and the disaster recovery capability. You also need to edit the cluster initialization configuration file according to the planned topology:

```
server_configs:
  pd:
    replication.location-labels: ["zone","az","rack","host"]

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r1", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r2", host: "32" }
  - host: 10.63.10.33
    config:
```

```
    server.labels: { zone: "z1", az: "az1", rack: "r2", host: "33" }

- host: 10.63.10.34
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r1", host: "34" }
- host: 10.63.10.35
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r1", host: "35" }
- host: 10.63.10.36
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r2", host: "36" }
- host: 10.63.10.37
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r2", host: "37" }

- host: 10.63.10.38
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r1", host: "38" }
- host: 10.63.10.39
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r1", host: "39" }
- host: 10.63.10.40
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r2", host: "40" }
- host: 10.63.10.41
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r2", host: "41" }
```

In the preceding example, `zone` is the logical availability zone layer that controls the isolation of replicas (three replicas in the example cluster).

Considering that the AZs might be scaled out in the future, the three-layer label structure (`az`, `rack`, and `host`) is not directly adopted. Assuming that `AZ2`, `AZ3`, and `AZ4` are to be scaled out, you only need to scale out the AZs in the corresponding availability zone and scale out the racks in the corresponding AZ.

If this three-layer label structure is directly adopted, after scaling out an AZ, you might need to apply new labels and the data in TiKV needs to be rebalanced.

12.1.2.4 High availability and disaster recovery analysis

The multiple AZs in one region deployment can guarantee that if one AZ fails, the cluster can automatically recover services without manual intervention. Data consistency is also guaranteed. Note that scheduling policies are used to optimize performance, but when a failure occurs, these policies prioritize availability over performance.

12.2 Three Availability Zones in Two Regions Deployment

This document introduces the architecture and configuration of the three availability zones (AZs) in two regions deployment.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.2.1 Overview

The architecture of three AZs in two regions is a highly available and disaster tolerant deployment solution that provides a production data AZ, a disaster recovery AZ in the same region, and a disaster recovery AZ in another region. In this mode, the three AZs in two regions are interconnected. If one AZ fails or suffers from a disaster, other AZs can still operate well and take over the key applications or all applications. Compared with the multi-AZ in one region deployment, this solution has the advantage of cross-region high availability and can survive region-level natural disasters.

The distributed database TiDB natively supports the three-AZ-in-two-region architecture by using the Raft algorithm, and guarantees the consistency and high availability of data within a database cluster. Because the network latency across AZs in the same region is relatively low, the application traffic can be dispatched to two AZs in the same region, and the traffic load can be shared by these two AZs by controlling the distribution of TiKV Region leaders and PD leaders.

12.2.2 Deployment architecture

This section takes the example of Seattle and San Francisco to explain the deployment mode of three AZs in two regions for the distributed database of TiDB.

In this example, two AZs (AZ1 and AZ2) are located in Seattle and another AZ (AZ3) is located in San Francisco. The network latency between AZ1 and AZ2 is lower than 3 milliseconds. The network latency between AZ3 and AZ1/AZ2 in Seattle is about 20 milliseconds (ISP dedicated network is used).

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to three AZs in two regions: AZ1 in Seattle, AZ2 in Seattle, and AZ3 in San Francisco.
- The cluster has five replicas, two in AZ1, two in AZ2, and one in AZ3. For the TiKV component, each rack has a label, which means that each rack has a replica.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

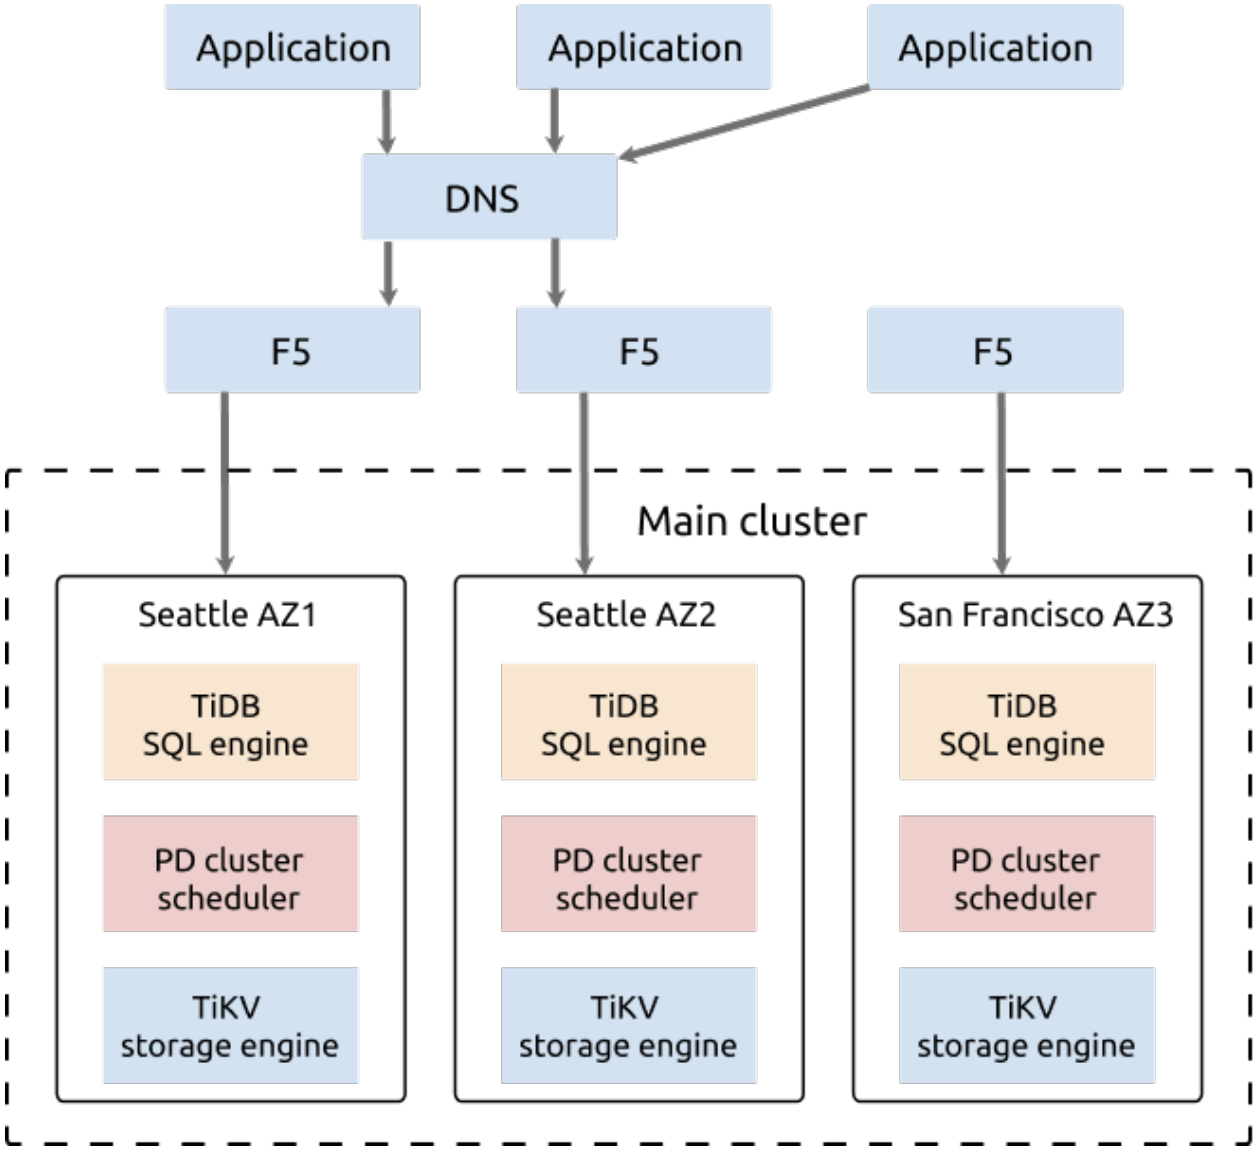

Figure 396: 3-AZ-in-2-region architecture

This architecture is highly available. The distribution of Region leaders is restricted to the two AZs (AZ1 and AZ2) that are in the same region (Seattle). Compared with the three-AZ solution in which the distribution of Region leaders is not restricted, this architecture has the following advantages and disadvantages:

- **Advantages**
    - Region leaders are in AZs of the same region with low latency, so the write is faster.
    - The two AZs can provide services at the same time, so the resource usage rate is higher.

- If one AZ fails, services are still available and data safety is ensured.

- **Disadvantages**

  - Because the data consistency is achieved by the Raft algorithm, when two AZs in the same region fail at the same time, only one surviving replica remains in the disaster recovery AZ in another region (San Francisco). This cannot meet the requirement of the Raft algorithm that most replicas survive. As a result, the cluster can be temporarily unavailable. Maintenance staff needs to recover the cluster from the one surviving replica and a small amount of hot data that has not been replicated will be lost. But this case is a rare occurrence.
  - Because the ISP dedicated network is used, the network infrastructure of this architecture has a high cost.
  - Five replicas are configured in three AZs in two regions, data redundancy increases, which brings a higher storage cost.

12.2.2.1 Deployment details

The configuration of the three AZs in two regions (Seattle and San Francisco) deployment plan is illustrated as follows:

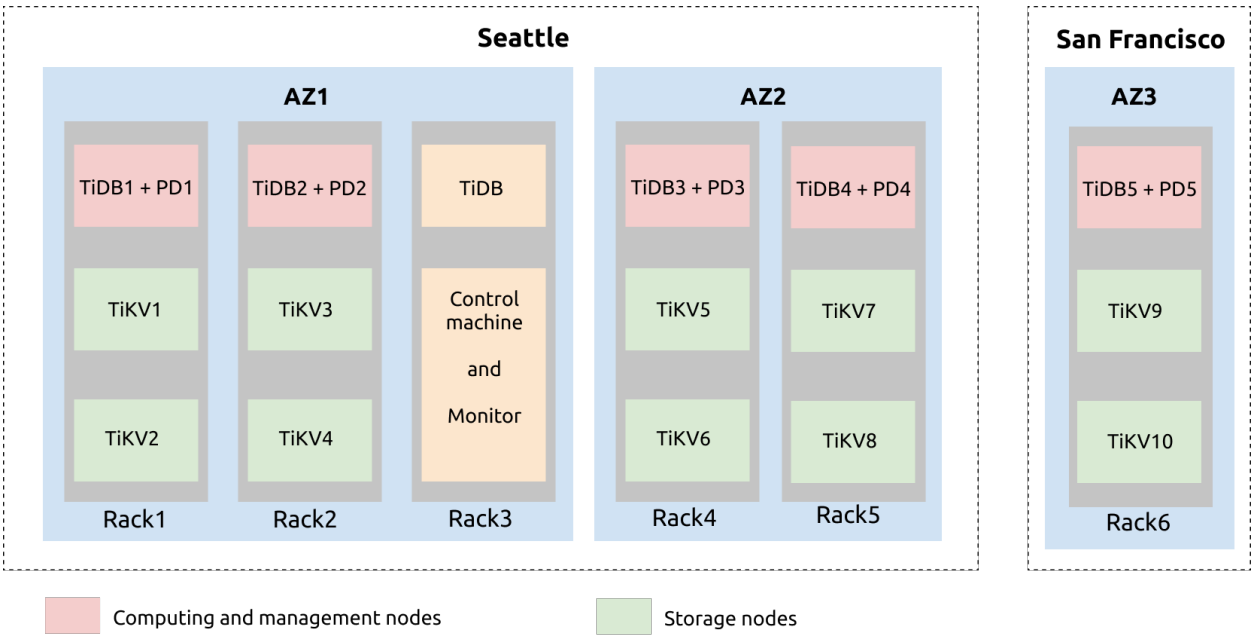

Figure 397: 3-AZ-2-region

From the preceding illustration, you can see that Seattle has two AZs: AZ1 and AZ2. AZ1 has three sets of racks: rac1, rac2, and rac3. AZ2 has two racks: rac4 and rac5. The AZ3 in San Francisco has the rac6 rack.

In the rac1 of AZ1, one server is deployed with TiDB and PD services, and the other two servers are deployed with TiKV services. Each TiKV server is deployed with two TiKV instances (tikv-server). This is similar to rac2, rac4, rac5, and rac6.

The TiDB server, the control machine, and the monitoring server are on rac3. The TiDB server is deployed for regular maintenance and backup. Prometheus, Grafana, and the restore tools are deployed on the control machine and monitoring machine.

Another backup server can be added to deploy Drainer. Drainer saves binlog data to a specified location by outputting files, to achieve incremental backup.

12.2.3 Configuration

12.2.3.1 Example

See the following `tiup topology.yaml` yaml file for example:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
  tikv:
    server.grpc-compression-type: gzip
  pd:
    replication.location-labels: ["az","replication zone","rack","host"]

pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
  - host: 10.63.10.13
    name: "pd-13"
  - host: 10.63.10.14
    name: "pd-14"

tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
```

```
  - host: 10.63.10.12
  - host: 10.63.10.13
  - host: 10.63.10.14

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
          ↪ }
  - host: 10.63.10.31
    config:
      server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
          ↪ }
  - host: 10.63.10.32
    config:
      server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
          ↪ }
  - host: 10.63.10.33
    config:
      server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
          ↪ }
  - host: 10.63.10.34
    config:
      server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
          ↪ }
      raftstore.raft-min-election-timeout-ticks: 50
      raftstore.raft-max-election-timeout-ticks: 60

monitoring_servers:
  - host: 10.63.10.60

grafana_servers:
  - host: 10.63.10.60

alertmanager_servers:
  - host: 10.63.10.60
```

12.2.3.2 Labels design

In the deployment of three AZs in two regions, the label design requires taking availability and disaster recovery into account. It is recommended that you define the four levels (`az`, `replication zone`, `rack`, and `host`) based on the physical structure of the deployment.

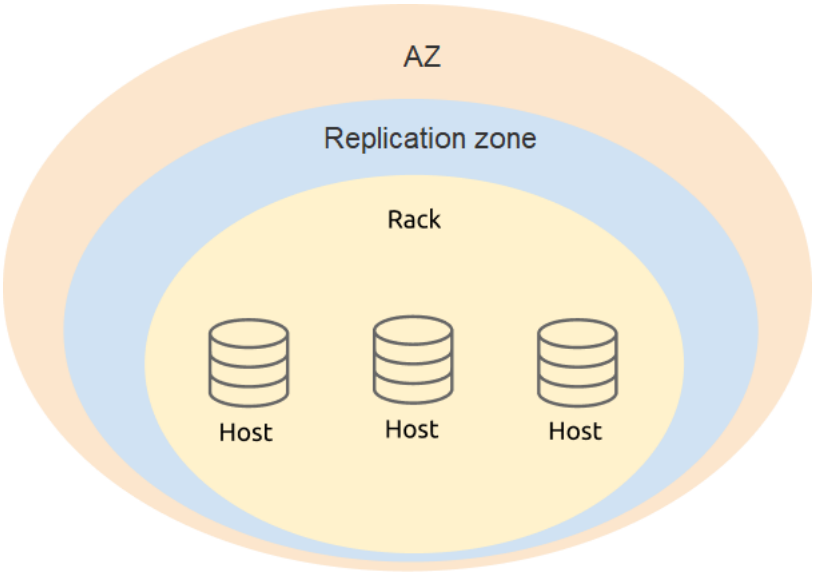

Figure 398: Label logical definition

In the PD configuration, add level information of TiKV labels:

```
server_configs:
  pd:
    replication.location-labels: ["az","replication zone","rack","host"]
```

The configuration of `tikv_servers` is based on the label information of the real physical deployment location of TiKV, which makes it easier for PD to perform global management and scheduling.

```
tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
          ↪ }
  - host: 10.63.10.31
    config:
      server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
          ↪ }
  - host: 10.63.10.32
    config:
      server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
          ↪ }
  - host: 10.63.10.33
    config:
      server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
          ↪ }
  - host: 10.63.10.34
```

```
config:
  server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
    ↪ }
```

12.2.3.3 Optimize parameter configuration

In the deployment of three AZs in two regions, to optimize performance, you need to not only configure regular parameters, but also adjust component parameters.

- Enable gRPC message compression in TiKV. Because data of the cluster is transmitted in the network, you can enable the gRPC message compression to lower the network traffic.

```
server.grpc-compression-type: gzip
```

- Optimize the network configuration of the TiKV node in another region (San Francisco). Modify the following TiKV parameters for AZ3 in San Francisco and try to prevent the replica in this TiKV node from participating in the Raft election.

```
raftstore.raft-min-election-timeout-ticks: 50
raftstore.raft-max-election-timeout-ticks: 60
```

> **Note:**
>
> Using `raftstore.raft-min-election-timeout-ticks` and `raftstore.` ↪ `raft-max-election-timeout-ticks` to configure larger election timeout ticks for a TiKV node can significantly decrease the likelihood of Regions on that node becoming Leaders. However, in a disaster scenario where some TiKV nodes are offline and the remaining active TiKV nodes lag behind in Raft logs, only Regions on this TiKV node with large election timeout ticks can become Leaders. Because Regions on this TiKV node must wait for at least the duration set by 'raftstore.raft-min-election-timeout-ticks' before initiating an election, it is recommended to avoid setting these values excessively large to prevent potential impact on the cluster availability in such scenarios.

- Configure scheduling. After the cluster is enabled, use the `tiup ctl:v{CLUSTER_VERSION` ↪ `} pd` tool to modify the scheduling policy. Modify the number of TiKV Raft replicas. Configure this number as planned. In this example, the number of replicas is five.

```
config set max-replicas 5
```

- Forbid scheduling the Raft leader to AZ3. Scheduling the Raft leader to another region (AZ3) causes unnecessary network overhead between AZ1/AZ2 in Seattle and AZ3 in San Francisco. The network bandwidth and latency also affect the performance of the TiDB cluster.

```
config set label-property reject-leader dc 3
```

> **Note:**
>
> Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

- Configure the priority of PD. To avoid the situation where the PD leader is in another region (AZ3), you can increase the priority of local PD (in Seattle) and decrease the priority of PD in another region (San Francisco). The larger the number, the higher the priority.

```
member leader_priority PD-10 5
member leader_priority PD-11 5
member leader_priority PD-12 5
member leader_priority PD-13 5
member leader_priority PD-14 1
```

12.3 Two Availability Zones in One Region Deployment

This document introduces the deployment mode of two availability zones (AZs) in one region, including the architecture, configuration, how to enable this deployment mode, and how to use replicas in this mode.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.3.1 Introduction

TiDB usually adopts the multi-AZ deployment solution to ensure high availability and disaster recovery capability. The multi-AZ deployment solution includes multiple deployment modes, such as multiple AZs in one region and multiple AZs in two regions. This document introduces the deployment mode of two AZs in one region. Deployed in this mode, TiDB can also meet the requirements of high availability and disaster recovery, with a lower cost. This

deployment solution adopts Data Replication Auto Synchronous mode, or the DR Auto-Sync mode.

Under the mode of two AZs in one region, the two AZs are less than 50 kilometers apart. They are usually located in the same region or in two adjacent regions. The network latency between the two AZs is lower than 1.5 milliseconds and the bandwidth is higher than 10 Gbps.

12.3.2 Deployment architecture

This section takes the example of a region where two availability zones AZ1 and AZ2 are located respectively in the east and west. AZ1 is the primary AZ and AZ2 is the disaster recovery (DR) AZ.

The architecture of the cluster deployment is as follows:

- The cluster has six replicas: three Voter replicas in AZ1, and two Voter replicas along with one Learner replica in AZ2. For the TiKV component, each rack has a proper label.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

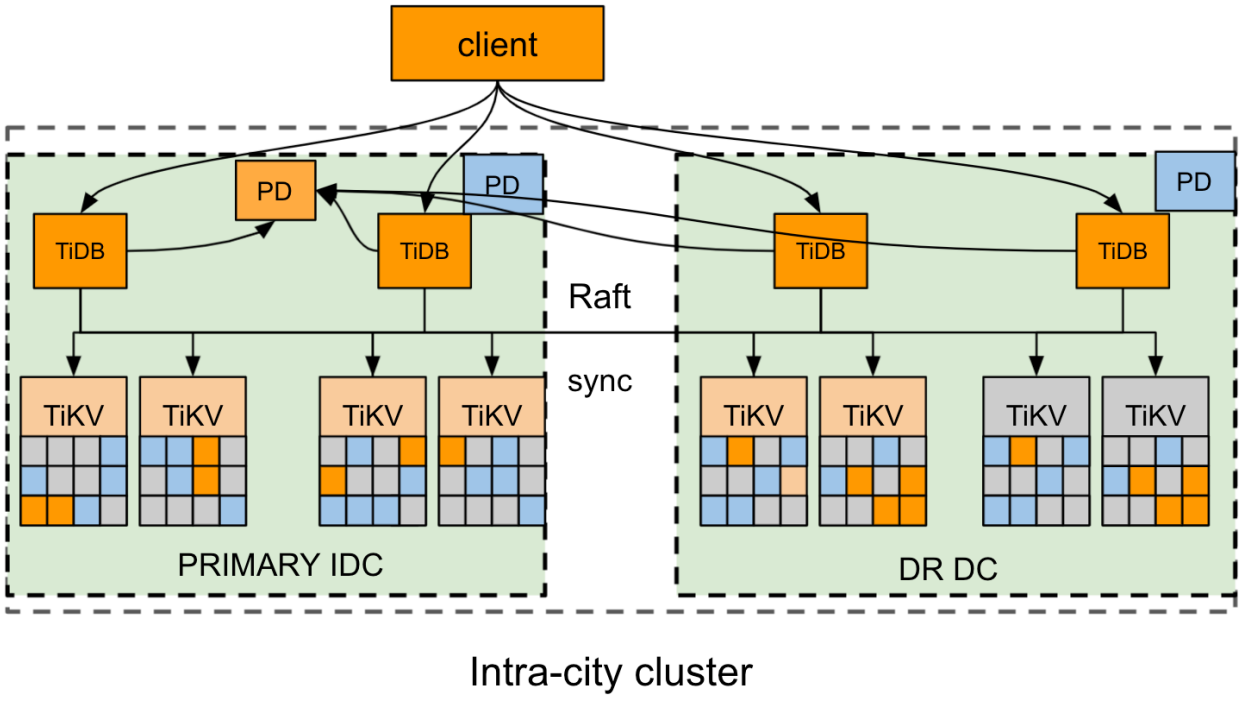

Figure 399: 2-AZ-in-1-region architecture

This deployment solution defines three statuses to control and identify the replication status of the cluster, which restricts the replication mode of TiKV. The replication mode of the cluster can automatically and adaptively switch between the three statuses. For details, see the Status switch section.

- **sync**: Synchronous replication mode. In this mode, at least one replica in the disaster recovery AZ synchronizes with the primary AZ. The Raft algorithm ensures that each log is replicated to the DR based on the label.
- **async**: Asynchronous replication mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. The Raft algorithm follows the majority protocol to replicate logs.
- **sync-recover**: Synchronous recovery mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. Raft gradually switches to the label replication mode and then reports the label information to PD.

12.3.3 Configuration

12.3.3.1 Example

The following `tiup topology.yaml` example file is a typical topology configuration for the two availability zones in one region deployment mode:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"
server_configs:
  pd:
    replication.location-labels: ["az","rack","host"]
pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
  - host: 10.63.10.12
tikv_servers:
  - host: 10.63.10.30
```

```
    config:
      server.labels: { az: "east", rack: "east-1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { az: "east", rack: "east-2", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { az: "east", rack: "east-3", host: "32" }
  - host: 10.63.10.33
    config:
      server.labels: { az: "west", rack: "west-1", host: "33" }
  - host: 10.63.10.34
    config:
      server.labels: { az: "west", rack: "west-2", host: "34" }
  - host: 10.63.10.35
    config:
      server.labels: { az: "west", rack: "west-3", host: "35" }
monitoring_servers:
  - host: 10.63.10.60
grafana_servers:
  - host: 10.63.10.60
alertmanager_servers:
  - host: 10.63.10.60
```

12.3.3.2 Placement Rules

To deploy a cluster based on the planned topology, you need to use Placement Rules to determine the locations of the cluster replicas. Taking the deployment of four replicas (two Voter replicas are at the primary AZ, one Voter replica, and one Learner replica are at the disaster recovery AZ) as an example, you can use the Placement Rules to configure the replicas as follows:

```
cat rule.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "az-east",
        "start_key": "",
        "end_key": "",
        "role": "voter",
```

```
    "count": 3,
    "label_constraints": [
      {
        "key": "az",
        "op": "in",
        "values": [
          "east"
        ]
      }
    ],
    "location_labels": [
      "az",
      "rack",
      "host"
    ]
  },
  {
    "group_id": "pd",
    "id": "az-west-1",
    "start_key": "",
    "end_key": "",
    "role": "follower",
    "count": 2,
    "label_constraints": [
      {
        "key": "az",
        "op": "in",
        "values": [
          "west"
        ]
      }
    ],
    "location_labels": [
      "az",
      "rack",
      "host"
    ]
  },
  {
    "group_id": "pd",
    "id": "az-west-2",
    "start_key": "",
    "end_key": "",
    "role": "learner",
    "count": 1,
```

```
      "label_constraints": [
        {
          "key": "az",
          "op": "in",
          "values": [
            "west"
          ]
        }
      ],
      "location_labels": [
        "az",
        "rack",
        "host"
      ]
    }
  ]
 }
]
```

To use the configurations in `rule.json`, run the following command to back up the existing configuration to the `default.json` file and overwrite the existing configuration with `rule.json`:

```
pd-ctl config placement-rules rule-bundle load --out="default.json"
pd-ctl config placement-rules rule-bundle save --in="rule.json"
```

If you need to roll back to the previous configuration, you can restore the backup file `default.json` or write the following JSON file manually and overwrite the current configuration with this JSON file:

```
cat default.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "default",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 5
      }
    ]
```

```
  }
]
```

12.3.3.3 Enable the DR Auto-Sync mode

The replication mode is controlled by PD. You can configure the replication mode in the PD configuration file using one of the following methods:

- Method 1: Configure the PD configuration file, and then deploy a cluster.

```
[replication-mode]
replication-mode = "dr-auto-sync"
[replication-mode.dr-auto-sync]
label-key = "az"
primary = "east"
dr = "west"
primary-replicas = 3
dr-replicas = 2
wait-store-timeout = "1m"
pause-region-split = false
```

- Method 2: If you have deployed a cluster, use pd-ctl commands to modify the configurations of PD.

```
config set replication-mode dr-auto-sync
config set replication-mode dr-auto-sync label-key az
config set replication-mode dr-auto-sync primary east
config set replication-mode dr-auto-sync dr west
config set replication-mode dr-auto-sync primary-replicas 3
config set replication-mode dr-auto-sync dr-replicas 2
```

Descriptions of configuration items:

- `replication-mode` is the replication mode to be enabled. In the preceding example, it is set to `dr-auto-sync`. By default, the majority protocol is used.
- `label-key` is used to distinguish different AZs and needs to match Placement Rules. In this example, the primary AZ is "east" and the disaster recovery AZ is "west".
- `primary-replicas` is the number of Voter replicas in the primary AZ.
- `dr-replicas` is the number of Voter replicas in the disaster recovery (DR) AZ.
- `wait-store-timeout` is the waiting time for switching to asynchronous replication mode when network isolation or failure occurs. If the time of network failure exceeds the waiting time, asynchronous replication mode is enabled. The default waiting time is 60 seconds.

- `pause-region-split` controls whether to pause Region split operations in the `async_wait` and `async` statuses. Pausing Region split can prevent temporary partial data loss in the DR AZ when synchronizing data in the `sync-recover` status. The default value is `false`.

To check the current replication status of the cluster, use the following API:

```
curl http://pd_ip:pd_port/pd/api/v1/replication_mode/status
```

```
{
  "mode": "dr-auto-sync",
  "dr-auto-sync": {
    "label-key": "az",
    "state": "sync"
  }
}
```

12.3.3.3.1 Status switch

The replication mode of a cluster can automatically and adaptively switch between three statuses:

- When the cluster is normal, the synchronous replication mode is enabled to maximize the data integrity of the disaster recovery AZ.
- When the network connection between the two AZs fails or the disaster recovery AZ breaks down, after a pre-set protective interval, the cluster enables the asynchronous replication mode to ensure the availability of the application.
- When the network reconnects or the disaster recovery AZ recovers, the TiKV node joins the cluster again and gradually replicates the data. Finally, the cluster switches to the synchronous replication mode.

The details for the status switch are as follows:

1. **Initialization**: At the initialization stage, the cluster is in the synchronous replication mode. PD sends the status information to TiKV, and all TiKV nodes strictly follow the synchronous replication mode to work.
2. **Switch from sync to async**: PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node fails or is disconnected. If the number of failed nodes exceeds the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can no longer serve the data replication and it is necessary to switch the status. When the failure or disconnect time exceeds the time set by `wait-store-timeout`, PD switches the status of the cluster to the async mode. Then PD sends the status of async to all TiKV nodes, and the replication mode for TiKV switches from two-availability-zone replication to the native Raft majority.

3. **Switch from async to sync**: PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node is reconnected. If the number of failed nodes is less than the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can be enabled again. PD first switches the status of the cluster to sync-recover and sends the status information to all TiKV nodes. All Regions of TiKV gradually switch to the two-availability-zone synchronous replication mode and then report the heartbeat information to PD. PD records the status of TiKV Regions and calculates the recovery progress. When all TiKV Regions finish the switching, PD switches the replication mode to sync.

12.3.3.4 Disaster recovery

This section introduces the disaster recovery solution of the two AZs in one region deployment.

When a disaster occurs to a cluster in the synchronous replication mode, you can perform data recovery with `RPO = 0`:

- If the primary AZ fails and most of the Voter replicas are lost, but complete data exists in the disaster recovery AZ, the lost data can be recovered from the disaster recovery AZ. At this time, manual intervention is required with professional tools. You can get support from PingCAP or the community for a recovery solution.
- If the disaster recovery AZ fails and a few Voter replicas are lost, the cluster automatically switches to the asynchronous replication mode.

When a disaster occurs to a cluster that is not in the synchronous replication mode and you cannot perform data recovery with `RPO = 0`:

- If most of the Voter replicas are lost, manual intervention is required with professional tools. You can get support from PingCAP or the community for a recovery solution.

12.4 Read Historical Data

12.4.1 Use Stale Read (Recommended)

12.4.1.1 Usage Scenarios of Stale Read

This document describes the usage scenarios of Stale Read. Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes.

When you are using Stale Read, TiDB will randomly select a replica for data reading, which means that all replicas are available for data reading. If your application cannot tolerate reading non-real-time data, do not use Stale Read; otherwise, the data read from the replica might not be the latest data written into TiDB.

12.4.1.1.1 Scenario examples

- Scenario one: If a transaction only involves read operations and is tolerant of data staleness to some extent, you can use Stale Read to get historical data. Using Stale Read, TiDB makes the query requests sent to any replica at the expense of some real-time performance, and thus increases the throughput of query executions. Especially in some scenarios where small tables are queried, if strongly consistent reads are used, leader might be concentrated on a certain storage node, causing the query pressure to be concentrated on that node as well. Therefore, that node might become a bottleneck for the whole query. Stale Read, however, can improve the overall query throughput and significantly improve the query performance.
- Scenario two: In some scenarios of geo-distributed deployment, if strongly consistent follower reads are used, to make sure that the data read from the Followers is consistent with that stored in the Leader, TiDB requests `Readindex` from different data centers for verification, which increases the access latency for the whole query process. With Stale Read, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query. For more information, see Local Read under Three Data Centers Deployment.

12.4.1.1.2 Usages

TiDB provides the methods of performing Stale Read at the statement level, the session level and the global level as follows:

- Statement level
  - Specifying an exact point in time (**recommended**): If you need TiDB to read data that is globally consistent from a specific point in time without violating the isolation level, you can specify the corresponding timestamp of that point in time in the query statement. For detailed usage, see `AS OF TIMESTAMP` clause.
  - Specifying a time range: If you need TiDB to read the data as new as possible within a time range without violating the isolation level, you can specify the time range in the query statement. Within the specified time range, TiDB selects a suitable timestamp to read the corresponding data. "Suitable" means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. For detailed usage, refer to the introduction of the `AS OF TIMESTAMP` Clause and the `TIDB_BOUNDED_STALENESS` function.
- Session level
  - Specifying a time range: In a session, if you need TiDB to read the data as new as possible within a time range in subsequent queries without violating the isolation level, you can specify the time range by setting the `tidb_read_staleness` system variable. For detailed usage, refer to `tidb_read_staleness`.

Besides, TiDB provides a way to specify an exact point in time by setting the `tidb_external_ts` system variable on session or global level. For detailed usage, refer to Perform Stale Read Using `tidb_external_ts`.

Reduce Stale Read latency

The Stale Read feature periodically advances the Resolved TS timestamp of the TiDB cluster, which ensures that TiDB reads data that meets transaction consistency. If the timestamp used by Stale Read (for example, `AS OF TIMESTAMP '2016-10-08 16:45:26'`) is greater than the Resolved TS, Stale Read will trigger TiDB to advance the Resolved TS first and wait for the advance to complete before reading the data, leading to an increase in latency.

To reduce the Stale Read latency, you can modify the following TiKV configuration item to make TiDB advance the Resolved TS timestamp more frequently:

```
[resolved-ts]
advance-ts-interval = "20s" # The default value is "20s". You can set it to
    ↪ a smaller value such as "1s" to advance the Resolved TS timestamp
    ↪ more frequently.
```

> **Note:**
>
> Decreasing the preceding TiKV configuration item will lead to an increase in TiKV CPU usage and traffic between nodes.

For more information about the internals of Resolved TS and diagnostic techniques, see Understanding Stale Read and safe-ts in TiKV.

12.4.1.1.3 Restrictions

When a Stale Read query for a table is pushed down to TiFlash, the query will return an error if this table has newer DDL operations executed after the read timestamp specified by the query. This is because TiFlash only supports reading data from the tables with the latest schemas.

Take the following table as an example:

```
create table t1(id int);
alter table t1 set tiflash replica 1;
```

Execute the following DDL operation after one minute:

```
alter table t1 add column c1 int not null;
```

Then, use Stale Read to query the data from one minute ago:

```
set @@session.tidb_enforce_mpp=1;
select * from t1 as of timestamp NOW() - INTERVAL 1 minute;
```

TiFlash will report an error as follows:

```
ERROR 1105 (HY000): other error for mpp stream: From MPP<query:<query_ts
    ↪ :1673950975508472943, local_query_id:18, server_id:111947, start_ts
    ↪ :438816196526080000>,task_id:1>: Code: 0, e.displayText() = DB::
    ↪ TiFlashException: Table 323 schema version 104 newer than query
    ↪ schema version 100, e.what() = DB::TiFlashException,
```

To avoid this error, you can change the read timestamp specified by Stale Read to the time after the DDL operation.

12.4.1.2 Read Historical Data Using the `AS OF TIMESTAMP` Clause

This document describes how to perform the Stale Read feature using the `AS OF TIMESTAMP` clause to read historical data in TiDB, including specific usage examples and strategies for saving historical data.

TiDB supports reading historical data through a standard SQL interface, which is the `AS OF TIMESTAMP` SQL clause, without the need for special clients or drivers. After data is updated or deleted, you can read the historical data before the update or deletion using this SQL interface.

> **Note:**
>
> When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

12.4.1.2.1 Syntax

You can use the `AS OF TIMESTAMP` clause in the following three ways:

- `SELECT ... FROM ... AS OF TIMESTAMP`
- `START TRANSACTION READ ONLY AS OF TIMESTAMP`
- `SET TRANSACTION READ ONLY AS OF TIMESTAMP`

If you want to specify an exact point of time, you can set a datetime value or use a time function in the `AS OF TIMESTAMP` clause. The format of datetime is like "2016-10-08 16:45:26.999", with millisecond as the minimum time unit, but for most of the time, the time unit of second is enough for specifying a datetime, such as "2016-10-08 16:45:26". You

can also get the current time to the millisecond using the `NOW(3)` function. If you want to read the data of several seconds ago, it is **recommended** to use an expression such as `NOW()- INTERVAL 10 SECOND`.

If you want to specify a time range, you can use the `TIDB_BOUNDED_STALENESS()` function in the clause. When this function is used, TiDB selects a suitable timestamp within the specified time range. "Suitable" means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. You need to use `TIDB_BOUNDED_STALENESS(t1, t2)` to call this function. `t1` and `t2` are the two ends of the time range, which can be specified using either datetime values or time functions.

Here are some examples of the `AS OF TIMESTAMP` clause:

- `AS OF TIMESTAMP '2016-10-08 16:45:26'`: Tells TiDB to read the latest data stored at 16:45:26 on October 8, 2016.
- `AS OF TIMESTAMP NOW()- INTERVAL 10 SECOND`: Tells TiDB to read the latest data stored 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 16:45:29')`: Tells TiDB to read the data as new as possible within the time range of 16:45:26 to 16:45:29 on October 8, 2016.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW()- INTERVAL 20 SECOND, NOW())`: Tells TiDB to read the data as new as possible within the time range of 20 seconds ago to the present.

Note:

In addition to specifying a timestamp, the most common use of the `AS OF TIMESTAMP` clause is to read data that is several seconds old. If this approach is used, it is recommended to read historical data older than 5 seconds.

You need to deploy the NTP service for your TiDB and PD nodes when you use Stale Read. This avoids the situation where the specified timestamp used by TiDB goes ahead of the latest TSO allocating progress (such as a timestamp several seconds ahead), or is later than the GC safe point timestamp. When the specified timestamp goes beyond the service scope, TiDB returns an error.

To reduce the latency and improve the timeliness of the Stale Read data, you can modify the TiKV `advance-ts-interval` configuration item. See Reduce Stale Read latency for details.

12.4.1.2.2 Usage examples

This section describes different ways to use the `AS OF TIMESTAMP` clause with several examples. It first introduces how to prepare the data for recovery, and then shows how to use `AS OF TIMESTAMP` in `SELECT`, `START TRANSACTION READ ONLY AS OF TIMESTAMP`, and `SET TRANSACTION READ ONLY AS OF TIMESTAMP` respectively.

Prepare data sample

To prepare data for recovery, create a table first and insert several rows of data:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

View the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

View the current time:

```
select now();
```

```
+---------------------+
| now()               |
+---------------------+
| 2021-05-26 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

Confirm that the data of the row is updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Read historical data using the SELECT statement

You can use the SELECT ... FROM ... AS OF TIMESTAMP statement to read data from a time point in the past.

```
select * from t as of timestamp '2021-05-26 16:45:26';
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Note:

When reading multiple tables using one SELECT statement, you need to make sure that the format of TIMESTAMP EXPRESSIONs is consistent. For example, `select * from t as of timestamp NOW()- INTERVAL 2 SECOND, c as of timestamp NOW()- INTERVAL 2 SECOND;`. In addition, you must specify the AS OF information for the relevant table in the SELECT statement; otherwise, the SELECT statement reads the latest data by default.

Read historical data using the START TRANSACTION READ ONLY AS OF TIMESTAMP statement

You can use the START TRANSACTION READ ONLY AS OF TIMESTAMP statement to start a read-only transaction based on a time point in the past. The transaction reads historical data of the given time.

```
start transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> If you start a transaction with the statement `START TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

Read historical data using the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement to set the next transaction as a read-only transaction based on a specified time point in the past. The transaction reads historical data of the given time.

```
set transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
begin;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Note:

If you start a transaction with the statement `SET TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

12.4.1.3 Read Historical Data Using the `tidb_read_staleness` System Variable

To support reading the historical data, in v5.4, TiDB introduces a new system variable `tidb_read_staleness`. This document describes how to read historical data through this system variable, including detailed operating procedures.

12.4.1.3.1 Feature description

The `tidb_read_staleness` system variable is used to set the time range of historical data that TiDB can read in the current session. The data type of this variable is int type, and the scope of it is `SESSION`. After setting the value, TiDB selects a timestamp as new as possible from the range allowed by this variable, and all subsequent read operations are performed against this timestamp. For example, if the value of this variable is set to `-5`, on the condition that TiKV has the corresponding historical version's data, TiDB selects a timestamp as new as possible within a 5-second time range.

After enabling `tidb_read_staleness`, you still can perform the following operations:

- Insert, modify, delete data or perform DML operations in the current session. These statements are not affected by `tidb_read_staleness`.
- Start an interactive transaction in the current session. Queries within this transaction still read the latest data.

After reading the historical data, you can read the latest data in the following two ways:

- Start a new session.
- Set the value of the `tidb_read_staleness` variable to `""` using the `SET` statement.

> **Note:**
>
> To reduce the latency and improve the timeliness of the Stale Read data, you can modify the TiKV `advance-ts-interval` configuration item. See Reduce Stale Read latency for details.

12.4.1.3.2 Usage examples

This section describes how to use `tidb_read_staleness` with examples.

1. Create a table, and insert a few rows of data into the table:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. Check out the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

4. Confirm that the data has been updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

5. Set the `tidb_read_staleness` system variable.

   The scope of this variable is `SESSION`. After setting its value, TiDB reads the latest version data before the time set by the value.

   The following setting indicates that TiDB selects a timestamp as new as possible within the time range from 5 seconds ago to now and uses it as the timestamp for reading historical data:

```
set @@tidb_read_staleness="-5";
```

```
Query OK, 0 rows affected (0.00 sec)
```

Note:

- Use `@@` instead of `@` before `tidb_read_staleness`. `@@` means system variables, and `@` means user variables.
- You need to set the historical time range (the value of `tidb_read_staleness`) according to the total time that you spent in step 3 and step 4. Otherwise, the latest data will be displayed in the query results, not the historical data. Therefore, you need to adjust this time range according to the time you spent on operations. For example, in this example, since the set time range is 5 seconds, you need to complete step 3 and step 4 within 5 seconds.

The data read here is the data before the update, that is, the historical data:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. After un-setting this variable as follows, TiDB can read the latest data:

```
set @@tidb_read_staleness="";
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
```

```
|   3 |
+------+
3 rows in set (0.00 sec)
```

12.4.1.4 Read Historical Data Using the `tidb_external_ts` Variable

To support reading the historical data, TiDB v6.4.0 introduces a system variable `tidb_external_ts`. This document describes how to read historical data through this system variable, including detailed usage examples.

12.4.1.4.1 Scenarios

Read historical data from a specified point in time is very useful for data replication tools such as TiCDC. After the data replication tool completes the data replication before a certain point in time, you can set the `tidb_external_ts` system variable of the downstream TiDB to read the data before that point in time. This prevents the data inconsistency caused by data replication.

12.4.1.4.2 Feature description

The system variable `tidb_external_ts` specifies the timestamp of the historical data to be read when `tidb_enable_external_ts_read` is enabled.

The system variable `tidb_enable_external_ts_read` controls whether to read historical data in the current session or globally. The default value is `OFF`, which means the feature of reading historical data is disabled, and the `tidb_external_ts` value is ignored. When `tidb_enable_external_ts_read` is set to `ON` globally, all queries read historical data before the time specified by `tidb_external_ts`. If `tidb_enable_external_ts_read` is set to `ON` only for a certain session, only queries in that session read historical data.

When the `tidb_enable_external_ts_read` is enabled, TiDB becomes read-only. All write queries will fail with an error like `ERROR 1836 (HY000): Running in read-only mode`.

12.4.1.4.3 Usage examples

This section describes how to use the `tidb_external_ts` variable to read historical data with examples.

1. Create a table and insert some rows into the table:

```
CREATE TABLE t (c INT);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
INSERT INTO t VALUES (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
SELECT * FROM t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. Set `tidb_external_ts` to `@@tidb_current_ts`:

```
START TRANSACTION;
SET GLOBAL tidb_external_ts=@@tidb_current_ts;
COMMIT;
```

4. Insert a new row and confirm that it is inserted:

```
INSERT INTO t VALUES (4);
```

```
Query OK, 1 row affected (0.001 sec)
```

```
SELECT * FROM t;
```

```
+------+
| id   |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
+------+
4 rows in set (0.00 sec)
```

5. Set `tidb_enable_external_ts_read` to `ON` and then view data in the table:

```
SET tidb_enable_external_ts_read=ON;
SELECT * FROM t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Because `tidb_external_ts` is set to the timestamp before the new row is inserted, the newly inserted row is not returned after the `tidb_enable_external_ts_read` is enabled.

12.4.2 Read Historical Data Using the System Variable `tidb_snapshot`

This document describes how to read data from the history versions using the system variable `tidb_snapshot`, including specific usage examples and strategies for saving historical data.

> **Note:**
>
> You can also use the Stale Read feature to read historical data, which is more recommended.

12.4.2.1 Feature description

TiDB implements a feature to read history data using the standard SQL interface directly without special clients or drivers.

> **Note:**
>
> - Even when data is updated or removed, its history versions can be read using the SQL interface.
> - When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

12.4.2.2 How TiDB reads data from history versions

The tidb_snapshot system variable is introduced to support reading history data. About the tidb_snapshot variable:

- The variable is valid in the SESSION scope.
- Its value can be modified using the SET statement.
- The data type for the variable is text.
- The variable accepts TSO (Timestamp Oracle) and datetime. TSO is a globally unique time service, which is obtained from PD. The acceptable datetime format is "2016-10-08 16:45:26.999". Generally, the datetime can be set using second precision, for example "2016-10-08 16:45:26".
- When the variable is set, TiDB creates a Snapshot using its value as the timestamp, just for the data structure and there is no any overhead. After that, all the SELECT operations will read data from this Snapshot.

> **Note:**
>
> Because the timestamp in TiDB transactions is allocated by Placement Driver (PD), the version of the stored data is also marked based on the timestamp allocated by PD. When a Snapshot is created, the version number is based on the value of the tidb_snapshot variable. If there is a large difference between the local time of the TiDB server and the PD server, use the time of the PD server.

After reading data from history versions, you can read data from the latest version by ending the current Session or using the SET statement to set the value of the tidb_snapshot variable to "" (empty string).

12.4.2.3 How TiDB manages the data versions

TiDB implements Multi-Version Concurrency Control (MVCC) to manage data versions. The history versions of data are kept because each update/removal creates a new version of the data object instead of updating/removing the data object in-place. But not all the versions are kept. If the versions are older than a specific time, they will be removed completely to reduce the storage occupancy and the performance overhead caused by too many history versions.

In TiDB, Garbage Collection (GC) runs periodically to remove the obsolete data versions. For GC details, see TiDB Garbage Collection (GC)

Pay special attention to the following:

- tidb_gc_life_time: This system variable is used to configure the retention time of earlier modifications (default: 10m0s).

- The output of `SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point ↪ '`. This is the current `safePoint` where you can read historical data up to. It is updated every time the garbage collection process is run.

12.4.2.4 Example

1. At the initial stage, create a table and insert several rows of data:

```
mysql> create table t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into t values (1), (2), (3);
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. View the timestamp of the table:

```
mysql> select now();
+---------------------+
| now()               |
+---------------------+
| 2016-10-08 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

4. Update the data in one row:

```
mysql> update t set c=22 where c=2;
Query OK, 1 row affected (0.00 sec)
```

5. Make sure the data is updated:

```
mysql> select * from t;
+------+
| c    |
```

```
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. Set the `tidb_snapshot` variable whose scope is Session. The variable is set so that the latest version before the value can be read.

> **Note:**
> In this example, the value is set to be the time before the update operation.

```
mysql> set @@tidb_snapshot="2016-10-08 16:45:26";
Query OK, 0 rows affected (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

Result: The read from the following statement is the data before the update operation, which is the history data.

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

7. Set the `tidb_snapshot` variable to be "" (empty string) and you can read the data from the latest version:

```
mysql> set @@tidb_snapshot="";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

12.4.2.5 How to restore historical data

Before you restore data from an older version, make sure that Garbage Collection (GC) does not clear the history data while you are working on it. This can be done by setting the `tidb_gc_life_time` variable as the following example shows. Do not forget to set the variable back to the previous value after the restore.

```
SET GLOBAL tidb_gc_life_time="60m";
```

> **Note:**
>
> Increasing the GC life time from the default 10 minutes to half an hour or more will result in additional versions of rows being retained, which might require more disk space. This might also affect the performance of certain operations such as scans when TiDB needs to skip these additional versions of the same rows during data reads.

To restore data from an older version, you can use one of the following methods:

- For simple cases, use `SELECT` after setting the `tidb_snapshot` variable and copy-paste the output, or use `SELECT ... INTO OUTFILE` and then use `LOAD DATA` to import the data later on.
- Use Dumpling to export a historical snapshot. Dumpling performs well in exporting larger sets of data.

12.5 Best Practices

12.5.1 TiDB Best Practices

This document summarizes the best practices of using TiDB, including the use of SQL and optimization tips for Online Analytical Processing (OLAP) and Online Transactional Processing (OLTP) scenarios, especially the optimization options specific for TiDB.

Before you read this document, it is recommended that you read three blog posts that introduce the technical principles of TiDB:

- TiDB Internal (I) - Data Storage
- TiDB Internal (II) - Computing
- TiDB Internal (III) - Scheduling

12.5.1.1 Preface

Database is a generic infrastructure system. It is important to consider various user scenarios during the development process and to modify the data parameters or the way to use according to actual situations in specific business scenarios.

TiDB is a distributed database compatible with the MySQL protocol and syntax. But with the internal implementation and supporting of distributed storage and transactions, the way of using TiDB is different from MySQL.

12.5.1.2 Basic concepts

The best practices are closely related to its implementation principles. It is recommended that you learn some of the basic mechanisms, including the Raft consensus algorithm, distributed transactions, data sharding, load balancing, the mapping solution from SQL to Key-Value (KV), the implementation method of secondary indexing, and distributed execution engines.

This section is an introduction to these concepts. For detailed information, refer to PingCAP blog posts.

12.5.1.2.1 Raft

Raft is a consensus algorithm that ensures data replication with strong consistency. At the bottom layer, TiDB uses Raft to replicate data. TiDB writes data to the majority of the replicas before returning the result of success. In this way, even though a few replicas might get lost, the system still has the latest data. For example, if there are three replicas, the system does not return the result of success until data has been written to two replicas. Whenever a replica is lost, at least one of the remaining two replicas have the latest data.

To store three replicas, compared with the replication of Source-Replica, Raft is more efficient. The write latency of Raft depends on the two fastest replicas, instead of the slowest one. Therefore, the implementation of geo-distributed and multiple active data centers

becomes possible by using the Raft replication. In the typical scenario of three data centers distributing in two sites, to guarantee the data consistency, TiDB just needs to successfully write data into the local data center and the closer one, instead of writing to all three data centers. However, this does not mean that cross-data center deployment can be implemented in any scenario. When the amount of data to be written is large, the bandwidth and latency between data centers become the key factors. If the write speed exceeds the bandwidth or the latency is too high, the Raft replication mechanism still cannot work well.

12.5.1.2.2 Distributed transactions

TiDB provides complete distributed transactions and the model has some optimizations on the basis of Google Percolator. This document introduces the following features:

- Optimistic transaction model

  TiDB's optimistic transaction model does not detect conflicts until the commit phase. If there are conflicts, the transaction needs retry. But this model is inefficient if the conflict is severe, because operations before retry are invalid and need to repeat.

  Assume that the database is used as a counter. High access concurrency might lead to severe conflicts, resulting in multiple retries or even timeouts. Therefore, in the scenario of severe conflicts, it is recommended to use the pessimistic transaction mode or to solve problems at the system architecture level, such as placing counter in Redis. Nonetheless, the optimistic transaction model is efficient if the access conflict is not very severe.

- Pessimistic transaction mode

  In TiDB, the pessimistic transaction mode has almost the same behavior as in MySQL. The transaction applies a lock during the execution phase, which avoids retries in conflict situations and ensures a higher success rate. By applying the pessimistic locking, you can also lock data in advance using `SELECT FOR UPDATE`.

  However, if the application scenario has fewer conflicts, the optimistic transaction model has better performance.

- Transaction size limit

  As distributed transactions need to conduct two-phase commit and the bottom layer performs Raft replication, if a transaction is very large, the commit process would be quite slow, and the following Raft replication process is thus stuck. To avoid this problem, the transaction size is limited:

  - A transaction is limited to 5,000 SQL statements (by default)
  - Each Key-Value entry is no more than 6 MB (by default)
  - The total size of Key-Value entries is no more than 10 GB.

  You can find similar limits in Google Cloud Spanner.

12.5.1.2.3 Data sharding

TiKV automatically shards bottom-layered data according to the range of keys. Each Region is a range of keys, which is a left-closed and right-open interval, `[StartKey, EndKey ↪ )`. When the amount of Key-Value pairs in a Region exceeds a certain value, the Region automatically splits into two.

12.5.1.2.4 Load balancing

Placement Driver (PD) balances the load of the cluster according to the status of the entire TiKV cluster. The unit of scheduling is Region and the logic is the strategy configured by PD.

12.5.1.2.5 SQL on KV

TiDB automatically maps the SQL structure into Key-Value structure. For details, see TiDB Internal (II) - Computing.

Simply put, TiDB performs the following operations:

- A row of data is mapped to a Key-Value pair. The key is prefixed with `TableID` and suffixed with the row ID.
- An index is mapped as a Key-Value pair. The key is prefixed with `TableID+IndexID` and suffixed with the index value.

The data or indexes in the same table have the same prefix. These Key-Values are at adjacent positions in the key space of TiKV. Therefore, when the amount of data to be written is large and all is written to one table, the write hotspot is created. The situation gets worse when some index values of the continuous written data is also continuous (for example, fields that increase with time, like `update time`), which creates a few write hotspots and becomes the bottleneck of the entire system.

Similarly, if all data is read from a focused small range (for example, the continuous tens or hundreds of thousands of rows of data), an access hotspot of data is likely to occur.

12.5.1.2.6 Secondary index

TiDB supports the complete secondary indexes, which are also global indexes. Many queries can be optimized by index. Thus, it is important for applications to make good use of secondary indexes.

Lots of MySQL experience is also applicable to TiDB. It is noted that TiDB has its unique features. The following are a few notes when using secondary indexes in TiDB.

- The more secondary indexes, the better?

  Secondary indexes can speed up queries, but adding an index has side effects. The previous section introduces the storage model of indexes. For each additional index,

there will be one more Key-Value when inserting a row. Therefore, the more indexes, the slower the writing speed and the more space it takes up.

In addition, too many indexes affects the runtime of the optimizer, and inappropriate indexes mislead the optimizer. Thus, more secondary indexes does not mean better performance.

- Which columns should create indexes?

  As is mentioned above, index is important but the number of indexes should be proper. You must create appropriate indexes according to the application characteristics. In principle, you need to create an index on the columns involved in the query to improve the performance. The following are situations that need to create indexes:

  - For columns with a high degree of differentiation, filtered rows are remarkably reduced through indexes.
  - If there are multiple query criteria, you can choose composite indexes. Note to put the columns with the equivalent condition before composite indexes.

  For example, if a commonly used query is `select * from t where c1 = 10 and c2 = 100 and c3 > 10`, you can create a composite index `Index cidx (c1, c2, c3)`. In this way, you can use the query condition to create an index prefix and then scan.

- The difference between querying through indexes and directly scanning the table

  TiDB has implemented global indexes, so indexes and data of the table are not necessarily on the same data sharding. When querying through indexes, it should firstly scan indexes to get the corresponding row ID and then use the row ID to get the data. Thus, this method involves two network requests and has a certain performance overhead.

  If the query involves lots of rows, scanning index proceeds concurrently. When the first batch of results is returned, getting the data of the table can then proceed. Therefore, this is a parallel + pipeline model. Though the two accesses create overhead, the latency is not high.

  The following two conditions do not have the problem of two accesses:

  - Columns of the index have already met the query requirement. Assume that the `c` column on the `t` table has an index and the query is `select c from t where c > 10;`. At this time, all needed data can be obtained if you access the index. This situation is called `Covering Index`. But if you focus more on the query performance, you can put into index a portion of columns that do not need to be filtered but need to be returned in the query result, creating composite index. Take `select c1, c2 from t where c1 > 10;` as an example. You can optimize this query by creating composite index `Index c12 (c1, c2)`.

    - The primary key of the table is integer. In this case, TiDB uses the value of the primary key as row ID. Thus, if the query condition is on the primary key, you can directly construct the range of the row ID, scan the table data, and get the result.

- Query concurrency

  As data is distributed across many Regions, queries run in TiDB concurrently. But the concurrency by default is not high in case it consumes lots of system resources. Besides, the OLTP query usually does not involve a large amount of data and the low concurrency is enough. But for the OLAP query, the concurrency is high and TiDB modifies the query concurrency through the following system variables:

    - `tidb_distsql_scan_concurrency`:

      The concurrency of scanning data, including scanning the table and index data.
    - `tidb_index_lookup_size`:

      If it needs to access the index to get row IDs before accessing the table data, it uses a batch of row IDs as a single request to access the table data. This parameter sets the size of a batch. The larger batch increases latency, while the smaller one might lead to more queries. The proper size of this parameter is related to the amount of data that the query involves. Generally, no modification is required.
    - `tidb_index_lookup_concurrency`:

      If it needs to access the index to get row IDs before accessing the table data, the concurrency of getting data through row IDs every time is modified through this parameter.

- Ensure the order of results through indexes

  You can use indexes to filter or sort data. Firstly, get row IDs according to the index order. Then, return the row content according to the return order of row IDs. In this way, the returned results are ordered according to the index column. It has been mentioned earlier that the model of scanning index and getting row is parallel + pipeline. If the row is returned according to the index order, a high concurrency between two queries does not reduce latency. Thus, the concurrency is low by default, but it can be modified through the `tidb_index_serial_scan_concurrency` variable.

- Reverse index scan

  TiDB supports scanning an ascending index in reverse order, at a speed slower than normal scan by 20%. If the data is changed frequently and thus too many versions exist, the performance overhead might be higher. It is recommended to avoid reverse index scans as much as possible.

12.5.1.3 Scenarios and practices

In the last section, we discussed some basic implementation mechanisms of TiDB and their influence on usage. This section introduces specific usage scenarios and operation practices, from deployment to application usage.

12.5.1.3.1 Deployment

Before deployment, read Software and Hardware Requirements.

It is recommended to deploy the TiDB cluster using TiUP. This tool can deploy, stop, destroy, and upgrade the whole cluster, which is quite convenient. It is not recommended to manually deploy the TiDB cluster, which might be troublesome to maintain and upgrade later.

12.5.1.3.2 Data import

To improve the write performance during the import process, you can tune TiKV's parameters as stated in Tune TiKV Memory Parameter Performance.

12.5.1.3.3 Write

As mentioned before, TiDB limits the size of a single transaction in the Key-Value layer. As for the SQL layer, a row of data is mapped to a Key-Value entry. For each additional index, one more Key-Value entry is added.

> **Note:**
>
> When you set the size limit for transactions, you need to consider the overhead of TiDB encoding and the extra transaction key. It is recommended that **the number of rows of each transaction is less than 200 and the data size of a single row is less than 100 KB**; otherwise, the performance is bad.

It is recommended to split statements into batches or add a limit to the statements, whether they are `INSERT`, `UPDATE` or `DELETE` statements.

When deleting a large amount of data, it is recommended to use `Delete from t where xx limit 5000;`. It deletes through the loop and use `Affected Rows == 0` as a condition to end the loop.

If the amount of data that needs to be deleted at a time is large, this loop method gets slower and slower because each deletion traverses backward. After deleting the previous data, lots of deleted flags remain for a short period (then all is cleared by Garbage Collection) and affect the following `DELETE` statement. If possible, it is recommended to refine the `WHERE` condition. Assume that you need to delete all data on `2017-05-26`, you can use the following statements:

```
for i from 0 to 23:
    while affected_rows > 0:
        delete from t where insert_time >= i:00:00 and insert_time < (i+1)
            ↪ :00:00 limit 5000;
```

```
    affected_rows = select affected_rows()
```

This pseudocode means to split huge chunks of data into small ones and then delete, so that the earlier `Delete` statements do not affect the later ones.

12.5.1.3.4 Query

For query requirements and specific statements, refer to System Variables.

You can control the concurrency of SQL execution through the `SET` statement and the selection of the `Join` operator through hints.

In addition, you can also use MySQL's standard index selection, the hint syntax, or control the optimizer to select indexes through `Use Index/Ignore Index hint`.

If the application scenario has both OLTP and OLAP workloads, you can send the OLTP request and OLAP request to different TiDB servers, diminishing the impact of OLAP on OLTP. It is recommended to use machines with high-performance hardware (for example, more processor cores and larger memory) for the TiDB server that processes OLAP workloads.

To completely isolate OLTP and OLAP workloads, it is recommended to run OLAP applications on TiFlash. TiFlash is a columnar storage engine with great performance on OLAP workloads. TiFlash can achieve physical isolation on the storage layer and guarantees consistent reads.

12.5.1.3.5 Monitoring and log

The monitoring metrics is the best method to learn the status of the system. It is recommended that you deploy the monitoring system along with your TiDB cluster.

TiDB uses Grafana + Prometheus to monitor the system status. The monitoring system is automatically deployed and configured if you deploy TiDB using TiUP.

There are lots of items in the monitoring system, the majority of which are for TiDB developers. You do not have to understand these items without an in-depth knowledge of the source code. Some items that are related to applications or to the state of system key components are selected and put in a separate `overview` panel for users.

In addition to monitoring, you can also view the system logs. The three components of TiDB, tidb-server, tikv-server, and pd-server, each has a `--log-file` parameter. If this parameter has been configured when the cluster is started, logs are stored in the file configured by the parameter and log files are automatically archived on a daily basis. If the `--log-file` parameter has not been configured, the log is output to `stderr`.

Starting from TiDB 4.0, TiDB provides TiDB Dashboard UI to improve usability. You can access TiDB Dashboard by visiting http://PD_IP :{PD_PORT}/dashboard in your browser. TiDB Dashboard provides features such as viewing cluster status, performance analysis, traffic visualization, cluster diagnostics, and log searching.

12.5.1.3.6 Documentation

The best way to learn about a system or solve the problem is to read its documentation and understand its implementation principles.

TiDB has a large number of official documents both in Chinese and English. If you have met an issue, you can start from FAQ and TiDB Cluster Troubleshooting Guide. You can also search the issue list or create an issue in TiDB repository on GitHub.

TiDB also has many useful migration tools. See Migration Tool Overview for details.

For more articles on the technical details of TiDB, see the PingCAP official blog site.

12.5.1.4 Best scenarios for TiDB

TiDB is suitable for the following scenarios:

- The data volume is too large for a standalone database
- You do not want to do sharding
- The access mode has no obvious hotspot
- Transactions, strong consistency, and disaster recovery are required
- You hope to have real-time Hybrid Transaction/Analytical Processing (HTAP) analytics and reduce storage links

12.5.2 Best Practices for Developing Java Applications with TiDB

This document introduces the best practice for developing Java applications to better use TiDB. Based on some common Java application components that interact with the backend TiDB database, this document also provides the solutions to commonly encountered issues during development.

12.5.2.1 Database-related components in Java applications

Common components that interact with the TiDB database in Java applications include:

- Network protocol: A client interacts with a TiDB server via the standard MySQL protocol.
- JDBC API and JDBC drivers: Java applications usually use the standard JDBC (Java Database Connectivity) API to access a database. To connect to TiDB, you can use a JDBC driver that implements the MySQL protocol via the JDBC API. Such common JDBC drivers for MySQL include MySQL Connector/J and MariaDB Connector/J.
- Database connection pool: To reduce the overhead of creating a connection each time it is requested, applications usually use a connection pool to cache and reuse connections. JDBC DataSource defines a connection pool API. You can choose from different open-source connection pool implementations as needed.
- Data access framework: Applications usually use a data access framework such as MyBatis and Hibernate to further simplify and manage the database access operations.

- Application implementation: The application logic controls when to send what commands to the database. Some applications use Spring Transaction aspects to manage transactions' start and commit logics.

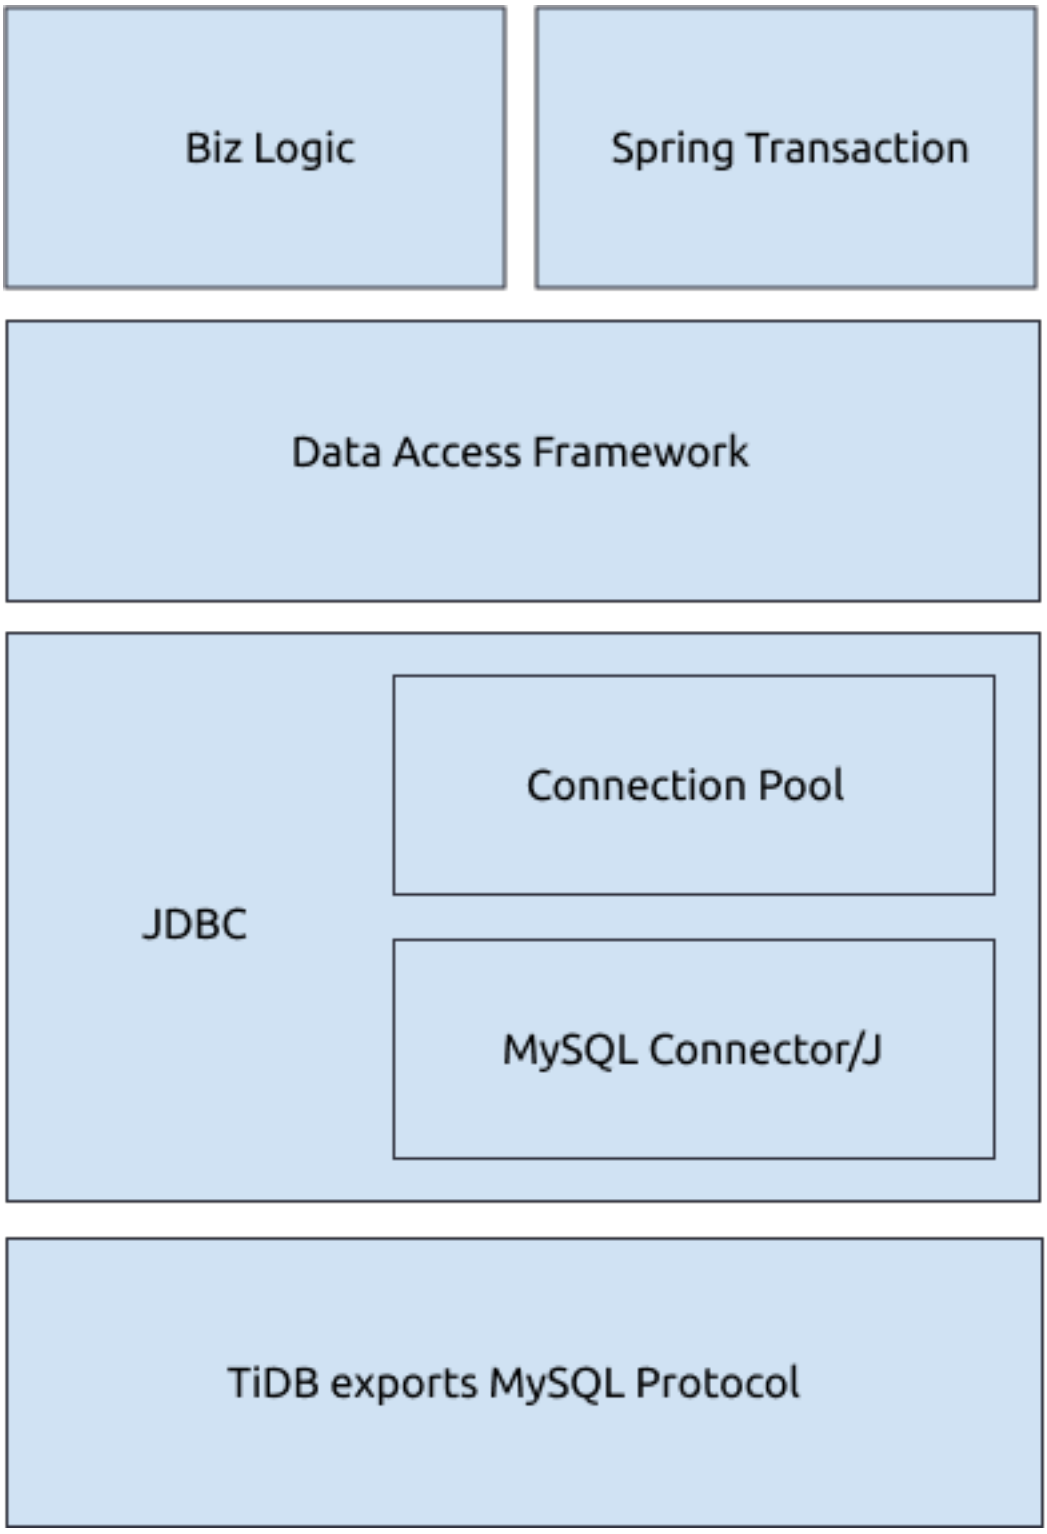

Figure 400: Java application components

From the above diagram, you can see that a Java application might do the following things:

- Implement the MySQL protocol via the JDBC API to interact with TiDB.
- Get a persistent connection from the connection pool.
- Use a data access framework such as MyBatis to generate and execute SQL statements.
- Use Spring Transaction to automatically start or stop a transaction.

The rest of this document describes the issues and their solutions when you develop a Java application using the above components.

12.5.2.2 JDBC

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

12.5.2.2.1 JDBC API

For JDBC API usage, see JDBC official tutorial. This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use Prepared Statements instead of regular execution from a text file and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see MySQL JDBC parameters.

Use Batch API

For batch inserts, you can use the `addBatch/executeBatch` API. The `addBatch()` method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

Note:

In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.

If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see Batch-related parameters.

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and save them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time, and waits until the client's memory is ready and it requests for the next batch.

Usually, there are two kinds of processing methods in JDBC:

- Set `FetchSize` to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

  When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise, the error `No statements may be issued when any streaming result sets are open and in use on a given connection. Ensure that you have called .close()on any active streaming result sets before attempting more queries.` is returned.

  To avoid such an error in queries before the client finishes reading or closes `resultset`, you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- To use Cursor Fetch, first set `FetchSize` as a positive integer and configure `useCursorFetch=true` in the JDBC URL.

TiDB supports both methods, but it is preferred that you use the first method, because it is a simpler implementation and has a better execution efficiency.

12.5.2.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces MySQL Connector/J's parameter configurations (If

you use MariaDB, see MariaDB's parameter configurations). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to `Prepare`.

`useServerPrepStmts`

`useServerPrepStmts` is set to `false` by default, that is, even if you use the Prepare API, the "prepare" operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

`cachePrepStmts`

Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the "prepare" operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

`prepStmtCacheSqlLimit`

After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` configuration (the default value is `256`). This configuration controls the maximum length of the Prepared Statements cached on the client.

The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

You need to check whether this setting is too small if you:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

`prepStmtCacheSize`

`prepStmtCacheSize` controls the number of cached Prepared Statements (the default value is `25`). If your application requires "preparing" many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare("insert into t (a) values(?)");
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
insert into t(a) values(10);
insert into t(a) values(11);
insert into t(a) values(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
insert into t(a) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple "values" keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
insert into t (a) values (10) on duplicate key update a = 10;
insert into t (a) values (11) on duplicate key update a = 11;
insert into t (a) values (12) on duplicate key update a = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
insert into t (a) values (10) on duplicate key update a = values(a);
insert into t (a) values (11) on duplicate key update a = values(a);
insert into t (a) values (12) on duplicate key update a = values(a);
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
insert into t (a) values (10), (11), (12) on duplicate key update a =
    ↪ values(a);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
update t set a = 10 where id = 1; update t set a = 11 where id = 2; update
    ↪ t set a = 12 where id = 3;
```

In addition, because of a client bug, if you want to configure `rewriteBatchedStatements ↪ =true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Integrate parameters

Through monitoring, you might notice that although the application only performs `INSERT` operations to the TiDB cluster, there are a lot of redundant `SELECT` statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` includes a group of configurations. To get the detailed configurations in MySQL Connector/J 8.0 and those in MySQL Connector/J 5.1, see mysql-connector-j 8.0 and mysql-connector-j 5.1 respectively.

After it is configured, you can check the monitoring to see a decreased number of `SELECT` statements.

Note:

> Enabling `useConfigs=maxPerformance` requires MySQL Connector/J version 8.0.33 or later. For more details, see MySQL JDBC Bug.

Timeout-related parameters

TiDB provides two MySQL-compatible parameters that controls the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. The default value of both parameters is `0`, which by default allows the connection to be infinitely idle and infinitely busy (an infinite duration for one SQL statement to execute).

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables=wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

Typical JDBC connection string parameters

Combining the preceding parameter values, the JDBC connection string configuration is as follows:

```
jdbc:mysql://<IP_ADDRESS>:<PORT_NUMBER>/<DATABASE_NAME>?characterEncoding=
    ↪ UTF-8&useSSL=false&useServerPrepStmts=true&cachePrepStmts=true&
    ↪ prepStmtCacheSqlLimit=10000&prepStmtCacheSize=1000&useConfigs=
    ↪ maxPerformance&rewriteBatchedStatements=true
```

> **Note:**
>
> If you are connecting over a public network, you need to set `useSSL=true` and enable TLS between TiDB clients and servers.

12.5.2.3 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least), because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

TiDB supports the following Java connection pools:

- HikariCP
- tomcat-jdbc
- druid
- c3p0
- dbcp

In practice, some connection pools might persistently use specific active sessions. Although the total number of connections appears evenly distributed across TiDB compute nodes, uneven distribution of active connections can lead to actual load imbalance. In distributed scenarios, it is recommended to use HikariCP, which manages connection lifecycles effectively and helps prevent active connections from being fixed on certain nodes, achieving balanced load distribution.

12.5.2.3.1 Typical connection pool configuration

The following is an example configuration for HikariCP:

```
hikari:
  maximumPoolSize: 20
  poolName: hikariCP
  connectionTimeout: 30000
  maxLifetime: 1200000
  keepaliveTime: 120000
```

The parameter explanations are as follows. For more details, refer to the official HikariCP documentation.

- `maximumPoolSize`: the maximum number of connections in the pool. The default value is `10`. In containerized environments, it is recommended to set this to 4–10 times the number of CPU cores available to the Java application. Setting this value too high can lead to resource wastage, while setting it too low can slow down connection acquisition. See About Pool Sizing for more details.
- `minimumIdle`: HikariCP recommends not setting this parameter. The default value is equal to the value of `maximumPoolSize`, which disables connection pool scaling. This ensures that connections are readily available during traffic spikes and avoids delays caused by connection creation.
- `connectionTimeout`: the maximum time (in milliseconds) that an application waits to acquire a connection from the pool. The default value is `30000` milliseconds (30 seconds). If no available connection is obtained within this time, a `SQLException` exception occurs.
- `maxLifetime`: the maximum lifetime (in milliseconds) of a connection in the pool. The default value is `1800000` milliseconds (30 minutes). Connections in use are not affected. After the connection is closed, it will be removed according to this setting. Setting this value too low can cause frequent reconnections. If you are using `graceful-wait-before-shutdown`, ensure this value is less than the wait time.

- `keepaliveTime`: the interval (in milliseconds) between keepalive operations on connections in the pool. This setting helps prevent disconnections caused by database or network idle timeouts. The default value is `120000` milliseconds (2 minutes). The pool prefers using the JDBC4 `isValid()` method to keep idle connections alive.

12.5.2.3.2 Probe configuration

The connection pool maintains persistent connections from clients to TiDB as follows:

- Before v5.4, TiDB does not proactively close client connections by default (unless an error is reported).
- Starting from v5.4, TiDB automatically closes client connections after `28800` seconds (this is, `8` hours) of inactivity by default. You can control this timeout setting using the TiDB and MySQL compatible `wait_timeout` variable. For more information, see JDBC Query Timeout.

Moreover, there might be network proxies such as LVS or HAProxy between clients and TiDB. These proxies typically proactively clean up connections after a specific idle period (determined by the proxy's idle configuration). In addition to monitoring the proxy's idle configuration, connection pools also need to maintain or probe connections for keep-alive.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
    ↪ . The driver has not received any packets from the server. com.mysql.
    ↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
    ↪ failure
```

If `n` in `n milliseconds ago` is `0` or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as `3600000` in the above example), it is likely that this connection was idle for a long time and then closed by the intermediate proxy. The usual solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

12.5.2.4 Data access framework

Applications often use some kind of data access framework to simplify database access.

12.5.2.4.1 MyBatis

MyBatis is a popular Java data access framework. It is mainly used to manage SQL queries and complete the mapping between result sets and Java objects. MyBatis is highly compatible with TiDB. MyBatis rarely has problems based on its historical issues.

Here this document mainly focuses on the following configurations.

Mapper parameters

MyBatis Mapper supports two parameters:

- `select 1 from t where id = #{param1}` will be converted to `select 1 from t where id =?` as a Prepared Statement and be "prepared", and the actual parameter will be used for reuse. You can get the best performance when using this parameter with the previously mentioned Prepare connection parameters.
- `select 1 from t where id = ${param2}` will be replaced with `select 1 from t where id = 1` as a text file and be executed. If this statement is replaced with different parameters and is executed, MyBatis will send different requests for "preparing" the statements to TiDB. This might cause TiDB to cache a large number of Prepared Statements, and executing SQL operations this way has injection security risks.

Dynamic SQL Batch

Dynamic SQL - foreach

To support the automatic rewriting of multiple `INSERT` statements into the form of `insert ... values(...), (...), ...`, in addition to configuring `rewriteBatchedStatements=true` in JDBC as mentioned before, MyBatis can also use dynamic SQL to semi-automatically generate batch inserts. Take the following mapper as an example:

```
<insert id="insertTestBatch" parameterType="java.util.List" fetchSize="1">
  insert into test
   (id, v1, v2)
  values
  <foreach item="item" index="index" collection="list" separator=",">
  (
   #{item.id}, #{item.v1}, #{item.v2}
  )
  </foreach>
  on duplicate key update v2 = v1 + values(v1)
</insert>
```

This mapper generates an `insert on duplicate key update` statement. The number of `(?,?,?)` following "values" is determined by the number of passed lists. Its final effect is similar to using `rewriteBatchStatements=true`, which also effectively reduces communication overhead between the client and TiDB.

As mentioned before, you also need to note that the Prepared Statements will not be cached after their maximum length exceeds the value of `prepStmtCacheSqlLimit`.

Streaming result

A previous section introduces how to stream read execution results in JDBC. In addition to the corresponding configurations of JDBC, if you want to read a super large result set in MyBatis, you also need to note that:

- You can set `fetchSize` for a single SQL statement in the mapper configuration (see the previous code block). Its effect is equivalent to calling `setFetchSize` in JDBC.
- You can use the query interface with `ResultHandler` to avoid getting the entire result set at once.
- You can use the `Cursor` class for stream reading.

If you configure mappings using XML, you can stream read results by configuring `fetchSize="-2147483648"(Integer.MIN_VALUE)` in the mapping's `<select>` section.

```
<select id="getAll" resultMap="postResultMap" fetchSize="-2147483648">
  select * from post;
</select>
```

If you configure mappings using code, you can add the `@Options(fetchSize = Integer .MIN_VALUE)` annotation and keep the type of results as `Cursor` so that the SQL results can be read in streaming.

```
@Select("select * from post")
@Options(fetchSize = Integer.MIN_VALUE)
Cursor<Post> queryAllPost();
```

12.5.2.4.2 ExecutorType

You can choose `ExecutorType` during `openSession`. MyBatis supports three types of executors:

- Simple: The Prepared Statements are called to JDBC for each execution (if the JDBC configuration item `cachePrepStmts` is enabled, repeated Prepared Statements will be reused)
- Reuse: The Prepared Statements are cached in `executor`, so that you can reduce duplicate calls for Prepared Statements without using the JDBC `cachePrepStmts`

- Batch: Each update operation (`INSERT`/`DELETE`/`UPDATE`) will first be added to the batch, and will be executed until the transaction commits or a `SELECT` query is performed. If `rewriteBatchStatements` is enabled in the JDBC layer, it will try to rewrite the statements. If not, the statements will be sent one by one.

Usually, the default value of `ExecutorType` is `Simple`. You need to change `ExecutorType` when calling `openSession`. If it is the batch execution, you might find that in a transaction the `UPDATE` or `INSERT` statements are executed pretty fast, but it is slower when reading data or committing the transaction. This is actually normal, so you need to note this when troubleshooting slow SQL queries.

12.5.2.5 Spring Transaction

In the real world, applications might use Spring Transaction and AOP aspects to start and stop transactions.

By adding the `@Transactional` annotation to the method definition, AOP starts the transaction before the method is called, and commits the transaction before the method returns the result. If your application has a similar need, you can find `@Transactional` in code to determine when the transaction is started and closed.

Pay attention to a special case of embedding. If it occurs, Spring will behave differently based on the Propagation configuration.

12.5.2.6 Misc

This section introduces some useful tools for Java to help you troubleshoot issues.

12.5.2.6.1 Troubleshooting tools

Using the powerful troubleshooting tools of JVM is recommended when an issue occurs in your Java application and you do not know the application logic. Here are a few common tools:

jstack

jstack is similar to pprof/goroutine in Go, which can easily troubleshoot the process stuck issue.

By executing `jstack pid`, you can output the IDs and stack information of all threads in the target process. By default, only the Java stack is output. If you want to output the C++ stack in the JVM at the same time, add the `-m` option.

By using jstack multiple times, you can easily locate the stuck issue (for example, a slow query from application's view due to using Batch ExecutorType in Mybatis) or the application deadlock issue (for example, the application does not send any SQL statement because it is preempting a lock before sending it).

In addition, `top -p $ PID -H` or Java swiss knife are common methods to view the thread ID. Also, to locate the issue of "a thread occupies a lot of CPU resources and I don't know what it is executing", do the following steps:

- Use `printf "%x\n" pid` to convert the thread ID to hexadecimal.
- Go to the jstack output to find the stack information of the corresponding thread.

jmap & mat

Unlike pprof/heap in Go, jmap dumps the memory snapshot of the entire process (in Go, it is the sampling of the distributor), and then the snapshot can be analyzed by another tool mat.

Through mat, you can see the associated information and attributes of all objects in the process, and you can also observe the running status of the thread. For example, you can use mat to find out how many MySQL connection objects exist in the current application, and what is the address and status information of each connection object.

Note that mat only handles reachable objects by default. If you want to troubleshoot young GC issues, you can adjust mat configuration to view unreachable objects. In addition, for investigating the memory allocation of young GC issues (or a large number of short-lived objects), using Java Flight Recorder is more convenient.

trace

Online applications usually do not support modifying the code, but it is often desired that dynamic instrumentation is performed in Java to locate issues. Therefore, using btrace or arthas trace is a good option. They can dynamically insert trace code without restarting the application process.

Flame graph

Obtaining flame graphs in Java applications is tedious. For details, see Java Flame Graphs Introduction: Fire For Everyone!.

12.5.2.7 Conclusion

Based on commonly used Java components that interact with databases, this document describes the common problems and solutions for developing Java applications with TiDB. TiDB is highly compatible with the MySQL protocol, so most of the best practices for MySQL-based Java applications also apply to TiDB.

12.5.2.8 Need help?

Ask questions on TiDB Community, or create a support ticket.

12.5.3 Best Practices for Using HAProxy in TiDB

This document describes best practices for configuration and usage of HAProxy in TiDB. HAProxy provides load balancing for TCP-based applications. From TiDB clients, you can manipulate data just by connecting to the floating virtual IP address provided by HAProxy, which helps to achieve load balance in the TiDB server layer.

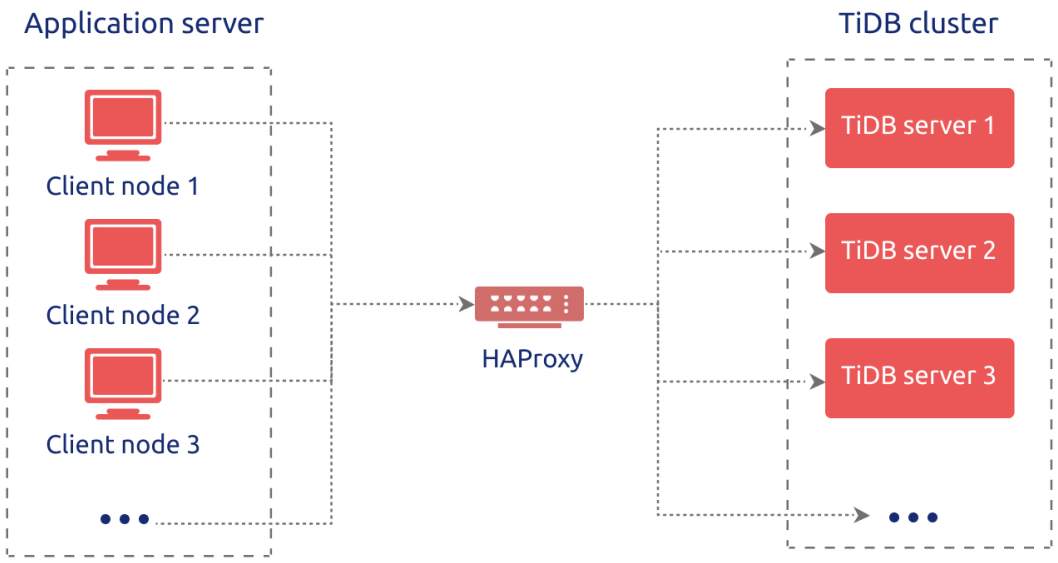

Figure 401: HAProxy Best Practices in TiDB

Note:

The minimum version of HAProxy that works with all versions of TiDB is v1.5. Between v1.5 and v2.1, you need to set the `post-41` option in `mysql-check`. It is recommended to use HAProxy v2.2 or newer.

12.5.3.1 HAProxy overview

HAProxy is free, open-source software written in C language that provides a high availability load balancer and proxy server for TCP and HTTP-based applications. Because of its fast and efficient use of CPU and memory, HAProxy is now widely used by many well-known websites such as GitHub, Bitbucket, Stack Overflow, Reddit, Tumblr, Twitter, Tuenti, and AWS (Amazon Web Services).

HAProxy is written in the year 2000 by Willy Tarreau, the core contributor to the Linux kernel, who is still responsible for the maintenance of the project and provides free software updates in the open-source community. In this guide, HAProxy 2.6 is used. It is recommended to use the latest stable version. See the released version of HAProxy for details.

12.5.3.2 Basic features

- High Availability: HAProxy provides high availability with support for a graceful shutdown and a seamless switchover;
- Load Balancing: Two major proxy modes are supported: TCP, also known as layer 4, and HTTP, also known as layer 7. No less than 9 load balancing algorithms are supported, such as roundrobin, leastconn and random;
- Health Check: HAProxy periodically checks the status of HTTP or TCP mode of the server;
- Sticky Session: HAProxy can stick a client to a specific server for the duration when the application does not support sticky sessions;
- SSL: HTTPS communication and resolution are supported;
- Monitoring and Statistics: Through the web page, you can monitor the service state and traffic flow in real time.

12.5.3.3 Before you begin

Before you deploy HAProxy, make sure that you meet the hardware and software requirements.

12.5.3.3.1 Hardware requirements

According to the HAProxy documentation, the minimum hardware configuration for HAProxy is shown in the following table. Under the Sysbench `oltp_read_write` workload, the maximum QPS for this configuration is about 50K. You can increase the server configuration according to your load balancing environment.

Hardware resource	Minimum specification
CPU	2 cores, 3.5 GHz
Memory	4 GB
Storage	50 GB (SATA)
Network Interface Card	10G Network Card

12.5.3.3.2 Software requirements

You can use the following operating systems and make sure the required dependencies are installed. If you use yum to install HAProxy, the dependencies are installed along with it and you do not need to separately install them again.

Operating systems

Linux distribution	Version
Red Hat Enterprise Linux	7 or 8
CentOS	7 or 8
Oracle Enterprise Linux	7 or 8
Ubuntu LTS	18.04 or later versions

Note:

- For more information about other supported operating systems, see HAProxy documentation.

Dependencies

- epel-release
- gcc
- systemd-devel

To install the dependencies above, run the following command:

```
yum -y install epel-release gcc systemd-devel
```

12.5.3.4 Deploy HAProxy

You can easily use HAProxy to configure and set up a load-balanced database environment. This section shows general deployment operations. You can customize the configuration file based on your actual scenario.

12.5.3.4.1 Install HAProxy

1. Download the package of the HAProxy 2.6.2 source code:

   ```
   wget https://www.haproxy.org/download/2.6/src/haproxy-2.6.2.tar.gz
   ```

2. Extract the package:

   ```
   tar zxf haproxy-2.6.2.tar.gz
   ```

3. Compile the application from the source code:

```
cd haproxy-2.6.2
make clean
make -j 8 TARGET=linux-glibc USE_THREAD=1
make PREFIX=${/app/haproxy} SBINDIR=${/app/haproxy/bin} install #
    ↪ Replace `${/app/haproxy}` and `${/app/haproxy/bin}` with your
    ↪ custom directories.
```

4. Reconfigure the profile:

```
echo 'export PATH=/app/haproxy/bin:$PATH' >> /etc/profile
. /etc/profile
```

5. Check whether the installation is successful:

```
which haproxy
```

HAProxy commands

Execute the following command to print a list of keywords and their basic usage:

```
haproxy --help
```

Option	Description
`-v`	Reports the version and build date.
`-vv`	Displays the version, build options, libraries versions and usable pollers.
`-d`	Enables debug mode.
`-db`	Disables background mode and multi-process mode.

Option	Description
`-dM [< ↪ byte ↪ >]`	Forces memory poisoning, which means that each and every memory region allocated with malloc() or pool_alloc2() will be filled with `<byte>` before being passed to the caller.
`-V`	Enables verbose mode (disables quiet mode).
`-D`	Starts as a daemon.
`-C <dir>`	Changes to directory `<dir>` before loading configuration files.
`-W`	Master-worker mode.

Option	Description
`-q`	Sets “quiet” mode: This disables some messages during the configuration parsing and during startup.
`-c`	Only performs a check of the configuration files and exits before trying to bind.
`-n <` ↪ `limit` ↪ `>`	Limits the per-process connection limit to `<limit>`.
`-m <` ↪ `limit` ↪ `>`	Limits the total allocatable memory to `<limit>` megabytes across all processes.

Option	Description
`-N <limit>`	Sets the default per-proxy maxconn to `<limit>` instead of the builtin default value (usually 2000).
`-L <name>`	Changes the local peer name to `<name>`, which defaults to the local hostname.
`-p <file>`	Writes all processes' PIDs into `<file>` during startup.
`-de`	Disables the use of epoll(7). epoll(7) is available only on Linux 2.6 and some custom Linux 2.4 systems.
`-dp`	Disables the use of poll(2). select(2) might be used instead.

Option	Description
`-dS`	Disables the use of splice(2), which is broken on older kernels.
`-dR`	Disables SO_REUSEPORT usage.
`-dr`	Ignores server address resolution failures.
`-dV`	Disables SSL verify on the server side.

Option	Description
`-sf <pidlist>`	Sends the "finish" signal to the PIDs in pidlist after startup. The processes which receive this signal wait for all sessions to finish before exiting. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGUSR1 are sent.

Option	Description
`-st <` ↪ `pidlist` ↪ `>`	Sends the "terminate" signal to the PIDs in pidlist after startup. The processes which receive this signal terminate immediately, closing all active sessions. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGTERM are sent.

Option	Description
`-x <unix_socket>`	Connects to the specified socket and retrieves all the listening sockets from the old process. Then, these sockets are used instead of binding new ones.
`-S <bind>[,<bind_options>...]`	In master-worker mode, creates a master CLI. This CLI enables access to the CLI of every worker. Useful for debugging, it's a convenient way of accessing a leaving process.

For more details on HAProxy command line options, refer to Management Guide of HAProxy and General Commands Manual of HAProxy.

12.5.3.4.2 Configure HAProxy

A configuration template is generated when you use yum to install HAProxy. You can also customize the following configuration items according to your scenario.

```
global                                  # Global configuration.
   log         127.0.0.1 local2         # Global syslog servers (up to two).
   chroot      /var/lib/haproxy         # Changes the current directory and
      ↪ sets superuser privileges for the startup process to improve
      ↪ security.
   pidfile     /var/run/haproxy.pid     # Writes the PIDs of HAProxy processes
      ↪  into this file.
   maxconn     4096                     # The maximum number of concurrent
      ↪ connections for a single HAProxy process. It is equivalent to the
      ↪ command-line argument "-n".
   nbthread    48                       # The maximum number of threads. (The
      ↪ upper limit is equal to the number of CPUs)
   user        haproxy                  # Same with the UID parameter.
   group       haproxy                  # Same with the GID parameter. A
      ↪ dedicated user group is recommended.
   daemon                               # Makes the process fork into
      ↪ background. It is equivalent to the command line "-D" argument. It
      ↪ can be disabled by the command line "-db" argument.
   stats socket /var/lib/haproxy/stats # The directory where statistics
      ↪ output is saved.

defaults                                # Default configuration.
   log global                           # Inherits the settings of the global
      ↪ configuration.
   retries 2                            # The maximum number of retries to
      ↪ connect to an upstream server. If the number of connection attempts
      ↪  exceeds the value, the backend server is considered unavailable.
   timeout connect 2s                   # The maximum time to wait for a
      ↪ connection attempt to a backend server to succeed. It should be set
      ↪  to a shorter time if the server is located on the same LAN as
      ↪ HAProxy.
   timeout client 30000s                # The maximum inactivity time on the
      ↪ client side.
   timeout server 30000s                # The maximum inactivity time on the
      ↪ server side.

listen admin_stats                      # The name of the Stats page reporting
   ↪  information from frontend and backend. You can customize the name
   ↪ according to your needs.
   bind 0.0.0.0:8080                    # The listening port.
   mode http                            # The monitoring mode.
   option httplog                       # Enables HTTP logging.
   maxconn 10                           # The maximum number of concurrent
      ↪ connections.
```

```
  stats refresh 30s                   # Automatically refreshes the Stats
     ↪ page every 30 seconds.
  stats uri /haproxy                  # The URL of the Stats page.
  stats realm HAProxy                 # The authentication realm of the
     ↪ Stats page.
  stats auth admin:pingcap123         # User name and password in the Stats
     ↪ page. You can have multiple user names.
  stats hide-version                  # Hides the version information of
     ↪ HAProxy on the Stats page.
  stats admin if TRUE                 # Manually enables or disables the
     ↪ backend server (supported in HAProxy 1.4.9 or later versions).

listen tidb-cluster                   # Database load balancing.
  bind 0.0.0.0:3390                   # The Floating IP address and
     ↪ listening port.
  mode tcp                            # HAProxy uses layer 4, the transport
     ↪ layer.
  balance leastconn                   # The server with the smallest number
     ↪ of connections receives the connection. "leastconn" is recommended
     ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
     ↪  than protocols using short sessions, such as HTTP. The algorithm
     ↪ is dynamic, which means that server weights might be adjusted on
     ↪ the fly for slow starts for instance.
  server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
     ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
     ↪ detected as successful twice, the server is considered available;
     ↪ if it is detected as failed three times, the server is considered
     ↪ unavailable.
  server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

To check the source IP address using `SHOW PROCESSLIST`, you need to configure the PROXY protocol to connect to TiDB.

```
  server tidb-1 10.9.18.229:4000 send-proxy check inter 2000 rise 2 fall 3
  server tidb-2 10.9.39.208:4000 send-proxy check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 send-proxy check inter 2000 rise 2 fall 3
```

Note:

Before using the PROXY protocol, you need to configure `proxy-protocol.networks` in the configuration file of the TiDB server.

12.5.3.4.3 Start HAProxy

To start HAProxy, run `haproxy`. `/etc/haproxy/haproxy.cfg` is read by default (recommended).

```
haproxy -f /etc/haproxy/haproxy.cfg
```

12.5.3.4.4 Stop HAProxy

To stop HAProxy, use the `kill -9` command.

1. Run the following command:

```
ps -ef | grep haproxy
```

2. Terminate the process of HAProxy:

```
kill -9 ${haproxy.pid}
```

12.5.4 Highly Concurrent Write Best Practices

This document describes best practices for handling highly-concurrent write-heavy workloads in TiDB, which can help to facilitate your application development.

12.5.4.1 Target audience

This document assumes that you have a basic understanding of TiDB. It is recommended that you first read the following three blog articles that explain TiDB fundamentals, and TiDB Best Practices:

- Data Storage
- Computing
- Scheduling

12.5.4.2 Highly-concurrent write-intensive scenario

The highly concurrent write scenario often occurs when you perform batch tasks in applications, such as clearing and settlement. This scenario has the following features:

- A huge volume of data
- The need to import historical data into database in a short time
- The need to read a huge volume of data from database in a short time

These features pose these challenges to TiDB:

- The write or read capacity must be linearly scalable.
- Database performance is stable and does not decrease as a huge volume of data is written concurrently.

For a distributed database, it is important to make full use of the capacity of all nodes and to prevent a single node from becoming the bottleneck.

12.5.4.3 Data distribution principles in TiDB

To address the above challenges, it is necessary to start with the data segmentation and scheduling principle of TiDB. Refer to Scheduling for more details.

TiDB splits data into Regions, each representing a range of data with a size limit of 96M by default. Each Region has multiple replicas, and each group of replicas is called a Raft Group. In a Raft Group, the Region Leader executes the read and write tasks (TiDB supports Follower-Read) within the data range. The Region Leader is automatically scheduled by the Placement Driver (PD) component to different physical nodes evenly to distribute the read and write pressure.

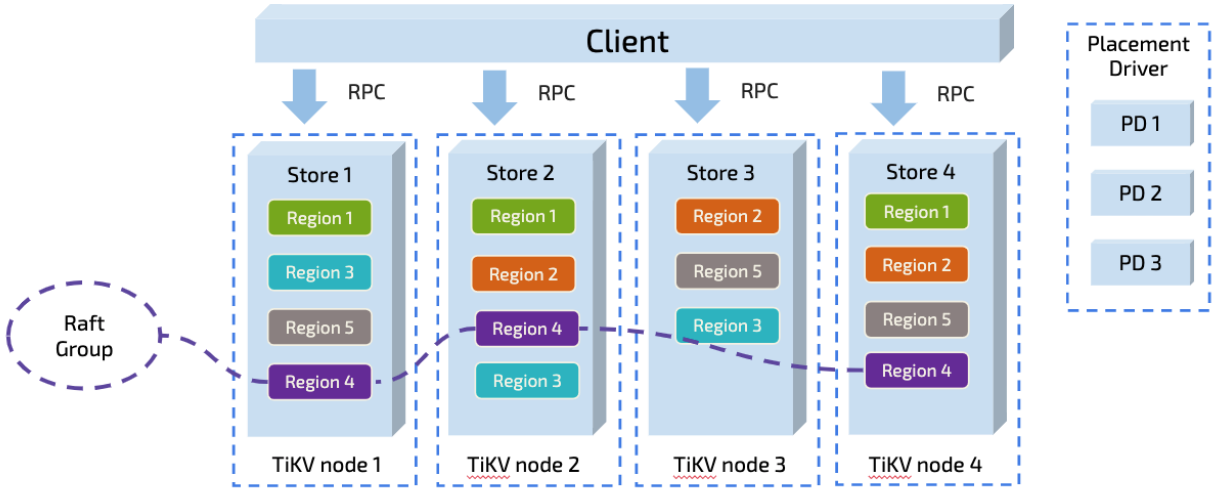

Figure 402: TiDB Data Overview

In theory, if an application has no write hotspot, TiDB, by the virtue of its architecture, can not only linearly scale its read and write capacities, but also make full use of the distributed resources. From this point of view, TiDB is especially suitable for the high-concurrent and write-intensive scenario.

However, the actual situation often differs from the theoretical assumption.

> **Note:**
>
> No write hotspot in an application means the write scenario does not have any `AUTO_INCREMENT` primary key or monotonically increasing index.

12.5.4.4 Hotspot case

The following case explains how a hotspot is generated. Take the table below as an example:

```
CREATE TABLE IF NOT EXISTS TEST_HOTSPOT(
     id        BIGINT PRIMARY KEY,
     age       INT,
     user_name VARCHAR(32),
     email     VARCHAR(128)
)
```

This table is simple in structure. In addition to `id` as the primary key, no secondary index exists. Execute the following statement to write data into this table. `id` is discretely generated as a random number.

```
SET SESSION cte_max_recursion_depth = 1000000;
INSERT INTO TEST_HOTSPOT
SELECT
  n,                                    -- ID
  RAND()*80,                            -- Number between 0 and 80
  CONCAT('user-',n),
  CONCAT(
    CHAR(65 + (RAND() * 25) USING ascii), -- Number between 65 and 65+25,
       ↪ converted to a character, A-Z
    '-user-',
    n,
    '@example.com'
  )
FROM
  (WITH RECURSIVE nr(n) AS
    (SELECT 1                           -- Start CTE at 1
      UNION ALL SELECT n + 1            -- increase n with 1 every loop
      FROM nr WHERE n < 1000000         -- stop loop at 1_000_000
    ) SELECT n FROM nr
  ) a;
```

The load comes from executing the above statement intensively in a short time.

In theory, the above operation seems to comply with the TiDB best practices, and no hotspot is caused in the application. The distributed capacity of TiDB can be fully used with adequate machines. To verify whether it is truly in line with the best practices, a test is conducted in the experimental environment, which is described as follows:

For the cluster topology, 2 TiDB nodes, 3 PD nodes and 6 TiKV nodes are deployed. Ignore the QPS performance, because this test is to clarify the principle rather than for benchmark.

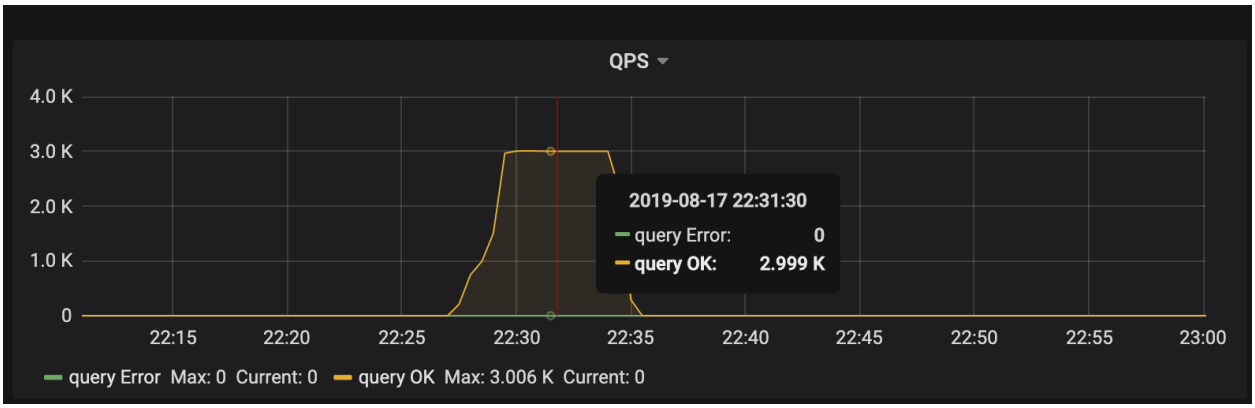

Figure 403: QPS1

The client starts "intensive" write requests in a short time, which is 3K QPS received by TiDB. In theory, the load pressure should be evenly distributed to 6 TiKV nodes. However, from the CPU usage of each TiKV node, the load distribution is uneven. The `tikv-3` node is the write hotspot.

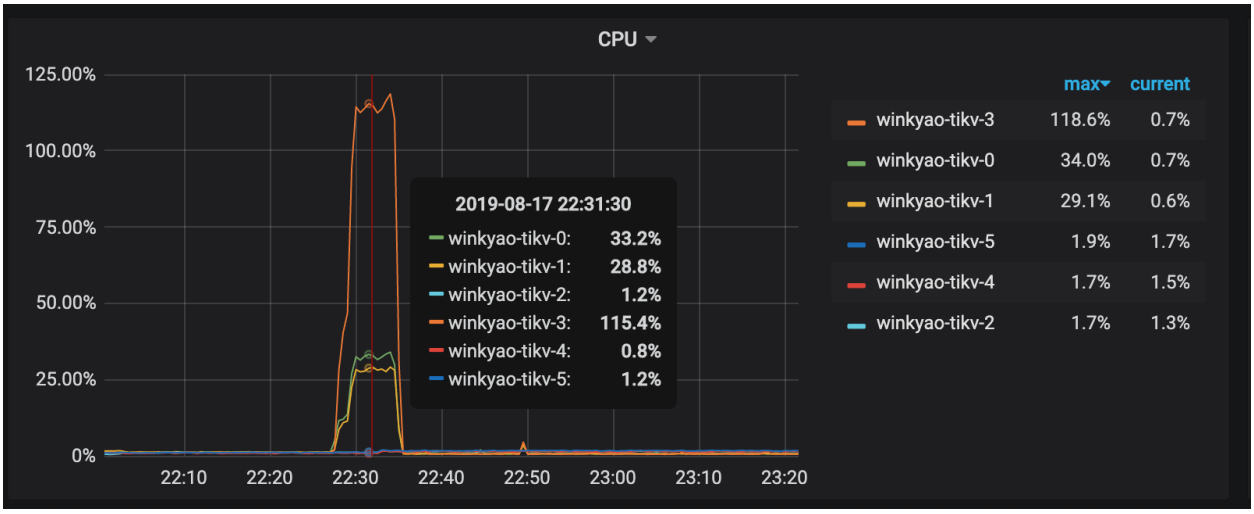

Figure 404: QPS2

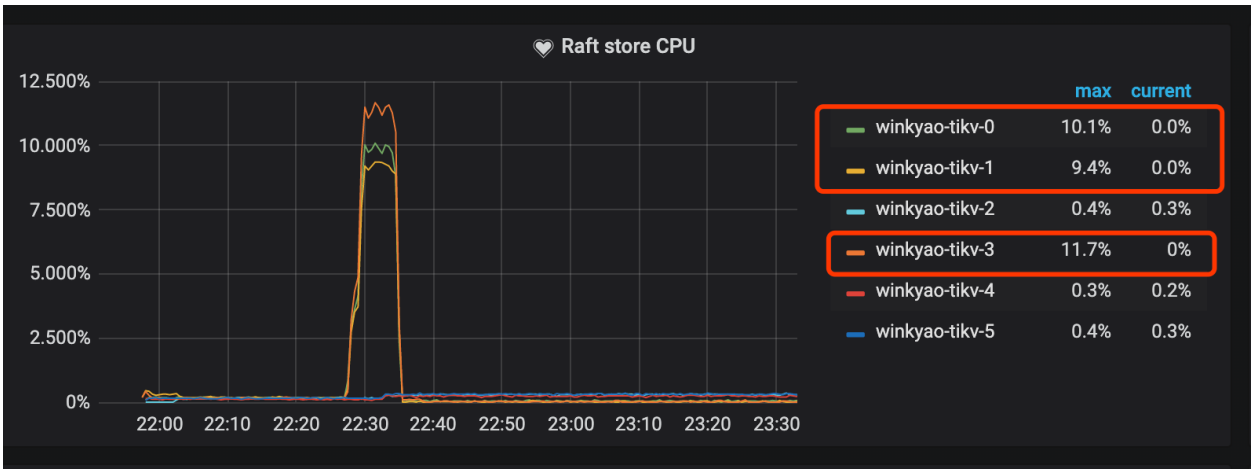

Figure 405: QPS3

Raft store CPU is the CPU usage rate for the `raftstore` thread, usually representing the write load. In this scenario, `tikv-3` is the Leader of this Raft Group; `tikv-0` and `tikv-1` are the followers. The loads of other nodes are almost empty.

The monitoring metrics of PD also confirms that hotspot has been caused.

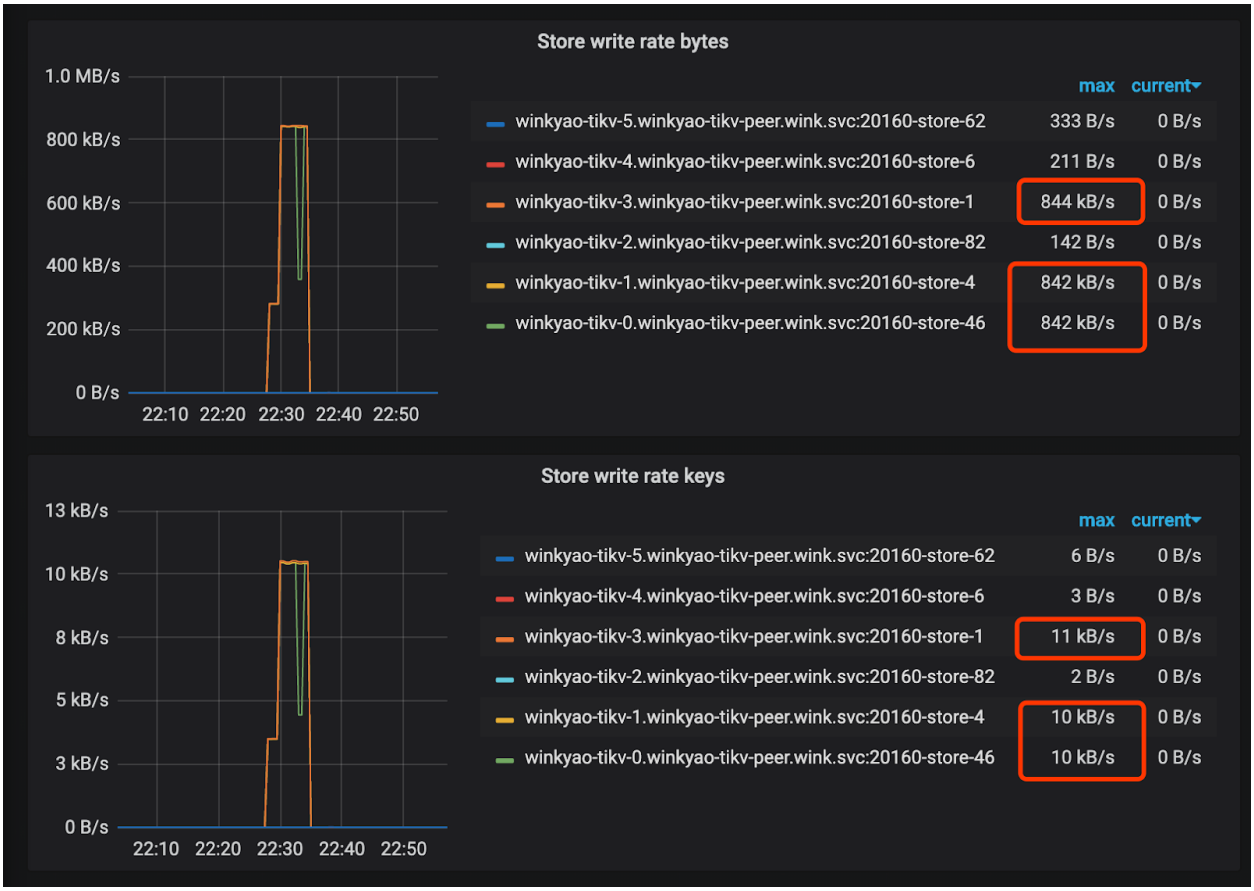

Figure 406: QPS4

12.5.4.5 Hotspot causes

In the above test, the operation does not reach the ideal performance expected in the best practices. This is because only one Region is split by default to store the data of each newly created table in TiDB, with the following data range:

```
[CommonPrefix + TableID, CommonPrefix + TableID + 1)
```

In a short period of time, a huge volume of data is continuously written to the same Region.

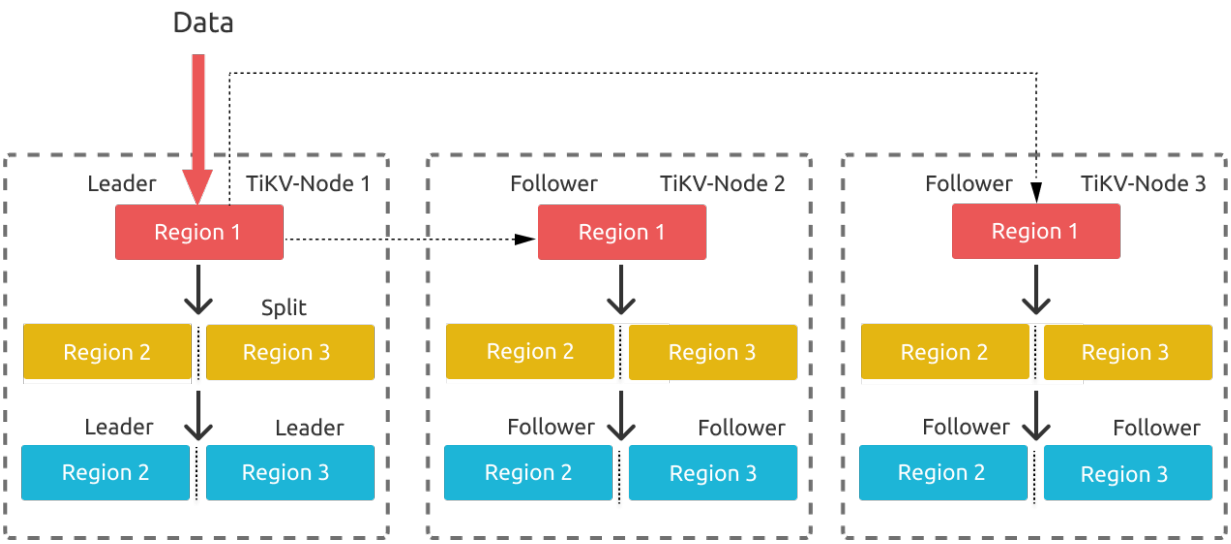

Figure 407: TiKV Region Split

The above diagram illustrates the Region splitting process. As data is continuously written into TiKV, TiKV splits a Region into multiple Regions. Because the leader election is started on the original store where the Region Leader to be split is located, the leaders of the two newly split Regions might be still on the same store. This splitting process might also happen on the newly split Region 2 and Region 3. In this way, write pressure is concentrated on TiKV-Node 1.

During the continuous write process, after finding that hotspot is caused on Node 1, PD evenly distributes the concentrated Leaders to other nodes. If the number of TiKV nodes is more than the number of Region replicas, TiKV will try to migrate these Regions to idle nodes. These two operations during the write process are also reflected in the PD's monitoring metrics:

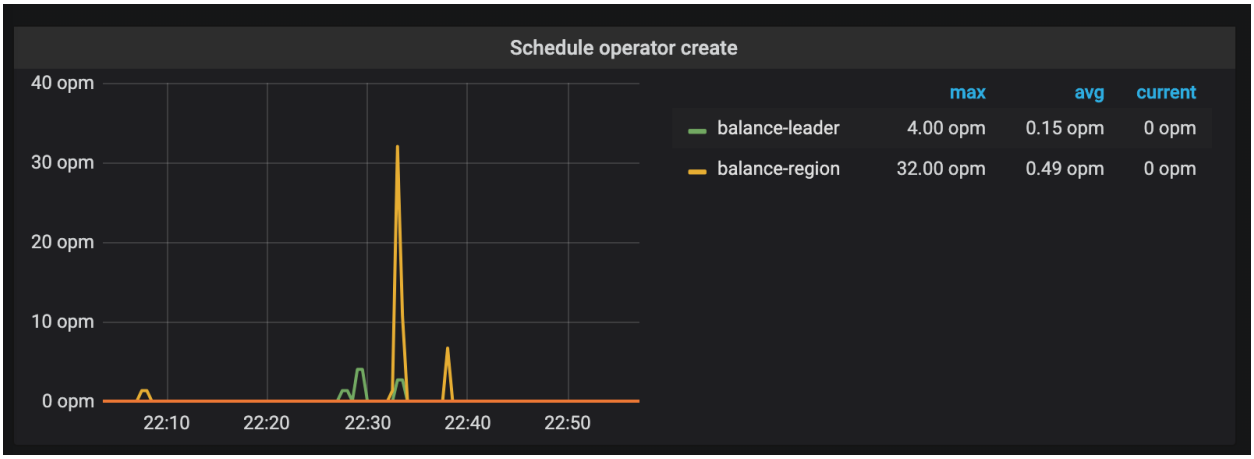

Figure 408: QPS5

After a period of continuous writes, PD automatically schedules the entire TiKV cluster to a state where pressure is evenly distributed. By that time, the capacity of the whole cluster can be fully used.

In most cases, the above process of causing a hotspot is normal, which is the Region warm-up phase of database. However, you need to avoid this phase in highly-concurrent write-intensive scenarios.

12.5.4.6 Hotspot solution

To achieve the ideal performance expected in theory, you can skip the warm-up phase by directly splitting a Region into the desired number of Regions and scheduling these Regions in advance to other nodes in the cluster.

In v3.0.x, v2.1.13 and later versions, TiDB supports a new feature called Split Region. This new feature provides the following new syntaxes:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (
    ↪ upper_value) REGIONS region_num
```

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_list)]
```

However, TiDB does not automatically perform this pre-split operation. The reason is related to the data distribution in TiDB.

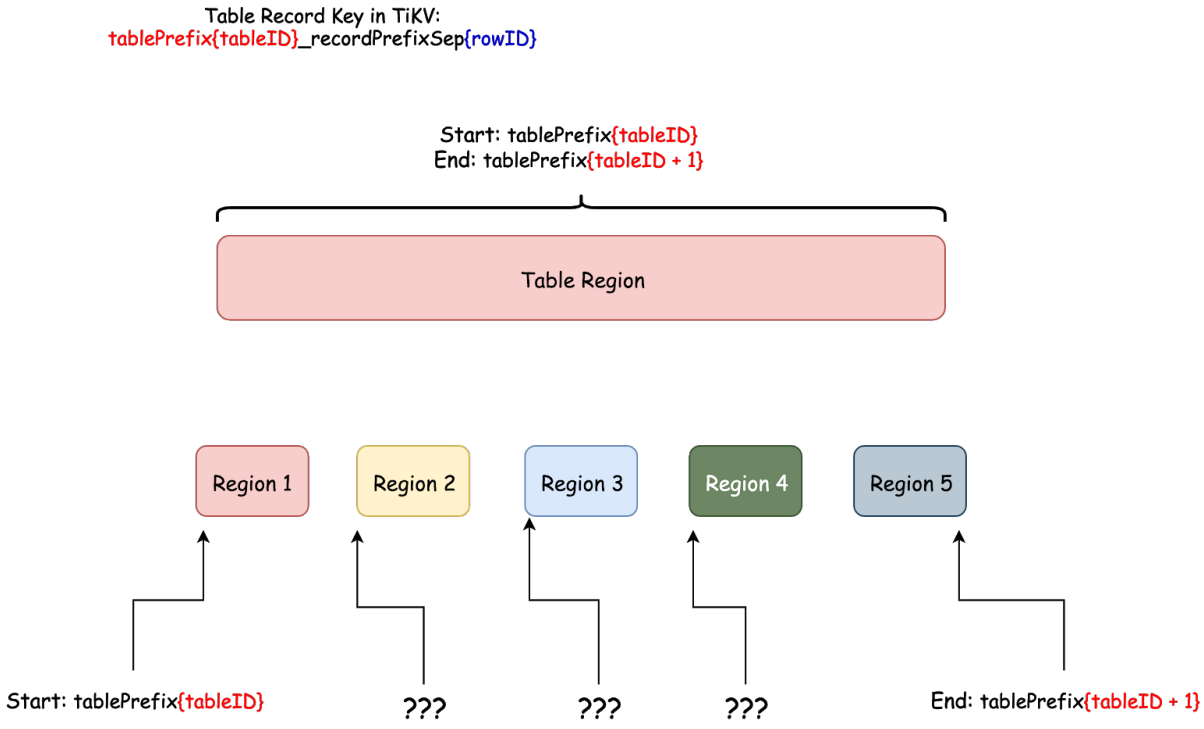

Figure 409: Table Region Range

From the diagram above, according to the encoding rule of a row's key, the `rowID` is the only variable part. In TiDB, `rowID` is an `Int64` integer. However, you might not need to evenly split the `Int64` integer range to the desired number of ranges and then to distribute these ranges to different nodes, because Region split must also be based on the actual situation.

If the write of `rowID` is completely discrete, the above method will not cause hotspots. If the row ID or index has a fixed range or prefix (for example, discretely insert data into the range of `[2000w, 5000w)`), no hotspot will be caused either. However, if you split a Region using the above method, data might still be written to the same Region at the beginning.

TiDB is a database for general usage and does not make assumptions about the data distribution. So it uses only one Region at the beginning to store the data of a table and automatically splits the Region according to the data distribution after real data is inserted.

Given this situation and the need to avoid the hotspot problem, TiDB offers the `Split Region` syntax to optimize performance for the highly-concurrent write-heavy scenario. Based on the above case, now scatter Regions using the `Split Region` syntax and observe the load distribution.

Because the data to be written in the test is entirely discrete within the positive range, you can use the following statement to pre-split the table into 128 Regions within the range of `minInt64` and `maxInt64`:

```
SPLIT TABLE TEST_HOTSPOT BETWEEN (0) AND (9223372036854775807) REGIONS 128;
```

After the pre-split operation, execute the `SHOW TABLE test_hotspot REGIONS;` statement to check the status of Region scattering. If the values of the `SCATTERING` column are all `0`, the scheduling is successful.

You can also check the Region leader distribution using the following SQL statement. You need to replace `table_name` with the actual table name.

```
SELECT
    p.STORE_ID,
    COUNT(s.REGION_ID) PEER_COUNT
FROM
    INFORMATION_SCHEMA.TIKV_REGION_STATUS s
    JOIN INFORMATION_SCHEMA.TIKV_REGION_PEERS p ON s.REGION_ID = p.REGION_ID
WHERE
    TABLE_NAME = 'table_name'
    AND p.is_leader = 1
GROUP BY
    p.STORE_ID
ORDER BY
    PEER_COUNT DESC;
```

Then operate the write load again:

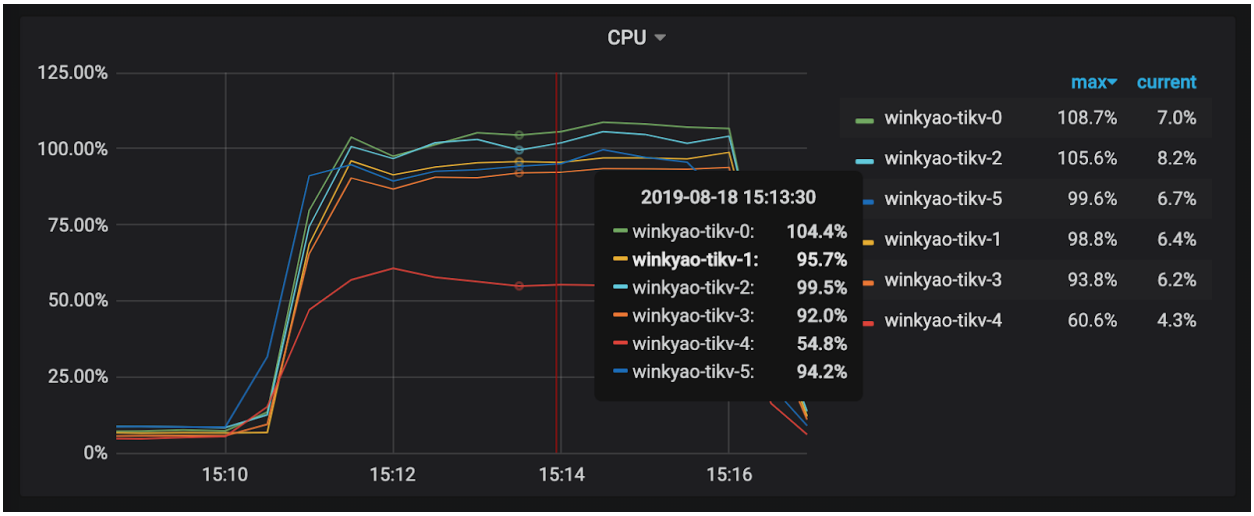

Figure 410: QPS6

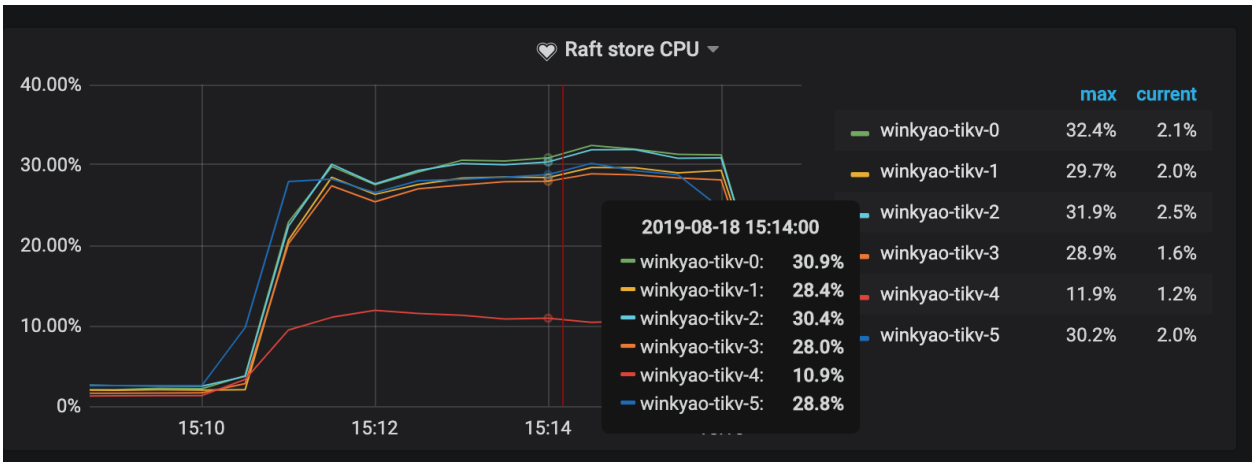

Figure 411: QPS7

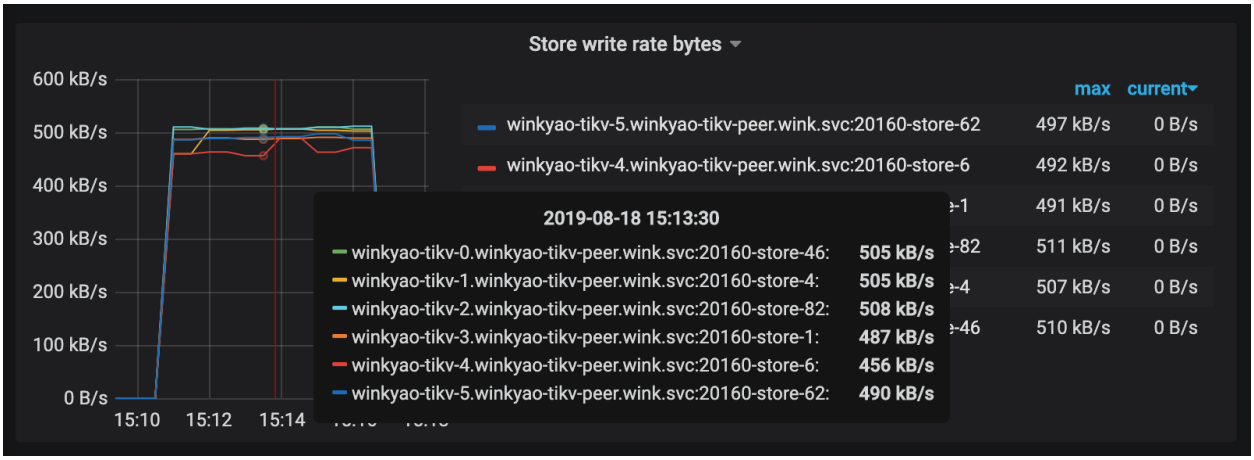

Figure 412: QPS8

You can see that the apparent hotspot problem has been resolved now.

In this case, the table is simple. In other cases, you might also need to consider the hotspot problem of index. For more details on how to pre-split the index Region, refer to Split Region.

12.5.4.7 Complex hotspot problems

Problem one:

If a table does not have a primary key, or the primary key is not the `Int` type and you do not want to generate a randomly distributed primary key ID, TiDB provides an implicit `_tidb_rowid` column as the row ID. Generally, when you do not use the `SHARD_ROW_ID_BITS` parameter, the values of the `_tidb_rowid` column are also monotonically increasing, which might causes hotspots too. Refer to `SHARD_ROW_ID_BITS` for more details.

To avoid the hotspot problem in this situation, you can use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` when creating a table. For more details about `PRE_SPLIT_REGIONS`, refer to Pre-split Regions.

`SHARD_ROW_ID_BITS` is used to randomly scatter the row ID generated in the `_tidb_rowid` column. `PRE_SPLIT_REGIONS` is used to pre-split the Region after a table is created.

> **Note:**
>
> The value of `PRE_SPLIT_REGIONS` must be smaller than or equal to that of `SHARD_ROW_ID_BITS`.

Example:

```
create table t (a int, b int) SHARD_ROW_ID_BITS = 4 PRE_SPLIT_REGIONS=3;
```

- `SHARD_ROW_ID_BITS = 4` means that the values of `tidb_rowid` will be randomly distributed into 16 (16=2^4) ranges.
- `PRE_SPLIT_REGIONS=3` means that the table will be pre-split into 8 (2^3) Regions after it is created.

When data starts to be written into table `t`, the data is written into the pre-split 8 Regions, which avoids the hotspot problem that might be caused if only one Region exists after table creation.

> **Note:**
>
> The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`.
>
> This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to `1`, then TiDB will not return the results to the client until all the Regions are split and scattered. Otherwise, TiDB writes data before the scattering is completed, which will have a significant impact on write performance.

Problem two:

If a table's primary key is an integer type, and if the table uses `AUTO_INCREMENT` to ensure the uniqueness of the primary key (not necessarily continuous or incremental), you cannot use `SHARD_ROW_ID_BITS` to scatter the hotspot on this table because TiDB directly uses the row values of the primary key as `_tidb_rowid`.

To address the problem in this scenario, you can replace `AUTO_INCREMENT` with `AUTO_RANDOM` (a column attribute) when inserting data. Then TiDB automatically assigns values to the integer primary key column, which eliminates the continuity of the row ID and scatters the hotspot.

12.5.4.8 Parameter configuration

In v2.1, the latch mechanism is introduced in TiDB to identify transaction conflicts in advance in scenarios where write conflicts frequently appear. The aim is to reduce the retry of transaction commits in TiDB and TiKV caused by write conflicts. Generally, batch tasks use the data already stored in TiDB, so the write conflicts of transaction do not exist. In this situation, you can disable the latch in TiDB to reduce memory allocation for small objects:

```
[txn-local-latches]
enabled = false
```

12.5.5 Best Practices for Monitoring TiDB Using Grafana

When you deploy a TiDB cluster using TiUP and have added Grafana and Prometheus in the topology configuration, a set of Grafana + Prometheus monitoring platform is deployed simultaneously to collect and display metrics for various components and machines in the TiDB cluster. This document describes best practices for monitoring TiDB using Grafana. It aims to help you use metrics to analyze the status of the TiDB cluster and diagnose problems.

12.5.5.1 Monitoring architecture

Prometheus is a time series database with a multi-dimensional data model and a flexible query language. Grafana is an open source monitoring system for analyzing and visualizing metrics.

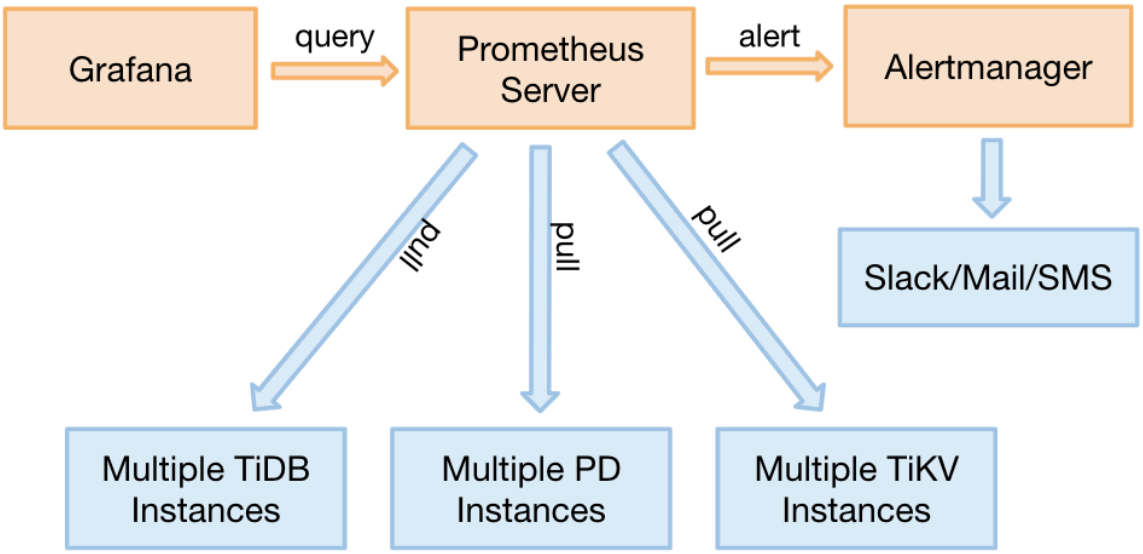

Figure 413: The monitoring architecture in the TiDB cluster

For TiDB 2.1.3 or later versions, TiDB monitoring supports the pull method. It is a good adjustment with the following benefits:

- There is no need to restart the entire TiDB cluster if you need to migrate Prometheus. Before adjustment, migrating Prometheus requires restarting the entire cluster because the target address needs to be updated.

- You can deploy 2 separate sets of Grafana + Prometheus monitoring platforms (not highly available) to prevent a single point of monitoring.
- The Pushgateway which might become a single point of failure is removed.

12.5.5.2 Source and display of monitoring data

The three core components of TiDB (TiDB server, TiKV server and PD server) obtain metrics through the HTTP interface. These metrics are collected from the program code, and the default ports are as follows:

Component	Port
TiDB server	10080
TiKV server	20180
PD server	2379

Execute the following command to check the QPS of a SQL statement through the HTTP interface. Take the TiDB server as an example:

```
curl http://__tidb_ip__:10080/metrics |grep tidb_executor_statement_total
```

```
### Check the real-time QPS of different types of SQL statements. The
    ↪ numbers below are the cumulative values of counter type (scientific
    ↪ notation).
tidb_executor_statement_total{type="Delete"} 520197
tidb_executor_statement_total{type="Explain"} 1
tidb_executor_statement_total{type="Insert"} 7.20799402e+08
tidb_executor_statement_total{type="Select"} 2.64983586e+08
tidb_executor_statement_total{type="Set"} 2.399075e+06
tidb_executor_statement_total{type="Show"} 500531
tidb_executor_statement_total{type="Use"} 466016
```

The data above is stored in Prometheus and displayed on Grafana. Right-click the panel and then click the **Edit** button (or directly press the E key) shown in the following figure:

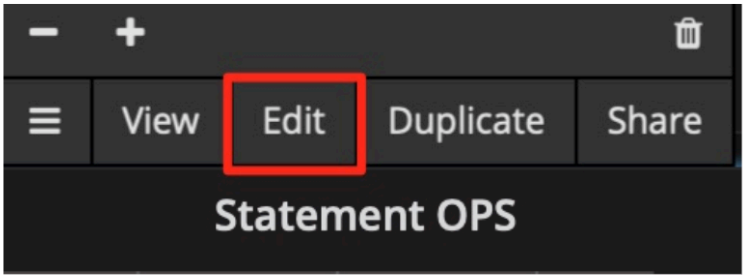

Figure 414: The Edit entry for the Metrics tab

After clicking the **Edit** button, you can see the query expression with the `tidb_executor_statement_t` ↪ metric name on the Metrics tab. The meanings of some items on the panel are as follows:

- `rate[1m]`: The growth rate in one minute. It can only be used for the data of counter type.
- `sum`: The sum of values.
- `by type`: The summed data is grouped by type in the original metric value.
- `Legend format`: The format of the metric name.
- `Resolution`: The step width defaults to 15 seconds. Resolution means whether to generate one data point for multiple pixels.

The query expression on the **Metrics** tab is as follows:

Figure 415: The query expression on the Metrics tab

Prometheus supports many query expressions and functions. For more details, refer to Prometheus official website.

12.5.5.3 Grafana tips

This section introduces seven tips for efficiently using Grafana to monitor and analyze the metrics of TiDB.

12.5.5.3.1 Tip 1: Check all dimensions and edit the query expression

In the example shown in the source and display of monitoring data section, the data is grouped by type. If you want to know whether you can group by other dimensions and quickly check which dimensions are available, you can use the following method: **Only keep**

the metric name on the query expression, no calculation, and leave the `Legend format` field blank. In this way, the original metrics are displayed. For example, the following figure shows that there are three dimensions (`instance`, `job` and `type`):

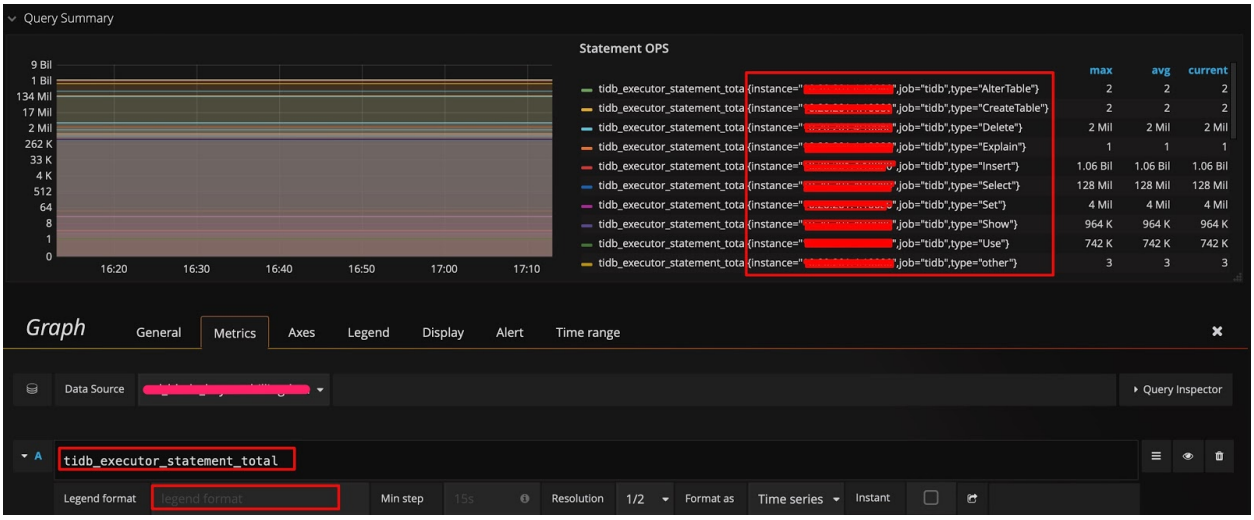

Figure 416: Edit query expression and check all dimensions

Then you can modify the query expression by adding the `instance` dimension after `type`, and adding `{{instance}}` to the `Legend format` field. In this way, you can check the QPS of different types of SQL statements that are executed on each TiDB server:

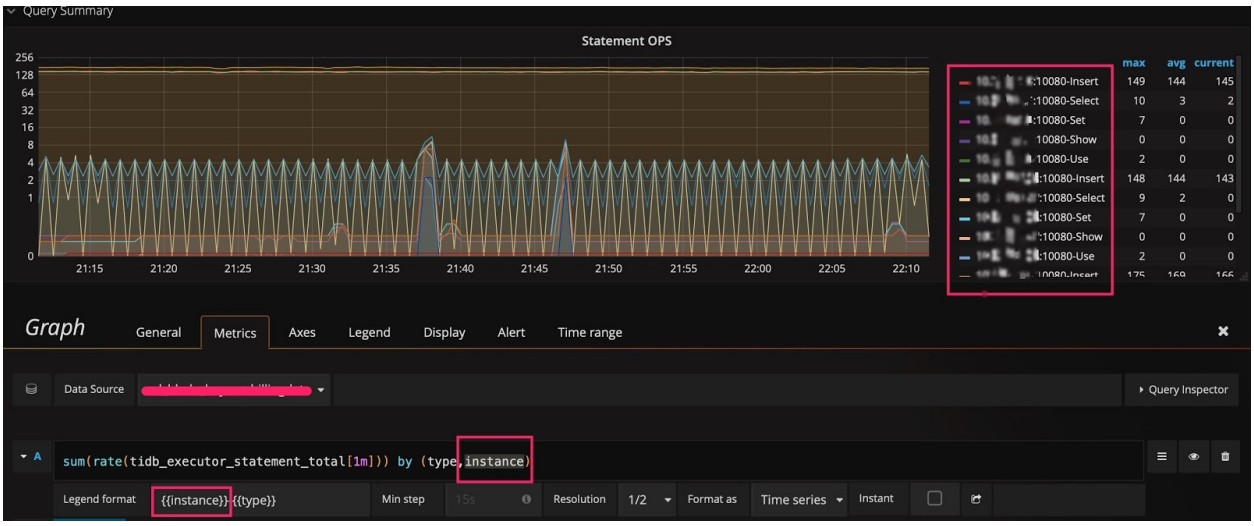

Figure 417: Add an instance dimension to the query expression

12.5.5.3.2 Tip 2: Switch the scale of the Y-axis

Take Query Duration as an example, the Y-axis defaults to be on a binary logarithmic scale (log2n), which narrows the gap in display. To amplify changes, you can switch it to a linear scale. Comparing the following two figures, you can easily notice the difference in display, and locate the time when an SQL statement runs slowly.

Of course, a linear scale is not suitable for all situations. For example, if you observe the performance trend for the duration of a month, there might be noises with a linear scale, making it hard to observe.

The Y-axis uses a binary logarithmic scale by default:

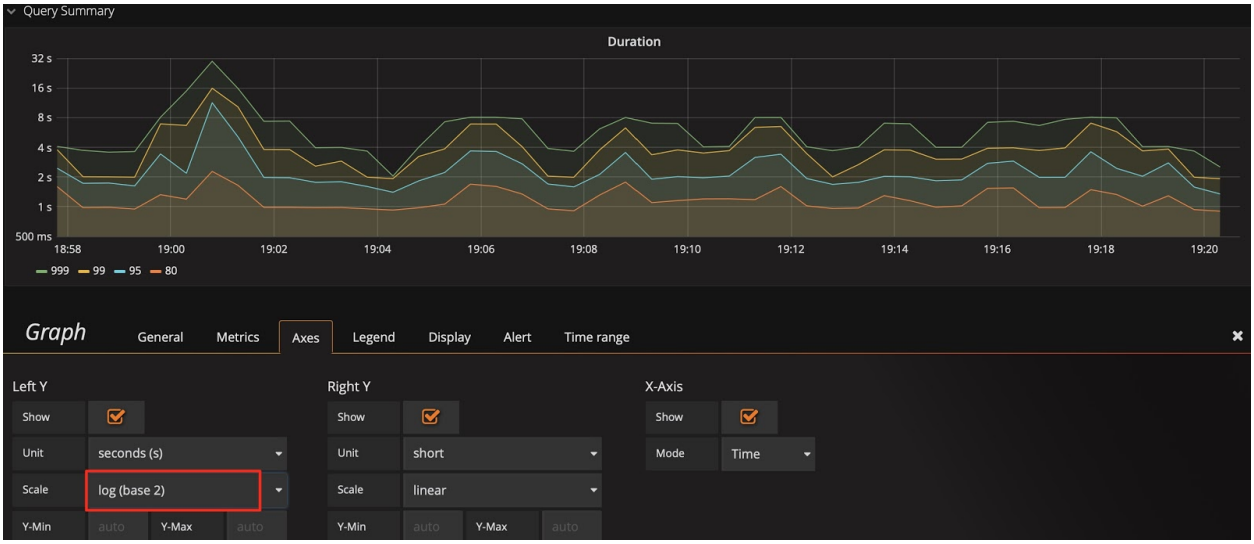

Figure 418: The Y-axis uses a binary logarithmic scale

Switch the Y-axis to a linear scale:

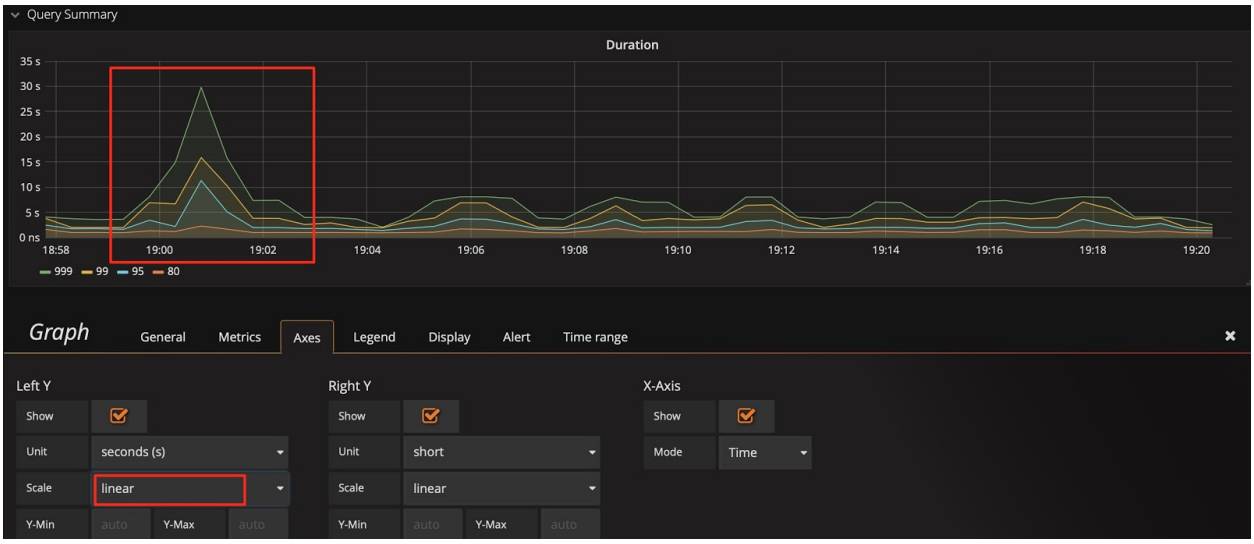

Figure 419: Switch to a linear scale

Tip:

Combining tip 2 with tip 1, you can find a `sql_type` dimension to help you immediately analyze whether the `SELECT` statement or the `UPDATE` statement is slow; you can even locate the instance with slow SQL statements.

12.5.5.3.3 Tip 3: Modify the baseline of the Y-axis to amplify changes

You might still cannot see the trend after switching to the linear scale. For example, in the following figure, you want to observe the real-time change of `Store size` after scaling the cluster, but due to the large baseline, small changes are not visible. In this situation, you can modify the baseline of the Y-axis from `0` to `auto` to zoom in the upper part. Check the two figures below, you can see data migration begins.

The baseline defaults to `0`:

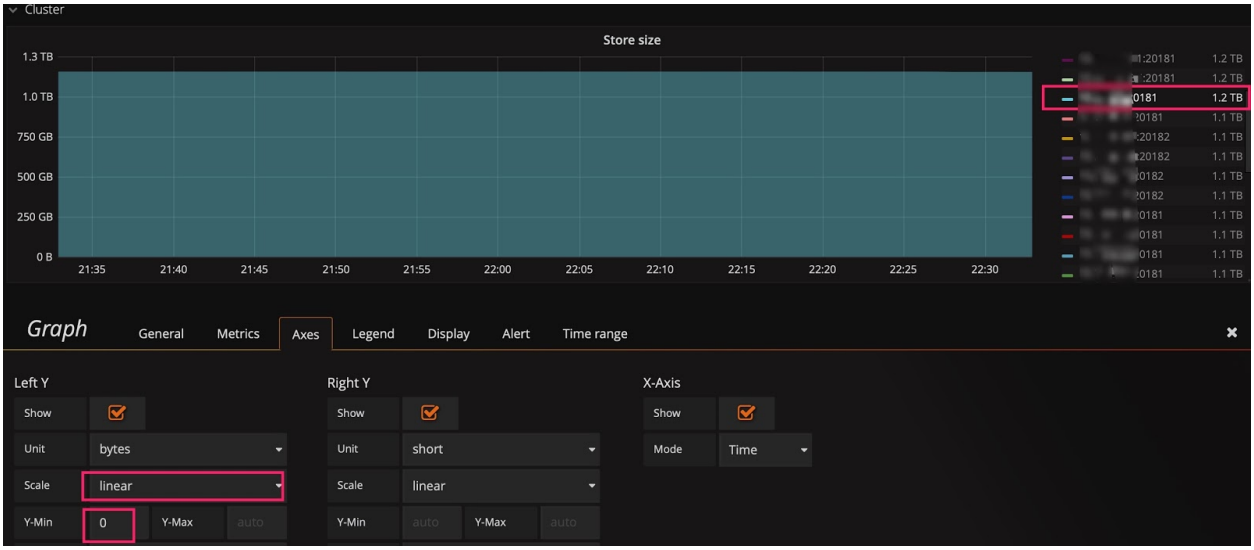

Figure 420: Baseline defaults to 0

Change the baseline to `auto`:

Figure 421: Change the baseline to auto

12.5.5.3.4 Tip 4: Use Shared crosshair or Tooltip

In the **Settings** panel, there is a **Graph Tooltip** panel option which defaults to **Default**.

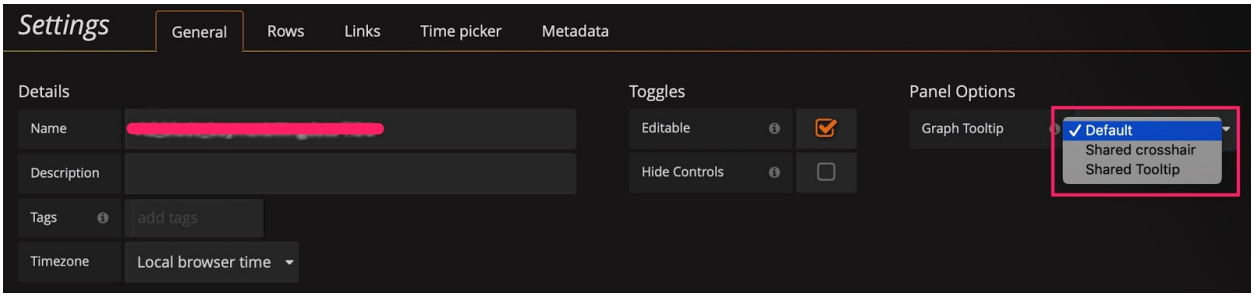

Figure 422: Graphic presentation tools

You can use **Shared crosshair** and **Shared Tooltip** respectively to test the effect as shown in the following figures. Then, the scales are displayed in linkage, which is convenient to confirm the correlation of two metrics when diagnosing problems.

Set the graphic presentation tool to **Shared crosshair**:

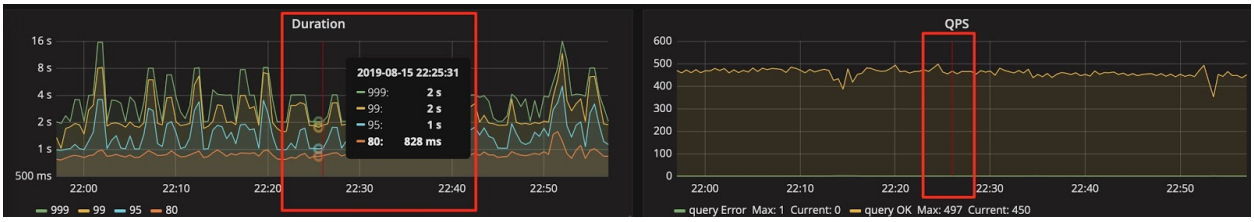

Figure 423: Set the graphical presentation tool to Shared crosshair

Set the graphical presentation tool to **Shared Tooltip**:

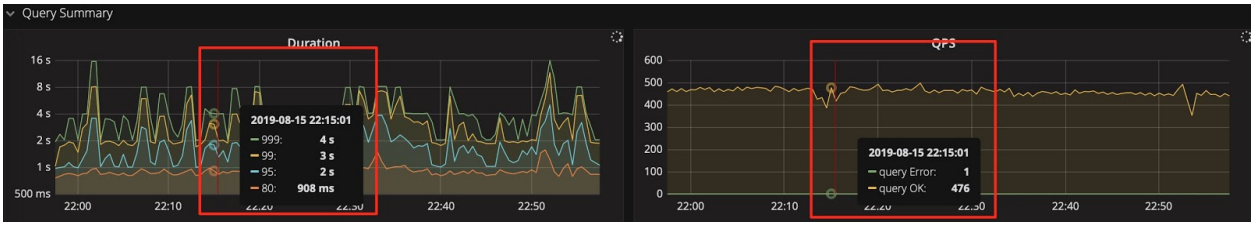

Figure 424: Set the graphic presentation tool to Shared Tooltip

12.5.5.3.5 Tip 5: Enter `IP address:port number` to check the metrics in history

PD's dashboard only shows the metrics of the current leader. If you want to check the status of a PD leader in history and it no longer exists in the drop-down list of the `instance` field, you can manually enter `IP address:2379` to check the data of the leader.

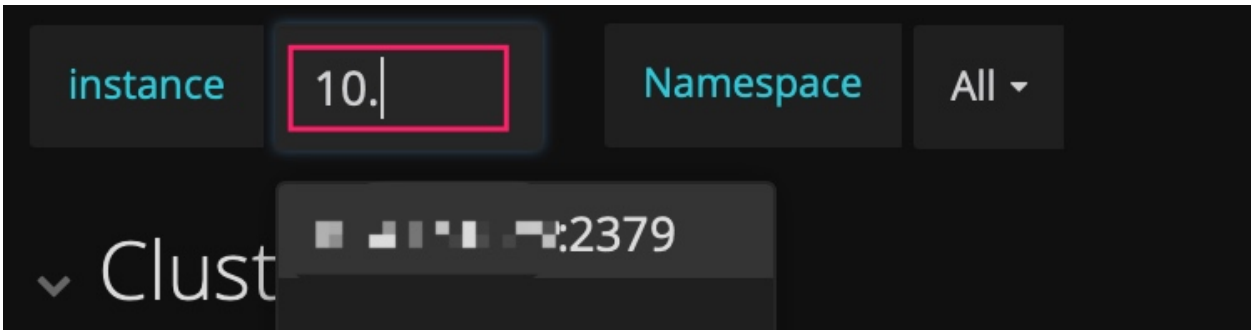

Figure 425: Check the metrics in history

12.5.5.3.6 Tip 6: Use the `Avg` function

Generally, only `Max` and `Current` functions are available in the legend by default. When the metrics fluctuate greatly, you can add other summary functions such as the `Avg` function to the legend to check the overall trend for the duration of time.

Add summary functions such as the `Avg` function:

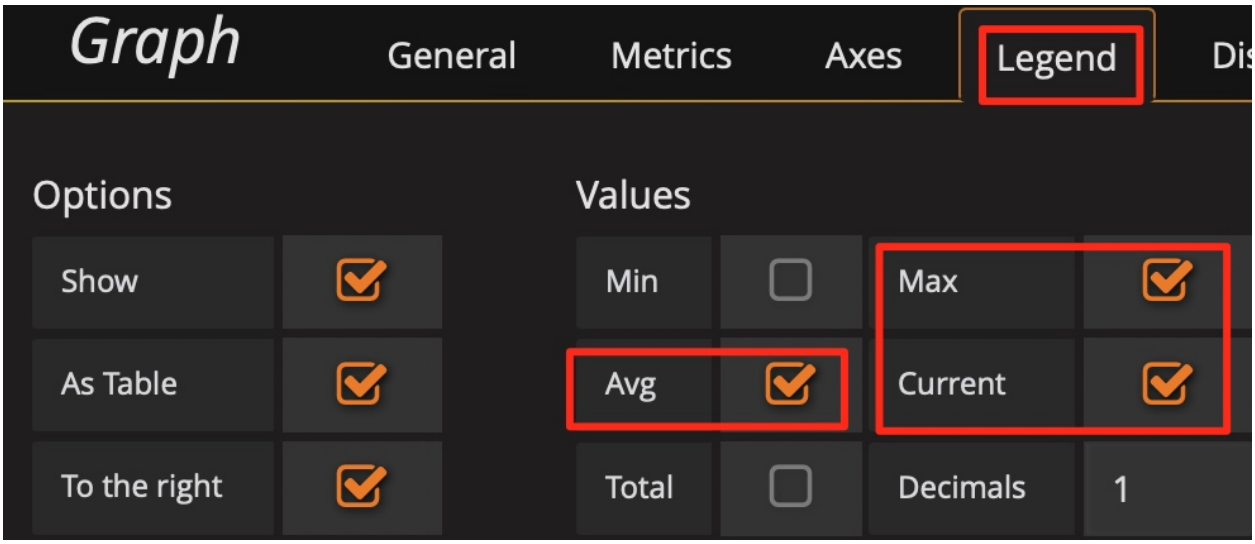

Figure 426: Add summary functions such as Avg

Then check the overall trend:

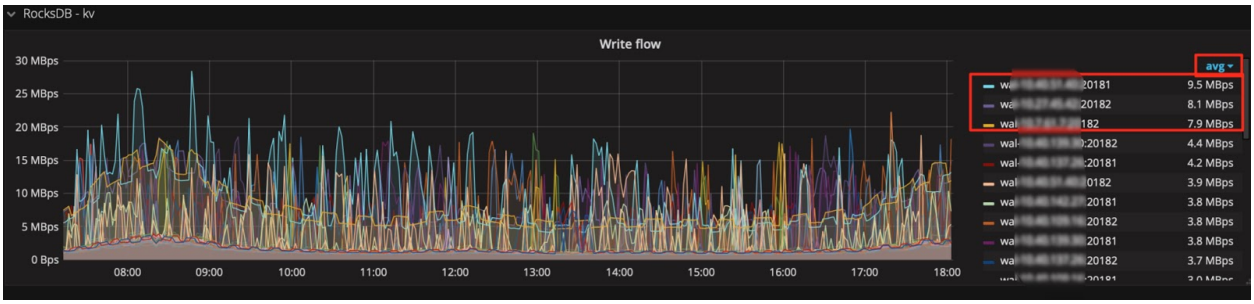

Figure 427: Add Avg function to check the overall trend

12.5.5.3.7 Tip 7: Use the API of Prometheus to obtain the result of query expressions

Grafana obtains data through the API of Prometheus and you can use this API to obtain information as well. In addition, it also has the following usages:

- Automatically obtains information such as the cluster size and status.
- Makes minor changes to the expression to provide information for the report, such as counting the total amount of QPS per day, the peak value of QPS per day, and the response time per day.
- Performs regular health inspection on the important metrics.

The API of Prometheus is shown as follows:

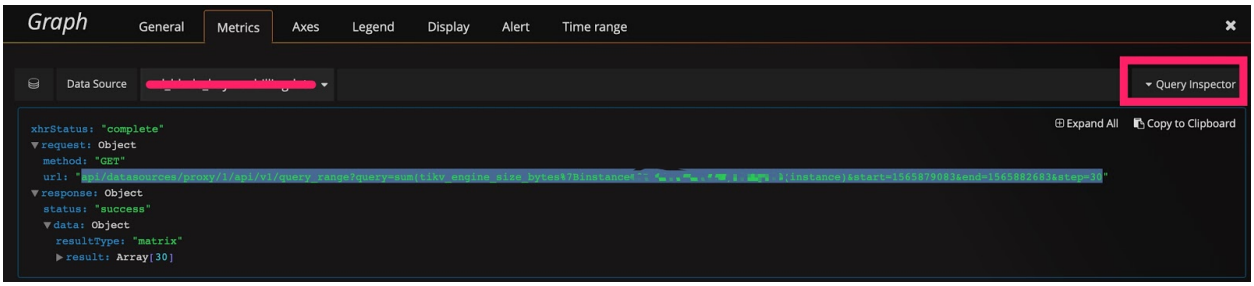

Figure 428: The API of Prometheus

```
curl -u user:pass 'http://__grafana_ip__:3000/api/datasources/proxy/1/api/v1
    ↪ /query_range?query=sum(tikv_engine_size_bytes%7
    ↪ Binstancexxxxxxxxx20180%22%7D)%20by%20(instance)&start=1565879269&end
    ↪ =1565882869&step=30' |python -m json.tool
```

```
{
    "data": {
```

```
        "result": [
            {
                "metric": {
                    "instance": "xxxxxxxxxx:20180"
                },
                "values": [
                    [
                        1565879269,
                        "1006046235280"
                    ],
                    [
                        1565879299,
                        "1006057877794"
                    ],
                    [
                        1565879329,
                        "1006021550039"
                    ],
                    [
                        1565879359,
                        "1006021550039"
                    ],
                    [
                        1565882869,
                        "1006132630123"
                    ]
                ]
            }
        ],
        "resultType": "matrix"
    },
    "status": "success"
}
```

12.5.5.4 Summary

The Grafana + Prometheus monitoring platform is a very powerful tool. Making good use of it can improve efficiency, saving you a lot of time on analyzing the status of the TiDB cluster. More importantly, it can help you diagnose problems. This tool is very useful in the operation and maintenance of TiDB clusters, especially when there is a large amount of data.

12.5.6 PD Scheduling Best Practices

This document details the principles and strategies of PD scheduling through common scenarios to facilitate your application. This document assumes that you have a basic understanding of TiDB, TiKV and PD with the following core concepts:

- leader/follower/learner
- operator
- operator step
- pending/down
- region/peer/Raft group
- region split
- scheduler
- store

> **Note:**
>
> This document initially targets TiDB 3.0. Although some features are not supported in earlier versions (2.x), the underlying mechanisms are similar and this document can still be used as a reference.

12.5.6.1 PD scheduling policies

This section introduces the principles and processes involved in the scheduling system.

12.5.6.1.1 Scheduling process

The scheduling process generally has three steps:

1. Collect information

   Each TiKV node periodically reports two types of heartbeats to PD:

   - `StoreHeartbeat`: Contains the overall information of stores, including disk capacity, available storage, and read/write traffic
   - `RegionHeartbeat`: Contains the overall information of regions, including the range of each region, peer distribution, peer status, data volume, and read/write traffic

   PD collects and restores this information for scheduling decisions.

2. Generate operators

   Different schedulers generate the operators based on their own logic and requirements, with the following considerations:

- Do not add peers to a store in abnormal states (disconnected, down, busy, low space)
- Do not balance regions in abnormal states
- Do not transfer a leader to a pending peer
- Do not remove a leader directly
- Do not break the physical isolation of various region peers
- Do not violate constraints such as label property

3. Execute operators

   To execute the operators, the general procedure is:

   1. The generated operator first joins a queue managed by `OperatorController`.
   2. `OperatorController` takes the operator out of the queue and executes it with a certain amount of concurrency based on the configuration. This step is to assign each operator step to the corresponding region leader.
   3. The operator is marked as "finish" or "timeout" and removed from the queue.

12.5.6.1.2 Load balancing

Region primarily relies on `balance-leader` and `balance-region` schedulers to achieve load balance. Both schedulers target distributing regions evenly across all stores in the cluster but with separate focuses: `balance-leader` deals with region leader to balance incoming client requests, whereas `balance-region` concerns itself with each region peer to redistribute the pressure of storage and avoid exceptions like out of storage space.

`balance-leader` and `balance-region` share a similar scheduling process:

1. Rate stores according to their resource availability.
2. `balance-leader` or `balance-region` constantly transfer leaders or peers from stores with high scores to those with low scores.

However, their rating methods are different. `balance-leader` uses the sum of all region sizes corresponding to leaders in a store, whereas the way of `balance-region` is relatively complicated. Depending on the specific storage capacity of each node, the rating method of `balance-region` might:

- based on the amount of data when there is sufficient storage (to balance data distribution among nodes).
- based on the available storage when there is insufficient storage (to balance the storage availability on different nodes).
- based on the weighted sum of the two factors above when neither of the situations applies.

Because different nodes might differ in performance, you can also set the weight of load balancing for different stores. `leader-weight` and `region-weight` are used to control the leader weight and region weight respectively ("1" by default for both). For example, when the `leader-weight` of a store is set to "2", the number of leaders on the node is about twice as many as that of other nodes after the scheduling stabilizes. Similarly, when the `leader-weight` of a store is set to "0.5", the number of leaders on the node is about half as many as that of other nodes.

12.5.6.1.3 Hot regions scheduling

For hot regions scheduling, use `hot-region-scheduler`. Since TiDB v3.0, the process is performed as follows:

1. Count hot regions by determining read/write traffic that exceeds a certain threshold for a certain period based on the information reported by stores.
2. Redistribute these regions in a similar way to load balancing.

For hot write regions, `hot-region-scheduler` attempts to redistribute both region peers and leaders; for hot read regions, `hot-region-scheduler` only redistributes region leaders.

12.5.6.1.4 Cluster topology awareness

Cluster topology awareness enables PD to distribute replicas of a region as much as possible. This is how TiKV ensures high availability and disaster recovery capability. PD continuously scans all regions in the background. When PD finds that the distribution of regions is not optimal, it generates an operator to replace peers and redistribute regions.

The component to check region distribution is `replicaChecker`, which is similar to a scheduler except that it cannot be disabled. `replicaChecker` schedules based on the configuration of `location-labels`. For example, `[zone,rack,host]` defines a three-tier topology for a cluster. PD attempts to schedule region peers to different zones first, or to different racks when zones are insufficient (for example, 2 zones for 3 replicas), or to different hosts when racks are insufficient.

12.5.6.1.5 Scale-down and failure recovery

Scale-down refers to the process when you take a store offline and mark it as "offline" using a command. PD replicates the regions on the offline node to other nodes by scheduling. Failure recovery applies when stores failed and cannot be recovered. In this case, regions with peers distributed on the corresponding store might lose replicas, which requires PD to replenish on other nodes.

The processes of scale-down and failure recovery are basically the same. `replicaChecker` ↪ finds a region peer in abnormal states, and then generates an operator to replace the abnormal peer with a new one on a healthy store.

12.5.6.1.6 Region merge

Region merge refers to the process of merging adjacent small regions. It serves to avoid unnecessary resource consumption by a large number of small or even empty regions after data deletion. Region merge is performed by `mergeChecker`, which processes in a similar way to `replicaChecker`: PD continuously scans all regions in the background, and generates an operator when contiguous small regions are found.

Specifically, when a newly split Region exists for more than the value of `split-merge-interval` (`1h` by default), if the following conditions occur at the same time, this Region triggers the Region merge scheduling:

- The size of this Region is smaller than the value of the `max-merge-region-size` (20 MiB by default)
- The number of keys in this Region is smaller than the value of `max-merge-region-keys` (200,000 by default).

12.5.6.2 Query scheduling status

You can check the status of scheduling system through metrics, pd-ctl and logs. This section briefly introduces the methods of metrics and pd-ctl. Refer to PD Monitoring Metrics and PD Control for details.

12.5.6.2.1 Operator status

The **Grafana PD/Operator** page shows the metrics about operators, among which:

- Schedule operator create: Operator creating information
- Operator finish duration: Execution time consumed by each operator
- Operator step duration: Execution time consumed by the operator step

You can query operators using pd-ctl with the following commands:

- `operator show`: Queries all operators generated in the current scheduling task
- `operator show [admin | leader | region]`: Queries operators by type

12.5.6.2.2 Balance status

The **Grafana PD/Statistics - Balance** page shows the metrics about load balancing, among which:

- Store leader/region score: Score of each store
- Store leader/region count: The number of leaders/regions in each store
- Store available: Available storage on each store

You can use store commands of pd-ctl to query balance status of each store.

12.5.6.2.3 Hot Region status

The **Grafana PD/Statistics - hotspot** page shows the metrics about hot regions, among which:

- Hot write region's leader/peer distribution: the leader/peer distribution in hot write regions
- Hot read region's leader distribution: the leader distribution in hot read regions

You can also query the status of hot regions using pd-ctl with the following commands:

- `hot read`: Queries hot read regions
- `hot write`: Queries hot write regions
- `hot store`: Queries the distribution of hot regions by store
- `region topread [limit]`: Queries the region with top read traffic
- `region topwrite [limit]`: Queries the region with top write traffic

12.5.6.2.4 Region health

The **Grafana PD/Cluster/Region health** panel shows the metrics about regions in abnormal states.

You can query the list of regions in abnormal states using pd-ctl with region check commands:

- `region check miss-peer`: Queries regions without enough peers
- `region check extra-peer`: Queries regions with extra peers
- `region check down-peer`: Queries regions with down peers
- `region check pending-peer`: Queries regions with pending peers

12.5.6.3 Control scheduling strategy

You can use pd-ctl to adjust the scheduling strategy from the following three aspects. Refer to PD Control for more details.

12.5.6.3.1 Add/delete scheduler manually

PD supports dynamically adding and removing schedulers directly through pd-ctl. For example:

- `scheduler show`: Shows currently running schedulers in the system
- `scheduler remove balance-leader-scheduler`: Removes (disable) balance-leader-scheduler
- `scheduler add evict-leader-scheduler 1`: Adds a scheduler to remove all leaders in Store 1

12.5.6.3.2 Add/delete Operators manually

PD also supports adding or removing operators directly through pd-ctl. For example:

- `operator add add-peer 2 5`: Adds peers to Region 2 in Store 5
- `operator add transfer-leader 2 5`: Migrates the leader of Region 2 to Store 5
- `operator add split-region 2`: Splits Region 2 into two regions evenly in size
- `operator remove 2`: Removes currently pending operator in Region 2

12.5.6.3.3 Adjust scheduling parameter

You can check the scheduling configuration using the `config show` command in pd-ctl, and adjust the values using `config set {key} {value}`. Common adjustments include:

- `leader-schedule-limit`: Controls the concurrency of transferring leader scheduling
- `region-schedule-limit`: Controls the concurrency of adding/deleting peer scheduling
- `enable-replace-offline-replica`: Determines whether to enable the scheduling to take nodes offline
- `enable-location-replacement`: Determines whether to enable the scheduling that handles the isolation level of regions
- `max-snapshot-count`: Controls the maximum concurrency of sending/receiving snapshots for each store

12.5.6.4 PD scheduling in common scenarios

This section illustrates the best practices of PD scheduling strategies through several typical scenarios.

12.5.6.4.1 Leaders/regions are not evenly distributed

The rating mechanism of PD determines that leader count and region count of different stores cannot fully reflect the load balancing status. Therefore, it is necessary to confirm whether there is load imbalancing from the actual load of TiKV or storage usage.

Once you have confirmed that leaders/region are not evenly distributed, you need to check the rating of different stores.

If the scores of different stores are close, it means PD mistakenly believes that leaders/regions are evenly distributed. Possible reasons are:

- There are hot regions that cause load imbalancing. In this case, you need to analyze further based on hot regions scheduling.
- There are a large number of empty regions or small regions, which leads to a great difference in the number of leaders in different stores and high pressure on Raft store. This is the time for a region merge scheduling.

- Hardware and software environment varies among stores. To control the distribution of leader/region, you can refer to Load balancing and adjust the values of `leader-weight` and `region-weight`.
- Other unknown reasons. Still you can adjust the values of `leader-weight` and `region-weight` to control the distribution of leader/region.

If there is a big difference in the rating of different stores, you need to examine the operator-related metrics, with special focus on the generation and execution of operators. There are two main situations:

- When operators are generated normally but the scheduling process is slow, it is possible that:
    - The scheduling speed is limited by default for load balancing purpose. You can adjust `leader-schedule-limit` or `region-schedule-limit` to larger values without significantly impacting regular services. In addition, you can also properly ease the restrictions specified by `max-pending-peer-count` and `max-snapshot-count`.
    - Other scheduling tasks are running concurrently, which slows down the balancing. In this case, if the balancing takes precedence over other scheduling tasks, you can stop other tasks or limit their speeds. For example, if you take some nodes offline when balancing is in progress, both operations consume the quota of `region-schedule-limit`. In this case, you can limit the speed of scheduler to remove nodes, or simply set `enable-replace-offline-replica = false` to temporarily disable it.
    - The scheduling process is too slow. You can check the **Operator step duration** metric to confirm the cause. Generally, steps that do not involve sending and receiving snapshots (such as `TransferLeader`, `RemovePeer`, `PromoteLearner`) should be completed in milliseconds, while steps that involve snapshots (such as `AddLearner` and `AddPeer`) are expected to be completed in tens of seconds. If the duration is obviously too long, it could be caused by high pressure on TiKV or bottleneck in network, which needs specific analysis.
- PD fails to generate the corresponding balancing scheduler. Possible reasons include:
    - The scheduler is not activated. For example, the corresponding scheduler is deleted, or its limit it set to "0".
    - Other constraints. For example, `evict-leader-scheduler` in the system prevents leaders from being migrating to the corresponding store. Or label property is set, which makes some stores reject leaders.
    - Restrictions from the cluster topology. For example, in a cluster of 3 replicas across 3 data centers, 3 replicas of each region are distributed in different data centers due to replica isolation. If the number of stores is different among these data centers, the scheduling can only reach a balanced state within each data center, but not balanced globally.

12.5.6.4.2 Taking nodes offline is slow

This scenario requires examining the generation and execution of operators through related metrics.

If operators are successfully generated but the scheduling process is slow, possible reasons are:

- The scheduling speed is limited by default. You can adjust `leader-schedule-limit` or `replica-schedule-limit` to larger values. Similarly, you can consider loosening the limits on `max-pending-peer-count` and `max-snapshot-count`.
- Other scheduling tasks are running concurrently and racing for resources in the system. You can refer to the solution in Leaders/regions are not evenly distributed.
- When you take a single node offline, a number of region leaders to be processed (around 1/3 under the configuration of 3 replicas) are distributed on the node to remove. Therefore, the speed is limited by the speed at which snapshots are generated by this single node. You can speed it up by manually adding an `evict-leader-scheduler` to migrate leaders.

If the corresponding operator fails to generate, possible reasons are:

- The operator is stopped, or `replica-schedule-limit` is set to "0".
- There is no proper node for region migration. For example, if the available capacity size of the replacing node (of the same label) is less than 20%, PD will stop scheduling to avoid running out of storage on that node. In such case, you need to add more nodes or delete some data to free the space.

12.5.6.4.3 Bringing nodes online is slow

Currently, bringing nodes online is scheduled through the balance region mechanism. You can refer to Leaders/regions are not evenly distributed for troubleshooting.

12.5.6.4.4 Hot regions are not evenly distributed

Hot regions scheduling issues generally fall into the following categories:

- Hot regions can be observed via PD metrics, but the scheduling speed cannot keep up to redistribute hot regions in time.

  Solution: adjust `hot-region-schedule-limit` to a larger value, and reduce the limit quota of other schedulers to speed up hot regions scheduling. Or you can adjust `hot-region-cache-hits-threshold` to a smaller value to make PD more sensitive to traffic changes.

- Hotspot formed on a single region. For example, a small table is intensively scanned by a massive amount of requests. This can also be detected from PD metrics. Because you cannot actually distribute a single hotspot, you need to manually add a `split-region` operator to split such a region.

- The load of some nodes is significantly higher than that of other nodes from TiKV-related metrics, which becomes the bottleneck of the whole system. Currently, PD counts hotspots through traffic analysis only, so it is possible that PD fails to identify hotspots in certain scenarios. For example, when there are intensive point lookup requests for some regions, it might not be obvious to detect in traffic, but still the high QPS might lead to bottlenecks in key modules.

  Solutions: Firstly, locate the table where hot regions are formed based on the specific business. Then add a `scatter-range-scheduler` scheduler to make all regions of this table evenly distributed. TiDB also provides an interface in its HTTP API to simplify this operation. Refer to TiDB HTTP API for more details.

12.5.6.4.5 Region merge is slow

Similar to slow scheduling, the speed of region merge is most likely limited by the configurations of `merge-schedule-limit` and `region-schedule-limit`, or the region merge scheduler is competing with other schedulers. Specifically, the solutions are:

- If it is known from metrics that there are a large number of empty regions in the system, you can adjust `max-merge-region-size` and `max-merge-region-keys` to smaller values to speed up the merge. This is because the merge process involves replica migration, so the smaller the region to be merged, the faster the merge is. If the merge operators are already generated rapidly, to further speed up the process, you can set `patrol-region-interval` to `10ms` (the default value of this configuration item is `10ms` in v5.3.0 and later versions of TiDB). This makes region scanning faster at the cost of more CPU consumption.
- A lot of tables have been created and then emptied (including truncated tables). These empty Regions cannot be merged if the split table attribute is enabled. You can disable this attribute by adjusting the following parameters:
  - TiKV: Set `split-region-on-table` to `false`. You cannot modify the parameter dynamically.
  - PD: Use PD Control to set the parameters required by your cluster situation.
    - Suppose that your cluster has no TiDB instance, and the value of `key-type` is set to `raw` or `txn`. In this case, PD can merge Regions across tables, regardless of the value of `enable-cross-table-merge setting`. You can modify the `key-type` parameter dynamically.

```
config set key-type txn
```

    - Suppose that your cluster has a TiDB instance, and the value of `key-type` is set to `table`. In this case, PD can merge Regions across tables only if the value of `enable-cross-table-merge` is set to `true`. You can modify the `key-type` parameter dynamically.

```
config set enable-cross-table-merge true
```

If the modification does not take effect, refer to FAQ - Why the modified `toml` configuration for TiKV/PD does not take effect?.

> **Note:**
> After enabling Placement Rules, properly switch the value of `key-type` to avoid the failure of decoding.

For v3.0.4 and v2.1.16 or earlier, the `approximate_keys` of regions are inaccurate in specific circumstances (most of which occur after dropping tables), which makes the number of keys break the constraints of `max-merge-region-keys`. To avoid this problem, you can adjust `max-merge-region-keys` to a larger value.

12.5.6.4.6 Troubleshoot TiKV node

If a TiKV node fails, PD defaults to setting the corresponding node to the **down** state after 30 minutes (customizable by configuration item `max-store-down-time`), and rebalancing replicas for regions involved.

Practically, if a node failure is considered unrecoverable, you can immediately take it offline. This makes PD replenish replicas soon in another node and reduces the risk of data loss. In contrast, if a node is considered recoverable, but the recovery cannot be done in 30 minutes, you can temporarily adjust `max-store-down-time` to a larger value to avoid unnecessary replenishment of the replicas and resources waste after the timeout.

In TiDB v5.2.0, TiKV introduces the mechanism of slow TiKV node detection. By sampling the requests in TiKV, this mechanism works out a score ranging from 1 to 100. A TiKV node with a score higher than or equal to 80 is marked as slow. You can add `evict-slow-store-scheduler` to detect and schedule slow nodes. If only one TiKV is detected as slow, and the slow score reaches the limit (80 by default), the Leader in this node will be evicted (similar to the effect of `evict-leader-scheduler`).

> **Note:**
>
> **Leader eviction** is accomplished by PD sending scheduling requests to TiKV slow nodes and then TiKV executing the received scheduling requests sequentially. Due to factors such as **slow I/O**, slow nodes might experience request accumulation, causing some Leaders to wait until the delayed requests are processed before handling **Leader eviction** requests. This results in an overall extended time for **Leader eviction**. Therefore, when you enable `evict-slow-store-scheduler`, it is recommended to enable `store-io-pool-size` as well to mitigate this situation.

12.5.7 Best Practices for TiKV Performance Tuning with Massive Regions

In TiDB, data is split into Regions, each storing data for a specific key range. These Regions are distributed among multiple TiKV instances. As data is written into a cluster, millions of Regions might be created. Too many Regions on a single TiKV instance can bring a heavy burden to the cluster and affect its performance.

This document introduces the workflow of Raftstore (a core module of TiKV), explains why a massive amount of Regions affect the performance, and offers methods for tuning TiKV performance.

12.5.7.1 Raftstore workflow

A TiKV instance has multiple Regions on it. The Raftstore module drives the Raft state machine to process Region messages. These messages include processing read or write requests on Regions, persisting or replicating Raft logs, and processing Raft heartbeats. However, an increasing number of Regions can affect performance of the whole cluster. To understand this, it is necessary to learn the workflow of Raftstore shown as follows:

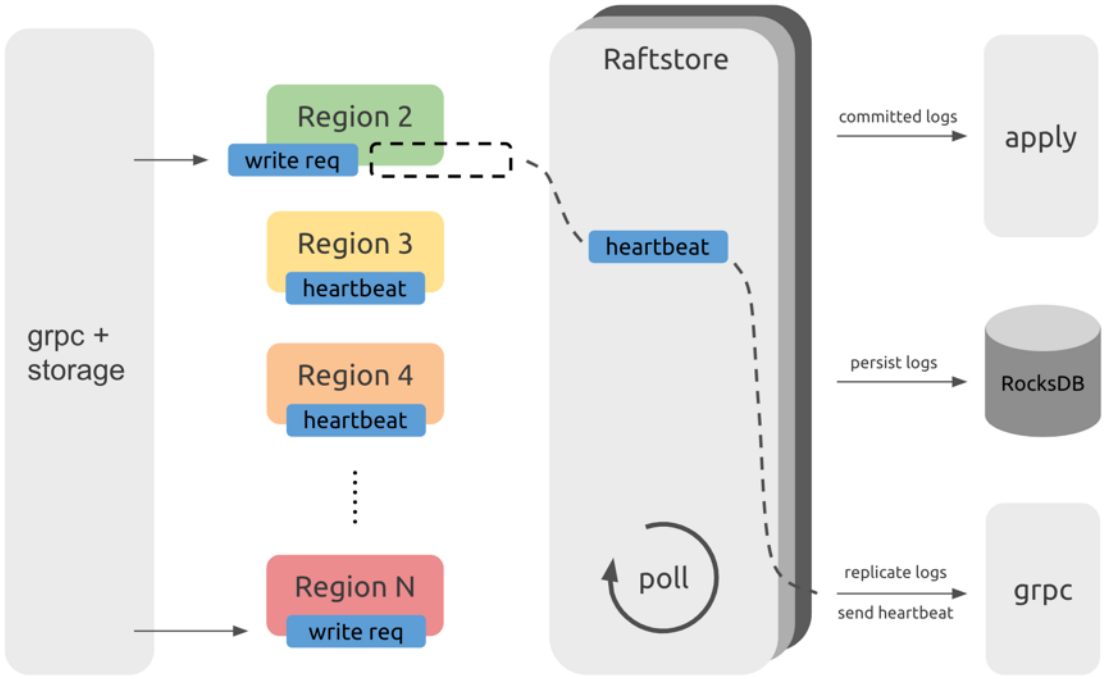

Figure 429: Raftstore Workflow

> **Note:**
>
> This diagram only illustrates the workflow of Raftstore and does not represent the actual code structure.

From the above diagram, you can see that requests from the TiDB servers, after passing through the gRPC and storage modules, become read and write messages of KV (key-value), and are sent to the corresponding Regions. These messages are not immediately processed but are temporarily stored. Raftstore polls to check whether each Region has messages to process. If a Region has messages to process, Raftstore drives the Raft state machine of this Region to process these messages and perform subsequent operations according to the state changes of these messages. For example, when write requests come in, the Raft state machine stores logs into disk and sends logs to other Region replicas; when the heartbeat interval is reached, the Raft state machine sends heartbeat information to other Region replicas.

12.5.7.2 Performance problem

From the Raftstore workflow diagram, messages in each Region are processed one by one. When a large number of Regions exist, it takes Raftstore some time to process the heartbeats of these Regions, which can cause some delay. As a result, some read and write requests are not processed in time. If read and write pressure is high, the CPU usage of the Raftstore thread might easily become the bottleneck, which further increases the delay and affects the performance.

Generally, if the CPU usage of the loaded Raftstore reaches 85% or higher, Raftstore goes into a busy state and becomes the bottleneck. At the same time, `propose wait duration` can be as high as hundreds of milliseconds.

Note:

- For the CPU usage of Raftstore as mentioned above, Raftstore is single-threaded. If Raftstore is multi-threaded, you can increase the CPU usage threshold (85%) proportionally.
- Because I/O operations exist in the Raftstore thread, CPU usage cannot reach 100%.

12.5.7.2.1 Performance monitoring

You can check the following monitoring metrics in Grafana's **TiKV Dashboard**:

- `Raft store CPU` in the **Thread-CPU** panel

  Reference value: lower than `raftstore.store-pool-size * 85%`.

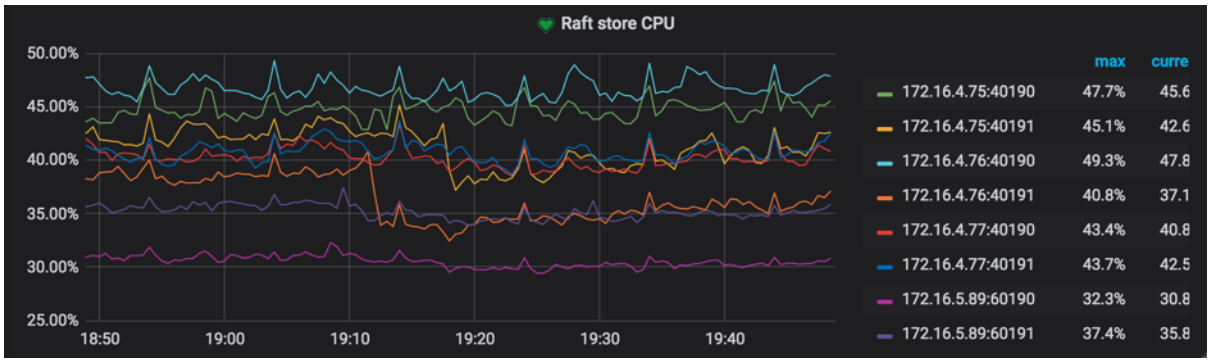

Figure 430: Check Raftstore CPU

- `Propose wait duration` in the **Raft Propose** panel

  `Propose wait duration` is the delay between the time a request is sent to Raftstore and the time Raftstore actually starts processing the request. Long delay means that Raftstore is busy, or that processing the append log is time-consuming, making Raftstore unable to process the request in time.

  Reference value: lower than 50~100 ms according to the cluster size

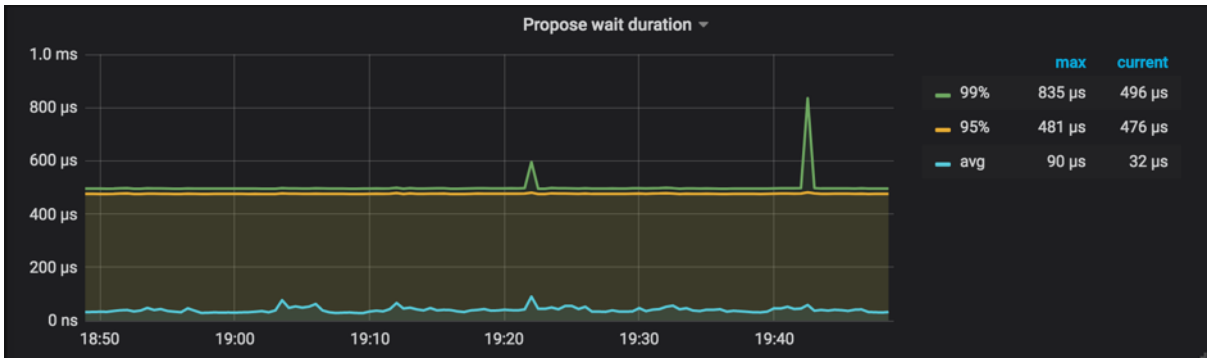

Figure 431: Check Propose wait duration

- `Commit log duration` in the **Raft IO** panel

  `Commit log duration` is the time Raftstore takes to commit Raft logs to the majority of members in the respective Region. The possible reasons for a high value of this metric with significant fluctuations include the following:

  - The workload on Raftstore is heavy.
  - The append log operation is slow.
  - Raft logs cannot be committed timely due to network congestion.

Reference value: lower than 200-500 ms.

```
![Check Commit log duration](./media/best-practices/commit-log-duration.png)
```

12.5.7.3 Performance tuning methods

After finding out the cause of a performance problem, try to solve it from the following two aspects:

- Reduce the number of Regions on a single TiKV instance
- Reduce the number of messages for a single Region

12.5.7.3.1 Method 1: Increase Raftstore concurrency

Raftstore has been upgraded to a multi-threaded module since TiDB v3.0, which greatly reduces the possibility that a Raftstore thread becomes the bottleneck.

By default, `raftstore.store-pool-size` is configured to `2` in TiKV. If a bottleneck occurs in Raftstore, you can properly increase the value of this configuration item according to the actual situation. But to avoid introducing unnecessary thread switching overhead, it is recommended that you do not set this value too high.

12.5.7.3.2 Method 2: Enable Hibernate Region

In the actual situation, read and write requests are not evenly distributed on every Region. Instead, they are concentrated on a few Regions. Then you can minimize the number of messages between the Raft leader and the followers for the temporarily idle Regions, which is the feature of Hibernate Region. In this feature, Raftstore doesn't send tick messages to the Raft state machines of idle Regions if not necessary. Then these Raft state machines will not be triggered to generate heartbeat messages, which can greatly reduce the workload of Raftstore.

Hibernate Region is enabled by default in TiKV master. You can configure this feature according to your needs. For details, refer to Configure Hibernate Region.

12.5.7.3.3 Method 3: Enable `Region Merge`

> **Note:**
>
> `Region Merge` is enabled by default since TiDB v3.0.

You can also reduce the number of Regions by enabling `Region Merge`. Contrary to `Region Split`, `Region Merge` is the process of merging adjacent small Regions through scheduling. After dropping data or executing the `Drop Table` or `Truncate Table` statement, you can merge small Regions or even empty Regions to reduce resource consumption.

Enable `Region Merge` by configuring the following parameters:

```
config set max-merge-region-size 20
config set max-merge-region-keys 200000
config set merge-schedule-limit 8
```

Refer to Region Merge and the following three configuration parameters in the PD configuration file for more details:

- max-merge-region-size
- max-merge-region-keys
- merge-schedule-limit

The default configuration of the `Region Merge` parameters is rather conservative. You can speed up the `Region Merge` process by referring to the method provided in PD Scheduling Best Practices.

12.5.7.3.4 Method 4: Increase the number of TiKV instances

If I/O resources and CPU resources are sufficient, you can deploy multiple TiKV instances on a single machine to reduce the number of Regions on a single TiKV instance; or you can increase the number of machines in the TiKV cluster.

12.5.7.3.5 Method 5: Adjust `raft-base-tick-interval`

In addition to reducing the number of Regions, you can also reduce pressure on Raftstore by reducing the number of messages for each Region within a unit of time. For example, you can properly increase the value of the `raft-base-tick-interval` configuration item:

```
[raftstore]
raft-base-tick-interval = "2s"
```

In the above configuration, `raft-base-tick-interval` is the time interval at which Raftstore drives the Raft state machine of each Region, which means at this time interval, Raftstore sends a tick message to the Raft state machine. Increasing this interval can effectively reduce the number of messages from Raftstore.

Note that this interval between tick messages also determines the intervals between `election timeout` and `heartbeat`. See the following example:

```
raft-election-timeout = raft-base-tick-interval * raft-election-timeout-
    ↪ ticks
raft-heartbeat-interval = raft-base-tick-interval * raft-heartbeat-ticks
```

If Region followers have not received the heartbeat from the leader within the `raft ↪ -election-timeout` interval, these followers determine that the leader has failed and start a new election. `raft-heartbeat-interval` is the interval at which a leader sends a heartbeat to followers. Therefore, increasing the value of `raft-base-tick-interval` can reduce the number of network messages sent from Raft state machines but also makes it longer for Raft state machines to detect the leader failure.

12.5.7.3.6 Method 6: Adjust Region size

The default size of a Region is 96 MiB, and you can reduce the number of Regions by setting Regions to a larger size. For more information, see Tune Region Performance.

> **Note:**
>
> Customized Region size is an experimental feature before TiDB v6.5.0. If you need to resize the Region size, it is recommended that you upgrade to v6.5.0 or a later version.

12.5.7.3.7 Method 7: Increase the maximum number of connections for Raft communication

By default, the maximum number of connections used for Raft communication between TiKV nodes is 1. Increasing this number can help alleviate blockage issues caused by heavy communication workloads of a large number of Regions. For detailed instructions, see `grpc-raft-conn-num`.

> **Note:**
>
> To reduce unnecessary thread switching overhead and mitigate potential negative impacts from batch processing, it is recommended to set the number within the range of `[1, 4]`.

12.5.7.4 Other problems and solutions

This section describes some other problems and solutions.

12.5.7.4.1 Switching PD Leader is slow

PD needs to persist Region Meta information on etcd to ensure that PD can quickly resume to provide Region routing services after switching the PD Leader node. As the number of Regions increases, the performance problem of etcd appears, making it slower for PD to get Region Meta information from etcd when PD is switching the Leader. With millions of Regions, it might take more than ten seconds or even tens of seconds to get the meta information from etcd.

To address this problem, `use-region-storage` is enabled by default in PD since TiDB v3.0. With this feature enabled, PD stores Region Meta information on local LevelDB and synchronizes the information among PD nodes through other mechanisms.

12.5.7.4.2 PD routing information is not updated in time

In TiKV, pd-worker regularly reports Region Meta information to PD. When TiKV is restarted or switches the Region leader, PD needs to recalculate Region's `approximate size / keys` through statistics. Therefore, with a large number of Regions, the single-threaded pd-worker might become the bottleneck, causing tasks to be piled up and not processed in time. In this situation, PD cannot obtain certain Region Meta information in time so that the routing information is not updated in time. This problem does not affect the actual reads and writes, but might cause inaccurate PD scheduling and require several round trips when TiDB updates Region cache.

You can check **Worker pending tasks** under **Task** in the **TiKV Grafana** panel to determine whether pd-worker has tasks piled up. Generally, `pending tasks` should be kept at a relatively low value.

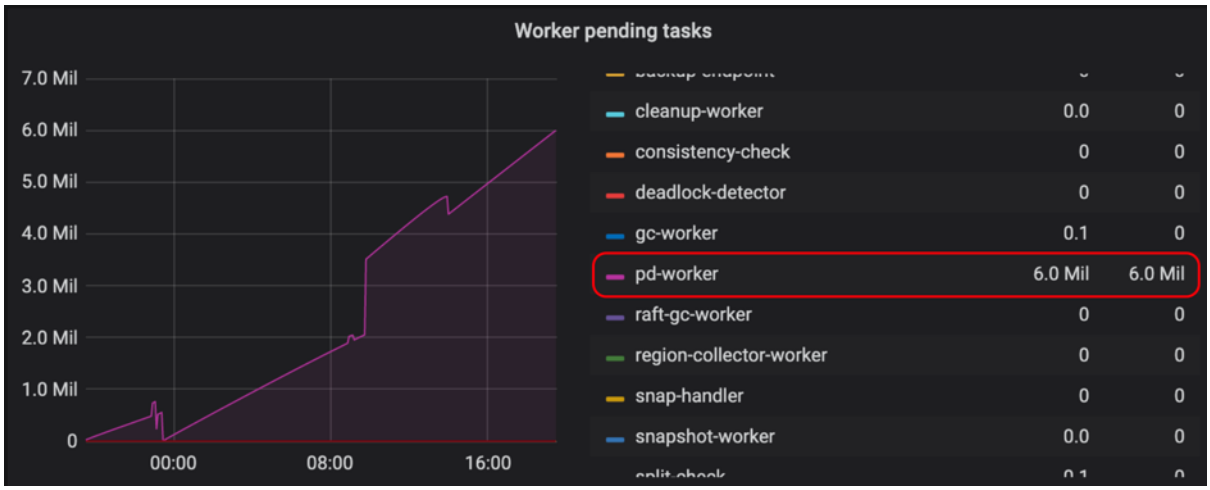

Figure 432: Check pd-worker

pd-worker has been optimized for better performance since v3.0.5. If you encounter a similar problem, it is recommended to upgrade to the latest version.

12.5.7.4.3 Prometheus is slow to query metrics

In a large-scale cluster, as the number of TiKV instances increases, Prometheus has greater pressure to query metrics, making it slower for Grafana to display these metrics. To ease this problem, metrics pre-calculation is configured since v3.0.

12.5.8 Best Practices for Three-Node Hybrid Deployment

For a TiDB cluster, if you have no requirements on high performance but need to control the cost, you can deploy the TiDB, TiKV, and PD components on three machines in a hybrid way.

This document offers an example of three-node hybrid deployment and a TPC-C test against the deployed cluster. Based on this example, this document offers best practices for the deployment scenario and its parameter adjustment.

12.5.8.1 Prerequisites for deployment and the test method

In this example, three physical machines are used for deployment, each with 16 CPU cores and 32 GB of memory. On each machine (node), one TiDB instance, one TiKV instance, and one PD instance are deployed in a hybrid way.

Because PD and TiKV both store information on the disk, the read and write latency of disk directly affects the latency of the PD and TiKV services. To avoid the situation that PD and TiKV compete for disk resources and affect each other, it is recommended to use different disks for PD and TiKV.

In this example, the TPC-C 5000 Warehouse data is used in TiUP bench and the test lasts 12 hours with the `terminals` parameter set to `128` (concurrency). Close attention is paid to metrics related to performance stability of the cluster.

The image below shows the QPS monitor of the cluster within 12 hours with the default parameter configuration. From the image, you can see an obvious performance jitter.

Figure 433: QPS with default config

After the parameter adjustment, the performance is improved.

Figure 434: QPS with modified config

12.5.8.2 Parameter adjustment

Performance jitter occurs in the image above, because the default thread pool configuration and the resource allocation to background tasks are for machines with sufficient resources. In the hybrid deployment scenario, the resources are shared among multiple components, so you need to limit the resource consumption via configuration parameters.

The final cluster configuration for this test is as follows:

```
tikv:
    readpool.unified.max-thread-count: 6
    server.grpc-concurrency: 2
    storage.scheduler-worker-pool-size: 2
    gc.max-write-bytes-per-sec: 300K
    rocksdb.max-background-jobs: 3
    rocksdb.max-sub-compactions: 1
    rocksdb.rate-bytes-per-sec: "200M"

  tidb:
    performance.max-procs: 8
```

The following sections introduce the meanings and the adjustment methods of these parameters.

12.5.8.2.1 Configuration of TiKV thread pool size

This section offers best practices for adjusting parameters that relate to the resource allocation of thread pools for foreground applications. Reducing these thread pool sizes will compromise performance, but in the hybrid deployment scenario with limited resources, the cluster itself is hard to achieve high performance. In this scenario, the overall stability of the cluster is preferred over performance.

If you conduct an actual load test, you can first use the default configuration and observe the actual resource usage of each thread pool. Then you can adjust the corresponding configuration items and reduce the sizes of the thread pools that have lower usage.

`readpool.unified.max-thread-count`

The default value of this parameter is 80% of the number of machine threads. In a hybrid deployment scenario, you need to manually calculate and specify this value. You can first set it to 80% of the expected number of CPU threads used by TiKV.

`server.grpc-concurrency`

This parameter defaults to `4`. Because in the existing deployment plan, the CPU resources are limited and the actual requests are few. You can observe the monitoring panel, lower the value of this parameter, and keep the usage rate below 80%.

In this test, the value of this parameter is set to `2`. Observe the **gRPC poll CPU** panel and you can see that the usage rate is just around 80%.

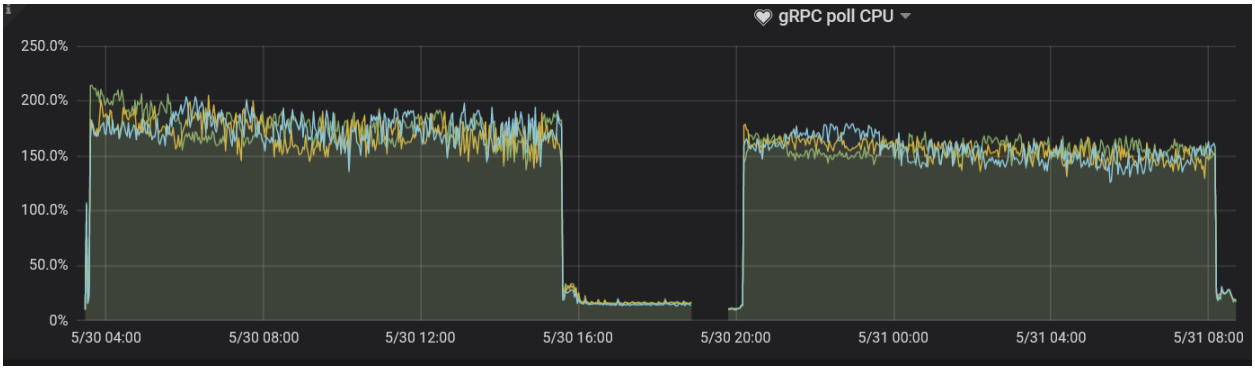

Figure 435: gRPC Pool CPU

`storage.scheduler-worker-pool-size`

When TiKV detects that the CPU core number of the machine is greater than or equal to `16`, this parameter value defaults to `8`. When the CPU core number is smaller than `16`, the parameter value defaults to `4`. This parameter is used when TiKV converts complex transaction requests to simple key-value reads or writes, but the scheduler thread pool does not performs any writes.

Ideally, the usage rate of the scheduler thread pool is kept between 50% and 75%. Similar to the gRPC thread pool, the `storage.scheduler-worker-pool-size` parameter defaults to a larger value during the hybrid deployment, which makes resource usage insufficient. In this test, the value of this parameter is set to `2`, which is in line with the best practices, a conclusion drawn by observing the corresponding metrics in the **Scheduler worker CPU** panel.

Figure 436: Scheduler Worker CPU

12.5.8.2.2 Resource configuration for TiKV background tasks

In addition to foreground tasks, TiKV regularly sorts data and cleans outdated data in background tasks. The default configuration allocates sufficient resources to these tasks for

the scenario of high-traffic writes.

However, in the hybrid deployment scenario, this default configuration is not in line with the best practices. You need to limit the resource usage of background tasks by adjusting the following parameters.

`rocksdb.max-background-jobs` and `rocksdb.max-sub-compactions`

The RocksDB thread pool is used to perform compaction and flush jobs. The default value of `rocksdb.max-background-jobs` is `8`, which obviously exceeds the resource that is in need. Therefore, the value should be adjusted to limit the resource usage.

`rocksdb.max-sub-compactions` indicates the number of concurrent sub-tasks allowed for a single compaction job, which defaults to `3`. You can lower this value when the write traffic is not high.

In the test, the `rocksdb.max-background-jobs` value is set to `3` and the `rocksdb.max-sub-compactions` value is set to `1`. No write stall occurs during the 12-hour test with the TPC-C load. When optimizing the two parameter values according to the actual load, you can lower the values gradually based on monitoring metrics:

- If write stall occurs, increase the value of `rocksdb.max-background-jobs`.
- If the write stall persists, set the value of `rocksdb.max-sub-compactions` to `2` or `3`.

`rocksdb.rate-bytes-per-sec`

This parameter is used to limit the disk traffic for the background compaction jobs. The default configuration has no limit for this parameter. To avoid the situation that compaction jobs occupy the resources of foreground services, you can adjust this parameter value according to the sequential read and write speed of the disk, which reserves enough disk bandwidth for foreground services.

The method of optimizing the RocksDB thread pool is similar to that of optimizing the compaction thread pool. You can determine whether the value you have adjusted is suitable according to whether write stall occurs.

`gc.max_write_bytes_per_sec`

Because TiDB uses the multi-version concurrency control (MVCC) model, TiKV periodically cleans old version data in the background. When the available resources are limited, this operation causes periodical performance jitter. You can use the `gc.max_write_bytes_per_sec` parameter to limit the resource usage of such an operation.

Figure 437: GC Impact

In addition to setting this parameter value in the configuration file, you can also dynamically adjust this value in tikv-ctl.

```
tiup ctl:v<CLUSTER_VERSION> tikv --host=${ip:port} modify-tikv-config -n gc.
    ↪ max_write_bytes_per_sec -v ${limit}
```

Note:

In application scenarios with frequent updates, limiting GC traffic might cause the MVCC versions to pile up and affect read performance. Currently, to achieve a balance between performance jitter and performance decrease, you might need to try multiple times to adjust the value of this parameter.

12.5.8.2.3 TiDB parameter adjustment

Generally, you can adjust the TiDB parameters of execution operators using system variables such as `tidb_hash_join_concurrency` and `tidb_index_lookup_join_concurrency`.

In this test, these parameters are not adjusted. In the load test of your actual application, if the execution operators consume an excessive amount of CPU resources, you can limit the resource usage of specific operators according to your application scenario. For more details, see TiDB system variables.

`performance.max-procs`

This parameter is used to control how many CPU cores an entire Go process can use. By default, the value is equal to the number of CPU cores of the current machine or cgroups.

When Go is running, a proportion of threads is used for background tasks such as GC. If you do not limit the value of the `performance.max-procs` parameter, these background tasks will consume too much CPU.

12.5.9 Local Read under Three Data Centers Deployment

In the model of three data centers, a Region has three replicas which are isolated in each data center. However, due to the requirement of strongly consistent read, TiDB must access the Leader replica of the corresponding data for every query. If the query is generated in a data center different from that of the Leader replica, TiDB needs to read data from another data center, thus causing the access latency to increase.

This document describes how to use the Stale Read feature to avoid cross-center access and reduce the access latency at the expense of real-time data availability.

12.5.9.1 Deploy a TiDB cluster of three data centers

For the three-data-center deployment method, refer to Multiple Data Centers in One City Deployment.

Note that if both the TiKV and TiDB nodes have the configuration item `labels` configured, the TiKV and TiDB nodes in the same data center must have the same value for the `zone` label. For example, if a TiKV node and a TiDB node are both in the data center `dc-1`, then the two nodes need to be configured with the following label:

```
[labels]
zone=dc-1
```

12.5.9.2 Perform local read using Stale Read

Stale Read is a mechanism that TiDB provides for the users to read historical data. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes. When using Stale Read in some scenarios of geo-distributed deployment, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query process.

When TiDB receives a Stale Read query, if the `zone` label of that TiDB node is configured, and `tidb_replica_read` is set to `closest-replicas`, then TiDB sends the request to the TiKV node with the same `zone` label where the corresponding data replica resides.

For how to perform Stale Read, see Perform Stale Read using the `AS OF TIMESTAMP` clause.

12.5.10 UUID Best Practices

12.5.10.1 Overview of UUIDs

When used as a primary key, instead of an `AUTO_INCREMENT` integer value, a universally unique identifier (UUID) delivers the following benefits:

- UUIDs can be generated on multiple systems without risking conflicts. In some cases, this means that the number of network trips to TiDB can be reduced, leading to improved performance.
- UUIDs are supported by most programming languages and database systems.
- When used as a part of a URL, a UUID is not vulnerable to enumeration attacks. In comparison, with an `auto_increment` number, it is possible to guess the invoice IDs or user IDs.

12.5.10.2 Best practices

12.5.10.2.1 Store as binary

The textual UUID format looks like this: `ab06f63e-8fe7-11ec-a514-5405db7aad56`, which is a string of 36 characters. By using `UUID_TO_BIN()`, the textual format can be converted into a binary format of 16 bytes. This allows you to store the text in a `BINARY (16)` column. When retrieving the UUID, you can use the `BIN_TO_UUID()` function to get back to the textual format.

12.5.10.2.2 UUID format binary order and a clustered PK

The `UUID_TO_BIN()` function can be used with one argument, the UUID or with two arguments where the second argument is a `swap_flag`.

It is recommended to not set the `swap_flag` with TiDB to avoid hotspots.

You can also explicitly set the `CLUSTERED` option for UUID based primary keys to avoid hotspots.

To demonstrate the effect of the `swap_flag`, here are two tables with an identical structure. The difference is that the data inserted into `uuid_demo_1` uses `UUID_TO_BIN(?, 0)` and `uuid_demo_2` uses `UUID_TO_BIN(?, 1)`.

In the screenshot of the Key Visualizer below, you can see that writes are concentrated in a single region of the `uuid_demo_2` table that has the order of the fields swapped in the binary format.

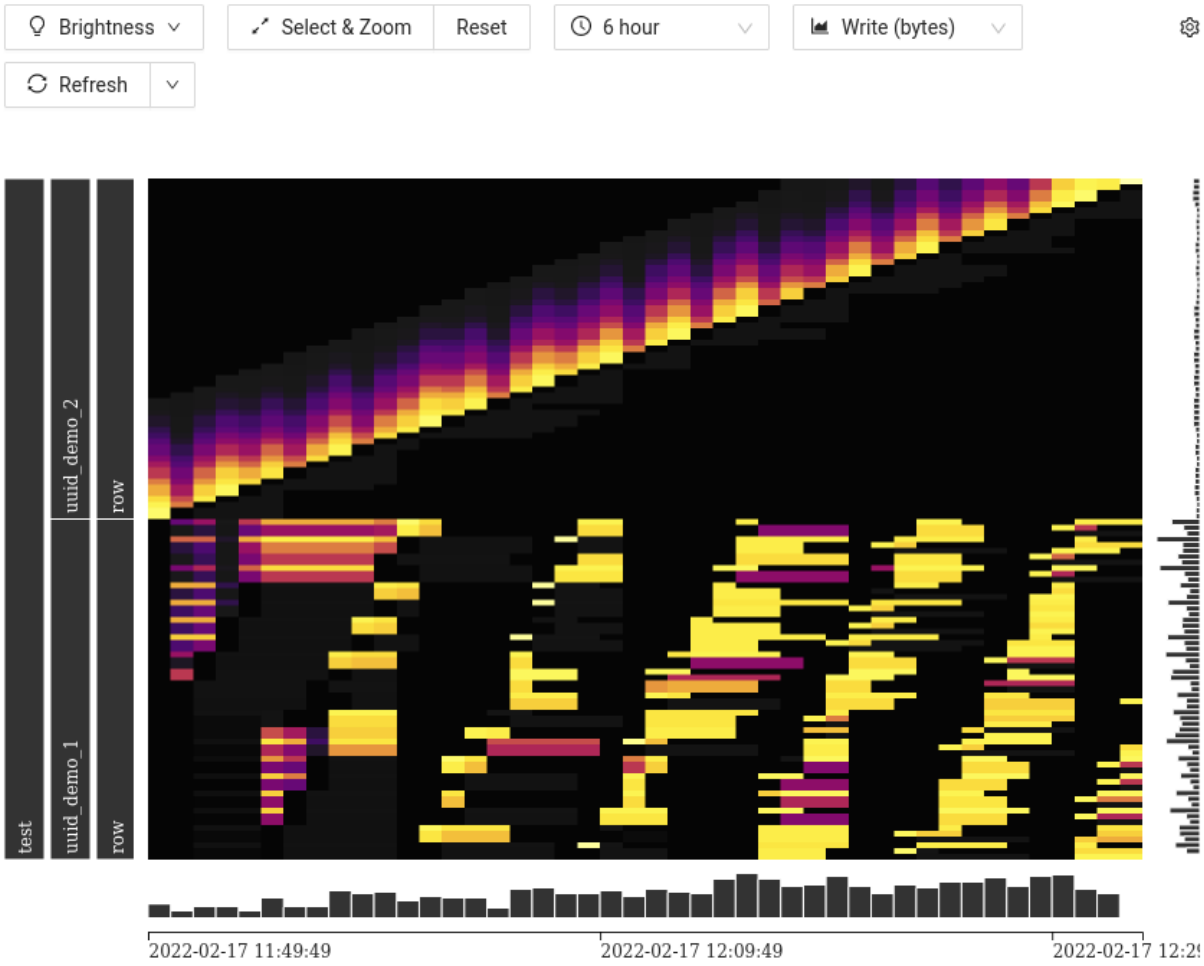

Figure 438: Key Visualizer

```
CREATE TABLE `uuid_demo_1` (
  `uuid` varbinary(16) NOT NULL,
  `c1` varchar(255) NOT NULL,
  PRIMARY KEY (`uuid`) CLUSTERED
)
```

```
CREATE TABLE `uuid_demo_2` (
  `uuid` varbinary(16) NOT NULL,
  `c1` varchar(255) NOT NULL,
  PRIMARY KEY (`uuid`) CLUSTERED
)
```

12.5.10.3 MySQL compatibility

UUIDs can be used in MySQL as well. The `BIN_TO_UUID()` and `UUID_TO_BIN()` functions were introduced in MySQL 8.0. The `UUID()` function is available in earlier MySQL versions as well.

12.5.11 Best Practices for Read-Only Storage Nodes

This document introduces how to configure read-only storage nodes and how to direct backup, analysis, testing, and other traffic to these nodes. In this way, loads with high tolerance for delay can be physically isolated from important online services.

12.5.11.1 Procedures

12.5.11.1.1 1. Specify some TiKV nodes as read-only

To specify some TiKV nodes as read-only, you can mark these nodes with a special label (use `$` as the prefix of the label key). Unless you explicitly specify these nodes to store some data using Placement Rules, PD does not schedule any data to these nodes.

You can configure a read-only node by running the `tiup cluster edit-config` command:

```
tikv_servers:
  - host: ...
    ...
    labels:
      $mode: readonly
```

12.5.11.1.2 2. Use Placement Rules to store data on read-only nodes as learners

1. Run the `pd-ctl config placement-rules` command to export the default Placement Rules:

   ```
   pd-ctl config placement-rules rule-bundle load --out="rules.json"
   ```

   If you have not configured Placement Rules before, the output is as follows:

   ```
   [
     {
       "group_id": "pd",
       "group_index": 0,
       "group_override": false,
       "rules": [
         {
           "group_id": "pd",
   ```

```
      "id": "default",
      "start_key": "",
      "end_key": "",
      "role": "voter",
      "count": 3
    }
  ]
 }
]
```

2. Store all data on the read-only nodes as a learner. The following example is based on the default configuration:

```
[
 {
  "group_id": "pd",
  "group_index": 0,
  "group_override": false,
  "rules": [
   {
    "group_id": "pd",
    "id": "default",
    "start_key": "",
    "end_key": "",
    "role": "voter",
    "count": 3
   },
   {
    "group_id": "pd",
    "id": "readonly",
    "start_key": "",
    "end_key": "",
    "role": "learner",
    "count": 1,
    "label_constraints": [
     {
      "key": "$mode",
      "op": "in",
      "values": [
       "readonly"
      ]
     }
    ],
    "version": 1
   }
```

```
    ]
  }
]
```

3. Use the `pd-ctl config placement-rules` command to write the preceding configurations to PD:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

Note:

- If you perform the preceding operations on a cluster with a large dataset, the entire cluster might need some time to completely replicate data to read-only nodes. During this period, the read-only nodes might not be able to provide services.
- Because of the special implementation of backup, the learner number of each label cannot exceed 1. Otherwise, it will generate duplicate data during backup.

12.5.11.1.3 3. Use Follower Read to read data from read-only nodes

3.1 Use Follower Read in TiDB

To read data from read-only nodes when using TiDB, you can set the system variable `tidb_replica_read` to `learner`:

```
set tidb_replica_read=learner;
```

3.2 Use Follower Read in TiSpark

To read data from read-only nodes when using TiSpark, you can set the configuration item `spark.tispark.replica_read` to `learner` in the Spark configuration file:

```
spark.tispark.replica_read learner
```

3.3 Use Follower Read when backing up cluster data

To read data from read-only nodes when backing up cluster data, you can specify the `--replica-read-label` option in the br command line. Note that when running the following command in shell, you need to use single quotes to wrap the label to prevent `$` from being parsed.

```
br backup full ... --replica-read-label '$mode:readonly'
```

12.6 Placement Rules

> **Note:**
>
> This document introduces how to manually specify placement rules in Placement Driver (PD). It is now recommended to use Placement Rules in SQL. This offers a more convenient way to configure the placement of tables and partitions.

Placement Rules, introduced in v5.0, is a replica rule system that guides PD to generate corresponding schedules for different types of data. By combining different scheduling rules, you can finely control the attributes of any continuous data range, such as the number of replicas, the storage location, the host type, whether to participate in Raft election, and whether to act as the Raft leader.

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to Disable Placement Rules.

12.6.1 Rule system

The configuration of the whole rule system consists of multiple rules. Each rule can specify attributes such as the number of replicas, the Raft role, the placement location, and the key range in which this rule takes effect. When PD is performing schedule, it first finds the rule corresponding to the Region in the rule system according to the key range of the Region, and then generates the corresponding schedule to make the distribution of the Region replica comply with the rule.

The key ranges of multiple rules can have overlapping parts, which means that a Region can match multiple rules. In this case, PD decides whether the rules overwrite each other or take effect at the same time according to the attributes of rules. If multiple rules take effect at the same time, PD will generate schedules in sequence according to the stacking order of the rules for rule matching.

In addition, to meet the requirement that rules from different sources are isolated from each other, these rules can be organized in a more flexible way. Therefore, the concept of "Group" is introduced. Generally, users can place rules in different groups according to different sources.

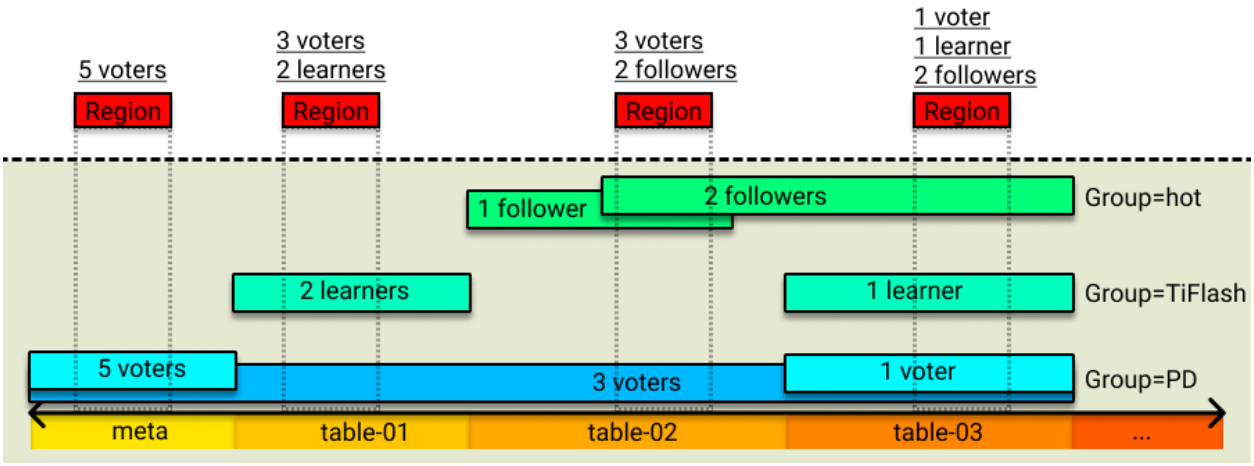

Figure 439: Placement rules overview

12.6.1.1 Rule fields

The following table shows the meaning of each field in a rule:

Field name	Type and restriction	Description
`GroupID`	`string`	The group ID that marks the source of the rule.
`ID`	`string`	The unique ID of a rule in a group.
`Index`	`int`	The stacking sequence of rules in a group.
`Override`	`true/false`	Whether to overwrite rules with smaller index (in a g
`StartKey`	`string`, in hexadecimal form	Applies to the starting key of a range.
`EndKey`	`string`, in hexadecimal form	Applies to the ending key of a range.
`Role`	`string`	Replica roles, including voter/leader/follower/learner.
`Count`	`int`, positive integer	The number of replicas.
`LabelConstraint`	`[]Constraint`	Filters nodes based on the label.
`LocationLabels`	`[]string`	Used for physical isolation.
`IsolationLevel`	`string`	Used to set the minimum physical isolation level

`LabelConstraint` is similar to the function in Kubernetes that filters labels based on these four primitives: `in`, `notIn`, `exists`, and `notExists`. The meanings of these four primitives are as follows:

- `in`: the label value of the given key is included in the given list.
- `notIn`: the label value of the given key is not included in the given list.
- `exists`: includes the given label key.
- `notExists`: does not include the given label key.

The meaning and function of `LocationLabels` are the same with those earlier than v4.0. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology:

the cluster has multiple zones (Availability Zones), each zone has multiple racks, and each rack has multiple hosts. When performing schedule, PD first tries to place the Region's peers in different zones. If this try fails (such as there are three replicas but only two zones in total), PD guarantees to place these replicas in different racks. If the number of racks is not enough to guarantee isolation, then PD tries the host-level isolation.

The meaning and function of `IsolationLevel` is elaborated in Cluster topology configuration. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology with `LocationLabels` and set `IsolationLevel` to `zone`, then PD ensures that all peers of each Region are placed in different zones during the scheduling. If the minimum isolation level restriction on `IsolationLevel` cannot be met (for example, 3 replicas are configured but there are only 2 data zones in total), PD will not try to make up to meet this restriction. The default value of `IsolationLevel` is an empty string, which means that it is disabled.

12.6.1.2 Fields of the rule group

The following table shows the description of each field in a rule group:

Field name	Type and restriction	Description
`ID`	`string`	The group ID that marks the source of the rule.
`Index`	`int`	The stacking sequence of different groups.
`Override`	`true/false`	Whether to override groups with smaller indexes.

12.6.2 Configure rules

The operations in this section are based on pd-ctl, and the commands involved in the operations also support calls via HTTP API.

12.6.2.1 Enable Placement Rules

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to Disable Placement Rules. To enable this feature after it has been disabled, you can modify the PD configuration file as follows before initializing the cluster:

```
[replication]
enable-placement-rules = true
```

In this way, PD enables this feature after the cluster is successfully bootstrapped and generates corresponding rules according to the `max-replicas`, `location-labels`, and `isolation-level` configurations:

```
{
  "group_id": "pd",
  "id": "default",
  "start_key": "",
```

```
  "end_key": "",
  "role": "voter",
  "count": 3,
  "location_labels": ["zone", "rack", "host"],
  "isolation_level": ""
}
```

For a bootstrapped cluster, you can also enable Placement Rules dynamically through pd-ctl:

```
pd-ctl config placement-rules enable
```

PD also generates default rules based on the `max-replicas`, `location-labels`, and `isolation-level` configurations.

Note:

- When Placement Rules are enabled and multiple rules exist, the previously configured `max-replicas`, `location-labels`, and `isolation-level` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.
- When Placement Rules are enabled and only one default rule exists, TiDB will automatically update this default rule when `max-replicas`, `location-labels`, or `isolation-level` configurations are changed.

12.6.2.2 Disable Placement Rules

You can use pd-ctl to disable the Placement Rules feature and switch to the previous scheduling strategy.

```
pd-ctl config placement-rules disable
```

Note:

After disabling Placement Rules, PD uses the original `max-replicas`, `location-labels`, and `isolation-level` configurations. The modification of rules (when Placement Rules is enabled) will not update these three configurations in real time. In addition, all the rules that have been configured remain in PD and will be used the next time you enable Placement Rules.

12.6.2.3 Set rules using pd-ctl

> **Note:**
>
> The change of rules affects the PD scheduling in real time. Improper rule setting might result in fewer replicas and affect the high availability of the system.

pd-ctl supports using the following methods to view rules in the system, and the output is a JSON-format rule or a rule list.

- To view the list of all rules:

```
pd-ctl config placement-rules show
```

- To view the list of all rules in a PD Group:

```
pd-ctl config placement-rules show --group=pd
```

- To view the rule of a specific ID in a Group:

```
pd-ctl config placement-rules show --group=pd --id=default
```

- To view the rule list that matches a Region:

```
pd-ctl config placement-rules show --region=2
```

  In the above example, `2` is the Region ID.

Adding rules and editing rules are similar. You need to write the corresponding rules into a file and then use the `save` command to save the rules to PD:

```
cat > rules.json <<EOF
[
    {
        "group_id": "pd",
        "id": "rule1",
        "role": "voter",
        "count": 3,
        "location_labels": ["zone", "rack", "host"]
    },
    {
        "group_id": "pd",
```

```
        "id": "rule2",
        "role": "voter",
        "count": 2,
        "location_labels": ["zone", "rack", "host"]
    }
]
EOF

» ./pd-ctl -u 127.0.0.1:2379 config placement-rules save --in=rules.json
Success!
```

The above operation writes `rule1` and `rule2` to PD. If a rule with the same `GroupID` + `ID` already exists in the system, this rule is overwritten.

To delete a rule, you only need to set the `count` of the rule to `0`, and the rule with the same `GroupID` + `ID` will be deleted. The following command deletes the `pd / rule2` rule:

```
cat > rules.json <<EOF
[
    {
        "group_id": "pd",
        "id": "rule2"
    }
]
EOF

» ./pd-ctl -u 127.0.0.1:2379 config placement-rules save --in=rules.json
Success!
```

12.6.2.4 Use pd-ctl to configure rule groups

- To view the list of all rule groups:

```
pd-ctl config placement-rules rule-group show
```

- To view the rule group of a specific ID:

```
pd-ctl config placement-rules rule-group show pd
```

- To set the `index` and `override` attributes of the rule group:

```
pd-ctl config placement-rules rule-group set pd 100 true
```

- To delete the configuration of a rule group (use the default group configuration if there is any rule in the group):

```
pd-ctl config placement-rules rule-group delete pd
```

12.6.2.5 Use pd-ctl to batch update groups and rules in groups

To view and modify the rule groups and all rules in the groups at the same time, execute the `rule-bundle` subcommand.

In this subcommand, `get {group_id}` is used to query a group, and the output result shows the rule group and rules of the group in a nested form:

```
pd-ctl config placement-rules rule-bundle get pd
```

The output of the above command:

```
{
  "group_id": "pd",
  "group_index": 0,
  "group_override": false,
  "rules": [
    {
      "group_id": "pd",
      "id": "default",
      "start_key": "",
      "end_key": "",
      "role": "voter",
      "count": 3
    }
  ]
}
```

To write the output to a file, add the `--out` argument to the `rule-bundle get` subcommand, which is convenient for subsequent modification and saving.

```
pd-ctl config placement-rules rule-bundle get pd --out="group.json"
```

After the modification is finished, you can use the `rule-bundle set` subcommand to save the configuration in the file to the PD server. Unlike the `save` command described in Set rules using pd-ctl, this command replaces all the rules of this group on the server side.

```
pd-ctl config placement-rules rule-bundle set pd --in="group.json"
```

12.6.2.6 Use pd-ctl to view and modify all configurations

You can also view and modify all configuration using pd-ctl. To do that, save all configuration to a file, edit the configuration file, and then save the file to the PD server to overwrite the previous configuration. This operation also uses the `rule-bundle` subcommand.

For example, to save all configuration to the `rules.json` file, execute the following command:

```
pd-ctl config placement-rules rule-bundle load --out="rules.json"
```

After editing the file, execute the following command to save the configuration to the PD server:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

12.6.2.7 Use tidb-ctl to query the table-related key range

If you need special configuration for metadata or a specific table, you can execute the `keyrange` command in tidb-ctl to query related keys. Remember to add `--encode` at the end of the command.

```
tidb-ctl keyrange --database test --table ttt --encode
```

```
global ranges:
  meta: (6d00000000000000f8, 6e00000000000000f8)
  table: (7400000000000000f8, 7500000000000000f8)
table ttt ranges: (NOTE: key range might be changed after DDL)
  table: (7480000000000000ff2d000000000000f8, 7480000000000000
    ↪ ff2e00000000000000f8)
  table indexes: (7480000000000000ff2d5f690000000000fa, 7480000000000000
    ↪ ff2d5f720000000000fa)
    index c2: (7480000000000000ff2d5f698000000000ff0000010000000000fa,
      ↪ 7480000000000000ff2d5f698000000000ff0000020000000000fa)
    index c3: (7480000000000000ff2d5f698000000000ff0000020000000000fa,
      ↪ 7480000000000000ff2d5f698000000000ff0000030000000000fa)
    index c4: (7480000000000000ff2d5f698000000000ff0000030000000000fa,
      ↪ 7480000000000000ff2d5f698000000000ff0000040000000000fa)
  table rows: (7480000000000000ff2d5f720000000000fa, 7480000000000000
    ↪ ff2e00000000000000f8)
```

> **Note:**
>
> DDL and other operations can cause table ID changes, so you need to update the corresponding rules at the same time.

12.6.3 Typical usage scenarios

This section introduces the typical usage scenarios of Placement Rules.

12.6.3.1 Scenario 1: Use three replicas for normal tables and five replicas for the metadata to improve cluster disaster tolerance

You only need to add a rule that limits the key range to the range of metadata, and set the value of `count` to `5`. Here is an example of this rule:

```
{
  "group_id": "pd",
  "id": "meta",
  "index": 1,
  "override": true,
  "start_key": "6d00000000000000f8",
  "end_key": "6e00000000000000f8",
  "role": "voter",
  "count": 5,
  "location_labels": ["zone", "rack", "host"]
}
```

12.6.3.2 Scenario 2: Place five replicas in three data centers in the proportion of 2:2:1, and the Leader should not be in the third data center

Create three rules. Set the number of replicas to `2`, `2`, and `1` respectively. Limit the replicas to the corresponding data centers through `label_constraints` in each rule. In addition, change `role` to `follower` for the data center that does not need a Leader.

```
[
   {
       "group_id": "pd",
       "id": "zone1",
       "start_key": "",
       "end_key": "",
       "role": "voter",
       "count": 2,
       "label_constraints": [
          {"key": "zone", "op": "in", "values": ["zone1"]}
       ],
       "location_labels": ["rack", "host"]
   },
   {
       "group_id": "pd",
       "id": "zone2",
       "start_key": "",
       "end_key": "",
       "role": "voter",
       "count": 2,
       "label_constraints": [
          {"key": "zone", "op": "in", "values": ["zone2"]}
       ],
       "location_labels": ["rack", "host"]
```

```
    },
    {
        "group_id": "pd",
        "id": "zone3",
        "start_key": "",
        "end_key": "",
        "role": "follower",
        "count": 1,
        "label_constraints": [
            {"key": "zone", "op": "in", "values": ["zone3"]}
        ],
        "location_labels": ["rack", "host"]
    }
]
```

12.6.3.3 Scenario 3: Add two TiFlash replicas for a table

Add a separate rule for the row key of the table and limit `count` to `2`. Use `label_constraints` to ensure that the replicas are generated on the node of `engine = tiflash`. Note that a separate `group_id` is used here to ensure that this rule does not overlap or conflict with rules from other sources in the system.

```
{
  "group_id": "tiflash",
  "id": "learner-replica-table-ttt",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "learner",
  "count": 2,
  "label_constraints": [
    {"key": "engine", "op": "in", "values": ["tiflash"]}
  ],
  "location_labels": ["host"]
}
```

12.6.3.4 Scenario 4: Add two follower replicas for a table in the Beijing node with high-performance disks

The following example shows a more complicated `label_constraints` configuration. In this rule, the replicas must be placed in the `bj1` or `bj2` machine room, and the disk type must be `nvme`.

```
{
  "group_id": "follower-read",
  "id": "follower-read-table-ttt",
```

```
  "start_key": "7480000000000000ff2d00000000000000f8",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "follower",
  "count": 2,
  "label_constraints": [
    {"key": "zone", "op": "in", "values": ["bj1", "bj2"]},
    {"key": "disk", "op": "in", "values": ["nvme"]}
  ],
  "location_labels": ["host"]
}
```

12.6.3.5 Scenario 5: Migrate a table to the nodes with SSD disks

Different from scenario 3, this scenario is not to add new replica(s) on the basis of the existing configuration, but to forcibly override the other configuration of a data range. So you need to specify an `index` value large enough and set `override` to `true` in the rule group configuration to override the existing rule.

The rule:

```
{
  "group_id": "ssd-override",
  "id": "ssd-table-45",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "voter",
  "count": 3,
  "label_constraints": [
    {"key": "disk", "op": "in", "values": ["ssd"]}
  ],
  "location_labels": ["rack", "host"]
}
```

The rule group:

```
{
  "id": "ssd-override",
  "index": 1024,
  "override": true,
}
```

12.7 Load Base Split

Load Base Split is a new feature introduced in TiDB 4.0. It aims to solve the hotspot issue caused by unbalanced access between Regions, such as full table scans for small tables.

12.7.1 Scenarios

In TiDB, it is easy to generate hotspots when the load is concentrated on certain nodes. PD tries to schedule the hot Regions so that they are distributed as evenly as possible across all nodes for better performance.

However, the minimum unit for PD scheduling is Region. If the number of hotspots in a cluster is smaller than the number of nodes, or if a few hotspots have far more load than other Regions, PD can only move the hotspot from one node to another, but not make the entire cluster share the load.

This scenario is especially common with workloads that are mostly read requests, such as full table scans and index lookups for small tables, or frequent access to some fields.

Previously, the solution to this problem was to manually execute a command to split one or more hotspot Regions, but this approach has two problems:

- Evenly splitting a Region is not always the best choice, because requests might be concentrated on a few keys. In such cases, hotspots might still be on one of the Regions after evenly splitting, and it might take multiple even splits to realize the goal.
- Human intervention is not timely or simple.

12.7.2 Implementation principles

Load Base Split automatically splits the Region based on statistics. It identifies the Regions whose read load or CPU usage consistently exceeds the threshold for 10 seconds, and splits these Regions at a proper position. When choosing the split position, Load Base Split tries to balance the access load of both Regions after the split and avoid access across Regions.

The Region split by Load Base Split will not be merged quickly. On the one hand, PD's `MergeChecker` skips the hot Regions; on the other hand, PD also determines whether to merge two Regions according to `QPS` in the heartbeat information, to avoid the merging of two Regions with high `QPS`.

12.7.3 Usage

The Load Base Split feature is currently controlled by the following parameters:

- `split.qps-threshold`: The QPS threshold at which a Region is identified as a hotspot. The default value is `3000` per second when `region-split-size` is less than 4 GB; otherwise the default value is `7000`.
- `split.byte-threshold`: (Introduced in v5.0) The traffic threshold at which a Region is identified as a hotspot. The unit is byte. The default value is 30 MiB per second when `region-split-size` is less than 4 GB; otherwise the default value is 100 MiB per second.

- `split.region-cpu-overload-threshold-ratio`: (Introduced in v6.2.0) The CPU usage threshold (the percentage of CPU time of the read thread pool) at which a Region is identified as a hotspot. The default value is `0.25` when `region-split-size` is less than 4 GB; otherwise the default value is `0.75`.

If a Region meets one of the following conditions for 10 consecutive seconds, TiKV tries to split the Region:

- the sum of its read requests exceeds `split.qps-threshold`.
- its traffic exceeds `split.byte-threshold`.
- its CPU usage in the Unified Read Pool exceeds `split.region-cpu-overload-threshold-ratio`.

Load Base Split is enabled by default, but the parameter is set to a rather high value. If you want to disable this feature, set `split.qps-threshold` and `split.byte-threshold` high enough and set `split.region-cpu-overload-threshold-ratio` to `0` at the same time.

To modify the parameter, take either of the following two methods:

- Use a SQL statement:

```
# Set the QPS threshold to 1500
SET config tikv split.qps-threshold=1500;
# Set the byte threshold to 15 MiB (15 * 1024 * 1024)
SET config tikv split.byte-threshold=15728640;
# Set the CPU usage threshold to 50%
SET config tikv split.region-cpu-overload-threshold-ratio=0.5;
```

- Use TiKV:

```
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.qps-threshold":"1500"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.byte-threshold":"15728640"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.region-cpu-overload-threshold-ratio":"0.5"}'
```

Accordingly, you can view the configuration by either of the following two methods:

- Use a SQL statement:

```
show config where type='tikv' and name like '%split.qps-threshold%';
```

- Use TiKV:

```
curl "http://ip:status_port/config"
```

Note:

Starting from v4.0.0-rc.2, you can modify and view the configuration using SQL statements.

12.8 Store Limit

Store Limit is a feature of PD, introduced in TiDB 3.0. It is designed to control the scheduling speed in a finer manner for better performance in different scenarios.

12.8.1 Implementation principles

PD performs scheduling at the unit of operator. An operator might contain several scheduling operations. For example:

```
"replace-down-replica {mv peer: store [2] to [3]} (kind:region,replica,
    ↪ region:10(4,5), createAt:2020-05-18 06:40:25.775636418 +0000 UTC m
    ↪ =+2168762.679540369, startAt:2020-05-18 06:40:25.775684648 +0000 UTC
    ↪ m=+2168762.679588599, currentStep:0, steps:[add learner peer 20 on
    ↪ store 3, promote learner peer 20 on store 3 to voter, remove peer on
    ↪ store 2])"
```

In this above example, the `replace-down-replica` operator contains the following specific operations:

1. Add a learner peer with the ID `20` to `store 3`.
2. Promote the learner peer with the ID `20` on `store 3` to a voter.
3. Delete the peer on `store 2`.

Store Limit achieves the store-level speed limit by maintaining a mapping from store IDs to token buckets in memory. The different operations here correspond to different token buckets. Currently, Store Limit only supports limiting the speed of two operations: adding learners/peers and deleting peers. That is, each store has two types of token buckets.

Every time an operator is generated, it checks whether enough tokens exist in the token buckets for its operations. If yes, the operator is added to the scheduling queue, and the corresponding token is taken from the token bucket. Otherwise, the operator is abandoned. Because the token bucket replenishes tokens at a fixed rate, the speed limit is thus achieved.

Store Limit is different from other limit-related parameters in PD (such as `region-schedule-limit` and `leader-schedule-limit`) in that it mainly limits the consuming speed of operators, while other parameters limits the generating speed of operators. Before introducing the Store Limit feature, the speed limit of scheduling is mostly at the global scope. Therefore, even if the global speed is limited, it is still possible that the scheduling operations are concentrated on some stores, affecting the performance of the cluster. By limiting the speed at a finer level, Store Limit can better control the scheduling behavior.

12.8.2 Usage

The parameters of Store Limit can be configured using `pd-ctl`.

12.8.2.1 View setting of the current store

To view the limit setting of the current store, run the following commands:

```
store limit                     // Shows the speed limit of adding and deleting peers in all stores.
store limit add-peer            // Shows the speed limit of adding peers in all stores.
store limit remove-peer         // Shows the speed limit of deleting peers in all stores.
```

12.8.2.2 Set limit for all stores

To set the speed limit for all stores, run the following commands:

```
store limit all 5               // All stores can at most add and delete 5 peers per minute.
store limit all 5 add-peer      // All stores can at most add 5 peers per minute.
store limit all 5 remove-peer   // All stores can at most delete 5 peers per minute.
```

12.8.2.3 Set limit for a single store

To set the speed limit for a single store, run the following commands:

```
store limit 1 5                 // store 1 can at most add and delete 5 peers per minute.
store limit 1 5 add-peer        // store 1 can at most add 5 peers per minute.
store limit 1 5 remove-peer     // store 1 can at most delete 5 peers per minute.
```

12.8.2.4 Principles of store limit v2

> **Warning:**
>
> Store limit v2 is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

When `store-limit-version` is set to `v2`, store limit v2 takes effect. In v2 mode, the limit of operators are dynamically adjusted based on the capability of TiKV snapshots. When TiKV has fewer pending tasks, PD increases its scheduling tasks. Otherwise, PD reduces the scheduling tasks for the node. Therefore, you do not need to manually set `store limit` to speed up the scheduling process.

In v2 mode, the execution speed of TiKV becomes the main bottleneck during migration. You can check whether the current scheduling speed has reached the upper limit through the **TiKV Details** > **Snapshot** > **Snapshot Speed** panel. To increase or decrease the scheduling speed of a node, you can adjust the TiKV snapshot limit (`snap-io-max-bytes-per-sec`).

12.9 Execution Principles and Best Practices of DDL Statements

This document provides an overview of the execution principles and best practices related to DDL statements in TiDB. The principles include the DDL Owner module and the online DDL change process.

12.9.1 DDL execution principles

TiDB uses an online and asynchronous approach to execute DDL statements. This means that DML statements in other sessions are not blocked while DDL statements are being executed. In other words, you can change the definitions of database objects using online and asynchronous DDL statements while your applications are running.

12.9.1.1 Types of DDL statements

Based on whether DDL statements block the user application during execution, DDL statements can be divided into the following types:

- **Offline DDL statements**: When the database receives a DDL statement from the user, it first locks the database object to be modified and then changes the metadata. During the DDL execution, the database blocks the user application from modifying data.

- **Online DDL statements**: When a DDL statement is executed in the database, a specific method is used to ensure that the statement does not block the user application. This allows the user to submit modifications during the DDL execution. The method also ensures the correctness and consistency of the corresponding database object during the execution process.

Based on whether to operate the data included in the target DDL object, DDL statements can be divided into the following types:

- **Logical DDL statements**: Logical DDL statements usually only modify the metadata of the database object, without processing the data stored in the object, for example, changing the table name or changing the column name.

  In TiDB, logical DDL statements are also referred to as "general DDL". These statements typically have a short execution time, often taking only a few tens of milliseconds or seconds to complete. As a result, they do not consume much system resource and do not affect the workload on the application.

- **Physical DDL statements**: Physical DDL statements not only modify the metadata of the object to be changed, but also modify the user data stored in the object. For example, when TiDB creates an index for a table, it not only changes the definition of the table, but also performs a full table scan to build the newly added index.

  In TiDB, physical DDL statements are also referred to as "reorg DDL", which stands for reorganization. Currently, physical DDL statements only include `ADD INDEX` and lossy column type changes (such as changing from an `INT` type to a `CHAR` type). These statements take a long time to execute, and the execution time is affected by the amount of data in the table, the machine configuration, and the application workload.

  Executing physical DDL statements can have an impact on the workload of the application for two reasons. On the one hand, it consumes CPU and I/O resources from TiKV to read data and write new data. On the other hand, **the TiDB node serving as DDL Owners** or **those TiDB nodes scheduled by the TiDB Distributed eXecution Framework (DXF) to execute `ADD INDEX` tasks** consume CPU resources from TiDB to perform the corresponding computations.

> **Note:**
>
> The execution of a physical DDL task typically causes the greatest impact on the user application. Therefore, to minimize this impact, the key point is to optimize the design of physical DDL statements during execution. This helps to reduce the impact on the user application.

12.9.1.2 TiDB DDL module

The TiDB DDL module introduces the role of the DDL Owner (or Owner), which serves as a proxy for executing all DDL statements within the TiDB cluster. In the current implementation, only one TiDB node in the entire cluster can be elected as the Owner at any given time. Once a TiDB node is elected as Owner, the worker started in that TiDB node can handle the DDL tasks in the cluster.

TiDB uses the election mechanism of etcd to elect a node to host the Owner from multiple TiDB nodes. By default, each TiDB node can potentially be elected as the Owner (you can configure `run-ddl` to manage node participation in the election). The elected Owner node has a term, and it actively maintains the term by renewing it. When the Owner node is down, another node can be elected as the new Owner through etcd and continue executing DDL tasks in the cluster.

A simple illustration of the DDL Owner is as follows:

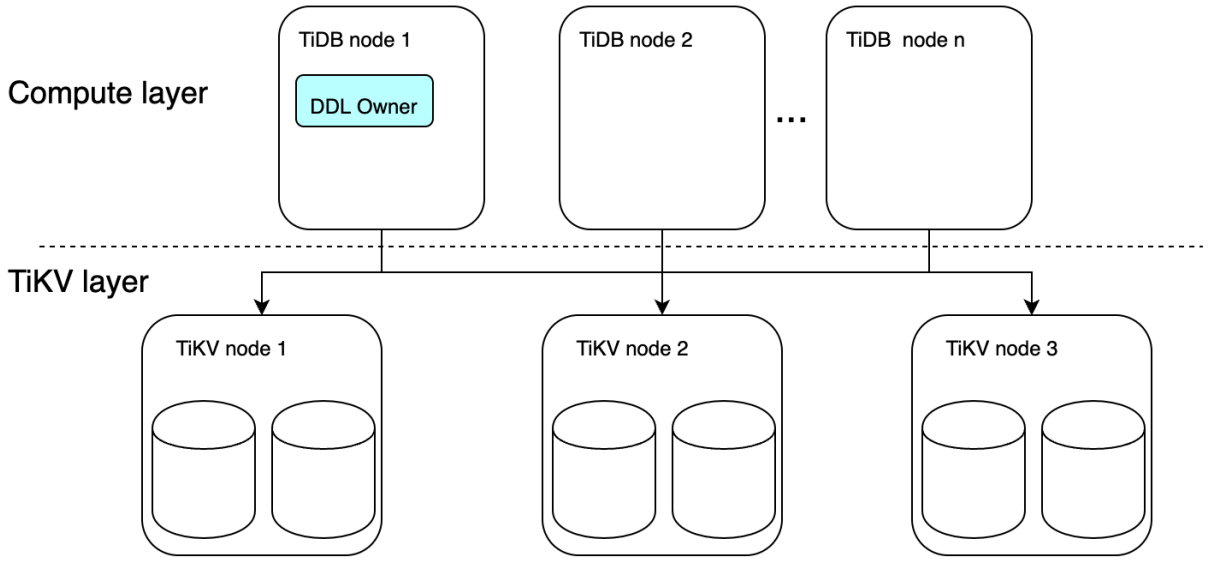

Figure 440: DDL Owner

You can use the `ADMIN SHOW DDL` statement to view the current DDL owner:

```
ADMIN SHOW DDL;
```

```
+--
    ↪ ----------+--------------------------------------+--------------+------------
    ↪
| SCHEMA_VER | OWNER_ID                             | OWNER_ADDRESS | RUNNING_JOBS
    ↪  | SELF_ID                          | QUERY |
+--
    ↪ ----------+--------------------------------------+--------------+------------
    ↪
```

```
|        26 | 2d1982af-fa63-43ad-a3d5-73710683cc63 | 0.0.0.0:4000 |      | 2
    ↪ d1982af-fa63-43ad-a3d5-73710683cc63 | |
+--
    ↪ ----------+--------------------------------------+--------------+-------------
    ↪
1 row in set (0.00 sec)
```

12.9.1.3 How the online DDL asynchronous change works in TiDB

From the beginning of its design, the TiDB DDL module has opted for an online asynchronous change mode, which lets you modify your applications without experiencing any downtime.

DDL changes involve transitioning from one state to another, typically from a "before change" state to an "after change" state. With online DDL changes, this transition occurs by introducing multiple small version states that are mutually compatible. During the execution of a DDL statement, TiDB nodes in the same cluster are allowed to have different small version changes, as long as the difference between the small versions of the change objects is not more than two versions. This is possible because adjacent small versions can be mutually compatible.

In this way, evolving through multiple small versions ensures that metadata can be correctly synchronized across multiple TiDB nodes. This helps maintain the correctness and consistency of user transactions that involve changing data during the process.

Taking `ADD INDEX` as an example, the entire process of state change is as follows:

```
absent -> delete only -> write only -> write reorg -> public
```

For users, the newly created index is unavailable before the `public` state.

Before v6.2.0, the process of handling asynchronous schema changes in the TiDB SQL layer is as follows:

1. MySQL Client sends a DDL request to a TiDB server.
2. After receiving the request, a TiDB server parses and optimizes the request at the MySQL Protocol layer, and then sends it to the TiDB SQL layer for execution.

   Once the SQL layer of TiDB receives the DDL request, it starts the `start job` module to encapsulate the request into a specific DDL job (that is, a DDL task), and then stores this job in the corresponding DDL job queue in the KV layer based on the statement type. The corresponding worker is notified of the job that requires processing.
3. When receiving the notification to process the job, the worker determines whether it has the role of the DDL Owner. If it does, it directly processes the job. Otherwise, it exits without any processing.

If a TiDB server is not the Owner role, then another node must be the Owner. The worker of the node in the Owner role periodically checks whether there is an available job that can be executed. If such a job is identified, the worker will process the job.

4. After the worker processes the Job, it removes the job from the job queue in the KV layer and places it in the `job history queue`. The `start job` module that encapsulated the job periodically checks the ID of the job in the `job history queue` to see whether it has been processed. If so, the entire DDL operation corresponding to the job ends.

5. TiDB server returns the DDL processing result to the MySQL Client.

Before TiDB v6.2.0, the DDL execution framework had the following limitations:

- The TiKV cluster only has two queues: `general job queue` and `add index job queue`, which handle logical DDL and physical DDL, respectively.
- The DDL Owner always processes DDL jobs in a first-in-first-out way.
- The DDL Owner can only execute one DDL task of the same type (either logical or physical) at a time, which is relatively strict, and affects the user experience.

These limitations might lead to some "unintended" DDL blocking behavior. For more details, see SQL FAQ - DDL Execution.

Before TiDB v6.2.0, because the Owner can only execute one DDL task of the same type (either logical or physical) at a time, which is relatively strict, and affects the user experience.

If there is no dependency between DDL tasks, parallel execution does not affect data correctness and consistency. For example, user A adds an index to the `T1` table, while user B deletes a column from the `T2` table. These two DDL statements can be executed in parallel.

To improve the user experience of DDL execution, starting from v6.2.0, TiDB enables the Owner to determine the relevance of DDL tasks. The logic is as follows:

- DDL statements to be performed on the same table are mutually blocked.
- `DROP DATABASE` and DDL statements that affect all objects in the database are mutually blocked.
- Adding indexes and column type changes on different tables can be executed concurrently.
- A logical DDL statement must wait for the previous logical DDL statement to be executed before it can be executed.
- In other cases, DDL can be executed based on the level of availability for concurrent DDL execution.

In specific, TiDB has upgraded the DDL execution framework in v6.2.0 in the following aspects:

- The DDL Owner can execute DDL tasks in parallel based on the preceding logic.
- The first-in-first-out issue in the DDL Job queue has been addressed. The DDL Owner no longer selects the first job in the queue, but instead selects the job that can be executed at the current time.
- The number of workers that handle physical DDL statements has been increased, enabling multiple physical DDL statements to be executed in parallel.

  Because all DDL tasks in TiDB are implemented using an online change approach, TiDB can determine the relevance of new DDL jobs through the Owner, and schedule DDL tasks based on this information. This approach enables the distributed database to achieve the same level of DDL concurrency as traditional databases.

The concurrent DDL framework enhances the execution capability of DDL statements in TiDB, making it more compatible with the usage patterns of commercial databases.

12.9.2 Best practices

12.9.2.1 Balance the physical DDL execution speed and the impact on application load through system variables

When executing physical DDL statements (including adding indexes or column type changes), you can adjust the values of the following system variables to balance the speed of DDL execution and the impact on application load:

- `tidb_ddl_reorg_worker_cnt`: This variable sets the number of reorg workers for a DDL operation, which controls the concurrency of backfilling.
- `tidb_ddl_reorg_batch_size`: This variable sets the batch size for a DDL operation in the `re-organize` phase, which controls the amount of data to be backfilled.

  Recommended values:

  - If there is no other load, you can increase the values of `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` to speed up the `ADD INDEX` operation. For example, you can set the values of the two variables to `20` and `2048`, respectively.
  - If there is other load, you can decrease the values of `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` to minimize the impact on other application. For example, you can set the values of the these variables to `4` and `256`, respectively.

Tip:

- The preceding two variables can be dynamically adjusted during the execution of a DDL task, and take effect in the next transaction batch.
- Choose the appropriate time to execute the DDL operation based on the type of the operation and the application load pressure. For example, it is recommended to run the `ADD INDEX` operation when the application load is low.
- Because the duration of adding an index is relatively long, TiDB will execute the task in the background after the command is sent. If the TiDB server is down, the execution will not be affected.

12.9.2.2 Quickly create many tables by concurrently sending DDL requests

A table creation operation takes about 50 milliseconds. The actual time taken to create a table might be longer because of the framework limitations.

To create tables faster, it is recommended to send multiple DDL requests concurrently to achieve the fastest table creation speed. If you send DDL requests serially and do not send them to the Owner node, the table creation speed will be very slow.

12.9.2.3 Make multiple changes in a single `ALTER` statement

Starting from v6.2.0, TiDB supports modifying multiple schema objects (such as columns and indexes) of a table in a single `ALTER` statement while ensuring the atomicity of the entire statement. Therefore, it is recommended to make multiple changes in a single `ALTER` statement.

12.9.2.4 Check the read and write performance

When TiDB is adding an index, the phase of backfilling data will cause read and write pressure on the cluster. After the `ADD INDEX` command is sent and the `write reorg` phase starts, it is recommended to check the read and write performance metrics of TiDB and TiKV on the Grafana dashboard and the application response time, to determine whether the `ADD INDEX` operation affects the cluster.

12.9.3 DDL-related commands

- `ADMIN SHOW DDL`: Used to view the status of TiDB DDL operations, including the current schema version number, the DDL ID and address of the DDL Owner, the DDL task and SQL being executed, and the DDL ID of the current TiDB instance. For details, see `ADMIN SHOW DDL`.
- `ADMIN SHOW DDL JOBS`: Used to view the detailed status of DDL tasks running in the cluster environment. For details, see `ADMIN SHOW DDL JOBS`.

- `ADMIN SHOW DDL JOB QUERIES job_id [, job_id]`: Used to view the original SQL statement of the DDL task corresponding to the `job_id`. For details, see ADMIN SHOW DDL JOB QUERIES.
- `ADMIN CANCEL DDL JOBS job_id, [, job_id]`: Used to cancel DDL tasks that have been submitted but not completed. After the cancellation is completed, the SQL statement that executes the DDL task returns the `ERROR 8214 (HY000): Cancelled DDL job` error.

  If a completed DDL task is canceled, you can see the `DDL Job:90 not found` error in the `RESULT` column, which means that the task has been removed from the DDL waiting queue.

12.9.4 Common questions

For common questions about DDL execution, see SQL FAQ - DDL execution.

13 TiDB Tools

13.1 TiDB Tools Overview

TiDB provides a rich set of tools to help you deploy and maintain TiDB, manage data (such as data migration, backup & restore, and data comparison), and run Spark SQL on TiKV. You can select the applicable tools according to your needs.

13.1.1 Deployment and operation Tools

TiDB provides TiUP and TiDB Operator to meet your deployment and operation needs in different system environments.

13.1.1.1 Deploy and operate TiDB on physical or virtual machines - TiUP

TiUP is a TiDB package manager on physical or virtual machines. TiUP can manage multiple TiDB components such as TiDB, PD, and TiKV. To start any component in the TiDB ecosystem, you just need to execute a single line of TiUP command.

TiUP provides TiUP cluster, a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

The following are the basics of TiUP:

- Terminology and Concepts
- Deploy a TiDB Cluster Using TiUP
- Manage TiUP Components with TiUP Commands
- Applicable TiDB versions: v4.0 and later versions

13.1.1.2 Deploy and operate TiDB on Kubernetes - TiDB Operator

TiDB Operator is an automatic operation system for managing TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

The following are the basics of TiDB Operator:

- TiDB Operator Architecture
- Get Started with TiDB Operator on Kubernetes
- Applicable TiDB versions: v2.1 and later versions

13.1.2 Data management tools

TiDB provides multiple data management tools, such as import and export, backup and restore, incremental data replication, and data validation.

13.1.2.1 Data migration - TiDB Data Migration (DM)

TiDB Data Migration (DM) is a tool that supports full data migration and incremental data replication from MySQL/MariaDB to TiDB.

The following are the basics of DM:

- Source: MySQL/MariaDB
- Target: TiDB clusters
- Supported TiDB versions: all versions
- Kubernetes support: use TiDB Operator to deploy TiDB DM on Kubernetes.

If the data volume is less than 1 TB, it is recommended to migrate data from MySQL/-MariaDB to TiDB directly using DM. The migration process includes full data migration and incremental data replication.

If the data volume is greater than 1 TB , take the following steps:

1. Use Dumpling to export the full data from MySQL/MariaDB.
2. Use TiDB Lightning to import the data exported in Step 1 to the TiDB cluster.
3. Use TiDB DM to replicate the incremental data from MySQL/MariaDB to TiDB.

> **Note:**
>
> The Syncer tool is no longer maintained. For scenarios related to Syncer, it is recommended that you use DM to perform incremental replication.

13.1.2.2 Full data export - Dumpling

Dumpling supports logical full data export from MySQL or TiDB.

The following are the basics of Dumpling:

- Source: MySQL/TiDB clusters
- Output: SQL/CSV files
- Supported TiDB versions: all versions
- Kubernetes support: No

> **Note:**
>
> PingCAP previously maintained a fork of the mydumper project with enhancements specific to TiDB. For more information on Mydumper, refer to v4.0 Mydumper documentation. Starting from v7.5.0, Mydumper is deprecated and most of its features have been replaced by Dumpling. It is strongly recommended that you use Dumpling instead of Mydumper.

13.1.2.3 Full data import - TiDB Lightning

TiDB Lightning supports full data import of a large dataset into a TiDB cluster.

TiDB Lightning supports the following modes:

- `Physical Import Mode`: TiDB Lightning parses data into ordered key-value pairs and directly imports them into TiKV. This mode is usually for importing a large amount of data (at the TB level) to a new cluster. During the import, the cluster cannot provide services.
- `Logical Import Mode`: This mode uses TiDB/MySQL as the backend, which is slower than the `Physical Import Mode` but can be performed online. It also supports importing data to MySQL.

The following are the basics of TiDB Lightning:

- Data source:
  - The output files of Dumpling
  - Other compatible CSV files
  - Parquet files exported from Amazon Aurora or Apache Hive
- Supported TiDB versions: v2.1 and later versions
- Kubernetes support: Yes. See Quickly restore data into a TiDB cluster on Kubernetes using TiDB Lightning for details.

Note:

The Loader tool is no longer maintained. For scenarios related to Loader, it is recommended that you use `Logical Import Mode` instead.

13.1.2.4 Backup and restore - Backup & Restore (BR)

Backup & Restore (BR) is a command-line tool for distributed backup and restore of the TiDB cluster data. BR can effectively back up and restore TiDB clusters of huge data volume.

The following are the basics of BR:

- Input and output data source
  - Snapshot backup and restore: SST + `backupmeta` file
  - Log backup and PITR: Log backup files
- Supported TiDB versions: v4.0 and later versions
- Kubernetes support: Yes. See Back up Data to S3-Compatible Storage Using BR and Restore Data from S3-Compatible Storage Using BR for details.

13.1.2.5 Incremental data replication - TiCDC

TiCDC is a tool used for replicating incremental data of TiDB by pulling change logs from TiKV. It can restore data to a state consistent with any TSO in upstream. TiCDC also provides the TiCDC Open Protocol to support other systems to subscribe to data changes.

The following are the basics of TiCDC:

- Source: TiDB clusters
- Target: TiDB clusters, MySQL, Kafka, and Confluent
- Supported TiDB versions: v4.0.6 and later versions

13.1.2.6 Incremental log replication - TiDB Binlog

TiDB Binlog is a tool that collects binlog for TiDB clusters and provides nearly real-time data replication and backup. You can use it for incremental data replication between TiDB clusters, such as making a TiDB cluster the secondary cluster of the primary TiDB cluster.

The following are the basics of TiDB Binlog:

- Source: TiDB clusters

- Target: TiDB clusters, MySQL, Kafka, or incremental backup files
- Supported TiDB versions: v2.1 and later versions
- Kubernetes support: Yes. See TiDB Binlog Cluster Operations and TiDB Binlog Drainer Configurations on Kubernetes for details.

13.1.2.7 sync-diff-inspector

sync-diff-inspector is a tool that compares data stored in the MySQL or TiDB databases. In addition, you can also use sync-diff-inspector to repair data in the scenario where a small amount of data is inconsistent.

The following are the basics of sync-diff-inspector:

- Source: MySQL/TiDB clusters
- Target: MySQL/TiDB clusters
- Supported TiDB versions: all versions

13.1.3 OLAP Query tool - TiSpark

TiSpark is a product developed by PingCAP to address the complexiy of OLAP queries. It combines strengths of Spark, and the features of distributed TiKV clusters and TiDB to provide a one-stop Hybrid Transactional and Analytical Processing (HTAP) solution.

13.2 TiDB Tools Use Cases

This document introduces the common use cases of TiDB tools and how to choose the right tool for your scenario.

13.2.1 Deploy and operate TiDB on physical or virtual machines

If you need to deploy and operate TiDB on physical or virtual machines, you can install TiUP, and then use TiUP to manage TiDB components such as TiDB, PD, and TiKV.

13.2.2 Deploy and operate TiDB on Kubernetes

If you need to deploy and operate TiDB on Kubernetes, you can deploy a Kubernetes cluster, and then deploy TiDB Operator. After that, you can use TiDB Operator to deploy and operate a TiDB cluster.

13.2.3 Import data from CSV to TiDB

If you need to import the compatible CSV files exported by other tools to TiDB, use TiDB Lightning.

13.2.4 Import full data from MySQL/Aurora

If you need to import full data from MySQL/Aurora, use Dumpling first to export data as SQL dump files, and then use TiDB Lightning to import data into the TiDB cluster.

13.2.5 Migrate data from MySQL/Aurora

If you need to migrate both full data and incremental data from MySQL/Aurora, use TiDB Data Migration (DM) to perform the Migrate Data from Amazon Aurora to TiDB.

If the full data volume is large (at the TB level), you can first use Dumpling and TiDB Lightning to perform the full data migration, and then use DM to perform the incremental data migration.

13.2.6 Back up and restore TiDB cluster

If you need to back up a TiDB cluster or restore backed up data to the cluster, use BR (Backup & Restore).

In addition, BR can also be used to perform incremental backup and incremental restore of TiDB cluster data.

13.2.7 Migrate data to TiDB

If you need to migrate data from a TiDB cluster to another TiDB cluster, use Dumpling to export full data from TiDB as SQL dump files, and then use TiDB Lightning to import data to another TiDB cluster.

If you also need to migrate incremental data, you can use TiCDC.

13.2.8 TiDB incremental data subscription

If you need to subscribe to TiDB's incremental changes, you can use TiCDC.

13.3 Download TiDB Tools

This document describes how to download the TiDB Toolkit.

TiDB Toolkit contains frequently used TiDB tools, such as data export tool Dumpling, data import tool TiDB Lightning, and backup and restore tool BR.

Tip:

- If your deployment environment has internet access, you can deploy a TiDB tool using a single TiUP command, so there is no need to download the TiDB Toolkit separately.
- If you need to deploy and maintain TiDB on Kubernetes, instead of downloading the TiDB Toolkit, follow the steps in TiDB Operator offline installation.

13.3.1 Environment requirements

- Operating system: Linux
- Architecture: amd64 or arm64

13.3.2 Download link

You can download TiDB Toolkit from the following link:

```
https://download.pingcap.org/tidb-community-toolkit-{version}-linux-{arch}.
    ↪ tar.gz
```

`{version}` in the link indicates the version number of TiDB and `{arch}` indicates the architecture of the system, which can be `amd64` or `arm64`. For example, the download link for `v6.2.0` in the `amd64` architecture is `https://download.pingcap.org/tidb-community ↪ -toolkit-v6.2.0-linux-amd64.tar.gz`.

Note:

If you need to download the PD Control tool `pd-ctl`, download the TiDB installation package separately from `https://download.pingcap.org/tidb ↪ -community-server-{version}-linux-{arch}.tar.gz`.

13.3.3 TiDB Toolkit description

Depending on which tools you want to use, you can install the corresponding offline packages as follows:

Tool	Offline package name
TiUP	tiup-linux-{arch}.tar.gz tiup-{tiup-version}-linux-{arch}.tar.gz dm-{tiup-version}-linux-{arch}.tar.gz server-{version}-linux-{arch}.tar.gz
Dumpling	dumpling-{version}-linux-{arch}.tar.gz
TiDB Lightning	tidb-lightning-ctl tidb-lightning-{version}-linux-{arch}.tar.gz

Tool	Offline package name

TiDB Data Migration (DM)	dm-worker
	↪ -{
	↪ version
	↪ }-linux
	↪ -{arch
	↪ }.tar.
	↪ gz
	dm-master
	↪ -{
	↪ version
	↪ }-linux
	↪ -{arch
	↪ }.tar.
	↪ gz
	dmctl-{
	↪ version
	↪ }-linux
	↪ -{arch
	↪ }.tar.
	↪ gz

TiCDC	cdc-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz

TiDB Binlog	pump-{
	↪ version

	reparo

Tool	Offline package name
Backup & Restore (BR)	br-{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar. ↪ gz
sync-diff-inspector	sync_diff_inspector ↪

TiSpark	tispark-{
	↪ tispark
	↪ -
	↪ version
	↪ }-any-
	↪ any.tar
	↪ .gz
	spark-{
	↪ spark-
	↪ version
	↪ }-any-
	↪ any.tar
	↪ .gz

PD Recover	pd-recover ↪ -{ ↪ version ↪ }-linux ↪ -{arch ↪ }.tar

Note:

`{version}` depends on the version of the tool you are installing. `{arch}` depends on the architecture of the system, which can be `amd64` or `arm64`.

13.4 TiUP

13.4.1 TiUP Documentation Map

13.4.1.1 User guide

- TiUP Overview: Gives an overall introduction to TiUP, for example, how to install and use TiUP, and the related terminologies.
- TiUP Terminology and Concepts: Explains the terms that you might bump into when using TiUP, and help you understand the key concepts of TiUP
- TiUP Component Management: Introduces all TiUP commands in detail, and how to use TiUP to download, update and delete components
- TiUP FAQ: Introduces common issues when you use TiUP, including FAQs of the third-party components of TiUP
- TiUP Troubleshooting Guide: Introduces the troubleshooting methods and solutions if you encounter issues when using TiUP
- TiUP Reference Guide: Introduces detailed references, including commands, components, and mirrors.

13.4.1.2 TiUP resources

- TiUP Release Notes
- TiUP Issues: Lists TiUP GitHub issues

13.4.2 TiUP Overview

Starting with TiDB 4.0, TiUP, as the package manager, makes it far easier to manage different cluster components in the TiDB ecosystem. Now you can run any component with only a single line of TiUP commands.

13.4.2.1 Install TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

This command installs TiUP in the `$HOME/.tiup` folder. The installed components and the data generated by their operation are also placed in this folder. This command also automatically adds `$HOME/.tiup/bin` to the `PATH` environment variable in the Shell `.profile` file, so you can use TiUP directly.

After installation, you can check the version of TiUP:

```
tiup --version
```

> **Note:**
>
> For TiUP versions starting from v1.11.3, the telemetry is disabled by default in newly deployed TiUP, and usage information is not collected and shared with PingCAP. For details about what is shared and how to disable the sharing, see Telemetry.

13.4.2.2 TiUP ecosystem introduction

TiUP is not only a package manager in the TiDB ecosystem. Its ultimate mission is to enable everyone to use TiDB ecosystem tools **easier than ever before** by building its own ecosystem. This requires introducing additional packages to enrich the TiUP ecosystem.

This series of TiUP documents introduce what these packages do and how you can use them.

In the TiUP ecosystem, you can get help information by adding `--help` to any command, such as the following command to get help information for TiUP itself:

```
tiup --help
```

```
TiUP is a command-line component management tool that can help to download
    ↪ and install
TiDB platform components to the local system. You can run a specific version
    ↪  of a component via
"tiup <component>[:version]". If no version number is specified, the latest
    ↪ version installed
locally will be used. If the specified component does not have any version
    ↪ installed locally,
the latest stable version will be downloaded from the repository.

Usage:
  tiup [flags] <command> [args...]
  tiup [flags] <component> [args...]

Available Commands:
  install    Install a specific version of a component
  list       List the available TiDB components or versions
  uninstall  Uninstall components or versions of a component
  update     Update tiup components to the latest version
  status     List the status of instantiated components
  clean      Clean the data of instantiated components
  mirror     Manage a repository mirror for TiUP components
  help       Help about any command or component
```

```
Components Manifest:
  use "tiup list" to fetch the latest components manifest

Flags:
      --binary <component>[:version] Print binary path of a specific version
         ↪  of a component <component>[:version]
                                     and the latest version installed will be
                                        ↪ selected if no version specified
      --binpath string               Specify the binary path of component
         ↪ instance
  -h, --help                         help for tiup
  -T, --tag string                   Specify a tag for component instance
  -v, --version                      version for tiup

Component instances with the same "tag" will share a data directory (
   ↪ $TIUP_HOME/data/$tag):
  $ tiup --tag mycluster playground

Examples:
  $ tiup playground                  # Quick start
  $ tiup playground nightly          # Start a playground with the latest
     ↪ nightly version
  $ tiup install <component>[:version] # Install a component of specific
     ↪ version
  $ tiup update --all                # Update all installed components to the
     ↪ latest version
  $ tiup update --nightly            # Update all installed components to the
     ↪ nightly version
  $ tiup update --self               # Update the "tiup" to the latest version
  $ tiup list                        # Fetch the latest supported components
     ↪ list
  $ tiup status                      # Display all running/terminated
     ↪ instances
  $ tiup clean <name>                # Clean the data of running/terminated
     ↪ instance (Kill process if it's running)
  $ tiup clean --all                 # Clean the data of all running/
     ↪ terminated instances

Use "tiup [command] --help" for more information about a command.
```

The output is long but you can focus on only two parts:

- Available commands

- install: used to install components
- list: used to view the list of available components
- uninstall: used to uninstall components
- update: used to update the component version
- status: used to view the running history of components
- clean: used to clear the running log of components
- mirror: used to clone a private mirror from the official mirror
- help: used to print out help information

- Available components
  - playground: used to start a TiDB cluster locally
  - client: used to connect to a TiDB cluster in a local machine
  - cluster: used to deploy a TiDB cluster for production environments
  - bench: used to stress test the database

Note:

- The number of available components will continue to grow. To check the latest supported components, execute the `tiup list` command.
- The list of available versions of components will also continue to grow. To check the latest supported component versions, execute the `tiup list <component>` command.

TiUP commands are implemented in TiUP's internal code and used for package management operations, while TiUP components are independent component packages installed by TiUP commands.

For example, if you run the `tiup list` command, TiUP directly runs its own internal code; if you run the `tiup playground` command, TiUP first checks whether there is a local package named "playground", and if not, TiUP downloads the package from the mirror, and then run it.

13.4.3 TiUP Terminology and Concepts

This document explains important terms and concepts of TiUP.

13.4.3.1 TiUP components

The TiUP program contains only a few commands for downloading, updating, and uninstalling components. TiUP expands its functions with various components. A **component** is

a program or script that can be run. When running a component through `tiup <component >`, TiUP adds a set of environment variables, creates the data directory for the program, and then runs the program.

By running the `tiup <component>` command, you can run a component supported by TiUP. The running logic is:

- If you specify a version of a component through `tiup <component>[:version]`:
    - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
    - If the component has one or more versions installed locally, but there is no version specified by you, TiUP downloads the specified version from the mirror server.
    - If the specified version of the component is installed locally, TiUP sets the environment variable to run the installed version.
- If you run a component through `tiup <component>` and specify no version:
    - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
    - If one or more versions have been installed locally, TiUP sets the environment variable to run the latest installed version.

13.4.3.2 TiUP mirrors

All components of TiUP are downloaded from the TiUP mirrors. TiUP mirrors contain the TAR package of each component and the corresponding meta information (version, entry startup file, checksum). TiUP uses PingCAP's official mirrors by default. You can customize the mirror source through the `TIUP_MIRRORS` environment variable.

TiUP mirrors can be a local file directory or an online HTTP server:

- `TIUP_MIRRORS=/path/to/local tiup list`
- `TIUP_MIRRORS=https://private-mirrors.example.com tiup list`

13.4.4 Manage TiUP Components with TiUP Commands

You can use the following TiUP commands to manage components in the TiUP ecosystem:

- list: Queries the component list. By using this TiUP command, you can see all the optional components to install and all the optional versions of each component.
- install: Installs the specific version of a component.
- update: Updates a component to the latest version.
- uninstall: Uninstalls a component.
- status: Checks the status of a running component.

- clean: Cleans up the instance on which a component is deployed.
- help: Prints the help information. If you append another TiUP command to this command, the usage of the appended command is printed.

This document introduces the common component management operations and the corresponding TiUP commands.

13.4.4.1 Query the component list

You can use the `tiup list` command to query the component list. This usage of this command is as follows:

- `tiup list`: checks which components can be installed.
- `tiup list ${component}`: checks which versions of a specific component can be installed.

You can also use the following flags in the above commands:

- `--installed`: checks which components or which version of a specific component has been installed locally. `---all`: views all components, including the hidden ones `---verbose`: views all columns (including installed versions and supported platforms)

Example 1: View all currently installed components.

```
tiup list --installed
```

Example 2: Get a list of the TiKV component of all installable versions from the server.

```
tiup list tikv
```

13.4.4.2 Install components

You can use the `tiup install` command to query the component list. This usage of this command is as follows:

- `tiup install <component>`: installs the latest stable version of a specified component.
- `tiup install <component>:[version]`: installs the specified version of a specified component.

Example 1: Use TiUP to install the latest stable version of TiDB.

```
tiup install tidb
```

Example 2: Use TiUP to install the nightly version of TiDB.

```
tiup install tidb:nightly
```

Example 3: Use TiUP to install TiKV v7.1.5.

```
tiup install tikv:v7.1.5
```

13.4.4.3 Upgrade components

After a new version of a component is published, you can use the `tiup update` command to upgrade this component. The usage of this command is basically the same as that of `tiup install`, except for the following flags:

- `--all`: Upgrades all components.
- `--nightly`: Upgrades to the nightly version.
- `--self`: Upgrades TiUP itself to the latest version.
- `--force`: Forcibly upgrades to the latest version.

Example 1: Upgrade all components to the latest versions.

```
tiup update --all
```

Example 2: Upgrade all components to the nightly version.

```
tiup update --all --nightly
```

Example 3: Upgrade TiUP to the latest version.

```
tiup update --self
```

13.4.4.4 Operate components

After the installation is complete, you can use the `tiup <component>` command to start the corresponding component:

```
tiup [flags] <component>[:version] [args...]

Flags:
  -T, --tag string                Specifies the tag for the component
      ↪ instance.
```

To use this command, you need to specify the component name and the optional version. If no version is specified, the latest stable version (installed) of this component is used.

Before the component is started, TiUP creates a directory for it, and then puts this component into the directory for operation. The component generates all the data in this directory, and the name of this directory is the tag name specified when the component

operates. If no tag is specified, a tag name is randomly generated. This working directory will be *automatically deleted* when the instance is terminated.

If you want to start the same component multiple times and reuse the previous working directory, you can use `--tag` to specify the same name when the component is started. After the tag is specified, the working directory will *not be automatically deleted* when the instance is terminated, which makes it convenient to reuse the working directory.

Example 1: Operate TiDB v7.1.5.

```
tiup tidb:v7.1.5
```

Example 2: Specify the tag with which TiKV operates.

```
tiup --tag=experiment tikv
```

13.4.4.4.1 Query the operating status of a component

You can use the `tiup status` command to check the operating status of a component:

```
tiup status
```

By executing this command, you will get a list of instances, one instance per line. The list contains the following columns:

- `Name`: The tag name of the instance.
- `Component`: The component name of the instance.
- `PID`: The process ID of the operating instance.
- `Status`: The instance status. `RUNNING` means that the instance is operating. `TERM` means that the instance is terminated.
- `Created Time`: The starting time of the instance.
- `Directory`: The working directory of the instance, which can be specified using `--tag`.
- `Binary`: The executable program of the instance, which can be specified using `--binpath`.
- `Args`: The arguments of the operating instance.

13.4.4.4.2 Clean component instance

You can use the `tiup clean` command to clean up component instances and delete the working directory. If the instance is still operating before the cleaning, the related process is killed first. The command usage is as follows:

```
tiup clean [tag] [flags]
```

The following flag is supported:

- `--all`: Cleans up all instance information.

In the above command, `tag` is the instance tag to be cleaned. If `--all` is used, no tag is passed.

Example 1: Clean up the component instance with the `experiment` tag name.

```
tiup clean experiment
```

Example 2: Clean up all component instances.

```
tiup clean --all
```

13.4.4.4.3 Uninstall components

The components installed using TiUP take up local disk space. If you do not want to keep too many components of old versions, you can check which versions of a component are currently installed, and then uninstall this component.

You can use the `tiup uninstall` command to uninstall all versions or specific versions of a component. This command also supports uninstalling all components. The command usage is as follows:

```
tiup uninstall [component][:version] [flags]
```

The following flags are supported in this command:

- `--all`: Uninstalls all components or versions.
- `--self`: Uninstalls TiUP itself.

`component` is the component to be uninstalled. `version` is the version to be uninstalled. Both `component` and `version` can be ignored in the `tiup uninstall` command. If you ignore either one of these two, you need to add the `--all` flag.

- If the version is ignored, adding `--all` means to uninstall all versions of this component.
- If the version and the component are both ignored, adding `--all` means to uninstall all components of all versions.

Example 1: Uninstall TiDB v7.1.5.

```
tiup uninstall tidb:v7.1.5
```

Example 2: Uninstall TiKV of all versions.

```
tiup uninstall tikv --all
```

Example 3: Uninstall all installed components.

```
tiup uninstall --all
```

13.4.5 TiUP FAQs

This document collects the frequently asked questions (FAQs) about TiUP.

13.4.5.1 Can TiUP not use the official mirror source?

TiUP supports specifying the mirror source through the `TIUP_MIRRORS` environment variable. The address of the mirror source can be a local directory or an HTTP server address. If your environment cannot access the network, you can create your own offline mirror source to use TiUP.

After using an unofficial mirror, if you want the official mirror back and use it, take one of the following measures:

- Set the `TIUP_MIRRORS` variable to the official mirror address: `https://tiup-mirrors.pingcap.com`.
- Make sure that the `TIUP_MIRRORS` variable is not set, and then execute the `tiup mirror set https://tiup-mirrors.pingcap.com` command.

13.4.5.2 How do I put my own component into the TiUP mirrors?

TiUP does not support third-party components for the time being, but the TiUP Team has developed the TiUP component development specifications and is developing the tiup-publish component. After everything is ready, a contributor can publish their own components to TiUP's official mirrors by using the `tiup publish <comp> <version>` command.

13.4.5.3 What is the difference between the TiUP playground and TiUP cluster components?

The TiUP playground component is mainly used to build a stand-alone development environment on Linux or macOS operating systems. It helps you get started quickly and run a specified version of the TiUP cluster easily. The TiUP cluster component is mainly used to deploy and maintain a production environment cluster, which is usually a large-scale cluster.

13.4.5.4 How do I write the topology file for the TiUP cluster component?

Refer to these templates to write the topology file. The templates include:

- Multi-DC deployment topology
- Minimal deployment topology
- Complete topology file

You can edit your topology file based on the templates and your needs.

13.4.5.5 Can multiple instances be deployed on the same host?

You can use the TiUP cluster component to deploy multiple instances on the same host, but with different ports and directories configured; otherwise, directory and port conflicts might occur.

13.4.5.6 Are port and directory conflicts detected within the same cluster?

Port and directory conflicts in the same cluster are detected during deployment and scaling. If there is any directory or port conflict, the deployment or scaling process is interrupted.

13.4.5.7 Are port and directory conflicts detected among different clusters?

If multiple different clusters are deployed by the same TiUP control machine, the port and directory conflicts among these clusters are detected during deployment and scaling. If the clusters are deployed by different TiUP control machines, conflict detection is not supported currently.

13.4.5.8 During cluster deployment, TiUP received an `ssh: handshake failed: read tcp 10.10.10.34:38980 -> 10.10.10.34:3600: read: connection reset by peer` error

The error might occur because the default number of concurrent threads of TiUP exceeds the default maximum number of SSH connections. To solve the issue, you can increase the default number of SSH connections, and then restart the sshd service:

```
vi /etc/ssh/sshd_config
```

```
MaxSessions 1000
MaxStartups 1000
```

13.4.6 TiUP Troubleshooting Guide

This document introduces some common issues when you use TiUP and the troubleshooting methods. If this document does not include the issues you bump into, file a new issue in the Github TiUP repository.

13.4.6.1 Troubleshoot TiUP commands

13.4.6.1.1 Can't see the latest component list using `tiup list`

TiUP does not update the latest component list from the mirror server every time. You can forcibly refresh the component list by running `tiup list`.

13.4.6.1.2 Can't see the latest version information of a component using `tiup list <component>`

Same as the previous issue, the component version information is only obtained from the mirror server when there is no local cache. You can refresh the component list by running `tiup list <component>`.

13.4.6.1.3 Component downloading process is interrupted

Unstable network might result in an interrupted component downloading process. You can try to download the component again. If you cannot download it after trying multiple times, it might be caused by the CDN server and you can report the issue here.

13.4.6.1.4 A checksum error occurs during component downloading process

Because the CDN server has a short cache time, the new checksum file might not match the component package. Try to download again after 5 minutes. If the new checksum file still does not match the component package, report the issue here.

13.4.6.2 Troubleshoot TiUP cluster component

13.4.6.2.1 `unable to authenticate, attempted methods [none publickey]` is prompted during deployment

During deployment, component packages are uploaded to the remote host and the initialization is performed. This process requires connecting to the remote host. This error is caused by the failure to find the SSH private key to connect to the remote host.

To solve this issue, confirm whether you have specified the private key by running `tiup cluster deploy -i identity_file`:

- If the `-i` flag is not specified, it might be that TiUP does not automatically find the private key path. It is recommended to explicitly specify the private key path using `-i`.
- If the `-i` flag is specified, it might be that TiUP cannot log in to the remote host using the specified private key. You can verify it by manually executing the `ssh -i identity_file user@remote` command.
- If a password is used to log in to the remote host, make sure that you have specified the `-p` flag and entered the correct login password.

13.4.6.2.2 The process of upgrading the cluster using the TiUP cluster component is interrupted

To avoid misuse cases, the TiUP cluster component does not support the upgrade of specified nodes, so after the upgrade fails, you need to perform the upgrade operations again, including idempotent operations during the upgrade process.

The upgrade process can be divided into the following steps:

1. Back up the old version of components on all nodes
2. Distribute new components to remote
3. Perform a rolling restart to all components

If the upgrade is interrupted during a rolling restart, instead of repeating the `tiup cluster upgrade` operation, you can use `tiup cluster restart -N <node1> -N <node2>` to restart the nodes that have not completed the restart.

If the number of un-restarted nodes of the same component is relatively large, you can also restart a certain type of component by running `tiup cluster restart -R <component>`.

13.4.6.2.3 During the upgrade, you find that `node_exporter-9100.service/blackbox_expor` does not exist

If you previously migrated your cluster from TiDB Ansible and the exporter was not deployed in TiDB Ansible, this situation might happen. To solve it, you can manually copy the missing files from other nodes to the new node for the time being. The TiUP team will complete the missing components during the migration process.

13.4.7 Command Reference

13.4.7.1 TiUP Reference

TiUP serves as the package manager of the TiDB ecosystem. It manages components in the TiDB ecosystem, such as TiDB, PD, and TiKV.

13.4.7.1.1 Syntax

```
tiup [flags] <command> [args...]   # Executes a command
#### or
tiup [flags] <component> [args...] # Runs a component
```

You can use the `--help` command to get the information of a specific command. The summary of each command shows its parameters and their usage. Mandatory parameters are shown in angle brackets, and optional parameters are shown in square brackets.

`<command>` represents the command name. For the list of supported commands, see the Command list below. `<component>` represents the component name. For the list of supported components, see the Component list below.

13.4.7.1.2 Options

–binary

- If you enable this option, the specified binary file path is printed.
    - Executing `tiup --binary <component>` will have the path of the latest stable installed `<component>` component printed. If `<component>` is not installed, an error is returned.
    - Executing `tiup --binary <component>:<version>` will have the path of the installed `<component>` component's `<version>` printed. If this `<version>` is not printed, an error is returned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be used in commands of the `tiup [flags] <component > [args...]` format.

–binpath

> **Note:**
>
> This option can only be used in commands of the `tiup [flags] <component > [args...]` format.

- Specifies the path of the component to be executed. When a component is executed, if you do not want to use the binary file in the TiUP mirror, you can add this option to specify using the binary file in a custom path.
- Data type: `STRING`

-T, –tag

- Specifies a tag for the component to be started. Some components need to use disk storage during the execution, and TiUP allocates a temporary storage directory for this execution. If you want TiUP to allocate a fixed directory, you can use `-T/--tag` to specify the name of the directory, so that the same batch of files can be read and written in multiple executions with the same tag.
- Data type: `STRING`

-v, –version

Prints the TiUP version.

–help

Prints the help information.

13.4.7.1.3 Command list

TiUP has multiple commands, and these commands have multiple sub-commands. For the specific commands and their detailed descriptions, click the corresponding links in the list below:

- install: Installs a component.
- list: Shows the component list.
- uninstall: Uninstalls a component.
- update: Updates the installed component.
- status: Shows the running status of a component.
- clean: Cleans the data directory of a component.
- mirror: Manages the mirror.
- telemetry: Enables or disables the telemetry.
- completion: Completes the TiUP command.
- env: Shows the TiUP-related environment variables.
- help: Shows the help information of a command or component.

13.4.7.1.4 Component list

- cluster: Manages the TiDB cluster in a production environment.
- dm: Manages the TiDB Data Migration (DM) cluster in a production environment.

13.4.7.2 TiUP Commands

13.4.7.2.1 tiup clean

The `tiup clean` command is used to clear the data generated during component operation.

Syntax

```
tiup clean [name] [flags]
```

The value of `[name]` is the `Name` field output by the `status` command. If `[name]` is omitted, you must add the `--all` option in the `tiup clean` command.

Option

–all

- Clears all operation records
- Data type: Boolean
- Default: false

Output

```
Clean instance of `%s`, directory: %s
```

<< Back to the previous page - TiUP Reference command list

13.4.7.2.2 tiup completion

To reduce user costs, TiUP provides the `tiup completion` command to generate a configuration file for automatic command-line completion. Currently, TiUP supports completing `bash` and `zsh` commands.

If you want to complete `bash` commands, you need to install `bash-completion` first. See the following instructions:

- On macOS: If your bash version is earlier than 4.1, run `brew install bash-completion`; otherwise, run `brew install bash-completion@2`.
- On Linux: Use a package manager to install `bash-completion`. For example, run `yum install bash-completion` or `apt install bash-completion`.

Syntax

```
tiup completion <shell>
```

`<shell>` is used to set the type of shell you use. Currently, `bash` and `zsh` are supported.

Usage

bash

Write the `tiup completion bash` command into a file and source the file in `.bash_profile`. See the following example:

```
tiup completion bash > ~/.tiup.completion.bash

printf "
##### tiup shell completion
source '$HOME/.tiup.completion.bash'
" >> $HOME/.bash_profile

source $HOME/.bash_profile
```

zsh

```
tiup completion zsh > "${fpath[1]}/_tiup"
```

<< Back to the previous page - TiUP Reference command list

13.4.7.2.3 tiup env

TiUP provides users with flexible and customized interfaces, some of which are implemented using environment variables. The `tiup env` command is used to query the user-defined environment variables that TiUP supports and their values.

Syntax

```
tiup env [name1...N]
```

`[name1...N]` is used to view the specified environment variables. If it is not specified, all supported environment variables are viewed by default.

Option

None

Output

- If `[name1...N]` is not specified, a list of "{key}"="{value}" is output.
- If `[name1...N]` is specified, the "{value}" list is output in order.

In the above output, if `value` is empty, it means that the value of the environment variable is not set. In this case, TiUP uses the default value.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.4 tiup help

The TiUP command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option.

Syntax

```
tiup help [command]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of TiUP is viewed.

Option

None

Output

The help information of `[command]` or TiUP.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.5 tiup install

The `tiup install` command is used for component installation. It downloads the component package of a specified version from the mirror repository and decompresses it in the local TiUP data directory for later use. In addition, when TiUP needs to run a component that does not exist in the mirror repository, it tries to download the component first and then runs it automatically. If the component does not exist in the repository, an error is reported.

Syntax

```
tiup install <component1>[:version] [component2...N] [flags]
```

`<component1>` and `<component2>` represent component names, and `[version]` represents an optional version number. If `version` is not added, the latest stable version of the specified component is installed. `[component2...N]` means that you can specify multiple components or multiple versions of the same component at the same time.

Option

None

Output

- Normally outputs the download information of the component.
- If the component does not exist, the `The component "%s" not found` error is reported.
- If the version does not exist, the `version %s not supported by component %s` error is reported.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.6 tiup list

The command `tiup list` is used to get the list of available components of a mirror.

Syntax

```
tiup list [component] [flags]
```

`[component]` is an optional parameter used to specify a certain component. If `[component]` is set, TiUP lists all versions of the specified component; if not, TiUP lists all components.

Options

–all

- Displays all components. By default, TiUP does not show hidden components.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–installed

- Only displays components and versions that have been installed.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–verbose

- Displays installed component versions in the components list.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `[component]` is not set:
  - If `--verbose` is specified: TiUP outputs a component information list consisting of `Name` (component name), `Installed` (installed versions), `Owner` (component owner), and `Description` (component description).

- If `--verbose` is not specified: TiUP outputs a component information list consisting of `Name` (component name), `Owner` (component owner), and `Description` (component description).

- If `[component]` is set:
  - If the specified component exists: TiUP outputs a version information list of the specified component, consisting of `Version` (version number), `Installed` (installation status), `Release` (release date), and `Platforms` (supported platforms).
  - If the specified component does not exist: TiUP reports the error `failed to fetch component: unknown component`.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.7 tiup mirror

tiup mirror

In TiUP, mirror is an important concept. TiUP currently supports two forms of mirroring:

- Local mirror: the TiUP client and the mirror are on the same machine, and the client accesses the mirror through the file system.
- Remote mirror: the TiUP client and the mirror are not on the same machine, and the client accesses the mirror through network.

The `tiup mirror` command is used to manage mirrors and provides ways to create mirrors, distribute components, and manage keys.

Syntax

```
tiup mirror <command> [flags]
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the command list below.

Option

None

Command list

- genkey: generates the private key file
- sign: signs a specific file using a private key file
- init: initiates an empty mirror
- set: sets the current mirror
- grant: grants a new component owner for the current mirror
- publish: publishes new components to the current mirror

- modify: modifies the attributes of the components in the current mirror
- rotate: updates the root certificate in the current mirror
- clone: clones a new mirror from an existing one
- merge: merges mirrors

<< Back to the previous page - TiUP Reference command list

tiup mirror clone

The command `tiup mirror clone` is used to clone an existing mirror or clone some of its components to create a new mirror. The new mirror has the same components as the old one, but uses a different signature key.

Syntax

```
tiup mirror clone <target-dir> [global version] [flags]
```

- `<target-dir>` is used to set the local path to the cloned mirror. If the path does not exist, TiUP automatically creates one.
- If `[global version]` is specified, TiUP tries to clone all components of the specified version. If some components do not have the specified version, then TiUP clones its latest version.

Options

-f, –full

- Whether to clone the whole mirror. If this option is set, other options becomes ignored and TiUP completely clones all components of all versions from the targeted mirror.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-a, –arch

- Only clones components that can run on the specified platform.
- Data type: `STRING`
- Default: “amd64,arm64”

-o, –os

- Only clones components that can run on the specified operating system.
- Data type: `STRING`
- Default: “linux,darwin”

–prefix

- Whether to only match the prefix of versions. By default, TiUP downloads a component version when it is strictly matched. If this option is set, TiUP also downloads component versions of which prefixes are matched.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–{component}

- Specifies the version list of the component to be cloned. Fill component names in `{component}`. You can run `tiup list --all` to view available component names.
- Data type: Strings
- Default: Null

<< Back to the previous page - TiUP Mirror command list

tiup mirror genkey

TiUP mirror, according its definition, has three roles of users:

- Mirror administrators: They have the permission to modify `root.json`, `index.json`, `snapshot.json`, and `timestamp.json`.
- Component owners: They have the permission to modify the corresponding component.
- Normal users: They can download and use the components.

Because TiUP requires the signature of the corresponding owner/administrator to modify a file, owners/administrators must have his or her own private key. The command `tiup mirror genkey` is used to generate a private key.

> **Warning:**
>
> **DO NOT** transmit private keys over the Internet.

Syntax

```
tiup mirror genkey [flags]
```

Options

-n, –name

- Specifies the name of the key, which also determines the name of the final generated file. The path of the generated private key file is `${TIUP_HOME}/keys/{name}.json`. `TIUP_HOME` refers to the home directory of TiUP, which is `$HOME/.tiup` by default. `name` refers to the private key name that `-n/--name` specifies.
- Data type: `STRING`
- Default: "private"

-p, –public

- Shows the corresponding public key of the private key specified in the option `-n/--name`.
- TiUP does not create a new private key when `-p/--public` is specified. If the private key specified in `-n/--name` does not exist, TiUP returns an error.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–save

- Saves the information of the public key as a file in the current directory. The file name is `{hash-prefix}-public.json`. `hash-prefix` is the first 16 bits of the key ID.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `-p/--public` is not specified:
  - If the private key specified in `-n/--name` exists: TiUP outputs `Key already exists, skipped`.
  - If the private key specified in `-n/--name` does not exist: TiUP outputs `private key have been write to ${TIUP_HOME}/keys/{name}.json`.
- If `-p/--public` is specified:
  - If the private key specified in `-n/--name` does not exist: TiUP reports the error `Error: open ${TIUP_HOME}/keys/{name}.json: no such file or directory`.
  - If the private key specified in `-n/--name` exists: TiUP outputs the content of the corresponding public key.

<< Back to the previous page - TiUP Mirror command list

tiup mirror grant

The `tiup mirror grant` command is used to introduce a component owner to the current mirror.

Component owners can use their keys to publish new components or to modify components they previously published. Before adding a new component owner, the component owner to be added needs to send his or her own public key to the mirror administrator.

> **Note:**
>
> This command is only supported when the current mirror is a local mirror.

Syntax

```
tiup mirror grant <id> [flags]
```

`<id>` stands for the component owner's ID, which must be unique in the whole mirror. It is recommended to use an ID that matches the regular expression `^[a-z\d](?:[a-z\d]|-(?=[a-z\d])){0,38}$`.

Options

-k, –key

- Specifies the key of the introduced component owner. This key can either be public or private. If it is a private key, TiUP converts it to the corresponding public key before storing it in the mirror.
- A key can be used by only one component owner.
- Data type: `STRING`
- Default: "${TIUP_HOME}/keys/private.json"

-n, –name

- Specifies the name of the component owner. The name is displayed on the `Owner` field of the component list. If `-n/--name` is not specified, `<id>` is used as the component owner's name.
- Data type: `STRING`
- Default: `<id>`

Outputs

- If the command is executed successfully, there is no output.

- If the component owner's ID is duplicated, TiUP reports the error `Error: owner %s exists`.
- If the key is used by another component owner, TiUP reports the error `Error: key %s exists`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror init

The command `tiup mirror init` is used to initialize an empty mirror. The initialized mirror does not contain any components or component owners. The command only generates the following files for the initialized mirror:

```
+ <mirror-dir>                                # Mirror's root directory
|-- root.json                                 # Mirror's root certificate
|-- 1.index.json                              # Component/user index
|-- snapshot.json                             # Mirror's latest snapshot
|-- timestamp.json                            # Mirror's latest timestamp
|--+ keys                                     # Mirror's private key (can be
   ↪ moved to other locations)
   |-- {hash1..hashN}-root.json               # Private key of the root
      ↪ certificate
   |-- {hash}-index.json                      # Private key of the indexes
   |-- {hash}-snapshot.json                   # Private key of the snapshots
   |-- {hash}-timestamp.json                  # Private key of the timestamps
```

For the specific usage and content format of the above files, refer to TiUP Mirror Reference Guide.

Syntax

```
tiup mirror init <path> [flags]
```

`<path>` is used to specify a local directory where TiUP generates and stores mirror files. The local directory can be a relative path. If the specified directory already exists, it must be empty; if it does not exist, TiUP creates it automatically.

Options

-k, –key-dir

- Specifies the directory where TiUP generates private key files. If the specified directory does not exist, TiUP automatically creates it.
- Data type: `STRING`
- If this option is not specified in the command, TiUP generates private key files in `{path}/keys` by default.

Outputs

- If the command is executed successfully, there is no output.
- If the specified `<path>` is not empty, TiUP reports the error `Error: the target path '%s' is not an empty directory`.
- If the specified `<path>` is not a directory, TiUP reports the error `Error: fdopendir: not a directory`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror merge

The `tiup mirror merge` command is used to merge one or more mirrors to the current mirror.

To execute this command, the following conditions must be met:

- The owner IDs of all components of the target mirror exist in the current mirror.
- The `${TIUP_HOME}/keys` directory of the user who executes this command contains all the private keys corresponding to the above owner IDs in the current mirror (you can use the command `tiup mirror set` to switch the current mirror to the mirror that is currently authorized to modify).

Syntax

```
tiup mirror merge <mirror-dir-1> [mirror-dir-N] [flags]
```

- `<mirror-dir-1>`: the first mirror to be merged into the current mirror
- `[mirror-dir-N]`: the Nth mirror to be merged into the current mirror

Option

None

Outputs

- If the command is executed successfully, there is no output.
- If the current mirror does not have a component owner of the target mirror, or if `${TIUP_HOME}/keys` does not have the owner's private key, TiUP reports the `Error: missing owner keys for owner %s on component %s` error.

<< Back to the previous page - TiUP Mirror command list

tiup mirror modify

The `tiup mirror modify` command is used to modify published components. Only valid component owners can modify the components that they have published on their own. For the method to publish a component, refer to the `publish` command.

Syntax

```
tiup mirror modify <component>[:version] [flags]
```

Each parameter is explained as follows:

- `<component>`: the component name
- `[version]`: the component version to modify. If it is not specified, the entire component is modified.

Options

-k, –key

- Specifies the component owner's private key used for signing the component information (`{component}.json`).
- Data type: `STRING`
- If this option is not specified in the command, `"${TIUP_HOME}/keys/private.json"` is used by default to sign the component information.

–yank

Marks a specified component or version as unavailable.

- After the component is marked as unavailable, you can neither see it in the result list of `tiup list` nor install the new version of the component.
- After a component version is marked as unavailable, you can neither see it in the result list of `tiup list <component>` nor install this version.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–hide

- Specifies whether to hide the component. If a component is hidden, you cannot see it in the result list of `tiup list`. To see the hidden component, you can use `tiup list --all`.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be applied to the component, not to the component version.

–standalone

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be applied to the component, not to the component version.

Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
    - If the mirror is a remote mirror, TiUP reports the error `Error: The server refused, make sure you have access to this component`.
    - If the mirror is a local mirror, TiUP reports the error `Error: the signature is not correct`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror publish

The command `tiup mirror publish` is used to publish a new component or a new version of an existing component. Only component owner that has the access to the target component can publish it. To add a new component owner, see the usage of the grant command.

Syntax

```
tiup mirror publish <comp-name> <version> <tarball> <entry> [flags]
```

The meaning of each parameter is as follows:

- `<comp-name>`: The name of the components, such as `tidb`. It is recommended to use a string that matches the regular expression `^[a-z\d](?:[a-z\d]|-(?=[a-z\d])){0,38}$`.
- `<version>`: The version of the component to be published. The version number needs to follow the requirements of Semantic Versioning.
- `<tarball>`: The local directory of the `.tar.gz` package. You need to put dependencies and the executable file of the component in this package. TiUP uploads this package to the mirror.
- `<entry>`: The location of the component's executable file in `<tarball>`.

Options

-k, –key

- Specifies the component owner's private key. The client uses the private key to sign `{component}.json` files.
- Data type: `STRING`
- Default: "${TIUP_HOME}/keys/private.json"

–arch

- Specifies the platform on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the platform from the following options:
  - `amd64`: Indicates that the files run on AMD64 machines.
  - `arm64`: Indicates that the files run on ARM64 machines.
  - `any`: Indicates that the files, such as scripts, run on both AMD64 and ARM64 machines.
- Data type: `STRING`
- Default: "${GOARCH}"

> **Note:**
>
> If `--arch` is set to `any`, then `--os` must be set to `any` as well.

–os

- Specifies the operating system on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the operating system from the following options:
    - `linux`: Indicates that the files run on the Linux operating system.
    - `darwin`: Indicates that the files run on the Darwin operating system.
    - `any`: Indicates that the files, such as scripts, run on both the Linux and Darwin operating systems.
- Data type: `STRING`
- Default: "${GOOS}"

> **Note:**
>
> If `--os` is set to `any`, then `--arch` must be set to `any` as well.

–desc

- Specifies the description of the component.
- Data type: `String`
- Default: NULL

–hide

- Specifies whether the component is hidden. If it is a hidden component, it can be seen in the result list of `tiup list -all`, but not in that of `tiup list`.
- Data type: `STRING`
- Default: NULL

–standalone

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
    - If the mirror is a remote mirror, TiUP reports the error `Error: The server refused, make sure you have access to this component`.
    - If the mirror is a local mirror, TiUP reports the error `Error: the signature is not correct`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror rotate

`root.json` is an important file in a TiUP mirror. It stores the public keys needed for the entire system and is the basis of the chain of trust in TiUP. It mainly contains the following parts:

- Signatures of mirror administrators. For the official mirror, there are five signatures. For an initialized mirror, there are three signatures by default.
- The public keys used to verify the following files:
    - root.json
    - index.json
    - snapshot.json
    - timestamp.json
- Expiration date of `root.json`. For the official mirror, the expiration date is one year later than the creation date of `root.json`.

For detailed description of TiUP mirror, see TiUP Mirror Reference.

You need to update `root.json` in the following cases:

- Replace the key of the mirror.
- Update the expiration date of certificate files.

After the content of `root.json` is updated, the file must be re-signed by all administrators; otherwise, the client rejects the file. The update process is as follows:

1. The user (client) updates the content of `root.json`.
2. All administrators sign the new `root.json` file.
3. tiup-server updates `snapshot.json` to record the version of the new `root.json` file.
4. tiup-server signs the new `snapshot.json` file.
5. tiup-server updates `timestamp.json` to record the hash value of the new `snapshot.json` file.
6. tiup-server signs the new `timestamp.json` file.

TiUP uses the command `tiup mirror rotate` to automate the above process.

Note:

- For TiUP versions earlier than v1.5.0, running this command does not returns a correct new `root.json` file. See #983.
- Before using this command, make sure that all TiUP clients are upgraded to v1.5.0 or a later version.

Syntax

```
tiup mirror rotate [flags]
```

After executing this command, TiUP starts an editor for the user to modify the file content to the target value, such as changing the value of the `expires` field to a later date. Then, TiUP changes the `version` field from `N` to `N+1` and saves the file. After the file is saved, TiUP starts a temporary HTTP server and waits for all mirror administrators to sign the file.

For how mirror administrators sign files, refer to the `sign` command.

Options

–addr

- Specifies the listening address of the temporary server. You need to make sure that the address is accessible to other mirror administrators so that they can use the `sign` command to sign the file.
- Data type: `STRING`
- If this option is not specified in the command, TiUP listens on `0.0.0.0:8080` by default.

Outputs

The current signature status of each mirror administrator.

<< Back to the previous page - TiUP Mirror command list

tiup mirror set

The `tiup mirror set` command is used to switch the current mirror and supports two forms of mirrors: local file system and remote network address.

The address of the official mirror is `https://tiup-mirrors.pingcap.com`.

Syntax

```
tiup mirror set <mirror-addr> [flags]
```

`<mirror-addr>` is the mirror address, which has two forms:

- Network address: starts with `http` or `https`. For example, `http://172.16.5.5:8080`, `https://tiup-mirrors.pingcap.com`.
- Local file path: the absolute path of the mirror directory. For example, `/path/to/local-tiup-mirror`.

Option

-r, –root

This option specifies the root certificate.

As the most critical part of mirror security, the root certificate of each mirror is different from one another. When you use the network mirror, it might suffer from man-in-the-middle attacks. To avoid such attacks, it is recommended to manually download the root certificate of the root network mirror to the local:

```
wget <mirror-addr>/root.json -O /path/to/local/root.json
```

Perform a manual check to ensure that the root certificate is correct, and then switch the mirror by manually specifying the root certificate:

```
tiup mirror set <mirror-addr> -r /path/to/local/root.json
```

In the steps above, if the mirror is attacked before the `wget` command, you can find that the root certificate is incorrect. If the mirror is attacked after the `wget` command, TiUP will find that the mirror does not match the root certificate.

- Data type: `String`
- Default: `{mirror-dir}/root.json`

Output

None

<< Back to the previous page - TiUP Mirror command list

tiup mirror sign

The `tiup mirror sign` command is used to sign the metadata files (*.json) defined in TiUP mirror. These metadata files might be stored on the local file system or remotely stored using the HTTP protocol to provide a signature entry.

Syntax

```
tiup mirror sign <manifest-file> [flags]
```

`<manifest-file>` is the address of the file to be signed, which has two forms:

- Network address, which starts with HTTP or HTTPS, such as `http://172.16.5.5:8080/rotate/root.json`
- Local file path, which is a relative path or an absolute path

If it is a network address, this address must provide the following features:

- Supports the access via `http get` that returns the complete content of the signed file (including the `signatures` field).
- Supports the access via `http post`. The client adds the signature to the `signatures` field of the content that is returned by `http get` and posts to this network address.

Options

-k, –key

- Specifies the location of the private key used for signing the `{component}.json` file.
- Data type: `STRING`
- - If this option is not specified in the command, `"${TIUP_HOME}/keys/private.json"` is used by default.

–timeout

- Specifies the access timeout time for signing through the network. The unit is in seconds.
- Data type: `INT`
- Default: 10

> **Note:**
>
> This option is valid only when `<manifest-file>` is a network address.

Output

- If the command is executed successfully, there is no output.
- If the file has been signed by the specified key, TiUP reports the error `Error: this manifest file has already been signed by specified key`.
- If the file is not a valid manifest, TiUP reports the error `Error: unmarshal manifest : %s`.

<< Back to the previous page - TiUP Mirror command list

13.4.7.2.8 tiup status

The `tiup status` command is used to view the operation information of the components after you run the components using the `tiup [flags] <component> [args...]` command.

> **Note:**
>
> You can only check the information of the following components:
>
> - Components that are still in operation
> - Components that run through the tag specified by `tiup -T/--tag`

Syntax

```
tiup status [flags]
```

Option

None

Output

A table consisting of the following fields:

- `Name`: The tag name specified by `-T/--tag`. If not specified, it is a random string.
- `Component`: The operating components.
- `PID`: The corresponding process ID of the operating components.
- `Status`: The status of the operating components.
- `Created Time`: The starting time of the components.
- `Directory`: The data directory of the components.
- `Binary`: The binary file path of the components.
- `Args`: The starting arguments of the operating components.

Component status

A component can run in one of the following statuses:

- Up: The component is running normally.
- Down or Unreachable: The component is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the component has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- Pending Offline: The data on the component is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- Unknown: The running status of the component is unknown.

> **Note:**
>
> `Pending Offline` in TiUP, `Offline` returned by PD API, and `Leaving` in TiDB Dashboard indicate the same status.

Component status derives from the PD scheduling information. For more details, see Information collection.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.9 tiup telemetry

Starting from v1.11.3, the telemetry is disabled by default in newly deployed TiUP, and usage information is not collected and shared with PingCAP. In versions earlier than v1.11.3, the telemetry is enabled by default in TiUP, and usage information is collected and shared with PingCAP to improve the product.

When TiUP telemetry is enabled, usage information is shared with PingCAP when TiUP commands are executed, including (but not limited to):

- Randomly generated telemetry identifiers.
- The execution status of the TiUP command, such as whether the command execution is successful and the duration of command execution.
- Situations using TiUP for deployment, such as target machine hardware information, component version number, and modified deployment configuration name.

The information below is not shared:

- The accurate name of the cluster
- The cluster topology
- The cluster configuration file

TiUP uses the `tiup telemetry` command to control telemetry.

Syntax

```
tiup telemetry <command>
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the commands section below.

Commands

status

The `tiup telemetry status` command is used to view the current telemetry settings and output the following information:

- `status`: specifies enabling or disabling the telemetry `(enable|disable)`.
- `uuid`: specifies the randomly generated telemetry identifiers.

reset

The `tiup telemetry reset` command is used to reset the current telemetry identifier and replaces it with a new random identifier.

enable

The `tiup telemetry enable` command is used to enable the telemetry.

disable

The `tiup telemetry disable` command is used to disable the telemetry.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.10 tiup uninstall

The `tiup uninstall` command is used to uninstall the installed components.

Syntax

```
tiup uninstall <component1>:<version> [component2...N] [flags]
```

- `<component1>`: the name of the component to uninstall.
- `<version>`: the version to uninstall. If this field is omitted, all installed versions of the component are uninstalled. For security reasons, the `--all` option must be added when `<version>` is omitted, indicating that all versions of a component need to be uninstalled.
- `[component2...N]`: multiple components or versions to uninstall.

Options

–all

- Uninstalls all installed versions of the specified component(s). You must use this option when `<version>` is omitted.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–self

- Uninstalls TiUP itself. When this option is used, all data downloaded from the mirror is deleted, but the data generated by TiUP and its components is retained. The data is stored in the directory specified by the `TIUP_HOME` environment variable. If `TIUP_HOME` is not set, the default value is `~/.tiup/`.

- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the command exits without any error, `Uninstalled component "%s" successfully ↪ !` is output.
- If neither `<version>` nor `--all` is specified, the `Use "tiup uninstall tidbx --all ↪ " if you want to remove all versions.` error is reported.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.11 tiup update

The `tiup update` command is used to update the installed components or TiUP itself.

Syntax

```
tiup update [component1][:version] [component2..N] [flags]
```

- `[component1]`: the name of the component to update.
- `[version]`: the version to update. If this field is omitted, it means updating to the latest stable version of the component.
- `[component2...N]`: specifies updating multiple components or versions. If no component is specified, which means `[component1][:version] [component2..N]` is empty, you need to use the `--all` or the `--self` option together.

The update operation does not delete the old version. You can still specify using the old version during execution.

Options

–all

- If no component is specified, this option must be specified.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–force

- If the specified version of the component is already installed, the update operation is skipped by default. Specifying this option will have the installed version forcibly updated.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–nightly

- Updates the specified components to the nightly version. The `tiup update` command with this option is equivalent to the `tiup update <component>:nightly` command.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–self

- Updates TiUP itself.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the update is successful, `Updated successfully!` is output.
- If target version does not exist, the `Error: version %s not supported by component %s` error is reported.

<< Back to the previous page - TiUP Reference command list

13.4.7.3 TiUP Cluster Commands

13.4.7.3.1 TiUP Cluster

TiUP Cluster is a cluster management component of TiUP written in Golang. You can use the TiUP Cluster component to perform daily operations and maintenance, including deploying, starting, shutting down, destroying, elastic scaling, upgrading TiDB clusters, and managing TiDB cluster parameters.

Syntax

```
tiup cluster [command] [flags]
```

`[command]` is the name of the command. For the supported commands, refer to the command list below.

Options

–ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: `STRING`
- Supported values:
  - `builtin`: uses the easyssh client built in tiup-cluster as the SSH client.
  - `system`: uses the default SSH client of the current operating system.
  - `none`: The SSH client is not used. The deployment is only for the current machine.
- If this option is not specified in the command, `builtin` is used as the default value.

–ssh-timeout

- Specifies the SSH connection timeout in seconds.
- Data type: `UINT`
- If this option is not specified in the command, the default timeout is `5` seconds.

–wait-timeout

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying systemctl to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each step is `120` seconds.

-y, –yes

- Skips the secondary confirmation of all risky operations. Using this option is not recommended, unless you are using a script to call TiUP.

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-v, –version

- Prints the current version of TiUP Cluster.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- import: imports a cluster deployed by Ansible
- template: outputs the topology template
- check: checks a cluster before and after the deployment
- deploy: deploys a cluster based on a specified topology
- list: queries the list of deployed clusters
- display: displays the status of a specified cluster
- start: starts a specified cluster
- stop: stops a specified cluster
- restart: restarts a specified cluster
- scale-in: scales in a specified cluster
- scale-out: scales out a specified cluster
- upgrade: upgrades a specified cluster
- prune: cleans up the instances in the Tombstone status for a specified cluster
- edit-config: modifies the configuration of a specified cluster
- reload: reloads the configuration of a specified cluster
- patch: replaces a service in a deployed cluster
- rename: renames a cluster
- clean: deletes data from the specified cluster
- destroy: destroys a specified cluster
- audit: queries the operation audit log of a specified cluster
- replay: retries the specified command
- enable: enables the auto-enabling of the cluster service after a machine is restarted
- disable: disables the auto-enabling of the cluster service after a machine is restarted
- meta backup: backs up the TiUP meta file required for the operation and maintenance of a specified cluster

- meta restore: restores the TiUP meta file of a specified cluster
- help: prints the help information

<< Back to the previous page - TiUP Reference component list

13.4.7.3.2 tiup cluster audit

The `tiup cluster audit` command is used to view commands executed on all clusters in the history and the execution log of each command.

Syntax

```
tiup cluster audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, it means checking the execution log of the specified `audit-id`.

Option

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `[audit-id]` is specified, the corresponding execution log is output.
- If `[audit-id]` is not specified, a table with the following fields is output:
  - ID: the `audit-id` corresponding to the record
  - Time: the execution time of the command corresponding to the record
  - Command: the command corresponding to the record

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.3 tiup cluster audit cleanup

The `tiup cluster audit cleanup` command is used to clean up the logs generated in executing the `tiup cluster`command.

Syntax

```
tiup cluster audit cleanup [flags]
```

Options

–retain-days

- Specifies the days for which logs are retained.
- Data type: `INT`
- Default value: `60`, in the unit of day.
- By default, logs generated within the last 60 days are retained, which means logs generated before 60 days are removed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

```
clean audit log successfully
```

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.4 tiup cluster check

For a formal production environment, before the environment goes live, you need to perform a series of checks to ensure the clusters are in their best performance. To simplify the manual check steps, TiUP Cluster provides the `check` command to check whether the hardware and software environments of the target machines of a specified cluster meet the requirements to work normally.

List of check items

Operating system version

Check the operating system distribution and version of the deployed machines. For a list of supported versions, see OS and platform requirements.

CPU EPOLLEXCLUSIVE

Check whether the CPU of the target machine supports EPOLLEXCLUSIVE.

numactl

Check whether `numactl` is installed on the target machine. If tied cores are configured on the target machine, you must install `numactl`.

System time

Check whether the system time of the target machine is synchronized. Compare the system time of the target machine with that of the central control machine, and report an error if the deviation exceeds a certain threshold (500 ms).

System time zone

Check whether the system time zone of the target machines is synchronized. Compare the time zone configuration of these machines and report an error if the time zone is inconsistent.

Time synchronization service

Check whether the time synchronization service is configured on the target machine. Namely, check whether ntpd is running.

Swap partitioning

Check whether swap partitioning is enabled on the target machine. It is recommended to disable swap partitioning.

Kernel parameters

Check the values of the following kernel parameters:

- `net.ipv4.tcp_tw_recycle`: 0
- `net.ipv4.tcp_syncookies`: 0
- `net.core.somaxconn`: 32768
- `vm.swappiness`: 0
- `vm.overcommit_memory`: 0 or 1
- `fs.file-max`: 1000000

Transparent Huge Pages (THP)

Check whether THP is enabled on the target machine. It is recommended to disable THP.

System limits

Check the limit values in the `/etc/security/limits.conf` file:

```
<deploy-user> soft nofile 1000000
<deploy-user> hard nofile 1000000
<deploy-user> soft stack 10240
```

`<deploy-user>` is the user who deploys and runs the TiDB cluster, and the last column is the minimum value required for the system.

SELinux

Check whether SELinux is enabled. It is required to disable SELinux.

Firewall

Check whether the FirewallD service is enabled. It is recommended to either disable the FirewallD service or add permission rules for each service in the TiDB cluster.

irqbalance

Check whether the irqbalance service is enabled. It is recommended to enable the irqbalance service.

Disk mount options

Check the mount options for ext4 partitions. Make sure the mount options include the nodelalloc option and the noatime option.

Port usage

Check if the ports defined in the topology (including the auto-completion default ports) are already used by the processes on the target machine.

> **Note:**
>
> The port usage check assumes that a cluster is not started yet. If a cluster is already deployed and started, the port usage check on the cluster fails because the ports must be in use in this case.

CPU core number

Check the CPU information of the target machine. For a production cluster, it is recommended that the number of the CPU logical core is greater than or equal to 16.

> **Note:**
>
> CPU core number is not checked by default. To enable the check, you need to add the `-enable-cpu` option to the command.

Memory size

Check the memory size of the target machine. For a production cluster, it is recommended that the total memory capacity is greater than or equal to 32GB.

> **Note:**
>
> Memory size is not checked by default. To enable the check, you need to add the `-enable-mem` option to the command.

Fio disk performance test

Use flexible I/O tester (fio) to test the performance of the disk where `data_dir` is located, including the following three test items:

- fio_randread_write_latency
- fio_randread_write
- fio_randread

> **Note:**
>
> The fio disk performance test is not performed by default. To perform the test, you need to add the `-enable-disk` option to the command.

Syntax

```
tiup cluster check <topology.yml | cluster-name> [flags]
```

- If a cluster is not deployed yet, you need to pass the topology.yml file that is used to deploy the cluster. According to the content in this file, tiup-cluster connects to the corresponding machine to perform the check.
- If a cluster is already deployed, you can use the `<cluster-name>` as the check object.
- If you want to check the scale-out YAML file for an existing cluster, you can use both `<scale-out.yml>` and `<cluster-name>` as the check objects.

> **Note:**
>
> If `<cluster-name>` is used for the check, you need to add the `--cluster` option in the command.

Options

–apply

- Attempts to automatically repair the failed check items. Currently, tiup-cluster only attempts to repair the following check items:
  - SELinux
  - firewall
  - irqbalance
  - kernel parameters
  - System limits
  - THP (Transparent Huge Pages)
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Note:

`tiup cluster check` also supports repairing the `scale-out.yml` file for an existing cluster with the following command format:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --
    ↪ apply --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

–cluster

- Indicates that the check is for a cluster that has been deployed.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.
- Command format:

```
tiup cluster check <topology.yml | cluster-name> --cluster [flags]
```

Note:

- If the `tiup cluster check <cluster-name>` command is used, you must add the `--cluster` option: `tiup cluster check <cluster-name > --cluster`.

- `tiup cluster check` also supports checking the `scale-out.yml` file for an existing cluster with the following command format:

```
shell  tiup cluster check <cluster-name> scale-out.yml --
↪ cluster --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

-N, –node

- Specifies the nodes to be checked. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are checked by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

-R, –role

- Specifies the roles to be checked. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are checked by default.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

–enable-cpu

- Enables the check of CPU core number.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–enable-disk

- Enables the fio disk performance test.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–enable-mem

- Enables the memory size check.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–u, –user

- Specifies the user name to connect to the target machine. The specified user needs to have the password-free sudo root privileges on the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the user who executes the command is used as the default value.

Note:

This option is valid only if the `-cluster` option is false. Otherwise, the value of this option is fixed to the username specified in the topology file for the cluster deployment.

-i, –identity_file

- Specifies the key file to connect to the target machine.
- Data type: `STRING`
- The option is enabled by default with `~/.ssh/id_rsa` (the default value) passed in.

Note:

This option is valid only if the `--cluster` option is false. Otherwise, the value of this option is fixed to `${TIUP_HOME}/storage/cluster/clusters/<cluster-name>/ssh/id_rsa`.

-p, –password

- Logs in with a password when connecting to the target machine.
  - If the `--cluster` option is added for a cluster, the password is the password of the user specified in the topology file when the cluster was deployed.
  - If the `--cluster` option is not added for a cluster, the password is the password of the user specified in the `-u/--user` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

A table containing the following fields:

- `Node`: the target node
- `Check`: the check item
- `Result`: the check result (Pass, Warn, or Fail)
- `Message`: the result description

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.5 tiup cluster clean

In the test environment, sometimes you might need to reset the cluster back to the state as it has been just deployed, which means deleting all data. You can do that easily using the `tiup cluster clean` command. After running it, the cluster is stopped and then cluster data is deleted. After restarting the cluster manually, you will get a clean cluster.

> **Warning:**
>
> This command will first stop the cluster even if you choose only to clean up logs. Therefore, do not use it in a production environment.

Syntax

```
tiup cluster clean <cluster-name> [flags]
```

`<cluster-name>` is the cluster to clean.

Options

–all

- Cleans data and the log at the same time. It is equivalent to specifying `--data` and `--log` at the same time.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.
- If it is not specified, you must specify at lease one of the following options:
  - –data: Cleans data
  - –log: Cleans the log

–data

- Cleans data. If neither of it nor `--all` is specified, data will not be cleaned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–log

- Cleans the log. If neither of it nor `--all` is specified, the log will not be cleaned.

- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–ignore-node

- Specifies the node that does not need cleaning. To specify multiple nodes, you can use this option multiple times. For example, `--ignore-node <node-A> --ignore-node <node-B>`.
- Data type: `StringArray`
- Default: empty

–ignore-role

- Specifies the role that does not need cleaning. To specify multiple roles, you can use this option multiple times. For example, `--ignore-role <role-A> --ignore-role <role-B>`.
- Data type: `StringArray`
- Default: empty

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.6 tiup cluster deploy

The `tiup cluster deploy` command is used to deploy a new cluster.

Syntax

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

- `<cluster-name>`: the name of the new cluster, which cannot be the same as the existing cluster names.

- `<version>`: the version number of the TiDB cluster to deploy, such as `v7.1.5`.
- `<topology.yaml>`: the prepared topology file.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option with `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–ignore-config-check

- This option is used to skip the configuration check. After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration.
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.
- Default: false

–no-labels

- This option is used to skip the label check.

- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD cannot learn the cluster topology, so PD might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See Schedule Replicas by Topology Labels for label configuration.
- For the test environment, this risk might matter and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–skip-create-user

- During the cluster deployment, tiup-cluster checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The deployment log.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.7 tiup cluster destroy

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup cluster destroy` command performs the following operations:

- Stops the cluster.

- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by tiup-cluster, also delete the parent directory.

Syntax

```
tiup cluster destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to destroy.

Options

–force

- In some cases, some nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to ignore these errors.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–retain-node-data

- Specifies the nodes that need to retain data. If you need to specify more than one node, use this option multiple times: `--retain-node-data <node-A> --retain-node-data ↪ <node-B>`.
- Data type: `StringArray`
- Default: empty

–retain-role-data

- Specifies the role that needs to retain data. If you need to specify more than one role, use this option multiple times: `--retain-role-data <role-A> --retain-role ↪ -data <role-B>`.
- Data type: `StringArray`
- Default: empty

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.8 tiup cluster disable

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup cluster disable` command. This command executes `systemctl disable <service >` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup cluster disable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be disabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.9 tiup cluster display

If you want to see the operation status of each component in the cluster, it is obviously inefficient to log in to each machine one by one. Therefore, tiup-cluster provides the `tiup cluster display` command to efficiently complete this task.

Syntax

```
tiup cluster display <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

–dashboard

- By default, all node information of the entire cluster is displayed. With the `--dashboard` option, only dashboard information is displayed.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-N, –node

- Specifies the node to display. If this option is not specified, all nodes are displayed. The value of this option is a comma-separated list of node IDs. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are checked by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

-R, –role

- Specifies the role to display. If it is not specified, all roles are displayed. The value of this option is a comma-separated list of node roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are displayed by default.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are displayed.

–process

- Displays the CPU and memory usage information of the node when this option is enabled. This option is disabled by default.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–uptime

- Displays the `uptime` information of the node when this option is enabled. This option is disabled by default.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–status-timeout

- Specifies the timeout period for obtaining the node status information.
- Data type: `INT`
- Default value: `10`, in the unit of second.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- The cluster name
- The cluster version
- SSH Client Type
- Dashboard address
- The table with the following fields:
    - ID: the node ID, composed of `IP:PORT`
    - Role: the service role deployed on this node (such as TiDB, TiKV)
    - Host: the IP of the machine corresponding to the node
    - Ports: the port number occupied by the service
    - OS/Arch: the operating system and the machine architecture of this node
    - Status: the current status of the node service
    - Data Dir: the data directory of the service. `-` means no data directory.
    - Deploy Dir: the deployment directory of the service

Node service status

A node service can run in one of the following statuses:

- Up: The node service is running normally.
- Down or Unreachable: The node service is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the node service has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- Pending Offline: The data on the node service is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- Unknown: The running status of the node service is unknown.

> **Note:**
>
> `Pending Offline` in TiUP, `Offline` returned by PD API, and `Leaving` in TiDB Dashboard indicate the same status.

Node service status derives from the PD scheduling information. For more details, see Information collection.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.10 tiup cluster edit-config

If you need to modify the cluster configuration after the cluster is deployed, you can use the `tiup cluster edit-config` command that starts an editor for you to modify the topology file of a cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

> **Note:**
>
> - When you modify the configuration, you cannot add or delete machines. For how to add machines, see Scale out a cluster. For how to delete machines, see Scale in a cluster.
> - After you execute the `tiup cluster edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup cluster reload` command to reload the configuration.

Syntax

```
tiup cluster edit-config <cluster-name> [flags]
```

`<cluster-name>` is the cluster to operate on.

Option

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

- If the command is successfully executed, there is no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error will be reported, reminding you to edit the file again. For the fields that cannot be modified, see the topology file.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.11 tiup cluster enable

The `tiup cluster enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

> **Note:**
>
> When all clusters are shut down and restarted, the order of service startup is determined by the node's operating system startup order. When the restart order is incorrect, in some cases, the restarted cluster still cannot provide services. For example, if TiKV is started first but PD is not started, systemd gives up if TiKV is restarted multiple times while PD is not found).

Syntax

```
tiup cluster enable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be enabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

Note:

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

Note:

If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.12 tiup cluster help

tiup-cluster provides a wealth of help information for users in the command line interface. You can obtain it via the `help` command or the `--help` option. `tiup cluster help <command>` is basically equivalent to `tiup cluster <command> --help`.

Syntax

```
tiup cluster help [command] [flags]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of tiup-cluster is viewed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The help information of the `[command]` or tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.13 tiup cluster import

Before TiDB v4.0, TiDB clusters were mainly deployed using TiDB Ansible. For TiDB v4.0 and later releases, TiUP Cluster provides the `import` command to transfer the clusters to the tiup-cluster component for management.

Note:

- After importing the TiDB Ansible configuration to TiUP for management, **DO NOT** use TiDB Ansible for cluster operations anymore. Otherwise, conflicts might be caused due to inconsistent meta information.
- If the clusters deployed using TiDB Ansible are in any of the following situations, do not use the `import` command.
  - Clusters with TLS encryption enabled
  - Pure KV clusters (clusters without TiDB instances)
  - Clusters with Kafka enabled
  - Clusters with Spark enabled
  - Clusters with TiDB Lightning/TiKV Importer enabled
  - Clusters still using the old `push` mode to collect monitoring metrics (if you keep the default mode `pull` unchanged, using the `import` command is supported)
  - Clusters in which the non-default ports (the ports configured in the `group_vars` directory are compatible) are separately configured in the `inventory.ini` configuration file using `node_exporter_port` / `blackbox_exporter_port`

- If some nodes in the cluster deployed using TiDB Ansible are deployed without monitoring components, you should first use TiDB Ansible to add the corresponding node information in the `monitored_servers` section of the `inventory.ini` file, and then use the `deploy.yaml` playbook to fully deploy monitoring components. Otherwise, when you perform maintenance operations after the cluster is imported into TiUP, errors might occur due to the lack of monitoring components.

Syntax

```
tiup cluster import [flags]
```

Options

-d, –dir

- Specifies the directory where TiDB Ansible is located.
- Data type: `STRING`
- The option is enabled by default with the current directory (the default value) passed in.

–ansible-config

- Specifies the path of the Ansible configuration file.
- Data type: `STRING`
- The option is enabled by default with `. /ansible.cfg` (the default value) passed in.

–inventory

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- The option is enabled by default with `inventory.ini` (the default value) passed in.

–no-backup

- Controls whether to disable the backup of files in the directory where TiDB Ansible is located.
- Data type: `BOOLEAN`

- This option is disabled by default with the `false` value. After a successful import, everything in the directory specified by the `-dir` option is backed up to the `${TIUP_HOME}/.tiup/storage/cluster/clusters/{cluster-name}/ansible-backup` directory. If there are multiple inventory files (when multiple clusters are deployed) in this directory, it is recommended to enable this option. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–rename

- Renames the imported cluster.
- Data type: `STRING`
- Default: NULL. If this option is not specified in the command, the cluster_name specified in inventory is used as the cluster name.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the import process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.14 tiup cluster list

tiup-cluster supports deploying multiple clusters using the same control machine. The `tiup cluster list` command outputs all clusters deployed by the currently logged-in user using this control machine.

> **Note:**
>
> The deployed cluster data is stored in the `~/.tiup/storage/cluster/clusters/` directory by default, so on the same control machine, the currently logged-in user cannot view the clusters deployed by other users.

Syntax

```
tiup cluster list [flags]
```

Options

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

Outputs the table with the following fields:

- Name: the cluster name
- User: the deployment user
- Version: the cluster version
- Path: the path of the cluster deployment data on the control machine
- PrivateKey: the path of the private key that is used to connect the cluster

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.15 tiup cluster meta backup

The TiUP meta file is used for cluster operation and maintenance (OM). If this file is lost, you cannot use TiUP to manage the cluster. To avoid this situation, you can use the `tiup cluster meta backup` command to back up the TiUP meta file regularly.

Syntax

```
tiup cluster meta backup <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

–file (string, defaults to the current directory)

Specifies the target directory to store the TiUP meta backup file.

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.16 tiup cluster meta restore

To restore the TiUP meta file, you can use the `tiup cluster meta restore` command to restore from the backup file.

Syntax

```
tiup cluster meta restore <cluster-name> <backup-file> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on.
- `<backup-file>` is the path to the TiUP meta backup file.

> **Note:**
>
> The restore operation overwrites the current meta file. It is recommended to restore the meta file only when it is lost.

Options

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.17 tiup cluster patch

If you need to dynamically replace the binaries of a service while the cluster is running (namely, keep the cluster available during the replacement process), you can use the `tiup cluster patch` command. After the command is executed, TiUP does the following things:

- Uploads the binary package for replacement to the target machine.
- If the target service is a storage service such as TiKV, TiFlash, or TiDB Binlog, TiUP first takes the related nodes offline via the API.
- Stops the target service.
- Unpacks the binary package and replace the service.
- Starts the target service.

Syntax

```
tiup cluster patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated.
- `<package-path>`: The path to the binary package used for replacement.

Preparation

Before running the `tiup cluster patch` command, you need to pack the binary package required. Take the following steps:

1. Determine the following variables:

    - `${component}`: the name of the component to be replaced (such as `tidb`, `tikv`, or `pd`).
    - `${version}`: the version of the component (such as `v7.1.5` or `v6.5.9`).
    - `${os}`: the operating system (`linux`).
    - `${arch}`: the platform on which the component runs (`amd64`, `arm64`).

2. Download the current component package using the command:

    ```
    wget https://tiup-mirrors.pingcap.com/${component}-${version}-${os}-${
        ↪ arch}.tar.gz -O /tmp/${component}-${version}-${os}-${arch}.tar.gz
    ```

3. Create a temporary directory to pack files and change to it:

    ```
    mkdir -p /tmp/package && cd /tmp/package
    ```

4. Extract the original binary package:

    ```
    tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz
    ```

5. Check out the file structure in the temporary directory:

    ```
    find .
    ```

6. Copy the binary files or configuration files to their corresponding locations in the temporary directory.

7. Pack all files in the temporary directory:

```
tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *
```

After you have completed the preceding steps, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the `<package-path>` in the `tiup cluster patch` command.

Options

–overwrite

- After you patch a certain component (such as TiDB or TiKV), when the tiup cluster scales out the component, TiUP uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specified the option `--overwrite` in the command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–transfer-timeout

- When restarting the PD or TiKV service, TiKV/PD first transfers the leader of the node to be restarted to another node. Because the transfer process takes some time, you can use the option `--transfer-timeout` to set the maximum waiting time (in seconds). After the timeout, TiUP directly restarts the service.
- Data type: `UINT`
- If this option is not specified, TiUP directly restarts the service after waiting for `600` seconds.

> **Note:**
>
> If TiUP directly restarts the service after the timeout, the service performance might jitter.

-N, –node

- Specifies nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node ID from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any nodes to replace by default.

Note:

If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the role deployed on a node from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any roles to replace by default.

Note:

If the option `-N, --node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

–offline

- Declares that the current cluster is not running. When the option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.18 tiup cluster prune

When scaling in the cluster, for some components, TiUP does not immediately stop their services or delete their data. You need to wait for the data scheduling to complete and then manually execute the `tiup cluster prune` command to clean up.

Syntax

```
tiup cluster prune <cluster-name> [flags]
```

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of the cleanup process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.19 tiup cluster reload

After modifying the cluster configuration, the cluster needs to be reloaded using the `tiup cluster reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running, and follows the upgrade process to restart the services in order according to the upgrade process. The cluster is still available during the restart process.

Syntax

```
tiup cluster reload <cluster-name> [flags]
```

`<cluster-name>`: the cluster name to operate on.

Options

–force

- Ignores errors in the reloading process and forces reload.
- Data type: `BOOLEAN`
- Default: false

–transfer-timeout

- When restarting PD or TiKV, the leader of the restarted node is migrated to other nodes first, and the migration process takes some time. You can set the maximum wait time (in seconds) by setting `-transfer-timeout`. After the timeout, the service can be restarted directly without waiting.
- Data type: `UINT`
- Default: 600

> **Note:**
>
> In the case of skipping the waiting and restarting directly, the service performance might jitter.

–ignore-config-check

- After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration. If you want to skip this check, you can use this option.
- Data type: `BOOLEAN`
- Default: false

-N, –node

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

> **Note:**
>
> - If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
> - If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

-R, –role

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. The role is the second column of the cluster status table.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

Note:

1. If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
2. If the `--skip-restart` option is specified, the `-R, --role` option is invalid.

–skip-restart

The `tiup cluster reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.20 tiup cluster rename

The cluster name is specified when the cluster is deployed. If you want to change the cluster name after the cluster is deployed, you can use the command `tiup cluster rename`.

> **Note:**
>
> If the `dashboard_dir` field of `grafana_servers` is configured for the TiUP cluster, after you execute the command `tiup cluster rename` to rename the cluster, the following additional steps are required:
>
> - For the `*.json` files in the local dashboards directory, update the `datasource` field of each file to the new cluster name, because the value of `datasource` must be the name of the cluster.
> - Execute the command `tiup cluster reload -R grafana`.

Syntax

```
tiup cluster rename <old-cluster-name> <new-cluster-name> [flags]
```

- `<old-cluster-name>`: The old cluster name.
- `<new-cluster-name>`: The new cluster name.

Options

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.21 tiup cluster replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup cluster replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup cluster replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-id`s using the `tiup cluster audit` command.

Option

-h, –help

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.22 tiup cluster restart

The command `tiup cluster restart` is used to restart all or some of the services of the specified cluster.

> **Note:**
>
> During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup cluster restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

Note:

If the option `-R, --role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specified the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

Note:

If the option `-N, --node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.23 tiup cluster scale-in

The `tiup cluster scale-in` command is used to scale in the cluster, which takes the services of the specified nodes offline, removes the specified nodes from the cluster, and deletes the remaining files from those nodes.

Particular handling of components' offline process

Because the TiKV, TiFlash, and TiDB Binlog components are taken offline asynchronously (which requires TiUP to remove the node through API first) and the stopping process takes a long time (which requires TiUP to continuously check whether the node is successfully taken offline), the TiKV, TiFlash, and TiDB Binlog components are handled particularly as follows:

- For TiKV, TiFlash, and TiDB Binlog components:

    1. TiUP Cluster takes the node offline through API and directly exits without waiting for the process to be completed.
    2. To check the status of the nodes being scaled in, you need to execute the `tiup cluster display` command and wait for the status to become `Tombstone`.
    3. To clean up the nodes in the `Tombstone` status, you need to execute the `tiup cluster prune` command. The `tiup cluster prune` command performs the following operations:
        - Stops the services of the nodes that have been taken offline.
        - Cleans up the data files of the nodes that have been taken offline.
        - Updates the cluster topology and removes the nodes that have been taken offline.

For other components:

- When taking the PD components offline, TiUP Cluster quickly deletes the specified nodes from the cluster through API, stops the service of the specified PD nodes, and then deletes the related data files from the nodes.
- When taking other components down, TiUP Cluster directly stops the node services and deletes the related data files from the specified nodes.

Syntax

```
tiup cluster scale-in <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to scale in. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

-N, –node

- Specifies the nodes to take down. Multiple nodes are separated by commas.
- Data type: `STRING`
- There is no default value. This option is mandatory and the value must be not null.

–force

- Controls whether to forcibly remove the specified nodes from the cluster. Sometimes, the host of the node to take offline might be down, which makes it impossible to connect to the node via SSH for operations, so you can forcibly remove the node from the cluster using the `--force` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

> **Warning:**
>
> When you use this option to forcibly remove TiKV or TiFlash nodes that are in service or are pending offline, these nodes will be deleted immediately without waiting for data to be migrated. This imposes a very high risk of data loss. If data loss occurs in the region where the metadata is located, the entire cluster will be unavailable and unrecoverable.

–transfer-timeout

- When a PD or TiKV node is to be removed, the Region leader on the node will be transferred to another node first. Because the transferring process takes some time, you can set the maximum waiting time (in seconds) by configuring `--transfer-timeout`. After the timeout, the `tiup cluster scale-in` command skips waiting and starts the scaling-in directly.
- Data type: `UINT`
- The option is enabled by default with `600` seconds (the default value) passed in.

> **Note:**
>
> If a PD or TiKV node is taken offline directly without waiting for the leader transfer to be completed, the service performance might jitter.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the scaling-in process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.24 tiup cluster scale-out

The `tiup cluster scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The tiup-cluster component first establishes an SSH connection to the new node, creates the necessary directories on the target node, then performs the deployment and starts the service.

When PD is scaled out, new PD nodes are added to the cluster by the join operation, and the configuration of the services associated with PD is updated; other services are directly started and added to the cluster.

Syntax

```
tiup cluster scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

`<topology.yaml>`: the prepared topology file. This topology file should only contain the new nodes that are to be added to the current cluster.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: false

–no-labels

- This option is used to skip the label check.

- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD does not know the cluster topology, so it might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point of failure. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See Schedule Replicas by Topology Labels for label configuration.
- For the test environment, this risk might not matter, and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- Default: false

–skip-create-user

- During the cluster deployment, tiup-cluster checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of scaling out.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.25 tiup cluster start

The `tiup cluster start` command is used to start all services or some services of the specified cluster.

Syntax

```
tiup cluster start <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

–init

Starts the cluster in a safe way. It is recommended to use this option when the cluster is started for the first time. This method generates the password of the TiDB root user at startup and returns the password in the command line interface.

Note:

- After safe start of a TiDB cluster, you cannot log in to the database using the root user without a password. Therefore, you need to record the password returned by the command line for future logins.
- The password is generated only once. If you do not record or forget the password, refer to Forget the `root` password to change the password.

-N, –node

- Specifies the nodes to be started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-R, –role

- Specifies the roles of nodes to be started. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started by default.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of starting the service.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.26 tiup cluster stop

The `tiup cluster stop` command is used to stop all services or some services of the specified cluster.

> **Note:**
>
> If the core services of a cluster are stopped, the cluster cannot provide services anymore.

Syntax

```
tiup cluster stop <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

-N, –node

- Specifies the nodes to be stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the command stops all the nodes by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-R, –role

- Specifies the roles of nodes to be stopped. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the command stops all the roles by default.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of stopping the service.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.27 tiup cluster template

Before deploying the cluster, you need to prepare a topology file of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup cluster template` command.

Syntax

```
tiup cluster template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 PD instances
- 3 TiKV instances
- 1 TiDB instance
- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

–full

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

–local

- Outputs a simple topology template for the local cluster, which can be used directly, and the `global` parameter can be adjusted as needed.
- This template creates a PD service, a TiDB service, a TiKV service, a monitoring service, and a Grafana service.

–multi-dc

- Outputs the topology template of multiple data centers. To enable this option, add it to the command.
- If this option is not specified, the topology template of a single data center is output by default.

-h, –help

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.28 tiup cluster upgrade

The `tiup cluster upgrade` command is used to upgrade the specified cluster to a specific version.

Syntax

```
tiup cluster upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>`: the cluster name to operate on. If you forget the cluster name, you can check it with the cluster list command.
- `<version>`: the target version to upgrade to, such as `v7.1.5`. Currently, it is only allowed to upgrade to a version higher than the current cluster, that is, no downgrade is allowed. It is also not allowed to upgrade to the nightly version.

Options

–force

- To upgrade the cluster, you need to ensure that the cluster is currently started. In some cases, you might want to upgrade when the cluster is not started. At this time, you can use `--force` to ignore the error during the upgrade, forcibly replace the binary file and start the cluster.
- Data type: `BOOLEAN`
- Default: false

> **Note:**
>
> Forcing an upgrade of the cluster that is providing services might result in service unavailability. Unstarted clusters are started automatically after a successful upgrade.

–transfer-timeout

- When upgrading PD or TiKV, the leader of the upgraded node is migrated to other nodes first. The migration process takes some time, and you can set the maximum wait time (in seconds) by the `-transfer-timeout` option. After the timeout, the wait is skipped and the service is upgraded directly.
- Data type: `uint`
- Default: 600

> **Note:**
>
> If the wait is skipped and the service is upgraded directly, the service performance might jitter.

–ignore-config-check

- After the binary is updated, a configuration check is performed on the TiDB, TiKV and PD components using `<binary> --config-check <config-file>`. `<binary>` is the path to the newly deployed binary and `<config-file>` is the configuration file generated based on the user configuration. To skip this check, you can use the `--ignore-config-check` option.
- Data type: `BOOLEAN`
- Default: false

–offline

- Declares that the current cluster is not running. When this option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of the cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of the upgrading progress.

<< Back to the previous page - TiUP Cluster command list

13.4.7.4 TiUP DM Commands

13.4.7.4.1 TiUP DM

Similar to TiUP Cluster which is used to manage TiDB clusters, TiUP DM is used to manage DM clusters. You can use the TiUP DM component to perform daily operations and maintenance tasks of DM clusters, including deploying, starting, stopping, destroying, elastic scaling, upgrading DM clusters, and managing the configuration parameters of DM clusters.

Syntax

```
tiup dm [command] [flags]
```

`[command]` is used to pass the name of the command. See the Command list for supported commands.

Options

–ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: `STRING`
- Support values:
  - `builtin`: Uses the built-in easyssh client of tiup-cluster as the SSH client.
  - `system`: Uses the default SSH client of the current operating system.
  - `none`: No SSH client is used. The deployment is only for the current machine.
- If this option is not specified in the command, `builtin` is used as the default value.

–ssh-timeout

- Specifies the SSH connection timeout in seconds.
- Data type: `UINT`
- If this option is not specified in the command, the default timeout is `5` seconds.

–wait-timeout

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying systemctl to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each steps is `120` seconds.

-y, –yes

- Skips the secondary confirmation of all risky operations. It is not recommended to use this option unless you use a script to call TiUP.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-v, –version

- Prints the current version of TiUP DM.
- Data type:`BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints help information about the specified command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- import: Imports a DM v1.0 cluster deployed by DM-Ansible.
- template: Outputs the topology template.
- deploy: Deploys a cluster based on a specified topology.
- list: Queries the list of deployed clusters.
- display: Displays the status of a specified cluster.
- start: Starts a specified cluster.
- stop: Stops a specified cluster.
- restart: Restarts a specified cluster.
- scale-in: Scales in a specified cluster.
- scale-out: Scales out a specified cluster.
- upgrade: Upgrades a specified cluster.
- prune: Cleans up instances in the Tombstone status for a specified cluster.
- edit-config: Modifies the configuration of a specified cluster.
- reload: Reloads the configuration of a specified cluster.
- patch: Replaces a specified service in a deployed cluster.
- destroy: Destroys a specified cluster.
- audit: Queries the operation audit log of a specified cluster.
- replay: Replays the specified commands
- enable: Enables the auto-enabling of the cluster service after a machine is restarted.
- disable: Disables the auto-enabling of the cluster service after a machine is restarted.
- help: Prints help information.

<< Back to the previous page - TiUP Reference component list

13.4.7.4.2 tiup dm audit

The `tiup dm audit` command is used to view historical commands executed on all clusters and the execution log of each command.

Syntax

```
tiup dm audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, the execution log of the specified `audit-id` is checked.

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

- If `[audit-id]` is specified, the corresponding execution log is output.
- If `[audit-id]` is not specified, a table with the following fields is output:
  - ID: the `audit-id` corresponding to this record
  - Time: the execution time of the command corresponding to the record
  - Command: the command corresponding to the record

<< Back to the previous page - TiUP DM command list

13.4.7.4.3 tiup dm deploy

The `tiup dm deploy` command is used to deploy a new cluster.

Syntax

```
tiup dm deploy <cluster-name> <version> <topology.yaml> [flags]
```

- `<cluster-name>`: the name of the new cluster, which cannot be the same as the existing cluster names.
- `<version>`: the version number of the DM cluster to be deployed, such as `v2.0.0`.
- `<topology.yaml>`: the prepared topology file.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- Default: `~/.ssh/id_rsa`

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The deployment log.

<< Back to the previous page - TiUP DM command list

13.4.7.4.4 tiup dm destroy

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup dm destroy` command performs the following operations:

- Stops the cluster.
- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by `tiup-dm`, also delete the parent directory.

Syntax

```
tiup dm destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to be destroyed.

Option

-h, –help

- Prints the help information.
- Data type: `Boolean`
- Default: false

Output

The execution log of the tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.5 tiup dm disable

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup dm disable` command. This command executes `systemctl disable <service>` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup dm disable <cluster-name> [flags]
```

`<cluster-name>` is the cluster whose service auto-enabling is to be disabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-h, –help

Prints the help information.

Output

The execution log of the tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.6 tiup dm display

If you want to check the operational status of each component in a DM cluster, it is inefficient to log in to each machine one by one. Therefore, tiup-dm provides the `tiup dm display` command to do this job efficiently.

Syntax

```
tiup dm display <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated. If you forget the cluster name, you can check it using the `tiup dm list` command.

Options

-N, –node

- Specifies the IDs of the nodes to query, splitting by commas for multiple nodes. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: `STRING`

- This option is enabled by default with `[]` (which means all nodes) passed in.

> **Note:**
>
> If `-R, --role` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

-R, –role

- Specifies the roles to query, splitting by commas for multiple roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: `STRING`
- This option is enabled by default with `[]` (which means all roles) passed in.

> **Note:**
>
> If `-N, --node` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

- Cluster name
- Cluster version
- SSH client type
- A table containing the following fields:
    - `ID`: the node ID, consisting of IP:PORT.
    - `Role`: the service role deployed on the node (for example, TiDB or TiKV).
    - `Host`: the IP address of the machine corresponding to the node.
    - `Ports`: the port number used by the service.

- `OS/Arch`: the operating system and machine architecture of the node.
- `Status`: the current status of the services on the node.
- `Data Dir`: the data directory of the service. `-` means that there is no data directory.
- `Deploy Dir`: the deployment directory of the service.

<< Back to the previous page - TiUP DM command list

13.4.7.4.7 tiup dm edit-config

If you need to modify the cluster service configuration after the cluster is deployed, you can use the `tiup dm edit-config` command that starts an editor for you to modify the topology file. of the specified cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

Note:

- When you modify the configuration, you cannot add or delete machines. For how to add machines, see Scale out a cluster. For how to delete machines, see Scale in a cluster.
- After you execute the `tiup dm edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup dm reload` command to reload the configuration.

Syntax

```
tiup dm edit-config <cluster-name> [flags]
```

`<cluster-name>`: the cluster to operate on.

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

- Normally, no output.

- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error is reported, reminding you to edit the file again. For the fields that cannot be modified, see the topology file.

<< Back to the previous page - TiUP DM command list

13.4.7.4.8 tiup dm enable

The `tiup dm enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

Syntax

```
tiup dm enable <cluster-name> [flags]
```

`<cluster-name>` is the cluster whose service auto-enabling is to be enabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

Note:

If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-h, –help

Prints the help information.

Output

the execution log of tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.9 tiup dm help

tiup-dm command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option. Basically, `tiup dm help <command >` is equivalent to `tiup dm <command> --help`.

Syntax

```
tiup dm help [command] [flags]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of `tiup-dm` is viewed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The help information of `[command]` or `tiup-dm`.

<< Back to the previous page - TiUP DM command list

13.4.7.4.10 tiup dm import Only for upgrading DM v1.0

This command is used only for upgrading DM clusters from v1.0 to v2.0 or later versions.

In DM v1.0, the cluster is basically deployed using TiDB Ansible. TiUP DM provides the `import` command to import v1.0 clusters and redeploy the clusters in DM v2.0.

Note:

- The command does not support importing DM Portal components from DM v1.0 clusters.
- Before importing the cluster, stop running the original cluster first.
- For data migration tasks that need to be upgraded to v2.0, do not execute `stop-task` on these tasks.
- The command only supports importing to DM v2.0.0-rc.2 and later versions.
- The `import` command is used to import a DM v1.0 cluster to a new DM v2.0 cluster. If you need to import data migration tasks to an existing v2.0 cluster, refer to Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+
- The deployment directories of some components might be different from those in the original cluster. You can check it with the `display` command.
- Before importing the cluster, run `tiup update --self && tiup update dm` to upgrade TiUP DM components to the latest version.
- After the cluster is imported, there is only one DM-master node in the cluster. You can refer to the `scale out` command to scale out the DM-master node.

Syntax

```
tiup dm import [flags]
```

Options

-v, –cluster-version

- Specifies the version number for redeploying. You must use a version later than v2.0.0-rc.2 (including v2.0.0-rc.2).
- Data type: `STRING`
- This option is **required** to execute the command.

-d, –dir

- Specifies the directory of TiDB Ansible.
- Data type: `STRING`
- If this option is not specified in the command, the current directory is the default directory.

–inventory

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- If this option is not specified in the command, the default file name is `"inventory.ini"`.

–rename

- Renames the imported cluster.
- Data type: `STRING`
- If this option is not specified in the command, the default cluster name is the `cluster_name` specified in the inventory file.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the importing process.

<< Back to the previous page - TiUP DM command list

13.4.7.4.11 tiup dm list

`tiup-dm` supports deploying multiple clusters using the same control machine. You can use the `tiup dm list` command to check which clusters are deployed using the control machine by the currently logged-in user.

> **Note:**
>
> By default, the data of the deployed clusters is stored in the `~/.tiup/storage/dm/clusters/` directory. The currently logged-in user cannot view the clusters deployed by other users on the same control machine.

Syntax

```
tiup dm list [flags]
```

Options

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

A table consisting of the following fields:

- `Name`: the cluster name.
- `User`: the user who deployed the cluster.
- `Version`: the cluster version.
- `Path`: the path of the cluster deployment data on the control machine.
- `PrivateKey`: the path of the private key to the cluster.

<< Back to the previous page - TiUP DM command list

13.4.7.4.12 Apply Hotfix to DM Clusters Online

If you need to dynamically replace the binaries of a service while the cluster is running (that is, to keep the cluster available during the replacement), you can use the `tiup dm patch` command. The command does the following:

- Uploads the binary package for replacement to the target machine.
- Takes the related nodes offline using the API.
- Stops the target service.
- Unpacks the binary package and replaces the service.
- Starts the target service.

Syntax

```
tiup dm patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated
- `<package-path>`: The path to the binary package used for replacement

Preparation

You need to pack the binary package required for this command in advance according to the following steps:

- Determine the name `${component}` of the component to be replaced (dm-master, dm-worker ...), the `${version}` of the component (v2.0.0, v2.0.1 ...), and the operating system `${os}` and platform `${arch}` on which the component runs.
- Download the current component package using the command `wget https://tiup-mirrors.pingcap.com/${component}-${version}-${os}-${arch}.tar.gz -O /tmp/${component}-${version}-${os}-${arch}.tar.gz`.
- Run `mkdir -p /tmp/package && cd /tmp/package` to create a temporary directory to pack files.
- Run `tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz` to unpack the original binary package.
- Run `find .` to view the file structure in the temporary package directory.
- Copy the binary files or configuration files to the corresponding locations in the temporary directory.
- Run `tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *` to pack the files in the temporary directory.
- Finally, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the value of `<package-path>` in the `tiup dm patch` command.

Options

–overwrite

- After you patch a certain component (such as dm-worker), when the tiup-dm scales out the component, tiup-dm uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specify the option `--overwrite` in the command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-N, –node

- Specifies the nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all nodes to replace by default.

> **Note:**
>
> If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all roles to replace by default.

> **Note:**
>
> If the option `-N, --node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

–offline

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Example

The following example shows how to apply `v5.3.0-hotfix` to the `v5.3.0` cluster deployed using TiUP. The operations might vary if you deploy the cluster using other methods.

> **Note:**
>
> Hotfix is used only for emergency fixes. Its daily maintenance is complicated. It is recommend that you upgrade the DM cluster to an official version as soon as it is released.

Preparations

Before applying a hotfix, prepare the hotfix package `dm-linux-amd64.tar.gz` and confirm the current DM software version:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0

Git Commit Hash: 20626babf21fc381d4364646c40dd84598533d66
Git Branch: heads/refs/tags/v5.3.0
UTC Build Time: 2021-11-29 08:29:49
Go Version: go version go1.16.4 linux/amd64
```

Prepare the patch package and apply it to the DM cluster

1. Prepare the DM software package that matches the current version:

```
mkdir -p /tmp/package
tar -zxvf /root/.tiup/storage/dm/packages/dm-master-v5.3.0-linux-amd64.
    ↪ tar.gz -C /tmp/package/
tar -zxvf /root/.tiup/storage/dm/packages/dm-worker-v5.3.0-linux-amd64.
    ↪ tar.gz -C /tmp/package/
```

2. Replace the binary file with the hotfix package:

```
# Decompress the hotfix package and use it to replace the binary file.
cd /root; tar -zxvf dm-linux-amd64.tar.gz
cp /root/dm-linux-amd64/bin/dm-master /tmp/package/dm-master/dm-master
cp /root/dm-linux-amd64/bin/dm-worker /tmp/package/dm-worker/dm-worker
# Re-package the modified files.
# Note that the packaging method might be different for other
    ↪ deployment methods.
cd /tmp/package/ && tar -czvf dm-master-hotfix-linux-amd64.tar.gz dm-
    ↪ master/
cd /tmp/package/ && tar -czvf dm-worker-hotfix-linux-amd64.tar.gz dm-
    ↪ worker/
```

3. Apply the hotfix:

   Query the cluster status. The following uses the cluster named `dm-test` as an example:

```
tiup dm display dm-test
```

   Output:

```
Cluster type:     dm
Cluster name:     dm-test
Cluster version:  v5.3.0
Deploy user:      tidb
SSH type:         builtin
ID                Role               Host          Ports     OS/Arch
   ↪ Status    Data Dir                           Deploy Dir
--                ----               ----          -----     -------
   ↪ ------    --------                           ----------
172.16.100.21:9093 alertmanager     172.16.100.21 9093/9094 linux/
   ↪ x86_64 Up      /home/tidb/dm/data/alertmanager-9093 /home/tidb/dm
   ↪ /deploy/alertmanager-9093
172.16.100.21:8261 dm-master        172.16.100.21 8261/8291 linux/
   ↪ x86_64 Healthy|L /home/tidb/dm/data/dm-master-8261 /home/tidb/dm/
   ↪ deploy/dm-master-8261
172.16.100.21:8262 dm-worker        172.16.100.21 8262     linux/x86_64
   ↪  Free     /home/tidb/dm/data/dm-worker-8262 /home/tidb/dm/deploy/
   ↪ dm-worker-8262
172.16.100.21:3000 grafana          172.16.100.21 3000     linux/x86_64
   ↪  Up       -                                 /home/tidb/dm/deploy/
   ↪ grafana-3000
172.16.100.21:9090 prometheus       172.16.100.21 9090     linux/x86_64
   ↪  Up       /home/tidb/dm/data/prometheus-9090 /home/tidb/dm/deploy
   ↪ /prometheus-9090
Total nodes: 5
```

Apply the hotfix to the specified node or specified role. If both `-R` and `-N` are specified, the intersection will be taken.

```
# Apply hotfix to a specified node.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -N
   ↪ 172.16.100.21:8261
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -N
   ↪ 172.16.100.21:8262
# Apply hotfix to a specified role.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -R dm-master
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -R dm-worker
```

4. Query the hotfix application result:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0-20211230
```

```
Git Commit Hash: ca7070c45013c24d34bd9c1e936071253451d707
Git Branch: heads/refs/tags/v5.3.0-20211230
UTC Build Time: 2022-01-05 14:19:02
Go Version: go version go1.16.4 linux/amd64
```

The cluster information changes accordingly:

```
tiup dm display dm-test
```

Output:

```
Starting component `dm`: /root/.tiup/components/dm/v1.8.1/tiup-dm
   ↪ display dm-test
Cluster type:     dm
Cluster name:     dm-test

<< Back to the previous page - TiUP DM command list

13.4.7.4.13 tiup dm prune

When you scale in the cluster(/tiup/tiup-component-dm-scale-in.md), a small amount of metadata in etcd is not cleaned up, which usually causes no problem. If you need to clean up the metadata, you can manually execute the `tiup dm prune` command.

Syntax

```
tiup dm prune <cluster-name> [flags]
```

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of the cleanup process.

<< Back to the previous page - TiUP DM command list

13.4.7.4.14 tiup dm reload

After modifying the cluster configuration, the cluster needs to be reloaded using the `tiup dm reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running and restarts the service in order according to the upgrade process. The cluster remains available during the restart process.

Syntax

```
tiup dm reload <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on.

Options

-N, –node

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

Note:

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

-R, –role

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

Note:

- If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-R, --role` option is invalid.

–skip-restart

The `tiup dm reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The execution log of the tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.15 tiup dm replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup dm replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup dm replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-id`s using the `tiup dm audit` command.

Option

-h, –help

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

<< Back to the previous page - TiUP DM command list

13.4.7.4.16 tiup dm restart

The command `tiup dm restart` is used to restart all or some of the services of the specified cluster.

> **Note:**
>
> During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup dm restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

> **Note:**
>
> If the option `-R, --role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specifies the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

> **Note:**
>
> If the option `-N, --node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

<< Back to the previous page - TiUP DM command list

13.4.7.4.17 tiup dm scale-in

The `tiup dm scale-in` command is used to scale in the cluster. Scaling in the cluster means taking the service offline, which eventually removes the specified node from the cluster and deletes the remaining related files.

Syntax

```
tiup dm scale-in <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be scaled in. If you need to scale in multiple nodes, split them by commas.
- Data type: `STRINGS`
- Default: no. This option is mandatory and the value must be not null.

–force

- In some cases, some scale-in nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to remove these nodes from the cluster.
- Data type: `BOOLEAN`
- Default: false. If this option is not specified in the command, the specified nodes are not forcibly removed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of scaling in.

<< Back to the previous page - TiUP DM command list

13.4.7.4.18 tiup dm scale-out

The `tiup dm scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The `tiup-dm` components first establish an SSH connection to the new node, create the necessary directories on the target node, then perform the deployment and start the service.

Syntax

```
tiup dm scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

`<topology.yaml>`: the prepared topology file. This topology file should only contain the new nodes that are to be added to the current cluster.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of scaling out.

<< Back to the previous page - TiUP DM command list

13.4.7.4.19 tiup dm start

The `tiup dm start` command is used to start all or part of the services of the specified cluster.

Syntax

```
tiup dm start <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be started. If not specified, all nodes are started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-R, –role

- Specifies the roles to be started. If not specified, all roles are started. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of starting the service.

<< Back to the previous page - TiUP DM command list

13.4.7.4.20 tiup dm stop

The `tiup dm stop` command is used to stop all or part of the services of the specified cluster.

> **Note:**
>
> The cluster cannot provide services after the core service is stopped.

Syntax

```
tiup dm stop <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be stopped. If not specified, all nodes are stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-R, –role

- Specifies the roles to be stopped. If not specified, all roles are stopped. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of stopping the service.

<< Back to the previous page - TiUP DM command list

13.4.7.4.21 tiup dm template

Before deploying the cluster, you need to prepare a topology file of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup dm template` command.

Syntax

```
tiup dm template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 DM-master instances
- 3 DM-worker instances

- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

–full

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

-h, –help

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

<< Back to the previous page - TiUP DM command list

13.4.7.4.22 tiup dm upgrade

The `tiup dm upgrade` command is used to upgrade a specified cluster to a specific version.

Syntax

```
tiup dm upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup dm list` command.
- `<version>` is the target version to be upgraded to, such as `v7.1.5`. Currently, only upgrading to a later version is allowed, and upgrading to an earlier version is not allowed, which means the downgrade is not allowed. Upgrading to a nightly version is not allowed either.

Options

–offline

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Log of the service upgrade process.

<< Back to the previous page - TiUP DM command list

13.4.8 Topology Configuration File for TiDB Deployment Using TiUP

To deploy or scale TiDB using TiUP, you need to provide a topology file (sample) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

13.4.8.1 File structure

A topology configuration file for TiDB deployment using TiUP might contain the following sections:

- global: The cluster's global configuration. Some of the configuration items use the default values and you can configure them separately in each instance.
- monitored: Configuration for monitoring services, namely, the blackbox_exporter and the `node_exporter`. On each machine, a `node_exporter` and a `blackbox_exporter` are deployed.
- server_configs: Components' global configuration. You can configure each component separately. If an instance has a configuration item with the same name, the instance's configuration item will take effect.
- pd_servers: The configuration of the PD instance. This configuration specifies the machines to which the PD component is deployed.
- tidb_servers: The configuration of the TiDB instance. This configuration specifies the machines to which the TiDB component is deployed.
- tikv_servers: The configuration of the TiKV instance. This configuration specifies the machines to which the TiKV component is deployed.
- tiflash_servers: The configuration of the TiFlash instance. This configuration specifies the machines to which the TiFlash component is deployed.
- pump_servers: The configuration of the Pump instance. This configuration specifies the machines to which the Pump component is deployed.
- drainer_servers: The configuration of the Drainer instance. This configuration specifies the machines to which the Drainer component is deployed.

- cdc_servers: The configuration of the TiCDC instance. This configuration specifies the machines to which the TiCDC component is deployed.
- tispark_masters: The configuration of the TiSpark master instance. This configuration specifies the machines to which the TiSpark master component is deployed. Only one node of TiSpark master can be deployed.
- tispark_workers: The configuration of the TiSpark worker instance. This configuration specifies the machines to which the TiSpark worker component is deployed.
- monitoring_servers: Specifies the machines to which Prometheus and NGMonitoring are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- grafana_servers: The configuration of the Grafana instance. This configuration specifies the machines to which Grafana is deployed.
- alertmanager_servers: The configuration of the Alertmanager instance. This configuration specifies the machines to which Alertmanager is deployed.

13.4.8.1.1 `global`

The `global` section corresponds to the cluster's global configuration and has the following fields:

- `user`: The user used to start the deployed cluster. The default value is `"tidb"`. If the user specified in the `<user>` field does not exist on the target machine, this user is automatically created.
- `group`: The user group to which a user belongs. It is specified when the user is created. The value defaults to that of the `<user>` field. If the specified group does not exist, it is automatically created.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. The default value is 22.
- `enable_tls`: Specifies whether to enable TLS for the cluster. After TLS is enabled, the generated TLS certificate must be used for connections between components or between the client and the component. The default value is `false`.
- `deploy_dir`: The deployment directory of each component. The default value is `"deployed"`. Its application rules are as follows:
  - If the absolute path of `deploy_dir` is configured at the instance level, the actual deployment directory is `deploy_dir` configured for the instance.
  - For each instance, if you do not configure `deploy_dir`, its default value is the relative path `<component-name>-<component-port>`.
  - If `global.deploy_dir` is an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.

    - If `global.deploy_dir` is a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.

- `data_dir`: The data directory. Default value: `"data"`. Its application rules are as follows:

    - If the absolute path of `data_dir` is configured at the instance level, the actual deployment directory is `data_dir` configured for the instance.
    - For each instance, if you do not configure `data_dir`, its default value is `<global.data_dir>`.
    - If `data_dir` is a relative path, the component data is placed in `<deploy_dir>/<data_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.

- `log_dir`: The log directory. Default value: `"log"`. Its application rules are as follows:

    - If the absolute path `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
    - For each instance, if you not configure `log_dir`, its default value is `<global.log_dir>`.
    - If `log_dir` is a relative path, the component log is placed in `<deploy_dir>/<log_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.

- `os`: The operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is "linux".

- `arch`: The CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are "amd64" and "arm64". The default value is "amd64".

- `resource_control`: Runtime resource control. All configurations in this field are written into the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:

    - `memory_limit`: Limits the maximum runtime memory. For example, "2G" means that the maximum memory of 2 GB can be used.
    - `cpu_quota`: Limits the maximum CPU usage at runtime. For example, "200%".
    - `io_read_bandwidth_max`: Limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M"`.
    - `io_write_bandwidth_max`: Limits maximum I/O bandwidth for disk writes. For example, `/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M`.

- `limit_core`: Controls the size of core dump.

A `global` configuration example is as follows:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the above configuration, the `tidb` user is used to start the cluster. At the same time, each component is restricted to a maximum of 2 GB of memory when it is running.

13.4.8.1.2 `monitored`

`monitored` is used to configure the monitoring service on the target machine: `node_exporter` and `blackbox_exporter`. The following fields are included:

- `node_exporter_port`: The service port of `node_exporter`. The default value is `9100`.
- `blackbox_exporter_port`: The service port of `blackbox_exporter`. The default value is `9115`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

A `monitored` configuration example is as follows:

```
monitored:
  node_exporter_port: 9100
  blackbox_exporter_port: 9115
```

The above configuration specifies that `node_exporter` uses the `9100` port and `blackbox_exporter` uses the `9115` port.

13.4.8.1.3 `server_configs`

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configuration of this section can be overwritten by the configurations with the same names in an instance. `server_configs` mainly includes the following fields:

- `tidb`: TiDB service-related configuration. For the complete configuration, see TiDB configuration file.
- `tikv`: TiKV service-related configuration. For the complete configuration, see TiKV configuration file.
- `pd`: PD service-related configuration. For the complete configuration, see PD configuration file.
- `tiflash`: TiFlash service-related configuration. For the complete configuration, see TiFlash configuration file.
- `tiflash_learner`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- `pump`: Pump service-related configuration. For the complete configuration, see TiDB Binlog configuration file.
- `drainer`: Drainer service-related configuration. For the complete configuration, see TiDB Binlog configuration file.
- `cdc`: TiCDC service-related configuration. For the complete configuration, see Deploy TiCDC.

A `server_configs` configuration example is as follows:

```
server_configs:
  tidb:
    lease: "45s"
    split-table: true
    token-limit: 1000
    instance.tidb_enable_ddl: true
  tikv:
    log-level: "info"
    readpool.unified.min-thread-count: 1
```

The above configuration specifies the global configuration of TiDB and TiKV.

13.4.8.1.4 pd_servers

pd_servers specifies the machines to which PD services are deployed. It also specifies the service configuration on each machine. pd_servers is an array, and each element of the array contains the following fields:

- host: Specifies the machine to which the PD services are deployed. The field value is an IP address and is mandatory.
- listen_host: When the machine has multiple IP addresses, listen_host specifies the listening IP address of the service. The default value is 0.0.0.0.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- name: Specifies the name of the PD instance. Different instances must have unique names; otherwise, instances cannot be deployed.
- client_port: Specifies the port that PD uses to connect to the client. The default value is 2379.
- peer_port: Specifies the port for communication between PDs. The default value is 2380.
- deploy_dir: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the deploy_dir directory configured in global.
- data_dir: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the data_dir directory configured in global.
- log_dir: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the log_dir directory configured in global.
- numa_node: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- config: The configuration rule of this field is the same as the pd configuration rule in server_configs. If this field is configured, the field content is merged with the pd content in server_configs (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in host.
- os: The operating system of the machine specified in host. If this field is not specified, the default value is the os value in global.

- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `name`
- `client_port`
- `peer_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `pd_servers` configuration example is as follows:

```
pd_servers:
  - host: 10.0.1.11
    config:
      schedule.max-merge-region-size: 20
      schedule.max-merge-region-keys: 200000
  - host: 10.0.1.12
```

The above configuration specifies that PD will be deployed on `10.0.1.11` and `10.0.1.12`, and makes specific configurations for the PD of `10.0.1.11`.

13.4.8.1.5 `tidb_servers`

`tidb_servers` specifies the machines to which TiDB services are deployed. It also specifies the service configuration on each machine. `tidb_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiDB services are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.

- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of TiDB services, which is used to provide connection to the MySQL client. The default value is `4000`.
- `status_port`: The listening port of the TiDB status service, which is used to view the status of the TiDB services from the external via HTTP requests. The default value is `10080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tidb` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tidb` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`

- log_dir
- arch
- os

A tidb_servers configuration example is as follows:

```
tidb_servers:
  - host: 10.0.1.14
    config:
      log.level: warn
      log.slow-query-file: tidb-slow-overwrited.log
  - host: 10.0.1.15
```

13.4.8.1.6 tikv_servers

tikv_servers specifies the machines to which TiKV services are deployed. It also specifies the service configuration on each machine. tikv_servers is an array, and each element of the array contains the following fields:

- host: Specifies the machine to which the TiKV services are deployed. The field value is an IP address and is mandatory.
- listen_host: When the machine has multiple IP addresses, listen_host specifies the listening IP address of the service. The default value is 0.0.0.0.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- port: The listening port of the TiKV services. The default value is 20160.
- status_port: The listening port of the TiKV status service. The default value is 20180.
- deploy_dir: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the deploy_dir directory configured in global.
- data_dir: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the data_dir directory configured in global.
- log_dir: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the log_dir directory configured in global.
- numa_node: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".

- `config`: The configuration rule of this field is the same as the `tikv` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tikv` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `tikv_servers` configuration example is as follows:

```
tikv_servers:
  - host: 10.0.1.14
    config:
      server.labels: { zone: "zone1", host: "host1" }
  - host: 10.0.1.15
    config:
      server.labels: { zone: "zone1", host: "host2" }
```

13.4.8.1.7 `tiflash_servers`

`tiflash_servers` specifies the machines to which TiFlash services are deployed. It also specifies the service configuration on each machine. This section is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiFlash services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `tcp_port`: The port of the TiFlash TCP service for internal testing purposes. The default value is `9000`. Starting from TiUP v1.12.5, this configuration item does not take effect on clusters that are v7.1.0 or later.
- `flash_service_port`: The port via which TiFlash provides services. TiDB reads data from TiFlash via this port. The default value is `3930`.
- `metrics_port`: TiFlash's status port, which is used to output metric data. The default value is `8234`.
- `flash_proxy_port`: The port of the built-in TiKV. The default value is `20170`.
- `flash_proxy_status_port`: The status port of the built-in TiKV. The default value is `20292`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`. TiFlash supports multiple `data_dir` directories separated by commas.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `tmp_path`: The storage path of TiFlash temporary files. The default value is [`path` or the first directory of `storage.latest.dir`] + "/tmp".
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tiflash` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tiflash` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `learner_config`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.

- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

After the deployment, for the fields above, you can only add directories to `data_dir`; for the fields below, you cannot modified these fields:

- `host`
- `tcp_port`
- `flash_service_port`
- `flash_proxy_port`
- `flash_proxy_status_port`
- `metrics_port`
- `deploy_dir`
- `log_dir`
- `tmp_path`
- `arch`
- `os`

A `tiflash_servers` configuration example is as follows:

```
tiflash_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

13.4.8.1.8 `pump_servers`

`pump_servers` specifies the machines to which the Pump services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. `pump_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the Pump services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.

- `port`: The listening port of the Pump services. The default value is `8250`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `pump` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pump` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `pump_servers` configuration example is as follows:

```
pump_servers:
  - host: 10.0.1.21
    config:
      gc: 7
  - host: 10.0.1.22
```

13.4.8.1.9 `drainer_servers`

`drainer_servers` specifies the machines to which the Drainer services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. `drainer_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Drainer services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of Drainer services. The default value is `8249`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `commit_ts` (deprecated): When Drainer starts, it reads the checkpoint. If Drainer gets no checkpoint, it uses this field as the replication time point for the initial startup. This field defaults to `-1` (Drainer always gets the latest timestamp from the PD as the commit_ts).
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `drainer` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `drainer` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.

- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

The `commit_ts` field is deprecated since TiUP v1.9.2 and is not recorded in the starting script of Drainer. If you still need to use this field, refer to the following example to configure the `initial-commit-ts` field in `config`.

A `drainer_servers` configuration example is as follows:

```
drainer_servers:
  - host: 10.0.1.21
    config:
      initial-commit-ts: -1
      syncer.db-type: "mysql"
      syncer.to.host: "127.0.0.1"
      syncer.to.user: "root"
      syncer.to.password: ""
      syncer.to.port: 3306
      syncer.ignore-table:
        - db-name: test
          tbl-name: log
        - db-name: test
          tbl-name: audit
```

13.4.8.1.10 `cdc_servers`

`cdc_servers` specifies the machines to which the TiCDC services are deployed. It also specifies the service configuration on each machine. `cdc_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiCDC services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the TiCDC services. The default value is `8300`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `gc-ttl`: The Time To Live (TTL) duration of the service level GC safepoint set by TiCDC in PD, in seconds. The default value is `86400`, which is 24 hours.
- `tz`: The time zone that the TiCDC services use. TiCDC uses this time zone when internally converting time data types such as timestamp and when replicating data to the downstream. The default value is the local time zone where the process runs.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config`: The field content is merged with the `cdc` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.
- `ticdc_cluster_id`: Specifies the TiCDC cluster ID corresponding to the service. If this field is not specified, the service joins the default TiCDC cluster. This field only takes effect in TiDB v6.3.0 or later versions.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`
- `ticdc_cluster_id`

A `cdc_servers` configuration example is as follows:

```
cdc_servers:
  - host: 10.0.1.20
    gc-ttl: 86400
    data_dir: "/cdc-data"
  - host: 10.0.1.21
    gc-ttl: 86400
    data_dir: "/cdc-data"
```

13.4.8.1.11 `tispark_masters`

`tispark_masters` specifies the machines to which the master node of TiSpark is deployed. It also specifies the service configuration on each machine. `tispark_masters` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiSpark master is deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.

- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path of the JRE environment to be used. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `spark_config`: Configures to configure the TiSpark services. Then, a configuration file is generated and sent to the machine specified in `host`.
- `spark_env`: Configures the environment variables when Spark starts.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`
- `deploy_dir`
- `arch`
- `os`

A `tispark_masters` configuration example is as follows:

```
tispark_masters:
  - host: 10.0.1.21
    spark_config:
      spark.driver.memory: "2g"
      spark.eventLog.enabled: "False"
      spark.tispark.grpc.framesize: 2147483647
      spark.tispark.grpc.timeout_in_sec: 100
      spark.tispark.meta.reload_period_in_sec: 60
      spark.tispark.request.command.priority: "Low"
      spark.tispark.table.scan_concurrency: 256
    spark_env:
```

```
    SPARK_EXECUTOR_CORES: 5
    SPARK_EXECUTOR_MEMORY: "10g"
    SPARK_WORKER_CORES: 5
    SPARK_WORKER_MEMORY: "10g"
- host: 10.0.1.22
```

13.4.8.1.12 `tispark_workers`

`tispark_workers` specifies the machines to which the worker nodes of TiSpark are deployed. It also specifies the service configuration on each machine. `tispark_workers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiSpark workers are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path in which the JRE environment to be used is located. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`

- deploy_dir
- arch
- os

A tispark_workers configuration example is as follows:

```
tispark_workers:
  - host: 10.0.1.22
  - host: 10.0.1.23
```

13.4.8.1.13 monitoring_servers

monitoring_servers specifies the machines to which the Prometheus services are deployed. It also specifies the service configuration on each machine. monitoring_servers is an array. Each array element contains the following fields:

- host: Specifies the machine to which the monitoring services are deployed. The field value is an IP address and is mandatory.
- ng_port: Specifies the port that NgMonitoring listens to. Introduced in TiUP v1.7.0, this field supports Continuous Profiling and Top SQL. The default value is 12020.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- port: The listening port of the Prometheus services. The default value is 9090.
- deploy_dir: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the deploy_dir directory configured in global.
- data_dir: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the data_dir directory configured in global.
- log_dir: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the log_dir directory configured in global.
- numa_node: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- storage_retention: The retention time of the Prometheus monitoring data. The default value is "30d".

- `rule_dir`: Specifies a local directory that should contain complete `*.rules.yml` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the rules for Prometheus.
- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
    - `remote_write`: See the Prometheus document `<remote_write>`.
    - `remote_read`: See the Prometheus document `<remote_read>`.
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.
- `additional_args`: Introduced in TiUP v1.15.0, this field configures additional parameters for running Prometheus. This field is an array, and each element of the array is a Prometheus running parameter. For example, to enable the Prometheus hot reload feature, you can set this field to `--web.enable-lifecycle`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:
  - host: 10.0.1.11
    rule_dir: /local/rule/dir
    additional_args:
    - --web.enable-lifecycle
    remote_config:
      remote_write:
      - queue_config:
          batch_send_deadline: 5m
          capacity: 100000
          max_samples_per_send: 10000
          max_shards: 300
        url: http://127.0.0.1:8003/write
      remote_read:
      - url: http://127.0.0.1:8003/read
      external_alertmanagers:
      - host: 10.1.1.1
        web_port: 9093
      - host: 10.1.1.2
        web_port: 9094
```

13.4.8.1.14 `grafana_servers`

`grafana_servers` specifies the machines to which the Grafana services are deployed. It also specifies the service configuration on each machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Grafana services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Grafana services. The default value is `3000`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `username`: The user name on the Grafana login interface.

- `password`: The password corresponding to Grafana.
- `dashboard_dir`: Specifies a local directory that should contain complete `dashboard (*.json)` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the dashboards for Grafana.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

> **Note:**
>
> If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:
>
> 1. For the `*.json` files in the local dashboards directory, update the value of the `datasource` field to the new cluster name (because `datasource` is named after the cluster name).
> 2. Execute the `tiup cluster reload -R grafana` command.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:
  - host: 10.0.1.11
    dashboard_dir: /local/dashboard/dir
```

13.4.8.1.15 `alertmanager_servers`

`alertmanager_servers` specifies the machines to which the Alertmanager services are deployed. It also specifies the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Alertmanager services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `web_port`: Specifies the port used that Alertmanager uses to provide web services. The default value is `9093`.
- `cluster_port`: Specifies the communication port between one Alertmanger and other Alertmanager. The default value is `9094`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config_file`: Specifies a local file that is transferred to the target machine during the initialization phase of the cluster configuration as the configuration of Alertmanager.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `web_port`
- `cluster_port`

- deploy_dir
- data_dir
- log_dir
- arch
- os

A alertmanager_servers configuration example is as follows:

```
alertmanager_servers:
  - host: 10.0.1.11
    config_file: /local/config/file
  - host: 10.0.1.12
    config_file: /local/config/file
```

13.4.9 Topology Configuration File for DM Cluster Deployment Using TiUP

To deploy or scale a TiDB Data Migration (DM) cluster, you need to provide a topology file (sample) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

13.4.9.1 File structure

A topology configuration file for DM cluster deployment using TiUP might contain the following sections:

- global: the cluster's global configuration. Some of the configuration items use the default values of the cluster, and you can configure them separately in each instance.
- server_configs: the components' global configuration. You can configure each component separately. If an instance has a configuration item with the same key, the instance's configuration item will take effect.
- master_servers: the configuration of the DM-master instance. The configuration specifies the machines to which the master service of the DM component is deployed.
- worker_servers: the configuration of the DM-worker instance. The configuration specifies the machines to which the worker service of the DM component is deployed.
- monitoring_servers: specifies the machines to which the Prometheus instances are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- grafana_servers: the configuration of the Grafana instances. The configuration specifies the machines to which the Grafana instances are deployed.
- alertmanager_servers: the configuration of the Alertemanager instances. The configuration specifies the machines to which the Alertmanager instances are deployed.

13.4.9.1.1 `global`

The `global` section corresponds to the cluster's global configuration and has the following fields:

- `user`: the user to start the deployed cluster. The default value is "tidb". If the user specified in the `<user>` field does not exist on the target machine, TiUP will automatically try to create the user.
- `group`: the user group to which a user belongs when the user is automatically created. The default value is the same as the `<user>` field. If the specified group does not exist, it will be created automatically.
- `ssh_port`: the SSH port to connect to the target machine for operations. The default value is "22".
- `deploy_dir`: the deployment directory for each component. The default value is "deploy". The construction rules are as follows:
    - If the absolute path `deploy_dir` is configured at the instance level, the actual deployment directory is the `deploy_dir` configured for the instance.
    - For each instance, if you do not configure `deploy_dir`, the default value is the relative path `<component-name>-<component-port>`.
    - If `global.deploy_dir` is set to an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.
    - If `global.deploy_dir` is set to a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.
- `data_dir`: the data directory. The default value is "data". The construction rules are as follows.
    - If the absolute path `data_dir` is configured at the instance level, the actual data directory is the `data_dir` configured for the instance.
    - For each instance, if `data_dir` is not configured, the default value is `<global.` ↪ `data_dir>`.
    - If `data_dir` is set to a relative path, the component data is stored in `<deploy_dir` ↪ `>/<data_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- `log_dir`: the data directory. The default value is "log". The construction rules are as follows.
    - If the absolute path of `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
    - For each instance, if `log_dir` is not configured by the user, the default value is `<global.log_dir>`.
    - If `log_dir` is a relative path, the component logs will be stored in `<deploy_dir>/<` ↪ `log_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.

- `os`: the operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is "linux".
- `arch`: the CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are "amd64" and "arm64". The default value is "amd64".
- `resource_control`: runtime resource control. All configurations in this field are written to the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
    - `memory_limit`: limits the maximum memory at runtime. For example, "2G" means that the maximum memory of 2 GB can be used.
    - `cpu_quota`: limits the maximum CPU usage at runtime. For example, "200%".
    - `io_read_bandwidth_max`: limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M"`.
    - `io_write_bandwidth_max`: limits the maximum I/O bandwidth for disk writes. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M"` ↪ .
    - `limit_core`: controls the size of core dump.

A `global` configuration example:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the example, the configuration specifies that the `tidb` user is used to start the cluster, and that each component is limited to a maximum of 2 GB of memory when it is running.

13.4.9.1.2 `server_configs`

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configurations in the `server_configs` section can be overwritten by the configurations with the same keys in an instance. `server_configs` mainly contains the following fields:

- `master`: the configuration related to the DM-master service. For all the supported configuration items, see DM-master Configuration File.
- `worker`: the configuration related to the DM-worker service, For all the supported configuration items, see DM-worker Configuration File.

A `server_configs` configuration example is as follows:

```
server_configs:
  master:
    log-level: info
    rpc-timeout: "30s"
    rpc-rate-limit: 10.0
    rpc-rate-burst: 40
  worker:
    log-level: info
```

13.4.9.2 master_servers

`master_servers` specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. `master_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `name`: specifies the name of the DM-master instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- `port`: specifies the port on which DM-master provides services. The default value is "8261".
- `peer_port`: specifies the port for communication between DM-masters. The default value is "8291".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: the configuration rules of this field are the same as that of `master` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `master` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.

- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.
- `v1_source_path`: when upgrading from v1.0.x, you can specify the directory where the configuration file of the V1 source is located in this field.

In the `master_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `name`
- `port`
- `peer_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`
- `v1_source_path`

A `master_servers` configuration example is as follows:

```
master_servers:
  - host: 10.0.1.11
    name: master1
    ssh_port: 22
    port: 8261
    peer_port: 8291
    deploy_dir: "/dm-deploy/dm-master-8261"
    data_dir: "/dm-data/dm-master-8261"
    log_dir: "/dm-deploy/dm-master-8261/log"
    numa_node: "0,1"
    # The following configs are used to overwrite the `server_configs.master
        ↪ ` values.
    config:
      log-level: info
      rpc-timeout: "30s"
      rpc-rate-limit: 10.0
```

```
    rpc-rate-burst: 40
- host: 10.0.1.18
  name: master2
- host: 10.0.1.19
  name: master3
```

13.4.9.3 worker_servers

worker_servers specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. worker_servers is an array. Each array element contains the following fields:

- host: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- ssh_port: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the ssh_port in the global section is used.
- name: specifies the name of the DM-worker instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- port: specifies the port on which DM-worker provides services. The default value is "8262".
- deploy_dir: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the deploy_dir configuration in the global section.
- data_dir: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the data_dir configuration in the global section.
- log_dir: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the log_dir configuration in the global section.
- numa_node: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1".
- config: the configuration rules of this field are the same as that of worker in the server_configs section. If config is specified, the configuration of config will be merged with the configuration of worker in server_configs (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the host field.
- os: the operating system of the machine specified in the host field. If the field is not specified, the default value is the os value configured in the global section.
- arch: the architecture of the machine specified in the host field. If the field is not specified, the default value is the arch value configured in the global section.
- resource_control: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of resource_control

in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `worker_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `name`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `worker_servers` configuration example is as follows:

```
worker_servers:
  - host: 10.0.1.12
    ssh_port: 22
    port: 8262
    deploy_dir: "/dm-deploy/dm-worker-8262"
    log_dir: "/dm-deploy/dm-worker-8262/log"
    numa_node: "0,1"
    # config is used to overwrite the `server_configs.worker` values
    config:
      log-level: info
  - host: 10.0.1.19
```

13.4.9.3.1 `monitoring_servers`

`monitoring_servers` specifies the machines to which the Prometheus service is deployed. You can also specify the service configuration on the machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Prometheus provides services. The default value is "9090".

- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1"
- `storage_retention`: specifies the retention time of the Prometheus monitoring data. The default value is "15d".
- `rule_dir`: specifies a local directory where the complete `*.rules.yml` files are located. The files in the specified directory will be sent to the target machine as the Prometheus rules during the initialization phase of the cluster configuration.
- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
    - `remote_write`: See the Prometheus document `<remote_write>`.
    - `remote_read`: See the Prometheus document `<remote_read>`.
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `monitoring_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`

- data_dir
- log_dir
- arch
- os

A monitoring_servers configuration example is as follows:

```
monitoring_servers:
  - host: 10.0.1.11
    rule_dir: /local/rule/dir
    remote_config:
      remote_write:
      - queue_config:
          batch_send_deadline: 5m
          capacity: 100000
          max_samples_per_send: 10000
          max_shards: 300
        url: http://127.0.0.1:8003/write
      remote_read:
      - url: http://127.0.0.1:8003/read\
      external_alertmanagers:
      - host: 10.1.1.1
      web_port: 9093
      - host: 10.1.1.2
      web_port: 9094
```

13.4.9.3.2 grafana_servers

grafana_servers specifies the machines to which the Grafana service is deployed. You can also specify the service configuration on the machine. grafana_servers is an array. Each array element contains the following fields:

- host: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- ssh_port: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the ssh_port in the global section is used.
- port: specifies the port on which Grafana provides services. The default value is "3000".
- deploy_dir: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the deploy_dir configuration in the global section.
- os: the operating system of the machine specified in the host field. If the field is not specified, the default value is the os value configured in the global section.
- arch: the architecture of the machine specified in the host field. If the field is not specified, the default value is the arch value configured in the global section.

- `username`: specifies the username of the Grafana login screen.
- `password`: specifies the corresponding password of Grafana.
- `dashboard_dir`: specifies a local directory where the complete `dashboard(*.json)` files are located. The files in the specified directory will be sent to the target machine as Grafana dashboards during the initialization phase of the cluster configuration.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

Note:

If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. In the local `dashboards` directory, update the value of the `datasource` field to the new cluster name (the `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

In `grafana_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:
  - host: 10.0.1.11
    dashboard_dir: /local/dashboard/dir
```

13.4.9.3.3 `alertmanager_servers`

`alertmanager_servers` specifies the machines to which the Alertmanager service is deployed. You can also specify the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `web_port`: specify the port on which Alertmanager provides web services. The default value is "9093".
- `cluster_port`: Specify the communication port between one Alertmanger and other Alertmanager. The default value is "9094".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1"
- `config_file`: specifies a local file. The specified file will be sent to the target machine as the configuration for Alertmanager during the initialization phase of the cluster configuration.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In `alertmanager_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`

- arch
- os

An `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
  - host: 10.0.1.11
    config_file: /local/config/file
  - host: 10.0.1.12
    config_file: /local/config/file
```

13.4.10 TiUP Mirror Reference Guide

TiUP mirrors are TiUP's component warehouse, which stores components and their metadata. TiUP mirrors take the following two forms:

- Directory on the local disk: serves the local TiUP client, which is called a local mirror in this document.
- HTTP mirror started based on the remote disk directory: serves the remote TiUP client, which is called a remote mirror in this document.

13.4.10.1 Create and update mirror

You can create a TiUP mirror using one of the following two methods:

- Execute `tiup mirror init` to create a mirror from scratch.
- Execute `tiup mirror clone` to clone from an existing mirror.

After the mirror is created, you can add components to or delete components from the mirror using the `tiup mirror` commands. TiUP updates a mirror by adding files and assigning a new version number to it, rather than deleting any files from the mirror.

13.4.10.2 Mirror structure

A typical mirror structure is as follows:

```
+ <mirror-dir>                                  # Mirror's root directory
|-- root.json                                   # Mirror's root certificate
|-- {2..N}.root.json                            # Mirror's root certificate
|-- {1..N}.index.json                           # Component/user index
|-- {1..N}.{component}.json                     # Component metadata
|-- {component}-{version}-{os}-{arch}.tar.gz # Component binary package
|-- snapshot.json                               # Mirror's latest snapshot
|-- timestamp.json                              # Mirror's latest timestamp
|--+ commits                                    # Mirror's update log (deletable)
```

```
   |--+ commit-{ts1..tsN}
      |-- {N}.root.json
      |-- {N}.{component}.json
      |-- {N}.index.json
      |-- {component}-{version}-{os}-{arch}.tar.gz
      |-- snapshot.json
      |-- timestamp.json
|--+ keys                                    # Mirror's private key (can be
   ↪ moved to other locations)
   |-- {hash1..hashN}-root.json              # Private key of the root
      ↪ certificate
   |-- {hash}-index.json                     # Private key of the indexes
   |-- {hash}-snapshot.json                  # Private key of the snapshots
   |-- {hash}-timestamp.json                 # Private key of the timestamps
```

Note:

- The `commits` directory stores the logs generated in the process of mirror update and is used to roll back the mirror. You can delete the old log directories regularly when the disk space is insufficient.
- The private key stored in the `keys` directory is sensitive. It is recommended to keep it separately.

13.4.10.2.1 Root directory

In a TiUP mirror, the root certificate is used to store the public key of other metadata files. Each time any metadata file (`*.json`) is obtained, TiUP client needs to find the corresponding public key in the installed `root.json` based on the metadata file type (root, index, snapshot, timestamp). Then TiUP client uses the public key to verify whether the signature is valid.

The root certificate's format is as follows:

```
{
   "signatures": [                                    # Each metadata file
      ↪  has some signatures which are signed by several private keys
      ↪ corresponding to the file.
      {
         "keyid": "{id-of-root-key-1}",               # The ID of the
            ↪ first private key that participates in the signature. This
            ↪ ID is obtained by hashing the content of the public key
            ↪ that corresponds to the private key.
```

```
        "sig": "{signature-by-root-key-1}"           # The signed part of
           ↪  this file by this private key.
    },
    ...
    {
        "keyid": "{id-of-root-key-N}",               # The ID of the Nth
           ↪ private key that participates in the signature.
        "sig": "{signature-by-root-key-N}"           # The signed part of
           ↪  this file by this private key.
    }
],
"signed": {                                          # The signed part.
    "_type": "root",                                 # The type of this
       ↪ file. root.json's type is root.
    "expires": "{expiration-date-of-this-file}",     # The expiration
       ↪ time of the file. If the file expires, the client rejects the
       ↪ file.
    "roles": {                                       # Records the keys
       ↪ used to sign each metadata file.
       "{role:index,root,snapshot,timestamp}": {     # Each involved
          ↪ metadata file includes index, root, snapshot, and timestamp
          ↪ .
          "keys": {                                  # Only the key's
             ↪ signature recorded in `keys` is valid.
             "{id-of-the-key-1}": {                  # The ID of the
                ↪ first key used to sign {role}.
                "keytype": "rsa",                    # The key's type.
                   ↪ Currently, the key type is fixed as rsa.
                "keyval": {                          # The key's payload.
                    "public": "{public-key-content}" # The public key's
                       ↪  content.
                },
                "scheme": "rsassa-pss-sha256"        # Currently, the
                   ↪ scheme is fixed as rsassa-pss-sha256.
             },
             "{id-of-the-key-N}": {                  # The ID of the Nth
                ↪ key used to sign {role}.
                "keytype": "rsa",
                "keyval": {
                    "public": "{public-key-content}"
                },
                "scheme": "rsassa-pss-sha256"
             }
          },
          "threshold": {N},                          # Indicates that the
```

```
                ↪  metadata file needs at least N key signatures.
            "url": "/{role}.json"                    # The address from
                ↪ which the file can be obtained. For index files, prefix
                ↪  it with the version number (for example, /{N}.index.
                ↪ json).
        }
    },
    "spec_version": "0.1.0",                         # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": {N}                                   # The version number
        ↪  of this file. You need to create a new {N+1}.root.json every
        ↪ time you update the file, and set its version to N + 1.
  }
}
```

13.4.10.2.2 Index

The index file records all the components in the mirror and the owner information of the components.

The index file's format is as follows:

```
{
  "signatures": [                                    # The file's
      ↪ signature.
    {
      "keyid": "{id-of-index-key-1}",                # The ID of the
          ↪ first private key that participates in the signature.
      "sig": "{signature-by-index-key-1}",           # The signed part of
          ↪  this file by this private key.
    },
    ...
    {
      "keyid": "{id-of-root-key-N}",                 # The ID of the Nth
          ↪ private key that participates in the signature.
      "sig": "{signature-by-root-key-N}"             # The signed part of
          ↪  this file by this private key.
    }
  ],
  "signed": {
    "_type": "index",                                # The file type.
    "components": {                                  # The component list
        ↪ .
```

```
    "{component1}": {                               # The name of the
       ↪ first component.
        "hidden": {bool},                           # Whether it is a
           ↪ hidden component.
        "owner": "{owner-id}",                      # The component
           ↪ owner's ID.
        "standalone": {bool},                       # Whether it is a
           ↪ standalone component.

        }
    }
    "spec_version": "0.1.0",                           # The specified
       ↪ version followed by this file. If the file structure is
       ↪ changed in the future, the version number needs to be upgraded
       ↪ . The current version number is 0.1.0.
    "version": {N}                                     # The version number
       ↪  of this file. You need to create a new {N+1}.index.json every
       ↪  time you update the file, and set its version to N + 1.
}
}
```

13.4.10.2.3 Component

The component's metadata file records information of the component-specific platform and the version.

The component metadata file's format is as follows:

```
{
    "signatures": [                                    # The file's
       ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",            # The ID of the
               ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",       # The signed part of
               ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",             # The ID of the Nth
               ↪ private key that participates in the signature.
```

```
        "sig": "{signature-by-root-key-N}"           # The signed part of
           ↪  this file by this private key.
    }
],
"signed": {
    "_type": "component",                            # The file type.
    "description": "{description-of-the-component}", # The description of
       ↪  the component.
    "expires": "{expiration-date-of-this-file}",     # The expiration
       ↪ time of the file. If the file expires, the client rejects the
       ↪ file.
    "id": "{component-id}",                          # The globally
       ↪ unique ID of the component.
    "nightly": "{nightly-cursor}",                   # The nightly cursor
       ↪ , and the value is the latest nightly version number (for
       ↪ example, v5.0.0-nightly-20201209).
    "platforms": {                                   # The component's
       ↪ supported platforms (such as darwin/amd64, linux/arm64).
        "{platform-pair-1}": {
            "{version-1}": {                         # The semantic
               ↪ version number (for example, v1.0.0).
                "dependencies": null,                # Specifies the
                   ↪ dependency relationship between components. The
                   ↪ field is not used yet and is fixed as null.
                "entry": "{entry}",                  # The relative path
                   ↪ of the entry binary file in the tar package.
                "hashs": {                           # The checksum of
                   ↪ the tar package. sha256 and sha512 are used.
                    "sha256": "{sum-of-sha256}",
                    "sha512": "{sum-of-sha512}",
                },
                "length": {length-of-tar},           # The length of the
                   ↪ tar package.
                "released": "{release-time}",        # The release date
                   ↪ of the version.
                "url": "{url-of-tar}",               # The download
                   ↪ address of the tar package.
                "yanked": {bool}                     # Indicates whether
                   ↪ this version is disabled.
            }
        },
        ...
        "{platform-pair-N}": {
            ...
        }
```

```
        },
        "spec_version": "0.1.0",                                # The specified
            ↪ version followed by this file. If the file structure is
            ↪ changed in the future, the version number needs to be upgraded
            ↪ . The current version number is 0.1.0.
        "version": {N}                                          # The version number
            ↪  of this file. You need to create a new {N+1}.{component}.json
            ↪  every time you update the file, and set its version to N + 1.
}
```

13.4.10.2.4 Snapshot

The snapshot file records the version number of each metadata file:

The snapshot file's structure is as follows:

```
{
    "signatures": [                                             # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                     # The ID of the
                ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",                # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                      # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"                  # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "snapshot",                                    # The file type.
        "expires": "{expiration-date-of-this-file}",            # The expiration
            ↪ time of the file. If the file expires, the client rejects the
            ↪ file.
        "meta": {                                               # Other metadata
            ↪ files' information.
            "/root.json": {
                "length": {length-of-json-file},                # The length of root
                    ↪ .json
                "version": {version-of-json-file}               # The version of
                    ↪ root.json
            },
```

```
            "/index.json": {
                "length": {length-of-json-file},
                "version": {version-of-json-file}
            },
            "/{component-1}.json": {
                "length": {length-of-json-file},
                "version": {version-of-json-file}
            },
            ...
            "/{component-N}.json": {
                ...
            }
        },
        "spec_version": "0.1.0",                            # The specified
            ↪ version followed by this file. If the file structure is
            ↪ changed in the future, the version number needs to be upgraded
            ↪ . The current version number is 0.1.0.
        "version": 0                                        # The version number
            ↪  of this file, which is fixed as 0.
    }
```

13.4.10.2.5 Timestamp

The timestamp file records the checksum of the current snapshot.

The timestamp file's format is as follows:

```
{
    "signatures": [                                         # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                 # The ID of the
                ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",            # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "timestamp",                               # The file type.
```

```
    "expires": "{expiration-date-of-this-file}",     # The expiration
       ↪ time of the file. If the file expires, the client rejects the
       ↪ file.
    "meta": {                                        # The information of
       ↪  snapshot.json.
       "/snapshot.json": {
          "hashes": {
             "sha256": "{sum-of-sha256}"             # snapshot.json's
                ↪ sha256.
          },
          "length": {length-of-json-file}            # The length of
             ↪ snapshot.json.
       }
    },
    "spec_version": "0.1.0",                         # The specified
       ↪ version followed by this file. If the file structure is
       ↪ changed in the future, the version number needs to be upgraded
       ↪ . The current version number is 0.1.0.
    "version": {N}                                   # The version number
       ↪  of this file. You need to overwrite timestamp.json every time
       ↪  you update the file, and set its version to N + 1.
```

13.4.10.3 Client workflow

The client uses the following logic to ensure that the files downloaded from the mirror are safe:

- A `root.json` file is included with the binary when the client is installed.
- The running client performs the following tasks based on the existing `root.json`:

    1. Obtain the version from `root.json` and mark it as `N`.
    2. Request `{N+1}.root.json` from the mirror. If the request is successful, use the public key recorded in `root.json` to verify whether the file is valid.
    3. Request `timestamp.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
    4. Check whether the checksum of `snapshot.json` recorded in `timestamp.json` matches the checksum of the local `snapshot.json`. If the two do not match, request the latest `snapshot.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
    5. Obtain the version number `N` of the `index.json` file from `snapshot.json` and request `{N}.index.json` from the mirror. Then use the public key recorded in `root.json` to verify whether the file is valid.
    6. For components such as `tidb.json` and `tikv.json`, the client obtains the version numbers `N` of the components from `snapshot.json` and requests `{N}.{component ↪ }.json` from the mirror. Then the client uses the public key recorded in

`index.json` to verify whether the file is valid.

7. For component's tar files, the client obtains the URLs and checksums of the files from `{component}.json` and request the URLs for the tar packages. Then the client verifies whether the checksum is correct.

13.4.11 TiUP Components

13.4.11.1 Quickly Deploy a Local TiDB Cluster

The TiDB cluster is a distributed system that consists of multiple components. A typical TiDB cluster consists of at least three PD nodes, three TiKV nodes, and two TiDB nodes. If you want to have a quick experience on TiDB, you might find it time-consuming and complicated to manually deploy so many components. This document introduces the playground component of TiUP and how to use it to quickly build a local TiDB test environment.

13.4.11.1.1 TiUP playground overview

The basic usage of the playground component is shown as follows:

```
tiup playground ${version} [flags]
```

If you directly execute the `tiup playground` command, TiUP uses the locally installed TiDB, TiKV, and PD components or installs the stable version of these components to start a TiDB cluster that consists of one TiKV instance, one TiDB instance, one PD instance, and one TiFlash instance.

This command actually performs the following operations:

- Because this command does not specify the version of the playground component, TiUP first checks the latest version of the installed playground component. Assume that the latest version is v1.11.3, then this command works the same as `tiup playground:v1 ↪ .11.3`.
- If you have not used TiUP playground to install the TiDB, TiKV, and PD components, the playground component installs the latest stable version of these components, and then start these instances.
- Because this command does not specify the version of the TiDB, PD, and TiKV component, TiUP playground uses the latest version of each component by default. Assume that the latest version is v7.1.5, then this command works the same as `tiup ↪ playground:v1.11.3 v7.1.5`.
- Because this command does not specify the number of each component, TiUP playground, by default, starts a smallest cluster that consists of one TiDB instance, one TiKV instance, one PD instance, and one TiFlash instance.
- After starting each TiDB component, TiUP playground reminds you that the cluster is successfully started and provides you some useful information, such as how to connect to the TiDB cluster through the MySQL client and how to access the TiDB Dashboard.

The command-line flags of the playground component are described as follows:

```
Flags:
      --db int                Specify the number of TiDB instances (default:
         ↪ 1)
      --db.host host          Specify the listening address of TiDB
      --db.port int           Specify the port of TiDB
      --db.binpath string     Specify the TiDB instance binary path (optional
         ↪ , for debugging)
      --db.config string      Specify the TiDB instance configuration file (
         ↪ optional, for debugging)
      --db.timeout int        Specify TiDB maximum wait time in seconds for
         ↪ starting. 0 means no limit
      --drainer int           Specify Drainer data of the cluster
      --drainer.binpath string Specify the location of the Drainer binary
         ↪ files (optional, for debugging)
      --drainer.config string Specify the Drainer configuration file
  -h, --help                  help for tiup
      --host string           Specify the listening address of each component
         ↪  (default: `127.0.0.1`). Set it to `0.0.0.0` if provided for
         ↪ access of other machines
      --kv int                Specify the number of TiKV instances (default:
         ↪ 1)
      --kv.binpath string     Specify the TiKV instance binary path (optional
         ↪ , for debugging)
      --kv.config string      Specify the TiKV instance configuration file (
         ↪ optional, for debugging)
      --mode string           Specify the playground mode: 'tidb' (default)
         ↪ and 'tikv-slim'
      --pd int                Specify the number of PD instances (default: 1)
      --pd.host host          Specify the listening address of PD
      --pd.binpath string     Specify the PD instance binary path (optional,
         ↪ for debugging)
      --pd.config string      Specify the PD instance configuration file (
         ↪ optional, for debugging)
      --pump int              Specify the number of Pump instances. If the
         ↪ value is not `0`, TiDB Binlog is enabled.
      --pump.binpath string   Specify the location of the Pump binary files (
         ↪ optional, for debugging)
      --pump.config string    Specify the Pump configuration file (optional,
         ↪ for debugging)
      -T, --tag string        Specify a tag for playground
      --ticdc int             Specify the number of TiCDC instances (default:
         ↪  0)
      --ticdc.binpath string  Specify the TiCDC instance binary path (
         ↪ optional, for debugging)
```

```
    --ticdc.config string   Specify the TiCDC instance configuration file (
        ↪ optional, for debugging)
    --tiflash int           Specify the number of TiFlash instances (
        ↪ default: 1)
    --tiflash.binpath string Specify the TiFlash instance binary path (
        ↪ optional, for debugging)
    --tiflash.config string Specify the TiFlash instance configuration
        ↪ file (optional, for debugging)
    --tiflash.timeout int   Specify TiFlash maximum wait time in seconds
        ↪ for starting. 0 means no limit
    -v, --version           Specify the version of playground
    --without-monitor       Disable the monitoring function of Prometheus
        ↪ and Grafana. If you do not add this flag, the monitoring
        ↪ function is enabled by default.
```

13.4.11.1.2 Examples

Check available TiDB versions

```
tiup list tidb
```

Start a TiDB cluster of a specific version

```
tiup playground ${version}
```

Replace `${version}` with the target version number.

Start a TiDB cluster of the nightly version

```
tiup playground nightly
```

In the command above, `nightly` indicates the latest development version of TiDB.

Override PD's default configuration

First, you need to copy the PD configuration template. Assume you place the copied file to `~/config/pd.toml` and make some changes according to your need, then you can execute the following command to override PD's default configuration:

```
tiup playground --pd.config ~/config/pd.toml
```

Replace the default binary files

By default, when playground is started, each component is started using the binary files from the official mirror. If you want to put a temporarily compiled local binary file into the cluster for testing, you can use the `--{comp}.binpath` flag for replacement. For example, execute the following command to replace the binary file of TiDB:

```
tiup playground --db.binpath /xx/tidb-server
```

Start multiple component instances

By default, only one instance is started for each TiDB, TiKV, and PD component. To start multiple instances for each component, add the following flag:

```
tiup playground --db 3 --pd 3 --kv 3
```

Specify a tag when starting the TiDB cluster

After you stop a TiDB cluster started using TiUP playground, all cluster data is cleaned up as well. To start a TiDB cluster using TiUP playground and ensure that the cluster data is not cleaned up automatically, you can specify a tag when starting the cluster. After specifying the tag, you can find the cluster data in the `~/.tiup/data` directory. Run the following command to specify a tag:

```
tiup playground --tag <tagname>
```

For a cluster started in this way, the data files are retained after the cluster is stopped. You can use this tag to start the cluster next time so that you can use the data kept since the cluster was stopped.

13.4.11.1.3 Quickly connect to the TiDB cluster started by playground

TiUP provides the `client` component, which is used to automatically find and connect to a local TiDB cluster started by playground. The usage is as follows:

```
tiup client
```

This command provides a list of TiDB clusters that are started by playground on the current machine on the console. Select the TiDB cluster to be connected. After clicking Enter, a built-in MySQL client is opened to connect to TiDB.

13.4.11.1.4 View information of the started cluster

```
tiup playground display
```

The command above returns the following results:

```
Pid   Role    Uptime
---   ----    ------
84518 pd      35m22.929404512s
84519 tikv    35m22.927757153s
84520 pump    35m22.92618275s
86189 tidb    exited
86526 tidb    34m28.293148663s
86190 drainer 35m19.91349249s
```

13.4.11.1.5 Scale out a cluster

The command-line parameter for scaling out a cluster is similar to that for starting a cluster. You can scale out two TiDB instances by executing the following command:

```
tiup playground scale-out --db 2
```

13.4.11.1.6 Scale in a cluster

You can specify a `pid` in the `tiup playground scale-in` command to scale in the corresponding instance. To view the `pid`, execute `tiup playground display`.

```
tiup playground scale-in --pid 86526
```

13.4.11.2 Deploy and Maintain an Online TiDB Cluster Using TiUP

This document focuses on how to use the TiUP cluster component. For the complete steps of online deployment, refer to Deploy a TiDB Cluster Using TiUP.

Similar to the TiUP playground component used for a local test deployment, the TiUP cluster component quickly deploys TiDB for production environment. Compared with playground, the cluster component provides more powerful production cluster management features, including upgrading, scaling, and even operation and auditing.

For the help information of the cluster component, run the following command:

```
tiup cluster
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.11.3/
    ↪ cluster
Deploy a TiDB cluster for production

Usage:
  tiup cluster [command]

Available Commands:
  check       Precheck a cluster
  deploy      Deploy a cluster for production
  start       Start a TiDB cluster
  stop        Stop a TiDB cluster
  restart     Restart a TiDB cluster
  scale-in    Scale in a TiDB cluster
  scale-out   Scale out a TiDB cluster
  destroy     Destroy a specified cluster
  clean       (Experimental) Clean up a specified cluster
  upgrade     Upgrade a specified TiDB cluster
  display     Display information of a TiDB cluster
```

```
  list       List all clusters
  audit      Show audit log of cluster operation
  import     Import an existing TiDB cluster from TiDB-Ansible
  edit-config Edit TiDB cluster config
  reload     Reload a TiDB cluster's config and restart if needed
  patch      Replace the remote package with a specified package and restart
     ↪  the service
  help       Help about any command

Flags:
  -c, --concurrency int  Maximum number of concurrent tasks allowed (
     ↪ defaults to `5`)
      --format string    (EXPERIMENTAL) The format of output, available
         ↪ values are [default, json] (default "default")
  -h, --help             help for tiup
      --ssh string       (Experimental) The executor type. Optional values
         ↪ are 'builtin', 'system', and 'none'.
      --ssh-timeout uint Timeout in seconds to connect a host via SSH.
         ↪ Operations that don't need an SSH connection are ignored. (
         ↪ default 5)
  -v, --version         TiUP version
      --wait-timeout uint Timeout in seconds to wait for an operation to
         ↪ complete. Inapplicable operations are ignored. (defaults to
         ↪ `120`)
  -y, --yes              Skip all confirmations and assumes 'yes'
```

13.4.11.2.1 Deploy the cluster

To deploy the cluster, run the `tiup cluster deploy` command. The usage of the command is as follows:

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

This command requires you to provide the cluster name, the TiDB cluster version (such as `v7.1.5`), and a topology file of the cluster.

To write a topology file, refer to the example. The following file is an example of the simplest topology:

> **Note:**
>
> The topology file used by the TiUP cluster component for deployment and scaling is written using yaml syntax, so make sure that the indentation is correct.

```
---

pd_servers:
  - host: 172.16.5.134
    name: pd-134
  - host: 172.16.5.139
    name: pd-139
  - host: 172.16.5.140
    name: pd-140

tidb_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

tikv_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

tiflash_servers:
  - host: 172.16.5.141
  - host: 172.16.5.142
  - host: 172.16.5.143

grafana_servers:
  - host: 172.16.5.134

monitoring_servers:
  - host: 172.16.5.134
```

By default, TiUP is deployed as the binary files running on the amd64 architecture. If the target machine is the arm64 architecture, you can configure it in the topology file:

```
global:
  arch: "arm64"        # Configures all machines to use the binary files of
     ↪ the arm64 architecture by default

tidb_servers:
  - host: 172.16.5.134
    arch: "amd64"      # Configures this machine to use the binary files of
       ↪ the amd64 architecture
  - host: 172.16.5.139
    arch: "arm64"      # Configures this machine to use the binary files of
       ↪ the arm64 architecture
```

```
  - host: 172.16.5.140 # Machines that are not configured with the arch
    ↪ field use the default value in the global field, which is arm64 in
    ↪ this case.

...
```

Save the file as `/tmp/topology.yaml`. If you want to use TiDB v7.1.5 and your cluster name is `prod-cluster`, run the following command:

```
tiup cluster deploy -p prod-cluster v7.1.5 /tmp/topology.yaml
```

During the execution, TiUP asks you to confirm your topology again and requires the root password of the target machine (the `-p` flag means inputting password):

```
Please confirm your topology:
TiDB Cluster: prod-cluster
TiDB Version: v7.1.5
Type       Host         Ports                          OS/Arch      Directories

```

```
Attention:
    1. If the topology is not what you expected, check your yaml file.
    2. Please confirm there is no port/directory conflicts in same host.
Do you want to continue? [y/N]:
```

After you enter the password, TiUP cluster downloads the required components and deploy them on the corresponding machines. When you see the following message, the deployment is successful:

```
Deployed cluster `prod-cluster` successfully
```

13.4.11.2.2 View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup cluster list
```

```
Starting /root/.tiup/components/cluster/v1.11.3/cluster list
Name         User Version   Path
    ↪ PrivateKey
----         ---- -------   ----
    ↪ ----------
prod-cluster tidb v7.1.5  /root/.tiup/storage/cluster/clusters/prod-cluster
    ↪  /root/.tiup/storage/cluster/clusters/prod-cluster/ssh/id_rsa
```

13.4.11.2.3 Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup cluster start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup cluster list`.

TiUP uses `systemd` to start a daemon process. If the process terminates unexpectedly, it will be pulled up after 15 seconds.

13.4.11.2.4 Check the cluster status

TiUP provides the `tiup cluster display` command to view the status of each component in the cluster. With this command, you don't have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.11.3/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v7.1.5
ID                  Role       Host         Ports                            OS/
   ↪ Arch     Status Data Dir           Deploy Dir

```

The `Status` column uses `Up` or `Down` to indicate whether the service is running normally.

For the PD component, `|L` or `|UI` might be appended to `Up` or `Down`. `|L` indicates that the PD node is a Leader, and `|UI` indicates that TiDB Dashboard is running on the PD node.

13.4.11.2.5 Scale in a cluster

Note:

This section describes only the syntax of the scale-in command. For detailed steps of online scaling, refer to Scale a TiDB Cluster Using TiUP.

Scaling in a cluster means making some node(s) offline. This operation removes the specific node(s) from the cluster and deletes the remaining files.

Because the offline process of the TiKV, TiFlash, and TiDB Binlog components is asynchronous (which requires removing the node through API), and the process takes a long time (which requires continuous observation on whether the node is successfully taken offline), special treatment is given to the TiKV, TiFlash, and TiDB Binlog components.

- For TiKV, TiFlash, and Binlog:
    - TiUP cluster takes the node offline through API and directly exits without waiting for the process to be completed.
    - Afterwards, when a command related to the cluster operation is executed, TiUP cluster examines whether there is a TiKV, TiFlash, or Binlog node that has been taken offline. If not, TiUP cluster continues with the specified operation; If there is, TiUP cluster takes the following steps:
        1. Stop the service of the node that has been taken offline.
        2. Clean up the data files related to the node.
        3. Remove the node from the cluster topology.
- For other components:
    - When taking the PD component down, TiUP cluster quickly deletes the specified node from the cluster through API, stops the service of the specified PD node, and deletes the related data files.
    - When taking other components down, TiUP cluster directly stops the node service and deletes the related data files.

The basic usage of the scale-in command:

```
tiup cluster scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two flags: the cluster name and the node ID. The node ID can be obtained by using the `tiup cluster display` command in the previous section.

For example, to make the TiKV node on `172.16.5.140` offline, run the following command:

```
tiup cluster scale-in prod-cluster -N 172.16.5.140:20160
```

By running `tiup cluster display`, you can see that the TiKV node is marked `Offline`:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.11.3/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v7.1.5
ID                  Role        Host         Ports                            OS/

```

After PD schedules the data on the node to other TiKV nodes, this node will be deleted automatically.

13.4.11.2.6 Scale out a cluster

> **Note:**
>
> This section describes only the syntax of the scale-out command. For detailed steps of online scaling, refer to Scale a TiDB Cluster Using TiUP.

The scale-out operation has an inner logic similar to that of deployment: the TiUP cluster component firstly ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

When you scale out PD, the node is added to the cluster by `join`, and the configurations of services associated with PD are updated. When you scale out other services, the service is started directly and added to the cluster.

All services conduct correctness validation when they are scaled out. The validation results show whether the scaling-out is successful.

To add a TiKV node and a PD node in the `tidb-test` cluster, take the following steps:

1. Create a `scale.yaml` file, and add IPs of the new TiKV and PD nodes:

> **Note:**
>
> You need to create a topology file, which includes only the description of the new nodes, not the existing nodes.

```
---

pd_servers:
  - host: 172.16.5.140

tikv_servers:
  - host: 172.16.5.140
```

2. Perform the scale-out operation. TiUP cluster adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup cluster scale-out tidb-test scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup cluster display tidb-test`.

13.4.11.2.7 Rolling upgrade

> **Note:**
>
> This section describes only the syntax of the upgrade command. For detailed steps of online upgrade, refer to Upgrade TiDB Using TiUP.

The rolling upgrade feature leverages the distributed capabilities of TiDB. The upgrade process is made as transparent as possible to the application, and does not affect the business.

Before the upgrade, TiUP cluster checks whether the configuration file of each component is rational. If so, the components are upgraded node by node; if not, TiUP reports an error and exits. The operations vary with different nodes.

Operations for different nodes

- Upgrade the PD node
    - First, upgrade non-Leader nodes.
    - After all the non-Leader nodes are upgraded, upgrade the Leader node.
        - The upgrade tool sends a command to PD that migrates Leader to an already upgraded node.
        - After the Leader role is switched to another node, upgrade the previous Leader node.
    - During the upgrade, if any unhealthy node is detected, the tool stops this upgrade operation and exits. You need to manually analyze the cause, fix the issue and run the upgrade again.
- Upgrade the TiKV node
    - First, add a scheduling operation in PD that migrates the Region Leader of this TiKV node. This ensures that the upgrade process does not affect the business.
    - After the Leader is migrated, upgrade this TiKV node.
    - After the upgraded TiKV is started normally, remove the scheduling of the Leader.
- Upgrade other services
    - Stop the service normally and update the node.

Upgrade command

The flags for the upgrade command is as follows:

```
Usage:
  cluster upgrade <cluster-name> <version> [flags]

Flags:
      --force                Force upgrade won't transfer leader
  -h, --help                 help for upgrade
      --transfer-timeout int Timeout in seconds when transferring PD and
         ↪ TiKV store leaders (default 600)

Global Flags:
      --ssh string       (Experimental) The executor type. Optional values
         ↪ are 'builtin', 'system', and 'none'.
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes              Skip all confirmations and assumes 'yes'
```

For example, the following command upgrades the cluster to v7.1.5:

```
tiup cluster upgrade tidb-test v7.1.5
```

13.4.11.2.8 Update configuration

If you want to dynamically update the component configurations, the TiUP cluster component saves a current configuration for each cluster. To edit this configuration, execute the `tiup cluster edit-config <cluster-name>` command. For example:

```
tiup cluster edit-config prod-cluster
```

TiUP cluster opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano`.

After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup cluster reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

> **Note:**
>
> For monitoring components, customize the configuration by executing the `tiup cluster edit-config` command to add a custom configuration path on the corresponding instance. For example:

```
---

grafana_servers:
  - host: 172.16.5.134
    dashboard_dir: /path/to/local/dashboards/dir

monitoring_servers:
  - host: 172.16.5.134
    rule_dir: /path/to/local/rules/dir

alertmanager_servers:
  - host: 172.16.5.134
    config_file: /path/to/local/alertmanager.yml
```

The content and format requirements for files under the specified path are as follows:

- The folder specified in the `dashboard_dir` field of `grafana_servers` must contain full `*.json` files.
- The folder specified in the `rule_dir` field of `monitoring_servers` must contain full `*.rules.yml` files.
- For the format of files specified in the `config_file` field of `alertmanager_servers`, refer to the Alertmanager configuration template.

When you execute `tiup reload`, TiUP first deletes all old configuration files in the target machine and then uploads the corresponding configuration from the control machine to the corresponding configuration directory of the target machine. Therefore, if you want to modify a particular configuration file, make sure that all configuration files (including the unmodified ones) are in the same directory. For example, to modify Grafana's `tidb.json` file, you need to first copy all the `*.json` files from Grafana's `dashboards` directory to your local directory. Otherwise, other JSON files will be missing from the target machine.

Note:

If you have configured the `dashboard_dir` field of `grafana_servers`, after executing the `tiup cluster rename` command to rename the cluster, you need to complete the following operations:

1. In the local `dashboards` directory, change the cluster name to the new cluster name.
2. In the local `dashboards` directory, change `datasource` to the new cluster name, because `datasource` is named after the cluster name.
3. Execute the `tiup cluster reload -R grafana` command.

13.4.11.2.9 Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  cluster patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --offline             Patch a stopped cluster
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the roles
      --transfer-timeout uint Timeout in seconds when transferring PD and
          ↪ TiKV store leaders, also for TiCDC drain one capture (default
          ↪ 600)

Global Flags:
  -c, --concurrency int  max number of parallel tasks allowed (default 5)
      --format string    (EXPERIMENTAL) The format of output, available
          ↪ values are [default, json] (default "default")
      --ssh string       (EXPERIMENTAL) The executor type: 'builtin', '
          ↪ system', 'none'.
      --ssh-timeout uint Timeout in seconds to connect host via SSH, ignored
          ↪  for operations that don't need an SSH connection. (default 5)
      --wait-timeout uint Timeout in seconds to wait for an operation to
          ↪ complete, ignored for operations that don't fit. (default 120)
  -y, --yes              Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

13.4.11.2.10 Import TiDB Ansible cluster

> **Note:**
>
> Currently, TiUP cluster's support for TiSpark is still **experimental**. It is not supported to import a TiDB cluster with TiSpark enabled.

Before TiUP is released, TiDB Ansible is often used to deploy TiDB clusters. To enable TiUP to take over the cluster deployed by TiDB Ansible, use the `import` command.

The usage of the `import` command is as follows:

```
tiup cluster import --help
```

```
Import an exist TiDB cluster from TiDB-Ansible

Usage:
  cluster import [flags]

Flags:
  -d, --dir string      The path to TiDB-Ansible directory
  -h, --help            help for import
      --inventory string The name of inventory file (default "inventory.ini
         ↪ ")
      --no-backup       Don't backup ansible dir, useful when there're
         ↪ multiple inventory files
  -r, --rename NAME     Rename the imported cluster to NAME

Global Flags:
      --ssh string      (Experimental) The executor type. Optional values are
         ↪  'builtin', 'system', and 'none'.
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

You can use either of the following commands to import a TiDB Ansible cluster:

```
cd tidb-ansible
tiup cluster import
```

```
tiup cluster import --dir=/path/to/tidb-ansible
```

13.4.11.2.11 View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
  tiup cluster audit [audit-id] [flags]

Flags:
  -h, --help help for audit
```

If the `[audit-id]` flag is not specified, the command shows a list of commands that have been executed. For example:

```
tiup cluster audit
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.11.3/
    ↪ cluster audit
ID     Time                       Command
--     ----                       -------
4BLhr0 2024-04-26T23:55:09+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .11.3/cluster deploy test v7.1.5 /tmp/topology.yaml
4BKWjF 2024-04-26T23:36:57+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .11.3/cluster deploy test v7.1.5 /tmp/topology.yaml
4BKVwH 2024-04-26T23:02:08+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .11.3/cluster deploy test v7.1.5 /tmp/topology.yaml
4BKKH1 2024-04-26T16:39:04+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .11.3/cluster destroy test
4BKKDx 2024-04-26T16:36:57+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .11.3/cluster deploy test v7.1.5 /tmp/topology.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` of a command as the flag as follows:

```
tiup cluster audit 4BLhr0
```

13.4.11.2.12 Run commands on a host in the TiDB cluster

To run command on a host in the TiDB cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
  cluster exec <cluster-name> [flags]

Flags:
      --command string the command run on cluster host (default "ls")
  -h, --help           help for exec
```

```
  -N, --node strings  Only exec on host with specified nodes
  -R, --role strings  Only exec on host with specified roles
      --sudo          use root permissions (default false)

Global Flags:
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes            Skip all confirmations and assumes 'yes'
```

For example, to execute `ls /tmp` on all TiDB nodes, run the following command:

```
tiup cluster exec test-cluster --command='ls /tmp'
```

13.4.11.2.13 Cluster controllers

Before TiUP is released, you can control the cluster using `tidb-ctl`, `tikv-ctl`, `pd-ctl`, and other tools. To make the tools easier to download and use, TiUP integrates them into an all-in-one component, `ctl`.

```
Usage:
  tiup ctl:v<CLUSTER_VERSION> {tidb/pd/tikv/binlog/etcd} [flags]

Flags:
  -h, --help help for tiup
```

This command has a corresponding relationship with those of the previous tools:

```
tidb-ctl [args] = tiup ctl tidb [args]
pd-ctl [args] = tiup ctl pd [args]
tikv-ctl [args] = tiup ctl tikv [args]
binlogctl [args] = tiup ctl bindlog [args]
etcdctl [args] = tiup ctl etcd [args]
```

For example, if you previously view the store by running `pd-ctl -u http://127.0.0.1:2379 store`, now you can run the following command in TiUP:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://127.0.0.1:2379 store
```

13.4.11.2.14 Environment checks for target machines

You can use the `check` command to perform a series of checks on the environment of the target machine and output the check results. By executing the `check` command, you can find common unreasonable configurations or unsupported situations. The command flag list is as follows:

```
Usage:
  tiup cluster check <topology.yml | cluster-name> [flags]
Flags:
      --apply               Try to fix failed checks
      --cluster             Check existing cluster, the input is a cluster
         ↪ name.
      --enable-cpu          Enable CPU thread count check
      --enable-disk         Enable disk IO (fio) check
      --enable-mem          Enable memory size check
  -h, --help                help for check
  -i, --identity_file string The path of the SSH identity file. If specified
     ↪ , public key authentication will be used.
  -p, --password            Use password of target hosts. If specified,
     ↪ password authentication will be used.
      --user string         The user name to login via SSH. The user must
         ↪ has root (or sudo) privilege.
```

By default, this command is used to check the environment before deployment. By specifying the `--cluster` flag to switch the mode, you can also check the target machines of an existing cluster, for example:

```
#### check deployed servers before deployment
tiup cluster check topology.yml --user tidb -p
#### check deployed servers of an existing cluster
tiup cluster check <cluster-name> --cluster
```

The CPU thread count check, memory size check, and disk performance check are disabled by default. For the production environment, it is recommended that you enable the three checks and make sure they pass to obtain the best performance.

- CPU: If the number of threads is greater than or equal to 16, the check is passed.
- Memory: If the total size of physical memory is greater than or equal to 32 GB, the check is passed.
- Disk: Execute `fio` test on the partitions of `data_dir` and record the results.

When running the checks, if the `--apply` flag is specified, the program automatically repairs the failed items. Automatic repair is limited to some items that can be adjusted by modifying the configuration or system parameters. Other unrepaired items need to be handled manually according to the actual situation.

Environment checks are not necessary for deploying a cluster. For the production environment, it is recommended to perform environment checks and pass all check items before deployment. If not all the check items are passed, the cluster might be deployed and run normally, but the best performance might not be obtained.

13.4.11.2.15 Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--ssh=system` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup cluster deploy <cluster-name> <version> <topo> --ssh=system`. Fill in the name of your cluster for `<cluster-name>`, the TiDB version to be deployed (such as `v7.1.5`) for `<version>`, and the topology file for `<topo>`.
- Start a cluster: `tiup cluster start <cluster-name> --ssh=system`
- Upgrade a cluster: `tiup cluster upgrade ... --ssh=system`

You can add `--ssh=system` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
#### or
export TIUP_NATIVE_SSH=1
#### or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--ssh` at the same time, `--ssh` has higher priority.

> **Note:**
>
> During the process of cluster deployment, if you need to use a password for connection (`-p`) or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

13.4.11.2.16 Migrate control machine and back up TiUP data

The TiUP data is stored in the `.tiup` directory in the user's home directory. To migrate the control machine, you can take the following steps to copy the `.tiup` directory to the corresponding target machine:

1. Execute `tar czvf tiup.tar.gz .tiup` in the home directory of the original machine.
2. Copy `tiup.tar.gz` to the home directory of the target machine.
3. Execute `tar xzvf tiup.tar.gz` in the home directory of the target machine.
4. Add the `.tiup` directory to the `PATH` environment variable.

   If you use `bash` and you are a `tidb` user, you can add `export PATH=/home/tidb` ↪ `/.tiup/bin:$PATH` in `~/.bashrc` and execute `source ~/.bashrc`. Then make corresponding adjustments according to the shell and the user you use.

> **Note:**
>
> It is recommended that you back up the `.tiup` directory regularly to avoid the loss of TiUP data caused by abnormal conditions, such as disk damage of the control machine.

13.4.11.2.17 Back up and restore meta files for cluster deployment and O&M

If the meta files used for operation and maintenance (O&M) are lost, managing the cluster using TiUP will fail. It is recommended that you back up the meta files regularly by running the following command:

```
tiup cluster meta backup ${cluster_name}
```

If the meta files are lost, you can restore them by running the following command:

```
tiup cluster meta restore ${cluster_name} ${backup_file}
```

> **Note:**
>
> The restore operation overwrites the current meta files. Therefore, it is recommended to restore the meta files only when they are lost.

13.4.11.3 Create a Private Mirror

When creating a private cloud, usually, you need to use an isolated network environment, where the official mirror of TiUP is not accessible. Therefore, you can create a private mirror, which is mainly implemented by the `mirror` command. You can also use the `mirror` command for offline deployment. A private mirror also allows you to use components that you build and package by yourself.

13.4.11.3.1 TiUP `mirror` overview

Execute the following command to get the help information of the `mirror` command:

```
tiup mirror --help
```

```
The `mirror` command is used to manage a component repository for TiUP, you
    ↪  can use
it to create a private repository, or to add new component to an existing
    ↪ repository.
The repository can be used either online or offline.
It also provides some useful utilities to help manage keys, users, and
    ↪ versions
of components or the repository itself.

Usage:
  tiup mirror <command> [flags]

Available Commands:
  init       Initialize an empty repository
  sign       Add signatures to a manifest file
  genkey     Generate a new key pair
  clone      Clone a local mirror from a remote mirror and download all
      ↪ selected components
  merge      Merge two or more offline mirrors
  publish    Publish a component
  show       Show the mirror address
  set        Set mirror address
  modify     Modify published component
  renew      Renew the manifest of a published component.
  grant      grant a new owner
  rotate     Rotate root.json

Global Flags:
      --help              Help for this command

Use "tiup mirror [command] --help" for more information about a command.
```

13.4.11.3.2 Clone a mirror

You can run the `tiup mirror clone` command to build a local mirror:

```
tiup mirror clone <target-dir> [global-version] [flags]
```

- `target-dir`: used to specify the directory in which cloned data is stored.
- `global-version`: used to quickly set a global version for all components.

The `tiup mirror clone` command provides many optional flags (might provide more in the future). These flags can be divided into the following categories according to their intended usages:

- Determines whether to use prefix matching to match the version when cloning

  If the `--prefix` flag is specified, the version number is matched by prefix for the clone. For example, if you specify `--prefix` as "v5.0.0", then "v5.0.0-rc", and "v5.0.0" are matched.

- Determines whether to use the full clone

  If you specify the `--full` flag, you can clone the official mirror fully.

> **Note:**
> If `--full`, `global-version` flags, and the component versions are not specified, only some meta information is cloned.

- Determines whether to clone packages from the specific platform

  If you want to clone packages only for a specific platform, use `-os` and `-arch` to specify the platform. For example:

  - Execute the `tiup mirror clone <target-dir> [global-version] --os=linux` command to clone for linux.
  - Execute the `tiup mirror clone <target-dir> [global-version] --arch=amd64` command to clone for amd64.
  - Execute the `tiup mirror clone <target-dir> [global-version] --os=linux --arch=amd64` command to clone for linux/amd64.

- Determines whether to clone a specific version of a package

  If you want to clone only one version (not all versions) of a component, use `--<component>=<version>` to specify this version. For example:

  - Execute the `tiup mirror clone <target-dir> --tidb v7.1.5` command to clone the v7.1.5 version of the TiDB component.

- Run the `tiup mirror clone <target-dir> --tidb v7.1.5 --tikv all` command to clone the v7.1.5 version of the TiDB component and all versions of the TiKV component.
- Run the `tiup mirror clone <target-dir> v7.1.5` command to clone the v7.1.5 version of all components in a cluster.

After cloning, signing keys are set up automatically.

Manage the private repository

You can share the repository cloned using `tiup mirror clone` among hosts either by sharing files via SCP, NFS, or by making the repository available over the HTTP or HTTPS protocol. Use `tiup mirror set <location>` to specify the location of the repository.

```
tiup mirror set /shared_data/tiup
```

```
tiup mirror set https://tiup-mirror.example.com/
```

Note:

If you run `tiup mirror set...` on the machine where you run `tiup mirror clone`, the next time you run `tiup mirror clone...`, the machine clones from the local mirror, not the remote one. Therefore, you need to reset the mirror by running `tiup mirror set --reset` before updating the private mirror.

Another way of using a mirror is to use the `TIUP_MIRRORS` environment variable. Here is an example for running `tiup list` with a private repository.

```
export TIUP_MIRRORS=/shared_data/tiup
tiup list
```

`TIUP_MIRRORS` setting can permanently change the mirror configuration, for example, `tiup mirror set`. For details, see tiup issue #651.

Update the private repository

If you run the `tiup mirror clone` command again with the same `target-dir`, the machine will create new manifests and download the latest versions of components available.

Note:

Before recreating the manifest, ensure that all components and versions (including earlier ones downloaded previously) are included.

13.4.11.3.3 Custom repository

You can create a custom repository to work with TiDB components like TiDB, TiKV, or PD that you build by yourself. It is also possible to create your own tiup components.

To create your own components, run the `tiup package` command and perform as instructed in Component packaging.

Create a custom repository

To create an empty repository in `/data/mirror`:

```
tiup mirror init /data/mirror
```

As part of creating the repository, keys will be written to `/data/mirror/keys`.

To create a new private key in `~/.tiup/keys/private.json`:

```
tiup mirror genkey
```

Grant `jdoe` with private key `~/.tiup/keys/private.json` ownership of `/data/mirror`:

```
tiup mirror set /data/mirror
tiup mirror grant jdoe
```

Work with custom components

1. Create a custom component called hello.

```
$ cat > hello.c << END
> #include <stdio.h>
int main() {
  printf("hello\n");
  return (0);
}
END
$ gcc hello.c -o hello
$ tiup package hello --entry hello --name hello --release v0.0.1
```

`package/hello-v0.0.1-linux-amd64.tar.gz` is created.

2. Create a repository and a private key, and grant ownership to the repository.

```
$ tiup mirror init /tmp/m
$ tiup mirror genkey
$ tiup mirror set /tmp/m
$ tiup mirror grant $USER
```

```
tiup mirror publish hello v0.0.1 package/hello-v0.0.1-linux-amd64.tar.
    ↪ gz hello
```

3. Run the component. If it is not installed yet, it will be downloaded first.

```
$ tiup hello
```

```
The component `hello` version is not installed; downloading from
    ↪ repository.
Starting component `hello`: /home/dvaneeden/.tiup/components/hello/v0
    ↪ .0.1/hello
hello
```

With `tiup mirror merge`, you can merge a repository with custom components into another one. This assumes that all components in `/data/my_custom_components` are signed by the current `$USER`.

```
$ tiup mirror set /data/my_mirror
$ tiup mirror grant $USER
$ tiup mirror merge /data/my_custom_components
```

13.4.11.4 Stress Test TiDB Using TiUP Bench Component

When you test the performance of a database, it is often required to stress test the database. To facilitate this, TiUP has integrated the bench component, which provides multiple workloads for stress testing. You can access these workloads by the following commands:

```
tiup bench tpcc # Benchmark a database using TPC-C
tiup bench tpch # Benchmark a database using TPC-H
tiup bench ch   # Benchmark a database using CH-benCHmark
tiup bench ycsb # Benchmark a database using YCSB
tiup bench rawsql # Benchmark a database using arbitrary SQL files
```

`tpcc`, `tpch`, `ch`, and `rawsql` share the following common command flags. However, `ycsb` is mainly configured by a `.properties` file, which is described in its usage guide.

```
  -t, --acThreads int      OLAP client concurrency, only for CH-benCHmark (
    ↪ default to 1)
      --conn-params string Session variables, such as setting `--conn-params
        ↪  tidb_isolation_read_engines='tiflash'` for TiDB queries and
        ↪ setting `--conn-params sslmode=disable` for PostgreSQL
        ↪ connections
      --count int          Total execution count (0 means infinite count)
  -D, --db string          Database name (default to "test")
  -d, --driver string      Database driver: mysql, postgres (default to "
    ↪ mysql")
      --dropdata           Clean up historical data before preparing
  -H, --host strings       Database host (default to [127.0.0.1])
```

```
    --ignore-error       Ignore errors when running workload
    --interval duration  Output interval time (default to 10s)
    --isolation int      Isolation Level (0: Default; 1: ReadUncommitted;
                         2: ReadCommitted; 3: WriteCommitted; 4:
                            ↪ RepeatableRead;
                         5: Snapshot; 6: Serializable; 7: Linerizable)
    --max-procs int      runtime.GOMAXPROCS of golang, the limits of how
       ↪ many cores can be used
    --output string      Output style. Valid values can be { plain | table
       ↪  | json } (default to "plain")
-p, --password string    Database password
-P, --port ints          Database port (default to [4000])
    --pprof string       Address of pprof endpoint
    --silence            Don't print errors when running workload
-S, --statusPort int     Database status port (default to 10080)
-T, --threads int        Thread concurrency (default to 1)
    --time duration      Total execution time (default to 2562047h47m16
       ↪ .854775807s)
-U, --user string        Database user (default to "root")
```

- You can pass comma-separated values to `--host` and `--port` to enable client-side load balancing. For example, when you specify `--host 172.16.4.1,172.16.4.2 ↪ --port 4000,4001`, the program will connect to 172.16.4.1:4000, 172.16.4.1:4001, 172.16.4.2:4000, and 172.16.4.2:4001, chosen in round-robin fashion.
- `--conn-params` must follow the format of query string. Different databases might have different parameters. For example:
  - `--conn-params tidb_isolation_read_engines='tiflash'` forces TiDB to read from TiFlash.
  - `--conn-params sslmode=disable` disables SSL when you connect to PostgreSQL.
- When running CH-benCHmark, you can use `--ap-host`, `--ap-port`, and `--ap-conn- ↪ params` to specify a standalone TiDB server for OLAP queries.

The following sections describe how to run TPC-C, TPC-H, YCSB tests using TiUP.

13.4.11.4.1 Run TPC-C test using TiUP

The TiUP bench component supports the following commands and flags to run the TPC-C test:

```
Available Commands:
  check      Check data consistency for the workload
  cleanup    Cleanup data for the workload
```

```
  prepare    Prepare data for the workload
  run        Run workload

Flags:
      --check-all         Run all consistency checks
  -h, --help              Help for TPC-C
      --partition-type int Partition type: 1 - HASH, 2 - RANGE, 3 - LIST (
          ↪ HASH-like), 4 - LIST (RANGE-like) (default to 1)
      --parts int         Number of partitions (default to 1)
      --warehouses int    Number of warehouses (default to 10)
```

Test procedures

The following provides simplified steps for running a TPC-C test. For detailed steps, see How to Run TPC-C Test on TiDB.

1. Create 4 warehouses using 4 partitions via hash:

```
tiup bench tpcc --warehouses 4 --parts 4 prepare
```

2. Run the TPC-C test:

```
tiup bench tpcc --warehouses 4 --time 10m run
```

3. Check the consistency:

```
tiup bench tpcc --warehouses 4 check
```

4. Clean up data:

```
tiup bench tpcc --warehouses 4 cleanup
```

Preparing data via SQL might be slow when you want to run a benchmark with a large data set. In that case, you can generate data in the CSV format by the following commands and then import it to TiDB via TiDB Lightning.

- Generate the CSV file:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
    ↪ csv
```

- Generate the CSV file for the specified table:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
    ↪ csv --tables history,orders
```

13.4.11.4.2 Run TPC-H test using TiUP

The TiUP bench component supports the following commands and parameters to run the TPC-H test:

```
Available Commands:
  cleanup    Cleanup data for the workload
  prepare    Prepare data for the workload
  run        Run workload

Flags:
      --check          Check output data, only when the scale factor equals 1
  -h, --help           help for tpch
      --queries string All queries (default "q1,q2,q3,q4,q5,q6,q7,q8,q9,q10,
          ↪ q11,q12,q13,q14,q15,q16,q17,q18,q19,q20,q21,q22")
      --sf int         scale factor
```

Test procedures

1. Prepare data:

```
tiup bench tpch --sf=1 prepare
```

2. Run the TPC-H test by executing one of the following commands:

   - If you check the result, run this command:

```
tiup bench tpch --count=22 --sf=1 --check=true run
```

   - If you do not check the result, run this command:

```
tiup bench tpch --count=22 --sf=1 run
```

3. Clean up data:

```
tiup bench tpch cleanup
```

13.4.11.4.3 Run YCSB test using TiUP

You can stress test both TiDB and TiKV via YCSB.

Stress test TiDB

1. Prepare data:

```
tiup bench ycsb load tidb -p tidb.instances="127.0.0.1:4000" -p
    ↪ recordcount=10000
```

2. Run the YCSB workload:

```
# The read-write percent is 95% by default
tiup bench ycsb run tidb -p tidb.instances="127.0.0.1:4000" -p
    ↪ operationcount=10000
```

Stress test TiKV

1. Prepare data:

```
tiup bench ycsb load tikv -p tikv.pd="127.0.0.1:2379" -p recordcount
    ↪ =10000
```

2. Run the YCSB workload:

```
# The read-write percent is 95% by default
tiup bench ycsb run tikv -p tikv.pd="127.0.0.1:2379" -p operationcount
    ↪ =10000
```

13.4.11.4.4 Run RawSQL test using TiUP

You can write an arbitrary query in a SQL file, and then use it for the test by executing `tiup bench rawsql` as follows:

1. Prepare data and the query:

```
-- Prepare data
CREATE TABLE t (a int);
INSERT INTO t VALUES (1), (2), (3);

-- Save your query in a SQL file. For example, you can save the
    ↪ following query in `demo.sql`.
SELECT a, sleep(rand()) FROM t WHERE a < 4*rand();
```

2. Run the RawSQL test:

```
shell   tiup bench rawsql run --count 60 --query-files demo.sql
```

13.5 TiDB Operator

TiDB Operator is an automatic operation system for TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB Operator documentation (also named as TiDB on Kubernetes documentation) is independent of the TiDB documentation. To access the documentation, click the following link:

- TiDB on Kubernetes documentation

13.6 TiDB Data Migration

13.6.1 TiDB Data Migration Overview

TiDB Data Migration (DM) is an integrated data migration task management platform, which supports the full data migration and the incremental data replication from MySQL-compatible databases (such as MySQL, MariaDB, and Aurora MySQL) into TiDB. It can help to reduce the operation cost of data migration and simplify the troubleshooting process.

13.6.1.1 Basic features

- **Compatibility with MySQL.** DM is compatible with MySQL 5.7 protocols and most of the features and syntax of MySQL 5.7.
- **Replicating DML and DDL events.** It supports parsing and replicating DML and DDL events in MySQL binlog.
- **Migrating and merging MySQL shards.** DM supports migrating and merging multiple MySQL database instances upstream to one TiDB database downstream. It supports customizing replication rules for different migration scenarios. It can automatically detect and handle DDL changes of upstream MySQL shards, which greatly reduces the operational cost.
- **Various types of filters.** You can predefine event types, regular expressions, and SQL expressions to filter out MySQL binlog events during the data migration process.
- **Centralized management.** DM supports thousands of nodes in a cluster. It can run and manage a large number of data migration tasks concurrently.
- **Optimization of the third-party Online Schema Change process.** In the MySQL ecosystem, tools such as gh-ost and pt-osc are widely used. DM optimizes its change process to avoid unnecessary migration of intermediate data. For details, see online-ddl.
- **High availability.** DM supports data migration tasks to be scheduled freely on different nodes. The running tasks are not affected when a small number of nodes crash.

13.6.1.2 Quick installation

Run the following command to install DM:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
tiup install dm dmctl
```

13.6.1.3 Usage restrictions

Before using the DM tool, note the following restrictions:

- Database version requirements
    - MySQL version 5.5 ~ 5.7
    - MySQL version 8.0 (experimental features)
    - MariaDB version >= 10.1.2 (experimental features)

> **Note:**
>
> If there is a primary-secondary migration structure between the upstream MySQL/MariaDB servers, then choose the following version.
>
> - MySQL version > 5.7.1
> - MariaDB version >= 10.1.3

- DDL syntax compatibility
    - Currently, TiDB is not compatible with all the DDL statements that MySQL supports. Because DM uses the TiDB parser to process DDL statements, it only supports the DDL syntax supported by the TiDB parser. For details, see MySQL Compatibility.
    - DM reports an error when it encounters an incompatible DDL statement. To solve this error, you need to manually handle it using dmctl, either skipping this DDL statement or replacing it with specified DDL statements. For details, see Skip or replace abnormal SQL statements.
    - DM does not replicate view-related DDL statements and DML statements to the downstream TiDB cluster. It is recommended that you create the view in the downstream TiDB cluster manually.
- GBK character set compatibility
    - DM does not support migrating `charset=GBK` tables to TiDB clusters earlier than v5.4.0.

13.6.1.4 Contributing

You are welcome to participate in the DM open sourcing project. Your contribution would be highly appreciated. For more details, see CONTRIBUTING.md.

13.6.1.5 Community support

You can learn about DM through the online documentation. If you have any questions, contact us on GitHub.

13.6.1.6 License

DM complies with the Apache 2.0 license. For more details, see LICENSE.

13.6.1.7 DM versions

Before v5.4, the DM documentation is independent of the TiDB documentation. To access these earlier versions of the DM documentation, click one of the following links:

- DM v5.3 documentation
- DM v2.0 documentation
- DM v1.0 documentation

Note:

- Since October 2021, DM's GitHub repository has been moved to pingcap/tiflow. If you see any issues with DM, submit your issue to the `pingcap/tiflow` repository for feedback.
- In earlier versions (v1.0 and v2.0), DM uses version numbers that are independent of TiDB. Since v5.3, DM uses the same version number as TiDB. The next version of DM v2.0 is DM v5.3. There are no compatibility changes from DM v2.0 to v5.3, and the upgrade process is the same as a normal upgrade, only an increase in version number.

13.6.2 Data Migration Architecture

This document introduces the architecture of Data Migration (DM).

DM consists of three components: DM-master, DM-worker, and dmctl.

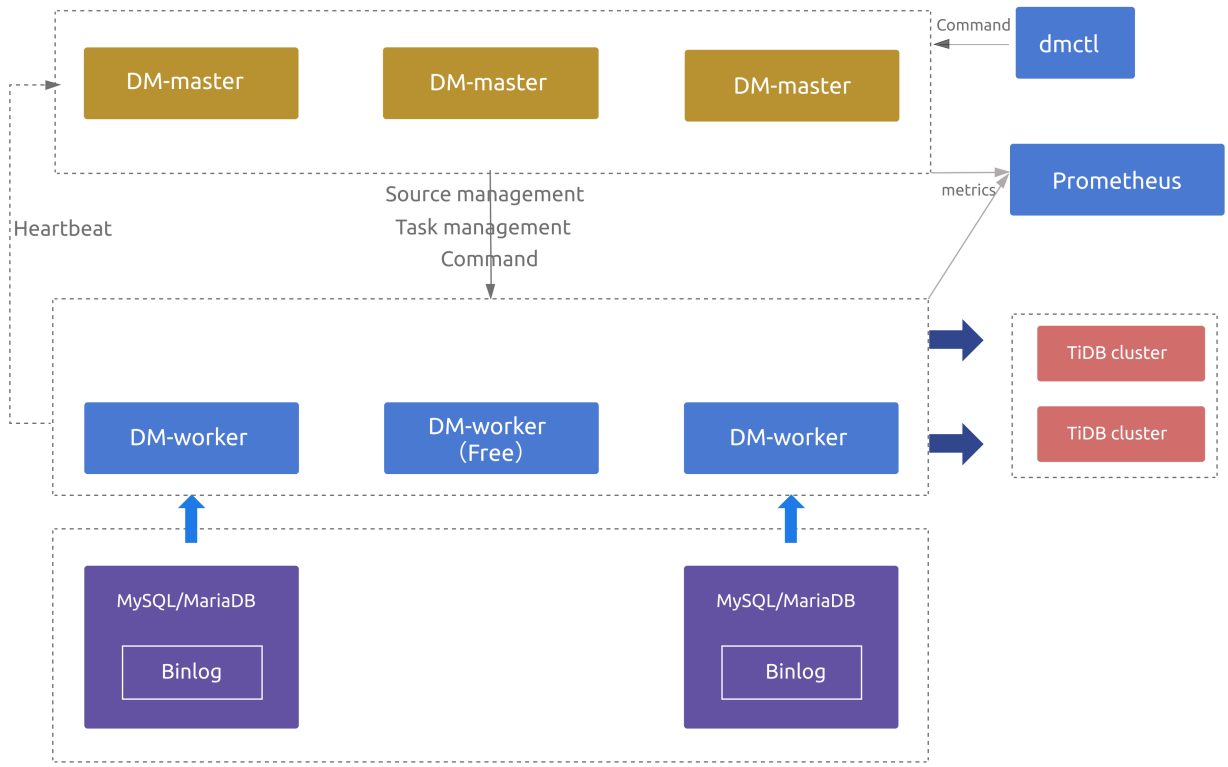

Figure 441: Data Migration architecture

13.6.2.1 Architecture components

13.6.2.1.1 DM-master

DM-master manages and schedules the operations of data migration tasks.

- Storing the topology information of the DM cluster
- Monitoring the running state of DM-worker processes
- Monitoring the running state of data migration tasks
- Providing a unified portal for the management of data migration tasks
- Coordinating the DDL migration of sharded tables in each instance under the sharding scenario

13.6.2.1.2 DM-worker

DM-worker executes specific data migration tasks.

- Persisting the binlog data to the local storage
- Storing the configuration information of the data migration subtasks
- Orchestrating the operation of the data migration subtasks

- Monitoring the running state of the data migration subtasks

For more details of DM-worker, see DM-worker Introduction.

13.6.2.1.3 dmctl

dmctl is a command line tool used to control the DM cluster.

- Creating, updating, or dropping data migration tasks
- Checking the state of data migration tasks
- Handling errors of data migration tasks
- Verifying the configuration correctness of data migration tasks

13.6.2.2 Architecture features

13.6.2.2.1 High availability

When you deploy multiple DM-master nodes, all DM-master nodes use the embedded etcd to form a cluster. The DM-master cluster is used to store metadata such as cluster node information and task configuration. The leader node elected through etcd is used to provide services such as cluster management and data migration task management. Therefore, if the number of available DM-master nodes exceeds half of the deployed nodes, the DM cluster can normally provide services.

When the number of deployed DM-worker nodes exceeds the number of upstream MySQL/MariaDB nodes, the extra DM-worker nodes are idle by default. If a DM-worker node goes offline or is isolated from the DM-master leader, DM-master automatically schedules data migration tasks of the original DM-worker node to other idle DM-worker nodes. (If a DM-worker node is isolated, it automatically stops the data migration tasks on it); if there are no available idle DM-worker nodes, the data migration tasks of the original DM-worker are temporarily hung until one DM-worker node becomes idle, and then the tasks are automatically resumed.

Note:

When the data migration task is in the process of full export or import, the migration task does not support high availability. Here are the main reasons:

- For the full export, MySQL does not support exporting from a specific snapshot point yet. This means that after the data migration task is rescheduled or restarted, the export cannot resume from the previous interruption point.

- For the full import, DM-worker does not support reading exported full data across the nodes yet. This means that after the data migration task is scheduled to a new DM-worker node, you cannot read the exported full data on the original DM-worker node before the scheduling happens.

13.6.3 Quick Start Guide for TiDB Data Migration

This document describes how to migrate data from MySQL to TiDB using TiDB Data Migration (DM). This guide is a quick demo of DM features and is not recommended for any production environment.

13.6.3.1 Step 1: Deploy a DM cluster

1. Install TiUP, and install `dmctl` using TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
tiup install dm dmctl
```

2. Generate the minimal deployment topology file of a DM cluster:

```
tiup dm template
```

3. Copy the configuration information in the output, and save it as the `topology.yaml` file with the modified IP address. Deploy the DM cluster with the `topology.yaml` file using TiUP:

```
tiup dm deploy dm-test 7.1.6 topology.yaml -p
```

13.6.3.2 Step 2: Prepare the data source

You can use one or multiple MySQL instances as an upstream data source.

1. Create a configuration file for each data source as follows:

```
source-id: "mysql-01"
from:
  host: "127.0.0.1"
  user: "root"
  password: "fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg=" # encrypt with `tiup
      ↪ dmctl --encrypt "123456"`
  port: 3306
```

2. Add the source to the DM cluster by running the following command. `mysql-01.yaml` is the configuration file created in the previous step.

```
tiup dmctl --master-addr=127.0.0.1:8261 operate-source create mysql-01.
    ↪ yaml # use one of master_servers as the argument of --master-
    ↪ addr
```

If you do not have a MySQL instance for testing, you can create a MySQL instance in Docker by taking the following steps:

1. Create a MySQL configuration file:

```
mkdir -p /tmp/mysqltest && cd /tmp/mysqltest

cat > my.cnf <<EOF
[mysqld]
bind-address   = 0.0.0.0
character-set-server=utf8
collation-server=utf8_bin
default-storage-engine=INNODB
transaction-isolation=READ-COMMITTED
server-id      = 100
binlog_format  = row
log_bin        = /var/lib/mysql/mysql-bin.log
show_compatibility_56 = ON
EOF
```

2. Start the MySQL instance using Docker:

```
docker run --name mysql-01 -v /tmp/mysqltest:/etc/mysql/conf.d -e
    ↪ MYSQL_ROOT_PASSWORD=my-secret-pw -d -p 3306:3306 mysql:5.7
```

3. After the MySQL instance is started, access the instance:

> **Note:**
> This command is only suitable for trying out data migration, and cannot be used in production environments or stress tests.

```
mysql -uroot -p -h 127.0.0.1 -P 3306
```

13.6.3.3 Step 3: Prepare a downstream database

You can choose an existing TiDB cluster as a target for data migration.

If you do not have a TiDB cluster for testing, you can quickly build a demonstration environment by running the following command:

```
tiup playground
```

13.6.3.4 Step 4: Prepare test data

Create a test table and data in one or multiple data sources. If you use an existing MySQL database, and the database contains available data, you can skip this step.

```
drop database if exists `testdm`;
create database `testdm`;
use `testdm`;
create table t1 (id bigint, uid int, name varchar(80), info varchar(100),
    ↪ primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=utf8mb4
    ↪ COLLATE=utf8mb4_bin;
create table t2 (id bigint, uid int, name varchar(80), info varchar(100),
    ↪ primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=utf8mb4
    ↪ COLLATE=utf8mb4_bin;
insert into t1 (id, uid, name) values (1, 10001, 'Gabriel García Márquez'),
    ↪  (2, 10002, 'Cien años de soledad');
insert into t2 (id, uid, name) values (3, 20001, 'José Arcadio Buendía'),
    ↪ (4, 20002, 'Úrsula Iguarán'), (5, 20003, 'José Arcadio');
```

13.6.3.5 Step 5: Create a data migration task

1. Create a task configuration file `testdm-task.yaml`:

```
name: testdm
task-mode: all

target-database:
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: "" # If the password is not empty, it is recommended to use
      ↪  a password encrypted with dmctl.

# Configure the information of one or multiple data sources
mysql-instances:
  - source-id: "mysql-01"
    block-allow-list: "ba-rule1"
```

```
block-allow-list:
  ba-rule1:
    do-dbs: ["testdm"]
```

2. Create the task using dmctl:

```
tiup dmctl --master-addr 127.0.0.1:8261 start-task testdm-task.yaml
```

You have successfully created a task that migrates data from a `mysql-01` database to TiDB.

13.6.3.6 Step 6: Check the status of the task

After the task is created, you can use the `dmctl query-status` command to check the status of the task:

```
tiup dmctl --master-addr 127.0.0.1:8261 query-status testdm
```

13.6.4 TiDB Data Migration (DM) Best Practices

TiDB Data Migration (DM) is a data migration tool developed by PingCAP. It supports full and incremental data migration from MySQL-compatible databases such as MySQL, Percona MySQL, MariaDB, Amazon RDS for MySQL, and Amazon Aurora into TiDB.

You can use DM in the following scenarios:

- Perform full and incremental data migration from a single MySQL-compatible database instance to TiDB
- Migrate and merge MySQL shards of small datasets (less than 1 TiB) to TiDB
- In the data hub scenario, such as the middle platform of business data, and real-time aggregation of business data, use DM as the middleware for data migration

This document introduces how to use DM in an elegant and efficient way, and how to avoid common mistakes when using DM.

13.6.4.1 Performance limitations

Performance item	Limitation
Max work nodes	1000
Max task number	600
Max QPS	30k QPS/worker
Max Binlog throughput	20 MB/s/worker
Table number limit per task	Unlimited

- DM supports managing 1000 work nodes simultaneously, and the maximum number of tasks is 600. To ensure the high availability of work nodes, you should reserve some work nodes as standby nodes. The recommended number of standby nodes is 20% to 50% of the number of the work nodes that have running migration tasks.
- A single work node can theoretically support replication QPS of up to 30K QPS/-worker. It varies for different schemas and workloads. The ability to handle upstream binlogs is up to 20 MB/s/worker.
- If you want to use DM as a data replication middleware for long-term use, you need to carefully design the deployment architecture of DM components. For more information, see Deploy DM-master and DM-worker

13.6.4.2 Before data migration

Before data migration, the design of the overall solution is critical. The following sections describe best practices and scenarios from the business perspective and the implementation perspective.

13.6.4.2.1 Best practices for the business side

To distribute the workload evenly on multiple nodes, the design for the distributed database is different from traditional databases. The solution needs to ensure both low migration cost and logic correctness after migration. The following sections describe best practices before data migration.

Business impact of AUTO_INCREMENT in schema design

`AUTO_INCREMENT` in TiDB is compatible with `AUTO_INCREMENT` in MySQL. However, as a distributed database, TiDB usually has multiple computing nodes (entries for the client end). When the application data is written, the workload is evenly distributed. This leads to the result that when there is an `AUTO_INCREMENT` column in the table, the auto-increment IDs of the column might be inconsecutive. For more details, see AUTO_INCREMENT.

If your business has a strong dependence on auto-increment IDs, consider using the SEQUENCE function.

Usage of clustered indexes

When you create a table, you can declare that the primary key is either a clustered index or a non-clustered index. The following sections describe the pros and cons of each choice.

- Clustered indexes

  Clustered indexes use the primary key as the handle ID (row ID) for data storage. Querying using the primary key can avoid table lookup, which effectively improves the query performance. However, if the table is write-intensive and the primary key uses `AUTO_INCREMENT`, it is very likely to cause write hotspot problems, resulting in a mediocre performance of the cluster and the performance bottleneck of a single storage node.

- Non-clustered indexes + `shard row id bit`

  Using non-clustered indexes and `shard row id bit`, you can avoid the write hotspot problem when using `AUTO_INCREMENT`. However, table lookup in this scenario can affect the query performance when querying using the primary key.

- Clustered indexes + external distributed ID generators

  If you want to use clustered indexes and keep the IDs consecutive, consider using external distributed ID generators, such as the Snowflake algorithm and Leaf. The application program generates sequence IDs, which can guarantee that the IDs are consecutive to a certain extent. It also retains the benefits of using clustered indexes. But you need to customize the applications.

- Clustered indexes + `AUTO_RANDOM`

  This solution can retain the benefits of using clustered indexes and avoid the write hotspot problem. It requires less effort for customization. You can modify the schema attribute when you switch to use TiDB as the write database. In subsequent queries, if you have to use the ID column to sort data, you can use the `AUTO_RANDOM` ID column and left shift 6 bits (1 sign bit + 5 shard bits) to ensure the order of the query data. For example:

```
CREATE TABLE t (a bigint PRIMARY KEY AUTO_RANDOM, b varchar(255));
Select a, a<<6 ,b from t order by a <<6 desc
```

The following table summarizes the pros and cons of each solution.

Scenario	Recommended solution	Pros	Cons
TiDB will act as the primary and write-intensive database. The business logic strongly relies on the continuity of the primary key IDs.	Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Use `SEQUENCE` as the primary key column.	It can avoid data write hotspots and ensure the continuity and monotonic increment of business data.	The throughput capacity of data write is decreased to ensure data write continuity. The performance of primary key queries is decreased.
TiDB will act as the primary and write-intensive database. The business logic strongly relies on the increment of the primary key IDs.	Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Use an application ID generator to generate the primary key IDs.	It can avoid data write hotspots,	

guarantee the performance of data write, and guarantee the increment of business data, but cannot guarantee continuity. |

You need to customize the application.

External ID generators strongly rely on the clock accuracy and might introduce failures.

| |

TiDB will act as the primary and write-intensive database.

The business logic does not rely on the continuity of the primary key IDs.

| Create tables with clustered indexes and set `AUTO_RANDOM` for the primary key column. |

It can avoid data write hotspots and has excellent query performance of primary keys.

You can smoothly switch from `AUTO_INCREMENT` to `AUTO_RANDOM`.

|

The primary key IDs are random.

The write throughput ability is limited.

It is recommended to sort the business data by using the insert time column.

If you have to use the primary key ID to sort data, you can left shift 5 bits to query, which can guarantee the increment of the data.

| | TiDB will act as a read-only database. | Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Keep the primary key column consistent with the data source. |

It can avoid data write hotspots.

It requires less customization cost.

The query performance of primary keys is impacted. |

13.6.4.2.2 Key points for MySQL shards

Splitting and merging

It is recommended that you use DM to migrate and merge MySQL shards of small datasets to TiDB.

Besides data merging, another typical scenario is data archiving. Data is constantly being written. As time goes by, large amounts of data gradually change from hot data to warm or even cold data. Fortunately, in TiDB, you can set different placement rules for data. The minimum granularity of the rules is a partition.

Therefore, it is recommended that for write-intensive scenarios, you need to evaluate from the beginning whether you need to archive data and store hot and cold data on different media separately. If you need to archive data, you can set the partitioning rules before migration (TiDB does not support Table Rebuild operations yet). It saves you from the need to recreate tables and import data in future.

The pessimistic mode and the optimistic mode

DM uses the pessimistic mode by default. In scenarios of migrating and merging MySQL shards, changes in upstream shard schemas can block DML writing to downstream databases. You need to wait until all the schemas are changed and have the same structure, and then continue the migration from the breakpoint.

- If the upstream schema changes take a long time, it might cause the upstream Binlog to be cleaned up. You can enable the relay log to avoid this problem. For more information, see Use the relay log.
- If you do not want to block data write due to upstream schema changes, consider using the optimistic mode. In this case, DM will not block the data migration even when it spots changes in the upstream shard schemas, but will continue to migrate the data. However, if DM spots incompatible formats in upstream and downstream, the migration task will stop. You need to resolve this issue manually.

The following table summarizes the pros and cons of optimistic mode and pessimistic modes.

Scenario	Pros	Cons

Scenario	Pros	Cons
Pessimistic mode (Default)	It can ensure that the data migrated to the downstream will not go wrong.	If there are a large number of shards, the migration task will be blocked for a long time, or even stop if the upstream binlogs have been cleaned up. You can enable the relay log to avoid this problem.

For more informa-

Scenario	Pros	Cons
Optimistic mode	Upstream schema changes will not cause data migration latency.	In this mode, ensure that schema changes are compatible (check whether the incremental column has a default value). It is possible that the inconsistent data can be overlooked. For more information, see Merge and Migrate Data

Scenario	Pros	Cons

13.6.4.2.3 Other restrictions and impact

Data types in upstream and downstream

TiDB supports most MySQL data types. However, some special types are not supported yet (such as `SPATIAL`). For the compatibility of data types, see Data Types.

Character sets and collations

Since TiDB v6.0.0, the new framework for collations is used by default. In earlier versions, if you want TiDB to support utf8_general_ci, utf8mb4_general_ci, utf8_unicode_ci, utf8mb4_unicode_ci, gbk_chinese_ci and gbk_bin, you need to explicitly declare it when creating the cluster by setting the value of `new_collations_enabled_on_first_bootstrap` to `true`. For more information, see New framework for collations.

The default character set in TiDB is utf8mb4. It is recommended that you use utf8mb4 for the upstream and downstream databases and applications. If the upstream database has explicitly specified a character set or collation, you need to check whether TiDB supports it.

Since TiDB v6.0.0, GBK is supported. For more information, see the following documents:

- Character Set and Collation
- GBK compatibility

13.6.4.2.4 Best practices for deployment

Deploy DM-master and DM-worker

DM consists of DM-master and DM-worker nodes.

- DM-master manages the metadata of migration tasks and schedules DM-worker nodes. It is the core of the whole DM platform. Therefore, you can deploy DM-master as clusters to ensure high availability of the DM platform.
- DM-worker executes upstream and downstream migration tasks. A DM-worker node is stateless. You can deploy at most 1000 DM-worker nodes. When using DM, it is recommended that you reserve some idle DM-workers to ensure high availability.

Plan the migration tasks

When migrating and merging MySQL shards, you can split a migration task according to the types of shards in the upstream. For example, if `usertable_1~50` and `Logtable_1~50` are two types of shards, you can create two migration tasks. It can simplify the migration task template and effectively control the impact of interruption in data migration.

For migration of large datasets, you can refer to the following suggestions to split the migration task:

- If you need to migrate multiple databases in the upstream, you can split the migration task according to the number of databases.
- Split the task according to the write pressure in the upstream, that is, split the tables with frequent DML operations in the upstream to a separate migration task. Use another migration task to migrate the tables without frequent DML operations. This method can speed up the migration progress, especially when there are a large number of logs written to a table in the upstream. But if this table that contains a large number of logs does not affect the whole business, this method still works well.

Note that splitting the migration task can only guarantee the final consistency of data. Real-time consistency may deviate significantly due to various reasons.

The following table describes the recommended deployment plans for DM-master and DM-worker in different scenarios.

Scenario	DM-master deployment	DM-worker deployment
Small dataset (less than 1 TiB) One-time data migration	Deploy 1 DM-master node	Deploy 1~N DM-worker nodes according to the number of upstream data sources. Generally, 1 DM-worker node is recommended.
Large dataset (more than 1 TiB) and migrating and merging MySQL shards One-time data migration	It is recommended to deploy 3 DM-master nodes to ensure the availability of the DM cluster during long-time data migration.	Deploy DM-worker nodes according to the number of data sources or migration tasks. Besides working DM-worker nodes, it is recommended to deploy 1~3 idle DM-worker nodes.
Long-term data replication	It is necessary to deploy 3 DM-master nodes. If you deploy DM-master nodes on the cloud, try to deploy them in different availability zones (AZ).	Deploy DM-worker nodes according to the number of data sources or migration tasks. It is necessary to deploy 1.5~2 times the number of DM-worker nodes that are actually needed.

Choose and configure the upstream data source

DM backs up the full data of the entire database when performing full data migration, and uses the parallel logical backup method. During backing up MySQL, it adds a global read lock `FLUSH TABLES WITH READ LOCK`. DML and DDL operations of the upstream database will be blocked for a short time. Therefore, it is strongly recommended to use a backup database in upstream to perform the full data backup, and enable the GTID function of the data source (`enable-gtid: true`). In this way, you can avoid the impact from the upstream, and switch to the master node in the upstream to reduce the latency during the

incremental migration. For the instructions of switching the upstream MySQL data source, see Switch DM-worker Connection between Upstream MySQL Instances.

Note the following:

- You can only perform full data backup on the master node of the upstream database.

  In this scenario, you can set the `consistency` parameter to `none` in the configuration file, `mydumpers.global.extra-args: "--consistency none"`, to avoid adding a global read lock to the master node. But this might affect the data consistency of the full backup, which may lead to inconsistent data between the upstream and downstream.

- Use backup snapshots to perform full data migration (only applicable to the migration of MySQL RDS and Aurora RDS on AWS)

  If the database to be migrated is AWS MySQL RDS or Aurora RDS, you can use RDS snapshots to directly migrate the backup data in Amazon S3 to TiDB to ensure data consistency. For more information, see Migrate Data from Amazon Aurora to TiDB.

13.6.4.2.5 Details of configurations

Capitalization

TiDB schema names are case-insensitive by default, that is, `lower_case_table_names` ↪ `:2`. But most upstream MySQL databases use Linux systems that are case-sensitive by default. In this case, you need to set `case-sensitive` to `true` in the DM task configuration file to ensure that the schema can be correctly migrated from the upstream.

In a special case, for example, if there is a database in the upstream that has both uppercase tables such as `Table` and lowercase tables such as `table`, then an error occurs when creating the schema:

```
ERROR 1050 (42S01): Table '{tablename}' already exists
```

Filter rules

You can configure the filter rules as soon as you start configuring the data source. For more information, see Data Migration Task Configuration Guide. The benefits of configuring the filter rules are:

- Reduce the number of Binlog events that the downstream needs to process, thereby improving migration efficiency.
- Reduce unnecessary relay log storage, thereby saving disk space.

Note:

> When you migrate and merge MySQL shards, if you have configured filter rules in the data source, you must make sure that the rules match between the data source and the migration task. If they do not match, it may cause the issue that the migration task cannot receive incremental data for a long time.

Use the relay log

In the MySQL master/standby mechanism, the standby node saves a copy of relay logs to ensure the reliability and efficiency of asynchronous replication. DM also supports saving a copy of relay logs on DM-worker. You can configure information such as the storage location and expiration time. This feature applies to the following scenarios:

- During full and incremental data migration, if the amount of full data is large, the entire process takes more time than the time for the upstream binlogs to be archived. It causes the incremental replication task to fail to start normally. If you enable the relay log, DM-worker will start receiving relay logs when the full migration is started. This avoids the failure of the incremental task.
- When you use DM to perform long-time data replication, sometimes the migration task is blocked for a long time due to various reasons. If you enable the relay log, you can effectively deal with the problem of upstream binlogs being recycled due to the blocking of the migration task.

There are some restrictions on using the relay log. DM supports high availability. When a DM-worker fails, it will try to promote an idle DM-worker instance to a working instance. If the upstream binlogs do not contain the necessary migration logs, it may cause interruption. You need to intervene manually to copy the relay log to the new DM-worker node as soon as possible, and modify the corresponding relay meta file. For details, see Troubleshooting.

Use PT-osc/GH-ost in upstream

In daily MySQL operation and maintenance, usually you use tools such as PT-osc/GH-ost to change the schema online to minimize impact on the business. However, the whole process will be logged to MySQL Binlog. Migrating such data to TiDB downstream will result in a lot of unnecessary write operations, which is neither efficient nor economical.

To resolve this issue, DM supports third-party data tools such as PT-osc and GH-ost when you configure the migration task. When you use such tools, DM does not migrate redundant data and ensure data consistency. For details, see Migrate from Databases that Use GH-ost/PT-osc.

13.6.4.3 Best practices during migration

This section introduces how to troubleshoot problems you might encounter during migration.

13.6.4.3.1 Inconsistent schemas in upstream and downstream

Common errors include:

- `messages: Column count doesn't match value count: 3 (columns)vs 2 (values)`
- `Schema/Column doesn't match`

Usually such issues are caused by changed or added indexes in the downstream TiDB, or there are more columns in the downstream. When such errors occur, check whether the upstream and downstream schemas are inconsistent.

To resolve such issues, update the schema information cached in DM to be consistent with the downstream TiDB schema. For details, see Manage Table Schemas of Tables to be Migrated.

If the downstream has more columns, see Migrate Data to a Downstream TiDB Table with More Columns.

13.6.4.3.2 Interrupted migration task due to failed DDL

DM supports skipping or replacing DDL statements that cause a migration task to interrupt. For details, see Handle Failed DDL Statements.

13.6.4.4 Data validation after data migration

It is recommended that you validate the consistency of data after data migration. TiDB provides sync-diff-inspector to help you complete the data validation.

Now sync-diff-inspector can automatically manage the table list to be checked for data consistency through DM tasks. Compared with the previous manual configuration, it is more efficient. For details, see Data Check in the DM Replication Scenario.

Since DM v6.2.0, DM supports continuous data validation for incremental replication. For details, see Continuous Data Validation in DM.

13.6.4.5 Long-term data replication

If you use DM to perform a long-term data replication task, it is necessary to back up the metadata. On the one hand, it ensures the ability to rebuild the migration cluster. On the other hand, it can implement the version control of the migration task. For details, see Export and Import Data Sources and Task Configuration of Clusters.

13.6.5 Deploy a DM cluster

13.6.5.1 Software and Hardware Requirements for TiDB Data Migration

TiDB Data Migration (DM) supports mainstream Linux operating systems. See the following table for specific version requirements:

Linux OS	Version
Red Hat Enterprise Linux	7.3 or later
CentOS	7.3 or later
Oracle Enterprise Linux	7.3 or later
Ubuntu LTS	16.04 or later

DM can be deployed and run on Intel architecture servers and mainstream virtualization environments.

13.6.5.1.1 Recommended server requirements

DM can be deployed and run on a 64-bit generic hardware server platform (Intel x86-64 architecture). For servers used in the development, testing, and production environments, this section illustrates recommended hardware configurations (these do not include the resources used by the operating system).

Development and test environments

Component	CPU	Memory	Local Storage	Network	Number of Instances (Minimum Requirement)
DM-master	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	1
DM-worker	8 core+	16 GB+	SAS, 200 GB+ (Greater than the size of the migrated data)	Gigabit network card	The number of upstream MySQL instances

Note:

- In the test environment, DM-master and DM-worker used for functional verification can be deployed on the same server.
- To prevent interference with the accuracy of the performance test results, it is **not recommended** to use low-performance storage and network hardware configurations.
- If you need to verify the function only, you can deploy a DM-master on a single machine. The number of DM-worker deployed must be greater than or equal to the number of upstream MySQL instances. To ensure high availability, it is recommended to deploy more DM-workers.
- DM-worker stores full data in the `dump` and `load` phases. Therefore, the disk space for DM-worker needs to be greater than the total amount of data to be migrated. If the relay log is enabled for the migration task, DM-worker needs additional disk space to store upstream binlog data.

Production environment

Component	CPU	Memory	Hard Disk Type	Network	Number of Instances (Minimum Requirement)
DM-master	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	3

Component	CPU	Memory	Hard Disk Type	Network	Number of Instances (Minimum Requirement)
DM-worker	16 core+	32 GB+	SSD, 200 GB+ (Greater than the size of the migrated data)	10 Gigabit network card	Greater than the number of upstream MySQL instances
Monitor	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	1

Note:

- In the production environment, it is not recommended to deploy and run DM-master and DM-worker on the same server, because when DM-worker writes data to disks, it might interfere with the use of disks by DM-master's high availability component.
- If a performance issue occurs, you are recommended to modify the task configuration file according to the Optimize Configuration of DM document. If the performance is not effectively optimized by tuning the configuration file, you can try to upgrade the hardware of your server.

13.6.5.1.2 Downstream storage space requirements

The target TiKV cluster must have enough disk space to store the imported data. In

addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has `x 2` because:

- Indexes might take extra space.
- RocksDB has a space amplification effect.

You can estimate the data volume by using the following SQL statements to summarize the `DATA_LENGTH` field:

```
-- Calculate the size of all schemas
SELECT
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(DATA_LENGTH)) AS 'Data Size',
  FORMAT_BYTES(SUM(INDEX_LENGTH)) 'Index Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_SCHEMA;

-- Calculate the 5 largest tables
SELECT
  TABLE_NAME,
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(data_length)) AS 'Data Size',
  FORMAT_BYTES(SUM(index_length)) AS 'Index Size',
  FORMAT_BYTES(SUM(data_length+index_length)) AS 'Total Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_NAME,
  TABLE_SCHEMA
ORDER BY
  SUM(DATA_LENGTH+INDEX_LENGTH) DESC
LIMIT
  5;
```

13.6.5.2 Deploy a DM Cluster Using TiUP

TiUP is a cluster operation and maintenance tool introduced in TiDB 4.0. TiUP provides TiUP DM, a cluster management component written in Golang. By using TiUP DM, you can easily perform daily TiDB Data Migration (DM) operations, including deploying, starting, stopping, destroying, scaling, and upgrading a DM cluster, and manage DM cluster parameters.

TiUP supports deploying DM v2.0 or later DM versions. This document introduces how to deploy DM clusters of different topologies.

> **Note:**
>
> If your target machine's operating system supports SELinux, make sure that SELinux is **disabled**.

13.6.5.2.1 Prerequisites

When DM performs a full data replication task, the DM-worker is bound with only one upstream database. The DM-worker first exports the full amount of data locally, and then imports the data into the downstream database. Therefore, the worker's host space must be large enough to store all upstream tables to be exported. The storage path is specified later when you create the task.

In addition, you need to meet the hardware and software requirements when deploying a DM cluster.

13.6.5.2.2 Step 1: Install TiUP on the control machine

Log in to the control machine using a regular user account (take the `tidb` user as an example). All the following TiUP installation and cluster management operations can be performed by the `tidb` user.

1. Install TiUP by executing the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

   After the installing, `~/.bashrc` has been modified to add TiUP to PATH, so you need to open a new terminal or redeclare the global environment variables `source ~/.bashrc` to use it.

2. Install the TiUP DM component:

```
tiup install dm dmctl
```

13.6.5.2.3 Step 2: Edit the initialization configuration file

According to the intended cluster topology, you need to manually create and edit the cluster initialization configuration file.

You need to create a YAML configuration file (named `topology.yaml` for example) according to the configuration file template. For other scenarios, edit the configuration accordingly.

You can use the command `tiup dm template > topology.yaml` to generate a configuration file template quickly.

The configuration of deploying three DM-masters, three DM-workers, and one monitoring component instance is as follows:

```
#### The global variables apply to all other components in the configuration
    ↪ . If one specific value is missing in the component instance, the
    ↪ corresponding global variable serves as the default value.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/dm-deploy"
  data_dir: "/dm-data"

server_configs:
  master:
    log-level: info
    # rpc-timeout: "30s"
    # rpc-rate-limit: 10.0
    # rpc-rate-burst: 40
  worker:
    log-level: info

master_servers:
  - host: 10.0.1.11
    name: master1
    ssh_port: 22
    port: 8261
    # peer_port: 8291
    # deploy_dir: "/dm-deploy/dm-master-8261"
    # data_dir: "/dm-data/dm-master-8261"
    # log_dir: "/dm-deploy/dm-master-8261/log"
    # numa_node: "0,1"
    # The following configs are used to overwrite the `server_configs.master
        ↪ ` values.
    config:
      log-level: info
      # rpc-timeout: "30s"
      # rpc-rate-limit: 10.0
      # rpc-rate-burst: 40
  - host: 10.0.1.18
    name: master2
```

```
    ssh_port: 22
    port: 8261
  - host: 10.0.1.19
    name: master3
    ssh_port: 22
    port: 8261
#### If you do not need to ensure high availability of the DM cluster,
    ↪ deploy only one DM-master node, and the number of deployed DM-worker
    ↪ nodes must be no less than the number of upstream MySQL/MariaDB
    ↪ instances to be migrated.
#### To ensure high availability of the DM cluster, it is recommended to
    ↪ deploy three DM-master nodes, and the number of deployed DM-worker
    ↪ nodes must exceed the number of upstream MySQL/MariaDB instances to
    ↪ be migrated (for example, the number of DM-worker nodes is two more
    ↪ than the number of upstream instances).
worker_servers:
  - host: 10.0.1.12
    ssh_port: 22
    port: 8262
    # deploy_dir: "/dm-deploy/dm-worker-8262"
    # log_dir: "/dm-deploy/dm-worker-8262/log"
    # numa_node: "0,1"
    # The following configs are used to overwrite the `server_configs.worker
       ↪ ` values.
    config:
      log-level: info
  - host: 10.0.1.19
    ssh_port: 22
    port: 8262

monitoring_servers:
  - host: 10.0.1.13
    ssh_port: 22
    port: 9090
    # deploy_dir: "/tidb-deploy/prometheus-8249"
    # data_dir: "/tidb-data/prometheus-8249"
    # log_dir: "/tidb-deploy/prometheus-8249/log"

grafana_servers:
  - host: 10.0.1.14
    port: 3000
    # deploy_dir: /tidb-deploy/grafana-3000

alertmanager_servers:
  - host: 10.0.1.15
```

```
  ssh_port: 22
  web_port: 9093
  # cluster_port: 9094
  # deploy_dir: "/tidb-deploy/alertmanager-9093"
  # data_dir: "/tidb-data/alertmanager-9093"
  # log_dir: "/tidb-deploy/alertmanager-9093/log"
```

Note:

- It is not recommended to run too many DM-workers on one host. Each DM-worker should be allocated at least 2 core CPU and 4 GiB memory.
- Make sure that the ports among the following components are interconnected:
  - The `peer_port` (`8291` by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `port` of all DM-worker nodes (`8262` by default).
  - Each DM-worker node can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-worker nodes (`8262` by default).

For more `master_servers.host.config` parameter description, refer to master parameter. For more `worker_servers.host.config` parameter description, refer to worker parameter.

13.6.5.2.4 Step 3: Execute the deployment command

Note:

You can use secret keys or interactive passwords for security authentication when you deploy TiDB using TiUP:

- If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;

- If you use passwords, add the `-p` flag to enter the password interaction window;
- If password-free login to the target machine has been configured, no authentication is required.

```
tiup dm deploy ${name} ${version} ./topology.yaml -u ${ssh_user} [-p] [-i /
    ↪ home/root/.ssh/gcp_rsa]
```

The parameters used in this step are as follows.

Parameter	Description
`${name}`	The name of the DM cluster, eg: dm-test

Parameter	Description
`${version}`	The version of the DM cluster. You can see other supported versions by running `tiup list dm-master`.
`./topology.yaml`	The topology of the topology configuration file.

Parameter	Description
`-u` or `--user`	Log in to the target machine as the root user or other user account with ssh and sudo privileges to complete the cluster deployment.

Parameter	Description
`-p` or `--password`	The password of target hosts. If specified, password authentication is used.

Parameter	Description
-i or --identity_file	The path of the SSH identity file. If specified, public key authentication is used (default “/root/.ssh/id_rsa”).

At the end of the output log, you will see `Deployed cluster `dm-test` successfully`. This indicates that the deployment is successful.

13.6.5.2.5 Step 4: Check the clusters managed by TiUP

```
tiup dm list
```

TiUP supports managing multiple DM clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

```
Name User Version Path                                       PrivateKey
---- ---- ------- ----                                       ----------
dm-test tidb ${version} /root/.tiup/storage/dm/clusters/dm-test /root/.tiup
   ↪ /storage/dm/clusters/dm-test/ssh/id_rsa
```

13.6.5.2.6 Step 5: Check the status of the deployed DM cluster

To check the status of the `dm-test` cluster, execute the following command:

```
tiup dm display dm-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down`/`inactive`), and directory information.

13.6.5.2.7 Step 6: Start the DM cluster

```
tiup dm start dm-test
```

If the output log includes `Started cluster` `` `dm-test` `` `successfully`, the start is successful.

13.6.5.2.8 Step 7: Verify the running status of the DM cluster

Check the DM cluster status using TiUP:

```
tiup dm display dm-test
```

If the `Status` is `Up` in the output, the cluster status is normal.

13.6.5.2.9 Step 8: Managing migration tasks using dmctl

dmctl is a command-line tool used to control DM clusters. You are recommended to use dmctl via TiUP.

dmctl supports both the command mode and the interactive mode. For details, see Maintain DM Clusters Using dmctl.

13.6.5.3 Deploy a DM Cluster Offline Using TiUP

This document describes how to deploy a DM cluster offline using TiUP.

13.6.5.3.1 Step 1: Prepare the TiUP offline component package

- Install the TiUP package manager online.

  1. Install the TiUP tool:

     ```
     curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.
        ↪ com/install.sh | sh
     ```

  2. Redeclare the global environment variables:

     ```
     source .bash_profile
     ```

3. Confirm whether TiUP is installed:

```
which tiup
```

- Pull the mirror using TiUP

1. Pull the needed components on a machine that has access to the Internet:

```
# You can modify ${version} to the needed version.
tiup mirror clone tidb-dm-${version}-linux-amd64 --os=linux --arch=
    ↪ amd64 \
    --dm-master=${version} --dm-worker=${version} --dmctl=${version
        ↪ } \
    --alertmanager=v0.17.0 --grafana=v4.0.3 --prometheus=v4.0.3 \
    --tiup=v$(tiup --version|grep 'tiup'|awk -F ' ' '{print $1}')
        ↪ --dm=v$(tiup --version|grep 'tiup'|awk -F ' ' '{print $1
        ↪ }')
```

The command above creates a directory named `tidb-dm-${version}-linux-
↪ amd64` in the current directory, which contains the component package managed by TiUP.

2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

```
tar czvf tidb-dm-${version}-linux-amd64.tar.gz tidb-dm-${version}-
    ↪ linux-amd64
```

`tidb-dm-${version}-linux-amd64.tar.gz` is an independent offline environment package.

13.6.5.3.2 Step 2: Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following command:

```
#### You can modify ${version} to the needed version.
tar xzvf tidb-dm-${version}-linux-amd64.tar.gz
sh tidb-dm-${version}-linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically executes the `tiup mirror set tidb-dm-
↪ ${version}-linux-amd64` command to set the current mirror address to `tidb-dm-${
↪ version}-linux-amd64`.

To switch the mirror to another directory, manually execute the `tiup mirror set
↪ <mirror-dir>` command. If you want to switch back to the official mirror, execute `tiup mirror set https://tiup-mirrors.pingcap.com`.

13.6.5.3.3 Step 3: Edit the initialization configuration file

You need to edit the cluster initialization configuration file according to different cluster topologies.

For the full configuration template, refer to the TiUP configuration parameter template. Create a configuration file `topology.yaml`. In other combined scenarios, edit the configuration file as needed according to the templates.

The configuration of deploying three DM-masters, three DM-workers, and one monitoring component instance is as follows:

```
---
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/home/tidb/dm/deploy"
  data_dir: "/home/tidb/dm/data"
  # arch: "amd64"

master_servers:
  - host: 172.19.0.101
  - host: 172.19.0.102
  - host: 172.19.0.103

worker_servers:
  - host: 172.19.0.101
  - host: 172.19.0.102
  - host: 172.19.0.103

monitoring_servers:
  - host: 172.19.0.101

grafana_servers:
  - host: 172.19.0.101

alertmanager_servers:
  - host: 172.19.0.101
```

Note:

- If you do not need to ensure high availability of the DM cluster, deploy only one DM-master node, and the number of deployed DM-worker nodes must be no less than the number of upstream MySQL/MariaDB instances to be migrated.

- To ensure high availability of the DM cluster, it is recommended to deploy three DM-master nodes, and the number of deployed DM-worker nodes must be greater than the number of upstream MySQL/MariaDB instances to be migrated (for example, the number of DM-worker nodes is two more than the number of upstream instances).
- For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
- For parameters that should be effective on a specific node, configure these parameters in `config` of this node.
- Use `.` to indicate the subcategory of the configuration, such as `log.slow-threshold`. For more formats, see TiUP configuration template.
- For more parameter description, see master `config.toml.example` and worker `config.toml.example`.
- Make sure that the ports among the following components are interconnected:
  - The `peer_port` (`8291` by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `port` of all DM-worker nodes (`8262` by default).
  - Each DM-worker node can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-worker nodes (`8262` by default).

13.6.5.3.4 Step 4: Execute the deployment command

Note:

You can use secret keys or interactive passwords for security authentication when you deploy DM using TiUP:

- If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;
- If you use passwords, add the `-p` flag to enter the password interaction window;

- If password-free login to the target machine has been configured, no authentication is required.

```
tiup dm deploy dm-test ${version} ./topology.yaml --user root [-p] [-i /home
    ↪ /root/.ssh/gcp_rsa]
```

In the above command:

- The name of the deployed DM cluster is `dm-test`.
- The version of the DM cluster is `${version}`. You can view the latest versions supported by TiUP by running `tiup list dm-master`.
- The initialization configuration file is `topology.yaml`.
- `--user root`: Log in to the target machine through the `root` key to complete the cluster deployment, or you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]`: optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the `root` user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.
- TiUP DM uses the embedded SSH client. If you want to use the SSH client native to the control machine system, edit the configuration according to using the system's native SSH client to connect to the cluster.

At the end of the output log, you will see `Deployed cluster `dm-test` successfully`. This indicates that the deployment is successful.

13.6.5.3.5 Step 5: Check the clusters managed by TiUP

```
tiup dm list
```

TiUP supports managing multiple DM clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

```
Name  User  Version Path                                       PrivateKey
----  ----  ------- ----                                       ----------
dm-test tidb ${version} /root/.tiup/storage/dm/clusters/dm-test /root/.tiup
    ↪ /storage/dm/clusters/dm-test/ssh/id_rsa
```

13.6.5.3.6 Step 6: Check the status of the deployed DM cluster

To check the status of the `dm-test` cluster, execute the following command:

```
tiup dm display dm-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down/inactive`), and directory information of the `dm-test` cluster.

13.6.5.3.7 Step 7: Start the cluster

```
tiup dm start dm-test
```

If the output log includes `Started cluster` `` `dm-test` `` `successfully`, the start is successful.

13.6.5.3.8 Step 8: Verify the running status of the cluster

Check the DM cluster status using TiUP:

```
tiup dm display dm-test
```

If the `Status` is `Up` in the output, the cluster status is normal.

13.6.5.4 Deploy Data Migration Using DM Binary

This document introduces how to quickly deploy the Data Migration (DM) cluster using DM binary.

> **Note:**
>
> In the production environment, it is recommended to use TiUP to deploy a DM cluster.

13.6.5.4.1 Download DM binary

The DM binary is included in the TiDB Toolkit. To download the TiDB Toolkit, see Download TiDB Tools.

13.6.5.4.2 Sample scenario

Suppose that you deploy a DM cluster based on this sample scenario:

Two DM-worker nodes and three DM-master nodes are deployed on five servers.

Here is the address of each node:

Instance	Server address	Port
DM-master1	192.168.0.4	8261
DM-master2	192.168.0.5	8261
DM-master3	192.168.0.6	8261
DM-worker1	192.168.0.7	8262
DM-worker2	192.168.0.8	8262

Based on this scenario, the following sections describe how to deploy the DM cluster.

Note:

- If you deploy multiple DM-master or DM-worker instances in a single server, the port and working directory of each instance must be unique.
- If you do not need to ensure high availability of the DM cluster, deploy only one DM-master node, and the number of deployed DM-worker nodes must be no less than the number of upstream MySQL/MariaDB instances to be migrated.
- To ensure high availability of the DM cluster, it is recommended to deploy three DM-master nodes, and the number of deployed DM-worker nodes must be greater than the number of upstream MySQL/MariaDB instances to be migrated (for example, the number of DM-worker nodes is two more than the number of upstream instances).
- Make sure that the ports among the following components are interconnected:
  - The `8291` ports among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `8262` ports of all DM-worker nodes.
  - Each DM-worker node can connect to the `8261` port of all DM-master nodes.

Deploy DM-master

You can configure DM-master by using command-line parameters or the configuration file.

DM-master command-line parameters

The following is the description of DM-master command-line parameters:

```
./dm-master --help
```

```
Usage of dm-master:
  -L string
        log level: debug, info, warn, error, fatal (default "info")
  -V    prints version and exit
  -advertise-addr string
        advertise address for client traffic (default "${master-addr}")
  -advertise-peer-urls string
        advertise URLs for peer traffic (default "${peer-urls}")
  -config string
        path to config file
  -data-dir string
        path to the data directory (default "default.${name}")
  -initial-cluster string
        initial cluster configuration for bootstrapping, e.g. dm-master=http
           ↪ ://127.0.0.1:8291
  -join string
        join to an existing cluster (usage: cluster's "${master-addr}" list,
           ↪ e.g. "127.0.0.1:8261,127.0.0.1:18261"
  -log-file string
        log file path
  -master-addr string
        master API server and status addr
  -name string
        human-readable name for this DM-master member
  -peer-urls string
        URLs for peer traffic (default "http://127.0.0.1:8291")
  -print-sample-config
        print sample config file of dm-worker
```

> **Note:**
>
> In some situations, you cannot use the above method to configure DM-master because some configurations are not exposed to the command line. In such cases, use the configuration file instead.

DM-master configuration file

The following is the configuration file of DM-master. It is recommended that you configure DM-master by using this method.

1. Write the following configuration to `conf/dm-master1.toml`:

“‘toml # Master Configuration. name = “master1”

Log configurations. log-level = “info” log-file = “dm-master.log”

The listening address of DM-master. master-addr = “192.168.0.4:8261”

The peer URLs of DM-master. peer-urls = “192.168.0.4:8291”

The value of `initial-cluster` is the combination of the `advertise-peer-urls` value of all DM-master nodes in the initial cluster. initial-cluster = “master1=http://192.168.0.4:8291,master2=http://192.168.0.5:8291,master3=http://192.168.0.6:8291”

“‘

2. Execute the following command in the terminal to run DM-master:

```
bash  ./dm-master -config conf/dm-master1.toml
```

> **Note:**
> The console does not output logs after this command is executed. If you want to view the runtime log, you can execute `tail -f dm-master.log`.

3. For DM-master2 and DM-master3, change `name` in the configuration file to `master2` and `master3` respectively, and change `peer-urls` to `192.168.0.5:8291` and `192.168.0.6:8291` respectively. Then repeat Step 2.

Deploy DM-worker

You can configure DM-worker by using command-line parameters or the configuration file.

DM-worker command-line parameters

The following is the description of the DM-worker command-line parameters:

```
./dm-worker --help
```

```
Usage of worker:
  -L string
        log level: debug, info, warn, error, fatal (default "info")
  -V    prints version and exit
  -advertise-addr string
        advertise address for client traffic (default "${worker-addr}")
  -config string
        path to config file
  -join string
        join to an existing cluster (usage: dm-master cluster's "${master-addr}")
  -keepalive-ttl int
```

```
      dm-worker's TTL for keepalive with etcd (in seconds) (default 10)
-log-file string
      log file path
-name string
      human-readable name for DM-worker member
-print-sample-config
      print sample config file of dm-worker
-worker-addr string
      listen address for client traffic
```

Note:

In some situations, you cannot use the above method to configure DM-worker because some configurations are not exposed to the command line. In such cases, use the configuration file instead.

DM-worker configuration file

The following is the DM-worker configuration file. It is recommended that you configure DM-worker by using this method.

1. Write the following configuration to `conf/dm-worker1.toml`:

   “‘toml # Worker Configuration. name = “worker1”

   # Log configuration. log-level = “info” log-file = “dm-worker.log”

   # DM-worker address. worker-addr = “:8262”

   # The master-addr configuration of the DM-master nodes in the cluster. join = “192.168.0.4:8261,192.168.0.5:8261,192.168.0.6:8261” “‘

2. Execute the following command in the terminal to run DM-worker:

   `bash ./dm-worker -config conf/dm-worker1.toml`

3. For DM-worker2, change `name` in the configuration file to `worker2`. Then repeat Step 2.

Now, a DM cluster is successfully deployed.

13.6.5.5 Use Kubernetes

13.6.6 Tutorials

13.6.6.1 Create a Data Source for TiDB Data Migration

> **Note:**
>
> Before creating a data source, you need to Deploy a DM Cluster Using TiUP.

The document describes how to create a data source for the data migration task of TiDB Data Migration (DM).

A data source contains the information for accessing the upstream migration task. Because a data migration task requires referring its corresponding data source to obtain the configuration information of access, you need to create the data source of a task before creating a data migration task. For specific data source management commands, refer to Manage Data Source Configurations.

13.6.6.1.1 Step 1: Configure the data source

1. (optional) Encrypt the data source password

   In DM configuration files, it is recommended to use the password encrypted with dmctl. You can follow the example below to obtain the encrypted password of the data source, which can be used to write the configuration file later.

```
tiup dmctl encrypt 'abc!@#123'
```

```
MKxn0Qo3m3XOyjCnhEMtsUCm83EhGQDZ/T4=
```

2. Write the configuration file of the data source

   For each data source, you need an individual configuration file to create it. You can follow the example below to create a data source whose ID is "mysql-01". First create the configuration file `./source-mysql-01.yaml`:

```
source-id: "mysql-01" # The ID of the data source, you can refer this
    ↪ source-id in the task configuration and dmctl command to
    ↪ associate the corresponding data source.

from:
  host: "127.0.0.1"
  port: 3306
  user: "root"
```

```
  password: "MKxn0Qo3m3XOyjCnhEMtsUCm83EhGQDZ/T4=" # The user password
     ↪ of the upstream data source. It is recommended to use the
     ↪ password encrypted with dmctl.
  security:                                    # The TLS configuration of
     ↪  the upstream data source. If not necessary, it can be deleted.
    ssl-ca: "/path/to/ca.pem"
    ssl-cert: "/path/to/cert.pem"
    ssl-key: "/path/to/key.pem"
```

13.6.6.1.2 Step 2: Create a data source

You can use the following command to create a data source:

```
tiup dmctl --master-addr <master-addr> operate-source create ./source-mysql
   ↪ -01.yaml
```

For other configuration parameters, refer to Upstream Database Configuration File.

The returned results are as follows:

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

13.6.6.1.3 Step 3: Query the data source you created

After creating a data source, you can use the following command to query the data source:

- If you konw the `source-id` of the data source, you can use the `dmctl config source <source-id>` command to directly check the configuration of the data source:

```
tiup dmctl --master-addr <master-addr> config source mysql-01
```

```
{
  "result": true,
  "msg": "",
```

```
  "cfg": "enable-gtid: false
    flavor: mysql
    source-id: mysql-01
    from:
      host: 127.0.0.1
      port: 3306
      user: root
      password: '******'
}
```

- If you do not know the `source-id`, you can use the `dmctl operate-source show` command to check the source database list, from which you can find the corresponding data source.

```
tiup dmctl --master-addr <master-addr> operate-source show
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "source is added but there is no free worker to bound
                ↪ ",
            "source": "mysql-02",
            "worker": ""
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

13.6.6.2 Manage Data Source Configurations in TiDB Data Migration

This document introduces how to manage data source configurations, including encrypting the MySQL password, operating the data source, and changing the bindings between upstream MySQL instances and DM-workers using dmctl.

13.6.6.2.1 Encrypt the database password

In DM configuration files, it is recommended to use the password encrypted with dmctl. For one original password, the encrypted password is different after each encryption.

```
./dmctl -encrypt 'abc!@#123'
```

```
MKxn0Qo3m3XOyjCnhEMtsUCm83EhGQDZ/T4=
```

13.6.6.2.2 Operate data source

You can use the `operate-source` command to load, list or remove the data source configurations to the DM cluster.

```
help operate-source
```

```
`create`/`stop`/`show` upstream MySQL/MariaDB source.

Usage:
  dmctl operate-source <operate-type> [config-file ...] [--print-sample-
    ↪ config] [flags]

Flags:
  -h, --help                help for operate-source
  -p, --print-sample-config print sample config file of source

Global Flags:
  -s, --source strings MySQL Source ID
```

Flags description

- `create`: Creates one or more upstream database sources. When creating multiple data sources fails, DM rolls back to the state where the command was not executed.
- `stop`: Stops one or more upstream database sources. When stopping multiple data sources fails, some data sources might be stopped.
- `show`: Shows the added data source and the corresponding DM-worker.
- `config-file`: Specifies the file path of `source.yaml` and can pass multiple file paths.
- `--print-sample-config`: Prints the sample configuration file. This parameter ignores other parameters.

Usage example

Use the following `operate-source` command to create a source configuration file:

```
operate-source create ./source.yaml
```

For the configuration of `source.yaml`, refer to Upstream Database Configuration File Introduction.

The following is an example of the returned result:

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

Check data source configurations

> **Note:**
>
> The `config` command is only supported in DM v6.0 and later versions. For earlier versions, you must use the `get-config` command.

If you know the `source-id`, you can run `dmctl --master-addr <master-addr> ↪ config source <source-id>` to get the data source configuration.

```
config source mysql-replica-01
```

```
{
  "result": true,
    "msg": "",
    "cfg": "enable-gtid: false
      flavor: mysql
      source-id: mysql-replica-01
      from:
        host: 127.0.0.1
        port: 8407
        user: root
        password: '******'
}
```

If you don't know the `source-id`, you can run `dmctl --master-addr <master-addr> operate-source show` to list all data sources first.

```
operate-source show
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "source is added but there is no free worker to bound",
            "source": "mysql-replica-02",
            "worker": ""
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

13.6.6.2.3 Change the bindings between upstream MySQL instances and DM-workers

You can use the `transfer-source` command to change the bindings between upstream MySQL instances and DM-workers.

```
help transfer-source
```

```
Transfers an upstream MySQL/MariaDB source to a free worker.
Usage:
  dmctl transfer-source <source-id> <worker-id> [flags]
Flags:
  -h, --help help for transfer-source
Global Flags:
  -s, --source strings MySQL Source ID.
```

Before transferring, DM checks whether the worker to be unbound still has running tasks. If the worker has any running tasks, you need to pause the tasks first, change the binding, and then resume the tasks.

Usage example

If you do not know the bindings of DM-workers, you can run `dmctl --master-addr <master-addr> list-member --worker` to list the current bindings of all workers.

```
list-member --worker
```

```
{
    "result": true,
    "msg": "",
    "members": [
        {
            "worker": {
                "msg": "",
                "workers": [
                    {
                        "name": "dm-worker-1",
                        "addr": "127.0.0.1:8262",
                        "stage": "bound",
                        "source": "mysql-replica-01"
                    },
                    {
                        "name": "dm-worker-2",
                        "addr": "127.0.0.1:8263",
                        "stage": "free",
                        "source": ""
                    }
                ]
            }
        }
    ]
}
```

In the above example, `mysql-replica-01` is bound to `dm-worker-1`. The below command transfers the binding worker of `mysql-replica-01` to `dm-worker-2`.

```
transfer-source mysql-replica-01 dm-worker-2
```

```
{
    "result": true,
    "msg": ""
}
```

Check whether the command takes effect by running `dmctl --master-addr <master-addr> list-member --worker`.

```
list-member --worker
```

```
{
    "result": true,
    "msg": "",
    "members": [
        {
            "worker": {
                "msg": "",
                "workers": [
                    {
                        "name": "dm-worker-1",
                        "addr": "127.0.0.1:8262",
                        "stage": "free",
                        "source": ""
                    },
                    {
                        "name": "dm-worker-2",
                        "addr": "127.0.0.1:8263",
                        "stage": "bound",
                        "source": "mysql-replica-01"
                    }
                ]
            }
        }
    ]
}
```

13.6.6.3 Data Migration Task Configuration Guide

This document introduces how to configure a data migration task in Data Migration (DM).

13.6.6.3.1 Configure data sources to be migrated

Before configuring the data sources to be migrated for the task, you need to first make sure that DM has loaded the configuration files of the corresponding data sources. The following are some operation references:

- To view the data source, you can refer to Check the data source configuration.
- To create a data source, you can refer to Create data source.
- To generate a data source configuration file, you can refer to Source configuration file introduction.

The following example of `mysql-instances` shows how to configure data sources that need to be migrated for the data migration task:

```
---

##### ********* Basic configuration *********
name: test          # The name of the task. Should be globally unique.

##### ******** Data source configuration **********
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-01`.
  - source-id: "mysql-replica-02" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-02`.
```

13.6.6.3.2 Configure the downstream TiDB cluster

The following example of `target-database` shows how to configure the target TiDB cluster to be migrated to for the data migration task:

```
---

##### ********* Basic configuration *********
name: test          # The name of the task. Should be globally unique.

##### ******** Data source configuration **********
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-01`.
  - source-id: "mysql-replica-02" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-02`.

##### ******** Downstream TiDB database configuration **********
target-database:    # Configuration of target TiDB database.
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: ""      # If the password is not null, it is recommended to use
    ↪  a password encrypted with dmctl.
```

13.6.6.3.3 Configure tables to be migrated

Note:

> If you do not need to filter specific tables or migrate specific tables, skip this configuration.

To configure the block and allow list of data source tables for the data migration task, perform the following steps:

1. Configure a global filter rule set of the block and allow list in the task configuration file.

```
block-allow-list:
  bw-rule-1:                          # The name of the block and allow
    ↪ list rule.
    do-dbs: ["test.*", "user"]     # The allow list of upstream schemas
      ↪ to be migrated. Wildcard characters (*?) are supported. You
      ↪ only need to configure either `do-dbs` or `ignore-dbs`. If
      ↪ both fields are configured, only `do-dbs` takes effect.
    # ignore-dbs: ["mysql", "account"] # The block list of upstream
      ↪ schemas to be migrated. Wildcard characters (*?) are
      ↪ supported.
    do-tables:                        # The allow list of upstream tables
      ↪ to be migrated. You only need to configure either `do-tables`
      ↪  or `ignore-tables`. If both fields are configured, only `do-
      ↪ tables` takes effect.
    - db-name: "test.*"
      tbl-name: "t.*"
    - db-name: "user"
      tbl-name: "information"
  bw-rule-2:                        # The name of the block allow list
    ↪ rule.
    ignore-tables:                # The block list of data source tables
      ↪  needs to be migrated.
    - db-name: "user"
      tbl-name: "log"
```

For detailed configuration rules, see Block and allow table lists.

2. Reference the block and allow list rules in the data source configuration to filter tables to be migrated.

```
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source
    ↪ whose `source-id` is `mysql-replica-01`.
```

```
  block-allow-list: "bw-rule-1" # The name of the block and allow
    ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
    ↪ use `black-white-list` instead.
- source-id: "mysql-replica-02" # Migrate data from the data source
  ↪ whose `source-id` is `mysql-replica-02`.
  block-allow-list: "bw-rule-2" # The name of the block and allow
    ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
    ↪ use `black-white-list` instead.
```

13.6.6.3.4 Configure binlog events to be migrated

> **Note:**
>
> If you do not need to filter specific binlog events of certain schemas or tables, skip this configuration.

To configure the filters of binlog events for the data migration task, perform the following steps:

1. Configure a global filter rule set of binlog events in the task configuration file.

```
filters:                                  # The filter rule set of data
  ↪  source binlog events. You can set multiple rules at the same
  ↪ time.
 filter-rule-1:                           # The name of the filtering
    ↪ rule.
   schema-pattern: "test_*"               # The pattern of the data
     ↪ source schema name. Wildcard characters (*?) are supported.
   table-pattern: "t_*"                   # The pattern of the data
     ↪ source table name. Wildcard characters (*?) are supported.
   events: ["truncate table", "drop table"] # The event types to be
     ↪ filtered out in schemas or tables that match the `schema-
     ↪ pattern` or the `table-pattern`.
   action: Ignore                         # Whether to migrate (Do) or
     ↪ ignore (Ignore) the binlog that matches the filtering rule.
 filter-rule-2:
   schema-pattern: "test"
   events: ["all dml"]
   action: Do
```

For detailed configuration rules, see Binlog event filter.

2. Reference the binlog event filtering rules in the data source configuration to filter specified binlog events of specified tables or schemas in the data source.

```
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source
      ↪ whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-1" # The name of the block and allow
       ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-1"] # The name of the rule that filters
       ↪  specific binlog events of the data source. You can configure
       ↪  multiple rules here.
  - source-id: "mysql-replica-02" # Migrate data from the data source
      ↪ whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-2" # The name of the block and allow
       ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-2"] # The name of the rule that filters
       ↪  specific binlog events of the data source. You can configure
       ↪  multiple rules here.
```

13.6.6.3.5 Configure the mapping of data source tables to downstream TiDB tables

> **Note:**
>
> - If you do not need to migrate a certain table of the data source to the table with a different name in the downstream TiDB instance, skip this configuration.
> - If it is a shard merge task, you **must** set mapping rules in the task configuration file.

To configure the routing mapping rules for migrating data source tables to specified downstream TiDB tables, perform the following steps:

1. Configure a global routing mapping rule set in the task configuration file.

```
routes:                          # The routing mapping rule set between
   ↪ the data source tables and downstream TiDB tables. You can set
   ↪ multiple rules at the same time.
  route-rule-1:                  # The name of the routing mapping rule.
```

```
  schema-pattern: "test_*"  # The pattern of the upstream schema name
    ↪ . Wildcard characters (*?) are supported.
  table-pattern: "t_*"      # The pattern of the upstream table name.
    ↪  Wildcard characters (*?) are supported.
  target-schema: "test"     # The name of the downstream TiDB schema.
  target-table: "t"         # The name of the downstream TiDB table.
route-rule-2:
  schema-pattern: "test_*"
  target-schema: "test"
```

For detailed configuration rules, see Table Routing.

2. Reference the routing mapping rules in the data source configuration to filter tables to be migrated.

```
mysql-instances:
 - source-id: "mysql-replica-01"               # Migrate data from the
    ↪ data source whose `source-id` is `mysql-replica-01`.
   block-allow-list: "bw-rule-1"               # The name of the block
     ↪ and allow list rule. If the DM version is earlier than v2
     ↪ .0.0-beta.2, use `black-white-list` instead.
   filter-rules: ["filter-rule-1"]             # The name of the rule
     ↪ that filters specific binlog events of the data source. You
     ↪ can configure multiple rules here.
   route-rules: ["route-rule-1", "route-rule-2"] # The name of the
     ↪ routing mapping rule. You can configure multiple rules here.
 - source-id: "mysql-replica-02"               # Migrate data from the
    ↪ data source whose `source-id` is `mysql-replica-02`.
   block-allow-list: "bw-rule-2"               # The name of the block
     ↪ and allow list rule. If the DM version is earlier than v2
     ↪ .0.0-beta.2, use `black-white-list` instead.
   filter-rules: ["filter-rule-2"]             # The name of the rule
     ↪ that filters specific binlog events of the data source. You
     ↪ can configure multiple rules here.
```

13.6.6.3.6 Configure a shard merge task

Note:

- If you need to migrate sharding DDL statements in a shard merge scenario, you **must** explicitly configure the `shard-mode` field. Otherwise, **DO NOT** configure `shard-mode` at all.

- Migrating sharding DDL statements is likely to cause many issues. Make sure you understand the principles and restrictions of DM migrating DDL statements before using this feature, and you **must** use this feature with caution.

The following example shows how to configure the task as a shard merge task:

```
---

##### ********* Basic information *********
name: test                  # The name of the task. Should be globally
    ↪ unique.
shard-mode: "pessimistic"   # The shard merge mode. Optional modes are ""/"
    ↪ pessimistic"/"optimistic". The "" mode is used by default which means
    ↪  sharding DDL merge is disabled. If the task is a shard merge task,
    ↪ set it to the "pessimistic" mode. After getting a deep understanding
    ↪ of the principles and restrictions of the "optimistic" mode, you can
    ↪ set it to the "optimistic" mode.
```

13.6.6.3.7 Other configurations

The following is an overall task configuration example of this document. The complete task configuration template can be found in DM task configuration file full introduction.

```
---

##### ********* Basic configuration *********
name: test                  # The name of the task. Should be globally
    ↪ unique.
shard-mode: "pessimistic"   # The shard merge mode. Optional modes are ""/"
    ↪ pessimistic"/"optimistic". The "" mode is used by default which means
    ↪  sharding DDL merge is disabled. If the task is a shard merge task,
    ↪ set it to the "pessimistic" mode. After getting a deep understanding
    ↪ of the principles and restrictions of the "optimistic" mode, you can
    ↪ set it to the "optimistic" mode.
task-mode: all              # The task mode. Can be set to `full`(only
    ↪ migrates full data)/`incremental`(replicates binlog synchronously)/`
    ↪ all` (replicates both full and incremental binlogs).
timezone: "UTC"           # The timezone used in SQL Session. By default,
    ↪ DM uses the global timezone setting in the target cluster, which
    ↪ ensures the correctness automatically. A customized timezone does not
    ↪  affect data migration but is unnecessary.
```

```
##### ******** Data source configuration **********
mysql-instances:
  - source-id: "mysql-replica-01"            # Migrate data from the data
     ↪ source whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-1"            # The name of the block and
       ↪ allow list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-1"]          # The name of the rule that
       ↪ filters specific binlog events of the data source. You can
       ↪ configure multiple rules here.
    route-rules: ["route-rule-1", "route-rule-2"] # The name of the routing
       ↪ mapping rule. You can configure multiple rules here.
  - source-id: "mysql-replica-02"            # Migrate data from the data
     ↪ source whose `source-id` is `mysql-replica-02`.
    block-allow-list: "bw-rule-2"            # The name of the block and
       ↪ allow list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-2"]          # The name of the rule that
       ↪ filters specific binlog events of the data source. You can
       ↪ configure multiple rules here.
    route-rules: ["route-rule-2"]            # The name of the routing
       ↪ mapping rule. You can configure multiple rules here.

##### ******** Downstream TiDB instance configuration **********
target-database:    # Configuration of the downstream database instance.
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: ""      # If the password is not null, it is recommended to use
     ↪  a password encrypted with dmctl.

##### ******** Feature configuration set **********
#### The filter rule set of tables to be migrated from the upstream database
   ↪  instance. You can set multiple rules at the same time.
block-allow-list:                  # Use black-white-list if the DM version
   ↪ is earlier than v2.0.0-beta.2.
  bw-rule-1:                       # The name of the block and allow list
     ↪ rule.
    do-dbs: ["test.*", "user"]     # The allow list of upstream schemas to
       ↪ be migrated. Wildcard characters (*?) are supported. You only need
       ↪  to configure either `do-dbs` or `ignore-dbs`. If both fields are
       ↪ configured, only `do-dbs` takes effect.
    # ignore-dbs: ["mysql", "account"] # The block list of upstream schemas
       ↪ to be migrated. Wildcard characters (*?) are supported.
    do-tables:                       # The allow list of upstream tables to be
```

```
      ↪  migrated. You only need to configure either `do-tables` or `
      ↪ ignore-tables`. If both fields are configured, only `do-tables`
      ↪ takes effect.
    - db-name: "test.*"
      tbl-name: "t.*"
    - db-name: "user"
      tbl-name: "information"
  bw-rule-2:                    # The name of the block allow list rule.
    ignore-tables:              # The block list of data source tables
      ↪ needs to be migrated.
    - db-name: "user"
      tbl-name: "log"

#### The filter rule set of data source binlog events.
filters:                                # You can set multiple rules at
   ↪ the same time.
  filter-rule-1:                        # The name of the filtering rule.
    schema-pattern: "test_*"            # The pattern of the data source
      ↪ schema name. Wildcard characters (*?) are supported.
    table-pattern: "t_*"                # The pattern of the data source
      ↪ table name. Wildcard characters (*?) are supported.
    events: ["truncate table", "drop table"] # The event types to be
      ↪ filtered out in schemas or tables that match the `schema-pattern`
      ↪ or the `table-pattern`.
    action: Ignore                      # Whether to migrate (Do) or
      ↪ ignore (Ignore) the binlog that matches the filtering rule.
  filter-rule-2:
    schema-pattern: "test"
    events: ["all dml"]
    action: Do

#### The routing mapping rule set between the data source and target TiDB
   ↪ instance tables.
routes:                       # You can set multiple rules at the same time.
  route-rule-1:               # The name of the routing mapping rule.
    schema-pattern: "test_*"  # The pattern of the data source schema name.
      ↪ Wildcard characters (*?) are supported.
    table-pattern: "t_*"      # The pattern of the data source table name.
      ↪ Wildcard characters (*?) are supported.
    target-schema: "test"     # The name of the downstream TiDB schema.
    target-table: "t"         # The name of the downstream TiDB table.
  route-rule-2:
    schema-pattern: "test_*"
    target-schema: "test"
```

13.6.6.4 TiDB Data Migration Shard Merge

TiDB Data Migration (DM) supports merging the DML and DDL data in the upstream MySQL/MariaDB sharded tables and migrating the merged data to the downstream TiDB tables.

If you need to migrate and merge MySQL shards of small datasets to TiDB, refer to this tutorial.

13.6.6.4.1 Restrictions

Currently, the shard merge feature is supported only in limited scenarios. For details, refer to Sharding DDL usage Restrictions in the pessimistic mode and Sharding DDL usage Restrictions in the optimistic mode.

13.6.6.4.2 Configure parameters

In the task configuration file, set `shard-mode` to `pessimistic`:

```
shard-mode: "pessimistic"
#### The shard merge mode. Optional modes are ""/"pessimistic"/"optimistic".
   ↪  The "" mode is used by default
#### which means sharding DDL merge is disabled. If the task is a shard
   ↪ merge task, set it to the "pessimistic"
#### mode. After getting a deep understanding of the principles and
   ↪ restrictions of the "optimistic" mode, you
#### can set it to the "optimistic" mode.
```

13.6.6.4.3 Handle sharding DDL locks manually

In some abnormal scenarios, you need to handle sharding DDL Locks manually.

13.6.6.5 TiDB Data Migration Table Routing

When you migrate data using TiDB Data Migration (DM), you can configure the table routing to migrate a certain table of the upstream MySQL or MariaDB instance to the specified table in the downstream.

Note:

- Configuring multiple different routing rules for a single table is not supported.
- The match rule of schema needs to be configured separately, which is used to migrate `CREATE/DROP SCHEMA xx`, as shown in `rule-2` of the Configure table routing section.

13.6.6.5.1 Configure table routing

```
routes:
  rule-1:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    target-schema: "test"
    target-table: "t"
    # extract-table, extract-schema, and extract-source are optional and
    # are required only when you need to extract information about sharded
    # tables, sharded schemas, and source datatabase information.
    extract-table:
      table-regexp: "t_(.*)"
      target-column: "c_table"
    extract-schema:
      schema-regexp: "test_(.*)"
      target-column: "c_schema"
    extract-source:
      source-regexp: "(.*)"
      target-column: "c_source"
  rule-2:
    schema-pattern: "test_*"
    target-schema: "test"
```

Regular expressions and wildcards are supported to match database and table names. In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following:

- Wildcards including `*`, `?`, and `[]` are supported. There can only be one `*` symbol in a wildcard match, and it must be at the end. For example, in `table-pattern: "t_*"`, `"t_*"` indicates all tables starting with `t_`. See wildcard matching for details.
- `table-regexp`, `schema-regexp`, and `source-regexp` only support regular expressions and cannot start with the `~` symbol.
- `schema-pattern` and `table-pattern` support both wildcards and regular expressions. Regular expressions must begin with the `~` symbol.

13.6.6.5.2 Parameter descriptions

- DM migrates the upstream MySQL or MariaDB instance tables that match the `schema-pattern/table-pattern` rule provided by Table selector to the downstream `target-schema/target-table`.

- For sharded tables that match the `schema-pattern/table-pattern` rules, DM extracts the table name by using the `extract-table.table-regexp` regular expression, the schema name by using the `extract-schema.schema-regexp` regular expression, and source information by using the `extract-source.source-regexp` regular expression. Then DM writes the extracted information to the corresponding `target-column` in the merged table in the downstream.

13.6.6.5.3 Usage examples

This section shows the usage examples in four different scenarios.

If you need to migrate and merge MySQL shards of small datasets to TiDB, refer to this tutorial.

Merge sharded schemas and tables

Assuming in the scenario of sharded schemas and tables, you want to migrate the `test_{1,2,3...}.t_{1,2,3...}` tables in two upstream MySQL instances to the `test.t` table in the downstream TiDB instance.

To migrate the upstream instances to the downstream `test.t`, you must create the following routing rules:

- `rule-1` is used to migrate DML or DDL statements of the table that matches `schema-pattern: "test_*"` and `table-pattern: "t_*"` to the downstream `test.t`.
- `rule-2` is used to migrate DDL statements of the schema that matches `schema-pattern: "test_*"`, such as `CREATE/DROP SCHEMA xx`.

Note:

- If the downstream `schema: test` already exists and is not to be deleted, you can omit `rule-2`.
- If the downstream `schema: test` does not exist and only `rule-1` is configured, then it reports the `schema test doesn't exist` error during migration.

```
rule-1:
  schema-pattern: "test_*"
  table-pattern: "t_*"
  target-schema: "test"
  target-table: "t"
rule-2:
  schema-pattern: "test_*"
  target-schema: "test"
```

Extract table, schema, and source information and write into the merged table

Assuming in the scenario of sharded schemas and tables, you want to migrate the `test_{1,2,3...}.t_{1,2,3...}` tables in two upstream MySQL instances to the `test.t` table in the downstream TiDB instance. At the same time, you want to extract the source information of the sharded tables and write it to the downstream merged table.

To migrate the upstream instances to the downstream `test.t`, you must create routing rules similar to the previous section Merge sharded schemas and tables. In addtion, you need to add the `extract-table`, `extract-schema`, and `extract-source` configurations:

- `extract-table`: For a sharded table matching `schema-pattern` and `table-pattern`, DM extracts the sharded table name by using `table-regexp` and writes the name suffix without the `t_` part to `target-column` of the merged table, that is, the `c_table` column.
- `extract-schema`: For a sharded schema matching `schema-pattern` and `table-pattern`, DM extracts the sharded schema name by using `schema-regexp` and writes the name suffix without the `test_` part to `target-column` of the merged table, that is, the `c_schema` column.
- `extract-source`: For a sharded table matching `schema-pattern` and `table-pattern`, DM writes the source instance information to the `target-column` of the merged table, that is, the `c_source` column.

```
rule-1:
  schema-pattern: "test_*"
  table-pattern: "t_*"
  target-schema: "test"
  target-table: "t"
  extract-table:
    table-regexp: "t_(.*)"
    target-column: "c_table"
  extract-schema:
    schema-regexp: "test_(.*)"
    target-column: "c_schema"
  extract-source:
    source-regexp: "(.*)"
    target-column: "c_source"
rule-2:
  schema-pattern: "test_*"
  target-schema: "test"
```

To extract the source information of upstream sharded tables to the merged table in the downstream, you **must manually create a merged table in the downstream before starting the migration**. The merged table must contain the three `target-columns` (`c_table`, `c_schema`, and `c_source`) used for specifying the source information. In addition, these columns **must be the last columns and be string types**.

```
CREATE TABLE `test`.`t` (
    a int(11) PRIMARY KEY,
    c_table varchar(10) DEFAULT NULL,
    c_schema varchar(10) DEFAULT NULL,
    c_source varchar(10) DEFAULT NULL
);
```

Assume that the upstream has the following two data sources:

Data source `mysql-01`:

```
mysql> select * from test_11.t_1;
+---+
| a |
+---+
| 1 |
+---+
mysql> select * from test_11.t_2;
+---+
| a |
+---+
| 2 |
+---+
mysql> select * from test_12.t_1;
+---+
| a |
+---+
| 3 |
+---+
```

Data source `mysql-02`:

```
mysql> select * from test_13.t_3;
+---+
| a |
+---+
| 4 |
+---+
```

After migration using DM, data in the merged table will be as follows:

```
mysql> select * from test.t;
+---+---------+----------+----------+
| a | c_table | c_schema | c_source |
+---+---------+----------+----------+
| 1 | 1       | 11       | mysql-01 |
```

```
| 2 | 2      | 11       | mysql-01 |
| 3 | 1      | 12       | mysql-01 |
| 4 | 3      | 13       | mysql-02 |
+---+--------+----------+----------+
```

Incorrect examples of creating merged tables

> **Note:**
>
> If any of the following errors occur, source information of sharded tables and schemas might fail to be written to the merged table.

- `c-table` is not in the last three columns:

```
CREATE TABLE `test`.`t` (
    c_table varchar(10) DEFAULT NULL,
    a int(11) PRIMARY KEY,
    c_schema varchar(10) DEFAULT NULL,
    c_source varchar(10) DEFAULT NULL
);
```

- `c-source` is absent:

```
CREATE TABLE `test`.`t` (
    a int(11) PRIMARY KEY,
    c_table varchar(10) DEFAULT NULL,
    c_schema varchar(10) DEFAULT NULL,
);
```

- `c_schema` is not a string type:

```
CREATE TABLE `test`.`t` (
    a int(11) PRIMARY KEY,
    c_table varchar(10) DEFAULT NULL,
    c_schema int(11) DEFAULT NULL,
    c_source varchar(10) DEFAULT NULL,
);
```

Merge sharded schemas

Assuming in the scenario of sharded schemas, you want to migrate the `test_{1,2,3...}` ↪ `.t_{1,2,3...}` tables in the two upstream MySQL instances to the `test.t_{1,2,3...}` tables in the downstream TiDB instance.

To migrate the upstream schemas to the downstream `test.t_[1,2,3]`, you only need to create one routing rule.

```
rule-1:
  schema-pattern: "test_*"
  target-schema: "test"
```

Incorrect table routing

Assuming that the following two routing rules are configured and `test_1_bak.t_1_bak` matches both `rule-1` and `rule-2`, an error is reported because the table routing configuration violates the number limitation.

```
rule-1:
  schema-pattern: "test_*"
  table-pattern: "t_*"
  target-schema: "test"
  target-table: "t"
rule-2:
  schema-pattern: "test_1_bak"
  table-pattern: "t_1_bak"
  target-schema: "test"
  target-table: "t_bak"
```

13.6.6.6 TiDB Data Migration Block and Allow Lists

When you migrate data using TiDB Data Migration (DM), you can configure the block and allow lists to filter or only migrate all operations of some databases or some tables.

13.6.6.6.1 Configure the block and allow lists

In the task configuration file, add the following configuration:

```
block-allow-list:          # Use black-white-list if the DM version is
   ↪ earlier than or equal to v2.0.0-beta.2.
  rule-1:
    do-dbs: ["test*"]      # Starting with characters other than "~"
       ↪ indicates that it is a wildcard;
                           # v1.0.5 or later versions support the regular
                              ↪ expression rules.
    do-tables:
    - db-name: "test[123]" # Matches test1, test2, and test3.
```

```
    tbl-name: "t[1-5]"   # Matches t1, t2, t3, t4, and t5.
  - db-name: "test"
    tbl-name: "t"
rule-2:
  do-dbs: ["~^test.*"]   # Starting with "~" indicates that it is a
    ↪ regular expression.
  ignore-dbs: ["mysql"]
  do-tables:
  - db-name: "~^test.*"
    tbl-name: "~^t.*"
  - db-name: "test"
    tbl-name: "t*"
  ignore-tables:
  - db-name: "test"
    tbl-name: "log"
```

In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following version differences:

- Wildcards including `*`, `?`, and `[]` are supported. There can only be one `*` symbol in a wildcard match, and it must be at the end. For example, in `tbl-name: "t*"`, `"t*"` indicates all tables starting with `t`. See wildcard matching for details.
- A regular expression must begin with the `~` character.

13.6.6.6.2 Parameter descriptions

- `do-dbs`: allow lists of the schemas to be migrated, similar to `replicate-do-db` in MySQL.
- `ignore-dbs`: block lists of the schemas to be migrated, similar to `replicate-ignore-db` in MySQL.
- `do-tables`: allow lists of the tables to be migrated, similar to `replicate-do-table` in MySQL. Both `db-name` and `tbl-name` must be specified.
- `ignore-tables`: block lists of the tables to be migrated, similar to `replicate-ignore-table` in MySQL. Both `db-name` and `tbl-name` must be specified.

If a value of the above parameters starts with the `~` character, the subsequent characters of this value are treated as a regular expression. You can use this parameter to match schema or table names.

13.6.6.6.3 Filtering process

- The filtering rules corresponding to `do-dbs` and `ignore-dbs` are similar to the Evaluation of Database-Level Replication and Binary Logging Options in MySQL.

- The filtering rules corresponding to `do-tables` and `ignore-tables` are similar to the Evaluation of Table-Level Replication Options in MySQL.

> **Note:**
>
> In DM and in MySQL, the block and allow lists filtering rules are different in the following ways:
>
> - In MySQL, `replicate-wild-do-table` and `replicate-wild-ignore-table` support wildcard characters. In DM, some parameter values directly supports regular expressions that start with the `~` character.
> - DM currently only supports binlogs in the `ROW` format, and does not support those in the `STATEMENT` or `MIXED` format. Therefore, the filtering rules in DM correspond to those in the `ROW` format in MySQL.
> - MySQL determines a DDL statement only by the database name explicitly specified in the `USE` section of the statement. DM determines a statement first based on the database name section in the DDL statement. If the DDL statement does not contain such a section, DM determines the statement by the `USE` section. Suppose that the SQL statement to be determined is `USE test_db_2; CREATE TABLE test_db_1.test_table (c1 INT PRIMARY KEY)`; that `replicate-do-db=test_db_1` is configured in MySQL and `do-dbs: ["test_db_1"]` is configured in DM. Then this rule only applies to DM and not to MySQL.

The filtering process of a `test.t` table is as follows:

1. Filter at the **schema** level:
    - If `do-dbs` is not empty, check whether a matched schema exists in `do-dbs`.
        - If yes, continue to filter at the **table** level.
        - If not, filter `test.t`.
    - If `do-dbs` is empty and `ignore-dbs` is not empty, check whether a matched schema exits in `ignore-dbs`.
        - If yes, filter `test.t`.
        - If not, continue to filter at the **table** level.
    - If both `do-dbs` and `ignore-dbs` are empty, continue to filter at the **table** level.
2. Filter at the **table** level:
    1. If `do-tables` is not empty, check whether a matched table exists in `do-tables`.

- If yes, migrate `test.t`.
- If not, filter `test.t`.

2. If `ignore-tables` is not empty, check whether a matched table exists in `ignore-tables`.
   - If yes, filter `test.t`.
   - If not, migrate `test.t`.
3. If both `do-tables` and `ignore-tables` are empty, migrate `test.t`.

> **Note:**
>
> To check whether the schema `test` should be filtered, you only need to filter at the schema level.

13.6.6.6.4 Usage examples

Assume that the upstream MySQL instances include the following tables:

```
`logs`.`messages_2016`
`logs`.`messages_2017`
`logs`.`messages_2018`
`forum`.`users`
`forum`.`messages`
`forum_backup_2016`.`messages`
`forum_backup_2017`.`messages`
`forum_backup_2018`.`messages`
```

The configuration is as follows:

```
block-allow-list: # Use black-white-list if the DM version is earlier than
    ↪ or equal to v2.0.0-beta.2.
  bw-rule:
    do-dbs: ["forum_backup_2018", "forum"]
    ignore-dbs: ["~^forum_backup_"]
    do-tables:
    - db-name: "logs"
      tbl-name: "~_2018$"
    - db-name: "~^forum.*"
       tbl-name: "messages"
    ignore-tables:
    - db-name: "~.*"
       tbl-name: "^messages.*"
```

After applying the `bw-rule` rule:

Table	Whether to filter	Why filter
`logs` ↪ `.messages_2016`	Yes	The schema `logs` fails to match any `do-dbs`.
`logs` ↪ `.messages_2017`	Yes	The schema `logs` fails to match any `do-dbs`.
`logs` ↪ `.messages_2018`	Yes	The schema `logs` fails to match any `do-dbs`.
`forum_backup_2016` ↪ `.messages`	Yes	The schema `forum_backup_2016` ↪ fails to match any `do-dbs`.
`forum_backup_2017` ↪ `.messages`	Yes	The schema `forum_backup_2017` ↪ fails to match any `do-dbs`.
`forum` ↪ `.users`	Yes	1. The schema `forum` matches `do-dbs` and continues to filter at the table level. 2. The schema and table fail to match any of `do-tables` and `ignore-tables` and `do-tables` is not empty.

Table	Whether to filter	Why filter
`forum` ↪ `.messages` ↪	No	1. The schema `forum` matches `do-dbs` and continues to filter at the table level. 2. The table `messages` is in the `db-name: "~^ ↪ forum.*", ↪ tbl-name: ↪ "messages"` of `do-tables`.
`forum_backup_2018` ↪ `.messages` ↪	No	The schema `forum_backup_2018` ↪ matches `do-dbs` and continues to filter at the table level. 2. The schema and table match the `db-name: "~^ ↪ forum.*", ↪ tbl-name: ↪ "messages"` of `do-tables`.

13.6.6.7 TiDB Data Migration Binlog Event Filter

TiDB Data Migration (DM) provides the binlog event filter feature to filter out or only receive specified types of binlog events for some schemas or tables. For example, you can filter out all `TRUNCATE TABLE` or `INSERT` events. The binlog event filter feature is more fine-grained than the block and allow lists feature.

13.6.6.7.1 Configure the binlog event filter

In the task configuration file, add the following configuration:

```
filters:
  rule-1:
```

```
  schema-pattern: "test_*"
   table-pattern: "t_*"
   events: ["truncate table", "drop table"]
  sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
   action: Ignore
```

Starting from DM v2.0.2, you can configure the binlog event filter in the source configuration file. For details, see Upstream Database Configuration File.

When you use the wildcard for matching schemas and tables, note the following:

- `schema-pattern` and `table-pattern` only support wildcards, including `*`, `?`, and `[]`. There can only be one `*` symbol in a wildcard match, and it must be at the end. For example, in `table-pattern: "t_*"`, `"t_*"` indicates all tables starting with `t_`. See wildcard matching for details.
- `sql-pattern` only supports regular expressions.

13.6.6.7.2 Parameter descriptions

- schema-pattern/table-pattern: the binlog events or DDL SQL statements of upstream MySQL or MariaDB instance tables that match `schema-pattern/table-pattern` are filtered by the rules below.
- `events`: the binlog event array. You can only select one or more `Events` from the following table:

Events	Type	Description
`all`		Includes all the events below
`all dml`		Includes all DML events below
`all ddl`		Includes all DDL events below
`none`		Includes none of the events below
`none ddl`		Includes none of the DDL events below
`none dml`		Includes none of the DML events below
`insert`	DML	The `INSERT` DML event
`update`	DML	The `UPDATE` DML event
`delete`	DML	The `DELETE` DML event
`create database`	DDL	The `CREATE DATABASE` DDL event
`drop database`	DDL	The `DROP DATABASE` DDL event
`create table`	DDL	The `CREATE TABLE` DDL event
`create index`	DDL	The `CREATE INDEX` DDL event
`drop table`	DDL	The `DROP TABLE` DDL event
`truncate table`	DDL	The `TRUNCATE TABLE` DDL event
`rename table`	DDL	The `RENAME TABLE` DDL event
`drop index`	DDL	The `DROP INDEX` DDL event
`alter table`	DDL	The `ALTER TABLE` DDL event

- `sql-pattern`: it is used to filter specified DDL SQL statements. The matching rule supports using a regular expression. For example, `"^DROP\\s+PROCEDURE"`.
- `action`: the string (`Do`/`Ignore`). Based on the following rules, it judges whether to filter. If either of the two rules is satisfied, the binlog is filtered; otherwise, the binlog is not filtered.
    - `Do`: the allow list. The binlog is filtered in either of the following two conditions:
        - The type of the event is not in the `event` list of the rule.
        - The SQL statement of the event cannot be matched by `sql-pattern` of the rule.
    - `Ignore`: the block list. The binlog is filtered in either of the following two conditions:
        - The type of the event is in the `event` list of the rule.
        - The SQL statement of the event can be matched by `sql-pattern` of the rule.
    - When multiple rules match the same table, the rules are applied sequentially. The block list has a higher priority than the allow list. For example, if both the `Ignore` and `Do` rules are applied to the same table, the `Ignore` rule takes effect.

13.6.6.7.3 Usage examples

This section shows the usage examples in the scenario of sharding (sharded schemas and tables).

Filter all sharding deletion operations

To filter out all deletion operations, configure the following two filtering rules:

- `filter-table-rule` filters out the `TRUNCATE TABLE`, `DROP TABLE` and `DELETE STATEMENT` operations of all tables that match the `test_*.t_*` pattern.
- `filter-schema-rule` filters out the `DROP DATABASE` operation of all schemas that match the `test_*` pattern.

```
filters:
  filter-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table", "delete"]
    action: Ignore
  filter-schema-rule:
    schema-pattern: "test_*"
    events: ["drop database"]
    action: Ignore
```

Only migrate sharding DML statements

To only migrate sharding DML statements, configure the following two filtering rules:

- `do-table-rule` only migrates the `CREATE TABLE`, `INSERT`, `UPDATE` and `DELETE` statements of all tables that match the `test_*.t_*` pattern.
- `do-schema-rule` only migrates the `CREATE DATABASE` statement of all schemas that match the `test_*` pattern.

> **Note:**
>
> The reason why the `CREATE DATABASE/TABLE` statement is migrated is that you can migrate DML statements only after the schema and table are created.

```
filters:
  do-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["create table", "all dml"]
    action: Do
  do-schema-rule:
    schema-pattern: "test_*"
    events: ["create database"]
    action: Do
```

Filter out the SQL statements that TiDB does not support

To filter out the `PROCEDURE` statements that TiDB does not support, configure the following `filter-procedure-rule`:

```
filters:
  filter-procedure-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
    action: Ignore
```

`filter-procedure-rule` filters out the `^CREATE\\s+PROCEDURE` and `^DROP\\s+PROCEDURE` statements of all tables that match the `test_*.t_*` pattern.

Filter out the SQL statements that the TiDB parser does not support

For the SQL statements that the TiDB parser does not support, DM cannot parse them and get the `schema/table` information. So you must use the global filtering rule: `schema-pattern: "*"`.

Note:

To avoid filtering out data that need to be migrated, you must configure the global filtering rule as strictly as possible.

To filter out the `PARTITION` statements that the TiDB parser (of some version) does not support, configure the following filtering rule:

```
filters:
  filter-partition-rule:
    schema-pattern: "*"
    sql-pattern: ["ALTER\\s+TABLE[\\s\\S]*ADD\\s+PARTITION", "ALTER\\s+TABLE
       ↪ [\\s\\S]*DROP\\s+PARTITION"]
    action: Ignore
```

13.6.6.8 Filter DMLs Using SQL Expressions

13.6.6.8.1 Overview

In the process of incremental data migration, you can filter certain types of binlog events using the Filter Binlog Events feature. For example, for archiving or auditing purposes, you can filter out `DELETE` events when migrating data to the downstream. However, Binlog Event Filter cannot judge with a greater granularity on whether to filter out a specific row of `DELETE` events.

To solve the above issue, DM supports filtering data during incremental migration using `binlog value filter` since v2.0.5. The binlog in the `ROW` format supported by DM has the values of all columns in binlog events. You can configure SQL expressions according to these values. If the SQL expressions evaluate a row change as `TRUE`, DM will not migrate the row change downstream.

For detailed operation and implementation, see Filter DML Events Using SQL Expressions.

13.6.6.9 TiDB Data Migration Support for Online DDL Tools

In the MySQL ecosystem, tools such as gh-ost and pt-osc are widely used. TiDB Data Migration (DM) provides supports for these tools to avoid migrating unnecessary intermediate data.

This document introduces the support for common online DDL tools, usage, and precautions in DM.

For the working principles and implementation methods of DM for online DDL tools, refer to online-ddl.

13.6.6.9.1 Restrictions

- DM only supports gh-ost and pt-osc.
- When `online-ddl` is enabled, the checkpoint corresponding to incremental replication should not be in the process of online DDL execution. For example, if an upstream online DDL operation starts at `position-A` and ends at `position-B` of the binlog, the starting point of incremental replication should be earlier than `position-A` or later than `position-B`; otherwise, an error occurs. For details, refer to FAQ.

13.6.6.9.2 Configure parameters

In v2.0.5 and later versions, you need to use the `online-ddl` configuration item in the `task` configuration file.

- If the upstream MySQL/MariaDB (at the same time) uses the gh-ost or pt-osc tool, set `online-ddl` to `true` in the task configuration file:

```
online-ddl: true
```

> **Note:**
>
> Since v2.0.5, `online-ddl-scheme` has been deprecated, so you need to use `online-ddl` instead of `online-ddl-scheme`. That means that setting `online-ddl: true` overwrites `online-ddl-scheme`, and setting `online-ddl-scheme: "pt"` or `online-ddl-scheme: "gh-ost"` is converted to `online-ddl: true`.

Before v2.0.5 (not including v2.0.5), you need to use the `online-ddl-scheme` configuration item in the `task` configuration file.

- If the upstream MySQL/MariaDB uses the gh-ost tool, set it in the task configuration file:

```
online-ddl-scheme: "gh-ost"
```

- If the upstream MySQL/MariaDB uses the pt tool, set it in the task configuration file:

```
online-ddl-scheme: "pt"
```

13.6.6.10 Manage a Data Migration Task

13.6.6.10.1 Migration Task Precheck

Before using DM to migrate data from upstream to downstream, a precheck helps detect errors in the upstream database configurations and ensures that the migration goes smoothly. This document introduces the DM precheck feature, including its usage scenario, check items, and arguments.

Usage scenario

To run a data migration task smoothly, DM triggers a precheck automatically at the start of the task and returns the check results. DM starts the migration only after the precheck is passed.

To trigger a precheck manually, run the `check-task` command.

For example:

```
tiup dmctl check-task ./task.yaml
```

Descriptions of check items

After a precheck is triggered for a task, DM checks the corresponding items according to your migration mode configuration.

This section lists all the precheck items.

> **Note:**
>
> In this document, check items that must be passed are labeled "(Mandatory)".

- If a mandatory check item does not pass, DM returns an error after the check and does not proceed with the migration task. In this case, modify the configurations according to the error message and retry the task after meeting the precheck requirements.
- If a non-mandatory check item does not pass, DM returns a warning after the check. DM automatically starts a migration task if the check result contains only warnings but no errors.

Common check items

Regardless of the migration mode you choose, the precheck always includes the following common check items:

- Database version
    - MySQL version > 5.5
    - MariaDB version >= 10.1.2

> **Warning:**
>
> - Migrating data from MySQL 8.0 to TiDB using DM is an experimental feature (introduced since DM v2.0). It is NOT recommended that you use it in a production environment.
> - Migrating data from MariaDB to TiDB using DM is an experimental feature. It is NOT recommended that you use it in a production environment.

- Compatibility of the upstream MySQL table schema
    - Check whether the upstream tables have foreign keys, which are not supported by TiDB. A warning is returned if a foreign key is found in the precheck.
    - Check whether the upstream tables use character sets that are incompatible with TiDB. For more information, see TiDB Supported Character Sets.
    - Check whether the upstream tables have primary key constraints or unique key constraints (introduced from v1.0.7).

> **Warning:**
>
> - When the upstream uses incompatible character sets, you can still continue the replication by creating tables with the utf8mb4 character set in the downstream. However, this practice is not recommended. You are advised to replace the incompatible character set used by the upstream with another character set that is supported in downstream.
> - When the upstream tables have no primary key constraints or unique key constraints, the same row of data might be replicated multiple times to the downstream, which might also affect the performance of replication. In a production environment, it is recommended that you specify primary key constraints or unique key constraints for the upstream table.

Check items for full data migration

For the full data migration mode (`task-mode: full`), in addition to the common check items, the precheck also includes the following check items:

- (Mandatory) dump permission of the upstream database
    - SELECT permission on INFORMATION_SCHEMA and dump tables
    - RELOAD permission if `consistency=flush`
    - LOCK TABLES permission on the dump tables if `consistency=flush/lock`
- (Mandatory) Consistency of upstream MySQL multi-instance sharding tables
    - In the pessimistic mode, check whether the table schemas of all sharded tables are consistent in the following items:
        - Number of columns
        - Column name
        - Column order
        - Column type
        - Primary key
        - Unique index
    - In the optimistic mode, check whether the schemas of all sharded tables meet the optimistic compatibility.
    - If a migration task was started successfully by the `start-task` command, the precheck of this task skips the consistency check.
- Auto-increment primary key in sharded tables
    - If sharded tables have auto-increment primary keys, the precheck returns a warning. If there are conflicts in auto-increment primary keys, see Handle conflicts of auto-increment primary key for solutions.

Check items for physical import

If you set `import-mode: "physical"` in the task configuration, the following check items are added to ensure that Physical Import runs normally. After following the prompts, if you find it difficult to meet the requirements of these check items, you can try to use the logical import mode to import data.

- Empty Regions in the downstream database
    - If the number of empty Regions is greater than `max(1000, 3 * the number of tables)` (the larger of "1000" and "3 times the number of tables"), the precheck returns a warning. You can adjust related PD parameters to speed up the merging of empty Regions and wait for the number of empty Regions to decrease. See PD Scheduling Best Practices - Slow Region Merge.
- Region distribution in the downstream database

    - Checks the number of Regions on different TiKV nodes. Assuming that the TiKV node with the lowest Region count has `a` Regions and the TiKV node with the highest Region count has `b` Regions, if `a / b` is less than 0.75, the precheck returns a warning. You can adjust related PD parameters to speed up the scheduling of Regions and wait for the number of Regions to change. See PD Scheduling Best Practices - Leader/Region distribution is not balanced.

- The versions of TiDB, PD, and TiKV in the downstream database

    - Physical import must call the interfaces of TiDB, PD, and TiKV. If the versions are not compatible, the precheck returns an error.

- The free space of the downstream database

    - Estimates the total sizes of all tables in the allow list in the upstream database (`source_size`). If the free space of the downstream database is less than `source_size`, the precheck returns an error. If the free space of the downstream database is less than the number of TiKV replicas * `source_size` * 2, the precheck returns a warning.

- Whether the downstream database is running tasks that are incompatible with physical import

    - Currently, physical import is incompatible with TiCDC and PITR tasks. If these tasks are running in the downstream database, the precheck returns an error.

Check items for incremental data migration

For the incremental data migration mode (`task-mode: incremental`), in addition to the common check items, the precheck also includes the following check items:

- (Mandatory) Upstream database REPLICATION permission

    - REPLICATION CLIENT permission
    - REPLICATION SLAVE permission

- Database primary-secondary configuration

    - To avoid primary-secondary replication failures, it is recommended that you specify the database ID `server_id` for the upstream database (GTID is recommended for non-AWS Aurora environments).

- (Mandatory) MySQL binlog configuration

    - Check whether binlog is enabled (required by DM).
    - Check whether `binlog_format=ROW` is configured (DM only supports the migration of binlog in the ROW format).

  - Check whether `binlog_row_image=FULL` is configured (DM only supports `binlog_row_image=FULL`).
  - If `binlog_do_db` or `binlog_ignore_db` is configured, check whether the database tables to be migrated meet the conditions of `binlog_do_db` and `binlog_ignore_db`.

- (Mandatory) Check if the upstream database is in an Online-DDL process (in which the `ghost` table is created but the `rename` phase is not executed yet). If the upstream is in the online-DDL process, the precheck returns an error. In this case, wait until the DDL to complete and retry.

Check items for full and incremental data migration

For the full and incremental data migration mode (`task-mode: all`), in addition to the common check items, the precheck also includes the full data migration check items and the incremental data migration check items.

Ignorable check items

Prechecks can find potential risks in your environments. It is not recommended to ignore check items. If your data migration task has special needs, you can use the `ignore-checking-items` configuration item to skip some check items.

Check item	Description
`dump_privilege`	Checks the dump privilege of the user in the upstream MySQL instance.
`replication_privilege`	Checks the replication privilege of the user in the upstream MySQL instance.
`version`	Checks the version of the upstream database.

Check item	Description
`server_id`	Checks whether server_id is configured in the upstream database.
`binlog_enable` ↪	Checks whether binlog is enabled in the upstream database.
`table_schema` ↪	Checks the compatibility of the table schemas in the upstream MySQL tables.
`schema_of_shard_tables` ↪	Checks the consistency of the table schemas in the upstream MySQL multi-instance shards.
`auto_increment_ID` ↪	Checks whether the auto-increment primary key conflicts in the upstream MySQL multi-instance shards.
`online_ddl`	Checks whether the upstream is in the process of online-DDL.

Check item	Description
`empty_region`	Checks the number of empty Regions in the downstream database for physical import.
`region_distribution`	Checks the distribution of Regions in the downstream database for physical import.
`downstream_version`	Checks the versions of TiDB, PD, and TiKV in the downstream database.
`free_space`	Checks the free space of the downstream database.
`downstream_mutex_features`	Checks whether the downstream database is running tasks that are incompatible with physical import.

Note:

More ignorable check items are supported in versions earlier than v6.0. Since v6.0, DM does not allow ignoring some check items related to data safety.

For example, if you configure the `binlog_row_image` parameter incorrectly, data might be lost during the replication.

Configure precheck arguments

The migration task precheck supports processing in parallel. Even if the number of rows in sharded tables reaches a million level, the precheck can be completed in minutes.

To specify the number of threads for the precheck, you can configure the `threads` argument of the `mydumpers` field in the migration task configuration file.

```
mydumpers:                          # Configuration arguments of the dump
   ↪ processing unit
  global:                           # Configuration name
    threads: 4                      # The number of threads that access the
       ↪ upstream when the dump processing unit performs the precheck and
       ↪ exports data from the upstream database (4 by default)
    chunk-filesize: 64              # The size of the files generated by the
       ↪ dump processing unit (64 MB by default)
    extra-args: "--consistency none" # Other arguments of the dump
       ↪ processing unit. You do not need to manually configure table-list
       ↪ in `extra-args`, because it is automatically generated by DM.
```

Note:

The value of `threads` determines the number of physical connections between the upstream database and DM. An excessively large `threads` value might increase the load of the upstream. Therefore, you need to set `threads` to a proper value.

13.6.6.10.2 Create a Data Migration Task

You can use the `start-task` command to create a data migration task. When the data migration task is started, DM prechecks privileges and configurations.

```
help start-task
```

```
Starts a task as defined in the configuration file

Usage:
  dmctl start-task [-s source ...] [--remove-meta] <config-file> [flags]
```

```
Flags:
  -h, --help              help for start-task
      --remove-meta       whether to remove task's meta data
      --start-time string specify the start time of binlog replication, e.g.
         ↪  '2021-10-21 00:01:00' or 2021-10-21T00:01:00

Global Flags:
      --config string     Path to config file.
      --master-addr string Master API server address, this parameter is
         ↪ required when interacting with the dm-master
      --rpc-timeout string RPC timeout, default is 10m. (default "10m")
  -s, --source strings    MySQL Source ID.
      --ssl-ca string     Path of file that contains list of trusted SSL CAs
         ↪  for connection.
      --ssl-cert string   Path of file that contains X509 certificate in PEM
         ↪  format for connection.
      --ssl-key string    Path of file that contains X509 key in PEM format
         ↪ for connection.
  -V, --version           Prints version and exit.
```

Usage example

```
start-task [ -s "mysql-replica-01"] ./task.yaml
```

Flags description

- `-s`: (Optional) Specifies the MySQL source to execute `task.yaml`. If it is set, the command only starts the subtasks of the specified task on the MySQL source.
- `config-file`: (Required) Specifies the file path of `task.yaml`.
- `remove-meta`: (Optional) Specifies whether to remove the task's previous metadata when starting the task.
- `start-time`: (Optional) Specifies the start time of binlog replication.
    - Format: `'2021-10-21 00:01:00'` or `2021-10-21T00:01:00`.
    - For incremental tasks, you can specify a rough starting point for the task using this flag. This flag takes precedence over the binlog position in the task configuration file and the binlog position in the downstream checkpoint.
    - When the task already has a checkpoint, if you start the task using this flag, DM automatically enables safe mode until the replication passes the checkpoint. This is to avoid the data duplication error caused by resetting the task to an earlier position.
        - When you reset the task to an earlier position, if the table schema at that time point is different from the downstream at the current time point, the task might report an error.

- When you reset the task to a later position, note that the skipped binlog might have dirty data left in the downstream.

- When you specify an earlier start time, DM starts migration from the earliest binlog position available.
- When you specify a later start time, DM reports an error: `start-time {input-time} is too late, no binlog location matches it`.

Returned results

```
start-task task.yaml
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

13.6.6.10.3 Query Task Status in TiDB Data Migration

This document introduces how to use the `query-status` command to query the task status, and the subtask status of DM.

Query result

It is recommended that you use `query-status` by the following steps:

1. Use `query-status` to check whether each on-going task is in the normal state.
2. If any error occurs in a task, use the `query-status <taskName>` command to see detailed error information. `<taskName>` in this command indicates the name of the task that encounters the error.

A successful query result is as follows:

```
» query-status
```

```
{
    "result": true,
    "msg": "",
```

```
    "tasks": [
        {
            "taskName": "test",
            "taskStatus": "Running",
            "sources": [
                "mysql-replica-01",
                "mysql-replica-02"
            ]
        },
        {
            "taskName": "test2",
            "taskStatus": "Paused",
            "sources": [
                "mysql-replica-01",
                "mysql-replica-02"
            ]
        }
    ]
}
```

Some fields in the query result are described as follows:

- `result`: Whether the query is successful.
- `msg`: The error message returned when the query fails.
- `tasks`: The list of migration tasks. Each task contains the following fields:
    - `taskName`: The name of the task.
    - `taskStatus`: The status of the task. For detailed descriptions of `taskStatus`, refer to Task status.
    - `sources`: The list of upstream MySQL databases.

Task status

The status of a DM migration task depends on the status of each subtask assigned to DM-worker. For detailed descriptions of subtask status, see Subtask status. The table below shows how the subtask status is related to task status.

Subtask status in a task	Task status
One subtask is in the `paused` state and error information is returned.	`Error` - `Some error occurred in subtask`

Subtask status in a task	Task status
One subtask in the Sync phase is in the Running state but its Relay processing unit is not running (in the Error state).	`Error` / `Paused` / `Stopped`
-	`Relay status` is `Error` / `Paused` / `Stopped`

Subtask status in a task	Task status
One subtask is in the `Paused` state and no error information is returned.	`Paused`
All subtasks are in the `New` state.	`New`
All subtasks are in the `Finished` state.	`Finished`

Subtask status in a task	Task status
All subtasks are in the Stopped state.	Stopped
Other situations	Running

Detailed query result

```
» query-status test
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "test-`test`.`t_target`",
                    "sync": {
                        "masterBinlog": "(bin.000001, 3234)",
```

```
                "masterBinlogGtid": "c0149e17-dff1-11e8-b6a8-0242
                    ↪ ac110004:1-14",
                "syncerBinlog": "(bin.000001, 2525)",
                "syncerBinlogGtid": "",

                    "finishedRows": "32",
                    "estimateTotalRows": "563",
                    "progress": "30.52 %",
                    "bps": "445"
                }
            }
        ]
    },
]
}
```

Some fields in the returned result are described as follows:

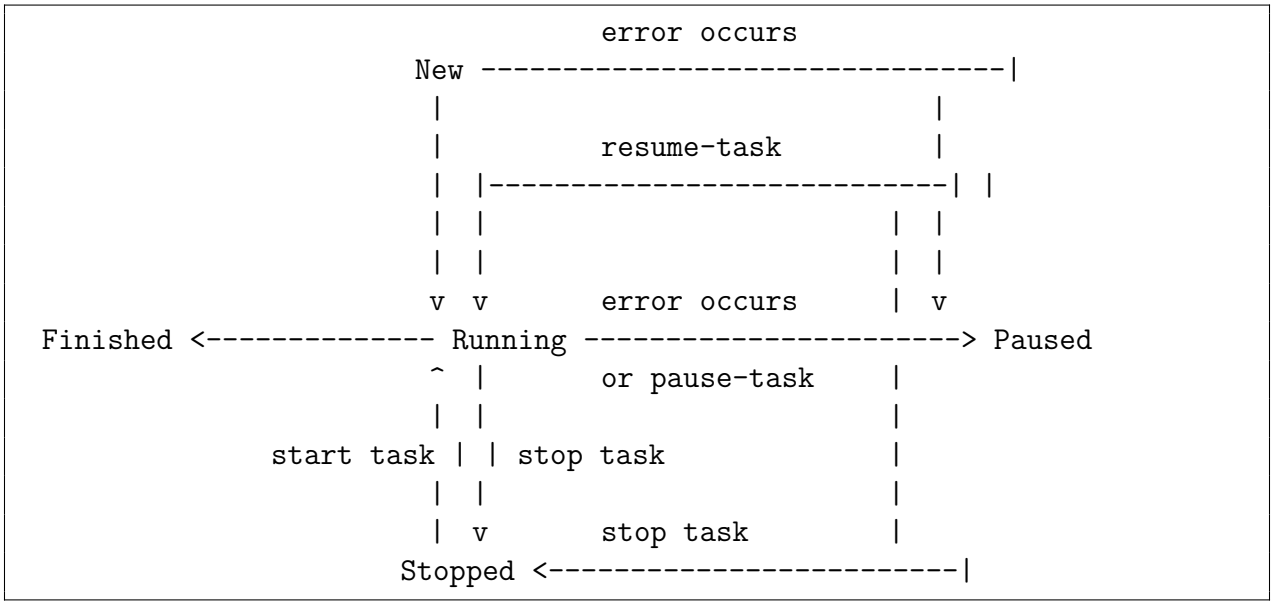
- `result`: Whether the query is successful.

- `msg`: The error message returned when the query fails.
- `sources`: The list of upstream MySQL instances. Each source contains the following fields:
    - `result`
    - `msg`
    - `sourceStatus`: The information of the upstream MySQL databases.
    - `subTaskStatus`: The information of all subtasks of upstream MySQL databases. Each subtask might contain the following fields:
        - `name`: The name of the subtask.
        - `stage`: The status of the subtask. For the status description and status switch relationship of "stage" of "subTaskStatus" of "sources", see the subtask status.
        - `unit`: The processing unit of DM, including "Check", "Dump", "Load", and "Sync".
        - `result`: Displays the error information if a subtask fails.
        - `unresolvedDDLLockID`: The sharding DDL lock ID, used for manually handling the sharding DDL lock in the abnormal condition. For operation details of "unresolvedDDLLockID" of "subTaskStatus" of "sources", see Handle Sharding DDL Locks Manually.
        - `sync`: The replication information of the `Sync` processing unit. This information is about the same component with the current processing unit.
            - `masterBinlog`: The binlog position in the upstream database.
            - `masterBinlogGtid`: The GTID information in the upstream database.
            - `syncerBinlog`: The position of the binlog that has been replicated in the `Sync` processing unit.
            - `syncerBinlogGtid`: The binlog position replicated using GTID.
            - `blockingDDLs`: The DDL list that is blocked currently. It is not empty only when all the upstream tables of this DM-worker are in the "synced" status. In this case, it indicates the sharding DDL statements to be executed or that are skipped.
            - `unresolvedGroups`: The sharding group that is not resolved. Each group contains the following fields:
                - `target`: The downstream database table to be replicated.
                - `DDLs`: A list of DDL statements.
                - `firstPos`: The starting position of the sharding DDL statement.
                - `synced`: The upstream sharded table whose executed sharding DDL statement has been read by the `Sync` unit.
                - `unsynced`: The upstream table that has not executed this sharding DDL statement. If any upstream tables have not finished replication, `blockingDDLs` is empty.
            - `synced`: Whether the incremental replication catches up with the upstream and has the same binlog position as that in the upstream. The save point is not refreshed in real time in the `Sync` background, so `false` of `synced` does not always mean a replication delay exits.

    - `totalRows`: The total number of rows that are replicated in this subtask.
    - `totalRps`: The number of rows that are replicated in this subtask per second.
    - `recentRps`: The number of rows that are replicated in this subtask in the last second.
  - `load`: The replication information of the `Load` processing unit.
    - `finishedBytes`: The number of bytes that have been loaded.
    - `totalBytes`: The total number of bytes that need to be loaded.
    - `progress`: The progress of the loading process.
    - `bps`: The speed of the full loading.
  - `dump`: The replication information of the `Dump` processing unit.
    - `totalTables`: The number of tables to be dumped.
    - `completedTables`: The number of tables that have been dumped.
    - `finishedBytes`: The number of bytes that have been dumped.
    - `finishedRows`: The number of rows that have been dumped.
    - `estimateTotalRows`: The estimated number of rows to be dumped.
    - `progress`: The progress of the dumping process.
    - `bps`: The dumping speed in bytes/second.

Subtask status

Status description



- `New`:
  - The initial status.
  - If the subtask does not encounter an error, it is switched to `Running`; otherwise it is switched to `Paused`.
- `Running`: The normal running status.
- `Paused`:
  - The paused status.
  - If the subtask encounters an error, it is switched to `Paused`.
  - If you run `pause-task` when the subtask is in the `Running` status, the task is switched to `Paused`.
  - When the subtask is in this status, you can run the `resume-task` command to resume the task.
- `Stopped`:
  - The stopped status.
  - If you run `stop-task` when the subtask is in the `Running` or `Paused` status, the task is switched to `Stopped`.

- When the subtask is in this status, you cannot use `resume-task` to resume the task.

- `Finished`:

  - The finished subtask status.
  - Only when the full replication subtask is finished normally, the task is switched to this status.

Status switch diagram

13.6.6.10.4 Pause a Data Migration Task

You can use the `pause-task` command to pause a data migration task.

`pause-task` differs from `stop-task` in that:

- `pause-task` only pauses a migration task. You can query the status information (retained in the memory) of the task using `query-status`. `stop-task` terminates a migration task and removes all information related to this task from the memory. This means you cannot use `query-status` to query the status information. `dm_meta` like "checkpoint" and data that have been migrated to the downstream are not removed.
- If `pause-task` is executed to pause the migration task, you cannot start a new task with the same name, neither can you get the relay log of the paused task removed, since this task does exist. If `stop-task` is executed to stop a task, you can start a new task with the same name, and you can get the relay log of the stopped task removed, since this task no longer exists.
- `pause-task` is usually used to pause a task for troubleshooting, while `stop-task` is to permanently remove a migration task, or to co-work with `start-task` to update the configuration information.

```
help pause-task
```

```
pause a specified running task

Usage:
 dmctl pause-task [-s source ...] <task-name | task-file> [flags]

Flags:
 -h, --help help for pause-task

Global Flags:
 -s, --source strings MySQL Source ID
```

Usage example

```
pause-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where you want to pause the subtasks of the migration task. If it is set, this command pauses only the subtasks on the specified MySQL source.
- `task-name| task-file`: (Required) Specifies the task name or task file path.

Returned results

```
pause-task test
```

```
{
    "op": "Pause",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

13.6.6.10.5 Resume a Data Migration Task

You can use the `resume-task` command to resume a data migration task in the `Paused` state. This is generally used in scenarios where you want to manually resume a data migration task after handling the error that get the task paused.

```
help resume-task
```

```
resume a specified paused task

Usage:
 dmctl resume-task [-s source ...] <task-name | task-file> [flags]

Flags:
 -h, --help help for resume-task

Global Flags:
 -s, --source strings MySQL Source ID
```

Usage example

```
resume-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where you want to resume the subtask of the migration task. If it is set, the command resumes only the subtasks on the specified MySQL source.
- `task-name | task-file`: (Required) Specifies the task name or task file path.

Returned results

```
resume-task test
```

```
{
    "op": "Resume",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

13.6.6.10.6 Stop a Data Migration Task

You can use the `stop-task` command to stop a data migration task. For differences between `stop-task` and `pause-task`, refer to Pause a Data Migration Task.

```
help stop-task
```

```
stop a specified task

Usage:
 dmctl stop-task [-s source ...] <task-name | task-file> [flags]

Flags:
 -h, --help  help for stop-task

Global Flags:
 -s, --source strings MySQL Source ID
```

Usage example

```
stop-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where the subtasks of the migration task (that you want to stop) run. If it is set, only subtasks on the specified MySQL source are stopped.
- `task-name | task-file`: (Required) Specifies the task name or task file path.

Returned results

```
stop-task test
```

```
{
    "op": "Stop",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

Note:

After you stop a migration task with the `stop-task` command, running `query-status` will no longer display the task. However, the checkpoint and other related information for this task is still retained in the `dm_meta` database.

- To start over the migration task, add the `--remove-meta` option when running the `start-task` command.
- To completely remove the migration task, manually delete the four tables that use the task name as a prefix from the `dm_meta` database.

13.6.7 Advanced Tutorials

13.6.7.1 Merge and Migrate Data from Sharded Tables

13.6.7.1.1 Merge and Migrate Data from Sharded Tables

This document introduces the sharding support feature provided by Data Migration (DM). This feature allows you to merge and migrate the data of tables with the same or different table schemas in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB. It supports not only migrating the upstream DML statements, but also coordinating to migrate the table schema change using DDL statements in multiple upstream sharded tables.

Overview

DM supports merging and migrating the data of multiple upstream sharded tables into one table in TiDB. During the migration, the DDL of each sharded table, and the DML before and after the DDL need to be coordinated. For the usage scenarios, DM supports two different modes: pessimistic mode and optimistic mode.

Note:

- To merge and migrate data from sharded tables, you must set `shard-mode` in the task configuration file.
- DM uses the pessimistic mode by default for the merge of the sharding support feature. (If there is no special description in the document, use the pessimistic mode by default.)

- It is not recommended to use this mode if you do not understand the principles and restrictions of the optimistic mode. Otherwise, it may cause serious consequences such as migration interruption and even data inconsistency.

The pessimistic mode

When an upstream sharded table executes a DDL statement, the migration of this sharded table will be suspended. After all other sharded tables execute the same DDL, the DDL will be executed in the downstream and the data migration task will restart. The advantage of this mode is that it can ensure that the data migrated to the downstream will not go wrong. For details, refer to shard merge in pessimistic mode. ####### The optimistic mode

DM will automatically modify the DDL executed on a sharded table into a statement compatible with other sharded tables, and then migrate to the downstream. This will not block the DML migration of any sharded tables. The advantage of this mode is that it will not block data migration when processing DDL. However, improper use will cause migration interruption or even data inconsistency. For details, refer to shard merge in optimistic mode.

Contrast

Pessimistic mode	Optimistic mode
Sharded tables that executes DDL suspend DML migration	Sharded tables that executes DDL continue DML migration
The DDL execution order and statements of each sharded table must be the same	Each sharded table only needs to keep the table schema compatible with each other

Pessimistic mode	Optimistic mode
The DDL is migrated to the downstream after the entire shard group is consistent	The DDL of each sharded table immediately affects the downstream
Wrong DDL operations can be intercepted after the detection	Wrong DDL operations will be migrated to the downstream, which may cause inconsistency between the upstream and downstream data before the detection

13.6.7.1.2 Merge and Migrate Data from Sharded Tables in the Pessimistic Mode

This document introduces the sharding support feature provided by Data Migration (DM) in the pessimistic mode (the default mode). This feature allows you to merge and migrate the data of tables with the same table schema in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB.

Restrictions

DM has the following sharding DDL usage restrictions in the pessimistic mode:

- For a logical **sharding group** (composed of all sharded tables that need to be merged and migrated into one same downstream table), it is limited to use one task containing exactly the sources of sharded tables to perform the migration.
- In a logical **sharding group**, the same DDL statements must be executed in the same order in all upstream sharded tables (the schema name and the table name can be different), and the next DDL statement cannot be executed unless the current DDL operation is completely finished.

    - For example, if you add `column A` to `table_1` before you add `column B`, then you cannot add `column B` to `table_2` before you add `column A`. Executing the DDL statements in a different order is not supported.

- In a sharding group, the corresponding DDL statements should be executed in all upstream sharded tables.
    - For example, if DDL statements are not executed on one or more upstream sharded tables corresponding to `DM-worker-2`, then other DM-workers that have executed the DDL statements pause their migration task and wait for `DM-worker -2` to receive the upstream DDL statements.
- The sharding group migration task does not support `DROP DATABASE`/`DROP TABLE`.
    - The sync unit in DM-worker automatically ignores the `DROP DATABASE`/`DROP TABLE` statement of upstream sharded tables.
- The sharding group migration task does not support `TRUNCATE TABLE`.
    - The sync unit in DM-worker automatically ignores the `TRUNCATE TABLE` statement of upstream sharded tables.
- The sharding group migration task supports `RENAME TABLE`, but with the following limitations (online DDL is supported in another solution):
    - A table can only be renamed to a new name that is not used by any other table.
    - A single `RENAME TABLE` statement can only involve a single `RENAME` operation.
- The sharding group migration task requires each DDL statement to involve operations on only one table.
- The table schema of each sharded table must be the same at the starting point of the incremental replication task, so as to make sure the DML statements of different sharded tables can be migrated into the downstream with a definite table schema, and the subsequent sharding DDL statements can be correctly matched and migrated.
- If you need to change the table routing rule, you have to wait for the migration of all sharding DDL statements to complete.
    - During the migration of sharding DDL statements, an error is reported if you use `dmctl` to change `router-rules`.
- If you need to `CREATE` a new table to a sharding group where DDL statements are being executed, you have to make sure that the table schema is the same as the newly modified table schema.
    - For example, both the original `table_1` and `table_2` have two columns (a, b) initially, and have three columns (a, b, c) after the sharding DDL operation, so after the migration the newly created table should also have three columns (a, b, c).
- Because the DM-worker that has received the DDL statements will pause the task to wait for other DM-workers to receive their DDL statements, the delay of data migration will be increased.

Background

Currently, DM uses the binlog in the `ROW` format to perform the migration task. The binlog does not contain the table schema information. When you use the `ROW` binlog to migrate data, if you have not migrated multiple upstream tables into the same downstream table, then there only exist DDL operations of one upstream table that can update the table schema of the downstream table. The `ROW` binlog can be considered to have the nature of self-description. During the migration process, the DML statements can be constructed accordingly with the column values and the downstream table schema.

However, in the process of merging and migrating sharded tables, if DDL statements are executed on the upstream tables to modify the table schema, then you need to perform extra operations to migrate the DDL statements so as to avoid the inconsistency between the DML statements produced by the column values and the actual downstream table schema.

Here is a simple example:

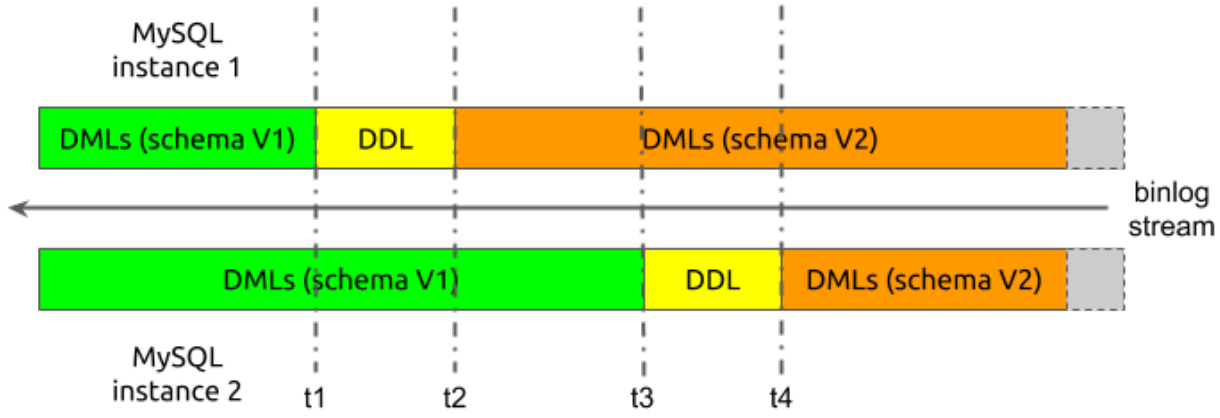


Figure 442: shard-ddl-example-1

In the above example, the merging process is simplified, where only two MySQL instances exist in the upstream and each instance has only one table. When the migration begins, the table schema version of two sharded tables is marked as `schema V1`, and the table schema version after executing DDL statements is marked as `schema V2`.

Now assume that in the migration process, the binlog data received from the two upstream sharded tables has the following time sequence:

1. When the migration begins, the sync unit in DM-worker receives the DML events of `schema V1` from the two sharded tables.
2. At `t1`, the sharding DDL events from instance 1 are received.
3. From `t2` on, the sync unit receives the DML events of `schema V2` from instance 1; but from instance 2, it still receives the DML events of `schema V1`.

4. At `t3`, the sharding DDL events from instance 2 are received.
5. From `t4` on, the sync unit receives the DML events of `schema V2` from instance 2 as well.

Assume that the DDL statements of sharded tables are not processed during the migration process. After DDL statements of instance 1 are migrated to the downstream, the downstream table schema is changed to `schema V2`. But for instance 2, the sync unit in DM-worker is still receiving DML events of `schema V1` from `t2` to `t3`. Therefore, when the DML statements of `schema V1` are migrated to the downstream, the inconsistency between the DML statements and the table schema can cause errors and the data cannot be migrated successfully.

Principles

This section shows how DM migrates DDL statements in the process of merging sharded tables based on the above example in the pessimistic mode.

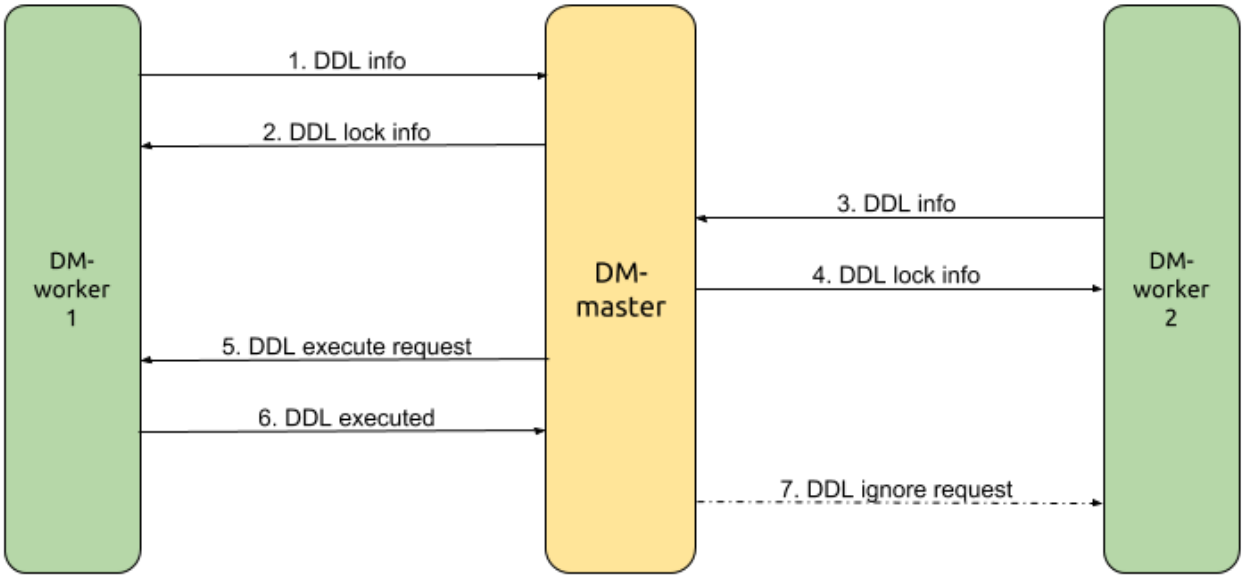

Figure 443: shard-ddl-flow

In this example, `DM-worker-1` migrates the data from MySQL instance 1 and `DM-worker-2` migrates the data from MySQL instance 2. `DM-master` coordinates the DDL migration among multiple DM-workers. Starting from `DM-worker-1` receiving the DDL statements, the DDL migration process is simplified as follows:

1. `DM-worker-1` receives the DDL statement from MySQL instance 1 at `t1`, pauses the data migration of the corresponding DDL and DML statements, and sends the DDL information to `DM-master`.

2. `DM-master` decides that the migration of this DDL statement needs to be coordinated based on the received DDL information, creates a lock for this DDL statement, sends the DDL lock information back to `DM-worker-1` and marks `DM-worker-1` as the owner of this lock at the same time.
3. `DM-worker-2` continues migrating the DML statement until it receives the DDL statement from MySQL instance 2 at `t3`, pauses the data migration of this DDL statement, and sends the DDL information to `DM-master`.
4. `DM-master` decides that the lock of this DDL statement already exists based on the received DDL information, and sends the lock information directly to `DM-worker-2`.
5. Based on the configuration information when the task is started, the sharded table information in the upstream MySQL instances, and the deployment topology information, `DM-master` decides that it has received this DDL statement of all upstream sharded tables to be merged, and requests the owner of the DDL lock (`DM-worker-1`) to migrate this DDL statement to the downstream.
6. `DM-worker-1` verifies the DDL statement execution request based on the DDL lock information received at Step #2, migrates this DDL statement to the downstream, and sends the results to `DM-master`. If this operation is successful, `DM-worker-1` continues migrating the subsequent (starting from the binlog at `t2`) DML statements.
7. `DM-master` receives the response from the lock owner that the DDL is successfully executed, and requests all other DM-workers (`DM-worker-2`) that are waiting for the DDL lock to ignore this DDL statement and then continue to migrate the subsequent (starting from the binlog at `t4`) DML statements.

The characteristics of DM handling the sharding DDL migration among multiple DM-workers can be concluded as follows:

- Based on the task configuration and DM cluster deployment topology information, a logical sharding group is built in `DM-master` to coordinate DDL migration. The group members are DM-workers that handle each sub-task divided from the migration task).
- After receiving the DDL statement from the binlog event, each DM-worker sends the DDL information to `DM-master`.
- `DM-master` creates or updates the DDL lock based on the DDL information received from each DM-worker and the sharding group information.
- If all members of the sharding group receive a same specific DDL statement, this indicates that all DML statements before the DDL execution on the upstream sharded tables have been completely migrated, and this DDL statement can be executed. Then DM can continue to migrate the subsequent DML statements.
- After being converted by the table router, the DDL statement of the upstream sharded tables must be consistent with the DDL statement to be executed in the downstream. Therefore, this DDL statement only needs to be executed once by the DDL owner and all other DM-workers can ignore this DDL statement.

In the above example, only one sharded table needs to be merged in the upstream MySQL instance corresponding to each DM-worker. But in actual scenarios, there might be multiple

sharded tables in multiple sharded schemas to be merged in one MySQL instance. And when this happens, it becomes more complex to coordinate the sharding DDL migration.

Assume that there are two sharded tables, namely `table_1` and `table_2`, to be merged in one MySQL instance:

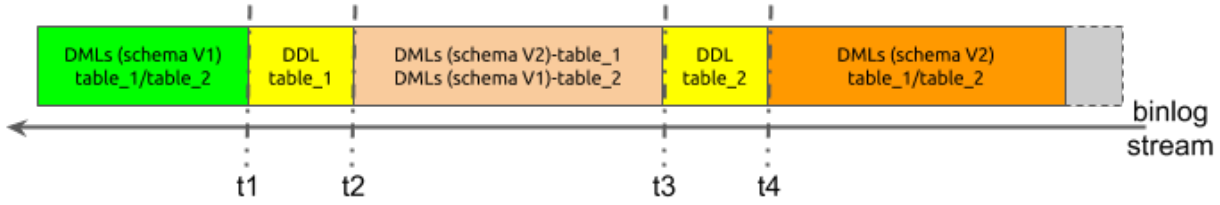

Figure 444: shard-ddl-example-2

Because data comes from the same MySQL instance, all the data is obtained from the same binlog stream. In this case, the time sequence is as follows:

1. The sync unit in DM-worker receives the DML statements of `schema V1` from both sharded tables when the migration begins.
2. At `t1`, the sync unit in DM-worker receives the DDL statements of `table_1`.
3. From `t2` to `t3`, the received data includes the DML statements of `schema V2` from `table_1` and the DML statements of `schema V1` from `table_2`.
4. At `t3`, the sync unit in DM-worker receives the DDL statements of `table_2`.
5. From `t4` on, the sync unit in DM-worker receives the DML statements of `schema V2` from both tables.

If the DDL statements are not processed particularly during the data migration, when the DDL statement of `table_1` is migrated to the downstream and changes the downstream table schema, the DML statement of `schema V1` from `table_2` cannot be migrated successfully. Therefore, within a single DM-worker, a logical sharding group similar to that within `DM-master` is created, except that members of this group are different sharded tables in the same upstream MySQL instance.

But when a DM-worker coordinates the migration of the sharding group within itself, it is not totally the same as that performed by `DM-master`. The reasons are as follows:

- When the DM-worker receives the DDL statement of `table_1`, it cannot pause the migration and needs to continue parsing the binlog to get the subsequent DDL statements of `table_2`. This means it needs to continue parsing between `t2` and `t3`.
- During the binlog parsing process between `t2` and `t3`, the DML statements of `schema V2` from `table_1` cannot be migrated to the downstream until the sharding DDL statement is migrated and successfully executed.

In DM, the simplified migration process of sharding DDL statements within the DM worker is as follows:

1. When receiving the DDL statement of `table_1` at `t1`, the DM-worker records the DDL information and the current position of the binlog.
2. DM-worker continues parsing the binlog between `t2` and `t3`.
3. DM-worker ignores the DML statement with the `schema V2` schema that belongs to `table_1`, and migrates the DML statement with the `schema V1` schema that belongs to `table_2` to the downstream.
4. When receiving the DDL statement of `table_2` at `t3`, the DM-worker records the DDL information and the current position of the binlog.
5. Based on the information of the migration task configuration and the upstream schemas and tables, the DM-worker decides that the DDL statements of all sharded tables in the MySQL instance have been received and migrates them to the downstream to modify the downstream table schema.
6. DM-worker sets the starting point of parsing the new binlog stream to be the position saved at Step #1.
7. DM-worker resumes parsing the binlog between `t2` and `t3`.
8. DM-worker migrates the DML statement with the `schema V2` schema that belongs to `table_1` to the downstream, and ignores the DML statement with the `schema V1` schema that belongs to `table_2`.
9. After parsing the binlog position saved at Step #4, the DM-worker decides that all DML statements that have been ignored in Step #3 have been migrated to the downstream again.
10. DM-worker resumes the migration starting from the binlog position at `t4`.

You can conclude from the above analysis that DM mainly uses two-level sharding groups for coordination and control when handling migration of the sharding DDL. Here is the simplified process:

1. Each DM-worker independently coordinates the DDL statements migration for the corresponding sharding group composed of multiple sharded tables within the upstream MySQL instance.
2. After the DM-worker receives the DDL statements of all sharded tables, it sends the DDL information to `DM-master`.
3. `DM-master` coordinates the DDL migration of the sharding group composed of the DM-workers based on the received DDL information.
4. After receiving the DDL information from all DM-workers, `DM-master` requests the DDL lock owner (a specific DM-worker) to execute the DDL statement.
5. The DDL lock owner executes the DDL statement and returns the result to `DM-master` ↪ . Then the owner restarts the migration of the previously ignored DML statements during the internal coordination of DDL migration.
6. After `DM-master` confirms that the owner has successfully executed the DDL statement, it asks all other DM-workers to continue the migration.

7. All other DM-workers separately restart the migration of the previously ignored DML statements during the internal coordination of DDL migration.
8. After finishing migrating the ignored DML statements again, all DM-workers resume the normal migration process.

13.6.7.1.3 Merge and Migrate Data from Sharded Tables in Optimistic Mode

This document introduces the sharding support feature provided by Data Migration (DM) in the optimistic mode. This feature allows you to merge and migrate the data of tables with the same or different table schema(s) in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB.

> **Note:**
>
> If you do not have an in-depth understanding of the optimistic mode and its restrictions, it is **NOT** recommended to use this mode. Otherwise, migration interruption or even data inconsistency might occur.

Background

DM supports executing DDL statements on sharded tables online, which is called sharding DDL, and uses the "pessimistic mode" by default. In this mode, when a DDL statement is executed in an upstream sharded table, data migration of this table is paused until the same DDL statement is executed in all other sharded tables. Only by then this DDL statement is executed in the downstream and data migration resumes.

The pessimistic mode guarantees that the data migrated to the downstream is always correct, but it pauses the data migration, which is bad for making A/B changes in the upstream. In some cases, users might spend a long time executing DDL statements in a single sharded table and change the schemas of other sharded tables only after a period of validation. In the pessimistic mode, these DDL statements block data migration and cause many binlog events to pile up.

Therefore, an "optimistic mode" is needed. In this mode, a DDL statement executed on a sharded table is automatically converted to a statement that is compatible with other sharded tables, and then immediately migrated to the downstream. In this way, the DDL statement does not block any sharded table from executing DML migration.

Configuration of the optimistic mode

To use the optimistic mode, specify the `shard-mode` item in the task configuration file as `optimistic`. For the detailed sample configuration file, see DM Advanced Task Configuration File.

Restrictions

It takes some risks to use the optimistic mode. Follow these rules when you use it:

- Ensure that the schema of every sharded table is consistent with each other before and after you execute a batch of DDL statements.
- If you perform an A/B test, perform the test **ONLY** on one sharded table.
- After the A/B test is finished, migrate only the most direct DDL statement(s) to the final schema. Do not re-execute every right or wrong step of the test.

  For example, if you have executed `ADD COLUMN A INT; DROP COLUMN A; ADD COLUMN A FLOAT;` in a sharded table, you only need to execute `ADD COLUMN A FLOAT` in other sharded tables. You do not need to execute all of the three DDL statements again.
- Observe the status of the DM migration when executing the DDL statement. When an error is reported, you need to determine whether this batch of DDL statements will cause data inconsistency.

In the optimistic mode, most of the DDL statements executed in the upstream are automatically migrated to the downstream with no extra effort required. These DDL statements are called "Type 1 DDL".

DDL statements that change the column name, the column type, or the column default value are called "Type 2 DDL". When you execute Type 2 DDL statements in the upstream, make sure that you execute the DDL statements in all sharded tables in the same order.

Some examples of Type 2 DDL statements are as follows:

- Alter the type of a column: `ALTER TABLE table_name MODIFY COLUMN column_name VARCHAR(20).`
- Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO column_2;.`
- Add a `NOT NULL` column without a default value: `ALTER TABLE table_name ADD COLUMN column_1 NOT NULL;.`
- Rename an index: `ALTER TABLE table_name RENAME INDEX index_1 TO index_2;.`

When the sharded tables execute the DDL statements above, if the execution order is different, the migration is interrupted. For example:

- Shard 1 renames a column and then alters the column type:
  1. Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO column_2;.`
  2. Alter the column type: `ALTER TABLE table_name MODIFY COLUMN column_3 VARCHAR(20);.`

- Shard 2 alters a column type and then renames the column:

    1. Alter a column type: `ALTER TABLE table_name MODIFY COLUMN column_3 VARCHAR(20)`.
    2. Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO column_2;`.

In addition, the following restrictions apply to both the optimistic mode and the pessimistic mode:

- `DROP TABLE` or `DROP DATABASE` is not supported.
- `TRUNCATE TABLE` is not supported.
- Each DDL statement must involve operations on only one table.
- The DDL statement that is not supported in TiDB is also not supported in DM.
- The default value of a newly added column must not contain `current_timestamp` , `rand()`, `uuid()`; otherwise, data inconsistency between the upstream and the downstream might occur.

Risks

When you use the optimistic mode for a migration task, a DDL statement is migrated to the downstream immediately. If this mode is misused, data inconsistency between the upstream and the downstream might occur.

Operations that cause data inconsistency

- The schema of each sharded table is incompatible with each other. For example:

    - Two columns of the same name are added to two sharded tables respectively, but the columns are of different types.
    - Two columns of the same name are added to two sharded tables respectively, but the columns have different default values.
    - Two generated columns of the same name are added to two sharded tables respectively, but the columns are generated using different expressions.
    - Two indexes of the same name are added to two sharded tables respectively, but the keys are different.
    - Other different table schemas with the same name.

- Execute the DDL statement that can corrupt data in the sharded table and then try to roll back.

    For example, drop a column `X` and then add this column back.

Example

Merge and migrate the following three sharded tables to TiDB:

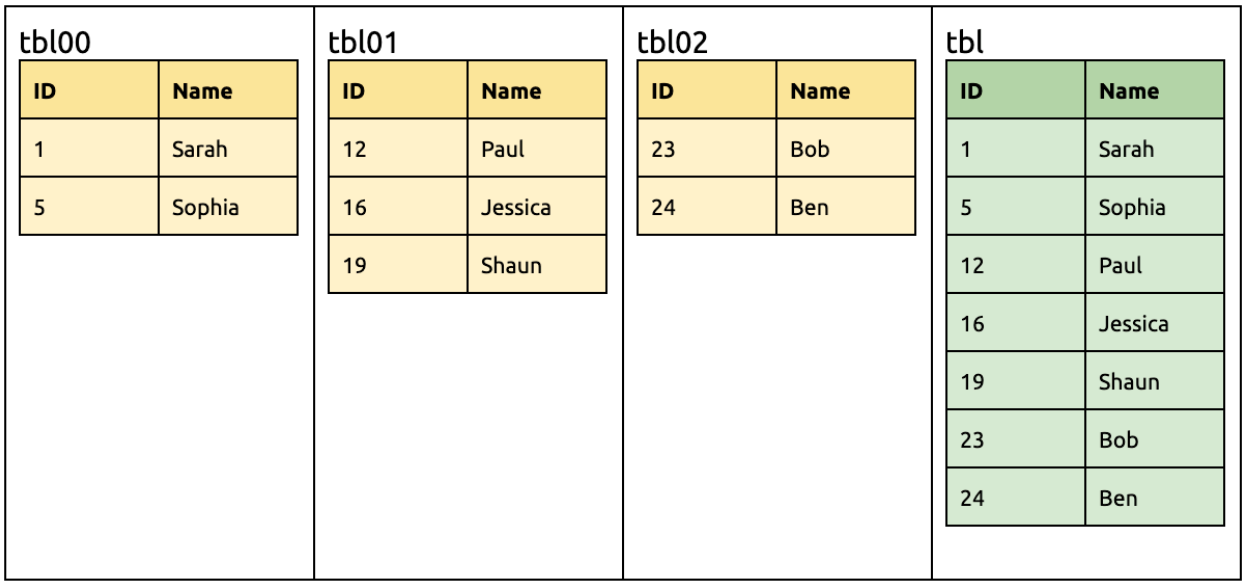

Figure 445: optimistic-ddl-fail-example-1

Add a new column `Age` in `tbl01` and set the default value of the column to `0`:

```
ALTER TABLE `tbl01` ADD COLUMN `Age` INT DEFAULT 0;
```

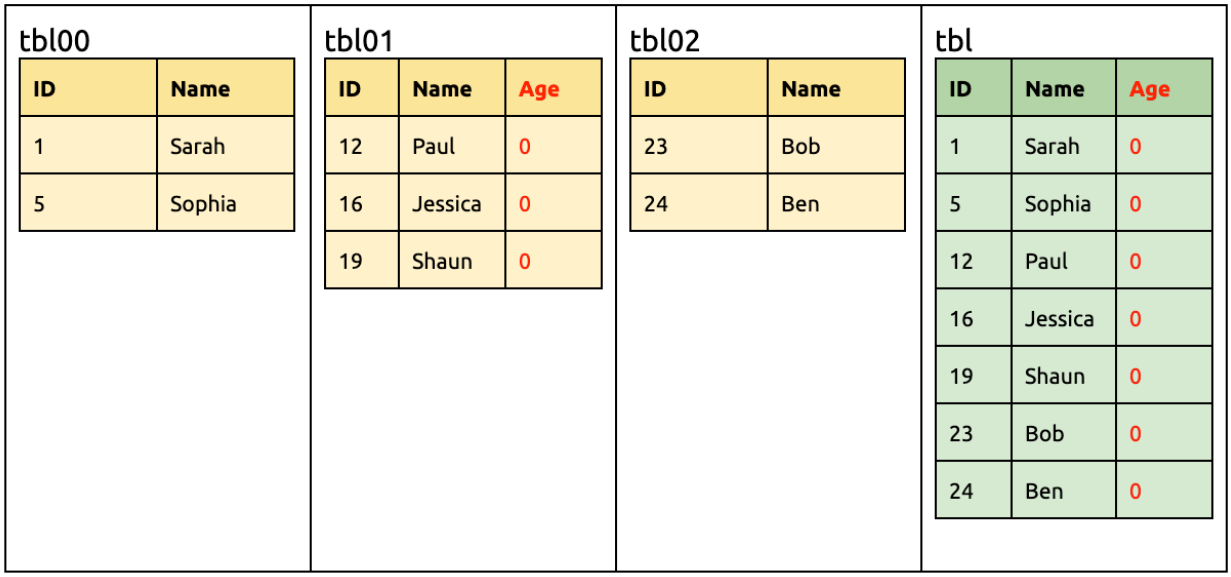

Figure 446: optimistic-ddl-fail-example-2

Add a new column `Age` in `tbl00` and set the default value of the column to `-1`:

```
ALTER TABLE `tbl00` ADD COLUMN `Age` INT DEFAULT -1;
```

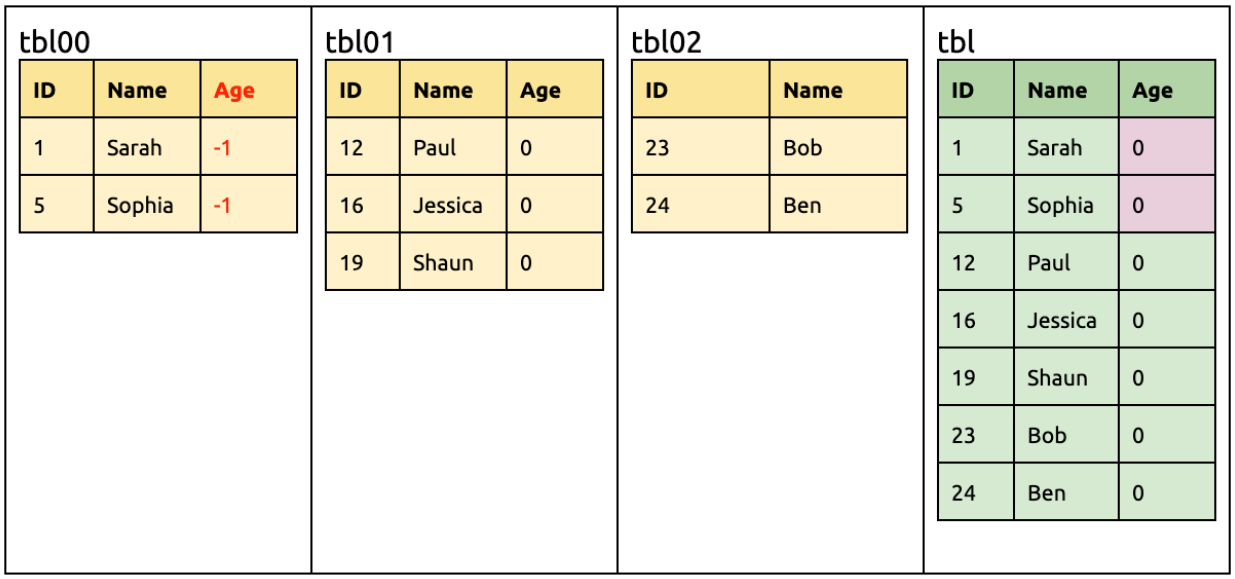

Figure 447: optimistic-ddl-fail-example-3

By then, the `Age` column of `tbl00` is inconsistent because `DEFAULT 0` and `DEFAULT -1` are incompatible with each other. In this situation, DM will report the error, but you have to manually fix the data inconsistency.

Implementation principle

In the optimistic mode, after DM-worker receives the DDL statement from the upstream, it forwards the updated table schema to DM-master. DM-worker tracks the current schema of each sharded table, and DM-master merges these schemas into a composite schema that is compatible with DML statements of every sharded table. Then DM-master migrates the corresponding DDL statement to the downstream. DML statements are directly migrated to the downstream.

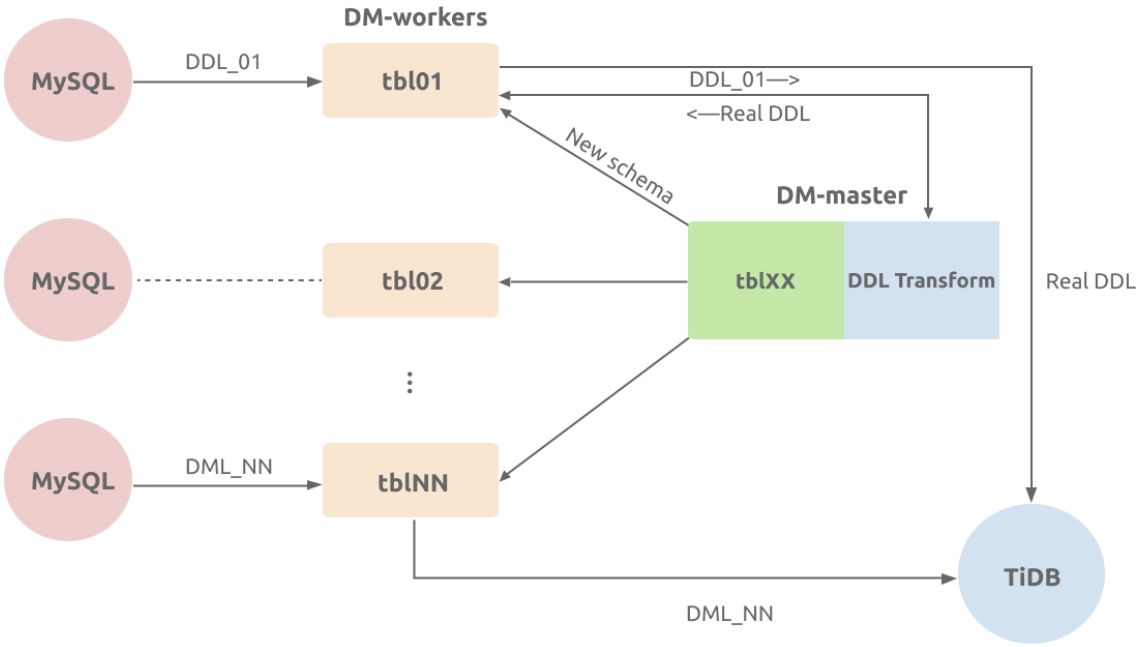

Figure 448: optimistic-ddl-flow

Examples

Assume the upstream MySQL has three sharded tables (`tbl00`, `tbl01`, and `tbl02`). Merge and migrate these sharded tables to the `tbl` table in the downstream TiDB. See the following image:

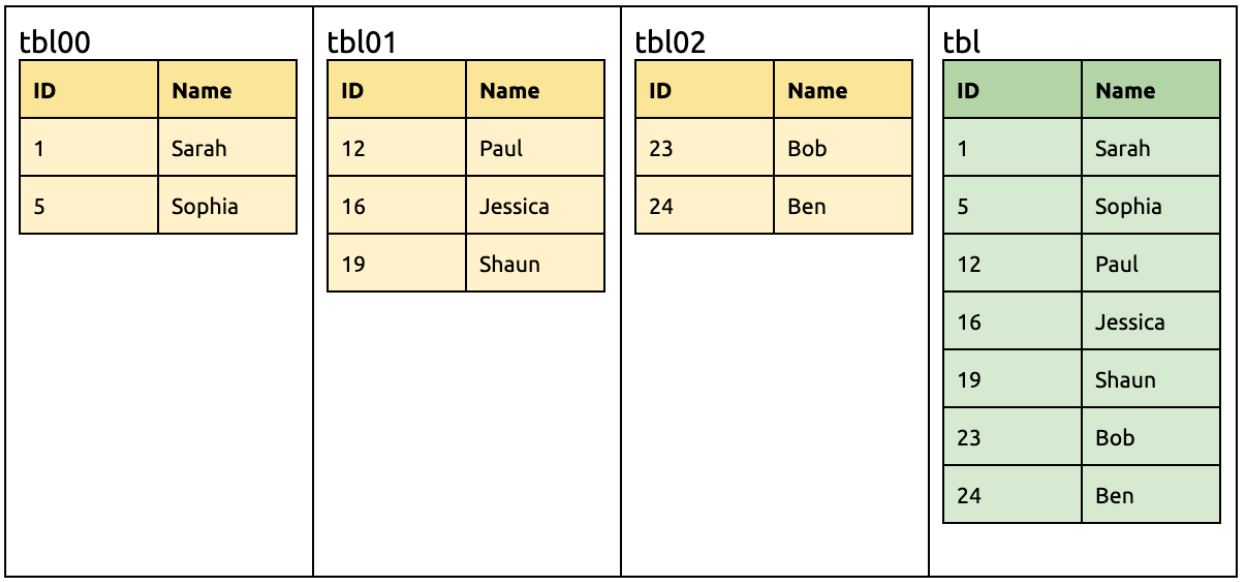

Figure 449: optimistic-ddl-example-1

Add a `Level` column in the upstream:

```
ALTER TABLE `tbl00` ADD COLUMN `Level` INT;
```

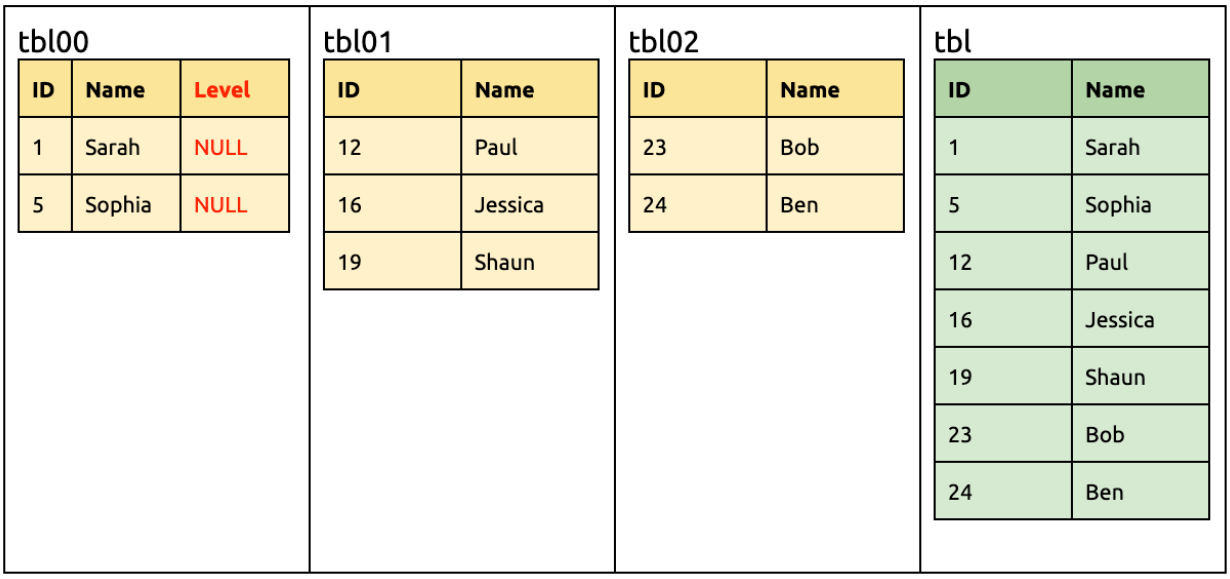

Figure 450: optimistic-ddl-example-2

Then TiDB will receive the DML statement from `tbl00` (with the `Level` column) and the DML statement from the `tbl01` and `tbl02` tables (without the `Level` column).

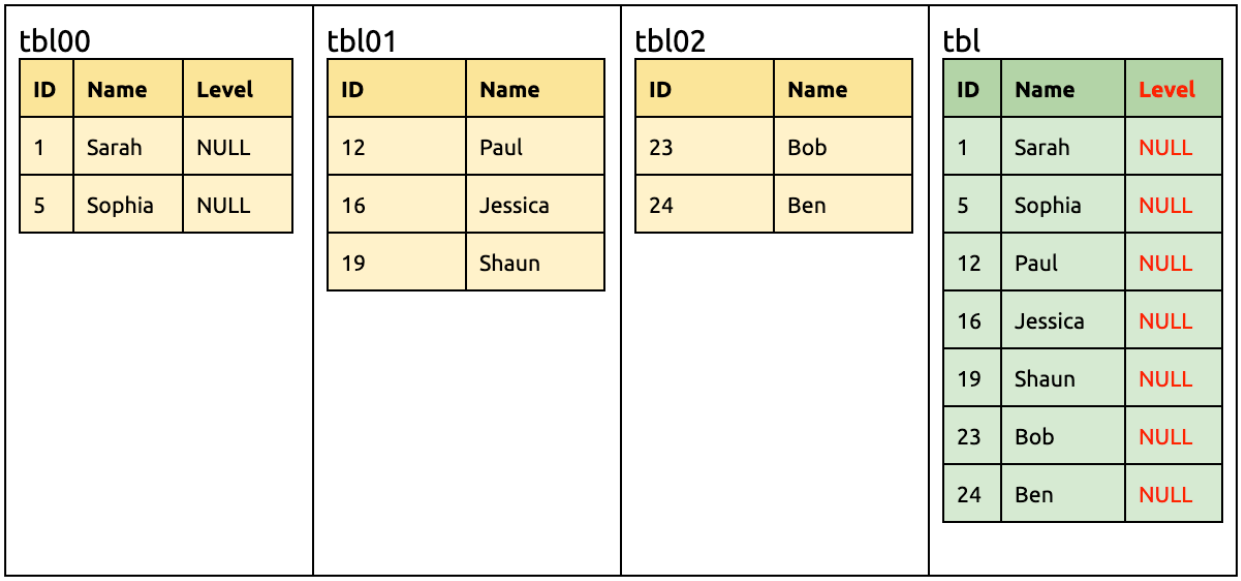

Figure 451: optimistic-ddl-example-3

The following DML statements can be migrated to the downstream without any modification:

```
UPDATE `tbl00` SET `Level` = 9 WHERE `ID` = 1;
INSERT INTO `tbl02` (`ID`, `Name`) VALUES (27, 'Tony');
```

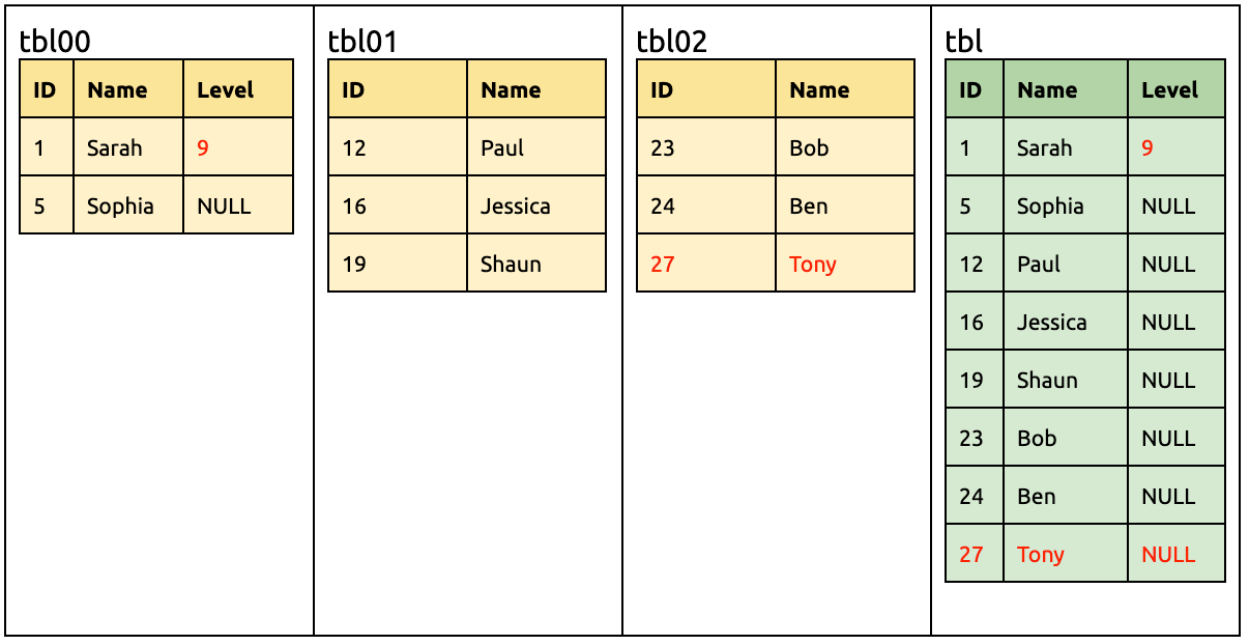

Figure 452: optimistic-ddl-example-4

Also add a `Level` column in `tbl01`:

```
ALTER TABLE `tbl01` ADD COLUMN `Level` INT;
```

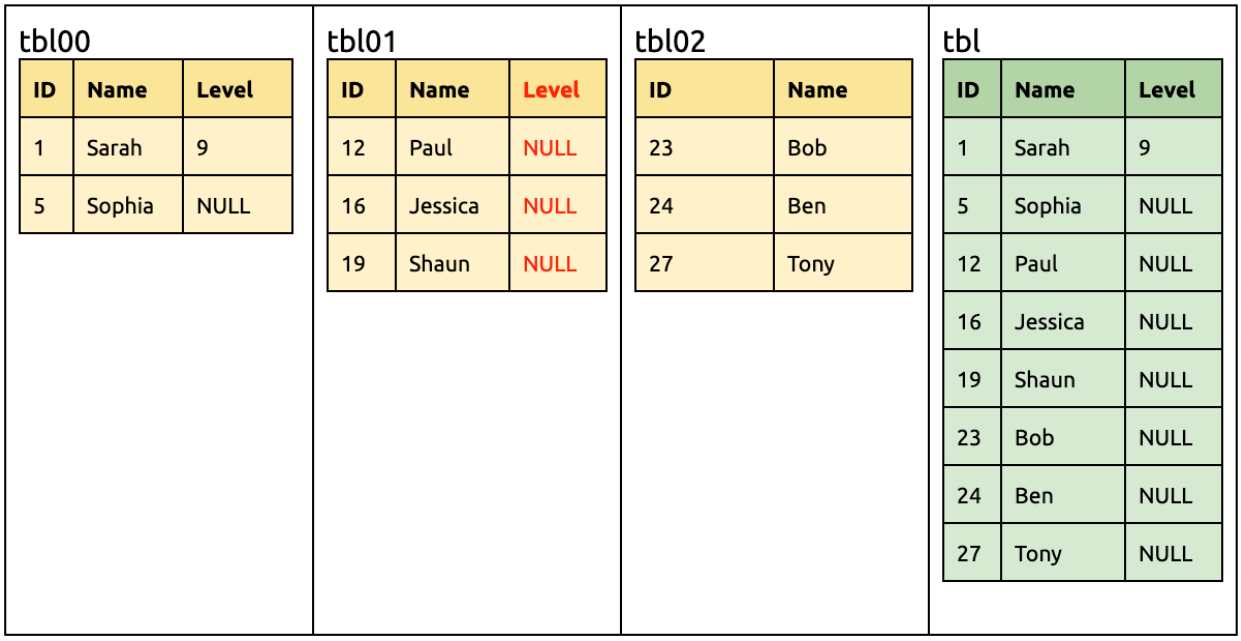

Figure 453: optimistic-ddl-example-5

At this time, the downstream already have had the same `Level` column, so DM-master performs no operation after comparing the table schemas.

Drop a `Name` column in `tbl01`:

```
ALTER TABLE `tbl01` DROP COLUMN `Name`;
```

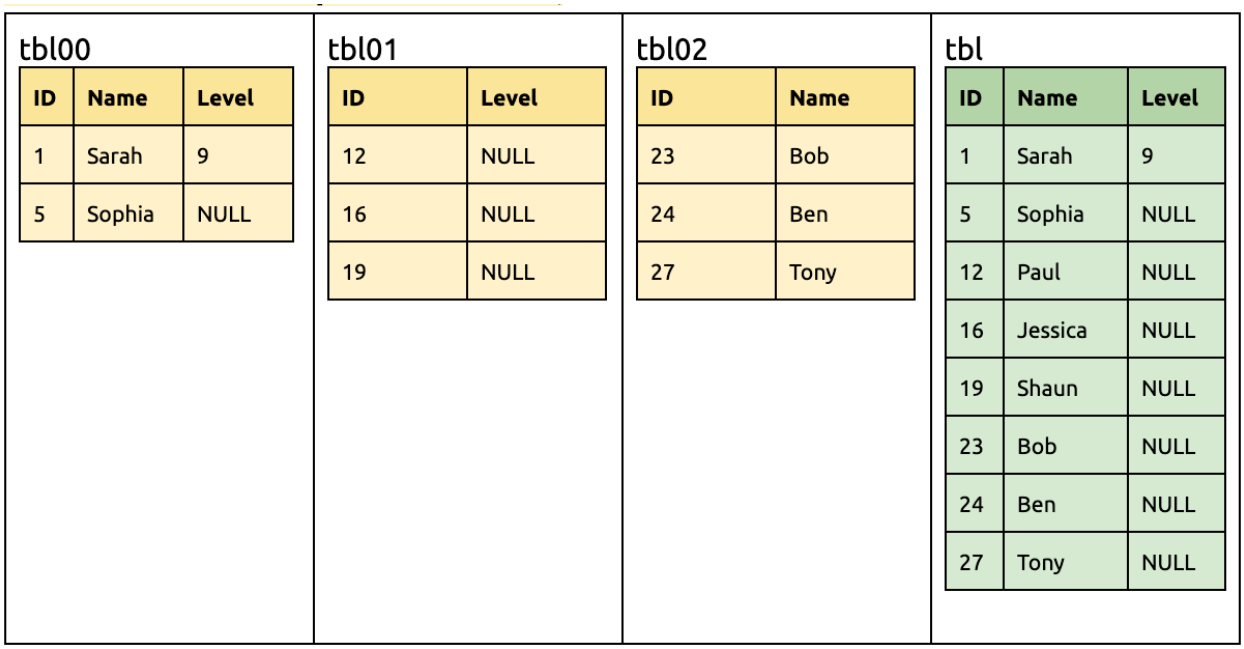

Figure 454: optimistic-ddl-example-6

Then the downstream will receive the DML statements from `tbl00` and `tbl02` with the `Name` column, so this column is not immediately dropped.

In the same way, all DML statements can still be migrated to the downstream:

```
INSERT INTO `tbl01` (`ID`, `Level`) VALUES (15, 7);
UPDATE `tbl00` SET `Level` = 5 WHERE `ID` = 5;
```

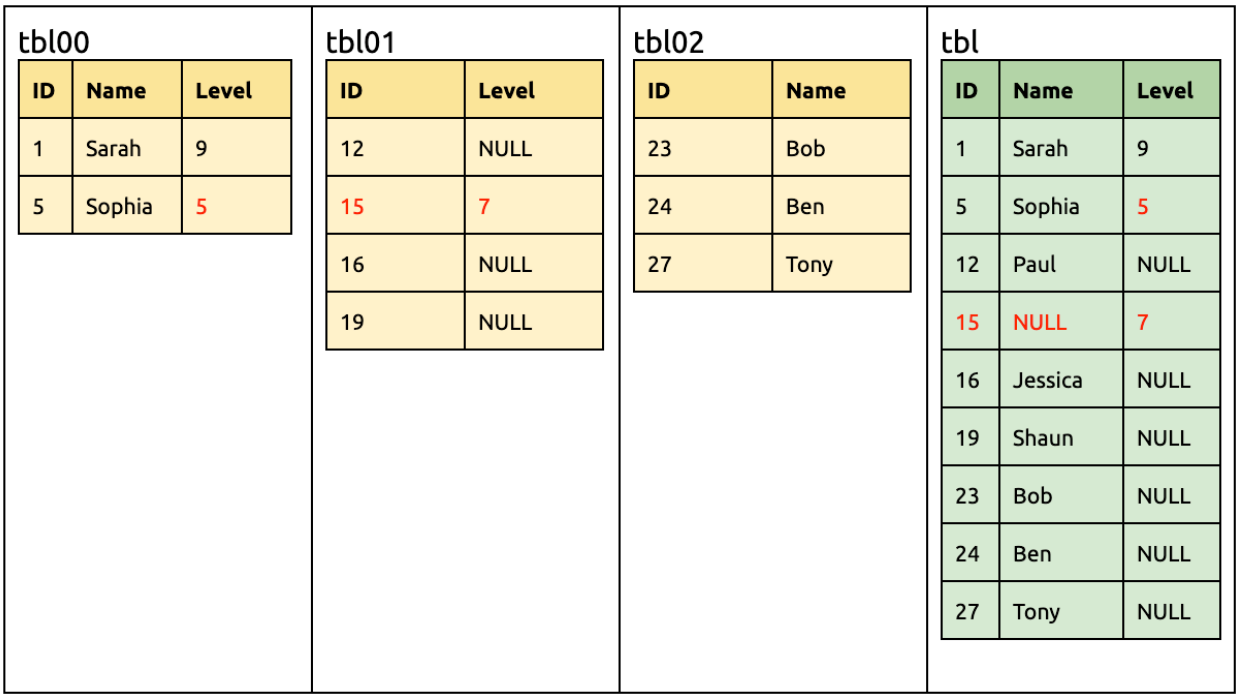

Figure 455: optimistic-ddl-example-7

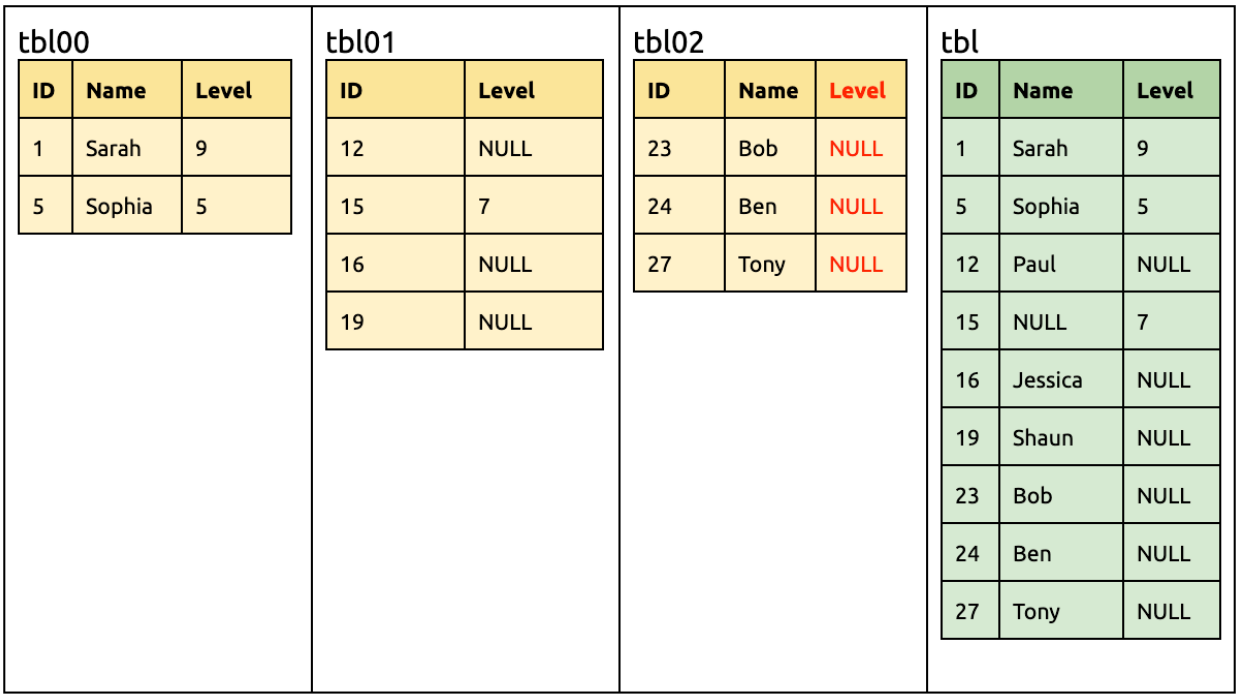
Add a `Level` column in `tbl02`:

```
ALTER TABLE `tbl02` ADD COLUMN `Level` INT;
```



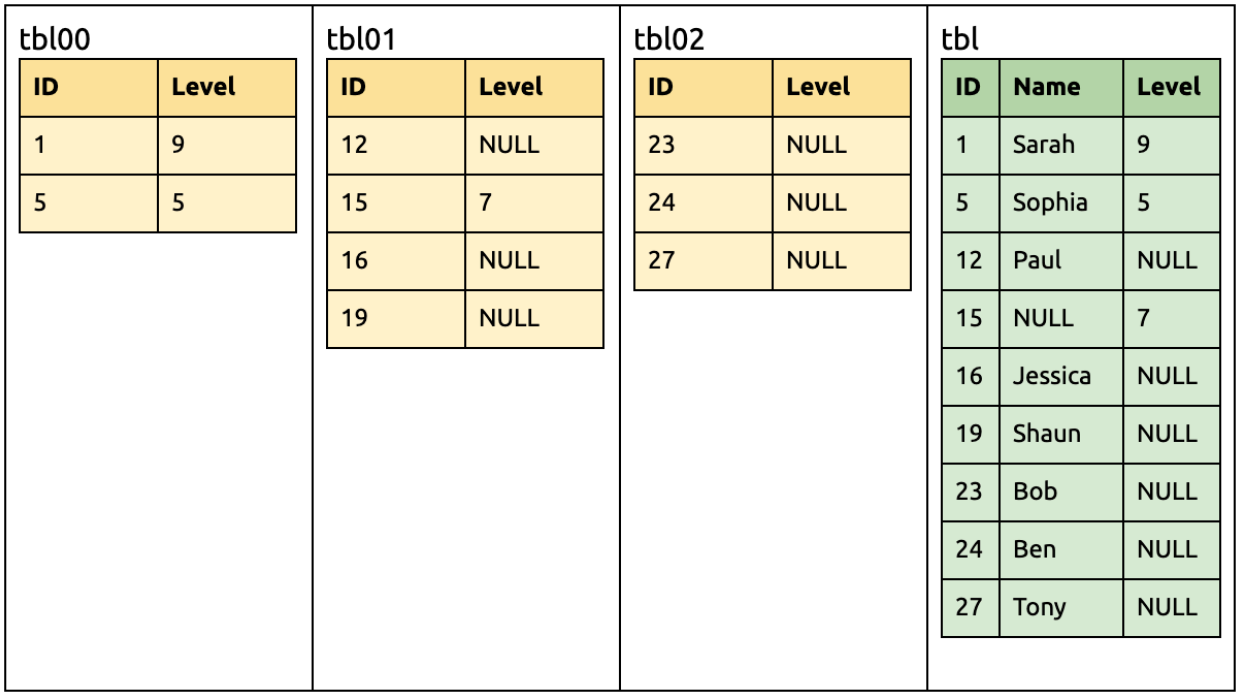


Figure 456: optimistic-ddl-example-8

By then, all sharded tables have the `Level` column.

Drop the `Name` columns in `tbl00` and `tbl02` respectively:

```
ALTER TABLE `tbl00` DROP COLUMN `Name`;
ALTER TABLE `tbl02` DROP COLUMN `Name`;
```

tbl00

ID	Level
1	9
5	5

tbl01

ID	Level
12	NULL
15	7
16	NULL
19	NULL

tbl02

ID	Level
23	NULL
24	NULL
27	NULL

tbl

ID	Name	Level
1	Sarah	9
5	Sophia	5
12	Paul	NULL
15	NULL	7
16	Jessica	NULL
19	Shaun	NULL
23	Bob	NULL
24	Ben	NULL
27	Tony	NULL

Figure 457: optimistic-ddl-example-9

By then, the `Name` columns are dropped from all sharded tables and can be safely dropped in the downstream:

```
ALTER TABLE `tbl` DROP COLUMN `Name`;
```

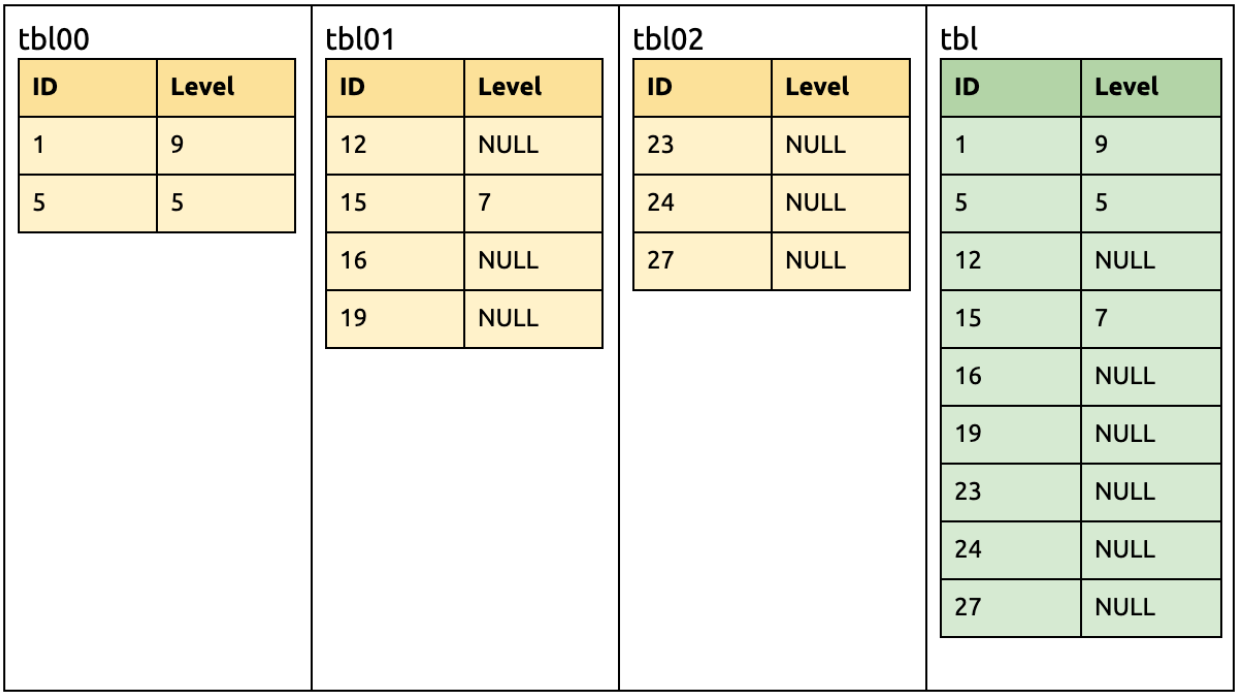

Figure 458: optimistic-ddl-example-10

13.6.7.1.4 Handle Sharding DDL Locks Manually in DM

DM uses the sharding DDL lock to ensure operations are performed in the correct order. This locking mechanism resolves sharding DDL locks automatically in most cases, but you need to use the `shard-ddl-lock` command to manually handle the abnormal DDL locks in some abnormal scenarios.

Note:

- This document only applies to the processing of sharding DDL lock in pessimistic coordination mode.
- The commands in the Command usage sections in this document are in interactive mode. In command-line mode, you need to add the escape characters to avoid an error report.
- Do not use `shard-ddl-lock unlock` unless you are totally aware of the possible impacts brought by the command and you can accept them.
- Before manually handling the abnormal DDL locks, make sure that you have already read the DM shard merge principles.

Command

`shard-ddl-lock`

You can use this command to view the DDL lock and request DM-master to release the specified DDL lock. This command is only supported in DM v6.0 and later. For earlier versions, you must use the `show-ddl-locks` and `unlock-ddl-locks` commands.

```
shard-ddl-lock -h
```

```
maintain or show shard-ddl locks information
Usage:
  dmctl shard-ddl-lock [task] [flags]
  dmctl shard-ddl-lock [command]
Available Commands:
  unlock    Unlock un-resolved DDL locks forcely
Flags:
  -h, --help help for shard-ddl-lock
Global Flags:
  -s, --source strings MySQL Source ID.
Use "dmctl shard-ddl-lock [command] --help" for more information about a
    ↪ command.
```

Arguments description

- `shard-ddl-lock [task] [flags]`: view the DDL lock information on the current DM-master.
- `shard-ddl-lock [command]`: request DM-master to release the specified DDL lock. `[command]` only accepts `unlock` as a value.

Usage examples

`shard-ddl-lock [task] [flags]`

You can use `shard-ddl-lock [task] [flags]` to view the DDL lock information on the current DM-master. For example:

```
shard-ddl-lock test
```

Expected output

```
{
    "result": true,                                 # The result of the
       ↪ query for the lock information.
    "msg": "",                                      # The additional message
       ↪  for the failure to query the lock information or other
       ↪ descriptive information (for example, the lock task does not exist
       ↪ ).
```

```
    "locks": [                                  # The existing lock
        ↪ information list.
        {
            "ID": "test-`shard_db`.`shard_table`",   # The lock ID, which is
                ↪ made up of the current task name and the schema/table
                ↪ information corresponding to the DDL.
            "task": "test",                     # The name of the task
                ↪ to which the lock belongs.
            "mode": "pessimistic"               # The shard DDL mode.
                ↪ Can be set to "pessimistic" or "optimistic".
            "owner": "mysql-replica-01",        # The owner of the lock
                ↪ (the ID of the first source that encounters this DDL
                ↪ operation in the pessimistic mode), which is always empty
                ↪ in the optimistic mode.
            "DDLs": [                           # The list of DDL
                ↪ operations corresponding to the lock in the pessimistic
                ↪ mode, which is always empty in the optimistic mode.
                "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` DROP
                    ↪ COLUMN `c2`;"
            ],
            "synced": [                         # The list of sources
                ↪ that have received all sharding DDL events in the
                ↪ corresponding MySQL instance.
                "mysql-replica-01"
            ],
            "unsynced": [                       # The list of sources
                ↪ that have not yet received all sharding DDL events in the
                ↪ corresponding MySQL instance.
                "mysql-replica-02"
            ]
        }
    ]
}
```

`shard-ddl-lock unlock`

This command actively requests `DM-master` to unlock the specified DDL lock, including requesting the owner to execute the DDL statement, requesting all other DM-workers that are not the owner to skip the DDL statement, and removing the lock information on `DM-master`.

Note:

> Currently, `shard-ddl-lock unlock` takes effect only for the lock in the `pessimistic` mode.

```
shard-ddl-lock unlock -h
```

```
Unlock un-resolved DDL locks forcely

Usage:
  dmctl shard-ddl-lock unlock <lock-id> [flags]

Flags:
  -a, --action string  accept skip/exec values which means whether to skip
      ↪ or execute ddls (default "skip")
  -d, --database string database name of the table
  -f, --force-remove   force to remove DDL lock
  -h, --help           help for unlock
  -o, --owner string   source to replace the default owner
  -t, --table string   table name

Global Flags:
  -s, --source strings MySQL Source ID.
```

`shard-ddl-lock unlock` accepts the following arguments:

- `-o, --owner`:
  - Flag; string; optional
  - If it is not specified, this command requests for the default owner (the owner in the result of `shard-ddl-lock`) to execute the DDL statement; if it is specified, this command requests for the MySQL source (the alternative of the default owner) to execute the DDL statement.
  - The new owner should not be specified unless the original owner is already removed from the cluster.
- `-f, --force-remove`:
  - Flag; boolean; optional
  - If it is not specified, this command removes the lock information only when the owner succeeds to execute the DDL statement; if it is specified, this command forcefully removes the lock information even though the owner fails to execute the DDL statement (after doing this you cannot query or operate on the lock again).
- `lock-id`:

- Non-flag; string; required
- It specifies the ID of the DDL lock that needs to be unlocked (the `ID` in the result of `shard-ddl-lock`).

The following is an example of the `shard-ddl-lock unlock` command:

```
shard-ddl-lock unlock test-`shard_db`.`shard_table`
```

```
{
    "result": true,                                     # The result of the
        ↪ unlocking operation.
    "msg": "",                                          # The additional message
        ↪  for the failure to unlock the lock.
}
```

Supported scenarios

Currently, the `shard-ddl-lock unlock` command only supports handling sharding DDL locks in the following two abnormal scenarios.

Scenario 1: Some MySQL sources are removed

The reason for the abnormal lock

Before `DM-master` tries to automatically unlock the sharding DDL lock, all the MySQL sources need to receive the sharding DDL events (for details, see shard merge principles). If the sharding DDL event is already in the migration process, and some MySQL sources have been removed and are not to be reloaded (these MySQL sources have been removed according to the application demand), then the sharding DDL lock cannot be automatically migrated and unlocked because not all the DM-workers can receive the DDL event.

> **Note:**
>
> If you need to make some DM-workers offline when not in the process of migrating sharding DDL events, a better solution is to use `stop-task` to stop the running tasks first, make the DM-workers go offline, remove the corresponding configuration information from the task configuration file, and finally use `start-task` and the new task configuration to restart the migration task.

Manual solution

Suppose that there are two instances `MySQL-1` (`mysql-replica-01`) and `MySQL-2` (`mysql-replica-02`) in the upstream, and there are two tables `shard_db_1.shard_table_1` and `shard_db_1.shard_table_2` in `MySQL-1` and two tables `shard_db_2.shard_table_1`

and `shard_db_2.shard_table_2` in `MySQL-2`. Now we need to merge the four tables and migrate them into the table `shard_db.shard_table` in the downstream TiDB.

The initial table structure is:

```
SHOW CREATE TABLE shard_db_1.shard_table_1;
+--------------+----------------------------------------+
| Table        | Create Table                           |
+--------------+----------------------------------------+
| shard_table_1 | CREATE TABLE `shard_table_1` (
  `c1` int(11) NOT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+--------------+----------------------------------------+
```

The following DDL operation will be executed on the upstream sharded tables to alter the table structure:

```
ALTER TABLE shard_db_*.shard_table_* ADD COLUMN c2 INT;
```

The operation processes of MySQL and DM are as follows:

1. The corresponding DDL operations are executed on the two sharded tables of `mysql-replica-01` to alter the table structures.

   ```
   ALTER TABLE shard_db_1.shard_table_1 ADD COLUMN c2 INT;
   ```

   ```
   ALTER TABLE shard_db_1.shard_table_2 ADD COLUMN c2 INT;
   ```

2. DM-worker sends the received DDL information of the two sharded tables of `mysql-replica-01` to DM-master, and DM-master creates the corresponding DDL lock.

3. Use `shard-ddl-lock` to check the information of the current DDL lock.

   ```
   » shard-ddl-lock test
   {
       "result": true,
       "msg": "",
       "locks": [
           {
               "ID": "test-`shard_db`.`shard_table`",
               "task": "test",
               "mode": "pessimistic"
               "owner": "mysql-replica-01",
               "DDLs": [
                   "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` ADD
                       ↪  COLUMN `c2` int(11);"
   ```

```
            ],
            "synced": [
                "mysql-replica-01"
            ],
            "unsynced": [
                "mysql-replica-02"
            ]
        }
    ]
}
```

4. Due to the application demand, the data corresponding to `mysql-replica-02` is no longer needed to be migrated to the downstream TiDB, and `mysql-replica-02` is removed.

5. The lock whose ID is `test-`shard_db`.`shard_table`` on `DM-master` cannot receive the DDL information of `mysql-replica-02`.

    - The returned result `unsynced` by `shard-ddl-lock` has always included the information of `mysql-replica-02`.

6. Use `shard-ddl-lock unlock` to request `DM-master` to actively unlock the DDL lock.

    - If the owner of the DDL lock has gone offline, you can use the parameter `--owner` to specify another DM-worker as the new owner to execute the DDL.
    - If any MySQL source reports an error, `result` will be set to `false`, and at this point you should check carefully if the errors of each MySQL source is acceptable and within expectations.

    ```
    shard-ddl-lock unlock test-`shard_db`.`shard_table`
    ```

    ```
    {
        "result": true,
        "msg": ""
    ```

7. Use `shard-ddl-lock` to confirm if the DDL lock is unlocked successfully.

```
» shard-ddl-lock test
{
    "result": true,
    "msg": "no DDL lock exists",
    "locks": [
    ]
}
```

8. Check whether the table structure is altered successfully in the downstream TiDB.

```
mysql> SHOW CREATE TABLE shard_db.shard_table;
+-------------+-----------------------------------------------------+
| Table       | Create Table                                        |
+-------------+-----------------------------------------------------+
| shard_table | CREATE TABLE `shard_table` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+-------------+-----------------------------------------------------+
```

9. Use `query-status` to confirm if the migration task is normal.

Impact

After you have manually unlocked the lock by using `shard-ddl-lock unlock`, if you don't deal with the offline MySQL sources included in the task configuration information, the lock might still be unable to be migrated automatically when the next sharding DDL event is received.

Therefore, after you have manually unlocked the DDL lock, you should perform the following operations:

1. Use `stop-task` to stop the running tasks.
2. Update the task configuration file, and remove the related information of the offline MySQL source from the configuration file.
3. Use `start-task` and the new task configuration file to restart the task.

> **Note:**
>
> After you run `shard-ddl-lock unlock`, if the MySQL source that went offline is reloaded and the DM-worker tries to migrate the data of the sharded tables, a match error between the data and the downstream table structure might occur.

Scenario 2: Some DM-workers stop abnormally or the network failure occurs during the DDL unlocking process

The reason for the abnormal lock

After `DM-master` receives the DDL events of all DM-workers, automatically running `unlock DDL lock` mainly include the following steps:

1. Ask the owner of the lock to execute the DDL and update the checkpoints of corresponding sharded tables.
2. Remove the DDL lock information stored on `DM-master` after the owner successfully executes the DDL.
3. Ask all other non-owners to skip the DDL and update the checkpoints of corresponding sharded tables after the owner successfully executes the DDL.
4. DM-master removes the corresponding DDL lock information after all the owners or non-owners' operations are successful.

Currently, the above unlocking process is not atomic. If the non-owner skips the DDL operation successfully, the DM-worker where the non-owner is located stops abnormally or a network anomaly occurs with the downstream TiDB, which can cause the checkpoint updating to fail.

When the MySQL source corresponding to the non-owner restores data migration, the non-owner tries to request the DM-master to re-coordinate the DDL operation that has been coordinated before the exception occurs and will never receives the corresponding DDL operation from other MySQL sources. This can cause the DDL operation to automatically unlock the corresponding lock.

Manual solution

Suppose that now we have the same upstream and downstream table structures and the same demand for merging tables and migration as in the manual solution of Some MySQL sources are removed.

When `DM-master` automatically executes the unlocking process, the owner (`mysql-replica-01`) successfully executes the DDL and continues the migration process. However, in the process of requesting the non-owner (`mysql-replica-02`) to skip the DDL operation, the checkpoint fails to update after the DM-worker skips the DDL operation because the corresponding DM-worker was restarted.

After the data migration subtask corresponding to `mysql-replica-02` restores, a new lock is created on the DM-master, but other MySQL sources have executed or skipped DDL operations and are performing subsequent migration.

The operation processes are:

1. Use `shard-ddl-lock` to confirm if the corresponding lock of the DDL exists on `DM-master`.

   Only `mysql-replica-02` is at the `synced` state.

```
» shard-ddl-lock
{
    "result": true,
    "msg": "",
    "locks": [
        {
```

```
            "ID": "test-`shard_db`.`shard_table`",
            "task": "test",
            "mode": "pessimistic"
            "owner": "mysql-replica-02",
            "DDLs": [
                "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` ADD
                    ↪  COLUMN `c2` int(11);"
            ],
            "synced": [
                "mysql-replica-02"
            ],
            "unsynced": [
                "mysql-replica-01"
            ]
        }
    ]
}
```

2. Use `shard-ddl-lock` to ask `DM-master` to unlock the lock.

    - During the unlocking process, the owner tries to execute the DDL operation to the downstream again (the original owner before restarting has executed the DDL operation to the downstream once). Make sure that the DDL operation can be executed multiple times.

    ```
    shard-ddl-lock unlock test-`shard_db`.`shard_table`
    {
        "result": true,
        "msg": "",
    }
    ```

3. Use `shard-ddl-lock` to confirm if the DDL lock has been successfully unlocked.

4. Use `query-status` to confirm if the migration task is normal.

Impact

After manually unlocking the lock, the following sharding DDL can be migrated automatically and normally.

13.6.7.2 Migrate from Databases that Use GH-ost/PT-osc

In production scenarios, table locking during DDL execution can block the reads from or writes to the database to a certain extent. Therefore, online DDL tools are often used to execute DDLs to minimize the impact on reads and writes. Common DDL tools are gh-ost and pt-osc.

When using DM to migrate data from MySQL to TiDB, you can enbale online-ddl to allow collaboration of DM and gh-ost or pt-osc. For details about how to enable online-ddl and the workflow after enabling this option, see Continuous Replication with gh-ost or pt-osc. This document focuses on the collaboration details of DM and online DDL tools.

13.6.7.2.1 Working details for DM with online DDL tools

This section describes the working details for DM with the online DDL tools gh-ost and pt-osc when implementing online-schema-change.

online-schema-change: gh-ost

When gh-ost implements online-schema-change, 3 types of tables are created:

- gho: used to apply DDLs. When the data is fully replicated and the gho table is consistent with the origin table, the origin table is replaced by renaming.
- ghc: used to store information that is related to online-schema-change.
- del: created by renaming the origin table.

In the process of migration, DM divides the above tables into 3 categories:

- ghostTable: `_*_gho`
- trashTable: `_*_ghc`, `_*_del`
- realTable: the origin table that executes online-ddl.

The SQL statements mostly used by gh-ost and the corresponding operation of DM are as follows:

1. Create the `_ghc` table:

```
Create /* gh-ost */ table `test`.`_test4_ghc` (
                    id bigint auto_increment,
                    last_update timestamp not null DEFAULT
                        ↪ CURRENT_TIMESTAMP ON UPDATE
                        ↪ CURRENT_TIMESTAMP,
                    hint varchar(64) charset ascii not null,
                    value varchar(4096) charset ascii not null,
                    primary key(id),
                    unique key hint_uidx(hint)
            ) auto_increment=256 ;
```

   DM does not create the `_test4_ghc` table.

2. Create the `_gho` table:

```
Create /* gh-ost */ table `test`.`_test4_gho` like `test`.`test4` ;
```

DM does not create the `_test4_gho` table. DM deletes the `dm_meta.{task_name}_onlineddl` record in the downstream according to `ghost_schema`, `ghost_table`, and the `server_id` of `dm_worker`, and clears the related information in memory.

```
DELETE FROM dm_meta.{task_name}_onlineddl WHERE id = {server_id} and
    ↪ ghost_schema = {ghost_schema} and ghost_table = {ghost_table};
```

3. Apply the DDL that needs to be executed in the `_gho` table:

```
Alter /* gh-ost */ table `test`.`_test4_gho` add column cl1 varchar
    ↪ (20) not null ;
```

DM does not perform the DDL operation of `_test4_gho`. It records this DDL in `dm_meta.{task_name}_onlineddl` and memory.

```
REPLACE INTO dm_meta.{task_name}_onlineddl (id, ghost_schema ,
    ↪ ghost_table , ddls) VALUES (......);
```

4. Write data to the `_ghc` table, and replicate the origin table data to the `_gho` table:

```
INSERT /* gh-ost */ INTO `test`.`_test4_ghc` VALUES (......);
INSERT /* gh-ost `test`.`test4` */ ignore INTO `test`.`_test4_gho` (`
    ↪ id`, `date`, `account_id`, `conversion_price`, `
    ↪ ocpc_matched_conversions`, `ad_cost`, `cl2`)
  (SELECT `id`, `date`, `account_id`, `conversion_price`, `
      ↪ ocpc_matched_conversions`, `ad_cost`, `cl2` FROM `test`.`test4`
      ↪  FORCE INDEX (`PRIMARY`)
    WHERE (((`id` > _binary'1') OR ((`id` = _binary'1'))) AND ((`id` <
        ↪ _binary'2') OR ((`id` = _binary'2')))) lock IN share mode
  )   ;
```

DM does not execute DML statements that are not for **realtable**.

5. After the migration is completed, both the origin table and `_gho` table are renamed, and the online DDL operation is completed:

```
Rename /* gh-ost */ table `test`.`test4` to `test`.`_test4_del`, `test
    ↪ `.`_test4_gho` to `test`.`test4`;
```

DM performs the following two operations:

- DM splits the above `rename` operation into two SQL statements.

```
rename test.test4 to test._test4_del;
rename test._test4_gho to test.test4;
```

- DM does not execute `rename to _test4_del`. When executing `rename ↪ ghost_table to origin table`, DM takes the following steps:

- Read the DDL recorded in memory in Step 3
- Replace `ghost_table` and `ghost_schema` with `origin_table` and its corresponding schema
- Execute the DDL that has been replaced

```
alter table test._test4_gho add column cl1 varchar(20) not null;
-- Replaced with:
alter table test.test4 add column cl1 varchar(20) not null;
```

Note:

The specific SQL statements of gh-ost vary with the parameters used in the execution. This document only lists the major SQL statements. For more details, refer to the gh-ost documentation.

13.6.7.2.2 online-schema-change: pt

When pt-osc implements online-schema-change, 2 types of tables are created:

- `new`: used to apply DDL. When the data is fully replicated and the `new` table is consistent with the origin table, the origin table is replaced by renaming.
- `old`: created by renaming the origin table.
- 3 kinds of Trigger: `pt_osc_*_ins`, `pt_osc_*_upd`, `pt_osc_*_del`. In the process of pt_osc, the new data generated by the origin table is replicated to `new` by the Trigger.

In the process of migration, DM divides the above tables into 3 categories:

- ghostTable: `_*_new`
- trashTable: `_*_old`
- realTable: the origin table that executes online-ddl.

The SQL statements mostly used by pt-osc and the corresponding operation of DM are as follows:

1. Create the `_new` table:

```
CREATE TABLE `test`.`_test4_new` ( id int(11) NOT NULL AUTO_INCREMENT,
date date DEFAULT NULL, account_id bigint(20) DEFAULT NULL,
    ↪ conversion_price decimal(20,3) DEFAULT NULL,
    ↪ ocpc_matched_conversions bigint(20) DEFAULT NULL, ad_cost
    ↪ decimal(20,3) DEFAULT NULL,cl2 varchar(20) COLLATE utf8mb4_bin
    ↪ NOT NULL,cl1 varchar(20) COLLATE utf8mb4_bin NOT NULL,PRIMARY
    ↪ KEY (id) ) ENGINE=InnoDB AUTO_INCREMENT=3 DEFAULT CHARSET=
    ↪ utf8mb4 COLLATE=utf8mb4_bin ;
```

DM does not create the `_test4_new` table. DM deletes the `dm_meta.{task_name}_onlineddl` record in the downstream according to `ghost_schema`, `ghost_table`, and the `server_id` of `dm_worker`, and clears the related information in memory.

```
DELETE FROM dm_meta.{task_name}_onlineddl WHERE id = {server_id} and
    ↪ ghost_schema = {ghost_schema} and ghost_table = {ghost_table};
```

2. Execute DDL in the `_new` table:

```
ALTER TABLE `test`.`_test4_new` add column c3 int;
```

DM does not perform the DDL operation of `_test4_new`. Instead, it records this DDL in `dm_meta.{task_name}_onlineddl` and memory.

```
REPLACE INTO dm_meta.{task_name}_onlineddl (id, ghost_schema ,
    ↪ ghost_table , ddls) VALUES (......);
```

3. Create 3 Triggers used for data migration:

```
CREATE TRIGGER `pt_osc_test_test4_del` AFTER DELETE ON `test`.`test4`
    ↪ ...... ;
CREATE TRIGGER `pt_osc_test_test4_upd` AFTER UPDATE ON `test`.`test4`
    ↪ ...... ;
CREATE TRIGGER `pt_osc_test_test4_ins` AFTER INSERT ON `test`.`test4`
    ↪ ...... ;
```

DM does not execute Trigger operations that are not supported in TiDB.

4. Replicate the origin table data to the `_new` table:

```
INSERT LOW_PRIORITY IGNORE INTO `test`.`_test4_new` (`id`, `date`, `
    ↪ account_id`, `conversion_price`, `ocpc_matched_conversions`, `
    ↪ ad_cost`, `cl2`, `cl1`) SELECT `id`, `date`, `account_id`, `
    ↪ conversion_price`, `ocpc_matched_conversions`, `ad_cost`, `cl2`,
    ↪ `cl1` FROM `test`.`test4` LOCK IN SHARE MODE /*pt-online-schema-
    ↪ change 3227 copy table*/
```

DM does not execute the DML statements that are not for **realtable**.

5. After the data migration is completed, the origin table and `_new` table are renamed, and the online DDL operation is completed:

```
RENAME TABLE `test`.`test4` TO `test`.`_test4_old`, `test`.`_test4_new`
    ↪  TO `test`.`test4`
```

DM performs the following two operations:

- DM splits the above `rename` operation into two SQL statements:

  ```
  sql rename test.test4 to test._test4_old; rename test._test4_new
  ↪ to test.test4;
  ```

- DM does not execute `rename to _test4_old`. When executing `rename ↪ ghost_table to origin table`, DM takes the following steps:
  - Read the DDL recorded in memory in Step 2
  - Replace `ghost_table` and `ghost_schema` with `origin_table` and its corresponding schema
  - Execute the DDL that has been replaced

```
ALTER TABLE `test`.`_test4_new` add column c3 int;
-- Replaced with:
ALTER TABLE `test`.`test4` add column c3 int;
```

6. Delete the `_old` table and 3 Triggers of the online DDL operation:

```
DROP TABLE IF EXISTS `test`.`_test4_old`;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_del` AFTER DELETE ON `test
   ↪ `.`test4` ..... ;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_upd` AFTER UPDATE ON `test
   ↪ `.`test4` ..... ;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_ins` AFTER INSERT ON `test
   ↪ `.`test4` ..... ;
```

DM does not delete `_test4_old` and Triggers.

Note:

The specific SQL statements of pt-osc vary with the parameters used in the execution. This document only lists the major SQL statements. For more details, refer to the pt-osc documentation.

13.6.7.2.3 Other online schema change tools

In some cases, you might need to change the default behavior of your online schema change tool. For example, you might use customized names for `ghost table` and `trash ↪ table`. In other cases, you might want to use other tools instead of gh-ost or pt-osc, with the same working principles and change processes.

To achieve such customized needs, you need to write regular expressions to match the names of the `ghost table` and `trash table`.

Starting from v2.0.7, DM experimentally supports the modified online schema change tools. By setting `online-ddl=true` in the DM task configuration and configuring `shadow-table-rules` and `trash-table-rules`, you can match the modified temporary tables with regular expressions.

For example, if you use a customized pt-osc with the name of `ghost table` being `_{origin_table}_pcnew` and the name of `trash table` being `_{origin_table}_pcold`, you can set the custom rules as follows:

```
online-ddl: true
shadow-table-rules: ["^_(.+)_(?:pcnew)$"]
trash-table-rules: ["^_(.+)_(?:pcold)$"]
```

13.6.7.3 Migrate Data to a Downstream TiDB Table with More Columns

This document provides the additional steps to be taken when you migrate data to a downstream TiDB table with more columns than the corresponding upstream table. For regular migration steps, see the following migration scenarios:

- Migrate Small Datasets from MySQL to TiDB
- Migrate Large Datasets from MySQL to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

13.6.7.3.1 Use DM to migrate data to a downstream TiDB table with more columns

When replicating the upstream binlog, DM tries to use the current table schema of the downstream to parse the binlog and generate the corresponding DML statements. If the column number of the table in the upstream binlog does not match the column number in the downstream table schema, the following error occurs:

```
"errors": [
    {
        "ErrCode": 36027,
        "ErrClass": "sync-unit",
        "ErrScope": "internal",
        "ErrLevel": "high",
        "Message": "startLocation: [position: (mysql-bin.000001, 2022), gtid-
            ↪ set:09bec856-ba95-11ea-850a-58f2b4af5188:1-9 ], endLocation: [
            ↪  position: (mysql-bin.000001, 2022), gtid-set: 09bec856-ba95
            ↪ -11ea-850a-58f2b4af5188:1-9]: gen insert sqls failed, schema:
            ↪ log, table: messages: Column count doesn't match value count:
            ↪ 3 (columns) vs 2 (values)",
        "RawCause": "",
        "Workaround": ""
```

```
    }
]
```

The following is an example upstream table schema:

```
#### Upstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
)
```

The following is an example downstream table schema:

```
#### Downstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  `message` varchar(255) DEFAULT NULL, # This is the additional column that
    ↪ only exists in the downstream table.
  PRIMARY KEY (`id`)
)
```

When DM tries to use the downstream table schema to parse the binlog event generated by the upstream, DM reports the above `Column count doesn't match` error.

In such cases, you can use the `binlog-schema` command to set a table schema for the table to be migrated from the data source. The specified table schema needs to correspond to the binlog event data to be replicated by DM. If you are migrating sharded tables, for each sharded table, you need to set a table schema in DM to parse binlog event data. The steps are as follows:

1. Create a SQL file in DM and add the `CREATE TABLE` statement that corresponds to the upstream table schema to the file. For example, save the following table schema to `log.messages.sql`. For DM v6.0 or later versions, you can update the table schema by adding the `--from-source` or `--from-target` flag without creating a SQL file. For details, see Manage Table Schemas of Tables to be Migrated.

   ```
   # Upstream table schema
   CREATE TABLE `messages` (
   `id` int(11) NOT NULL,
   PRIMARY KEY (`id`)
   )
   ```

2. Use the `binlog-schema` command to set the table schema for the table to be migrated from the data source. At this time, the data migration task should be in the Paused state due to the above `Column count doesn't match` error.

```
tiup dmctl --master-addr ${advertise-addr} binlog-schema update -s ${
    ↪ source-id} ${task-name} ${database-name} ${table-name} ${schema-
    ↪ file}
```

The descriptions of parameters in this command are as follows:

Parameter	Description
- master-addr	Specifies ${ advertise-addr } of any DM-master node in the cluster where dm-ctl is to be connected.
- advertise-addr	${ advertise-addr } indicates the address that DM-master advertises to the outside world.

Parameter	Description
`binlog-schema-set`	Manually set the schema information.
`-s`	Specifies the source. `${source-id}` indicates the source ID of MySQL data.

Parameter	Description
`${task-name}`	Specifies the name of the migration task defined in the `task.yaml` configuration file of the data migration task.

Parameter	Description
`${database-name}`	Specifies the database.
`${table-name}`	Specifies the name of the upstream table.
`${schema-file}`	Specifies the schema file to be set.

For example:

```
tiup dmctl --master-addr 172.16.10.71:8261 binlog-schema update -s
   ↪ mysql-01 task-test -d log -t message log.message.sql
```

3. Use the `resume-task` command to resume the migration task in the Paused state.

```
tiup dmctl --master-addr ${advertise-addr} resume-task ${task-name}
```

4. Use the `query-status` command to confirm that the data migration task is running correctly.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

13.6.7.4 Continuous Data Validation in DM

This document describes how to use continuous data validation in DM, its working principles, and its limitations.

13.6.7.4.1 User scenario

In the process of incrementally migrating data from the upstream database to the downstream database, there is a small probability that the flow of data leads to data corruption or data loss. For scenarios where data consistency is required, such as the credit and securities industries, after the migration is complete, you can perform full data validation to ensure data consistency.

However, in incremental migration scenarios, the upstream and downstream are continuously writing data. Because data is constantly changing in the upstream and downstream, it is difficult to perform full data validation (for example, use sync-diff-inspector) to all data in the tables.

In incremental migration scenarios, you can use the continuous data validation feature in DM. This feature ensures data integrity and consistency during incremental migration where data is continuously written into the downstream.

13.6.7.4.2 Enable continuous data validation

You can enable continuous data validation using either of the following methods:

- Enable in the task configuration file.
- Enable using dmctl.

Method 1: Enable in the task configuration file

To enable continuous data validation, add the following configuration items to the task configuration file:

```
#### Add the following configuration items to the upstream database that
   ↪ needs to be validated:
mysql-instances:
  - source-id: "mysql1"
    block-allow-list: "bw-rule-1"
    validator-config-name: "global"
validators:
  global:
```

```
mode: full # "fast" is also allowed. "none" is the default mode, which
    ↪ means no validation is performed.
worker-count: 4 # The number of validation workers in the background.
    ↪ The default value is 4.
row-error-delay: 30m # If a row cannot pass the validation within the
    ↪ specified time, it will be marked as an error row. The default
    ↪ value is 30m, which means 30 minutes.
```

The configuration items are described as follows:

- `mode`: validation mode. The possible values are `none`, `full`, and `fast`.
    - `none`: the default value, which means no validation is performed.
    - `full`: compares the changed row and the row obtained in the downstream database.
    - `fast`: only checks if the changed row exists in the downstream database.
- `worker-count`: the number of validation workers in the background. Each worker is a goroutine.
- `row-error-delay`: if a row cannot pass the validation within the specified time, it will be marked as an error row. The default value is 30 minutes.

For the complete configuration, refer to DM Advanced Task Configuration File.

Method 2: Enable using dmctl

To enable continuous data validation, run the `dmctl validation start` command:

```
Usage:
  dmctl validation start [--all-task] [task-name] [flags]

Flags:
      --all-task          whether applied to all tasks
  -h, --help              help for start
      --mode string       specify the mode of validation: full (default),
        ↪ fast; this flag will be ignored if the validation task has been
        ↪ ever enabled but currently paused (default "full")
      --start-time string specify the start time of binlog for validation, e
        ↪ .g. '2021-10-21 00:01:00' or 2021-10-21T00:01:00
```

- `--mode`: specify the validation mode. The possible values are `fast` and `full`.
- `--start-time`: specify the start time for validation. The format follows `2021-10-21 00:01:00` or `2021-10-21T00:01:00`.
- `task`: specify the name of the task to enable continuous validation for. You can use `--all-task` to enable validation for all tasks.

For example:

```
dmctl --master-addr=127.0.0.1:8261 validation start --start-time 2021-10-21
    ↪ T00:01:00 --mode full my_dm_task
```

13.6.7.4.3 Use continuous data validation

When you use continuous data validation, you can use dmctl to view the status of the validation and to handle the error rows. "Error rows" refers to the rows that are found to be inconsistent between the upstream and downstream databases.

View the validation status

You can view the validation status using either of the following methods:

Method 1: run the `dmctl query-status <task-name>` command. If continuous data validation is enabled, the validation result is displayed in the `validation` field of each subtask. Example output:

```
"subTaskStatus": [
    {
        "name": "test",
        "stage": "Running",
        "unit": "Sync",
        "result": null,
        "unresolvedDDLLockID": "",
        "sync": {
            ...
        },
        "validation": {
            "task": "test", // Task name
            "source": "mysql-01", // Source id
            "mode": "full", // Validation mode
            "stage": "Running", // Current stage. "Running" or "Stopped".
            "validatorBinlog": "(mysql-bin.000001, 5989)", // The binlog
                ↪ position of the validation
            "validatorBinlogGtid": "1642618e-cf65-11ec-9e3d-0242ac110002
                ↪ :1-30", // The GTID position of the validation
            "result": null, // When the validation is abnormal, show the
                ↪ error message
            "processedRowsStatus": "insert/update/delete: 0/0/0", //
                ↪ Statistics of the processed binlog rows.
            "pendingRowsStatus": "insert/update/delete: 0/0/0", // Statistics
                ↪  of the binlog rows that are not validated yet or that fail
                ↪  to be validated but are not marked as "error rows"
            "errorRowsStatus": "new/ignored/resolved: 0/0/0" // Statistics of
                ↪  the error rows. The three statuses are explained in the
                ↪ next section.
```

```
        }
    }
]
```

Method 2: run the `dmctl validation status <taskname>` command.

```
dmctl validation status [--table-stage stage] <task-name> [flags]
Flags:
  -h, --help              help for status
      --table-stage string filter validation tables by stage: running/
          ↪ stopped
```

In the preceding command, you can use `--table-stage` to filter the tables that are being validated or stop validation. Example output:

```
{
    "result": true,
    "msg": "",
    "validators": [
        {
            "task": "test",
            "source": "mysql-01",
            "mode": "full",
            "stage": "Running",
            "validatorBinlog": "(mysql-bin.000001, 6571)",
            "validatorBinlogGtid": "",
            "result": null,
            "processedRowsStatus": "insert/update/delete: 2/0/0",
            "pendingRowsStatus": "insert/update/delete: 0/0/0",
            "errorRowsStatus": "new/ignored/resolved: 0/0/0"
        }
    ],
    "tableStatuses": [
        {
            "source": "mysql-01", // Source id
            "srcTable": "`db`.`test1`", // Source table name
            "dstTable": "`db`.`test1`", // Target table name
            "stage": "Running", // Validation status
            "message": "" // Error message
        }
    ]
}
```

If you want to view the details of the error rows, such as error types and error time, run the `dmctl validation show-error` command:

```
Usage:
  dmctl validation show-error [--error error-state] <task-name> [flags]

Flags:
      --error string filtering type of error: all, ignored, or unprocessed (
          ↪ default "unprocessed")
  -h, --help         help for show-error
```

Example output:

```
{
    "result": true,
    "msg": "",
    "error": [
        {
            "id": "1", // Error row id, which will be used in processing
                ↪ error rows
            "source": "mysql-replica-01", // Source id
            "srcTable": "`validator_basic`.`test`", // Source table of the
                ↪ error row
            "srcData": "[0, 0]", // Data of the error row in the source table
            "dstTable": "`validator_basic`.`test`", // Target table of the
                ↪ error row
            "dstData": "[]", // Data of the error row in the target table
            "errorType": "Expected rows not exist", // Error type
            "status": "NewErr", // Error status
            "time": "2022-07-04 13:33:02", // Discovery time of the error row
            "message": "" // Additional information
        }
    ]
}
```

Handle error rows

After continuous data validation returns error rows, you need to manually handle the error rows.

When continuous data validation finds error rows, the validation does not stop immediately. Instead, it records the error rows for you to handle. Before the error rows are processed, the default status is `unprocessed`. If you manually correct the error rows in the downstream, the validation does not automatically retrieve the latest status of the corrected data. The error rows are still recorded in the `error` field.

If you do not want to see an error row in the validation status, or if you want to mark an error row as resolved, you can locate the error row id using the `validation show-error` command and subsequently handle it with the given error id:

dmctl provides three error handling commands:

- `clear-error`: clear the error row. The `show-error` command does not show the error row anymore.

```
Usage:
  dmctl validation clear-error <task-name> <error-id|--all> [flags]

Flags:
      --all   all errors
  -h, --help  help for clear-error
```

- `ignore-error`: ignore the error row. This error row is marked as "ignored".

```
Usage:
  dmctl validation ignore-error <task-name> <error-id|--all> [flags]

Flags:
      --all   all errors
  -h, --help  help for ignore-error
```

- `resolve-error`: the error row is manually handled and marked as "resolved".

```
Usage:
  dmctl validation resolve-error <task-name> <error-id|--all> [flags]

Flags:
      --all   all errors
  -h, --help  help for resolve-error
```

13.6.7.4.4 Stop continuous data validation

To stop the continuous data validation, run the `validation stop` command:

```
Usage:
  dmctl validation stop [--all-task] [task-name] [flags]

Flags:
      --all-task  whether applied to all tasks
  -h, --help      help for stop
```

For detailed usage, refer to `dmctl validation start`.

13.6.7.4.5 Implementation

The architecture of continuous data validation (validator) in DM is as follows:

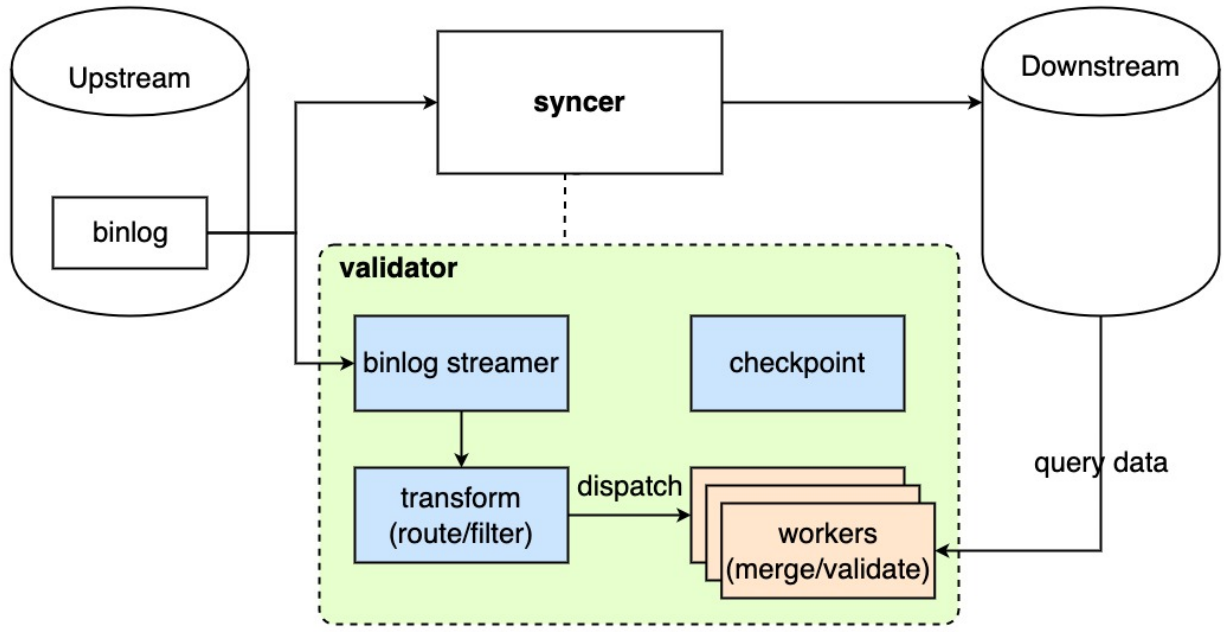

Figure 459: validator summary

The lifecycle of continuous data validation is as follows:

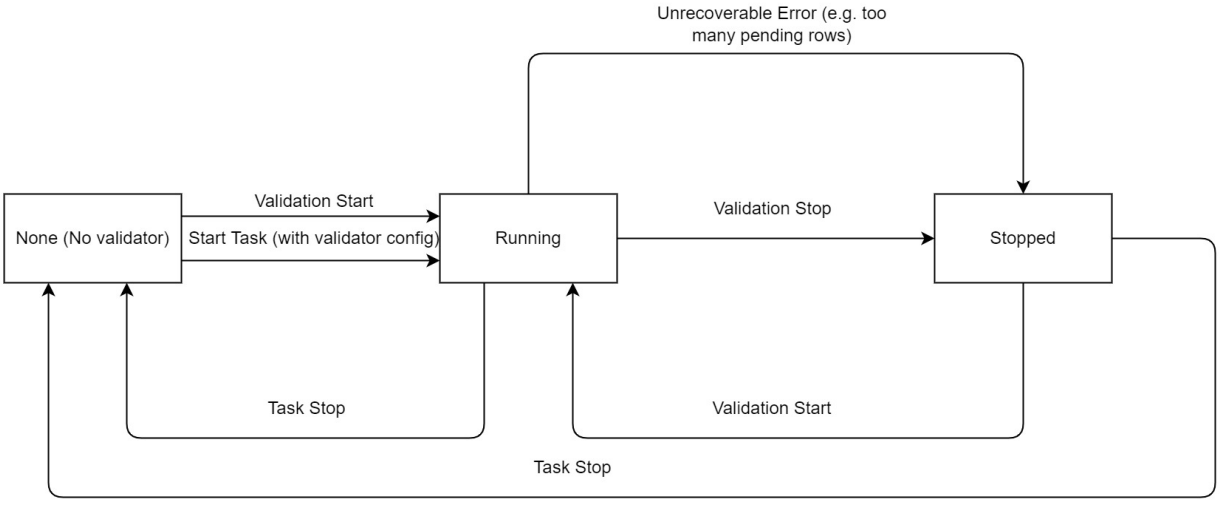

Figure 460: validator lifecycle

The detailed implementation of continuous data validation is as follows:

1. The validator pulls a binlog event from the upstream and gets the changed rows:
    - The validator only checks a event that has been incrementally migrated by the syncer. If the event has not been processed by the syncer, the validator pauses and waits for the syncer to complete processing.
    - If the event has been processed by the syncer, the validator moves on to the following steps.
2. The validator parses the binlog event and filters out the rows based on the block and allow lists, the table filters, and table routing. After that, the validator submits the changed rows to the validation worker that runs in the background.
3. The validation worker merges the changed rows that affect the same table and the same primary key to avoid validating "expired" data. The changed rows are cached in memory.
4. When the validation worker has accumulated a certain number of changed rows or when a certain time interval is passed, the validation worker queries the downstream database using the primary keys to get the current data and compares it with the changed rows.
5. The validation worker performs the data validation. If the validation mode is `full`, the validation worker compares data of the changed rows with data of the downstream database. if the validation mode is `fast`, the validation worker only checks the existence of the changed rows.
    - If the changed rows pass the validation, the changed row is removed from the memory.
    - If the changed rows fail the validation, the validator does not report an error immediately but waits for a certain time interval before validating the row again.
    - If a changed row cannot pass the validation within the specified time (specified by the user), the validator marks the row as an error row and writes it to the meta database in the downstream. You can view the information of error rows by querying the migration task. For details, refer to View the validation status and Handle error rows.

13.6.7.4.6 Limitations

- The source table to be validated must have a primary key or a not-null unique key.
- When DM migrates DDL from the upstream database, the following limitations apply:
    - The DDL must not change the primary key, or change the order of columns, or delete existing columns.
    - The table must not be dropped.
- Does not support tasks that use expressions to filter events.
- The precision of floating-point numbers is different between TiDB and MySQL. Differences smaller than 10^-6 are considered equal.
- Does not support the following data types:
    - JSON
    - Binary data

13.6.7.5 Cluster Upgrade

13.6.7.5.1 Maintain a DM Cluster Using TiUP

This document introduces how to maintain a DM cluster using the TiUP DM component.

If you have not deployed a DM cluster yet, you can refer to Deploy a DM Cluster Using TiUP for instructions.

> **Note:**
>
> - Make sure that the ports among the following components are interconnected
>   - The `peer_port` (`8291` by default) among the DM-master nodes are interconnected.
>   - Each DM-master node can connect to the `port` of all DM-worker nodes (`8262` by default).
>   - Each DM-worker node can connect to the `port` of all DM-master nodes (`8261` by default).
>   - The TiUP nodes can connect to the `port` of all DM-master nodes (`8261` by default).
>   - The TiUP nodes can connect to the `port` of all DM-worker nodes (`8262` by default).

For the help information of the TiUP DM component, run the following command:

```
tiup dm --help
```

```
Deploy a DM cluster for production

Usage:
  tiup dm [flags]
  tiup dm [command]

Available Commands:
  deploy     Deploy a DM cluster for production
  start      Start a DM cluster
  stop       Stop a DM cluster
  restart    Restart a DM cluster
  list       List all clusters
  destroy    Destroy a specified DM cluster
  audit      Show audit log of cluster operation
  exec       Run shell command on host in the dm cluster
```

```
  edit-config Edit DM cluster config
  display     Display information of a DM cluster
  reload      Reload a DM cluster's config and restart if needed
  upgrade     Upgrade a specified DM cluster
  patch       Replace the remote package with a specified package and restart
     ↪  the service
  scale-out   Scale out a DM cluster
  scale-in    Scale in a DM cluster
  import      Import an exist DM 1.0 cluster from dm-ansible and re-deploy
     ↪ 2.0 version
  help        Help about any command

Flags:
  -h, --help            help for tiup-dm
      --native-ssh      Use the native SSH client installed on local system
         ↪ instead of the build-in one.
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -v, --version         version for tiup-dm
      --wait-timeout int Timeout in seconds to wait for an operation to
         ↪ complete, ignored for operations that don't fit. (default 60)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup dm list
```

```
Name  User  Version Path                                       PrivateKey
----  ----  ------- ----                                       ----------
prod-cluster tidb ${version} /root/.tiup/storage/dm/clusters/test /root/.
   ↪ tiup/storage/dm/clusters/test/ssh/id_rsa
```

Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup dm start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup dm list`.

Check the cluster status

TiUP provides the `tiup dm display` command to view the status of each component in the cluster. With this command, you do not have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup dm display prod-cluster
```

```
dm Cluster: prod-cluster
dm Version: ${version}
ID                  Role        Host         Ports     OS/Arch      Status
   ↪ Data Dir                           Deploy Dir
--                  ----        ----         -----     -------      ------
   ↪ --------                           ----------

   ↪ home/tidb/data/prometheus-9090 /home/tidb/deploy/prometheus-9090
```

The `Status` column uses `Up` or `Down` to indicate whether the service is running normally.

For the DM-master component, `|L` might be appended to a status, which indicates that the DM-master node is a Leader. For the DM-worker component, `Free` indicates that the current DM-worker node is not bound to an upstream.

Scale in a cluster

Scaling in a cluster means making some node(s) offline. This operation removes the specified node(s) from the cluster and deletes the remaining data files.

When you scale in a cluster, DM operations on DM-master and DM-worker components are performed in the following order:

1. Stop component processes.
2. Call the API for DM-master to delete the `member`.
3. Clean up the data files related to the node.

The basic usage of the scale-in command:

```
tiup dm scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two arguments: the cluster name and the node ID. The node ID can be obtained by using the `tiup dm display` command in the previous section.

For example, to scale in the DM-worker node on `172.16.5.140` (similar to scaling in DM-master), run the following command:

```
tiup dm scale-in prod-cluster -N 172.16.5.140:8262
```

Scale out a cluster

The scale-out operation has an inner logic similar to that of deployment: the TiUP DM component first ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

For example, to scale out a DM-worker node in the `prod-cluster` cluster, take the following steps (scaling out DM-master has similar steps):

1. Create a `scale.yaml` file and add information of the new worker node:

> **Note:**
> You need to create a topology file, which includes only the description of the new nodes, not the existing nodes. For more configuration items (such as the deployment directory), refer to this TiUP configuration parameter example.

```
---

worker_servers:
  - host: 172.16.5.140
```

2. Perform the scale-out operation. TiUP DM adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup dm scale-out prod-cluster scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup dm display prod-cluster`.

Rolling upgrade

Note:

Since v2.0.5, dmctl support Export and Import Data Sources and Task Configuration of Clusters.

Before upgrading, you can use `config export` to export the configuration files of clusters. After upgrading, if you need to downgrade to an earlier version, you can first redeploy the earlier cluster and then use `config import` to import the previous configuration files.

For clusters earlier than v2.0.5, you can use dmctl v2.0.5 or later to export and import the data source and task configuration files.

For clusters later than v2.0.2, currently, it is not supported to automatically import the configuration related to relay worker. You can use `start-relay` command to manually start relay log.

The rolling upgrade process is made as transparent as possible to the application, and does not affect the business. The operations vary with different nodes.

Upgrade command

You can run the `tiup dm upgrade` command to upgrade a DM cluster. For example, the following command upgrades the cluster to `${version}`. Modify `${version}` to your needed version before running this command:

```
tiup dm upgrade prod-cluster ${version}
```

Update configuration

If you want to dynamically update the component configurations, the TiUP DM component saves a current configuration for each cluster. To edit this configuration, execute the `tiup dm edit-config <cluster-name>` command. For example:

```
tiup dm edit-config prod-cluster
```

TiUP DM opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano` ↪ . After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup dm reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup dm patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  tiup dm patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the role
      --transfer-timeout int Timeout in seconds when transferring dm-master
          ↪ leaders (default 600)

Global Flags:
      --native-ssh      Use the native SSH client installed on local system
          ↪ instead of the build-in one.
      --ssh-timeout int  Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
      --wait-timeout int Timeout in seconds to wait for an operation to
          ↪ complete, ignored for operations that don't fit. (default 60)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

If a DM-master hotfix package is in `/tmp/dm-master-hotfix.tar.gz` and you want to replace all the DM-master packages in the cluster, run the following command:

```
tiup dm patch prod-cluster /tmp/dm-master-hotfix.tar.gz -R dm-master
```

You can also replace only one DM-master package in the cluster:

```
tiup dm patch prod-cluster /tmp/dm--hotfix.tar.gz -N 172.16.4.5:8261
```

Import and upgrade a DM 1.0 cluster deployed using DM-Ansible

Note:

- TiUP does not support importing the DM Portal component in a DM 1.0 cluster.

- You need to stop the original cluster before importing.
- Don't run `stop-task` for tasks that need to be upgraded to 2.0.
- TiUP only supports importing to a DM cluster of v2.0.0-rc.2 or a later version.
- The `import` command is used to import data from a DM 1.0 cluster to a new DM 2.0 cluster. If you need to import DM migration tasks to an existing DM 2.0 cluster, refer to Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+.
- The deployment directories of some components are different from those of the original cluster. You can execute the `display` command to view the details.
- Run `tiup update --self && tiup update dm` before importing to make sure that the TiUP DM component is the latest version.
- Only one DM-master node exists in the cluster after importing. Refer to Scale out a cluster to scale out the DM-master.

Before TiUP is released, DM-Ansible is often used to deploy DM clusters. To enable TiUP to take over the DM 1.0 cluster deployed by DM-Ansible, use the `import` command.

For example, to import a cluster deployed using DM Ansible:

```
tiup dm import --dir=/path/to/dm-ansible --cluster-version ${version}
```

Execute `tiup list dm-master` to view the latest cluster version supported by TiUP.

The process of using the `import` command is as follows:

1. TiUP generates a topology file `topology.yml` based on the DM cluster previously deployed using DM-Ansible.
2. After confirming that the topology file has been generated, you can use it to deploy the DM cluster of v2.0 or later versions.

After the deployment is completed, you can execute the `tiup dm start` command to start the cluster and begin the process of upgrading the DM kernel.

View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
  tiup dm audit [audit-id] [flags]

Flags:
  -h, --help help for audit
```

If the `[audit-id]` argument is not specified, the command shows a list of commands that have been executed. For example:

```
tiup dm audit
```

```
ID     Time                Command
--     ----                -------
4D5kQY 2020-08-13T05:38:19Z tiup dm display test
4D5kNv 2020-08-13T05:36:13Z tiup dm list
4D5kNr 2020-08-13T05:36:10Z tiup dm deploy -p prod-cluster ${version} ./
    ↪ examples/dm/minimal.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` argument as follows:

```
tiup dm audit 4D5kQY
```

Run commands on a host in the DM cluster

To run commands on a host in the DM cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
  tiup dm exec <cluster-name> [flags]

Flags:
      --command string the command run on cluster host (default "ls")
  -h, --help           help for exec
  -N, --node strings   Only exec on host with specified nodes
  -R, --role strings   Only exec on host with specified roles
      --sudo           use root permissions (default false)
```

For example, to execute `ls /tmp` on all DM nodes, run the following command:

```
tiup dm exec prod-cluster --command='ls /tmp'
```

dmctl

TiUP integrates the DM cluster controller `dmctl`.

Run the following command to use dmctl:

```
tiup dmctl [args]
```

Specify the version of dmctl. Modify `${version}` to your needed version before running this command:

```
tiup dmctl:${version} [args]
```

The previous dmctl command to add a source is `dmctl --master-addr master1:8261 ↪ operate-source create /tmp/source1.yml`. After dmctl is integrated into TiUP, the command is:

```
tiup dmctl --master-addr master1:8261 operate-source create /tmp/source1.
    ↪ yml
```

Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--native-ssh` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup dm deploy <cluster-name> <version> <topo> --native- ↪ ssh`. Fill in the name of your cluster for `<cluster-name>`, the DM version to be deployed (such as `v7.1.5`) for `<version>` , and the topology file name for `<topo>`.
- Start a cluster: `tiup dm start <cluster-name> --native-ssh`.
- Upgrade a cluster: `tiup dm upgrade ... --native-ssh`

You can add `--native-ssh` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
##### or
export TIUP_NATIVE_SSH=1
##### or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--native-ssh` at the same time, `--native ↪ -ssh` has higher priority.

> **Note:**
>
> During the process of cluster deployment, if you need to use a password for connection or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

13.6.7.5.2 Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+

This document introduces how to manually upgrade the TiDB DM tool from v1.0.x to v2.0+. The main idea is to use the global checkpoint information in v1.0.x to start a new data migration task in the v2.0+ cluster.

For how to automatically upgrade the TiDB DM tool from v1.0.x to v2.0+, refer to Using TiUP to automatically import the 1.0 cluster deployed by DM-Ansible.

Note:

- Currently, upgrading DM from v1.0.x to v2.0+ is not supported when the data migration task is in the process of full export or full import.
- As the gRPC protocol used for interaction between the components of the DM cluster is updated greatly, you need to make sure that the DM components (including dmctl) use the same version before and after the upgrade.
- Because the metadata storage of the DM cluster (such as checkpoint, shard DDL lock status, and online DDL metadata) is updated greatly, the metadata of v1.0.x cannot be reused automatically in v2.0+. So you need to make sure the following requirements are satisfied before performing the upgrade operation:
  - All data migration tasks are not in the process of shard DDL coordination.
  - All data migration tasks are not in the process of online DDL coordination.

The steps for manual upgrade are as follows.

Step 1: Prepare v2.0+ configuration file

The prepared configuration files of v2.0+ include the configuration files of the upstream database and the configuration files of the data migration task.

Upstream database configuration file

In v2.0+, the upstream database configuration file is separated from the process configuration of the DM-worker, so you need to obtain the source configuration based on the v1.0.x DM-worker configuration.

Note:

If `enable-gtid` in the source configuration is enabled during the upgrade from v1.0.x to v2.0+, you need to parse the binlog or relay log file to obtain the GTID sets corresponding to the binlog position.

Upgrade a v1.0.x cluster deployed by DM-Ansible

Assume that the v1.0.x DM cluster is deployed by DM-Ansible, and the following `dm_worker_servers` configuration is in the `inventory.ini` file:

```
[dm_master_servers]
dm_worker1 ansible_host=172.16.10.72 server_id=101 source_id="mysql-replica
    ↪ -01" mysql_host=172.16.10.81 mysql_user=root mysql_password='
    ↪ VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=' mysql_port=3306
dm_worker2 ansible_host=172.16.10.73 server_id=102 source_id="mysql-replica
    ↪ -02" mysql_host=172.16.10.82 mysql_user=root mysql_password='
    ↪ VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=' mysql_port=3306
```

Then you can convert it to the following two source configuration files:

```
##### The source configuration corresponding to the original dm_worker1. For
    ↪  example, it is named as source1.yaml.
server-id: 101                                # Corresponds to the original `
    ↪ server_id`.
source-id: "mysql-replica-01"                 # Corresponds to the original `
    ↪ source_id`.
from:
  host: "172.16.10.81"                        # Corresponds to the original `
     ↪ mysql_host`.
  port: 3306                                  # Corresponds to the original `
     ↪ mysql_port`.
  user: "root"                                # Corresponds to the original `
     ↪ mysql_user`.
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=" # Corresponds to the original
     ↪  `mysql_password`.
```

```
##### The source configuration corresponding to the original dm_worker2. For
    ↪  example, it is named as source2.yaml.
server-id: 102                                # Corresponds to the original `
    ↪ server_id`.
source-id: "mysql-replica-02"                 # Corresponds to the original `
    ↪ source_id`.
from:
  host: "172.16.10.82"                        # Corresponds to the original `
     ↪ mysql_host`.
  port: 3306                                  # Corresponds to the original `
     ↪ mysql_port`.
  user: "root"                                # Corresponds to the original `
     ↪ mysql_user`.
```

```
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=" # Corresponds to the original
    ↪ `mysql_password`.
```

Upgrade a v1.0.x cluster deployed by binary

Assume that the v1.0.x DM cluster is deployed by binary, and the corresponding DM-worker configuration is as follows:

```
log-level = "info"
log-file = "dm-worker.log"
worker-addr = ":8262"
server-id = 101
source-id = "mysql-replica-01"
flavor = "mysql"
[from]
host = "172.16.10.81"
user = "root"
password = "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU="
port = 3306
```

Then you can convert it to the following source configuration file:

```
server-id: 101                                # Corresponds to the original `
    ↪ server-id`.
source-id: "mysql-replica-01"                 # Corresponds to the original `
    ↪ source-id`.
flavor: "mysql"                               # Corresponds to the original `
    ↪ flavor`.
from:
  host: "172.16.10.81"                        # Corresponds to the original `
      ↪ from.host`.
  port: 3306                                  # Corresponds to the original `
      ↪ from.port`.
  user: "root"                                # Corresponds to the original `
      ↪ from.user`.
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=" # Corresponds to the original
      ↪ `from.password`.
```

Data migration task configuration file

For data migration task configuration guide, v2.0+ is basically compatible with v1.0.x. You can directly copy the configuration of v1.0.x.

Step 2: Deploy the v2.0+ cluster

Note:

Skip this step if you have other v2.0+ clusters available.

Use TiUP to deploy a new v2.0+ cluster according to the required number of nodes.

Step 3: Stop the v1.0.x cluster

If the original v1.0.x cluster is deployed by DM-Ansible, you need to use DM-Ansible to stop the v1.0.x cluster.

If the original v1.0.x cluster is deployed by binary, you can stop the DM-worker and DM-master processes directly.

Step 4: Upgrade data migration task

1. Use the `operate-source` command to load the upstream database source configuration from step 1 into the v2.0+ cluster.
2. In the downstream TiDB cluster, obtain the corresponding global checkpoint information from the incremental checkpoint table of the v1.0.x data migration task.
    - Assume that the v1.0.x data migration configuration does not specify `meta-schema` (or specify its value as the default `dm_meta`), and the corresponding task name is `task_v1`, the corresponding checkpoint information is in the `` `dm_meta`.`task_v1_syncer_checkpoint` `` table of the downstream TiDB.
    - Use the following SQL statements to obtain the global checkpoint information of all upstream database sources corresponding to the data migration task.

```
> SELECT `id`, `binlog_name`, `binlog_pos` FROM `dm_meta`.`task_v1_syncer_checkpoint` WHERE `is_global`=1;
+------------------+------------------------+------------+
| id               | binlog_name            | binlog_pos |
+------------------+------------------------+------------+
| mysql-replica-01 | mysql-bin|000001.000123 | 15847      |
| mysql-replica-02 | mysql-bin|000001.000456 | 10485      |
+------------------+------------------------+------------+
```

3. Update the v1.0.x data migration task configuration file to start a new v2.0+ data migration task.
    - If the data migration task configuration file of v1.0.x is `task_v1.yaml`, copy it and rename it to `task_v2.yaml`.
    - Make the following changes to `task_v2.yaml`:
        - Modify `name` to a new name, such as `task_v2`.

- Change `task-mode` to `incremental`.
- Set the starting point of incremental replication for each source according to the global checkpoint information obtained in step 2. For example:

```
mysql-instances:
  - source-id: "mysql-replica-01"   # Corresponds to the `id`
      ↪ of the checkpoint information.
    meta:
      binlog-name: "mysql-bin.000123" # Corresponds to the `
          ↪ binlog_name` in the checkpoint information,
          ↪ excluding the part of `|000001`.
      binlog-pos: 15847             # Corresponds to `
          ↪ binlog_pos` in the checkpoint information.

  - source-id: "mysql-replica-02"
    meta:
      binlog-name: "mysql-bin.000456"
      binlog-pos: 10485
```

> **Note:**
> If `enable-gtid` is enabled in the source configuration, currently you need to parse the binlog or relay log file to obtain the GTID sets corresponding to the binlog position, and set it to `binlog-` ↪ `gtid` in the `meta`.

4. Use the `start-task` command to start the upgraded data migration task through the v2.0+ data migration task configuration file.
5. Use the `query-status` command to confirm whether the data migration task is running normally.

If the data migration task runs normally, it indicates that the DM upgrade to v2.0+ is successful.

13.6.7.6 Tools

13.6.7.6.1 Use WebUI to Manage DM migration tasks

DM WebUI is a web-based GUI platform for managing TiDB Data Migration (DM) tasks. This platform provides a simple and intuitive way to manage a large number of migration tasks, which frees you from using the dmctl command-line tool.

This document introduces how to access DM WebUI, the prerequisites, the use cases of each page on the interface, and the attention points.

Warning:

- DM WebUI is currently an experimental feature. It is not recommended to use it in the production environment.
- The lifecycle of `task` in DM WebUI has been changed, and it is not recommended to use DM WebUI and dmctl at the same time.

DM WebUI has the following pages:

- **Migration**
  - **Task**: Provides an entry to task creation, and displays the detailed information of each migration task. This page helps you monitor, create, delete, and configure migration tasks.
  - **Source**: Configures the information of upstream data source for a migration task. On this page, you can manage the upstream configuration in a data migration environment, including creating and deleting upstream configuration, monitoring the task status corresponding to the upstream configuration, and modifying upstream configuration.
  - **Replication Detail**: Displays the detailed status information of migration tasks. On this page, you can view the detailed configuration and status information based on a specified filter, including the configuration information and database names of the upstream and downstream, the relation of source tables and target tables.
- **Cluster**
  - **Members**: Displays the list of all master and worker nodes in the DM cluster, and the binding relationship between worker nodes and the source. On this page, you can view the configuration information of the current DM cluster and the status information of each worker. In addition, basic management is also provided on this page.

The interface is as follows:

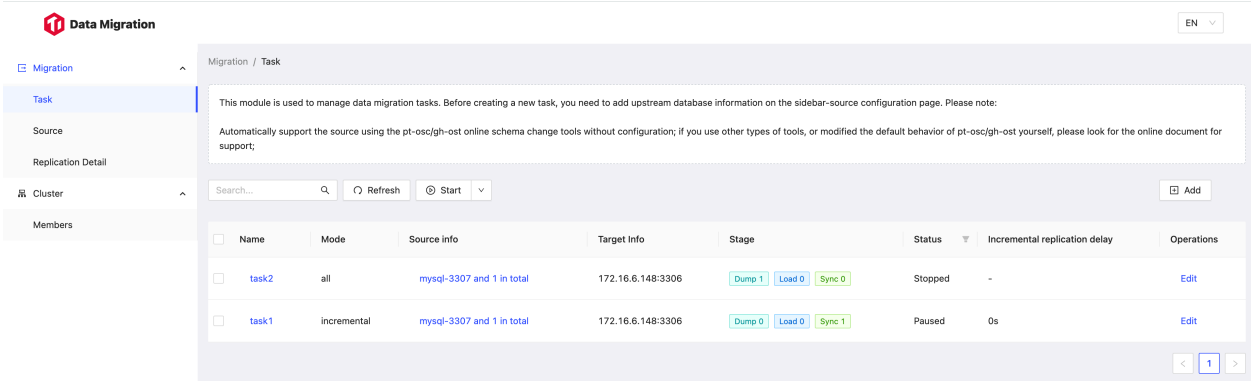

Figure 461: webui

Access method

When OpenAPI is enabled, you can access the DM WebUI from any master node of the DM cluster. The access port is `8261` by default and is the same as that of DM OpenAPI. Here is an example of an access address: `http://{master_ip}:{master_port}/dashboard/`.

Migration

Migration includes **Source**, **Task**, and **Replication Detail** pages.

Source

Before creating a migration task, you need to create the data source information of the upstream for the replication task. You can create the upstream configuration in the **Source** page. When creating sources, pay attention to the following items:

- If there is a auto failover between primary and secondary instance, enable GTID in the upstream MySQL and set GTID to `True` when creating the upstream configuration; otherwise, the migration task will be interrupted during the failover (except for AWS Aurora).
- If a MySQL instance needs to be temporarily offline, you can disable the instance. However, when the MySQL instance is being disabled, other MySQL instances running migration tasks should not execute DDL operations; otherwise, the disabled instance cannot properly migrate data after it is enabled.
- When multiple migration tasks use the same upstream, it might cause additional stress. Enabling relay log can reduce the impact on the upstream, so it is recommended to enable relay log.

Task

You can view the migration task details on the **Task** page, and create migration tasks.

View migration task details

In the task list, click the task name to view the Details page from the right. The Details page displays more detailed task status information. On this page, you can view the status of each sub-task and the current configuration information of the migration task.

In DM, each sub-task of a migration task might be at different stages, namely full dump -> full import (load) -> incremental replication (sync). Therefore, the current stage of a task is displayed with the statistics of the sub-task statuses, which can help you better understand the running status of the task.

Create migration tasks

To create a migration task on this page, click the **Add** button on the top right corner. You can use one of the following methods to create a migration task:

- By following the WebUI instruction. Fill in the required information step by step on the WebUI. This method is suitable for beginners and for daily use.
- By using a configuration file. Paste or write a JSON-formatted configuration file to create a migration task. This method supports adjusting more parameters and is suitable for advanced users.

Replication detail

You can view the status of the migration rules configured for a migration task on the **Replication Detail** page. This page supports querying by task, source, and database name.

The query result contains the corresponding information of the upstream table and the downstream table, so be careful using `.*` in case that too many query results slow down the page response.

Cluster

Members

The **Members** page displays all the master and worker nodes in the DM cluster, and the binding relationship between worker nodes and the source.

13.6.7.6.2 Maintain DM Clusters Using dmctl

> **Note:**
>
> For DM clusters deployed using TiUP, you are recommended to directly use `tiup dmctl` to maintain the clusters.

dmctl is a command line tool used to maintain DM clusters. It supports both the interactive mode and the command mode.

Interactive mode

Enter the interactive mode to interact with DM-master:

> **Note:**
>
> The interactive mode does not support Bash features. For example, you need to directly pass string flags instead of passing them in quotes.

```
./dmctl --master-addr 172.16.30.14:8261
```

```
Welcome to dmctl
Release Version: ${version}
Git Commit Hash: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
Git Branch: release-x.x
UTC Build Time: yyyy-mm-dd hh:mm:ss
Go Version: go version gox.xx linux/amd64

» help
DM control

Usage:
  dmctl [command]

Available Commands:
  binlog         manage or show binlog operations
  binlog-schema manage or show table schema in schema tracker
  check-task     Checks the configuration file of the task
  config         manage config operations
  decrypt        Decrypts cipher text to plain text
  encrypt        Encrypts plain text to cipher text
  help           Gets help about any command
  list-member    Lists member information
  offline-member Offlines member which has been closed
  operate-leader `evict`/`cancel-evict` the leader
  operate-source `create`/`stop`/`show` upstream MySQL/MariaDB source
  pause-relay    Pauses DM-worker's relay unit
  pause-task     Pauses a specified running task or all (sub)tasks bound to a
    ↪ source
  purge-relay    Purges relay log files of the DM-worker according to the
    ↪ specified filename
  query-status   Queries task status
  resume-relay   Resumes DM-worker's relay unit
  resume-task    Resumes a specified paused task or all (sub)tasks bound to a
    ↪ source
```

```
  shard-ddl-lock maintain or show shard-ddl locks information
  start-relay   Starts workers pulling relay log for a source
  start-task    Starts a task as defined in the configuration file
  stop-relay    Stops workers pulling relay log for a source
  stop-task     Stops a specified task or all (sub)tasks bound to a source
  transfer-source Transfers a upstream MySQL/MariaDB source to a free worker

Flags:
  -h, --help          Help for dmctl.
  -s, --source strings MySQL Source ID.

Use "dmctl [command] --help" for more information about a command.
```

Command mode

The command mode differs from the interactive mode in that you need to append the task operation right after the dmctl command. The parameters of the task operation in the command mode are the same as those in the interactive mode.

Note:

- A dmctl command must be followed by only one task operation.
- Starting from v2.0.4, DM supports reading the `-master-addr` parameter from the environment variable `DM_MASTER_ADDR`.

```
./dmctl --master-addr 172.16.30.14:8261 start-task task.yaml
./dmctl --master-addr 172.16.30.14:8261 stop-task task
./dmctl --master-addr 172.16.30.14:8261 query-status

export DM_MASTER_ADDR="172.16.30.14:8261"
./dmctl query-status
```

```
Available Commands:
  binlog        manage or show binlog operations
  binlog-schema manage or show table schema in schema tracker
  check-task    Checks the configuration file of the task
  config        manage config operations
  decrypt       Decrypts cipher text to plain text
  encrypt       Encrypts plain text to cipher text
  help          Gets help about any command
  list-member   Lists member information
  offline-member Offlines member which has been closed
```

```
  operate-leader `evict`/`cancel-evict` the leader
  operate-source `create`/`stop`/`show` upstream MySQL/MariaDB source
  pause-relay   Pauses DM-worker's relay unit
  pause-task    Pauses a specified running task or all (sub)tasks bound to a
     ↪  source
  purge-relay   Purges relay log files of the DM-worker according to the
     ↪ specified filename
  query-status  Queries task status
  resume-relay  Resumes DM-worker's relay unit
  resume-task   Resumes a specified paused task or all (sub)tasks bound to a
     ↪  source
  shard-ddl-lock maintain or show shard-ddl locks information
  start-relay   Starts workers pulling relay log for a source
  start-task    Starts a task as defined in the configuration file
  stop-relay    Stops workers pulling relay log for a source
  stop-task     Stops a specified task or all (sub)tasks bound to a source
  transfer-source Transfers a upstream MySQL/MariaDB source to a free worker

Flags:
      --config string     Path to config file.
  -h, --help              help for dmctl
      --master-addr string Master API server address, this parameter is
         ↪ required when interacting with the dm-master
      --rpc-timeout string RPC timeout, default is 10m. (default "10m")
  -s, --source strings    MySQL Source ID.
      --ssl-ca string     Path of file that contains list of trusted SSL CAs
         ↪  for connection.
      --ssl-cert string   Path of file that contains X509 certificate in PEM
         ↪  format for connection.
      --ssl-key string    Path of file that contains X509 key in PEM format
         ↪ for connection.
  -V, --version           Prints version and exit.

Use "dmctl [command] --help" for more information about a command.
```

13.6.7.7 Performance Tuning

13.6.7.7.1 DM 5.4.0 Benchmark Report

The benchmark data of TiDB Data Migration (DM) v5.4.0 is nearly the same as that of DM v5.3.0. To learn the test purpose, environment, scenarios, and results of DM v5.3.0, refer to DM 5.3.0 Benchmark Report.

13.6.7.7.2 Optimize Configuration of DM

This document introduces how to optimize the configuration of the data migration task to improve the performance of data migration.

Full data export

`mydumpers` is the configuration item related to full data export. This section describes how to configure performance-related options.

`rows`

Setting the `rows` option enables concurrently exporting data from a single table using multi-thread. The value of `rows` is the maximum number of rows contained in each exported chunk. After this option is enabled, DM selects a column as the split benchmark when the data of a MySQL single table is concurrently exported. This column can be one of the following columns: the primary key column, the unique index column, and the normal index column (ordered from highest priority to lowest). Make sure this column is of integer type (for example, `INT`, `MEDIUMINT`, `BIGINT`).

The value of `rows` can be set to 10000. You can change this value according to the total number of rows in the table and the performance of the database. In addition, you need to set `threads` to control the number of concurrent threads. By default, the value of `threads` is 4. You can adjust this value as needed.

`chunk-filesize`

During full backup, DM splits the data of each table into multiple chunks according to the value of the `chunk-filesize` option. Each chunk is saved in a file with a size of about `chunk-filesize`. In this way, data is split into multiple files and you can use the parallel processing of the DM Load unit to improve the import speed. The default value of this option is 64 (in MB). Normally, you do not need to set this option. If you set it, adjust the value of this option according to the size of the full data.

Note:

- You cannot update the value of `mydumpers` after the migration task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using dmctl, update the configuration file, and re-create the task.
- `mydumpers.threads` can be replaced with the `mydumper-thread` configuration item for simplicity.
- If `rows` is set, DM ignores the value of `chunk-filesize`.

Full data import

`loaders` is the configuration item related to full data import. This section describes how to configure performance-related options.

`pool-size`

The `pool-size` option determines the number of threads in the DM Load unit. The default value is 16. Normally, you do not need to set this option. If you set it, adjust the value of this option according to the size of the full data and the performance of the database.

Note:

- You cannot update the value of `loaders` after the migration task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using dmctl, update the configuration file, and re-create the task.
- `loaders.pool-size` can be replaced with the `loader-thread` configuration item for simplicity.

Incremental data replication

`syncers` is the configuration item related to incremental data replication. This section describes how to configure performance-related options.

`worker-count`

`worker-count` determines the number of threads for concurrent replication of DMLs in the DM Sync unit. The default value is 16. To speed up data replication, increase the value of this option appropriately.

`batch`

`batch` determines the number of DMLs included in each transaction when the data is replicated to the downstream database during the DM Sync unit. The default value is 100. Normally, you do not need to change the value of this option.

Note:

- You cannot update the value of `syncers` after the replication task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using dmctl, update the configuration file, and re-create the task.
- `syncers.worker-count` can be replaced with the `syncer-thread` configuration item for simplicity.
- You can change the values of `worker-count` and `batch` according to the actual scenario. For example, if there is a high network delay between DM and the downstream database, you can increase the value of `worker-count` and decrease the value of `batch` appropriately.

13.6.7.7.3 DM Cluster Performance Test

This document describes how to build a test scenario to do a performance test on the DM cluster, including the speed test and latency test regarding data migration.

Migration data flow

You can use a simple migration data flow, that is, MySQL -> DM -> TiDB, to test the data migration performance of the DM cluster.

Deploy test environment

- Deploy the TiDB test cluster using TiUP, with all default configurations.
- Deploy the MySQL service. Enable the `ROW` mode for binlog, and use default configurations for other configuration items.
- Deploy a DM cluster, with a DM-worker and a DM-master.

Performance test

Table schema

Use tables with the following schema for the performance test:

```
CREATE TABLE `sbtest` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `k` int(11) NOT NULL DEFAULT '0',
  `c` char(120) CHARSET utf8mb4 COLLATE utf8mb4_bin NOT NULL DEFAULT '',
  `pad` char(60) CHARSET utf8mb4 COLLATE utf8mb4_bin NOT NULL DEFAULT '',
  PRIMARY KEY (`id`),
  KEY `k_1` (`k`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

Full import benchmark case

Generate test data

Use `sysbench` to create test tables upstream and generate test data for full import. Execute the following `sysbench` command to generate test data:

```
sysbench --test=oltp_insert --tables=4 --mysql-host=172.16.4.40 --mysql-
    ↪ port=3306 --mysql-user=root --mysql-db=dm_benchmark --db-driver=mysql
    ↪  --table-size=50000000 prepare
```

Create a data migration task

1. Create an upstream MySQL source and set `source-id` to `source-1`. For details, see Load the Data Source Configurations.
2. Create a migration task (in `full` mode). The following is a task configuration template:

“‘yaml
name: test-full
task-mode: full

Configure the migration task using the TiDB information of your actual test environment. target-database: host: “192.168.0.1” port: 4000 user: “root” password: “”

mysql-instances: - source-id: “source-1” block-allow-list: “instance” mydumper-config-name: “global” loader-thread: 16

Configure the name of the database where sysbench generates data. block-allow-list: instance: do-dbs: [“dm_benchmark”]

mydumpers: global: rows: 32000 threads: 32 “‘

For details about how to create a migration task, see Create a Data Migration Task.

Note:

- To enable concurrently exporting data from a single table using multi-thread, you can use the `rows` option in the `mydumpers` configuration item. This speeds up data export.
- To test the performance under different configurations, you can tune `loader-thread` in the `mysql-instances` configuration, as well as `rows` and `threads` in the `mydumpers` configuration item.

Get test results

Observe the DM-worker log. When you see `all data files have been finished`, it means that full data has been imported. In this case, you can see the time consumed to import data. The sample log is as follows:

```
[INFO] [loader.go:604] ["all data files have been finished"] [task=test] [
    ↪ unit=load] ["cost time"=52.439796ms]
```

According to the size of the test data and the time consumed to import data, you can calculate the migration speed of the full data.

Incremental replication benchmark case

Initialize tables

Use `sysbench` to create test tables in the upstream.

Create a data migration task

1. Create the source of the upstream MySQL. Set `source-id` to `source-1` (if the source has been created in the full import benchmark case, you do not need to create it again). For details, see Load the Data Source Configurations.

2. Create a DM migration task (in `all` mode). The following is an example of the task configuration file:

“‘yaml
name: test-all
task-mode: all

Configure the migration task using the TiDB information of your actual test environment. target-database: host: “192.168.0.1” port: 4000 user: “root” password: “”

mysql-instances: - source-id: “source-1” block-allow-list: “instance” syncer-config-name: “global”

Configure the name of the database where sysbench generates data. block-allow-list: instance: do-dbs: [“dm_benchmark”]

syncers: global: worker-count: 16 batch: 100 “‘

For details about how to create a data migration task, see Create a Data Migration Task.

> **Note:**
>
> To test the performance under different configurations, you can tune `worker-count` and `batch` in the `syncers` configuration item.

Generate incremental data

To continuously generate incremental data in the upstream, run the `sysbench` command:

```
sysbench --test=oltp_insert --tables=4 --num-threads=32 --mysql-host
    ↪ =172.17.4.40 --mysql-port=3306 --mysql-user=root --mysql-db=
    ↪ dm_benchmark --db-driver=mysql --report-interval=10 --time=1800 run
```

> **Note:**
>
> You can test the data migration performance under different scenarios by using different `sysbench` statements.

Get test results

To observe the migration status of DM, you can run the `query-status` command. To observe the monitoring metrics of DM, you can use Grafana. Here the monitoring metrics refer to `finished sqls jobs` (the number of jobs finished per unit time), and other related metrics. For more information, see Binlog Migration Monitoring Metrics.

13.6.7.7.4 Handle Performance Issues of TiDB Data Migration

This document introduces common performance issues that might exist in DM and how to deal with them.

Before diagnosing an issue, you can refer to the DM Benchmark Report.

When diagnosing and handling performance issues, make sure that:

- The DM monitoring component is correctly configured and installed.
- You can view monitoring metrics on the Grafana monitoring dashboard.
- The component you diagnose works well; otherwise, possible monitoring metrics exceptions might interfere with the diagnosis of performance issues.

In the case of a large latency in the data migration, to quickly figure out whether the bottleneck is inside the DM component or in the TiDB cluster, you can first check `DML queue remain length` in Write SQL Statements to Downstream.

relay log unit

To diagnose performance issues in the relay log unit, you can check the `binlog file gap between master and relay` monitoring metric. For more information about this metric, refer to monitoring metrics of the relay log. If this metric is greater than 1 for a long time, it usually indicates that there is a performance issue; if this metric is 0, it usually indicates that there is no performance issue.

If the value of `binlog file gap between master and relay` is 0, but you suspect that there is a performance issue, you can check `binlog pos`. If `master` in this metric is much larger than `relay`, a performance issue might exist. In this case, diagnose and handle this issue accordingly.

Read binlog data

`read binlog event duration` refers to the duration that the relay log reads binlog from the upstream database (MySQL/MariaDB). Ideally, this metric is close to the network latency between DM-worker and MySQL/MariaDB instances.

- For data migration in one data center, reading binlog data is not a performance bottleneck. If the value of `read binlog event duration` is too large, check the network connection between DM-worker and MySQL/MariaDB.

- For data migration in the geo-distributed environment, try to deploy DM-worker and MySQL/MariaDB in one data center, while deploying the TiDB cluster in the target data center.

The process of reading binlog data from the upstream database includes the following sub-processes:

- The upstream MySQL/MariaDB reads the binlog data locally and sends it through the network. When no exception occurs in the MySQL/MariaDB load, this sub-process usually does not become a bottleneck.
- The binlog data is transferred from the machine where MySQL/MariaDB is located to the machine where DM-worker is located via the network. Whether this sub-process becomes a bottleneck mainly depends on the network connection between DM-worker and the upstream MySQL/MariaDB.
- DM-worker reads binlog data from the network data stream and constructs it as a binlog event. When no exception occurs in the DM-worker load, this sub-process usually does not become a bottleneck.

> **Note:**
>
> If the value of `read binlog event duration` is large, another possible reason is that the upstream MySQL/MariaDB has a low load. This means that no binlog event needs to be sent to DM for a period of time, and the relay log unit stays in a wait state, thus this value includes additional waiting time.

binlog data decoding and verification

After reading the binlog event into the DM memory, DM's relay processing unit decodes and verifies data. This usually does not lead to performance bottleneck; therefore, there is no related performance metric on the monitoring dashboard by default. If you need to view this metric, you can manually add a monitoring item in Grafana. This monitoring item corresponds to `dm_relay_read_transform_duration`, a metric from Prometheus.

Write relay log files

When writing a binlog event to a relay log file, the relevant performance metric is `write relay log duration`. This value should be microseconds when `binlog event size` is not too large. If `write relay log duration` is too large, check the write performance of the disk. To avoid low write performance, use local SSDs for DM-worker.

Load unit

The main operations of the Load unit are to read the SQL file data from the local and write it to the downstream. The related performance metric is `transaction execution latency`. If this value is too large, check the downstream performance by checking the

monitoring of the downstream database. You can also check whether there is a large network latency between DM and the downstream database.

Binlog replication unit

To diagnose performance issues in the Binlog replication unit, you can check the `binlog file gap between master and syncer` monitoring metric. For more information about this metric, refer to monitoring metrics of the Binlog replication.

- If this metric is greater than 1 for a long time, it usually indicates that there is a performance issue.
- If this metric is 0, it usually indicates that there is no performance issue.

When `binlog file gap between master and syncer` is greater than 1 for a long time, check `binlog file gap between relay and syncer` to figure out which unit the latency mainly exists in. If this value is usually 0, the latency might exist in the relay log unit. Then you can refer to relay log unit to resolve this issue; otherwise, continue checking the Binlog replication unit.

Read binlog data

The Binlog replication unit decides whether to read the binlog event from the upstream MySQL/MariaDB or from the relay log file according to the configuration. The related performance metric is `read binlog event duration`, which generally ranges from a few microseconds to tens of microseconds.

- If DM's Binlog replication processing unit reads the binlog event from upstream MySQL/MariaDB, to locate and resolve the issue, refer to read binlog data in the "relay log unit" section.
- If DM's Binlog replication processing unit reads the binlog event from the relay log file, when `binlog event size` is not too large, the value of `read binlog event duration` ↪ should be microseconds. If `read binlog event duration` is too large, check the read performance of the disk. To avoid low write performance, use local SSDs for DM-worker.

binlog event conversion

The Binlog replication unit constructs DML, parses DDL, and performs table router conversion from binlog event data. The related metric is `transform binlog event duration`.

The duration is mainly affected by the write operations upstream. Take the `INSERT` ↪ `INTO` statement as an example, the time consumed to convert a single `VALUES` greatly differs from that to convert a lot of `VALUES`. The time consumed might range from tens of microseconds to hundreds of microseconds. However, usually this is not a bottleneck of the system.

Write SQL statements to downstream

When the Binlog replication unit writes the converted SQL statements to the downstream, the related performance metrics are `DML queue remain length` and `transaction execution latency`.

After constructing SQL statements from binlog event, DM uses `worker-count` queues to concurrently write these statements to the downstream. However, to avoid too many monitoring entries, DM performs the modulo `8` operation on the IDs of concurrent queues. This means that all concurrent queues correspond to one item from `q_0` to `q_7`.

`DML queue remain length` indicates in the concurrent processing queue, the number of DML statements that have not been consumed and have not started to be written downstream. Ideally, the curves corresponding to each `q_*` are almost the same. If not, it indicates that the concurrent load is extremely unbalanced.

If the load is not balanced, confirm whether tables need to be migrated have primary keys or unique keys. If these keys do not exist, add the primary keys or the unique keys; if these keys do exist while the load is not balanced, upgrade DM to v1.0.5 or later versions.

- When there is no noticeable latency in the entire data migration link, the corresponding curve of `DML queue remain length` is almost always 0, and the maximum does not exceed the value of `batch` in the task configuration file.
- If you find a noticeable latency in the data migration link, and the curve of `DML queue remain length` corresponding to each `q_*` is almost the same and is almost always 0, it means that DM fails to read, convert, or concurrently write the data from the upstream in time (the bottleneck might be in the relay log unit). For troubleshooting, refer to the previous sections of this document.

If the corresponding curve of `DML queue remain length` is not 0 (usually the maximum is not more than 1024), it indicates that there is a bottleneck when writing SQL statements to the downstream. You can use `transaction execution latency` to view the time consumed to execute a single transaction to the downstream.

`transaction execution latency` is usually tens of milliseconds. If this value is too large, check the downstream performance based on the monitoring of the downstream database. You can also check whether there is a large network latency between DM and the downstream database.

To view the time consumed to write a single statement such as `BEGIN`, `INSERT`, `UPDATE`, `DELETE`, or `COMMIT` to the downstream, you can also check `statement execution latency`.

13.6.7.8 Manage Data Sources

13.6.7.8.1 Switch DM-worker Connection between Upstream MySQL Instances

When the upstream MySQL instance that DM-worker connects to needs downtime maintenance or when the instance crashes unexpectedly, you need to switch the DM-worker connection to another MySQL instance within the same migration group.

Note:

- You can switch the DM-worker connection to only an instance within the same primary-secondary migration cluster.
- The MySQL instance to be newly connected to must have the binlog required by DM-worker.
- DM-worker must operate in the GTID sets mode, which means you must specify `enable-gtid: true` in the corresponding source configuration file.
- The connection switch only supports the following two scenarios. Strictly follow the procedures for each scenario. Otherwise, you might have to re-deploy the DM cluster according to the newly connected MySQL instance and perform the data migration task all over again.

For more details on GTID set, refer to MySQL documentation.

Switch DM-worker connection via virtual IP

When DM-worker connects the upstream MySQL instance via a virtual IP (VIP), switching the VIP connection to another MySQL instance means switching the MySQL instance connected to DM-worker, without the upstream connection address changed.

Note:

Make necessary changes to DM in this scenario. Otherwise, when you switch the VIP connection to another MySQL instance, DM might connect to the new and old MySQL instances at the same time in different connections. In this situation, the binlog replicated to DM is not consistent with other upstream status that DM receives, causing unpredictable anomalies and even data damage.

To switch one upstream MySQL instance (when DM-worker connects to it via a VIP) to another, perform the following steps:

1. Use the `query-status` command to get the GTID sets (`syncerBinlogGtid`) corresponding to the binlog that the current processing unit of binlog replication has replicated to the downstream. Mark the sets as `gtid-S`.
2. Use the `SELECT @@GLOBAL.gtid_purged;` command on the new MySQL instance to get the GTID sets corresponding to the purged binlogs. Mark the sets as `gtid-P`.

3. Use the `SELECT @@GLOBAL.gtid_executed;` command on the new MySQL instance to get the GTID sets corresponding to all successfully executed transactions. Mark the sets as `gtid-E`.
4. Make sure that the following conditions are met. Otherwise, you cannot switch the DM-work connection to the new MySQL instance:

    - `gtid-S` contains `gtid-P`. `gtid-P` can be empty.
    - `gtid-E` contains `gtid-S`.

5. Use `pause-task` to pause all running tasks of data migration.
6. Change the VIP for it to direct at the new MySQL instance.
7. Use `resume-task` to resume the previous migration task.

Change the address of the upstream MySQL instance that DM-worker connects to

To make DM-worker connect to a new MySQL instance in the upstream by modifying the DM-worker configuration, perform the following steps:

1. Use the `query-status` command to get the GTID sets (`syncerBinlogGtid`) corresponding to the binlog that the current processing unit of binlog replication has replicated to the downstream. Mark this sets as `gtid-S`.
2. Use the `SELECT @@GLOBAL.gtid_purged;` command on the new MySQL instance to get the GTID sets corresponding to the purged binlogs. Mark this sets as `gtid-P`.
3. Use the `SELECT @@GLOBAL.gtid_executed;` command on the new MySQL instance to get the GTID sets corresponding to all successfully executed transactions. Mark this sets as `gtid-E`.
4. Make sure that the following conditions are met. Otherwise, you cannot switch the DM-work connection to the new MySQL instance:

    - `gtid-S` contains `gtid-P`. `gtid-P` can be empty.
    - `gtid-E` contains `gtid-S`.

5. Use `stop-task` to stop all running tasks of data migration.
6. Use the `operator-source stop` command to remove the source configuration corresponding to the address of the old MySQL instance from the DM cluster.
7. Update the address of the MySQL instance in the source configuration file and use the `operate-source create` command to reload the new source configuration in the DM cluster.
8. Use `start-task` to restart the migration task.

13.6.7.9 Manage Tasks

13.6.7.9.1 Handle Failed DDL Statements in TiDB Data Migration

This document introduces how to handle failed DDL statements when you're using the TiDB Data Migration (DM) tool to migrate data.

Currently, TiDB is not completely compatible with all MySQL syntax (see the DDL statements supported by TiDB). Therefore, when DM is migrating data from MySQL to TiDB and TiDB does not support the corresponding DDL statement, an error might occur and break the migration process. In this case, you can use the `binlog` command of DM to resume the migration.

Restrictions

Do not use this command in the following situations:

- It is unacceptable in the actual production environment that the failed DDL statement is skipped in the downstream TiDB.
- The failed DDL statement cannot be replaced with other DDL statements.
- Other DDL statements must not be injected into the downstream TiDB.

For example, `DROP PRIMARY KEY`. In this scenario, you can only create a new table in the downstream with the new table schema (after executing the DDL statement), and re-import all the data into this new table.

Supported scenarios

During the migration, the DDL statement unsupported by TiDB is executed in the upstream and migrated to the downstream, and as a result, the migration task gets interrupted.

- If it is acceptable that this DDL statement is skipped in the downstream TiDB, then you can use `binlog skip <task-name>` to skip migrating this DDL statement and resume the migration.
- If it is acceptable that this DDL statement is replaced with other DDL statements, then you can use `binlog replace <task-name>` to replace this DDL statement and resume the migration.
- If it is acceptable that other DDL statements are injected to the downstream TiDB, then you can use `binlog inject <task-name>` to inject other DDL statements and resume the migration.

Commands

When you use dmctl to manually handle the failed DDL statements, the commonly used commands include `query-status` and `binlog`.

query-status

The `query-status` command is used to query the current status of items such as the subtask and the relay unit in each MySQL instance. For details, see query status.

binlog

The `binlog` command is used to manage and show binlog operations. This command is only supported in DM v6.0 and later versions. For earlier versions, use the `handle-error` command.

The usage of `binlog` is as follows:

```
binlog -h
```

```
manage or show binlog operations

Usage:
  dmctl binlog [command]

Available Commands:
  inject    inject the current error event or a specific binlog position (
    ↪ binlog-pos) with some ddls
  list      list error handle command at binlog position (binlog-pos) or
    ↪ after binlog position (binlog-pos)
  replace   replace the current error event or a specific binlog position (
    ↪ binlog-pos) with some ddls
  revert    revert the current binlog operation or a specific binlog
    ↪ position (binlog-pos) operation
  skip      skip the current error event or a specific binlog position (
    ↪ binlog-pos) event

Flags:
  -b, --binlog-pos string position used to match binlog event if matched the
    ↪  binlog operation will be applied. The format like "mysql-bin
    ↪ |000001.000003:3270"
  -h, --help            help for binlog

Global Flags:
  -s, --source strings MySQL Source ID.

Use "dmctl binlog [command] --help" for more information about a command.
```

`binlog` supports the following sub-commands:

- `inject`: injects DDL statements into the current error event or a specific binlog position. To specify the binlog position, refer to `-b, --binlog-pos`.
- `list`: lists all valid `inject`, `skip`, and `replace` operations at the current binlog position or after the current binlog position. To specify the binlog position, refer to `-b, --binlog-pos`.
- `replace`: replaces the DDL statement at a specific binlog position with another DDL statement. To specify the binlog position, refer to `-b, --binlog-pos`.
- `revert`: reverts the `inject`, `skip` or `replace` operation at a specified binlog operation, only if the previous operation does not take effect. To specify the binlog position, refer to `-b, --binlog-pos`.
- `skip`: skips the DDL statement at a specific binlog position. To specify the binlog position, refer to `-b, --binlog-pos`.

`binlog` supports the following flags:

- `-b, --binlog-pos`:
  - Type: string.
  - Specifies a binlog position. When the position of the binlog event matches `binlog -pos`, the operation is executed. If it is not specified, DM automatically sets `binlog-pos` to the currently failed DDL statement.
  - Format: `binlog-filename:binlog-pos`, for example, `mysql-bin|000001.000003:3270`.
  - After the migration returns an error, the binlog position can be obtained from `position` in `startLocation` returned by `query-status`. Before the migration returns an error, the binlog position can be obtained by using `SHOW BINLOG EVENTS` in the upstream MySQL instance.
- `-s, --source`:
  - Type: string.
  - Specifies the MySQL instance in which the preset operation is to be executed.

Usage examples

Skip DDL if the migration gets interrupted

If you need to skip the DDL statement when the migration gets interrupted, run the `binlog skip` command:

```
binlog skip -h
```

```
skip the current error event or a specific binlog position (binlog-pos)
   ↪ event

Usage:
  dmctl binlog skip <task-name> [flags]

Flags:
  -h, --help help for skip

Global Flags:
  -b, --binlog-pos string position used to match binlog event if matched the
     ↪  binlog operation will be applied. The format like "mysql-bin
     ↪ |000001.000003:3270"
  -s, --source strings   MySQL Source ID.
```

Non-shard-merge scenario

Assume that you need to migrate the upstream table `db1.tbl1` to the downstream TiDB. The initial table schema is:

```
SHOW CREATE TABLE db1.tbl1;
```

```
+-------+-------------------------------------------------+
| Table | Create Table                                    |
+-------+-------------------------------------------------+
| tbl1 | CREATE TABLE `tbl1` (
  `c1` int(11) NOT NULL,
  `c2` decimal(11,3) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-------+-------------------------------------------------+
```

Now, the following DDL statement is executed in the upstream to alter the table schema (namely, alter DECIMAL(11, 3) of c2 into DECIMAL(10, 3)):

```
ALTER TABLE db1.tbl1 CHANGE c2 c2 DECIMAL (10, 3);
```

Because this DDL statement is not supported by TiDB, the migration task of DM gets interrupted. Execute the `query-status <task-name>` command, and you can see the following error:

```
ERROR 8200 (HY000): Unsupported modify column: can't change decimal column
    ↪ precision
```

Assume that it is acceptable in the actual production environment that this DDL statement is not executed in the downstream TiDB (namely, the original table schema is retained). Then you can use `binlog skip <task-name>` to skip this DDL statement to resume the migration. The procedures are as follows:

1. Execute `binlog skip <task-name>` to skip the currently failed DDL statement:

```
» binlog skip test
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

2. Execute `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
```

```
            ]
        }
    ]
}
```

You can see that the task runs normally and the wrong DDL is skipped.

Shard merge scenario

Assume that you need to merge and migrate the following four tables in the upstream to one same table `shard_db`.`shard_table` in the downstream. The task mode is "pessimistic".

- MySQL instance 1 contains the shard_db_1 schema, which includes the shard_table_1 ↪ and shard_table_2 tables.
- MySQL instance 2 contains the shard_db_2 schema, which includes the shard_table_1 ↪ and shard_table_2 tables.

The initial table schema is:

```
SHOW CREATE TABLE shard_db.shard_table;
```

```
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| tb    | CREATE TABLE `shard_table` (
  `id` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
```

Now, execute the following DDL statement to all upstream sharded tables to alter their character set:

```
ALTER TABLE `shard_db_*`.`shard_table_*` CHARACTER SET LATIN1 COLLATE
    ↪ LATIN1_DANISH_CI;
```

Because this DDL statement is not supported by TiDB, the migration task of DM gets interrupted. Execute the `query-status` command, and you can see the following errors reported by the `shard_db_1.shard_table_1` table in MySQL instance 1 and the `shard_db_2` ↪ `.shard_table_1` table in MySQL instance 2:

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_1`
       ↪ CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_1`
       ↪ CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

Assume that it is acceptable in the actual production environment that this DDL statement is not executed in the downstream TiDB (namely, the original table schema is retained). Then you can use `binlog skip <task-name>` to skip this DDL statement to resume the migration. The procedures are as follows:

1. Execute `binlog skip <task-name>` to skip the currently failed DDL statements in MySQL instance 1 and 2:

    ```
    » binlog skip test
    ```

    ```
    {
        "result": true,
        "msg": "",
        "sources": [
            {
                "result": true,
                "msg": "",
                "source": "mysql-replica-01",
                "worker": "worker1"
            },
            {
                "result": true,
                "msg": "",
                "source": "mysql-replica-02",
                "worker": "worker2"
            }
        ]
    }
    ```

2. Execute the `query-status` command, and you can see the errors reported by the `shard_db_1.shard_table_2` table in MySQL instance 1 and the `shard_db_2` ↪ `.shard_table_2` table in MySQL instance 2:

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`
        ↪ shard_table_2` CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to
        ↪ utf8"
}
```

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`
        ↪ shard_table_2` CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to
        ↪ utf8"
}
```

3. Execute `binlog skip <task-name>` again to skip the currently failed DDL statements in MySQL instance 1 and 2:

```
» handle-error test skip
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

4. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
            ]
        },
        {
```

```
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-02",
                "worker": "worker2",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
            ]
        }
    ]
}
```

You can see that the task runs normally with no error and all four wrong DDL statements are skipped.

Replace DDL if the migration gets interrupted

If you need to replace the DDL statement when the migration gets interrupted, run the `binlog replace` command:

```
binlog replace -h
```

```
replace the current error event or a specific binlog position (binlog-pos)
    ↪ with some ddls

Usage:
  dmctl binlog replace <task-name> <replace-sql1> <replace-sql2>... [flags]

Flags:
  -h, --help help for replace

Global Flags:
  -b, --binlog-pos string position used to match binlog event if matched the
     ↪  binlog operation will be applied. The format like "mysql-bin
     ↪ |000001.000003:3270"
  -s, --source strings   MySQL Source ID.
```

Non-shard-merge scenario

Assume that you need to migrate the upstream table `db1.tbl1` to the downstream TiDB. The initial table schema is:

```
SHOW CREATE TABLE db1.tbl1;
```

```
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| tb    | CREATE TABLE `tbl1` (
  `id` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
```

Now, perform the following DDL operation in the upstream to add a new column with the UNIQUE constraint:

```
ALTER TABLE `db1`.`tbl1` ADD COLUMN new_col INT UNIQUE;
```

Because this DDL statement is not supported by TiDB, the migration task gets interrupted. Execute the `query-status` command, and you can see the following error:

```
{
    "Message": "cannot track DDL: ALTER TABLE `db1`.`tbl1` ADD COLUMN `
        ↪ new_col` INT UNIQUE KEY",
    "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
        ↪ UNIQUE KEY when altering 'db1.tbl1'",
}
```

You can replace this DDL statement with two equivalent DDL statements. The steps are as follows:

1. Replace the wrong DDL statement by the following command:

```
» binlog replace test "ALTER TABLE `db1`.`tbl1` ADD COLUMN `new_col`
    ↪ INT;ALTER TABLE `db1`.`tbl1` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

2. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
```

```
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
            ]
        }
    ]
}
```

You can see that the task runs normally and the wrong DDL statement is replaced by new DDL statements that execute successfully.

Shard merge scenario

Assume that you need to merge and migrate the following four tables in the upstream to one same table `` `shard_db`.`shard_table` `` in the downstream. The task mode is "pessimistic".

- In the MySQL instance 1, there is a schema `shard_db_1`, which has two tables `shard_table_1` and `shard_table_2`.
- In the MySQL instance 2, there is a schema `shard_db_2`, which has two tables `shard_table_1` and `shard_table_2`.

The initial table schema is:

```
SHOW CREATE TABLE shard_db.shard_table;
```

```
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
| tb    | CREATE TABLE `shard_table` (
  `id` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
```

Now, perform the following DDL operation to all upstream sharded tables to add a new column with the UNIQUE constraint:

```
ALTER TABLE `shard_db_*`.`shard_table_*` ADD COLUMN new_col INT UNIQUE;
```

Because this DDL statement is not supported by TiDB, the migration task gets interrupted. Execute the `query-status` command, and you can see the following errors reported by the `shard_db_1.shard_table_1` table in MySQL instance 1 and the `shard_db_2` ↪ `.shard_table_1` table in MySQL instance 2:

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_1`
        ↪ ADD COLUMN `new_col` INT UNIQUE KEY",
    "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
        ↪ UNIQUE KEY when altering 'shard_db_1.shard_table_1'",
}
```

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_1`
        ↪ ADD COLUMN `new_col` INT UNIQUE KEY",
```

```
    "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
       ↪ UNIQUE KEY when altering 'shard_db_2.shard_table_1'",
}
```

You can replace this DDL statement with two equivalent DDL statements. The steps are as follows:

1. Replace the wrong DDL statements respectively in MySQL instance 1 and MySQL instance 2 by the following commands:

```
» binlog replace test -s mysql-replica-01 "ALTER TABLE `shard_db_1`.`
   ↪ shard_table_1` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_1
   ↪ `.`shard_table_1` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

```
» binlog replace test -s mysql-replica-02 "ALTER TABLE `shard_db_2`.`
   ↪ shard_table_1` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_2
   ↪ `.`shard_table_1` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

2. Use `query-status <task-name>` to view the task status, and you can see the following errors reported by the `shard_db_1.shard_table_2` table in MySQL instance 1 and the `shard_db_2.shard_table_2` table in MySQL instance 2:

```
{
    "Message": "detect inconsistent DDL sequence from source ... ddls:
       ↪ [ALTER TABLE `shard_db`.`tb` ADD COLUMN `new_col` INT UNIQUE
       ↪ KEY] source: `shard_db_1`.`shard_table_2`], right DDL
       ↪ sequence should be ..."
}
```

```
{
    "Message": "detect inconsistent DDL sequence from source ... ddls:
       ↪ [ALTER TABLE `shard_db`.`tb` ADD COLUMN `new_col` INT UNIQUE
       ↪ KEY] source: `shard_db_2`.`shard_table_2`], right DDL
       ↪ sequence should be ..."
}
```

3. Execute `handle-error <task-name> replace` again to replace the wrong DDL statements in MySQL instance 1 and 2:

```
» binlog replace test -s mysql-replica-01 "ALTER TABLE `shard_db_1`.`
   ↪ shard_table_2` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_1
   ↪ `.`shard_table_2` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

```
» binlog replace test -s mysql-replica-02 "ALTER TABLE `shard_db_2`.`
   ↪ shard_table_2` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_2
   ↪ `.`shard_table_2` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
```

```
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

4. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
```

```
                ],
                "unresolvedGroups": [
                ],
                "unresolvedGroups": [
                ],
                "synced": true,
                "binlogType": "remote",
                "totalRows": "4",
                "totalRps": "0",
                "recentRps": "0"
            }
        }
    ]
},
{
    "result": true,
    "msg": "",
    "sourceStatus": {
        "source": "mysql-replica-02",
        "worker": "worker2",
        "result": null,
        "relayStatus": null
    },
    "subTaskStatus": [
        {
            "name": "test",
            "stage": "Running",
            "unit": "Sync",
            "result": null,
            "unresolvedDDLLockID": "",
            "sync": {
                "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                    ↪ 2388)",
                "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                    ↪ de45f57:1-10",
                "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                    ↪ 2388)",
                "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                    ↪ de45f57:1-4",
                "blockingDDLs": [
                ],
                "unresolvedGroups": [
                ],
                "unresolvedGroups": [
                ],
```

```
                    "synced": try,
                    "binlogType": "remote",
                    "totalRows": "4",
                    "totalRps": "0",
                    "recentRps": "0"
                }
            }
        ]
    }
]
}
```

You can see that the task runs normally with no error and all four wrong DDL statements are replaced.

Other commands

For the usage of other commands of `binlog`, refer to the `binlog skip` and `binlog replace` examples above.

13.6.7.9.2 Manage Table Schemas of Tables to Be Migrated Using TiDB Data Migration

This document describes how to manage the schema of the table in DM during migration using dmctl.

When DM performs incremental replication, it first reads the upstream binlog, then creates SQL statements and executes them in the downstream. However, the upstream binlog does not contain the complete table schema. To generate the SQL statements, DM maintains internally the schema information of the table to be migrated. This is called the internal table schema.

To deal with some special occasions, or to handle migration interruptions caused by mismatch of the table schemas, DM provides the `binlog-schema` command to obtain, modify, and delete the internal table schema.

Implementation principles

The internal table schema comes from the following sources:

- For full data migration (`task-mode=all`), the migration task goes through three stages: dump/load/sync, which means full export, full import, and incremental replication. In the dump stage, DM exports the table schema information along with the data and automatically creates the corresponding table in the downstream. In the sync stage, this table schema is used as the starting table scheme for incremental replication.
- In the sync stage, when DM handles DDL statements such as `ALTER TABLE`, it updates the internal table schema at the same time.

- If the task is an incremental migration (`task-mode=incremental`), in which the downstream has completed creating the table to be migrated, DM obtains the table schema information from the downstream database. This behavior varies with DM versions.

For incremental replication, schema maintenance is complicated. During the whole data replication, the following four table schemas are involved. These schemas might be the consistent or inconsistent with one another:

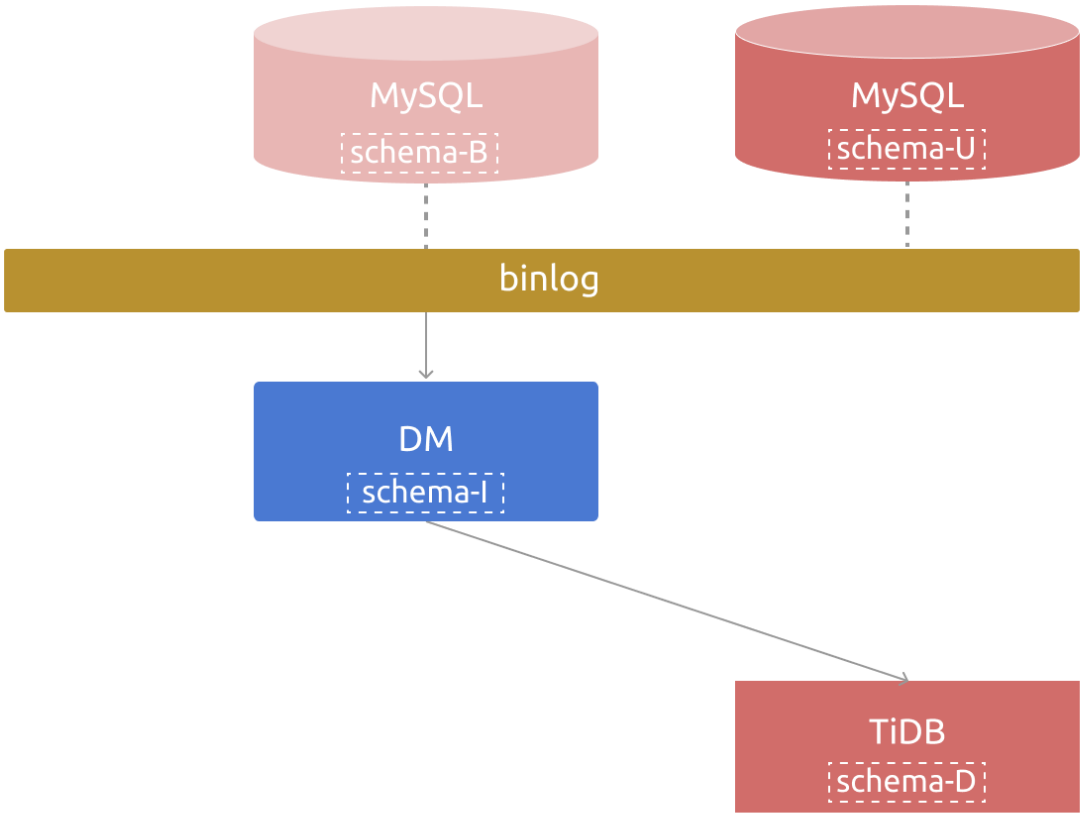

Figure 462: schema

- The upstream table schema at the current time, identified as `schema-U`.
- The table schema of the binlog event currently being consumed by DM, identified as `schema-B`. This schema corresponds to the upstream table schema at a historical time.
- The table schema currently maintained in DM (the schema tracker component), identified as `schema-I`.
- The table schema in the downstream TiDB cluster, identified as `schema-D`.

In most cases, the preceding four table schemas are consistent.

When the upstream database performs a DDL operation to change the table schema, `schema-U` is changed. By applying the DDL operation to the internal schema tracker component and the downstream TiDB cluster, DM updates `schema-I` and `schema-D` in an orderly manner to keep them consistent with `schema-U`. Therefore, DM can then normally consume the binlog event corresponding to the `schema-B` table schema. That is, after the DDL operation is successfully migrated, `schema-U`, `schema-B`, `schema-I`, and `schema-D` are still consistent.

Note the following situations that might cause inconsistency:

- During the migration with optimistic mode sharding DDL support enabled, the `schema-D` of the downstream table might be inconsistent with the `schema-B` and `schema-I` of some upstream sharded tables. In such cases, DM still keeps `schema-I` and `schema-B` consistent to ensure that the binlog event corresponding to DML can be parsed normally.
- When the downstream table has more columns than the upstream table, `schema-D` might be inconsistent with `schema-B` and `schema-I`. In the full data migration (`task-mode=all`), DM automatically handles inconsistency. In the incremental migration (`task-mode=incremental`), because the task is on a first start and there is no internal schema information yet, DM automatically reads the downstream schema (`schema-D`) and updates `schema-I` (this behavior varies with DM versions). After that, if DM uses `schema-I` to parse `schema-B`'s binlog, it will report `Column count doesn't match value count` error. For details, refer to Migrate Data to a Downstream TiDB Table with More Columns.

You can run the `binlog-schema` command to obtain, modify, or delete the `schema-I` table schema maintained in DM.

> **Note:**
>
> The `binlog-schema` command is supported only in DM v6.0 or later versions. For earlier versions, you must use the `operate-schema` command.

Command

```
help binlog-schema
```

```
manage or show table schema in schema tracker

Usage:
  dmctl binlog-schema [command]
```

```
Available Commands:
  delete     delete table schema structure
  list       show table schema structure
  update     update tables schema structure

Flags:
  -h, --help help for binlog-schema

Global Flags:
  -s, --source strings MySQL Source ID.

Use "dmctl binlog-schema [command] --help" for more information about a
    ↪ command.
```

Note:

- Because a table schema might change during data migration, to obtain a predictable table schema, currently the `binlog-schema` command can be used only when the data migration task is in the `Paused` state.
- To avoid data loss due to mishandling, it is **strongly recommended** to get and backup the table schema firstly before you modify the schema.

Parameters

- `delete`: Deletes the table schema.
- `list`: Lists the table schema.
- `update`: Updates the table schema.
- `-s` or `--source`:
  - Required.
  - Specifies the MySQL source that the operation is applied to.

Usage example

Get the table schema

To get the table schema, run the `binlog-schema list` command:

```
help binlog-schema list
```

```
show table schema structure
```

```
Usage:
  dmctl binlog-schema list <task-name> <database> <table> [flags]

Flags:
  -h, --help help for list

Global Flags:
  -s, --source strings MySQL Source ID.
```

If you want to get the table schema of the `db_single`.`t1` table corresponding to the mysql-replica-01 MySQL source in the db_single task, run the following command:

```
binlog-schema list -s mysql-replica-01 task_single db_single t1
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "CREATE TABLE `t1` ( `c1` int(11) NOT NULL, `c2` int(11)
                ↪ DEFAULT NULL, PRIMARY KEY (`c1`)) ENGINE=InnoDB DEFAULT
                ↪ CHARSET=latin1 COLLATE=latin1_bin",
            "source": "mysql-replica-01",
            "worker": "127.0.0.1:8262"
        }
    ]
}
```

Update the table schema

To update the table schema, run the binlog-schema update command:

```
help binlog-schema update
```

```
update tables schema structure

Usage:
  dmctl binlog-schema update <task-name> <database> <table> [schema-file] [
     ↪ flags]

Flags:
      --flush       flush the table info and checkpoint immediately (default
         ↪  true)
      --from-source use the schema from upstream database as the schema of
         ↪ the specified tables
```

```
      --from-target use the schema from downstream database as the schema of
          ↪ the specified tables
  -h, --help        help for update
      --sync        sync the table info to master to resolve shard ddl lock,
          ↪ only for optimistic mode now (default true)

Global Flags:
  -s, --source strings MySQL Source ID.
```

If you want to set the table schema of the `db_single`.`t1` table corresponding to the mysql-replica-01 MySQL source in the db_single task as follows:

```
CREATE TABLE `t1` (
    `c1` int(11) NOT NULL,
    `c2` bigint(11) DEFAULT NULL,
    PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin
```

Save the CREATE TABLE statement above as a file (for example, db_single.t1-schema.
↪ sql), and run the following command:

```
operate-schema set -s mysql-replica-01 task_single -d db_single -t t1
    ↪ db_single.t1-schema.sql
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "127.0.0.1:8262"
        }
    ]
}
```

Delete the table schema

To delete the table schema, run the binlog-schema delete command:

```
help binlog-schema delete
```

```
delete table schema structure

Usage:
  dmctl binlog-schema delete <task-name> <database> <table> [flags]
```

```
Flags:
  -h, --help  help for delete

Global Flags:
  -s, --source strings MySQL Source ID.
```

> **Note:**
>
> After the table schema maintained in DM is deleted, if a DDL/DML statement related to this table needs to be migrated to the downstream, DM will try to get the table schema from the following three sources in an orderly manner:
>
> - The `table_info` field in the checkpoint table
> - The meta information in the optimistic sharding DDL
> - The corresponding table in the downstream TiDB

If you want to delete the table schema of the `` `db_single`.`t1` `` table corresponding to the `mysql-replica-01` MySQL source in the `db_single` task, run the following command:

```
binlog-schema delete -s mysql-replica-01 task_single db_single t1
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "127.0.0.1:8262"
        }
    ]
}
```

13.6.7.10 Export and Import Data Sources and Task Configuration of Clusters

`config` command is used to export and import data sources and task configuration of clusters.

> **Note:**
>
> For clusters earlier than v2.0.5, you can use dmctl v2.0.5 or later to export and import the data source and task configuration files.

```
» help config
Commands to import/export config
Usage:
  dmctl config [command]
Available Commands:
  export    Export the configurations of sources and tasks.
  import    Import the configurations of sources and tasks.
Flags:
  -h, --help help for config
Global Flags:
  -s, --source strings MySQL Source ID.
Use "dmctl config [command] --help" for more information about a command.
```

13.6.7.10.1 Export the data source and task configuration of clusters

You can use `export` command to export the data source and task configuration of clusters to specified files.

```
config export [--dir directory]
```

Parameter explanation

- `dir`:
  - optional
  - specifies the file path for exporting
  - the default value is `./configs`

Returned results

```
config export -d /tmp/configs
```

```
export configs to directory `/tmp/configs` succeed
```

13.6.7.10.2 import the data source and task configuration of clusters

You can use `import` command to import the data source and task configuration of clusters from specified files.

```
config import [--dir directory]
```

> **Note:**
>
> For clusters later than v2.0.2, currently, it is not supported to automatically import the configuration related to relay worker. You can use `start-relay` command to manually start relay log.

Parameter explanation

- `dir`:
  - optional
  - specifies the file path for importing
  - the default value is `./configs`

Returned results

```
config import -d /tmp/configs
```

```
start creating sources
start creating tasks
import configs from directory `/tmp/configs` succeed
```

13.6.7.11 Handle Alerts in TiDB Data Migration

This document introduces how to deal with the alert information in DM.

13.6.7.11.1 Alerts related to high availability

`DM_master_all_down`

- Description:

  If all DM-master nodes are offline, this alert is triggered.

- Solution:

  You can take the following steps to handle the alert:

1. Check the environment of the cluster.
2. Check the logs of all DM-master nodes for troubleshooting.

`DM_worker_offline`

- Description:

  If a DM-worker node is offline for more than one hour, this alert is triggered. In a high-availability architecture, this alert might not directly interrupt the task but increases the risk of interruption.

- Solution:

  You can take the following steps to handle the alert:

  1. View the working status of the corresponding DM-worker node.
  2. Check whether the node is connected.
  3. Troubleshoot errors through logs.

`DM_DDL_error`

- Description:

  This error occurs when DM is processing the sharding DDL operations.

- Solution:

  Refer to Troubleshoot DM.

`DM_pending_DDL`

- Description:

  If a sharding DDL operation is pending for more than one hour, this alert is triggered.

- Solution:

  In some scenarios, the pending sharding DDL operation might be what users expect. Otherwise, refer to Handle Sharding DDL Locks Manually in DM for solution.

13.6.7.11.2 Alert rules related to task status

`DM_task_state`

- Description:

  When a sub-task of DM-worker is in the `Paused` state for over 20 minutes, an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

13.6.7.11.3 Alert rules related to relay log

`DM_relay_process_exits_with_error`

- Description:

  When the relay log processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_remain_storage_of_relay_log`

- Description:

  When the free space of the disk where the relay log is located is less than 10G, an alert is triggered.

- Solutions:

  You can take the following methods to handle the alert:

  - Delete unwanted data manually to increase free disk space.
  - Reconfigure the automatic data purge strategy of the relay log or purge data manually.
  - Execute the command `pause-relay` to pause the relay log pulling process. After there is enough free disk space, resume the process by running the command `resume-relay`. Note that you must not purge upstream binlog files that have not been pulled after the relay log pulling process is paused.

`DM_relay_log_data_corruption`

- Description:

  When the relay log processing unit validates the binlog event read from the upstream and detects abnormal checksum information, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_fail_to_read_binlog_from_master`

- Description:

  If an error occurs when the relay log processing unit tries to read the binlog event from the upstream, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_fail_to_write_relay_log`

- Description:

  If an error occurs when the relay log processing unit tries to write the binlog event into the relay log file, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_binlog_file_gap_between_master_relay`

- Description:

  When the number of the binlog files in the current upstream MySQL/MariaDB exceeds that of the latest binlog files pulled by the relay log processing unit by **more than** 1 for 10 minutes, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

13.6.7.11.4 Alert rules related to Dump/Load

`DM_dump_process_exists_with_error`

- Description:

  When the Dump processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_load_process_exists_with_error`

- Description:

  When the Load processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

13.6.7.11.5 Alert rules related to binlog replication

`DM_sync_process_exists_with_error`

- Description:

  When the binlog replication processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_binlog_file_gap_between_master_syncer`

- Description:

  When the number of the binlog files in the current upstream MySQL/MariaDB exceeds that of the latest binlog files processed by the relay log processing unit by **more than** 1 for 10 minutes, an alert is triggered.

- Solution:

  Refer to Handle Performance Issues.

`DM_binlog_file_gap_between_relay_syncer`

- Description:

  When the number of the binlog files in the current relay log processing unit exceeds that of the latest binlog files processed by the binlog replication processing unit by **more than** 1 for 10 minutes, an alert is triggered.

- Solution:

  Refer to Handle Performance Issues.

13.6.7.12 Daily Check for TiDB Data Migration

This document summarizes how to perform a daily check on TiDB Data Migration (DM).

- Method 1: Execute the `query-status` command to check the running status of the task and the error output (if any). For details, see Query Status.
- Method 2: If Prometheus and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. For example, suppose that the Grafana's address is `172.16.10.71`, go to http://172.16.10.71:3000, enter the Grafana dashboard, and select the DM Dashboard to check monitoring metrics of DM. For more information of these metrics, see DM Monitoring Metrics.
- Method 3: Check the running status of DM and the error (if any) using the log file.
    - DM-master log directory: It is specified by the `--log-file` DM-master process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-master node.
    - DM-worker log directory: It is specified by the `--log-file` DM-worker process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-worker node.

13.6.8 Reference

13.6.8.1 Architecture

13.6.8.1.1 DM-worker Introduction

DM-worker is a tool used to migrate data from MySQL/MariaDB to TiDB.

It has the following features:

- Acts as a secondary database of any MySQL or MariaDB instance
- Reads the binlog events from MySQL/MariaDB and persists them to the local storage
- A single DM-worker supports migrating the data of one MySQL/MariaDB instance to multiple TiDB instances
- Multiple DM-workers support migrating the data of multiple MySQL/MariaDB instances to one TiDB instance

DM-worker processing unit

A DM-worker task contains multiple logic units, including relay log, the dump processing unit, the load processing unit, and binlog replication.

Relay log

The relay log persistently stores the binlog data from the upstream MySQL/MariaDB and provides the feature of accessing binlog events for the binlog replication.

Its rationale and features are similar to the relay log of MySQL. For details, see MySQL Relay Log.

Dump processing unit

The dump processing unit dumps the full data from the upstream MySQL/MariaDB to the local disk.

Load processing unit

The load processing unit reads the dumped files of the dump processing unit and then loads these files to the downstream TiDB.

Binlog replication/sync processing unit

Binlog replication/sync processing unit reads the binlog events of the upstream MySQL/-MariaDB or the binlog events of the relay log, transforms these events to SQL statements, and then applies these statements to the downstream TiDB.

Privileges required by DM-worker

This section describes the upstream and downstream database users' privileges required by DM-worker, and the user privileges required by the respective processing unit.

Upstream database user privileges

The upstream database (MySQL/MariaDB) user must have the following privileges:

Privilege	Scope
`SELECT`	Tables
`RELOAD`	Global
`REPLICATION SLAVE`	Global
`REPLICATION CLIENT`	Global

If you need to migrate the data from `db1` to TiDB, execute the following `GRANT` statement:

```
GRANT RELOAD,REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO 'your_user'@'
    ↪ your_wildcard_of_host';
GRANT SELECT ON db1.* TO 'your_user'@'your_wildcard_of_host';
```

If you also need to migrate the data from other databases into TiDB, make sure the same privileges are granted to the user of the respective databases.

Downstream database user privileges

The downstream database (TiDB) user must have the following privileges:

Privilege	Scope
`SELECT`	Tables
`INSERT`	Tables
`UPDATE`	Tables

Privilege	Scope
DELETE	Tables
CREATE	Databases, tables
DROP	Databases, tables
ALTER	Tables
INDEX	Tables

Execute the following GRANT statement for the databases or tables that you need to migrate:

```
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,ALTER,INDEX ON db.table TO '
    ↪ your_user'@'your_wildcard_of_host';
GRANT ALL ON dm_meta.* TO 'your_user'@'your_wildcard_of_host';
```

Minimal privilege required by each processing unit

Processing unit	Minimal upstream (MySQL/MariaDB) privilege	Minimal downstream (TiDB) privilege	Minimal system privilege
Relay log	REPLICATION SLAVE (reads the binlog)REPLICATION ↪ CLIENT (show master ↪ status, show slave status)	NULL	Read/Write local files
Dump	SELECTRELOAD (flushes tables with Read lock and unlocks tables)	NULL	Write local files
Load	NULL	SELECT (Query the checkpoint history)CREATE (creates a database/table)DELETE ↪ (deletes checkpoint)INSERT (Inserts the Dump data)	Read/Write local files

Processing unit	Minimal upstream (MySQL/MariaDB) privilege	Minimal downstream (TiDB) privilege	Minimal system privilege
Binlog replication	`REPLICATION SLAVE` (reads the binlog)`REPLICATION CLIENT` (`show master status`, `show slave status`)	`SELECT` (shows the index and column)`INSERT` (DML)`UPDATE` (DML)`DELETE` (DML)`CREATE` (creates a database/table)`DROP` (drops databases/tables)`ALTER` (alters a table)`INDEX` (creates/drops an index)	Read/Write local files

Note:

These privileges are not immutable and they change as the request changes.

13.6.8.1.2 DM Safe Mode

Safe mode is a special operation mode for DM to perform incremental replication. In safe mode, when the DM incremental replication component replicates binlog events, DM forcibly rewrites all the `INSERT` and `UPDATE` statements before executing them in the downstream.

During safe mode, one binlog event can be replicated repeatedly to the downstream with idempotence guaranteed. Thus, the incremental replication is *safe*.

After resuming a data replication task from a checkpoint, DM might repeatedly replicate some binlog events, which leads to the following issues:

- During incremental replication, the operation of executing DML and the operation of writing checkpoints are not simultaneous. The operation of writing checkpoints and

writing data into the downstream database is not atomic. Therefore, **when DM exits abnormally, checkpoints might only record the restoration point before the exit point**.

- When DM restarts a replication task and resumes incremental replication from a checkpoint, some data between the checkpoint and the exit point might already be processed before the abnormal exit. This causes **some SQL statements to be executed repeatedly**.
- If an `INSERT` statement is executed repeatedly, the primary key or the unique index might encounter a conflict, which leads to a replication failure. If an `UPDATE` statement is executed repeatedly, the filter condition might not be able to locate the previously updated records.

In safe mode, DM can rewrite SQL statements to resolve the preceding issues.

Working principle

In safe mode, DM guarantees the idempotency of binlog events by rewriting SQL statements. Specifically, the following SQL statements are rewritten:

- `INSERT` statements are rewritten to `REPLACE` statements.
- `UPDATE` statements are analyzed to obtain the value of the primary key or the unique index of the row updated. `UPDATE` statements are then rewritten to `DELETE` + `REPLACE` statements in the following two steps: DM deletes the old record using the primary key or unique index, and inserts the new record using the `REPLACE` statement.

`REPLACE` is a MySQL-specific syntax for inserting data. When you insert data using `REPLACE`, and the new data and existing data have a primary key or unique constraint conflict, MySQL deletes all the conflicting records and executes the insert operation, which is equivalent to "force insert". For details, see REPLACE statement in MySQL documentation.

Assume that a `dummydb.dummytbl` table has a primary key `id`. Execute the following SQL statements repeatedly on this table:

```
INSERT INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123, 999, '
    ↪ abc');
UPDATE dummydb.dummytbl SET int_value = 888999 WHERE int_value = 999; --
    ↪ Suppose there is no other record with int_value = 999
UPDATE dummydb.dummytbl SET id = 999 WHERE id = 888; -- Update the primary
    ↪ key
```

With safe mode enabled, when the preceding SQL statements are executed again in the downstream, they are rewritten as follows:

```
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123, 999,
    ↪ 'abc');
DELETE FROM dummydb.dummytbl WHERE id = 123;
```

```
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123,
    ↪ 888999, 'abc');
DELETE FROM dummydb.dummytbl WHERE id = 888;
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (999,
    ↪ 888888, 'abc888');
```

In the preceding statements, `UPDATE` is rewritten as `DELETE` + `REPLACE`, rather than `DELETE` + `INSERT`. If `INSERT` is used here, when you insert a duplicate record with `id = 999`, the database reports a primary key conflict. This is why `REPLACE` is used instead. The new record will replace the existing record.

By rewriting SQL statements, DM overwrites the existing row data using the new row data when performing duplicate insert or update operations. This guarantees that insert and update operations are executed repeatedly.

Enable safe mode

You can enable safe mode either automatically or manually. This section describes the detailed steps.

Automatically enable

When DM resumes an incremental replication task from a checkpoint (For example, DM worker restart or network reconnection), DM automatically enables safe mode for a period (60 seconds by default).

Whether to enable safe mode is related to `safemode_exit_point` in the checkpoint. When an incremental replication task is paused abnormally, DM tries to replicate all DML statements in the memory to the downstream and records the latest binlog position among the DML statements as `safemode_exit_point`, which is saved to the last checkpoint.

The detailed logic is as follows:

- If the checkpoint contains `safemode_exit_point`, the incremental replication task is paused abnormally. When DM resumes the task, the binlog position of the checkpoint to be resumed (**begin position**) is earlier than `safemode_exit_point`, which represents the binlog events between the begin position and the `safemode_exit_point` might have been processed in the downstream. So, during the resume process, some binlog events might be executed repeatedly. Therefore, enabling safe mode can make these binlog positions **safe**. After the binlog position exceeds the `safemode_exit_point`, DM automatically disables safe mode unless safe mode is enabled manually.
- If the checkpoint does not contain `safemode_exit_point`, there are two cases:
    1. This is a new task, or this task is paused as expected.
    2. This task is paused abnormally but DM fails to record `safemode_exit_point`, or the DM process exits abnormally.

In the second case, DM does not know which binlog events after the checkpoint are executed in the downstream. To ensure that repeatedly executed binlog events do not cause any problems, DM automatically enables safe mode during the first two checkpoint intervals. The default interval between two checkpoints is 30 seconds, which means when a normal incremental replication task starts, safe mode is enforced for the first 60 seconds (2 * 30 seconds).

Usually, it is not recommended to change the checkpoint interval to adjust the safe mode period at the beginning of the incremental replication task. However, if you do need a change, you can manually enable safe mode (recommended) or change the `checkpoint-flush-interval` item in syncer configuration.

Manually enable

You can set the `safe-mode` item in the syncer configuration to enable safe mode during the entire replication process. `safe-mode` is a bool type parameter and is `false` by default. If it is set to `true`, DM enables safe mode for the whole incremental replication process.

The following is a task configuration example with safe mode enabled:

```
syncers:                           # The running configurations of the sync
   ↪ processing unit.
  global:                          # Configuration name.
    # Other configuration items are not provided in this example.
    safe-mode: true                # Enables safe mode for the whole
       ↪ incremental replication process.
    # Other configuration items are not provided in this example.
##### ----------- Instance configuration -----------
mysql-instances:
  -
    source-id: "mysql-replica-01"
    # Other configuration items are not provided in this example.
    syncer-config-name: "global"       # Name of the syncers configuration.
```

Notes for safe mode

If you want to enable safe mode during the entire replication process for safety reasons, be aware of the following:

- **Incremental replication in safe mode consumes extra overhead.** Frequent `DELETE` + `REPLACE` operations result in frequent changes to primary keys or unique indexes, which creates a greater performance overhead than executing `UPDATE` statements only.
- **Safe mode forces the replacement of records with the same primary key, which might result in data loss in the downstream.** When you merge and migrate shards from the upstream to the downstream, incorrect configuration might lead to a large number of primary key or unique key conflicts. If safe mode is enabled in

this situation, the downstream might lose lots of data without showing any exception, resulting in severe data inconsistency.

- **Safe mode relies on the primary key or unique index to detect conflicts.** If the downstream table has no primary key or unique index, DM cannot use `REPLACE` ↪ to replace and insert records. In this case, even if safe mode is enabled and DM rewrites `INSERT` to `REPLACE` statements, duplicate records are still inserted into the downstream.

In summary, if the upstream database has data with duplicate primary keys, and your application tolerates loss of duplicate records and performance overhead, you can enable safe mode to ignore data duplication.

13.6.8.1.3 Data Migration Relay Log

The Data Migration (DM) relay log consists of several sets of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

After relay log is enabled, DM-worker automatically migrates the upstream binlog to the local configuration directory (the default migration directory is `<deploy_dir>/<relay_log>` if DM is deployed using TiUP). The default value of `<relay_log>` is `relay-dir` and can be modified in Upstream Database Configuration File. Since v5.4.0, you can configure the local configuration directory through `relay-dir` in the DM-worker configuration file, which takes precedence over the configuration file of the upstream database.

User scenarios

In MySQL, storage space is limited, so the binlog is automatically purged when the maximum retention time is reached. After the upstream database purges the binlog, DM fails to pull the purged binlog and the migration task fails. For each migration task, DM creates a connection in the upstream to pull binlog. Too many connections might cause a heavy workload on the upstream database.

When the relay log is enabled, multiple migration task with the same upstream database can reuse the relay log that has been pulled to the local disk. This **relieves the pressure on the upstream database**.

For full and incremental data migration tasks (`task-mode=all`), DM needs to first migrate full data and then perform incremental migration based on binlog. If the full migration phase takes long, the upstream binlog might be purged, which results in incremental migration failure. To avoid this situation, you can enable the relay log feature so that DM automatically retains enough log in the local disk and **ensures the incremental migration task can be performed normally**.

It is generally recommended to enable relay log, but be aware of the following potential issue:

Because relay log must be written to the disk, it consumes external IO and CPU resources. This prolongs the whole data replication process and increases the data replication latency. For **latency-sensitive** scenarios, it is not recommended to enable relay log.

Note:

In DM v2.0.7 and later versions, relay log writes are optimized. The latency and CPU resource consumption is relatively low.

Use relay log

This section describes how to enable and disable relay log, query relay log status, and purge relay log.

Enable and disable relay log

In v5.4.0 and later versions, you can enable relay log by setting `enable-relay` to `true`. Since v5.4.0, when binding the upstream data source, DM-worker checks the `enable-relay` item in the configuration of the data source. If `enable-relay` is `true`, the relay log feature is enabled for this data source.

For the detailed configuration method, see Upstream Database Configuration File.

In addition, you can also dynamically adjust the `enable-relay` configuration of the data source using the `start-relay` or `stop-relay` command to enable or disable relay log in time.

```
start-relay -s mysql-replica-01
```

```
{
    "result": true,
    "msg": ""
}
```

Note:

In DM v2.0.x later than DM v2.0.2 and in v5.3.0, the configuration item `enable-relay` in the source configuration file is no longer valid, and you can only use `start-relay` and `stop-relay` to enable and disable relay log. If DM finds that `enable-relay` is set to `true` when loading the data source configuration, it outputs the following message:

```
Please use `start-relay` to specify which workers should pull
    ↪ relay log of relay-enabled sources.
```

Warning:

This startup method is marked as deprecated in v6.1 and might be removed in a future release. You can see the following prompt in the output of the relevant command: `start-relay/stop-relay with worker name will be deprecated soon. You can try stopping relay first and use start-relay without worker name instead.`

In the command `start-relay`, you can configure one or more DM-workers to migrate relay logs for the specified data source, but the DM-workers specified in the parameter must be free or have been bound to the upstream data source. Examples are as follows:

```
start-relay -s mysql-replica-01 worker1 worker2
```

```
{
    "result": true,
    "msg": ""
}
```

```
stop-relay -s mysql-replica-01 worker1 worker2
```

```
{
    "result": true,
    "msg": ""
}
```

In DM versions earlier than v2.0.2 (not including v2.0.2), DM checks the configuration item `enable-relay` in the source configuration file when binding a DM-worker to an upstream data source. If `enable-relay` is set to `true`, DM enables the relay log feature for the data source.

See Upstream Database Configuration File for how to set the configuration item `enable-relay`.

Query relay log status

You can use the command `query-status -s` to query the status of the relay log:

```
query-status -s mysql-replica-01
```

Expected output

```
{
    "result": true,
    "msg": "",
```

```
"sources": [
    {
        "result": true,
        "msg": "no sub task started",
        "sourceStatus": {
            "source": "mysql-replica-01",
            "worker": "worker2",
            "result": null,
            "relayStatus": {
                "masterBinlog": "(mysql-bin.000005, 916)",
                "masterBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ :1-28",
                "relaySubDir": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ .000001",
                "relayBinlog": "(mysql-bin.000005, 4)",
                "relayBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ :1-28",
                "relayCatchUpMaster": false,
                "stage": "Running",
                "result": null
            }
        },
        "subTaskStatus": [
        ]
    },
    {
        "result": true,
        "msg": "no sub task started",
        "sourceStatus": {
            "source": "mysql-replica-01",
            "worker": "worker1",
            "result": null,
            "relayStatus": {
                "masterBinlog": "(mysql-bin.000005, 916)",
                "masterBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ :1-28",
                "relaySubDir": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ .000001",
                "relayBinlog": "(mysql-bin.000005, 916)",
                "relayBinlogGtid": "",
                "relayCatchUpMaster": true,
                "stage": "Running",
                "result": null
            }
        },
```

```
            "subTaskStatus": [
            ]
        }
    ]
}
```

Pause and resume relay log

You can use the command `pause-relay` to pause the pulling process of relay logs and use the command `resume-relay` to resume the process. You need to specify the `source-id` of the upstream data source when executing these two commands. See the following examples:

```
pause-relay -s mysql-replica-01 -s mysql-replica-02
```

Expected output

```
{
    "op": "PauseRelay",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

```
resume-relay -s mysql-replica-01
```

Expected output

```
{
    "op": "ResumeRelay",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
```

```
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

Purge relay logs

DM provides two ways to purge relay logs: manual purge and automatic purge. Neither of these two methods purges active relay logs.

Note:

- Active relay log: The relay log is being used by a data migration task. An active relay log is currently only updated and written in the Syncer Unit. If a data migration task in All mode spends more time on full export/import than the expiration time configured in the purge of the data source, the relay log is still purged.
- Expired relay log: The difference between the last modification time of the relay log file and the current time is greater than the value of the `expires` field in the configuration file.

Automatic purge

You can enable automatic purge and configure its strategy in the source configuration file. See the following example:

```
##### relay log purge strategy
purge:
    interval: 3600
    expires: 24
    remain-space: 15
```

- `purge.interval`
    - The interval of automatic purge in the background, in seconds.
    - "3600" by default, indicating a background purge task is performed every 3600 seconds.
- `purge.expires`

    - The number of hours for which the relay log (that has been previously written to the relay processing unit, and that is not being used or will not be read later by the currently running data migration task) can be retained before being purged in the automatic background purge.
    - "0" by default, indicating data purge is not performed according to the update time of the relay log.

- `purge.remain-space`

    - The amount of remaining disk space in GB less than which the specified DM-worker machine tries to purge the relay log that can be purged securely in the automatic background purge. If it is set to `0`, data purge is not performed according to the remaining disk space.
    - "15" by default, indicating when the available disk space is less than 15 GB, DM-master tries to purge the relay log securely.

Manual purge

Manual purge means using the `purge-relay` command provided by dmctl to specify `subdir` and the binlog name thus to purge all the relay logs **before** the specified binlog. If the `-subdir` option in the command is not specified, all relay logs **before** the current relay log sub-directory are purged.

Assuming that the directory structure of the current relay log is as follows:

```
$ tree .
.
|-- deb76a2b-09cc-11e9-9129-5242cf3bb246.000001
|   |-- mysql-bin.000001
|   |-- mysql-bin.000002
|   |-- mysql-bin.000003
|   `-- relay.meta
|-- deb76a2b-09cc-11e9-9129-5242cf3bb246.000003
|   |-- mysql-bin.000001
|   `-- relay.meta
|-- e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
|   |-- mysql-bin.000001
|   `-- relay.meta
`-- server-uuid.index

$ cat server-uuid.index
deb76a2b-09cc-11e9-9129-5242cf3bb246.000001
e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
deb76a2b-09cc-11e9-9129-5242cf3bb246.000003
```

- Executing the following `purge-relay` command in dmctl purges all relay log files **before** `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002/mysql-bin.000001`, which

are all relay log files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000001`. Files in `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002` and `deb76a2b-09cc-11e9-9129-5242cf3bb246.000003` are retained.

```
purge-relay -s mysql-replica-01 --filename mysql-bin.000001 --sub-dir
    ↪ e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
```

- Executing the following `purge-relay` command in dmctl purges all relay log files **before the current** (`deb76a2b-09cc-11e9-9129-5242cf3bb246.000003`) directory's `mysql-bin.000001`, which are all relay log files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000001` and `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002`. Files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000003` are retained.

```
purge-relay -s mysql-replica-01 --filename mysql-bin.000001
```

Internal mechanism of relay log

This section introduces the internal mechanism of relay log.

Directory structure

An example of the directory structure of the local storage for a relay log:

```
<deploy_dir>/<relay_log>/
|-- 7e427cc0-091c-11e9-9e45-72b7c59d52d7.000001
|   |-- mysql-bin.000001
|   |-- mysql-bin.000002
|   |-- mysql-bin.000003
|   |-- mysql-bin.000004
|   `-- relay.meta
|-- 842965eb-091c-11e9-9e45-9a3bff03fa39.000002
|   |-- mysql-bin.000001
|   `-- relay.meta
`-- server-uuid.index
```

- `subdir`:
    - DM-worker stores the binlog migrated from the upstream database in the same directory. Each directory is a `subdir`.
    - `subdir` is named in the format of `<Upstream database UUID>.<Local subdir serial number>`.
    - After a switch between primary and secondary instances in the upstream, DM-worker generates a new `subdir` directory with an incremental serial number.
    - In the above example, for the `7e427cc0-091c-11e9-9e45-72b7c59d52d7.000001` directory, `7e427cc0-091c-11e9-9e45-72b7c59d52d7` is the upstream database UUID and `000001` is the local `subdir` serial number.

- `server-uuid.index`: records a list of the currently available `subdir` directories.
- `relay.meta`: stores the information of the migrated binlog in each `subdir`. For example,

```
cat c0149e17-dff1-11e8-b6a8-0242ac110004.000001/relay.meta
```

```
binlog-name = "mysql-bin.000010"                          # The name of the
    ↪ currently migrated binlog.
binlog-pos = 63083620                                     # The position of
    ↪ the currently migrated binlog.
binlog-gtid = "c0149e17-dff1-11e8-b6a8-0242ac110004:1-3328" # GTID of
    ↪ the currently migrated binlog.
```

There might also be multiple GTIDs:

```
cat 92acbd8a-c844-11e7-94a1-1866daf8accc.000001/relay.meta
```

```
binlog-name = "mysql-bin.018393"
binlog-pos = 277987307
binlog-gtid = "3ccc475b-2343-11e7-be21-6c0b84d59f30:1-14,406a3f61-690d
    ↪ -11e7-87c5-6c92bf46f384:1-94321383,53bfca22-690d-11e7-8a62-18
    ↪ ded7a37b78:1-495,686e1ab6-c47e-11e7-a42c-6c92bf46f384
    ↪ :1-34981190,03fc0263-28c7-11e7-a653-6c0b84d59f30:1-7041423,05474
    ↪ d3c-28c7-11e7-8352-203db246dd3d:1-170,10b039fc-c843-11e7-8f6a
    ↪ -1866daf8d810:1-308290454"
```

The position where DM receives the binlog

- DM obtains the earliest position that each migration task needs from the saved checkpoint (in the downstream `dm_meta` schema by default). If this position is later than any of the following positions, DM starts to migrate from this position.
- If the local relay log is valid, which means that the relay log contains valid `server-uuid.index`, `subdir`, and `relay.meta` files, DM-worker recovers the migration from the position recorded in `relay.meta`.
- If there is no valid local relay log, but the upstream data source configuration file specifies `relay-binlog-name` or `relay-binlog-gtid`:
  - In non-GTID mode, if `relay-binlog-name` is specified, DM-worker starts to migrate from the specified binlog file.
  - In GTID mode, if `relay-binlog-gtid` is specified, DM-worker starts to migrate from the specified GTID.
- If there is no valid local relay log and the `relay-binlog-name` or `relay-binlog-gtid` is not specified in the DM configuration file:

- In non-GTID mode, DM-worker starts to migrate from the earliest binlog that each subtask is migrating, until the latest binlog is migrated.
- In GTID mode, DM-worker starts to migrate from the earliest GTID that each subtask is migrating, until the latest GTID is migrated.

> **Note:**
>
> If the upstream relay log is purged, an error occurs. In this case, you need to configure `relay-binlog-gtid` to specify the start position of the migration.

13.6.8.1.4 Special Handling of DM DDLs

When TiDB Data Migration (DM) migrates data, it parses the DDL statements and handles them according to the statement type and the current migration stage.

Skip DDL statements

The following statements are not supported by DM, so DM skips them directly after parsing.

```
<tr>
    <th>Description</th>
    <th>SQL</th>
</tr>
<tr>
    <td>transaction</td>
    <td><code>^SAVEPOINT</code></td>
</tr>
<tr>
    <td>skip all flush sqls</td>
    <td><code>^FLUSH</code></td>
</tr>
<tr>
    <td rowspan="3">table maintenance</td>
    <td><code>^OPTIMIZE\\s+TABLE</code></td>
</tr>
<tr>
    <td><code>^ANALYZE\\s+TABLE</code></td>
</tr>
<tr>
    <td><code>^REPAIR\\s+TABLE</code></td>
</tr>
<tr>
    <td>temporary table</td>
```

```
    <td><code>^DROP\\s+(\\/\\*\\!40005\\s+)?TEMPORARY\\s+(\\*\\/\\s+)?TABLE
       ↪ </code></td>
</tr>
<tr>
    <td rowspan="2">trigger</td>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?TRIGGER</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+TRIGGER</code></td>
</tr>
<tr>
    <td rowspan="3">procedure</td>
    <td><code>^DROP\\s+PROCEDURE</code></td>
</tr>
<tr>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?PROCEDURE</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+PROCEDURE</code></td>
</tr>
<tr>
    <td rowspan="3">view</td>
    <td><code>^CREATE\\s*(OR REPLACE)?\\s+(ALGORITHM\\s?=.+?)?(DEFINER\\s
       ↪ ?=.+?)?\\s+(SQL SECURITY DEFINER)?VIEW</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+VIEW</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+(ALGORITHM\\s?=.+?)?(DEFINER\\s?=.+?)?(SQL SECURITY
       ↪ DEFINER)?VIEW</code></td>
</tr>
<tr>
    <td rowspan="4">function</td>
    <td><code>^CREATE\\s+(AGGREGATE)?\\s*?FUNCTION</code></td>
</tr>
<tr>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?FUNCTION</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+FUNCTION</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+FUNCTION</code></td>
</tr>
```

```
<tr>
    <td rowspan="3">tableSpace</td>
    <td><code>^CREATE\\s+TABLESPACE</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+TABLESPACE</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+TABLESPACE</code></td>
</tr>
<tr>
    <td rowspan="3">event</td>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?EVENT</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+(DEFINER\\s?=.+?)?EVENT</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+EVENT</code></td>
</tr>
<tr>
    <td rowspan="7">account management</td>
    <td><code>^GRANT</code></td>
</tr>
<tr>
    <td><code>^REVOKE</code></td>
</tr>
<tr>
    <td><code>^CREATE\\s+USER</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+USER</code></td>
</tr>
<tr>
    <td><code>^RENAME\\s+USER</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+USER</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+USER</code></td>
</tr>
```

Rewrite DDL statements

The following statements are rewritten before being replicated to the downstream.

Original statement	Rewritten statement
`^CREATE DATABASE...`	`^CREATE DATABASE...IF NOT EXISTS`
`^CREATE TABLE...`	`^CREATE TABLE..IF NOT EXISTS`
`^DROP DATABASE...`	`^DROP DATABASE...IF EXISTS`
`^DROP TABLE...`	`^DROP TABLE...IF EXISTS`
`^DROP INDEX...`	`^DROP INDEX...IF EXISTS`

Shard merge migration tasks

When DM merges and migrates tables in pessimistic or optimistic mode, the behavior of DDL replication is different from that in other scenarios. For details, refer to Pessimistic Mode and Optimistic Mode.

Online DDL

The Online DDL feature also handles DDL events in a special way. For details, refer to Migrate from Databases that Use GH-ost/PT-osc.

13.6.8.2 Mechanism

13.6.8.2.1 DML Replication Mechanism in Data Migration

This document introduces how the core processing unit Sync in DM processes DML statements read from the data source or relay log. This document introduces the complete processing flow of DML events in DM, including the logic of binlog reading, filtering, routing, transformation, optimization, and execution. This document also explains the DML optimization logic and DML execution logic in detail.

DML processing flow

The Sync unit processes DML statements as follows:

1. Read the binlog event from the MySQL, MariaDB, or relay log.
2. Transform the binlog event read from the data source:
    1. Binlog filter: filter binlog events according to binlog expressions, configured by `filters`.
    2. Table routing: transform the "database/table" name according to the "database/table" routing rule, configured by `routes`.
    3. Expression filter: filter binlog events according to SQL expressions, configured by `expression-filter`.
3. Optimize the DML execution plan:

1. Compactor: merge multiple operations on the same record (with the same primary key) into one operation. This feature is enabled by `syncer.compact`.
2. Causality: perform conflict detection on different records (with different primary keys) to improve the concurrency of replication.
3. Merger: merge multiple binlog events into one DML statement, enabled by `syncer.multiple-rows`.

4. Execute the DML to the downstream.

5. Periodically save the binlog position or GTID to the checkpoint.

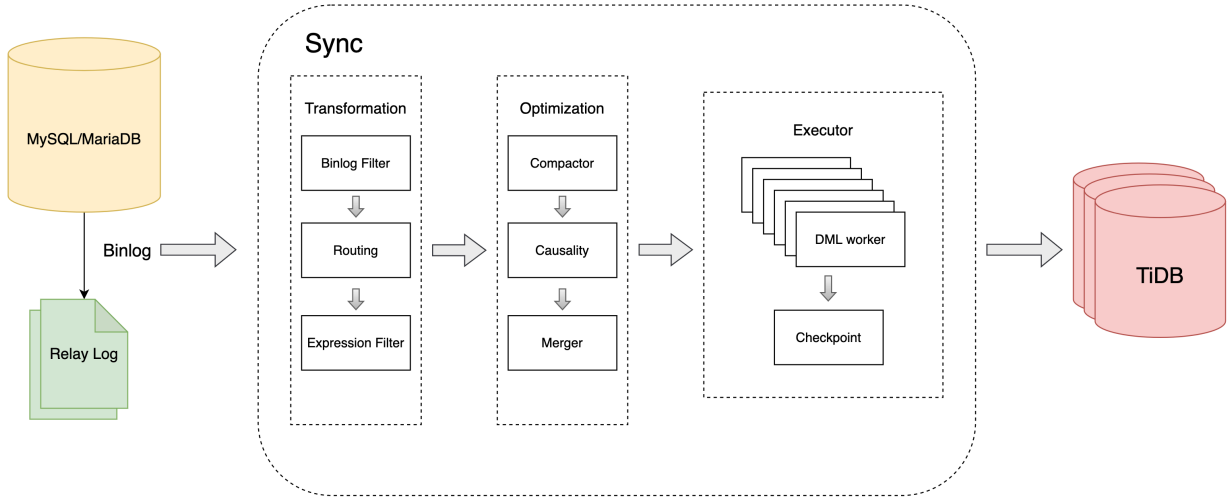

Figure 463: DML processing logic

DML optimization logic

The Sync unit implements the DML optimization logic through three steps: Compactor, Causality, and Merger.

Compactor

According to the binlog records of the upstream, DM captures the changes of the records and replicates them to the downstream. When the upstream makes multiple changes to the same record (`INSERT`/`UPDATE`/`DELETE`) in a short period of time, DM can compress multiple changes into one change through Compactor to reduce the pressure on the downstream and improve the throughput. For example:

```
INSERT + UPDATE => INSERT
INSERT + DELETE => DELETE
UPDATE + UPDATE => UPDATE
UPDATE + DELETE => DELETE
DELETE + INSERT => UPDATE
```

The Compactor feature is disabled by default. To enable it, you can set `syncer.compact` to `true` in the `sync` configuration module of the replication task, as shown below:

```
syncers:                          # The configuration parameters of the sync
    ↪ processing unit
  global:                         # Configuration name
    ...                            # Other configurations are omitted
    compact: true
```

Causality

The sequential replication model of MySQL binlog requires that binlog events be replicated in the order of binlog. This replication model cannot meet the requirements of high QPS and low replication latency. In addition, because not all operations involved in binlog have conflicts, sequential replication is not necessary in those cases.

DM recognizes the binlog that needs to be executed sequentially through conflict detection, and ensures that these binlog are executed sequentially while maximizing the concurrency of other binlog. This helps improve the performance of binlog replication.

Causality adopts an algorithm similar to the union-find algorithm to classify each DML and group DMLs that are related to each other.

Merger

According to the MySQL binlog protocol, each binlog corresponds to a change operation of one row of data. Through Merger, DM can merge multiple binlogs into one DML and execute it to the downstream, reducing the network interaction. For example:

```
  INSERT tb(a,b) VALUES(1,1);
+ INSERT tb(a,b) VALUES(2,2);
= INSERT tb(a,b) VALUES(1,1),(2,2);
  UPDATE tb SET a=1, b=1 WHERE a=1;
+ UPDATE tb SET a=2, b=2 WHERE a=2;
= INSERT tb(a,b) VALUES(1,1),(2,2) ON DUPLICATE UPDATE a=VALUES(a), b=VALUES
    ↪ (b)
  DELETE tb WHERE a=1
+ DELETE tb WHERE a=2
= DELETE tb WHERE (a) IN (1),(2);
```

The Merger feature is disabled by default. To enable it, you can set `syncer.multiple-rows` to `true` in the `sync` configuration module of the replication task, as shown below:

```
syncers:                          # The configuration parameters of the sync
    ↪ processing unit
  global:                         # Configuration name
    ...                            # Other configurations are omitted
    multiple-rows: true
```

DML execution logic

After the Sync unit optimizes the DML, it performs the execution logic.

DML generation

DM has an embedded schema tracker that records the schema information of the upstream and downstream:

- When DM receives a DDL statement, DM updates the table schema of the internal schema tracker.
- When DM receives a DML statement, DM generates the corresponding DML according to the table schema of the schema tracker.

The logic of generating DML is as follows:

1. The Sync unit records the initial table structure of the upstream:
    - When starting a full and incremental task, Sync uses the **table structure exported during the upstream full data migration** as the initial table structure of the upstream.
    - When starting an incremental task, because MySQL binlog does not record the table structure information, Sync uses the **table structure of the corresponding table in the downstream** as the initial table structure of the upstream.
2. The user's upstream and downstream table structures might be inconsistent, for example, the downstream might have additional columns than the upstream, or the upstream and downstream primary keys are inconsistent. Therefore, to ensure the correctness of data replication, DM records the **primary key and unique key information of the corresponding table in the downstream**.
3. DM generates DML:
    - Use the **the upstream table structure recorded in the schema tracker** to generate the column names of the DML statement.
    - Use the **column values recorded in the binlog** to generate the column values of the DML statement.
    - Use the **downstream primary key or unique key recorded in the schema tracker** to generate the `WHERE` condition of the DML statement. When the table structure has no unique key, DM uses all the column values recorded in the binlog as the `WHERE` condition.

Worker count

Causality can divide binlog into multiple groups through conflict detection and execute them concurrently to the downstream. DM controls the concurrency by setting `worker-count`. When the CPU usage of the downstream TiDB is not high, increasing the concurrency can effectively improve the throughput of data replication.

You can modify the number of threads that concurrently migrate DML by modifying the `syncer.worker-count` configuration item.

Batch

DM batches multiple DMLs into a single transaction and executes it to the downstream. When a DML worker receives a DML, it adds the DML to the cache. When the number of DMLs in the cache reaches the preset threshold, or the DML worker does not receive DML for a long time, the DML worker executes the DMLs in the cache to the downstream.

You can modify the number of DMLs contained in a transaction by modifying the `syncer.batch` configuration item.

checkpoint

The operation of executing DML and updating checkpoint is not atomic.

In DM, checkpoint is updated every 30 seconds by default. Because there are multiple DML worker processes, the checkpoint process calculates the binlog position of the earliest replication progress of all DML workers, and uses this position as the current replication checkpoint. All binlogs earlier than this position are guaranteed to be successfully executed to the downstream.

Notes

Transaction consistency

DM replicates data at the row level and does not guarantee transaction consistency. In DM, an upstream transaction is split into multiple rows and distributed to different DML workers for concurrent execution. Therefore, when the DM replication task reports an error and pauses, or when the user manually pauses the task, the downstream might be in an intermediate state. That is, the DML statements in an upstream transaction might be partially replicated to the downstream, which might cause the downstream to be in an inconsistent state.

To ensure that the downstream is in a consistent state when the task is paused as much as possible, starting from DM v5.3.0, DM waits for 10 seconds before pausing the task to ensure that all transactions from the upstream are replicated to the downstream. However, if a transaction is not replicated to the downstream within 10 seconds, the downstream might still be in an inconsistent state.

Safe mode

The operation of DML execution and checkpoint update is not atomic, and the operation of checkpoint update and writing data to the downstream is also not atomic. When DM exits abnormally, the checkpoint might only record a recovery point before the exit time. Therefore, when the task is restarted, DM might write the same data multiple times, which means that DM actually provides the “at least once processing” logic, and the same data might be processed more than once.

To make sure the data is reentrant, DM enters the safe mode when it restarts from an abnormal exit.

When the safe mode is enabled, to make sure that data can be processed multiple times, DM performs the following conversions:

- Rewrite the `INSERT` statement of the upstream to the `REPLACE` statement.
- Rewrite the `UPDATE` statement of the upstream to the `DELETE` + `REPLACE` statement.

Exactly-once processing

Currently, DM only guarantees eventual consistency and does not support "exactly-once processing" and "keeping the original order of transactions".

13.6.8.3 Command Line

13.6.8.3.1 TiDB Data Migration Command-line Flags

This document introduces DM's command-line flags.

DM-master

`--advertise-addr`

- The external address of DM-master used to receive client requests
- The default value is `"{master-addr}"`
- Optional flag. It can be in the form of `"domain-name:port"`

`--advertise-peer-urls`

- The external address for communication between DM-master nodes
- The default value is `"{peer-urls}"`
- Optional flag. It can be in the form of `"http(s)://domain-name:port"`

`--config`

- The configuration file path of DM-master
- The default value is `""`
- Optional flag

`--data-dir`

- The directory used to store data of DM-master
- The default value is `"default.{name}"`
- Optional flag

`--initial-cluster`

- The `"{node name}={external address}"` list used to bootstrap DM-master cluster
- The default value is `"{name}={advertise-peer-urls}"`
- This flag needs to be specified if the `join` flag is not specified. A configuration example of a 3-node cluster is `"dm-master-1=http://172.16.15.11:8291,dm-master-2=http ↪ ://172.16.15.12:8291,dm-master-3=http://172.16.15.13:8291"`

`--join`

- The existing cluster's `advertise-addr` list when a DM-master node joins this cluster
- The default value is `""`
- This flag needs to be specified if the `initial-cluster` flag is not specified. Suppose a new node joins a cluster that has 2 nodes, a configuration example is `"172.16.15.11:8261,172.16.15.12:8261"`

`--log-file`

- The output file name of the log
- The default value is `""`
- Optional flag

`-L`

- The log level
- The default value is `"info"`
- Optional flag

`--master-addr`

- The address on which DM-master listens to the client's requests
- The default value is `""`
- Required flag

`--name`

- The name of a DM-master node
- The default value is `"dm-master-{hostname}"`
- Required flag

`--peer-urls`

- The listening address for communications between DM-master nodes
- The default value is `"http://127.0.0.1:8291"`

- Required flag

DM-worker

`--advertise-addr`

- The external address of DM-worker used to receive client requests
- The default value is `"{worker-addr}"`
- Optional flag. It can be in the form of `"domain-name:port"`

`--config`

- The configuration file path of DM-worker
- The default value is `""`
- Optional flag

`--join`

- The `{advertise-addr}` list of DM-master nodes in a cluster when a DM-worker registers to this cluster
- The default value is `""`
- Required flag. A configuration example of 3-node (DM-master node) cluster is `"172.16.15.11:8261,172.16.15.12:8261,172.16.15.13:8261"`

`--log-file`

- The output file name of the log
- The default value is `""`
- Optional flag

`-L`

- The log level
- The default value is `"info"`
- Optional flag

`--name`

- The name of a DM-worker node
- The default value is `"{advertise-addr}"`
- Required flag

`--worker-addr`

- The address on which DM-worker listens to the client's requests
- The default value is `""`
- Required flag

dmctl

`--config`

- The configuration file path of dmctl
- The default value is `""`
- Optional flag

`--master-addr`

- The `{advertise-addr}` of any DM-master node in the cluster to be connected by dmctl
- The default value is `""`
- It is a required flag when dmctl interacts with DM-master

`--encrypt`

- Encrypts the plaintext database password into ciphertext
- The default value is `""`
- When this flag is specified, it is only used to encrypt the plaintext without interacting with the DM-master

`--decrypt`

- Decrypts ciphertext encrypted with dmctl into plaintext
- The default value is `""`
- When this flag is specified, it is only used to decrypt the ciphertext without interacting with the DM-master

13.6.8.4 Configuration Files

13.6.8.4.1 Data Migration Configuration File Overview

This document gives an overview of configuration files of DM (Data Migration).

DM process configuration files

- `dm-master.toml`: The configuration file of running the DM-master process, including the topology information and the logs of the DM-master. For more details, refer to DM-master Configuration File.
- `dm-worker.toml`: The configuration file of running the DM-worker process, including the topology information and the logs of the DM-worker. For more details, refer to DM-worker Configuration File.
- `source.yaml`: The configuration of the upstream database such as MySQL and MariaDB. For more details, refer to Upstream Database Configuration File.

DM migration task configuration

Data migration task creation

You can take the following steps to create a data migration task:

1. Load the data source configuration into the DM cluster using dmctl.
2. Refer to the description in the Task Configuration Guide and create the configuration file `your_task.yaml`.
3. Create the data migration task using dmctl.

Important concepts

This section shows description of some important concepts.

Concept	Description	Configuration File
`source-id`	Uniquely represents a MySQL or MariaDB instance, or a migration group with the primary-secondary structure. The maximum length of `source-id` is 32.	`source_id` of `source.yaml`; `source-id` of `task.yaml`
DM-master ID	Uniquely represents a DM-master (by the `master-addr` parameter of `dm-master.toml`)	`master-addr` of `dm-master.toml`
DM-worker ID	Uniquely represents a DM-worker (by the `worker-addr` parameter of `dm-worker.toml`)	`worker-addr` of `dm-worker.toml`

13.6.8.4.2 Upstream Database Configuration File of TiDB Data Migration

This document introduces the configuration file of the upstream database, including a configuration file template and the description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of the upstream database:

```
source-id: "mysql-replica-01"

##### Whether to enable GTID.
enable-gtid: false

##### Whether to enable relay log.
enable-relay: false
relay-binlog-name: ""  # The file name from which DM-worker starts to pull
    ↪ the binlog.
relay-binlog-gtid: ""  # The GTID from which DM-worker starts to pull the
    ↪ binlog.
##### relay-dir: "relay-dir" # The directory used to store relay log. The
    ↪ default value is "relay-dir". This configuration item is marked as
    ↪ deprecated since v6.1 and replaced by a parameter of the same name in
    ↪  the dm-worker configuration.

from:
  host: "127.0.0.1"
  port: 3306
  user: "root"
  password: "ZqMLjZ2j5khNelDEfDoUhkD5aV5fIJOe0fiog9w=" # The user password
      ↪ of the upstream database. It is recommended to use the password
      ↪ encrypted with dmctl.
  security:                   # The TLS configuration of the upstream
      ↪ database
    ssl-ca: "/path/to/ca.pem"
    ssl-cert: "/path/to/cert.pem"
    ssl-key: "/path/to/key.pem"

##### purge:
#####  interval: 3600
#####  expires: 0
#####  remain-space: 15

##### checker:
#####  check-enable: true
#####  backoff-rollback: 5m0s
#####  backoff-max: 5m0s    # The maximum value of backoff, should be larger
    ↪  than 1s

##### Configure binlog event filters. New in DM v2.0.2
```

```
##### case-sensitive: false
##### filters:
##### - schema-pattern: dmctl
#####  table-pattern: t_1
#####  events: []
#####  sql-pattern:
#####  - alter table .* add column `aaa` int
#####  action: Ignore
```

Note:

In DM v2.0.1, DO NOT set `enable-gtid` and `enable-relay` to `true` at the same time. Otherwise, it may cause loss of incremental data.

Configuration parameters

This section describes each configuration parameter in the configuration file.

Global configuration

Parameter	Description
`source-id`	Represents a MySQL instance ID.
`enable-gtid`	Determines whether to pull binlog from the upstream using GTID. The default value is `false`. In general, you do not need to configure `enable-gtid` manually. However, if GTID is enabled in the upstream database, and the primary/secondary switch is required, you need to set `enable-gtid` to `true`.
`enable-relay`	Determines whether to enable the relay log feature. The default value is `false`. This parameter takes effect from v5.4. Additionally, you can enable relay log dynamically using the `start-relay` command.

Parameter	Description
`relay-binlog-name`	Specifies the file name from which DM-worker starts to pull the binlog. For example, `"mysql-bin.000002"`. It only works when `enable_gtid` is `false`. If this parameter is not specified, DM-worker will start pulling from the earliest binlog file being replicated. Manual configuration is generally not required.
`relay-binlog-gtid`	Specifies the GTID from which DM-worker starts to pull the binlog. For example, `"e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849"`. It only works when `enable_gtid` is `true`. If this parameter is not specified, DM-worker will start pulling from the latest GTID being replicated. Manual configuration is generally not required.
`relay-dir`	Specifies the relay log directory.
`host`	Specifies the host of the upstream database.
`port`	Specifies the port of the upstream database.
`user`	Specifies the username of the upstream database.
`password`	Specifies the user password of the upstream database. It is recommended to use the password encrypted with dmctl.
`security`	Specifies the TLS config of the upstream database. The configured file paths of the certificates must be accessible to all nodes. If the configured file paths are local paths, then all the nodes in the cluster need to store a copy of the certificates in the same path of each host.

Relay log cleanup strategy configuration (`purge`)

Generally, there is no need to manually configure these parameters unless there is a large amount of relay logs and disk capacity is insufficient.

Parameter	Description	Default value
`interval`	Sets the time interval at which relay logs are regularly checked for expiration, in seconds.	`3600`

Parameter	Description	Default value
`expires`	Sets the expiration time for relay logs, in hours. The relay log that is not written by the relay processing unit, or does not need to be read by the existing data migration task will be deleted by DM if it exceeds the expiration time. If this parameter is not specified, the automatic purge is not performed.	`0`
`remain-space`	Sets the minimum amount of free disk space, in gigabytes. When the available disk space is smaller than this value, DM-worker tries to delete relay logs.	`15`

Note:

The automatic data purge strategy only takes effect when `interval` is not 0 and at least one of the two configuration items `expires` and `remain-space` is not 0.

Task status checker configuration (`checker`)

DM periodically checks the current task status and error message to determine if resuming the task will eliminate the error. If needed, DM automatically retries to resume the task. DM adjusts the checking interval using the exponential backoff strategy. Its behaviors can be adjusted by the following configuration.

Parameter	Description
`check-enable`	Whether to enable this feature.
`backoff-` ↪ `rollback`	If the current checking interval of backoff strategy is larger than this value and the task status is normal, DM will try to decrease the interval.
`backoff-max`	The maximum value of checking interval of backoff strategy, must be larger than 1 second.

Binlog event filter

Starting from DM v2.0.2, you can configure binlog event filters in the source configuration file.

Parameter	Description
`case-sensitive`	Determines whether the filtering rules are case-sensitive. The default value is `false`.
`filters`	Sets binlog event filtering rules. For details, see Binlog event filter parameter explanation.

13.6.8.4.3 DM Advanced Task Configuration File

This document introduces the advanced task configuration file of Data Migration (DM), including global configuration and instance configuration.

Important concepts

For description of important concepts including `source-id` and the DM-worker ID, see Important concepts.

Task configuration file template (advanced)

The following is the task configuration file template which allows you to perform **advanced** data migration tasks.

```
---

##### ----------- Global configuration -----------
###### ********* Basic configuration *********
name: test                  # The name of the task. Should be globally
   ↪ unique.
task-mode: all              # The task mode. Can be set to `full`(only
   ↪ migrates full data)/`incremental`(replicates binlogs synchronously)/`
   ↪ all` (replicates both full data and incremental binlogs).
shard-mode: "pessimistic"   # The shard merge mode. Optional modes are ""/"
   ↪ pessimistic"/"optimistic". The "" mode is used by default which means
   ↪  sharding DDL merge is disabled. If the task is a shard merge task,
   ↪ set it to the "pessimistic" mode.
                            # After understanding the principles and
                               ↪ restrictions of the "optimistic" mode,
                               ↪ you can set it to the "optimistic" mode.
meta-schema: "dm_meta"      # The downstream database that stores the `meta`
   ↪  information.
timezone: "Asia/Shanghai"   # The timezone used in SQL Session. By default,
   ↪ DM uses the global timezone setting in the target cluster, which
   ↪ ensures the correctness automatically. A customized timezone does not
   ↪  affect data migration but is unnecessary.
case-sensitive: false       # Determines whether the schema/table is case-
   ↪ sensitive.
```

```
online-ddl: true            # Supports automatic processing of upstream "gh-
    ↪ ost" and "pt".
online-ddl-scheme: "gh-ost" # `online-ddl-scheme` is deprecated, so it is
    ↪ recommended to use `online-ddl`.
clean-dump-file: true       # Whether to clean up the files generated during
    ↪  data dump. Note that these include `metadata` files.
collation_compatible: "loose" # The mode to sync the default collation in `
    ↪ CREATE` SQL statements. The supported values are "loose" (by default)
    ↪  or "strict". When the value is "strict", DM explicitly appends the
    ↪ corresponding collation of the upstream to the SQL statements; when
    ↪ the value is "loose", DM does not modify the SQL statements. In "
    ↪ strict" mode, if the downstream does not support the default
    ↪ collation in the upstream, the downstream might report an error.
ignore-checking-items: []   # Ignorable checking items. For the complete
    ↪ list of ignorable checking items, see DM precheck: https://docs.
    ↪ pingcap.com/tidb/stable/dm-precheck#ignorable-checking-items.

target-database:            # Configuration of the downstream database
    ↪ instance.
  host: "192.168.0.1"
  port: 4000
  user: "root"
  password: "/Q7B9DizNLLTTfiZHv9WoEAKamfpIUs=" # It is recommended to use a
      ↪ password encrypted with `dmctl encrypt`.
  max-allowed-packet: 67108864            # Sets the "max_allowed_packet"
      ↪ limit of the TiDB client (that is, the limit of the maximum accepted
      ↪  packet) when DM internally connects to the TiDB server. The unit is
      ↪  bytes. (67108864 by default)
                                          # Since DM v2.0.0, this
                                             ↪ configuration item is
                                             ↪ deprecated, and DM
                                             ↪ automatically obtains the "
                                             ↪ max_allowed_packet" value
                                             ↪ from TiDB.
  session:                                 # The session variables of TiDB,
      ↪ supported since v1.0.6. For details, go to `https://pingcap.com/docs
      ↪ /stable/system-variables`.
    sql_mode: "ANSI_QUOTES,NO_ZERO_IN_DATE,NO_ZERO_DATE" # Since DM v2.0.0,
        ↪ if this item does not appear in the configuration file, DM
        ↪ automatically fetches a proper value for "sql_mode" from the
        ↪ downstream TiDB. Manual configuration of this item has a higher
        ↪ priority.
    tidb_skip_utf8_check: 1               # Since DM v2.0.0, if this item
        ↪ does not appear in the configuration file, DM automatically
        ↪ fetches a proper value for "tidb_skip_utf8_check" from the
```

```
      ↪ downstream TiDB. Manual configuration of this item has a higher
      ↪ priority.
    tidb_constraint_check_in_place: 0
  security:                   # The TLS configuration of the downstream TiDB
    ssl-ca: "/path/to/ca.pem"
    ssl-cert: "/path/to/cert.pem"
    ssl-key: "/path/to/key.pem"

###### ******** Feature configuration set **********
##### The routing mapping rule set between the upstream and downstream
   ↪ tables.
routes:
  route-rule-1:             # The name of the routing mapping rule.
    schema-pattern: "test_*" # The pattern of the upstream schema name,
      ↪ wildcard characters (*?) are supported.
    table-pattern: "t_*"    # The pattern of the upstream table name,
      ↪ wildcard characters (*?) are supported.
    target-schema: "test"   # The name of the downstream schema.
    target-table: "t"       # The name of the downstream table.
    # Optional. Used for extracting the source information of sharded
      ↪ schemas and tables and writing the information to the user-defined
      ↪  columns in the downstream. If these options are configured, you
      ↪ need to manually create a merged table in the downstream. For
      ↪ details, see description of table routing in <https://docs.pingcap
      ↪ .com/tidb/v7.1/dm-table-routing>.
    # extract-table:                                  # Extracts and writes
      ↪ the table name suffix without the t_ part to the c-table column of
      ↪  the merged table. For example, 01 is extracted and written to the
      ↪  c-table column for the sharded table t_01.
    #   table-regexp: "t_(.*)"
    #   target-column: "c_table"
    # extract-schema:                                 # Extracts and writes
      ↪ the schema name suffix without the test_ part to the c_schema
      ↪ column of the merged table. For example, 02 is extracted and
      ↪ written to the c_schema column for the sharded schema test_02.
    #   schema-regexp: "test_(.*)"
    #   target-column: "c_schema"
    # extract-source:                                 # Extracts and writes
      ↪ the source instance information to the c_source column of the
      ↪ merged table. For example, mysql-replica-01 is extracted and
      ↪ written to the c_source column for the data source mysql-replica
      ↪ -01.
    #   source-regexp: "(.*)"
    #   target-column: "c_source"
```

```
  route-rule-2:
    schema-pattern: "test_*"
    target-schema: "test"

##### The binlog event filter rule set of the matched table of the upstream
    ↪ database instance.
filters:
  filter-rule-1:                          # The name of the filtering rule.
    schema-pattern: "test_*"              # The pattern of the upstream
       ↪ schema name, wildcard characters (*?) are supported.
    table-pattern: "t_*"                  # The pattern of the upstream
       ↪ schema name, wildcard characters (*?) are supported.
    events: ["truncate table", "drop table"] # What event types to match.
    action: Ignore                        # Whether to migrate (Do) or
       ↪ ignore (Ignore) the binlog that matches the filtering rule.
  filter-rule-2:
    schema-pattern: "test_*"
    events: ["all dml"]
    action: Do

expression-filter:                # Defines the filter rules for row changes
    ↪ when migrating data. Supports defining multiple rules.
  # Filter the value of inserted `c` in `expr_filter`.`tbl` when it is even.
  even_c:                         # The name of the filter rule.
    schema: "expr_filter"         # The name of upstream database to be
       ↪ matched. Wildcard match or regular match is not supported.
    table: "tbl"                  # The name of upstream table to be matched.
       ↪  Wildcard match or regular match is not supported.
    insert-value-expr: "c % 2 = 0"

##### The filter rule set of tables to be migrated from the upstream
    ↪ database instance. You can set multiple rules at the same time.
block-allow-list:                 # Use black-white-list if the DM version is
    ↪  earlier than or equal to v2.0.0-beta.2.
  bw-rule-1:                      # The name of the block allow list rule.
    do-dbs: ["~^test.*", "user"] # The allow list of upstream schemas needs
       ↪ to be migrated.
    ignore-dbs: ["mysql", "account"] # The block list of upstream schemas
       ↪ needs to be migrated.
    do-tables:                    # The allow list of upstream tables needs
       ↪ to be migrated.
    - db-name: "~^test.*"
      tbl-name: "~^t.*"
    - db-name: "user"
      tbl-name: "information"
```

```
  bw-rule-2:                    # The name of the block allow list rule.
    ignore-tables:              # The block list of upstream tables needs
       ↪ to be migrated.
    - db-name: "user"
      tbl-name: "log"

##### Configuration arguments of the dump processing unit.
mydumpers:
  global:                       # The configuration name of the processing
     ↪ unit.
    threads: 4                  # The number of threads that access the
       ↪ upstream when the dump processing unit performs the precheck and
       ↪ exports data from the upstream database (4 by default)
    chunk-filesize: 64          # The size of the file generated by the
       ↪ dump processing unit (64 MB by default).
    extra-args: "--consistency none" # Other arguments of the dump
       ↪ processing unit. You do not need to manually configure table-list
       ↪ in `extra-args`, because it is automatically generated by DM.

##### Configuration arguments of the load processing unit.
loaders:
  global:                       # The configuration name of the processing
     ↪ unit.
    pool-size: 16               # The number of threads that concurrently
       ↪ execute dumped SQL files in the load processing unit (16 by
       ↪ default). When multiple instances are migrating data to TiDB at
       ↪ the same time, slightly reduce the value according to the load.
    # The directory that stores full data exported from the upstream ("./
       ↪ dumped_data" by default).
    # Supoprts a local filesystem path or an Amazon S3 path. For example, "
       ↪ s3://dm_bucket/dumped_data?endpoint=s3-website.us-east-2.amazonaws
       ↪ .com&access_key=s3accesskey&secret_access_key=s3secretkey&
       ↪ force_path_style=true"
    dir: "./dumped_data"

    # The import mode during the full import phase. The following modes are
       ↪ supported:
    # - "logical" (default). Uses TiDB Lightning's logical import mode to
       ↪ import data. Document: https://docs.pingcap.com/tidb/stable/tidb-
       ↪ lightning-logical-import-mode
    # - "physical". Uses TiDB Lightning's physical import mode to import
       ↪ data. Document: https://docs.pingcap.com/zh/tidb/stable/tidb-
       ↪ lightning-physical-import-mode
    #   The "physical" mode is still an experimental feature and is not
       ↪ recommended in production.
```

```
import-mode: "logical"
#  Methods to resolve conflicts in logical import.
# - "replace" (default). Uses the new data to replace the existing data.
# - "ignore". Keeps the existing data, and ignores the new data.
# - "error". Reports errors when inserting duplicated data, and then
   ↪ stops the replication task.
on-duplicate-logical: "replace"

#  Methods to resolve conflicts in physical import.
# - "none". Corresponds to the "none" strategy of conflict detection in
   ↪ TiDB Lightning's physical import.
#   (https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
   ↪ mode-usage#conflict-detection).
#   Conflicting data is not resolved in this method. "none" has the best
   ↪ performance, but
#   might lead to inconsistent data in the downstream database.
# - "manual". Corresponds to the "remove" strategy of conflict detection
   ↪  in TiDB Lightning's physical import.
#   (https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
   ↪ mode-usage#conflict-detection).
#   When the import encounter conflicting data, DM removes all
   ↪ conflicting records from
#   the target table and records the data in the `${meta-schema}_${name}.
   ↪ conflict_error_v1`
#   table. In this configuration file, the conflicting data is recorded
   ↪ in the
#   `dm_meta_test.conflict_error_v1` table. When the full import phase is
   ↪  completed, the
#   tasks is paused and you are prompted to query this table and manually
   ↪  resolve the
#   conflicts. You need to resume the task and enter the incremental
   ↪ phase using the `resume-task` command.
on-duplicate-physical: "none"
# The directory used for local KV sorting in the physical import mode.
   ↪ The default value of this
# configuration is the same as the `dir` configuration. For details,
   ↪ refer to TiDB Lightning document: https://docs.pingcap.com/tidb/
   ↪ stable/tidb-lightning-physical-import-mode#environment-
   ↪ requirements
sorting-dir-physical: "./dumped_data"
# Disk quota. Corresponds to the disk-quota configuration of TiDB
   ↪ Lightning. For details, refer to TiDB Lightning document: https://
   ↪ docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-mode-
   ↪ usage#configure-disk-quota-new-in-v620
disk-quota-physical: "0"
```

```
    # DM performs `ADMIN CHECKSUM TABLE <table>` for each table to verify
      ↪ data integrity after the import.
    # - "required" (default): performs admin checksum after the import. If
      ↪ checksum fails,
    #  DM pauses the task and you need to manually handle the failure.
    # - "optional": performs admin checksum after the import. If checksum
      ↪ fails, DM logs a
    #  warning and continues to migrate data. The task is not paused.
    # - "off": does not perform admin checksum after the import.
    # If checksum fails, the import is abnormal, which means the data is
      ↪ inconsistent or lost.
    # Therefore, it is recommended to always enable checksum.
    checksum-physical: "required"
    # Only available for physical import. Determines whether to perform the
      ↪ `ANALYZE TABLE <table>` operation for each table after the
      ↪ CHECKSUM process is completed.
    # - "required" (default). Indicates that the Analyze operation will be
      ↪ performed after the import is complete. If the analysis fails, the
      ↪  task will pause and require manual processing by the user.
    # - "optional". Indicates that the data will be analyzed after the
      ↪ import is complete. If the analysis fails, a warning log will be
      ↪ printed and the task will not be paused.
    # - "off". Indicates that no data analysis will be performed after the
      ↪ import is complete.
    # Analyze only affects statistics data and it is recommended that
      ↪ Analyze is set to off in most scenarios.
    analyze: "off"
    # Only available for physical import. The concurrency of sending KV data
      ↪  to TiKV. This can be increased when the direct network transfer
      ↪ speed between dm-worker and TiKV exceeds 10,000 Mb/s.
    # range-concurrency: 16
    # Only available for physical import mode. Whether to enable compression
      ↪  when sending KV data to TiKV. Currently, only Gzip compression is
      ↪  supported and can be specified using either "gzip" or "gz".
      ↪ Compression is not enabled by default.
    # compress-kv-pairs: ""
    # One or more PD server addresses. If no address is specified, use the
      ↪ PD address information from the TiDB query by default.
    # pd-addr: "192.168.0.1:2379"

##### Configuration arguments of the sync processing unit.
syncers:
  global:                       # The configuration name of the processing
    ↪ unit.
    worker-count: 16            # The number of concurrent threads that
```

```
    ↪ apply binlogs which have been transferred to the local (16 by
    ↪ default). Adjusting this parameter has no effect on the
    ↪ concurrency of upstream pull logs, but has a significant effect on
    ↪  the downstream database.
batch: 100                  # The number of SQL statements in a
    ↪ transaction batch that the sync processing unit replicates to the
    ↪ downstream database (100 by default). Generally, it is recommended
    ↪  to set the value less than 500.
enable-ansi-quotes: true    # Enable this argument if `sql-mode: "
    ↪ ANSI_QUOTES"` is set in the `session`

# If set to true, `INSERT` statements from upstream are rewritten to `
    ↪ REPLACE` statements, and `UPDATE` statements are rewritten to `
    ↪ DELETE` and `REPLACE` statements. This ensures that DML statements
    ↪  can be imported repeatedly during data migration when there is
    ↪ any primary key or unique index in the table schema.
safe-mode: false
# The duration of the automatic safe mode.
# If this value is not set or set to "", the default value is twice of `
    ↪ checkpoint-flush-interval` (30s by default), which is 60s.
# If this value is set to "0s", DM reports an error when it
    ↪ automatically enters the safe mode.
# If this value is set to a normal value, such as "1m30s", when the task
    ↪  pauses abnormally, when DM fails to
# record safemode_exit_point, or when DM exits unexpectedly, the
    ↪ duration of the automatic safe mode is set to
# 1 minute 30 seconds.
safe-mode-duration: "60s"

# If set to true, DM compacts as many upstream statements on the same
    ↪ rows as possible into a single statements without increasing
    ↪ latency.
# For example, `INSERT INTO tb(a,b) VALUES(1,1); UPDATE tb SET b=11
    ↪ WHERE a=1`;` will be compacted to `INSERT INTO tb(a,b) VALUES
    ↪ (1,11);`, where "a" is the primary key
# `UPDATE tb SET b=1 WHERE a=1; UPDATE tb(a,b) SET b=2 WHERE a=1;` will
    ↪ be compacted to `UPDATE tb(a,b) SET b=2 WHERE a=1;`, where "a" is
    ↪ the primary key
# `DELETE FROM tb WHERE a=1; INSERT INTO tb(a,b) VALUES(1,1);` will be
    ↪ compacted to `REPLACE INTO tb(a,b) VALUES(1,1);`, where "a" is the
    ↪  primary key
compact: false
# If set to true, DM combines as many statements of the same type as
    ↪ possible into a single statement and generates a single SQL
    ↪ statement with multiple rows of data.
```

```
    # For example, `INSERT INTO tb(a,b) VALUES(1,1); INSERT INTO tb(a,b)
       ↪ VALUES(2,2);` will become `INSERT INTO tb(a,b) VALUES(1,1),(2,2);`
    # `UPDATE tb SET b=11 WHERE a=1; UPDATE tb(a,b) set b=22 WHERE a=2;`
       ↪ will become `INSERT INTO tb(a,b) VALUES(1,11),(2,22) ON DUPLICATE
       ↪ KEY UPDATE a=VALUES(a), b= VALUES(b);`, where "a" is the primary
       ↪ key
    # `DELETE FROM tb WHERE a=1; DELETE FROM tb WHERE a=2` will become `
       ↪ DELETE FROM tb WHERE (a) IN (1),(2)`, where "a" is the primary key
    multiple-rows: true

##### Configuration arguments of continuous data validation (validator).
validators:
  global:             # Configuration name.
    # full: validates the data in each row is correct.
    # fast: validates whether the row is successfully migrated to the
       ↪ downstream.
    # none: does not validate the data.
    mode: full        # Possible values are "full", "fast", and "none". The
       ↪ default value is "none", which does not validate the data.
    worker-count: 4   # The number of validation workers in the background.
       ↪ The default value is 4.
    row-error-delay: 30m # If a row cannot pass the validation within the
       ↪ specified time, it will be marked as an error row. The default
       ↪ value is 30m, which means 30 minutes.

##### ----------- Instance configuration -----------
mysql-instances:
  -
    source-id: "mysql-replica-01"             # The `source-id` in source.
       ↪ toml.
    meta:                                     # The position where the
       ↪ binlog replication starts when `task-mode` is `incremental` and
       ↪ the downstream database checkpoint does not exist. If the
       ↪ checkpoint exists, the checkpoint is used. If neither the `meta`
       ↪ configuration item nor the downstream database checkpoint exists,
       ↪ the migration starts from the latest binlog position of the
       ↪ upstream.

      binlog-name: binlog.000001
      binlog-pos: 4
      binlog-gtid: "03fc0263-28c7-11e7-a653-6c0b84d59f30:1-7041423,05474d3c
         ↪ -28c7-11e7-8352-203db246dd3d:1-170" # You need to set this
         ↪ argument if you specify `enable-gtid: true` for the source of
         ↪ the incremental task.
```

```
  route-rules: ["route-rule-1", "route-rule-2"] # The name of the mapping
    ↪ rule between the table matching the upstream database instance and
    ↪  the downstream database.
  filter-rules: ["filter-rule-1", "filter-rule-2"]         # The name of
    ↪ the binlog event filtering rule of the table matching the upstream
    ↪  database instance.
  block-allow-list: "bw-rule-1"             # The name of the block and
    ↪ allow lists filtering rule of the table matching the upstream
    ↪ database instance. Use black-white-list if the DM version is
    ↪ earlier than or equal to v2.0.0-beta.2.
  expression-filters: ["even_c"]            # Use expression filter rule
    ↪ named even_c.
  mydumper-config-name: "global"            # The name of the mydumpers
    ↪ configuration.
  loader-config-name: "global"              # The name of the loaders
    ↪ configuration.
  syncer-config-name: "global"              # The name of the syncers
    ↪ configuration.
  validator-config-name: "global"           # The name of the validators
    ↪ configuration.

-
  source-id: "mysql-replica-02"             # The `source-id` in source.
    ↪ toml.
  mydumper-thread: 4                        # The number of threads that
    ↪ the dump processing unit uses for dumping data. `mydumper-thread`
    ↪ corresponds to the `threads` configuration item of the mydumpers
    ↪ configuration. `mydumper-thread` has overriding priority when the
    ↪ two items are both configured.
  loader-thread: 16                         # The number of threads that
    ↪ the load processing unit uses for loading data. `loader-thread`
    ↪ corresponds to the `pool-size` configuration item of the loaders
    ↪ configuration. `loader-thread` has overriding priority when the
    ↪ two items are both configured. When multiple instances are
    ↪ migrating data to TiDB at the same time, reduce the value
    ↪ according to the load.
  syncer-thread: 16                         # The number of threads that
    ↪ the sync processing unit uses for replicating incremental data. `
    ↪ syncer-thread` corresponds to the `worker-count` configuration
    ↪ item of the syncers configuration. `syncer-thread` has overriding
    ↪ priority when the two items are both configured. When multiple
    ↪ instances are migrating data to TiDB at the same time, reduce the
    ↪ value according to the load.
```

Configuration order

From the sample configuration file, you can see that the configuration file contains two parts: `Global configuration` and `Instance configuration`, where the `Global configuration` contains `Basic configuration` and `Feature configuration set`. The configuration order is as follows:

1. Edit the global configuration.
2. Edit the instance configuration based on the global configuration.

Global configuration

Basic configuration

Refer to the comments in the template to see more details. Detailed explanations about `task-mode` are as follows:

- Description: the task mode that can be used to specify the data migration task to be executed.
- Value: string (`full`, `incremental`, or `all`).
    - `full` only makes a full backup of the upstream database and then imports the full data to the downstream database.
    - `incremental`: Only replicates the incremental data of the upstream database to the downstream database using the binlog. You can set the `meta` configuration item of the instance configuration to specify the starting position of incremental replication.
    - `all`: `full` + `incremental`. Makes a full backup of the upstream database, imports the full data to the downstream database, and then uses the binlog to make an incremental replication to the downstream database starting from the exported position during the full backup process (binlog position).

Feature configuration set

Arguments in each feature configuration set are explained in the comments in the template.

Parameter	Description
`routes`	The routing mapping rule set between the upstream and downstream tables. If the names of the upstream and downstream schemas and tables are the same, this item does not need to be configured. See Table Routing for usage scenarios and sample configurations.

Parameter	Description
`filters`	The binlog event filter rule set of the matched table of the upstream database instance. If binlog filtering is not required, this item does not need to be configured. See Binlog Event Filter for usage scenarios and sample configurations.
`block-allow-list`	The filter rule set of the block allow list of the matched table of the upstream database instance. It is recommended to specify the schemas and tables that need to be migrated through this item, otherwise all schemas and tables are migrated. See Binlog Event Filter and Block & Allow Lists for usage scenarios and sample configurations.
`mydumpers`	Configuration arguments of dump processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure `thread` only using `mydumper-thread`.
`loaders`	Configuration arguments of load processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure `pool-size` only using `loader-thread`.
`syncers`	Configuration arguments of sync processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure `worker-count` only using `syncer-thread`.

Instance configuration

This part defines the subtask of data migration. DM supports migrating data from one or multiple MySQL instances in the upstream to the same instance in the downstream.

For the configuration details of the above options, see the corresponding part in Feature configuration set, as shown in the following table.

Option	Corresponding part
`route-rules`	`routes`
`filter-rules`	`filters`
`block-allow-list`	`block-allow-list`

Option	Corresponding part
mydumper-config-name	mydumpers
loader-config-name	loaders
syncer-config-name	syncers

13.6.8.4.4 DM-master Configuration File

This document introduces the configuration of DM-master, including a configuration file template and a description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of DM-master.

```
name = "dm-master"

##### log configuration
log-level = "info"
log-file = "dm-master.log"

##### DM-master listening address
master-addr = ":8261"
advertise-addr = "127.0.0.1:8261"

##### URLs for peer traffic
peer-urls = "http://127.0.0.1:8291"
advertise-peer-urls = "http://127.0.0.1:8291"

##### cluster configuration
initial-cluster = "master1=http://127.0.0.1:8291,master2=http
    ↪ ://127.0.0.1:8292,master3=http://127.0.0.1:8293"
join = ""

ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/cert.pem"
ssl-key = "/path/to/key.pem"
cert-allowed-cn = ["dm"]
```

Configuration parameters

This section introduces the configuration parameters of DM-master.

Global configuration

Parameter	Description
name	The name of the DM-master.

Parameter	Description
`log-level`	Specifies a log level from `debug`, `info`, `warn`, `error`, and `fatal`. The default log level is `info`.
`log-file`	Specifies the log file directory. If the parameter is not specified, the logs are printed onto the standard output.
`master-addr`	Specifies the address of DM-master which provides services. You can omit the IP address and specify the port number only, such as ":8261".
`advertise-addr`	Specifies the address that DM-master advertises to the outside world.
`peer-urls`	Specifies the peer URL of the DM-master node.
`advertise-peer-urls`	Specifies the peer URL that DM-master advertises to the outside world. The value of `advertise-peer-urls` is by default the same as that of `peer-urls`.
`initial-cluster`	The value of `initial-cluster` is the combination of the `advertise-peer-urls` value of all DM-master nodes in the initial cluster.
`join`	The value of `join` is the combination of the `advertise-peer-urls` value of the existed DM-master nodes in the cluster. If the DM-master node is newly added, replace `initial-cluster` with `join`.
`ssl-ca`	The path of the file that contains list of trusted SSL CAs for DM-master to connect with other components.
`ssl-cert`	The path of the file that contains X509 certificate in PEM format for DM-master to connect with other components.
`ssl-key`	The path of the file that contains X509 key in PEM format for DM-master to connect with other components.
`cert-allowed-cn`	Common Name list.

13.6.8.4.5 DM-worker Configuration File

This document introduces the configuration of DM worker, including a configuration file template and a description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of the DM-worker:

```
##### Worker Configuration.
name = "worker1"

##### Log configuration.
log-level = "info"
log-file = "dm-worker.log"

##### DM-worker listen address.
worker-addr = ":8262"
advertise-addr = "127.0.0.1:8262"
join = "http://127.0.0.1:8261,http://127.0.0.1:8361,http://127.0.0.1:8461"

keepalive-ttl = 60
relay-keepalive-ttl = 1800 # New in DM v2.0.2.
##### relay-dir = "relay_log" # New in 5.4.0. When you use a relative path,
    ↪ check the deployment and start method of DM-worker to determine the
    ↪ full path.

ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/cert.pem"
ssl-key = "/path/to/key.pem"
cert-allowed-cn = ["dm"]
```

Configuration parameters

Global

Parameter	Description
`name`	The name of the DM-worker.
`log-level`	Specifies a log level from `debug`, `info`, `warn`, `error`, and `fatal`. The default log level is `info`.
`log-file`	Specifies the log file directory. If this parameter is not specified, the logs are printed onto the standard output.
`worker-addr`	Specifies the address of DM-worker which provides services. You can omit the IP address and specify the port number only, such as ":8262".
`advertise-addr`	Specifies the address that DM-worker advertises to the outside world.
`join`	Corresponds to one or more `master-addrs` in the DM-master configuration file.

Parameter	Description
`keepalive-ttl`	The keepalive time (in seconds) of a DM-worker node to the DM-master node if the upstream data source of the DM-worker node does not enable the relay log. The default value is 60s.
`relay-keepalive-ttl`	The keepalive time (in seconds) of a DM-worker node to the DM-master node if the upstream data source of the DM-worker node enables the relay log. The default value is 1800s. This parameter is added since DM v2.0.2.
`relay-dir`	When relay log is enabled in the bound upstream data source, DM-worker stores the relay log in this directory. This parameter is new in v5.4.0 and takes precedence over the configuration of the upstream data source.
`ssl-ca`	The path of the file that contains list of trusted SSL CAs for DM-worker to connect with other components.
`ssl-cert`	The path of the file that contains X509 certificate in PEM format for DM-worker to connect with other components.
`ssl-key`	The path of the file that contains X509 key in PEM format for DM-worker to connect with other components.
`cert-allowed-cn`	Common Name list.

13.6.8.4.6 Table Selector of TiDB Data Migration

Table selector provides a match rule based on wildcard characters for schema/table. To match a specified table, configure `schema-pattern/table-pattern`.

Wildcard character

Table selector uses the following two wildcard characters in `schema-pattern/table-pattern`:

- The asterisk character (`*`, also called "star")
  - `*` matches zero or more characters. For example, `doc*` matches `doc` and `document` but not `dodo`.
  - `*` can only be placed at the end of the word. For example, `doc*` is supported, while `do*c` is not supported.

- The question mark (`?`)

  `?` matches exactly one character except the empty character.

Match rules

- `schema-pattern` cannot be empty.
- `table-pattern` can be empty. When you configure it as empty, only `schema` is matched according to `schema-pattern`.
- When `table-pattern` is not empty, the `schema` is matched according to `schema-pattern` and `table` is matched according to `table-pattern`. Only when both `schema` and `table` are successfully matched, you can get the match result.

Usage examples

- Matching all schemas and tables that have a `schema_` prefix in the schema name:

```
schema-pattern: "schema_*"
table-pattern: ""
```

- Matching all tables that have a `schema_` prefix in the schema name and a `table_` prefix in the table name:

```
schema-pattern = "schema_*"
table-pattern = "table_*"
```

13.6.8.5 Maintain DM Clusters Using OpenAPI

DM provides the OpenAPI feature for easily querying and operating the DM cluster, which is similar to the feature of dmctl tools.

To enable OpenAPI, perform one of the following operations:

- If your DM cluster has been deployed directly using binary, add the following configuration to the DM-master configuration file.

```
openapi = true
```

- If your DM cluster has been deployed using TiUP, add the following configuration to the topology file:

```
server_configs:
  master:
    openapi: true
```

Note:

- DM provides the specification document that meets the OpenAPI 3.0.0 standard. This document contains all the request parameters and returned values. You can copy the document yaml and preview it in Swagger Editor.
- After you deploy the DM-master nodes, you can access `http://{master-addr}/api/v1/docs` to preview the documentation online.
- Some features supported in the configuration file are not supported in OpenAPI. Their capabilities are not fully aligned. In a production environment, it is recommended to use the configuration file.

You can use the APIs to perform the following maintenance operations on the DM cluster:

13.6.8.5.1 APIs for managing clusters

- Get the information of a DM-master node
- Stop a DM-master node
- Get the information of a DM-worker node
- Stop a DM-worker node

13.6.8.5.2 APIs for managing data sources

- Create a data source
- Get a data source
- Delete the data source
- Update a data source
- Enable a data source
- Disable a data source
- Get the information of a data source
- Get the data source list
- Start the relay-log feature for data sources
- Stop the relay-log feature for data sources
- Purge relay-log files that are no longer required
- Change the bindings between the data source and DM-workers
- Get the list of schema names of a data source
- Get the list of table names of a specified schema in a data source

13.6.8.5.3 APIs for managing replication tasks

- Create a replication task
- Get a replication task
- Delete a replication task
- Update a replication task
- Start a replication task
- Stop a replication task
- Get the information of a replication task
- Get the replication task list
- Get the migration rules of a replication task
- Get the list of schema names of the data source that is associated with a replication task
- Get the list of table names of a specified schema in the data source that is associated with a replication task
- Get the CREATE statement for schemas of the data source that is associated with a replication task
- Update the CREATE statement for schemas of the data source that is associated with a replication task
- Delete a schema of the data source that is associated with a replication task

The following sections describe the specific usage of the APIs.

13.6.8.5.4 API error message template

After sending an API request, if an error occurs, the returned error message is in the following format:

```
{
    "error_msg": "",
    "error_code": ""
}
```

From the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

13.6.8.5.5 Get the information of a DM-master node

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/cluster/masters`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/cluster/masters' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
      "name": "master1",
      "alive": true,
      "leader": true,
      "addr": "127.0.0.1:8261"
    }
  ]
}
```

13.6.8.5.6 Stop a DM-master node

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

`DELETE /api/v1/cluster/masters/{master-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/cluster/masters/master1' \
  -H 'accept: */*'
```

13.6.8.5.7 Get the information of a DM-worker node

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/cluster/workers`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/cluster/workers' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
      "name": "worker1",
      "addr": "127.0.0.1:8261",
      "bound_stage": "bound",
      "bound_source_name": "mysql-01"
    }
  ]
}
```

13.6.8.5.8 Stop a DM-worker node

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

`DELETE /api/v1/cluster/workers/{worker-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/cluster/workers/worker1' \
  -H 'accept: */*'
```

13.6.8.5.9 Create a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Request URI

`POST /api/v1/sources`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
```

```
  "enable": true,
  "enable_gtid": false,
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
    "expires": 0,
    "remain_space": 15
  }
}'
```

```
{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
  "enable": true,
  "enable_gtid": false,
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
    "expires": 0,
    "remain_space": 15
  },
  "status_list": [
    {
      "source_name": "mysql-replica-01",
      "worker_name": "worker-1",
      "relay_status": {
        "master_binlog": "(mysql-bin.000001, 1979)",
        "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
```

```
      "relay_dir": "./sub_dir",
      "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",

      "stage": "Running"
    },
    "error_msg": "string"
  }
 ]
}
```

13.6.8.5.10 Get a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Request URI

`GET /api/v1/sources/{source-name}`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/source-1?with_status=true' \
  -H 'accept: application/json'
```

```
{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
  "enable_gtid": false,
  "enable": false,
  "flavor": "mysql",
  "task_name_list": [
    "task1"
  ],
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
```

```
    "expires": 0,
    "remain_space": 15
  },
  "status_list": [
    {
      "source_name": "mysql-replica-01",
      "worker_name": "worker-1",
      "relay_status": {
        "master_binlog": "(mysql-bin.000001, 1979)",
        "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_dir": "./sub_dir",
        "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_catch_up_master": true,
        "stage": "Running"
      },
      "error_msg": "string"
    }
  ],
  "relay_config": {
    "enable_relay": true,
    "relay_binlog_name": "mysql-bin.000002",
    "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
    "relay_dir": "./relay_log"
  }
}
```

13.6.8.5.11 Delete the data source

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

`DELETE /api/v1/sources/{source-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01?force=true' \
  -H 'accept: application/json'
```

13.6.8.5.12 Update a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

> **Note:**
>
> When you use this API to update the data source configuration, make sure that there are no running tasks under the current data source.

Request URI

`PUT /api/v1/sources/{source-name}`

Example

```
curl -X 'PUT' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{
  "source": {
    "source_name": "mysql-01",
    "host": "127.0.0.1",
    "port": 3306,
    "user": "root",
    "password": "123456",
    "enable_gtid": false,
    "enable": false,
    "flavor": "mysql",
    "task_name_list": [
      "task1"
    ],
    "security": {
      "ssl_ca_content": "",
      "ssl_cert_content": "",
      "ssl_key_content": "",
      "cert_allowed_cn": [
        "string"
      ]
    },
    "purge": {
      "interval": 3600,
      "expires": 0,
      "remain_space": 15
    },
    "relay_config": {
      "enable_relay": true,
      "relay_binlog_name": "mysql-bin.000002",
```

```
    "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
    "relay_dir": "./relay_log"
   }
  }
}'
```

```
{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
  "enable": true,
  "enable_gtid": false,
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
    "expires": 0,
    "remain_space": 15
  }
}
```

13.6.8.5.13 Enable a data source

This is a synchronous interface that enables a data source on a successful request and starts all subtasks of the task that rely on this data source in batch.

Request URI

`POST /api/v1/sources/{source-name}/enable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/enable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json'
```

13.6.8.5.14 Disable a data source

This is a synchronous interface that deactivates this data source on a successful request and stops all subtasks of the task that rely on it in batch.

Request URI

`POST /api/v1/sources/{source-name}/disable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/disable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json'
```

13.6.8.5.15 Get the data source list

This API is a synchronous interface. If the request is successful, the data source list is returned.

Request URI

`GET /api/v1/sources`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources?with_status=true' \
  -H 'accept: application/json'
```

```
{
  "data": [
    {
      "enable_gtid": false,
      "host": "127.0.0.1",
      "password": "******",
      "port": 3306,
      "purge": {
        "expires": 0,
        "interval": 3600,
        "remain_space": 15
      },
      "security": null,
      "source_name": "mysql-01",
      "user": "root"
    },
    {
      "enable_gtid": false,
      "host": "127.0.0.1",
```

```
      "password": "******",
      "port": 3307,
      "purge": {
        "expires": 0,
        "interval": 3600,
        "remain_space": 15
      },
      "security": null,
      "source_name": "mysql-02",
      "user": "root"
    }
  ],
  "total": 2
}
```

13.6.8.5.16 Get the information of a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/sources/{source-name}/status`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-replica-01/status' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
      "source_name": "mysql-replica-01",
      "worker_name": "worker-1",
      "relay_status": {
        "master_binlog": "(mysql-bin.000001, 1979)",
        "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_dir": "./sub_dir",
        "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_catch_up_master": true,
        "stage": "Running"
      },
      "error_msg": "string"
    }
  ]
```

```
}
```

13.6.8.5.17 Start the relay-log feature for data sources

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a data source.

Request URI

`POST /api/v1/sources/{source-name}/relay/enable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/enable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "worker_name_list": [
    "worker-1"
  ],
  "relay_binlog_name": "mysql-bin.000002",
  "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
  "relay_dir": "./relay_log"
}'
```

13.6.8.5.18 Stop the relay-log feature for data sources

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a data source.

Request URI

`POST /api/v1/sources/{source-name}/relay/disable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/disable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "worker_name_list": [
    "worker-1"
  ]
}'
```

13.6.8.5.19 Purge relay log files that are no longer required

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a data source.

Request URI

`POST /api/v1/sources/{source-name}/relay/purge`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/purge' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "relay_binlog_name": "mysql-bin.000002",
  "relay_dir": "string"
}'
```

13.6.8.5.20 Change the bindings between the data source and DM-workers

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a DM-worker node.

Request URI

`POST /api/v1/sources/{source-name}/transfer`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/transfer' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "worker_name": "worker-1"
}'
```

13.6.8.5.21 Get the list of schema names of a data source

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

`GET /api/v1/sources/{source-name}/schemas`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/source-1/schemas' \
  -H 'accept: application/json'
```

```
[
  "db1"
]
```

13.6.8.5.22 Get the list of table names of a specified schema in a data source

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

`GET /api/v1/sources/{source-name}/schemas/{schema-name}`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/source-1/schemas/db1' \
  -H 'accept: application/json'
```

```
[
  "table1"
]
```

13.6.8.5.23 Create a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200. A successful request will return the information of the corresponding replication task.

Request URI

`POST /api/v1/tasks`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/tasks' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{
  "task": {
    "name": "task-1",
    "task_mode": "all",
```

13.6.8.5.24 Get a replication task

This API is a synchronous interface. If the request is successful, the information of the corresponding replication task is returned.

Request URI

GET /api/v1/tasks/{task-name}?with_status=true

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1?with_status=true' \
  -H 'accept: application/json'
```

```
{
  "name": "task-1",
  "task_mode": "all",
  "shard_mode": "pessimistic",
  "meta_schema": "dm-meta",
  "enhance_online_schema_change": true,
  "on_duplicate": "overwrite",

```

```
      }
    ]
  }
}
```

13.6.8.5.25 Delete a replication task

This interface is a synchronous interface and the Status Code of the returned body is 204 upon successful request.

Request URI

`DELETE /api/v1/tasks/{task-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1' \
  -H 'accept: application/json'
```

13.6.8.5.26 Update a replication task

This interface is a synchronous interface and a successful request returns the information of the task.

> **Note:**
>
> When you use this API to update the task configuration, make sure that the task is stopped and has run into incremental sync and that only some of the fields can be updated.

Request URI

`PUT /api/v1/tasks/{task-name}`

Example

```
curl -X 'PUT' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{

```

13.6.8.5.27 Start a replication task

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 204. To learn the latest status of a task, You can get the information of a replication task.

Request URI

`POST /api/v1/tasks/{task-name}/start`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/start' \
  -H 'accept: */*'
```

13.6.8.5.28 Stop a replication task

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn the latest status of a task, You can get the information of a replication task.

Request URI

`POST /api/v1/tasks/{task-name}/stop`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/stop' \
  -H 'accept: */*'
```

13.6.8.5.29 Get the information of a replication task

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/tasks/task-1/status`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/status?stage=running' \
  -H 'accept: application/json'
```

```

        }
      ]
    }
  }
 ]
}
```

13.6.8.5.31 Get the migration rules of a replication task

This API is a synchronous interface and a successful request returns a list of the migration rules of this task.

Request URI

`GET /api/v1/tasks/{task-name}/sources/{source-name}/migrate_targets`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/
     ↪ migrate_targets' \
  -H 'accept: application/json'
```

```
{
  "total": 0,
  "data": [
    {
      "source_schema": "db1",
      "source_table": "tb1",
      "target_schema": "db1",
      "target_table": "tb1"
    }
  ]
}
```

13.6.8.5.32 Get the list of schema names of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas
```

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas' \
  -H 'accept: application/json'
```

```
[
  "db1"
]
```

13.6.8.5.33 Get the list of table names of a specified schema in the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-name
↪ }
```

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1' \
  -H 'accept: application/json'
```

```
[
  "table1"
]
```

13.6.8.5.34 Get the CREATE statement for schemas of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding CREATE statement is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-name
↪ }/{table-name}
```

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1/
     ↪ table1' \
  -H 'accept: application/json'
```

```
{
  "schema_name": "db1",
  "table_name": "table1",
  "schema_create_sql": "CREATE TABLE `t1` (`id` int(11) NOT NULL
     ↪ AUTO_INCREMENT,PRIMARY KEY (`id`) /*T![clustered_index] CLUSTERED
     ↪ */) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin"
}
```

13.6.8.5.35 Update the CREATE statement for schemas of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200.

Request URI

```
POST /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-
↪ name}/{table-name}
```

Example

```
curl -X 'PUT' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/task-1/schemas/db1/
     ↪ table1' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "sql_content": "CREATE TABLE `t1` ( `c1` int(11) DEFAULT NULL, `c2` int
     ↪ (11) DEFAULT NULL, `c3` int(11) DEFAULT NULL) ENGINE=InnoDB DEFAULT
     ↪ CHARSET=utf8mb4 COLLATE=utf8mb4_bin;",
  "flush": true,
  "sync": true
}'
```

13.6.8.5.36 Delete a schema of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200.

Request URI

```
DELETE /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-
↪ name}/{table-name}
```

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1/
     ↪ table1' \
  -H 'accept: */*'
```

13.6.8.6 Compatibility Catalog of TiDB Data Migration

DM supports migrating data from different sources to TiDB clusters. Based on the data source type, DM has four compatibility levels:

- **Generally available (GA)**: The application scenario has been verified and passed the GA test.
- **Experimental**: Although the application scenario has been verified, the test does not cover all scenarios or involves only a limited number of users. The application scenario might encounter problems occasionally.
- **Not tested**: DM is expected to be always compatible with MySQL during iteration. However, due to resource constraints, not all MySQL forks are tested with DM. Therefore, the *not tested* source or target is technically compatible with DM, but is not fully tested, which means you need to verify its compatibility before you use.
- **Incompatible**: DM is proved to be incompatible with the data source and the application is not recommended for use in production environments.

13.6.8.6.1 Data sources

Data source	Compatibility level	Remarks
MySQL 5.5	Not tested	
MySQL 5.6	GA	
MySQL 5.7	GA	
MySQL 8.0	Experimental	
MariaDB < 10.1.2	Incompatible	Incompatible with binlog of the time type
MariaDB 10.1.2 ~ 10.5.10	Experimental	
MariaDB > 10.5.10	Incompatible	Permission errors reported in the check procedure

13.6.8.6.2 Target databases

Warning:

DM v5.3.0 is not recommended. If you have enabled GTID replication but do not enable relay log in DM v5.3.0, data replication fails with low probability.

Target database	Compatibility level	DM version
TiDB 8.x	GA	5.3.1
TiDB 7.x	GA	5.3.1
TiDB 6.x	GA	5.3.1
TiDB 5.4	GA	5.3.1
TiDB 5.3	GA	5.3.1
TiDB 5.2	GA	2.0.7, recommended: 5.4
TiDB 5.1	GA	2.0.4, recommended: 5.4
TiDB 5.0	GA	2.0.4, recommended: 5.4
TiDB 4.x	GA	2.0.1, recommended: 2.0.7
TiDB 3.x	GA	2.0.1, recommended: 2.0.7
MySQL	Experimental	
MariaDB	Experimental	

13.6.8.7 Secure

13.6.8.7.1 Enable TLS for DM Connections

This document describes how to enable encrypted data transmission for DM connections, including connections between the DM-master, DM-worker, and dmctl components, and connections between DM and the upstream or downstream database.

Enable encrypted data transmission between DM-master, DM-worker, and dmctl

This section introduces how to enable encrypted data transmission between DM-master, DM-worker, and dmctl.

Configure and enable encrypted data transmission

1. Prepare certificates.

   It is recommended to prepare a server certificate for DM-master and DM-worker separately. Make sure that the two components can authenticate each other. You can choose to share one client certificate for dmctl.

   To generate self-signed certificates, you can use `openssl`, `cfssl` and other tools based on `openssl`, such as `easy-rsa`.

   If you choose `openssl`, you can refer to generating self-signed certificates.

2. Configure certificates.

Note:

You can configure DM-master, DM-worker, and dmctl to use the same set of certificates.

- DM-master

  Configure in the configuration file or command-line arguments:

```
ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/master-cert.pem"
ssl-key = "/path/to/master-key.pem"
```

- DM-worker

  Configure in the configuration file or command-line arguments:

```
ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/worker-cert.pem"
ssl-key = "/path/to/worker-key.pem"
```

- dmctl

  After enabling encrypted transmission in a DM cluster, if you need to connect to the cluster using dmctl, specify the client certificate. For example:

```
./dmctl --master-addr=127.0.0.1:8261 --ssl-ca /path/to/ca.pem --ssl
    ↪ -cert /path/to/client-cert.pem --ssl-key /path/to/client-key
    ↪ .pem
```

Verify component caller's identity

The Common Name is used for caller verification. In general, the callee needs to verify the caller's identity, in addition to verifying the key, the certificates, and the CA provided by the caller. For example, DM-worker can only be accessed by DM-master, and other visitors are blocked even though they have legitimate certificates.

To verify component caller's identity, you need to mark the certificate user identity using `Common Name` (CN) when generating the certificate, and to check the caller's identity by configuring the `Common Name` list for the callee.

- DM-master

  Configure in the configuration file or command-line arguments:

```
cert-allowed-cn = ["dm"]
```

- DM-worker

  Configure in the configuration file or command-line arguments:

```
cert-allowed-cn = ["dm"]
```

Reload certificates

To reload the certificates and the keys, DM-master, DM-worker, and dmctl reread the current certificates and the key files each time a new connection is created.

When the files specified by `ssl-ca`, `ssl-cert` or `ssl-key` are updated, restart DM components to reload the certificates and the key files and reconnect with each other.

Enable encrypted data transmission between DM components and the upstream or downstream database

This section introduces how to enable encrypted data transmission between DM components and the upstream or downstream database.

Enable encrypted data transmission for upstream database

1. Configure the upstream database, enable the encryption support, and set the server certificate. For detailed operations, see Using encrypted connections.
2. Set the MySQL client certificate in the source configuration file:

> **Note:**
> Make sure that all DM-master and DM-worker components can read the certificates and the key files via specified paths.

```
from:
    security:
        ssl-ca: "/path/to/mysql-ca.pem"
        ssl-cert: "/path/to/mysql-cert.pem"
        ssl-key: "/path/to/mysql-key.pem"
```

Enable encrypted data transmission for downstream TiDB

1. Configure the downstream TiDB to use encrypted connections. For detailed operatons, refer to Configure TiDB server to use secure connections.
2. Set the TiDB client certificate in the task configuration file:

> **Note:**
> Make sure that all DM-master and DM-worker components can read the certificates and the key files via specified paths.

```
target-database:
    security:
        ssl-ca: "/path/to/tidb-ca.pem"
        ssl-cert: "/path/to/tidb-client-cert.pem"
        ssl-key: "/path/to/tidb-client-key.pem"
```

13.6.8.7.2 Generate Self-signed Certificates for TiDB Data Migration

This document provides an example of using `openssl` to generate a self-signed certificate for TiDB Data Migration (DM). You can also generate certificates and keys that meet requirements according to your demands.

Assume that the topology of the instance cluster is as follows:

Name	Host IP	Services
node1	172.16.10.11	DM-master1
node2	172.16.10.12	DM-master2
node3	172.16.10.13	DM-master3
node4	172.16.10.14	DM-worker1
node5	172.16.10.15	DM-worker2
node6	172.16.10.16	DM-worker3

Install OpenSSL

- For Debian or Ubuntu OS:

```
apt install openssl
```

- For RedHat or CentOS OS:

```
yum install openssl
```

You can also refer to OpenSSL's official download document for installation.

Generate the CA certificate

A certificate authority (CA) is a trusted entity that issues digital certificates. In practice, contact your administrator to issue the certificate or use a trusted CA. CA manages multiple certificate pairs. Here you only need to generate an original pair of certificates as follows.

1. Generate the CA key:

```
openssl genrsa -out ca-key.pem 4096
```

2. Generate the CA certificates:

```
openssl req -new -x509 -days 1000 -key ca-key.pem -out ca.pem
```

3. Validate the CA certificates:

```
openssl x509 -text -in ca.pem -noout
```

Issue certificates for individual components

Certificates that might be used in the cluster

- The `master` certificate used by DM-master to authenticate DM-master for other components.
- The `worker` certificate used by DM-worker to authenticate DM-worker for other components.
- The `client` certificate used by dmctl to authenticate clients for DM-master and DM-worker.

Issue certificates for DM-master

To issue a certificate to a DM-master instance, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out master-key.pem 2048
```

2. Make a copy of the OpenSSL configuration template file (Refer to the actual location of your template file because it might have more than one location):

```
cp /usr/lib/ssl/openssl.cnf .
```

If you do not know the actual location, look for it in the root directory:

```
find / -name openssl.cnf
```

3. Edit `openssl.cnf`, add `req_extensions = v3_req` under the `[ req ]` field, and add `subjectAltName = @alt_names` under the `[ v3_req ]` field. Finally, create a new field and edit the information of `Subject Alternative Name` (SAN) according to the cluster topology description above.

```
[ alt_names ]
IP.1 = 127.0.0.1
IP.2 = 172.16.10.11
IP.3 = 172.16.10.12
IP.4 = 172.16.10.13
```

The following checking items of SAN are currently supported:

- IP
- DNS
- URI

> **Note:**
>
> If a special IP such as `0.0.0.0` is to be used for connection or communication, you must also add it to `alt_names`.

4. Save the `openssl.cnf` file, and generate the certificate request file: (When giving input to `Common Name (e.g. server FQDN or YOUR name)[]:`, you assign a Common Name (CN) to the certificate, such as `dm`. It is used by the server to validate the identity of the client. Each component does not enable the validation by default. You can enable it in the configuration file.)

```
openssl req -new -key master-key.pem -out master-cert.pem -config
    ↪ openssl.cnf
```

5. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA ca.pem -CAkey ca-key.pem -
    ↪ CAcreateserial -in master-cert.pem -out master-cert.pem -
    ↪ extensions v3_req -extfile openssl.cnf
```

6. Verify that the certificate includes the SAN field (optional):

```
openssl x509 -text -in master-cert.pem -noout
```

7. Confirm that the following files exist in your current directory:

```
ca.pem
master-cert.pem
master-key.pem
```

> **Note:**
>
> The process of issuing certificates for the DM-worker instance is similar and will not be repeated in this document.

Issue certificates for the client (dmctl)

To issue a certificate to the client (dmctl), perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out client-key.pem 2048
```

2. Generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key client-key.pem -out client-cert.pem
```

3. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA ca.pem -CAkey ca-key.pem -
    ↪ CAcreateserial -in client-cert.pem -out client-cert.pem
```

13.6.8.8 Monitoring and Alerts

13.6.8.8.1 Data Migration Monitoring Metrics

If your DM cluster is deployed using TiUP, the monitoring system is also deployed at the same time. This document describes the monitoring metrics provided by DM-worker.

Task

In the Grafana dashboard, the default name of DM is `DM-task`.

`overview`

`Overview` contains some monitoring metrics of all the DM-worker and DM-master instances or sources in the currently selected task. The current default alert rule is only for a single DM-worker/DM-master instance/source.

Metric name	Description	Alert	Severity level
task state	The state of subtasks for migration	N/A	N/A
storage capacity	The total storage capacity of the disk occupied by relay logs	N/A	N/A

Metric name	Description	Alert	Severity level
storage remain	The remaining storage capacity of the disk occupied by relay logs	N/A	N/A
binlog file gap between master and relay	The number of binlog files by which the `relay` processing unit is behind the upstream master	N/A	N/A
load progress	The percentage of the completed loading process of the load unit. The value is between 0%~100%	N/A	N/A
binlog file gap between master and syncer	The number of binlog files by which the binlog replication unit is behind the upstream master	N/A	N/A

Metric name	Description	Alert	Severity level
shard lock resolving	Whether the current subtask is waiting for sharding DDL migration. A value greater than 0 means that the current subtask is waiting for sharding DDL migration	N/A	N/A

Operation errors

Metric name	Description	Alert	Severity level
before any operate error	The number of errors before any operation	N/A	N/A
source bound error	The number of errors of data source binding operations	N/A	N/A
start error	The number of errors during the start of a subtask	N/A	N/A
pause error	The number of errors during the pause of a subtask	N/A	N/A

Metric name	Description	Alert	Severity level
resume error	The number of errors during the resuming of a subtask	N/A	N/A
auto-resume error	The number of errors during the auto-resuming of a subtask	N/A	N/A
update error	The number of errors during the update of a subtask	N/A	N/A
stop error	The number of errors during the stop of a subtask	N/A	N/A

High availability

Metric name	Description	Alert	Severity level
number of dm-masters start leader components per minute	The number of DM-master attempts to enable leader related components per minute	N/A	N/A

Metric name	Description	Alert	Severity level
number of workers in different state	The number of DM-workers in different states	Some DM-worker(s) has (have) been offline for more than one hour	critical
workers' state	The state of the DM-worker	N/A	N/A
number of worker event error	The number of different types of DM-worker errors	N/A	N/A
shard ddl error per minute	The number of different types of sharding DDL errors per minute	Any sharding DDL error occurs	critical
number of pending sharding ddl	The number of pending sharding DDL operations	Any pending sharding DDL operation has existed for more than one hour	critical

Task state

Metric name	Description	Alert	Severity level
task state	The state of subtasks	An alert occurs when the sub-task has been in the `Paused` ↪ state for more than 20 min-utes	critical

Dump/Load unit

The following metrics show only when `task-mode` is in the `full` or `all` mode.

Metric name	Description	Alert	Severity level
dump progress	The percentage of the completed dumping process of the dump unit. The value range is 0%~100%	N/A	N/A

Metric name	Description	Alert	Severity level
load progress	The percentage of the completed loading process of the load unit. The value range is 0%~100%	N/A	N/A
checksum progress	The percentage of the completed checksum process after the load unit finishes dumping. The value range is 0%~100%	N/A	N/A
total bytes for load unit	The bytes processed in the parsing, in generating data KV, and in generating index KV stages of the import process by the load unit	N/A	N/A
chunk process duration	The duration of the load unit processing the data source file chunk (in seconds)	N/A	N/A

Metric name	Description	Alert	Severity level
data file size	The total size of the data files (includes the `INSERT INTO` statement) in the full data imported by the load unit	N/A	N/A
dump process exits with error	The dump unit encounters an error within the DM-worker and exits	Immediate alerts	critical
load process exits with error	The load unit encounters an error within the DM-worker and exits	Immediate alerts	critical

Binlog replication

The following metrics show only when `task-mode` is in the `incremental` or `all` mode.

Metric name	Description	Alert	Severity level
remaining time to sync	The predicted remaining time it takes for `syncer` to be completely migrated with the upstream master (in minutes)	N/A	N/A

Metric name	Description	Alert	Severity level
replicate lag gauge	The latency time it takes to replicate the binlog from upstream to downstream (in seconds)	N/A	N/A
replicate lag histogram	The histogram of replicating the binlog from upstream to downstream (in seconds). Note that due to different statistical mechanisms, the data might be inaccurate	N/A	N/A
process exist with error	The binlog replication unit encounters an error within the DM-worker and exits	Immediate alerts	critical

Metric name	Description	Alert	Severity level
binlog file gap between master and syncer	The number of binlog files by which the `syncer` processing unit is behind the upstream master	An alert occurs when the number of binlog files by which the `syncer` ↪ processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical

Metric name	Description	Alert	Severity level
binlog file gap between relay and syncer	The number of binlog files by which `syncer` is behind `relay`	An alert occurs when the number of binlog files by which the `syncer` ↪ processing unit is behind the `relay` processing unit exceeds one (>1) and the condition lasts over 10 minutes	critical

Metric name	Description	Alert	Severity level
binlog event QPS	The number of binlog events received per unit of time (this number does not include the events that need to be skipped)	N/A	N/A
skipped binlog event QPS	The number of binlog events received per unit of time that need to be skipped	N/A	N/A
read binlog event duration	The duration that the binlog replication unit reads the binlog from the relay log or the upstream MySQL (in seconds)	N/A	N/A
transform binlog event duration	The duration that the binlog replication unit parses and transforms the binlog into SQL statements (in seconds)	N/A	N/A

Metric name	Description	Alert	Severity level
dispatch binlog event duration	The duration that the binlog replication unit dispatches a binlog event (in seconds)	N/A	N/A
transaction execution latency	The duration that the binlog replication unit executes the transaction to the downstream (in seconds)	N/A	N/A
binlog event size	The size of a binlog event that the binlog replication unit reads from the relay log or the upstream MySQL	N/A	N/A
DML queue remain length	The length of the remaining DML job queue	N/A	N/A
total sqls jobs	The number of newly added jobs per unit of time	N/A	N/A
finished sqls jobs	The number of finished jobs per unit of time	N/A	N/A

Metric name	Description	Alert	Severity level
statement execution latency	The duration that the binlog replication unit executes the statement to the downstream (in seconds)	N/A	N/A
add job duration	The duration tht the binlog replication unit adds a job to the queue (in seconds)	N/A	N/A
DML conflict detect duration	The duration that the binlog replication unit detects the conflict in DML (in seconds)	N/A	N/A
skipped event duration	The duration that the binlog replication unit skips a binlog event (in seconds)	N/A	N/A
unsynced tables	The number of tables that have not received the shard DDL statement in the current subtask	N/A	N/A

Metric name	Description	Alert	Severity level
shard lock resolving	Whether the current subtask is waiting for the shard DDL lock to be resolved. A value greater than 0 indicates that it is waiting for the shard DDL lock to be resolved	N/A	N/A
ideal QPS	The highest QPS that can be achieved when the running time of DM is 0	N/A	N/A
binlog event row	The number of rows in a binlog event	N/A	N/A
finished transaction total	The number of finished transactions in total	N/A	N/A
replication transaction batch	The number of sql rows in the transaction executed to the downstream	N/A	N/A
flush checkpoints time interval	The time interval for flushing the checkpoints (in seconds)	N/A	N/A

Relay log

> **Note:**
>
> Currently, DM v2.0 does not support enabling the relay log feature.

Metric name	Description	Alert	Severity level
storage capacity	The storage capacity of the disk occupied by the relay log	N/A	N/A
storage remain	The remaining storage capacity of the disk occupied by the relay log	An alert is needed once the value is smaller than 10G	critical
process exits with error	The relay log encounters an error within the DM-worker and exits	Immediate alerts	critical
relay log data corruption	The number of corrupted relay log files	Immediate alerts	emergency

Metric name	Description	Alert	Severity level
fail to read binlog from master	The number of errors encountered when the relay log reads the binlog from the upstream MySQL	Immediate alerts	critical
fail to write relay log	The number of errors encountered when the relay log writes the binlog to disks	Immediate alerts	critical
binlog file index	The largest index number of relay log files. For example, "value = 1" indicates "relay-log.000001"	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and relay	The number of binlog files in the relay log that are behind the upstream master	An alert occurs when the number of binlog files by which the `relay` processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical
binlog pos	The write offset of the latest relay log file	N/A	N/A

Metric name	Description	Alert	Severity level
read binlog event duration	The duration that the relay log reads binlog from the upstream MySQL (in seconds)	N/A	N/A
write relay log duration	The duration that the relay log writes binlog into the disks each time (in seconds)	N/A	N/A
binlog event size	The size of a single binlog event that the relay log writes into the disks	N/A	N/A

Instance

In the Grafana dashboard, the default name of an instance is `DM-instance`.

Relay log

Metric name	Description	Alert	Severity level
storage capacity	The total storage capacity of the disk occupied by the relay log	N/A	N/A

Metric name	Description	Alert	Severity level
storage remain	The remaining storage capacity within the disk occupied by the relay log	An alert occurs once the value is smaller than 10G	critical
process exits with error	The relay log encounters an error in DM-worker and exits	Immediate alerts	critical
relay log data corruption	The number of corrupted relay logs	Immediate alerts	emergency
fail to read binlog from master	The number of errors encountered when relay log reads the binlog from the upstream MySQL	Immediate alerts	critical
fail to write relay log	The number of errors encountered when the relay log writes the binlog to disks	Immediate alerts	critical

Metric name	Description	Alert	Severity level
binlog file index	The largest index number of relay log files. For example, “value = 1” indicates “relay-log.000001”	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and relay	The number of binlog files by which the `relay` processing unit is behind the upstream master	An alert occurs when the number of binlog files by which the `relay` processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical
binlog pos	The write offset of the latest relay log file	N/A	N/A

Metric name	Description	Alert	Severity level
read binlog duration	The duration that the relay log reads the binlog from the upstream MySQL (in seconds)	N/A	N/A
write relay log duration	The duration that the relay log writes the binlog into the disk each time (in seconds)	N/A	N/A
binlog size	The size of a single binlog event that the relay log writes into the disks	N/A	N/A

Task

Metric name	Description	Alert	Severity level
task state	The state of subtasks for migration	An alert occurs when the sub-task has been paused for more than 10 min-utes	critical

Metric name	Description	Alert	Severity level
load progress	The percentage of the completed loading process of the load unit. The value range is 0%~100%	N/A	N/A
binlog file gap between master and syncer	The number of binlog files by which the binlog replication unit is behind the upstream master	N/A	N/A
shard lock resolving	Whether the current subtask is waiting for sharding DDL migration. A value greater than 0 means that the current subtask is waiting for sharding DDL migration	N/A	N/A

13.6.8.8.2 DM Alert Information

The alert system is deployed by default when you deploy a DM cluster using TiUP.

For more information about DM alert rules and the solutions, refer to handle alerts.

Both DM alert information and monitoring metrics are based on Prometheus. For more

information about their relationship, refer to DM monitoring metrics.

13.6.8.9 Handle Errors in TiDB Data Migration

This document introduces the error system and how to handle common errors when you use DM.

13.6.8.9.1 Error system

In the error system, usually, the information of a specific error is as follows:

- `code`: error code.

  DM uses the same error code for the same error type. An error code does not change as the DM version changes.

  Some errors might be removed during the DM iteration, while the error codes are not. DM uses a new error code instead of an existing one for a new error.

- `class`: error type.

  It is used to mark the component where an error occurs (error source).

  The following table displays all error types, error sources, and error samples.

  |

  Error Type

Error Source	Error Sample
database	Database operations	[code=10003:class=database:scope=downstream:level=medium] database driver: invalid connection
functional	Underlying functions of DM	[code=11005:class=functional:scope=internal:level=high] not allowed operation: alter multiple tables in one statement
config	Incorrect configuration	[code=20005:class=config:scope=internal:level=medium] empty source-id not valid
binlog-op	Binlog operations	[code=22001:class=binlog-op:scope=internal:level=high] empty UUIDs not valid
checkpoint	checkpoint operations	[code=24002:class=checkpoint:scope=internal:level=high] save point bin.1234 is older than current pos bin.1371
task-check	Performing task check	[code=26003:class=task-check:scope=internal:level=medium] new table router error

```
relay-event-lib| Executing the basic functions of the relay module | [code=28001:

[code=48001:class=dmctl:scope=internal:level=high],"can not create grpc
↪  connection" |
```

- `scope`: Error scope.

  It is used to mark the scope and source of DM objects when an error occurs. `scope` includes four types: `not-set`, `upstream`, `downstream`, and `internal`.

  If the logic of the error directly involves requests between upstream and downstream databases, the scope is set to `upstream` or `downstream`; otherwise, it is currently set to `internal`.

- `level`: Error level.

  The severity level of the error, including `low`, `medium`, and `high`.

  - The `low` level error usually relates to user operations and incorrect inputs. It does not affect migration tasks.
  - The `medium` level error usually relates to user configurations. It affects some newly started services; however, it does not affect the existing DM migration status.
  - The `high` level error usually needs your attention, since you need to resolve it to avoid the possible interruption of a migration task.

- `message`: Error descriptions.

  Detailed descriptions of the error. To wrap and store every additional layer of error message on the error call chain, the errors.Wrap mode is adopted. The message description wrapped at the outermost layer indicates the error in DM and the message description wrapped at the innermost layer indicates the error source.

- `workaround`: Error handling methods (optional)

  The handling methods for this error. For some confirmed errors (such as configuration errors), DM gives the corresponding manual handling methods in `workaround`.

- Error stack information (optional)

  Whether DM outputs the error stack information depends on the error severity and the necessity. The error stack records the complete stack call information when the error occurs. If you cannot figure out the error cause based on the basic information and the error message, you can trace the execution path of the code when the error occurs using the error stack.

For the complete list of error codes, refer to the error code lists.

13.6.8.9.2 Troubleshooting

If you encounter an error while running DM, take the following steps to troubleshoot this error:

1. Execute the `query-status` command to check the task running status and the error output.
2. Check the log files related to the error. The log files are on the DM-master and DM-worker nodes. To get key information about the error, refer to the error system. Then check the Handle Common Errors section to find the solution.
3. If the error is not covered in this document, and you cannot solve the problem by checking the log or monitoring metrics, get support from PingCAP or the community.
4. After the error is resolved, restart the task using dmctl.

```
resume-task ${task name}
```

However, you need to reset the data migration task in some cases. For details, refer to Reset the Data Migration Task.

13.6.8.9.3 Handle common errors

|

Error Code

Error Description	How to Handle
`code=10001`	Abnormal database operation.	Further analyze the error message and error stack.
`code=10002`	The `bad connection` error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is not sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, check the network or TiDB status.
`code=10003`	The `invalid connection` error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is partly sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, further check the error message and analyze the information based on the actual situation.
`code=10005`	Occurs when performing the `QUERY` type SQL statements.	
`code=10006`	Occurs when performing the `EXECUTE` type SQL statements, including DDL statements and DML statements of the `INSERT`, `UPDATE`or `DELETE` type. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.	
`code=11006`	Occurs when the built-in parser of DM parses the incompatible DDL statements.	Refer to Data Migration - incompatible DDL statements for solution.
`code=20010`	Occurs when decrypting the database password that is provided in task configuration.	Check whether the downstream database password provided in the configuration task is correctly encrypted using dmctl.
`code=26002`	The task check fails to establish database connection. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.	Check whether the machine where DM-master is located has permission to access the upstream.
`code=32001`	Abnormal dump processing unit	If the error message contains `mydumper: argument list too long.`, configure the table to be exported by manually adding the `--regex` regular expression in the Mydumper argument `extra-args` in the `task.yaml` file according to the block-allow list. For example, to export all tables named `hello`, add `--regex '.*\\.hello$'`; to export all tables, add `--regex '.*'`.
`code=38008`	An error occurs in the gRPC communication among DM components.	Check `class`. Find out the error occurs in the interaction of which components. Determine the type of communication error. If the error occurs when establishing gRPC connection, check

whether the communication server is working normally. |

What can I do when a migration task is interrupted with the `invalid connection` error returned?

Reason

The `invalid connection` error indicates that anomalies have occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy) and that a part of the data for the current request has been sent to TiDB.

Solutions

Because DM has the feature of concurrently migrating data to the downstream in migration tasks, several errors might occur when a task is interrupted. You can check these errors by using `query-status`.

- If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
- If DM does not or fails to retry automatically because of version problems, use `stop-task` to stop the task and then use `start-task` to restart the task.

A migration task is interrupted with the `driver: bad connection` error returned

Reason

The `driver: bad connection` error indicates that anomalies have occurred in the connection between DM and the upstream TiDB database (such as network failure and TiDB restart) and that the data of the current request has not yet been sent to TiDB at that moment.

Solution

The current version of DM automatically retries on error. If you use the previous version which does not support automatically retry, you can execute the `stop-task` command to stop the task. Then execute `start-task` to restart the task.

The relay unit throws error `event from * in * diff from passed-in event *` or a migration task is interrupted with failing to get or parse binlog errors like `get binlog error ERROR 1236 (HY000)` and `binlog checksum mismatch, data may be corrupted` returned

Reason

During the DM process of relay log pulling or incremental replication, this two errors might occur if the size of the upstream binlog file exceeds **4 GB**.

Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the size of the binlog file, and store the replicated binlog positions as checkpoints. However, the official MySQL uses `uint32` to store binlog positions. This means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

Solutions

For relay units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the DM-worker.

3. Copy the corresponding binlog file in the upstream to the relay log directory as the relay log file.

4. In the relay log directory, update the corresponding `relay.meta` file to pull from the next binlog file. If you have specified `enable_gtid` to `true` for the DM-worker, you need to modify the GTID corresponding to the next binlog file when updating the `relay.meta` file. Otherwise, you don't need to modify the GTID.

   Example: when the error occurs, `binlog-name = "mysql-bin.004451"` and `binlog-pos = 2453`. Update them respectively to `binlog-name = "mysql-bin.004452"` and `binlog-pos = 4`, and update `binlog-gtid` to `f0e914ef-54cf-11e7-813d-6c92bf2fa791:1-138218058`.

5. Restart the DM-worker.

For binlog replication processing units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the migration task using `stop-task`.

3. Update the `binlog_name` in the global checkpoints and in each table checkpoint of the downstream `dm_meta` database to the name of the binlog file in error; update `binlog_pos` to a valid position value for which migration has completed, for example, 4.

   Example: the name of the task in error is `dm_test`, the corresponding `source-id` is `replica-1`, and the corresponding binlog file is `mysql-bin|000001.004451`. Execute the following command:

   ```
   UPDATE dm_test_syncer_checkpoint SET binlog_name='mysql-bin
       ↪ |000001.004451', binlog_pos = 4 WHERE id='replica-1';
   ```

4. Specify `safe-mode: true` in the `syncers` section of the migration task configuration to ensure re-entrant.

5. Start the migration task using `start-task`.

6. View the status of the migration task using `query-status`. You can restore `safe-mode` to the original value and restart the migration task when migration is done for the original error-triggering relay log files.

`Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you query the task or check the log

For database related passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. For how to encrypt the plaintext password, see Encrypt the database password using dmctl.

In addition, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data migration task.

The `load` processing unit reports the error `packet for query is too large. Try adjusting the 'max_allowed_packet' variable`

Reasons

- Both MySQL client and MySQL/TiDB server have the quota limits for `max_allowed_packet` ↪ . If any `max_allowed_packet` exceeds a limit, the client receives the error message. Currently, for the latest version of DM and TiDB server, the default value of `max_allowed_packet` is `64M`.
- The full data import processing unit in DM does not support splitting the SQL file exported by the Dump processing unit in DM.

Solutions

- It is recommended to set the `statement-size` option of `extra-args` for the Dump processing unit:

  According to the default `--statement-size` setting, the default size of `Insert` ↪ `Statement` generated by the Dump processing unit is about `1M`. With this default setting, the load processing unit does not report the error `packet for query is` ↪ `too large. Try adjusting the 'max_allowed_packet' variable` in most cases.

  Sometimes you might receive the following `WARN` log during the data dump. This `WARN` log does not affect the dump process. This only means that wide tables are dumped.

  ```
  Row bigger than statement_size for xxx
  ```

- If the single row of the wide table exceeds `64M`, you need to modify the following configurations and make sure the configurations take effect.
  - Execute `set @@global.max_allowed_packet=134217728` (`134217728` = 128 MB) in the TiDB server.
  - First add the `max-allowed-packet: 134217728` (128 MB) to the `target-` ↪ `database` section in the DM task configuration file. Then, execute the `stop-task` command and execute the `start-task` command.

13.6.8.10 TiDB Data Migration Glossary

This document lists the terms used in the logs, monitoring, configurations, and documentation of TiDB Data Migration (DM).

13.6.8.10.1 B

Binlog

In TiDB DM, binlogs refer to the binary log files generated in the TiDB database. It has the same indications as that in MySQL or MariaDB. Refer to MySQL Binary Log and MariaDB Binary Log for details.

Binlog event

Binlog events are information about data modification made to a MySQL or MariaDB server instance. These binlog events are stored in the binlog files. Refer to MySQL Binlog Event and MariaDB Binlog Event for details.

Binlog event filter

Binlog event filter is a more fine-grained filtering feature than the block and allow lists filtering rule. Refer to binlog event filter for details.

Binlog position

The binlog position is the offset information of a binlog event in a binlog file. Refer to MySQL `SHOW BINLOG EVENTS` and MariaDB `SHOW BINLOG EVENTS` for details.

Binlog replication processing unit/sync unit

Binlog replication processing unit is the processing unit used in DM-worker to read upstream binlogs or local relay logs, and to migrate these logs to the downstream. Each subtask corresponds to a binlog replication processing unit. In the current documentation, the binlog replication processing unit is also referred to as the sync processing unit.

Block & allow table list

Block & allow table list is the feature that filters or only migrates all operations of some databases or some tables. Refer to block & allow table lists for details. This feature is similar to MySQL Replication Filtering and MariaDB Replication Filters.

13.6.8.10.2 C

Checkpoint

A checkpoint indicates the position from which a full data import or an incremental replication task is paused and resumed, or is stopped and restarted.

- In a full import task, a checkpoint corresponds to the offset and other information of the successfully imported data in a file that is being imported. A checkpoint is updated synchronously with the data import task.

- In an incremental replication, a checkpoint corresponds to the binlog position and other information of a binlog event that is successfully parsed and migrated to the downstream. A checkpoint is updated after the DDL operation is successfully migrated or 30 seconds after the last update.

In addition, the `relay.meta` information corresponding to a relay processing unit works similarly to a checkpoint. A relay processing unit pulls the binlog event from the upstream and writes this event to the relay log, and writes the binlog position or the GTID information corresponding to this event to `relay.meta`.

13.6.8.10.3 D

Dump processing unit/dump unit

The dump processing unit is the processing unit used in DM-worker to export all data from the upstream. Each subtask corresponds to a dump processing unit.

13.6.8.10.4 G

GTID

The GTID is the global transaction ID of MySQL or MariaDB. With this feature enabled, the GTID information is recorded in the binlog files. Multiple GTIDs form a GTID set. Refer to MySQL GTID Format and Storage and MariaDB Global Transaction ID for details.

13.6.8.10.5 L

Load processing unit/load unit

The load processing unit is the processing unit used in DM-worker to import the fully exported data to the downstream. Each subtask corresponds to a load processing unit. In the current documentation, the load processing unit is also referred to as the import processing unit.

13.6.8.10.6 M

Migrate/migration

The process of using the TiDB Data Migration tool to copy the **full data** of the upstream database to the downstream database.

In the case of clearly mentioning “full”, not explicitly mentioning “full or incremental”, and clearly mentioning “full + incremental”, use migrate/migration instead of replicate/replication.

13.6.8.10.7 R

Relay log

The relay log refers to the binlog files that DM-worker pulls from the upstream MySQL or MariaDB, and stores in the local disk. The format of the relay log is the standard binlog file, which can be parsed by tools such as mysqlbinlog of a compatible version. Its role is similar to MySQL Relay Log and MariaDB Relay Log.

For more details such as the relay log's directory structure, initial migration rules, and data purge in TiDB DM, see TiDB DM relay log.

Relay processing unit

The relay processing unit is the processing unit used in DM-worker to pull binlog files from the upstream and write data into relay logs. Each DM-worker instance has only one relay processing unit.

Replicate/replication

The process of using the TiDB Data Migration tool to copy the **incremental data** of the upstream database to the downstream database.

In the case of clearly mentioning "incremental", use replicate/replication instead of migrate/migration.

13.6.8.10.8 S

Safe mode

Safe mode is the mode in which DML statements can be imported more than once when the primary key or unique index exists in the table schema. In this mode, some statements from the upstream are migrated to the downstream only after they are re-written. The `INSERT` statement is re-written as `REPLACE`; the `UPDATE` statement is re-written as `DELETE` and `REPLACE`.

This mode is enabled in any of the following situations:

- The safe mode remains enabled when the `safe-mode` parameter in the task configuration file is set to `true`.
- In shard merge scenarios, the safe mode remains enabled before DDL statements are replicated in all sharded tables.
- If the argument `--consistency none` is configured for the dump processing unit of a full migration task, it cannot be determined whether the binlog changes at the beginning of the export affect the exported data or not. Therefore, the safe mode remains enabled for the incremental replication of these binlog changes.
- If the task is paused by error and then resumed, the operations on some data might be executed twice.

Shard DDL

The shard DDL is the DDL statement that is executed on the upstream sharded tables. It needs to be coordinated and migrated by TiDB DM in the process of merging the sharded tables. In the current documentation, the shard DDL is also referred to as the sharding DDL.

Shard DDL lock

The shard DDL lock is the lock mechanism that coordinates the migration of shard DDL. Refer to the implementation principles of merging and migrating data from sharded tables in the pessimistic mode for details. In the current documentation, the shard DDL lock is also referred to as the sharding DDL lock.

Shard group

A shard group is all the upstream sharded tables to be merged and migrated to the same table in the downstream. Two-level shard groups are used for implementation of TiDB DM. Refer to the implementation principles of merging and migrating data from sharded tables in the pessimistic mode for details. In the current documentation, the shard group is also referred to as the sharding group.

Subtask

The subtask is a part of a data migration task that is running on each DM-worker instance. In different task configurations, a single data migration task might have one subtask or multiple subtasks.

Subtask status

The subtask status is the status of a data migration subtask. The current status options include `New`, `Running`, `Paused`, `Stopped`, and `Finished`. Refer to subtask status for more details about the status of a data migration task or subtask.

13.6.8.10.9 T

Table routing

The table routing feature enables DM to migrate a certain table of the upstream MySQL or MariaDB instance to the specified table in the downstream, which can be used to merge and migrate sharded tables. Refer to table routing for details.

Task

The data migration task, which is started after you successfully execute a `start-task` ↪ command. In different task configurations, a single migration task can run on a single DM-worker instance or on multiple DM-worker instances at the same time.

Task status

The task status refers to the status of a data migration task. The task status depends on the statuses of all its subtasks. Refer to subtask status for details.

13.6.8.11 Example

13.6.8.11.1 Migrate Data Using Data Migration

This guide shows how to migrate data using the Data Migration (DM) tool.

Step 1: Deploy the DM cluster

It is recommended to deploy the DM cluster using TiUP. You can also deploy the DM cluster using binary for trial or test.

Note:

- For database passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. See Encrypt the database password using dmctl.
- The user of the upstream and downstream databases must have the corresponding read and write privileges.

Step 2: Check the cluster information

After the DM cluster is deployed using TiUP, the configuration information is like what is listed below.

- The configuration information of related components in the DM cluster:

Component	Host	Port
dm_worker1	172.16.10.72	8262
dm_worker2	172.16.10.73	8262
dm_master	172.16.10.71	8261

- The information of upstream and downstream database instances:

Database instance	Host	Port	Username	Encrypted password
Upstream MySQL-1	172.16.10.81	3306	root	VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=
Upstream MySQL-2	172.16.10.82	3306	root	VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=
Downstream TiDB	172.16.10.83	4000	root	

The list of privileges needed on the MySQL host can be found in the precheck documentation.

Step 3: Create data source

1. Write MySQL-1 related information to `conf/source1.yaml`:

```
# MySQL1 Configuration.

source-id: "mysql-replica-01"
# This indicates that whether DM-worker uses Global Transaction
    ↪ Identifier (GTID) to pull binlog. Before you use this
    ↪ configuration item, make sure that the GTID mode is enabled in
    ↪ the upstream MySQL.
enable-gtid: false

from:
  host: "172.16.10.81"
  user: "root"
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU="
  port: 3306
```

2. Execute the following command in the terminal, and use `tiup dmctl` to load the MySQL-1 data source configuration to the DM cluster:

```
tiup dmctl --master-addr 172.16.10.71:8261 operate-source create conf/
    ↪ source1.yaml
```

3. For MySQL-2, modify the relevant information in the configuration file and execute the same `dmctl` command.

Step 4: Configure the data migration task

The following example assumes that you need to migrate all the `test_table` table data in the `test_db` database of both the upstream MySQL-1 and MySQL-2 instances, to the downstream `test_table` table in the `test_db` database of TiDB, in the full data plus incremental data mode.

Edit the `task.yaml` task configuration file as below:

```
##### The task name. You need to use a different name for each of the
    ↪ multiple tasks that
##### run simultaneously.
name: "test"
##### The full data plus incremental data (all) migration mode.
task-mode: "all"
##### The downstream TiDB configuration information.
target-database:
  host: "172.16.10.83"
  port: 4000
  user: "root"
  password: ""
```

```
##### Configuration of all the upstream MySQL instances required by the
    ↪ current data migration task.
mysql-instances:
-
  # The ID of upstream instances or the migration group. You can refer to
     ↪ the configuration of `source_id` in the "inventory.ini" file or in
     ↪ the "dm-master.toml" file.
  source-id: "mysql-replica-01"
  # The configuration item name of the block and allow lists of the name of
     ↪ the
  # database/table to be migrated, used to quote the global block and allow
  # lists configuration that is set in the global block-allow-list below.
  block-allow-list: "global" # Use black-white-list if the DM version is
     ↪ earlier than or equal to v2.0.0-beta.2.
  # The configuration item name of the dump processing unit, used to quote
     ↪ the global configuration of the dump unit.
  mydumper-config-name: "global"

-
  source-id: "mysql-replica-02"
  block-allow-list: "global" # Use black-white-list if the DM version is
     ↪ earlier than or equal to v2.0.0-beta.2.
  mydumper-config-name: "global"

##### The global configuration of block and allow lists. Each instance can
    ↪ quote it by the
##### configuration item name.
block-allow-list:                  # Use black-white-list if the DM version
    ↪ is earlier than or equal to v2.0.0-beta.2.
  global:
    do-tables:                     # The allow list of upstream tables to be
       ↪ migrated.
    - db-name: "test_db"           # The database name of the table to be
       ↪ migrated.
      tbl-name: "test_table"       # The name of the table to be migrated.

##### The global configuration of the dump unit. Each instance can quote it
    ↪ by the configuration item name.
mydumpers:
  global:
    extra-args: ""
```

Step 5: Start the data migration task

To detect possible errors of data migration configuration in advance, DM provides the

precheck feature:

- DM automatically checks the corresponding privileges and configuration while starting the data migration task.
- You can also use the `check-task` command to manually precheck whether the upstream MySQL instance configuration satisfies the DM requirements.

For details about the precheck feature, see Precheck the upstream MySQL instance configuration.

> **Note:**
>
> Before starting the data migration task for the first time, you should have got the upstream configured. Otherwise, an error is reported while you start the task.

Run the `tiup dmctl` command to start the data migration tasks. `task.yaml` is the configuration file that is edited above.

```
tiup dmctl --master-addr 172.16.10.71:8261 start-task ./task.yaml
```

- If the above command returns the following result, it indicates the task is successfully started.

```
{
    "result": true,
    "msg": "",
    "workers": [
        {
            "result": true,
            "worker": "172.16.10.72:8262",
            "msg": ""
        },
        {
            "result": true,
            "worker": "172.16.10.73:8262",
            "msg": ""
        }
    ]
}
```

- If you fail to start the data migration task, modify the configuration according to the returned prompt and then run the `start-task task.yaml` command to restart the task.

Step 6: Check the data migration task

If you need to check the task state or whether a certain data migration task is running in the DM cluster, run the following command in `tiup dmctl`:

```
tiup dmctl --master-addr 172.16.10.71:8261 query-status
```

Step 7: Stop the data migration task

If you do not need to migrate data any more, run the following command in `tiup dmctl` to stop the task:

```
tiup dmctl --master-addr 172.16.10.71:8261 stop-task test
```

`test` is the task name that you set in the `name` configuration item of the `task.yaml` configuration file.

Step 8: Monitor the task and check logs

Assuming that Prometheus, Alertmanager, and Grafana are successfully deployed along with the DM cluster deployment using TiUP, and the Grafana address is `172.16.10.71`. To view the alert information related to DM, you can open http://172.16.10.71:9093 in a browser and enter into Alertmanager; to check monitoring metrics, go to http://172.16.10.71:3000, and choose the DM dashboard.

While the DM cluster is running, DM-master, DM-worker, and dmctl output the monitoring metrics information through logs. The log directory of each component is as follows:

- DM-master log directory: It is specified by the `--log-file` DM-master process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-master node.
- DM-worker log directory: It is specified by the `--log-file` DM-worker process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-worker node.

13.6.8.11.2 Create a Data Migration Task

This document describes how to create a simple data migration task after the DM cluster is successfully deployed.

Sample scenario

Suppose that you create a data migration task based on this sample scenario:

- Deploy two MySQL instances with binlog enabled and one TiDB instance locally
- Use a DM-master of the DM cluster to manage the cluster and data migration tasks.

The information of each node is as follows.

Instance	Server Address	Port
MySQL1	127.0.0.1	3306
MySQL2	127.0.0.1	3307
TiDB	127.0.0.1	4000
DM-master	127.0.0.1	8261

Based on this scenario, the following sections describe how to create a data migration task.

Start upstream MySQL

Prepare 2 runnable MySQL instances. You can also use Docker to quickly start MySQL. The commands are as follows:

```
docker run --rm --name mysql-3306 -p 3306:3306 -e MYSQL_ALLOW_EMPTY_PASSWORD
    ↪ =true mysql:5.7.22 --log-bin=mysql-bin --port=3306 --bind-address
    ↪ =0.0.0.0 --binlog-format=ROW --server-id=1 --gtid_mode=ON --enforce-
    ↪ gtid-consistency=true > mysql.3306.log 2>&1 &
docker run --rm --name mysql-3307 -p 3307:3307 -e MYSQL_ALLOW_EMPTY_PASSWORD
    ↪ =true mysql:5.7.22 --log-bin=mysql-bin --port=3307 --bind-address
    ↪ =0.0.0.0 --binlog-format=ROW --server-id=1 --gtid_mode=ON --enforce-
    ↪ gtid-consistency=true > mysql.3307.log 2>&1 &
```

Prepare data

- Write example data into mysql-3306:

```
drop database if exists `sharding1`;
create database `sharding1`;
use `sharding1`;
create table t1 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
create table t2 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
insert into t1 (id, uid, name) values (1, 10001, 'Gabriel García
    ↪ Márquez'), (2 ,10002, 'Cien años de soledad');
insert into t2 (id, uid, name) values (3,20001, 'José Arcadio Buendía'
    ↪ ), (4,20002, 'Úrsula Iguarán'), (5,20003, 'José Arcadio');
```

- Write example data into mysql-3307:

```
drop database if exists `sharding2`;
create database `sharding2`;
use `sharding2`;
```

```
create table t2 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
create table t3 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
insert into t2 (id, uid, name, info) values (6, 40000, 'Remedios
    ↪ Moscote', '{}');
insert into t3 (id, uid, name, info) values (7, 30001, 'Aureliano José
    ↪ ', '{}'), (8, 30002, 'Santa Sofía de la Piedad', '{}'), (9,
    ↪ 30003, '17 Aurelianos', NULL);
```

Start downstream TiDB

To run a TiDB server, use the following command:

```
wget https://download.pingcap.org/tidb-community-server-v7.1.5-linux-amd64.
    ↪ tar.gz
tar -xzvf tidb-latest-linux-amd64.tar.gz
mv tidb-latest-linux-amd64/bin/tidb-server ./
./tidb-server
```

> **Warning:**
>
> The deployment method of TiDB in this document **do not apply** to production or development environments.

Configure the MySQL data source

Before starting a data migration task, you need to configure the MySQL data source.

Encrypt the password

> **Note:**
>
> - You can skip this step if the database does not have a password.
> - You can use the plaintext password to configure the source information in DM v1.0.6 and later versions.

For safety reasons, it is recommended to configure and use encrypted passwords. You can use dmctl to encrypt the MySQL/TiDB password. Suppose the password is "123456":

```
./dmctl encrypt "123456"
```

```
fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg=
```

Save this encrypted value, and use it for creating a MySQL data source in the following steps.

Edit the source configuration file

Write the following configurations to `conf/source1.yaml`.

```
##### MySQL1 Configuration.

source-id: "mysql-replica-01"

##### Indicates whether GTID is enabled
enable-gtid: true

from:
  host: "127.0.0.1"
  user: "root"
  password: "fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg="
  port: 3306
```

In MySQL2 data source, copy the above configurations to `conf/source2.yaml`. You need to change `name` to `mysql-replica-02` and change `password` and `port` to appropriate values.

Create a source

To load the data source configurations of MySQL1 into the DM cluster using dmctl, run the following command in the terminal:

```
./dmctl --master-addr=127.0.0.1:8261 operate-source create conf/source1.
    ↪ yaml
```

For MySQL2, replace the configuration file in the above command with that of MySQL2.

Create a data migration task

After importing prepared data, there are several sharded tables on both MySQL1 and MySQL2 instances. These tables have identical structure and the same prefix "t" in the table names; the databases where these tables are located are all prefixed with "sharding"; and there is no conflict between the primary keys or the unique keys (in each sharded table, the primary keys or the unique keys are different from those of other tables).

Now, suppose that you need to migrate these sharded tables to the `db_target.t_target` table in TiDB. The steps are as follows.

1. Create the configuration file of the task:

```
---
name: test
task-mode: all
shard-mode: "pessimistic"
target-database:
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: "" # It is recommended to use password encrypted with dmctl
     ↪  if the password is not empty.

mysql-instances:
  - source-id: "mysql-replica-01"
    block-allow-list: "instance" # This configuration applies to DM
       ↪ versions higher than v2.0.0-beta.2. Use black-white-list
       ↪ otherwise.
    route-rules: ["sharding-route-rules-table", "sharding-route-rules-
       ↪ schema"]
    mydumper-thread: 4
    loader-thread: 16
    syncer-thread: 16
  - source-id: "mysql-replica-02"
    block-allow-list: "instance" # This configuration applies to DM
       ↪ versions higher than v2.0.0-beta.2. Use black-white-list
       ↪ otherwise.
    route-rules: ["sharding-route-rules-table", "sharding-route-rules-
       ↪ schema"]
    mydumper-thread: 4
    loader-thread: 16
    syncer-thread: 16
block-allow-list: # This configuration applies to DM versions higher
   ↪ than v2.0.0-beta.2. Use black-white-list otherwise.
  instance:
    do-dbs: ["~^sharding[\\d]+"]
    do-tables:
    - db-name: "~^sharding[\\d]+"
      tbl-name: "~^t[\\d]+"
routes:
  sharding-route-rules-table:
    schema-pattern: sharding*
    table-pattern: t*
    target-schema: db_target
    target-table: t_target
```

```
  sharding-route-rules-schema:
    schema-pattern: sharding*
    target-schema: db_target
```

2. To create a task using dmctl, write the above configurations to the `conf/task.yaml` file:

```
./dmctl --master-addr 127.0.0.1:8261 start-task conf/task.yaml
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

Now, you have successfully created a task to migrate the sharded tables from the MySQL1 and MySQL2 instances to TiDB.

Verify data

You can modify data in the upstream MySQL sharded tables. Then use sync-diff-inspector to check whether the upstream and downstream data are consistent. Consistent data means that the migration task works well, which also indicates that the cluster works well.

13.6.8.11.3 Best Practices of Data Migration in the Shard Merge Scenario

This document describes the features and limitations of TiDB Data Migration (DM) in the shard merge scenario and provides a data migration best practice guide for your application (the default "pessimistic" mode is used).

Use a separate data migration task

In the Merge and Migrate Data from Sharded Tables document, the definition of "sharding group" is given: A sharding group consists of all upstream tables that need to be merged and migrated into the same downstream table.

The current sharding DDL mechanism has some usage restrictions to coordinate the schema changes brought by DDL operations in different sharded tables. If these restrictions are violated due to unexpected reasons, you need to handle sharding DDL locks manually in DM, or even redo the entire data migration task.

To mitigate the impact on data migration when an exception occurs, it is recommended to merge and migrate each sharding group as a separate data migration task. **This might enable that only a small number of data migration tasks need to be handled manually while others remain unaffected.**

Handle sharding DDL locks manually

You can easily conclude from Merge and Migrate Data from Sharded Tables that DM's sharding DDL lock is a mechanism for coordinating the execution of DDL operations to the downstream from multiple upstream sharded tables.

Therefore, when you find any sharding DDL lock on `DM-master` through `shard-ddl-lock` ↪ command, or any `unresolvedGroups` or `blockingDDLs` on some DM-workers through `query-status` command, do not rush to manually release the sharding DDL lock through `shard-ddl-lock unlock` commands.

Instead, you can:

- Follow the corresponding manual solution to handle the scenario if the failure of automatically releasing the sharding DDL lock is one of the listed abnormal scenarios.
- Redo the entire data migration task if it is an unsupported scenario: First, empty the data in the downstream database and the `dm_meta` information associated with the migration task; then, re-execute the full and incremental data replication.

Handle conflicts between primary keys or unique indexes across multiple sharded tables

Data from multiple sharded tables might cause conflicts between the primary keys or unique indexes. You need to check each primary key or unique index based on the sharding logic of these sharded tables. The following are three cases related to primary keys or unique indexes:

- Shard key: Usually, the same shard key only exists in one sharded table, which means no data conflict is caused on shard key.
- Auto-increment primary key: The auto-increment primary key of each sharded tables counts separately, so their range might overlap. In this case, you need to refer to the next section Handle conflicts of auto-increment primary key to solve it.
- Other primary keys or unique indexes: you need to analyze them based on the business logic. If data conflict, you can also refer to the next section Handle conflicts of auto-increment primary key to solve it.

Handle conflicts of auto-increment primary key

This section introduces two recommended solutions to handle conflicts of auto-increment primary key.

Remove the `PRIMARY KEY` attribute from the column

Assume that the upstream schemas are as follows:

```
CREATE TABLE `tbl_no_pk` (
  `auto_pk_c1` bigint(20) NOT NULL,
  `uk_c2` bigint(20) NOT NULL,
  `content_c3` text,
  PRIMARY KEY (`auto_pk_c1`),
  UNIQUE KEY `uk_c2` (`uk_c2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

If the following requirements are satisfied:

- The `auto_pk_c1` column has no impact on the application and does not depend on the column's `PRIMARY KEY` attribute.
- The `uk_c2` column has the `UNIQUE KEY` attribute, and it is globally unique in all upstream sharded tables.

Then you can perform the following steps to fix the `ERROR 1062 (23000): Duplicate entry '***' for key 'PRIMARY'` error that is possibly caused by the `auto_pk_c1` column when you merge sharded tables.

1. Before the full data migration, create a table in the downstream database for merging and migrating data, and modify the `PRIMARY KEY` attribute of the `auto_pk_c1` column to normal index.

   ```
   CREATE TABLE `tbl_no_pk_2` (
     `auto_pk_c1` bigint(20) NOT NULL,
     `uk_c2` bigint(20) NOT NULL,
     `content_c3` text,
     INDEX (`auto_pk_c1`),
     UNIQUE KEY `uk_c2` (`uk_c2`)
   ) ENGINE=InnoDB DEFAULT CHARSET=latin1
   ```

2. Add the following configuration in `task.yaml` to skip the check of auto-increment primary key conflict:

   ```
   ignore-checking-items: ["auto_increment_ID"]
   ```

3. Start the full and incremental data replication task.

4. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from the upstream has already been merged and migrated to the downstream database.

Use a composite primary key

Assume that the upstream schemas are as follows:

```
CREATE TABLE `tbl_multi_pk` (
  `auto_pk_c1` bigint(20) NOT NULL,
  `uuid_c2` bigint(20) NOT NULL,
  `content_c3` text,
  PRIMARY KEY (`auto_pk_c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

If the following requirements are satisfied:

- The application does not depend on the `PRIMARY KEY` attribute of the `auto_pk_c1` column.
- The composite primary key that consists of the `auto_pk_c1` and `uuid_c2` columns is globally unique.
- It is acceptable to use a composite primary key in the application.

Then you can perform the following steps to fix the `ERROR 1062 (23000): Duplicate entry '***' for key 'PRIMARY'` error that is possibly caused by the `auto_pk_c1` column when you merge sharded tables.

1. Before the full data migration, create a table in the downstream database for merging and migrating data. Do not specify the `PRIMARY KEY` attribute for the `auto_pk_c1` column, but use the `auto_pk_c1` and `uuid_c2` columns to make up a composite primary key.

   ```
   CREATE TABLE `tbl_multi_pk_c2` (
     `auto_pk_c1` bigint(20) NOT NULL,
     `uuid_c2` bigint(20) NOT NULL,
     `content_c3` text,
     PRIMARY KEY (`auto_pk_c1`,`uuid_c2`)
   ) ENGINE=InnoDB DEFAULT CHARSET=latin1
   ```

2. Start the full and incremental data migration task.

3. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from upstream has already been merged and migrated to the downstream database.

Special processing when the upstream RDS contains sharded tables

If the upstream data source is an RDS and it contains sharded tables, the table names in MySQL binlog might be invisible when connecting to a SQL client. For example, if the upstream is a UCloud distributed database, the table name in the binlog might have an extra prefix `_0001`. Therefore, you need to configure table routing based on the table names in binlog, instead of those in the SQL client.

Create/drop tables in the upstream

In Merge and Migrate Data from Sharded Tables, it is clear that the coordination of sharding DDL lock depends on whether the downstream database receives the DDL statements of all upstream sharded tables. In addition, DM currently **does not support** dynamically creating or dropping sharded tables in the upstream. Therefore, to create or drop sharded tables in the upstream, it is recommended to perform the following steps.

Create sharded tables in the upstream

If you need to create a new sharded table in the upstream, perform the following steps:

1. Wait for the coordination of all executed sharding DDL in the upstream sharded tables to finish.
2. Run `stop-task` to stop the data migration task.
3. Create a new sharded table in the upstream.
4. Make sure that the configuration in the `task.yaml` file allows the newly added sharded table to be merged in one downstream table with other existing sharded tables.
5. Run `start-task` to start the task.
6. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from upstream has already been merged and migrated to the downstream database.

Drop sharded tables in the upstream

If you need to drop a sharded table in the upstream, perform the following steps:

1. Drop the sharded table, run `SHOW BINLOG EVENTS` to fetch the `End_log_pos` corresponding to the `DROP TABLE` statement in the binlog events, and mark it as *Pos-M*.
2. Run `query-status` to fetch the position (`syncerBinlog`) corresponding to the binlog event that has been processed by DM, and mark it as *Pos-S*.
3. When *Pos-S* is greater than *Pos-M*, it means that DM has processed all of the `DROP TABLE` statements, and the data of the table before dropping has been migrated to the downstream, so the subsequent operation can be performed. Otherwise, wait for DM to finish migrating the data.

4. Run `stop-task` to stop the task.
5. Make sure that the configuration in the `task.yaml` file ignores the dropped sharded table in the upstream.
6. Run `start-task` to start the task.
7. Run `query-status` to verify whether the data migration task is successfully processed.

Speed limits and traffic flow control

When data from multiple upstream MySQL or MariaDB instances is merged and migrated to the same TiDB cluster in the downstream, every DM-worker corresponding to each upstream instance executes full and incremental data replication concurrently. This means that the default degree of concurrency (`pool-size` in full data migration and `worker-count` in incremental data replication) accumulates as the number of DM-workers increases, which might overload the downstream database. In this case, you need to conduct a preliminary performance analysis based on TiDB and DM monitoring metrics and adjust the value of each concurrency parameter. In the future, DM is expected to support partially automated traffic flow control.

13.6.8.12 Troubleshoot

13.6.8.12.1 TiDB Data Migration FAQs

This document collects the frequently asked questions (FAQs) about TiDB Data Migration (DM).

Does DM support migrating data from Alibaba RDS or other cloud databases?

Currently, DM only supports decoding the standard version of MySQL or MariaDB binlog. It has not been tested for Alibaba Cloud RDS or other cloud databases. If you are confirmed that its binlog is in standard format, then it is supported.
