process_resident_memory_bytes{job=~"tikv",instance=~".*"} - (process
↪ _resident_memory_bytes{job=~"tikv",instance=~".*"} offset 5m)>
↪ 5*1024*1024*1024
```

- Description:

  Currently, there are no TiKV monitoring items about memory. You can monitor the memory usage of the machines in the cluster by Node_exporter. The above rule indicates that when the memory usage exceeds 5 GB within 5 minutes (the memory is occupied too fast in TiKV), an alert is triggered.

- Solution:

  Adjust the `block-cache-size` value of both `rocksdb.defaultcf` and `rocksdb.
  ↪ writecf`.

9.7.3.1.2 `TiKV_GC_can_not_work`

- Alert rule:

```
sum(increase(tikv_gcworker_gc_tasks_vec{task="gc"}[1d]))< 1 and (sum(
↪ increase(tikv_gc_compaction_filter_perform[1d]))< 1 and sum(increase
↪ (tikv_engine_event_total{db="kv", cf="write", type="compaction"}[1d
↪ ]))>= 1)
```

- Description:

  GC is not performed successfully on a TiKV instance within 24 hours, which indicates that GC is not working properly. If GC does not run in a short term, it will not cause much trouble; but if GC keeps down, more and more versions are retained, which slows down the query.

- Solution:

  1. Perform `SELECT VARIABLE_VALUE FROM mysql.tidb WHERE VARIABLE_NAME = "tikv_gc_leader_desc"` to locate the `tidb-server` corresponding to the GC leader;
  2. View the log of the `tidb-server`, and grep gc_worker tidb.log;
  3. If you find that the GC worker has been resolving locks (the last log is "start resolve locks") or deleting ranges (the last log is "start delete {number} ranges") during this time, it means the GC process is running normally. Otherwise, get support from PingCAP or the community.

9.7.3.2 Critical-level alerts

9.7.3.2.1 `TiKV_server_report_failure_msg_total`

- Alert rule:

```
sum(rate(tikv_server_report_failure_msg_total{type="unreachable"}[10m]) )BY (store_id)> 10
```

- Description:

  Indicates that the remote TiKV cannot be connected.

- Solution:

  1. Check whether the network is clear.
  2. Check whether the remote TiKV is down.
  3. If the remote TiKV is not down, check whether the pressure is too high. Refer to the solution in `TiKV_channel_full_total`.

9.7.3.2.2 `TiKV_channel_full_total`

- Alert rule:

```
sum(rate(tikv_channel_full_total[10m]))BY (type, instance)> 0
```

- Description:

  This issue is often caused by the stuck Raftstore thread and high pressure on TiKV.

- Solution:

1. Watch the **TiKV-Details > Raft Propose** dashboard, and see whether the alerted TiKV node has a much higher Raft propose than other TiKV nodes. If so, it means that there are one or more hot spots on this TiKV. You need to check whether the hot spot scheduling can work properly.
2. Watch the **TiKV-Details > Raft IO** dashboard, and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk.
3. Watch the **TiKV-Details > Raft process** dashboard, and see whether the `tick duration` is high. If so, you need to set `raftstore.raft-base-tick-interval` to `"2s"`.

9.7.3.2.3 TiKV_write_stall

- Alert rule:

  ```
  delta(tikv_engine_write_stall[10m])> 0
  ```

- Description:

  The write pressure on RocksDB is too high, and a stall occurs.

- Solution:

  1. View the disk monitor, and troubleshoot the disk issues;
  2. Check whether there is any write hot spot on the TiKV;
  3. Set `max-sub-compactions` to a larger value under the `[rocksdb]` and `[raftdb]` configurations.

9.7.3.2.4 TiKV_raft_log_lag

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_raftstore_log_lag_bucket[1m]))by
  ↪  (le, instance))> 5000
  ```

- Description:

  If this value is relatively large, it means Follower has lagged far behind Leader, and Raft cannot be replicated normally. It is possibly because the TiKV machine where Follower is located is stuck or down.

9.7.3.2.5 TiKV_async_request_snapshot_duration_seconds

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_
  ↪ duration_seconds_bucket{type="snapshot"}[1m]))by (le, instance, type
  ↪ ))> 1
  ```

- Description:

  If this value is relatively large, it means the load pressure on Raftstore is too high, and it might be stuck already.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

9.7.3.2.6 TiKV_async_request_write_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_
↪ duration_seconds_bucket{type="write"}[1m]))by (le, instance, type))>
↪  1
```

- Description:

  If this value is relatively large, it means the Raft write takes a long time.

- Solution:

  1. Watch the **TiKV-Details > Raft propose** dashboard and see whether the **99% Propose wait duration per server** metric of the alerted TiKV node is significantly higher than that of other TiKV nodes. If so, it indicates that hotspots exist on this TiKV node, and you need to check whether the hotspot scheduling works properly.
  2. Watch the **TiKV-Details > Raft IO** dashboard and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk.
  3. For further analysis of performance issues of the alerted TiKV node and tuning methods, see Performance analysis and tuning.

9.7.3.2.7 TiKV_coprocessor_request_wait_seconds

- Alert rule:

```
histogram_quantile(0.9999, sum(rate(tikv_coprocessor_request_wait_
↪ seconds_bucket[1m]))by (le, instance, req))> 10
```

- Description:

  If this value is relatively large, it means the pressure on the Coprocessor worker is high. There might be a slow task that makes the Coprocessor thread stuck.

- Solution:

  1. View the slow query log from the TiDB log to see whether the index or full table scan is used in a query, or see whether it is needed to analyze;

2. Check whether there is a hot spot;
3. View the Coprocessor monitor and see whether `total` and `process` in `coprocessor table/index scan` match. If they differ a lot, it indicates too many invalid queries are performed. You can see whether there is `over seek bound`. If so, there are too many versions that GC does not handle in time. Then you need to increase the number of parallel GC threads.

9.7.3.2.8 TiKV_raftstore_thread_cpu_seconds_total

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"raftstore_.*"}[1m]))by (
↪ instance)> 1.6
```

- Description:

  This rule monitors CPU usage by Raftstore. If the value is high, it indicates pressure on Raftstore threads is heavy.

  The alert threshold is 80% of the `raftstore.store-pool-size` value. `raftstore.store-pool-size` is 2 by default, so the alert threshold is 1.6.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

9.7.3.2.9 TiKV_raft_append_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_append_log_duration_
↪ seconds_bucket[1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of appending Raft log. If it is high, it usually means I/O is too busy.

9.7.3.2.10 TiKV_raft_apply_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_apply_log_duration_
↪ seconds_bucket[1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of applying Raft log. If it is high, it usually means I/O is too busy.

9.7.3.2.11 TiKV_scheduler_latch_wait_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_latch_wait_duration_
↪ seconds_bucket[1m]))by (le, instance, type))> 1
```

- Description:

  The waiting time for the write operations to obtain the memory lock in Scheduler. If it is high, there might be many write conflicts, or that some operations that lead to conflicts take a long time to finish and block other operations that wait for the same lock.

- Solution:

  1. View the scheduler command duration in the Scheduler-All monitor and see which command is most time-consuming;
  2. View the scheduler scan details in the Scheduler-All monitor and see whether `total` and `process` match. If they differ a lot, there are many invalid scans. You can also see whether there is `over seek bound`. If there is too much, it indicates GC does not work in time;
  3. View the storage async snapshot/write duration in the Storage monitor and see whether the Raft operation is performed in time.

9.7.3.2.12 TiKV_thread_apply_worker_cpu_seconds

- Alert rule:

```
max(rate(tikv_thread_cpu_seconds_total{name=~"apply_.*"}[1m]))by (
↪ instance)> 0.9
```

- Description:

  The apply Raft log thread is under great pressure and is approaching or has exceeded its limit. This is often caused by a burst of writes.

9.7.3.3 Warning-level alerts

9.7.3.3.1 TiKV_leader_drops

- Alert rule:

```
delta(tikv_pd_heartbeat_tick_total{type="leader"}[30s])< -10
```

- Description:

  It is often caused by a stuck Raftstore thread.

- Solution:

    1. Refer to TiKV_channel_full_total.
    2. It there is low pressure on TiKV, consider whether the PD scheduling is too frequent. You can view the Operator Create panel on the PD page, and check the types and number of the PD scheduling.

9.7.3.3.2 TiKV_raft_process_ready_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration
↪ _secs_bucket{type='ready'}[1m]))by (le, instance, type))> 2
```

- Description:

    Indicates the time cost of handling Raft ready. If this value is large, it is often caused by the stuck appending log task.

9.7.3.3.3 TiKV_raft_process_tick_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration
↪ _secs_bucket{type='tick'}[1m]))by (le, instance, type))> 2
```

- Description:

    Indicates the time cost of handling Raft tick. If this value is large, it is often caused by too many Regions.

- Solution:

    1. Consider using a higher-level log such as `warn` or `error`.
    2. Add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

9.7.3.3.4 TiKV_scheduler_context_total

- Alert rule:

```
abs(delta( tikv_scheduler_context_total[5m]))> 1000
```

- Description:

    The number of write commands that are being executed by Scheduler. If this value is large, it means the task is not finished timely.

- Solution:

    Refer to TiKV_scheduler_latch_wait_duration_seconds.

9.7.3.3.5 TiKV_scheduler_command_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_command_duration_
↪ seconds_bucket[1m]))by (le, instance, type))> 1
```

- Description:

  Indicates the time cost of executing the Scheduler command.

- Solution:

  Refer to TiKV_scheduler_latch_wait_duration_seconds.

9.7.3.3.6 TiKV_coprocessor_outdated_request_wait_seconds

- Alert rule:

```
delta(tikv_coprocessor_outdated_request_wait_seconds_count[10m])> 0
```

- Description:

  The waiting time of the expired requests by Coprocessor. If this value is large, it means there is high pressure on Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

9.7.3.3.7 TiKV_coprocessor_pending_request

- Alert rule:

```
delta(tikv_coprocessor_pending_request[10m])> 5000
```

- Description:

  The queuing requests of Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

9.7.3.3.8 TiKV_batch_request_snapshot_nums

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"cop_.*"}[1m]))by (instance
↪ )/ (count(tikv_thread_cpu_seconds_total{name=~"cop_.*"})* 0.9)/
↪ count(count(tikv_thread_cpu_seconds_total)by (instance))> 0
```

- Description:

  The Coprocessor CPU usage of a TiKV machine exceeds 90%.

9.7.3.3.9 TiKV_pending_task

- Alert rule:

  ```
  sum(tikv_worker_pending_task_total)BY (instance,name)> 1000
  ```

- Description:

  The number of pending tasks of TiKV.

- Solution:

  Check which kind of tasks has a higher value from the `Worker pending tasks` metric in the **TiKV-Details > Task** dashboard.

9.7.3.3.10 TiKV_low_space

- Alert rule:

  ```
  sum(tikv_store_size_bytes{type="available"})by (instance)/ sum(tikv_
  ↪ store_size_bytes{type="capacity"})by (instance)< 0.2
  ```

- Description:

  The data volume of TiKV exceeds 80% of the configured node capacity or the disk capacity of the machine.

- Solution:

  - Check the balance condition of node space.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.7.3.3.11 TiKV_approximate_region_size

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_raftstore_region_size_bucket[1m
  ↪ ]))by (le))> 1073741824
  ```

- Description:

  The maximum Region approximate size that is scanned by the TiKV split checker is continually larger than 1 GB within one minute.

- Solution:

  The speed of splitting Regions is slower than the write speed. To alleviate this issue, you'd better update TiDB to a version that supports batch-split (>= 2.1.0-rc1). If it is not possible to update temporarily, you can use `pd-ctl operator add split-region <region_id> --policy=approximate` to manually split Regions.

9.7.4 TiFlash alert rules

For the detailed descriptions of TiFlash alert rules, see TiFlash Alert Rules.

9.7.5 TiCDC Alert rules

For the detailed descriptions of TiCDC alert rules, see TiCDC Alert Rules.

9.7.6 Node_exporter host alert rules

This section gives the alert rules for the Node_exporter host.

9.7.6.1 Emergency-level alerts

9.7.6.1.1 NODE_disk_used_more_than_80%

- Alert rule:

```
node_filesystem_avail_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/boot"}
↪  / node_filesystem_size_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/
↪ boot"} * 100 <= 20
```

- Description:

  The disk space usage of the machine exceeds 80%.

- Solution:

  - Log in to the machine, run the `df -h` command to check the disk space usage.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.7.6.1.2 NODE_disk_inode_more_than_80%

- Alert rule:

```
node_filesystem_files_free{fstype=~"(ext.|xfs)"} / node_filesystem_
↪ files{fstype=~"(ext.|xfs)"} * 100 < 20
```

- Description:

  The inode usage of the filesystem on the machine exceeds 80%.

- Solution:

  - Log in to the machine and run the `df -i` command to view the node usage of the filesystem.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.7.6.1.3 NODE_disk_readonly

- Alert rule:

  ```
  node_filesystem_readonly{fstype=~"(ext.|xfs)"} == 1
  ```

- Description:

  The filesystem is read-only and data cannot be written in it. It is often caused by disk failure or filesystem corruption.

- Solution:

  - Log in to the machine and create a file to test whether it is normal.
  - Check whether the disk LED is normal. If not, replace the disk and repair the filesystem of the machine.

9.7.6.2 Critical-level alerts

9.7.6.2.1 NODE_memory_used_more_than_80%

- Alert rule:

  ```
  (((node_memory_MemTotal_bytes-node_memory_MemFree_bytes-node_memory_
  ↪ Cached_bytes)/(node_memory_MemTotal_bytes)*100))>= 80
  ```

- Description:

  The memory usage of the machine exceeds 80%.

- Solution:

  - View the Memory panel of the host in the Grafana Node Exporter dashboard, and see whether Used memory is too high and Available memory is too low.
  - Log in to the machine and run the `free -m` command to view the memory usage. You can run `top` to check whether there is any abnormal process that has an overly high memory usage.

9.7.6.3 Warning-level alerts

9.7.6.3.1 NODE_node_overload

- Alert rule:

  ```
  (node_load5 / count without (cpu, mode)(node_cpu_seconds_total{mode="
  ↪ system"}))> 1
  ```

- Description:

  The CPU load on the machine is relatively high.

- Solution:

  - View the CPU Usage and Load Average of the host in the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the load average and the CPU usage, and see whether there is any abnormal process that has an overly high CPU usage.

9.7.6.3.2 NODE_cpu_used_more_than_80%

- Alert rule:

```
avg(irate(node_cpu_seconds_total{mode="idle"}[5m]))by(instance)* 100 <=
↪ 20
```

- Description:

  The CPU usage of the machine exceeds 80%.

- Solution:

  - View the CPU Usage and Load Average of the host on the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the Load Average and the CPU Usage, and see whether there is any abnormal process that has an overly high CPU usage.

9.7.6.3.3 NODE_tcp_estab_num_more_than_50000

- Alert rule:

```
node_netstat_Tcp_CurrEstab > 50000
```

- Description:

  There are more than 50,000 TCP links in the "establish" status on the machine.

- Solution:

  - Log in to the machine and run `ss -s` to check the number of TCP links in the "estab" status in the current system.
  - Run `netstat` to check whether there is any abnormal link.

9.7.6.3.4 NODE_disk_read_latency_more_than_32ms

- Alert rule:

```
((rate(node_disk_read_time_seconds_total{device=~".+"}[5m])/ rate(node
↪ _disk_reads_completed_total{device=~".+"}[5m]))or (irate(node_disk_
↪ read_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_reads_
↪ completed_total{device=~".+"}[5m])))* 1000 > 32
```

- Description:

  The read latency of the disk exceeds 32 ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the read latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

9.7.6.3.5 NODE_disk_write_latency_more_than_16ms

- Alert rule:

```
((rate(node_disk_write_time_seconds_total{device=~".+"}[5m])/ rate(node
↪ _disk_writes_completed_total{device=~".+"}[5m]))or (irate(node_disk_
↪ write_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_writes_
↪ completed_total{device=~".+"}[5m])))> 16
```

- Description:

  The write latency of the disk exceeds 16ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the write latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

9.7.7 Blackbox_exporter TCP, ICMP, and HTTP alert rules

This section gives the alert rules for the Blackbox_exporter TCP, ICMP, and HTTP.

9.7.7.1 Emergency-level alerts

9.7.7.1.1 TiDB_server_is_down

- Alert rule:

  ```
  probe_success{group="tidb"} == 0
  ```

- Description:

  Failure to probe the TiDB service port.

- Solution:

  - Check whether the machine that provides the TiDB service is down.
  - Check whether the TiDB process exists.
  - Check whether the network between the monitoring machine and the TiDB machine is normal.

9.7.7.1.2 TiFlash_server_is_down

- Alert rule:

  ```
  probe_success{group="tiflash"} == 0
  ```

- Description:

  Failure to probe the TiFlash service port.

- Solution:

  - Check whether the machine that provides the TiFlash service is down.
  - Check whether the TiFlash process exists.
  - Check whether the network between the monitoring machine and the TiFlash machine is normal.

9.7.7.1.3 TiKV_server_is_down

- Alert rule:

  ```
  probe_success{group="tikv"} == 0
  ```

- Description:

  Failure to probe the TiKV service port.

- Solution:

  - Check whether the machine that provides the TiKV service is down.
  - Check whether the TiKV process exists.
  - Check whether the network between the monitoring machine and the TiKV machine is normal.

9.7.7.1.4 PD_server_is_down

- Alert rule:

  ```
  probe_success{group="pd"} == 0
  ```

- Description:

  Failure to probe the PD service port.

- Solution:

  - Check whether the machine that provides the PD service is down.
  - Check whether the PD process exists.
  - Check whether the network between the monitoring machine and the PD machine is normal.

9.7.7.1.5 Node_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="node_exporter"} == 0
  ```

- Description:

  Failure to probe the Node_exporter service port.

- Solution:

  - Check whether the machine that provides the Node_exporter service is down.
  - Check whether the Node_exporter process exists.
  - Check whether the network between the monitoring machine and the Node_exporter machine is normal.

9.7.7.1.6 Blackbox_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="blackbox_exporter"} == 0
  ```

- Description:

  Failure to probe the Blackbox_Exporter service port.

- Solution:

  - Check whether the machine that provides the Blackbox_Exporter service is down.
  - Check whether the Blackbox_Exporter process exists.
  - Check whether the network between the monitoring machine and the Blackbox_Exporter machine is normal.

9.7.7.1.7 Grafana_server_is_down

- Alert rule:

  ```
  probe_success{group="grafana"} == 0
  ```

- Description:

  Failure to probe the Grafana service port.

- Solution:

  - Check whether the machine that provides the Grafana service is down.
  - Check whether the Grafana process exists.
  - Check whether the network between the monitoring machine and the Grafana machine is normal.

9.7.7.1.8 Pushgateway_server_is_down

- Alert rule:

  ```
  probe_success{group="pushgateway"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service port.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

9.7.7.1.9 Kafka_exporter_is_down

- Alert rule:

  ```
  probe_success{group="kafka_exporter"} == 0
  ```

- Description:

  Failure to probe the Kafka_Exporter service port.

- Solution:

  - Check whether the machine that provides the Kafka_Exporter service is down.
  - Check whether the Kafka_Exporter process exists.
  - Check whether the network between the monitoring machine and the Kafka_Exporter machine is normal.

9.7.7.1.10 Pushgateway_metrics_interface

- Alert rule:

  ```
  probe_success{job="blackbox_exporter_http"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service http interface.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

9.7.7.2 Warning-level alerts

9.7.7.2.1 BLACKER_ping_latency_more_than_1s

- Alert rule:

  ```
  max_over_time(probe_duration_seconds{job=~"blackbox_exporter.*_icmp"}[1
  ↪ m])> 1
  ```

- Description:

  The ping latency exceeds 1 second.

- Solution:

  - View the ping latency between the two nodes on the Grafana Blackbox Exporter page to check whether it is too high.
  - Check the TCP panel on the Grafana Node Exporter page to check whether there is any packet loss.

9.8 TiFlash Alert Rules

This document introduces the alert rules of the TiFlash cluster.

9.8.1 TiFlash_schema_error

- Alert rule:

  ```
  increase(tiflash_schema_apply_count{type="failed"}[15m])> 0
  ```

- Description:

  When the schema apply error occurs, an alert is triggered.

- Solution:

  The error might be caused by some wrong logic. Get support from PingCAP or the community.

9.8.2 TiFlash_schema_apply_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_schema_apply_duration_seconds
  ↪ _bucket[1m]))BY (le, instance))> 20
  ```

- Description:

  When the probability that the apply duration exceeds 20 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by the internal problems of the TiFlash storage engine. Get support from PingCAP or the community.

9.8.3 TiFlash_raft_read_index_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_raft_read_index_duration_
  ↪ seconds_bucket[1m]))BY (le, instance))> 3
  ```

- Description:

  When the probability that the read index duration exceeds 3 seconds is over 99%, an alert is triggered.

> **Note:**
>
> `read index` is the kvproto request sent to the TiKV leader. TiKV region retries, busy store, or network problems might lead to long request time of `read index`.

- Solution:

  The frequent retries might be caused by frequent splitting or migration of the TiKV cluster. You can check the TiKV cluster status to identify the retry reason.

9.8.4 `TiFlash_raft_wait_index_duration`

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_raft_wait_index_duration_
↪ seconds_bucket[1m]))BY (le, instance))> 2
```

- Description:

  When the probability that the waiting time for Region Raft Index in TiFlash exceeds 2 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by a communication error between TiKV and the proxy. Get support from PingCAP or the community.

9.9 Customize Configurations of Monitoring Servers

When you deploy a TiDB cluster using TiUP, TiUP also deploys monitoring servers, such as Prometheus, Grafana, and Alertmanager. In the meantime, if you scale out this cluster, TiUP also adds the new nodes into monitoring scope.

To customize the configurations of the monitoring servers mentioned above, you can follow the instructions below to add related configuration items in the topology.yaml of the TiDB cluster.

Note:

- Do not modify the configurations files of the monitoring server directly. Because these modifications will be overwritten by later TiUP operations such as deployment, scaling out, scaling in, and reloading.
- If your monitoring servers are not deployed and managed by TiUP, you can directly modify the configuration files of the monitoring servers instead of referring to this document.
- This feature is supported in TiUP v1.9.0 and above. Therefore, check the TiUP version before using this feature.

9.9.1 Customize Prometheus configurations

Currently, TiUP supports customizing Prometheus rule and scrape configuration files.

9.9.1.1 Customize Prometheus rule configuration

1. Customize the rule configuration file and place it under a directory of the machine where TiUP locates.
2. In the topology.yaml file, set `rule_dir` to the directory of the customized rule configuration file.

   The following is a configuration example of monitoring_servers in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Prometheus
   ↪ Server.
monitoring_servers:
  # # The ip address of the Monitoring Server.
- host: 127.0.0.1
  rule_dir: /home/tidb/prometheus_rule # prometheus rule dir on TiUP
     ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized rule configurations from `rule_dir` (for example, `/home/tidb/prometheus_rule`) and sends them to the Prometheus Server to replace the default rule configuration.

9.9.1.2 Customize Prometheus scrape configuration

1. Open the topology.yaml file of the TiDB cluster.
2. In the `monitoring_servers` configuration, add the `additional_scrape_conf` field.

   The following is a configuration example of monitoring_servers in the topology.yaml file:

```
monitoring_servers:
- host: xxxxxxx
ssh_port: 22
port: 9090
deploy_dir: /tidb-deploy/prometheus-9090
data_dir: /tidb-data/prometheus-9090
log_dir: /tidb-deploy/prometheus-9090/log
external_alertmanagers: []
arch: amd64
```

```
os: linux
additional_scrape_conf:
  metric_relabel_configs:
    - source_labels: [__name__]
        separator: ;
        regex: tikv_thread_nonvoluntary_context_switches|tikv_thread_
            ↪ voluntary_context_switches|tikv_threads_io_bytes_total
        action: drop
    - source_labels: [__name__,name]
        separator: ;
        regex: tikv_thread_cpu_seconds_total;(tokio|rocksdb).+
        action: drop
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `additional_scrape_conf` field to the corresponding parameters of the Prometheus configuration file.

9.9.2 Customize Grafana configurations

Currently, TiUP supports customizing Grafana Dashboard and other configurations.

9.9.2.1 Customize Grafana Dashboard

1. Customize the configuration file of the Grafana Dashboard and place it under a directory of the machine where TiUP locates.
2. In the topology.yaml file, set `dashboard_dir` to the directory of the customized Dashboard configuration file.

   The following is a configuration example of grafana_servers in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
   ↪ Servers.
grafana_servers:
  # # The ip address of the Grafana Server.
 - host: 127.0.0.1
 dashboard_dir: /home/tidb/dashboards # grafana dashboard dir on TiUP
    ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized Dashboard configurations from `dashboard_dir` (for example, `/home/tidb/dashboards`) and sends the configurations to the Grafana Server to replace the default Dashboard configuration.

9.9.2.2 Customize other Grafana configurations

1. Open the topology.yaml file of the TiDB cluster.
2. Add other configuration items in the `grafana_servers` configuration.

   The following is a configuration example of the `[log.file] level` and `smtp` fields in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
   ↪ Servers.
grafana_servers:
# # The ip address of the Grafana Server.
- host: 127.0.0.1
    config:
    log.file.level: warning
    smtp.enabled: true
    smtp.host: {IP}:{port}
    smtp.user: example@pingcap.com
    smtp.password: {password}
    smtp.skip_verify: true
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `config` field to the Grafana configuration file `grafana.ini`.

9.9.3 Customize Alertmanager configurations

Currently, TiUP supports customizing the listening address of Alertmanager.

Alertmanager deployed by TiUP listens to `alertmanager_servers.host` by default. You cannot access Alertmanager if you use a proxy. To address this issue, you can specify the listening address by adding `listen_host` to the cluster configuration file topology.yaml. The recommended value is 0.0.0.0.

The following example sets the `listen_host` field to 0.0.0.0.

```
alertmanager_servers:
  # # The ip address of the Alertmanager Server.
  - host: 172.16.7.147
    listen_host: 0.0.0.0
    # # SSH port of the server.
    ssh_port: 22
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `listen_host` field to `--web.listen-address` in Alertmanager startup parameters.

9.10 Monitoring and Alert for Backup and Restore

This document describes the monitoring and alert of the backup and restore feature, including how to deploy monitoring components, monitoring metrics, and common alerts.

9.10.1 Snapshot backup and restore monitoring

To view the snapshot backup and restore metrics, go to the **TiKV-Details > Backup & Import** dashboard in Grafana.

9.10.2 Log backup monitoring

Log backup supports using Prometheus to collect monitoring metrics. Currently all monitoring metrics are built into TiKV.

9.10.2.1 Monitoring configuration

- For clusters deployed using TiUP, Prometheus automatically collects monitoring metrics.
- For clusters deployed manually, follow the instructions in TiDB Cluster Monitoring Deployment to add TiKV-related jobs to the `scrape_configs` section of the Prometheus configuration file.

9.10.2.2 Grafana configuration

- For clusters deployed using TiUP, the Grafana dashboard contains the point-in-time recovery (PITR) panel. The **Backup Log** panel in the TiKV-Details dashboard is the PITR panel.
- For clusters deployed manually, refer to Import a Grafana dashboard and upload the tikv_details JSON file to Grafana. Then find the **Backup Log** panel in the TiKV-Details dashboard.

9.10.2.3 Monitoring metrics

Metrics	Type	Description
tikv_log_backup_interal_actor_action_duration	Histogram	The duration of handling all internal messages and events. `message :: TaskType`
tikv_log_backup_initial_scan_reason	Counter	Statistics of the reasons why initial scan is triggered. The main reason is leader transfer or Region version change. `reason :: {"leader-changed", "region-changed", "retry"}`

Metrics	Type	Description
tikv_log_backup_event_handle_duration_sec	Histogram	The duration of handling KV events. Compared with tikv_log_backup_on_event_duration_seconds, this metric also includes the duration of internal conversion. stage :: {"to_stream_event", "save_to_temp_file ↪ "}
tikv_log_backup_handle_kv_batch	Histogram	Record log-level statistics of the sizes of KV pair batches sent by Raftstore.
tikv_log_backup_initial_scan_disk_read	Counter	The disk IO data read from the disk during initial scan. In Linux, this information is from procfs, which is the size of data actually read from the block device. The configuration item initial-scan-rate-limit applies to this metric.
tikv_log_backup_incremental_scan_bytes	Histogram	The size of KV pairs actually generated during initial scan. Because of compression and read amplification, this value might be different from that of tikv_log_backup_initial_scan_disk_read.
tikv_log_backup_skip_kv_count	Counter	The number of Raft events being skipped during the log backup because they are not helpful to the backup.
tikv_log_backup_errors	Counter	The errors that can be retried or ignored during the log backup. type :: ErrorType
tikv_log_backup_fatal_errors	Counter	The errors that cannot be retried or ignored during the log backup. When an error of this type occurs, the log backup is paused. type :: ErrorType
tikv_log_backup_heap_memory	Gauge	The memory occupied by events that are unconsumed and found by initial scan during log backup.
tikv_log_backup_on_event_duration_seconds	Histogram	The duration of writing KV events to temporary files. stage :: {"write_to_tempfile", "syscall_write"}
tikv_log_backup_store_checkpoint_ts	Gauge	The store-level checkpoint TS, which is deprecated. It is close to the GC safepoint registered by the current store. task :: string
tidb_log_backup_last_checkpoint	Gauge	The global checkpoint TS. It is a time point till which log data has been backed up. task :: string
tikv_log_backup_flush_duration_sec	Histogram	The duration of moving local temporary files to the external storage. stage :: {"generate_metadata", " ↪ save_files", "clear_temp_files"}
tikv_log_backup_flush_file_size	Histogram	Statistics of the sizes of files generated during the backup.
tikv_log_backup_initial_scan_duration_sec	Histogram	The duration of the overall duration of initial scan.
tikv_log_backup_skip_retry_observe	Counter	Statistics of the errors that can be ignored during log backup, or the reasons why retry is skipped. reason :: {"region-absent", "not-leader", " ↪ stale-command"}

Metrics	Type	Description
tikv_log_backup_initial_scan_operations	Counter	Statistics of RocksDB-related operations during initial scan. `cf :: {"default", "write", "lock"}, op :: RocksDBOP`
tikv_log_backup_enabled	Counter	Whether to enable log backup. If the value is greater than `0`, log backup is enabled.
tikv_log_backup_observed_region	Gauge	The number of Regions being listened to.
tikv_log_backup_task_status	Gauge	The status of the log backup task. `0` means running. `1` means paused. `2` means error. `task :: string`
tikv_log_backup_pending_initial_scan	Gauge	Statistics of pending initial scans. `stage :: {"queuing", "executing"}`

9.10.2.4 Log backup alerts

9.10.2.4.1 Alert configuration

Currently, PITR does not have built-in alert items. This section introduces how to configure alert items in PITR and recommends some items.

To configure alert items in PITR, follow these steps:

1. Create a configuration file (for example, `pitr.rules.yml`) for the alert rules on the node where Prometheus is located. In the file, fill in the alert rules according to the Prometheus documentation, the following recommended alert items, and the configuration sample.
2. In the `rule_files` field of the Prometheus configuration file, add the path of the alert rule file.
3. Send `SIGHUP` signal to the Prometheus process (`kill -HUP pid`) or send an HTTP `POST` request to `http://prometheus-addr/-/reload` (before you send the HTTP request, add the `--web.enable-lifecycle` parameter when starting Prometheus).

The recommended alert items are as follows:

9.10.2.4.2 LogBackupRunningRPOMoreThan10m

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 60 > 10 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 0`
- Alert level: warning
- Description: The log data is not persisted to the storage for more than 10 minutes. This alert item is a reminder. In most cases, it does not affect log backup.

A configuration sample of this alert item is as follows:

```
groups:
- name: PiTR
  rules:
  - alert: LogBackupRunningRPOMoreThan10m
    expr: max(time() - tidb_log_backup_last_checkpoint / 262144000) by (task
       ↪ ) / 60 > 10 and max(tidb_log_backup_last_checkpoint) by (task) > 0
       ↪  and max(tikv_log_backup_task_status) by (task) == 0
    labels:
      severity: warning
    annotations:
      summary: RPO of log backup is high
      message: RPO of the log backup task {{ $labels.task }} is more than 10
         ↪ m
```

9.10.2.4.3 LogBackupRunningRPOMoreThan30m

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 60 > 30 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 0`
- Alert level: critical
- Description: The log data is not persisted to the storage for more than 30 minutes. This alert often indicates anomalies. You can check the TiKV logs to find the cause.

9.10.2.4.4 LogBackupPausingMoreThan2h

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 3600 > 2 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 1`
- Alert level: warning
- Description: The log backup task is paused for more than 2 hours. This alert item is a reminder and you are expected to run `br log resume` as soon as possible.

9.10.2.4.5 LogBackupPausingMoreThan12h

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 3600 > 12 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 1`
- Alert level: critical
- Description: The log backup task is paused for more than 12 hours. You are expected to run `br log resume` as soon as possible to resume the task. Log tasks paused for too long have the risk of data loss.

9.10.2.4.6 LogBackupFailed

- Alert item: `max(tikv_log_backup_task_status)by (task)== 2 and max(tidb_log_backup_last_checkpoint)by (task)> 0`
- Alert level: critical
- Description: The log backup task fails. You need to run `br log status` to see the failure reason. If necessary, you need to further check the TiKV logs.

9.10.2.4.7 LogBackupGCSafePointExceedsCheckpoint

- Alert item: `min(tidb_log_backup_last_checkpoint)by (instance)- max(tikv_gcworker_autogc_safe_point)by (instance)< 0`
- Alert level: critical
- Description: Some data has been garbage-collected before the backup. This means that some data has been lost and is very likely to affect your services.

10 Troubleshoot

10.1 Issue Summary

10.1.1 TiDB Troubleshooting Map

This document summarizes common issues in TiDB and other components. You can use this map to diagnose and solve issues when you encounter related problems.

10.1.1.1 1. Service Unavailable

10.1.1.1.1 1.1 The client reports `Region is Unavailable` error

- 1.1.1 The `Region is Unavailable` error is usually because a Region is not available for a period of time. You might encounter `TiKV server is busy`, or the request to TiKV fails due to `not leader` or `epoch not match`, or the request to TiKV time out. In such cases, TiDB performs a `backoff` retry mechanism. When the `backoff` exceeds a threshold (20s by default), the error will be sent to the client. Within the `backoff` threshold, this error is not visible to the client.
- 1.1.2 Multiple TiKV instances are OOM at the same time, which causes no Leader during the OOM period. See case-991 in Chinese.
- 1.1.3 TiKV reports `TiKV server is busy`, and exceeds the `backoff` time. For more details, refer to 4.3. `TiKV server is busy` is a result of the internal flow control mechanism and should not be counted in the `backoff` time. This issue will be fixed.

- 1.1.4 Multiple TiKV instances failed to start, which causes no Leader in a Region. When multiple TiKV instances are deployed in a physical machine, the failure of the physical machine can cause no Leader in a Region if the label is not properly configured. See case-228 in Chinese.
- 1.1.5 When a Follower apply is lagged in a previous epoch, after the Follower becomes a Leader, it rejects the request with `epoch not match`. See case-958 in Chinese (TiKV needs to optimize its mechanism).

10.1.1.1.2 1.2 PD errors cause service unavailable

Refer to 5 PD issues.

10.1.1.2 2. Latency increases significantly

10.1.1.2.1 2.1 Transient increase

- 2.1.1 Wrong TiDB execution plan causes latency increase. Refer to 3.3.
- 2.1.2 PD Leader election issue or OOM. Refer to 5.2 and 5.3.
- 2.1.3 A significant number of Leader drops in some TiKV instances. Refer to 4.4.
- 2.1.4 For other causes, see Troubleshoot Increased Read and Write Latency.

10.1.1.2.2 2.2 Persistent and significant increase

- 2.2.1 TiKV single thread bottleneck
  - Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana** -> **TiKV-details** -> **Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue. See case-612 in Chinese.
  - For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana** -> **TiKV-details** -> **Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.
- 2.2.2 CPU load increases.
- 2.2.3 TiKV slow write. Refer to 4.5.
- 2.2.4 TiDB wrong execution plan. Refer to 3.3.
- 2.2.5 For other causes, see Troubleshoot Increased Read and Write Latency.

10.1.1.3 3. TiDB issues

10.1.1.3.1 3.1 DDL

- 3.1.1 An error `ERROR 1105 (HY000): unsupported modify decimal column precision` is reported when you modify the length of the `decimal` field. TiDB does not support changing the length of the `decimal` field.
- 3.1.2 TiDB DDL job hangs or executes slowly (use `admin show ddl jobs` to check DDL progress)
  - Cause 1: TiDB introduces the metadata lock in v6.3.0, and enables it by default in v6.5.0 and later versions. If the table involved in the DDL operation has intersections with the table involved in the uncommitted transaction, the DDL operation is blocked until the transaction is committed or rolled back.
  - Cause 2: Network issue with other components (PD/TiKV).
  - Cause 3: Early versions of TiDB (earlier than v3.0.8) have heavy internal load because of a lot of goroutine at high concurrency.
  - Cause 4: In early versions (v2.1.15 & versions < v3.0.0-rc1), PD instances fail to delete TiDB keys, which causes every DDL change to wait for two leases.
  - For other unknown causes, report a bug.
  - Solution:
    - For cause 1, check the network connection between TiDB and TiKV/PD.
    - For cause 2 and 3, the issues are already fixed in later versions. You can upgrade TiDB to a later version.
    - For other causes, you can use the following solution of migrating the DDL owner.
  - DDL owner migration:
    - If you can connect to the TiDB server, execute the owner election command again: `curl -X POST http://{TiDBIP}:10080/ddl/owner/resign`
    - If you cannot connect to the TiDB server, use `tidb-ctl` to delete the DDL owner from the etcd of the PD cluster to trigger re-election: `tidb-ctl etcd delowner [LeaseID] [flags] + ownerKey`
- 3.1.3 TiDB reports `information schema is changed` error in log
  - For the detailed causes and solution, see Why the `Information schema is changed` error is reported.
  - Background: The increased number of `schema version` is consistent with the number of `schema state` of each DDL change operation. For example, the `create table` operation has 1 version change, and the `add column` operation has 4 version changes. Therefore, too many column change operations might cause `schema version` to increase fast. For details, refer to online schema change.
- 3.1.4 TiDB reports `information schema is out of date` in log

- Cause 1: The TiDB server that is executing the DML statement is stopped by `graceful kill` and prepares to exit. The execution time of the transaction that contains the DML statement exceeds one DDL lease. An error is reported when the transaction is committed.
- Cause 2: The TiDB server cannot connect to PD or TiKV when it is executing the DML statement. As a result, the TiDB server did not load the new schema within one DDL lease (`45s` by default), or the TiDB server disconnects from PD with the `keep alive` setting.
- Cause 3: TiKV has high load or network timed out. Check the node loads in **Grafana** -> **TiDB** and **TiKV**.
- Solution:
  - For cause 1, retry the DML operation when TiDB is started.
  - For cause 2, check the network between the TiDB server and PD/TiKV.
  - For cause 3, investigate why TiKV is busy. Refer to 4 TiKV issues.

10.1.1.3.2 3.2 OOM issues

- 3.2.1 Symptom
  - Client: The client reports the error `ERROR 2013 (HY000): Lost connection to MySQL server during query`.
  - Check the log
    - Execute `dmesg -T | grep tidb-server`. The result shows the OOM-killer log around the time point when the error occurs.
    - Grep the "Welcome to TiDB" log in `tidb.log` around the time point after the error occurs (namely, the time when tidb-server restarts).
    - Grep `fatal error: runtime: out of memory` or `cannot allocate memory` in `tidb_stderr.log`.
    - In v2.1.8 or earlier versions, you can grep `fatal error: stack overflow` in the `tidb_stderr.log`.
  - Monitor: The memory usage of tidb-server instances increases sharply in a short period of time.
- 3.2.2 Locate the SQL statement that causes OOM. (Currently all versions of TiDB cannot locate SQL accurately. You still need to analyze whether OOM is caused by the SQL statement after you locate one.)
  - For versions >= v3.0.0, grep "expensive_query" in `tidb.log`. That log message records SQL queries that timed out or exceed memory quota.
  - For versions < v3.0.0, grep "memory exceeds quota" in `tidb.log` to locate SQL queries that exceed memory quota.

Note:

The default threshold for a single SQL memory usage is `1GB`. You can set this parameter by configuring the system variable `tidb_mem_quota_query`.

- 3.2.3 Mitigate OOM issues
    - By enabling `SWAP`, you can mitigate the OOM issue caused by overuse of memory by large queries. When the memory is insufficient, this method can have impact on the performance of large queries due to the I/O overhead. The degree to which the performance is affected depends on the remaining memory space and the disk I/O speed.
- 3.2.4 Typical reasons for OOM
    - The SQL query has `join`. If you view the SQL statement by using `explain`, you can find that the `join` operation selects the `HashJoin` algorithm and the `inner` table is large.
    - The data volume of a single `UPDATE/DELETE` query is too large. See case-882 in Chinese.
    - The SQL contains multiple sub-queries connected by `Union`. See case-1828 in Chinese.

For more information about troubleshooting OOM, see Troubleshoot TiDB OOM Issues.

10.1.1.3.3 3.3 Wrong execution plan

- 3.3.1 Symptom
    - SQL query execution time is much longer compared with that of previous executions, or the execution plan suddenly changes. If the execution plan is logged in the slow log, you can directly compare the execution plans.
    - SQL query execution time is much longer compared with that of other databases such as MySQL. Compare the execution plan with other databases to see the differences, such as `Join Order`.
    - In slow log, the number of SQL execution time `Scan Keys` is large.
- 3.3.2 Investigate the execution plan

- `explain analyze {SQL}`. When the execution time is acceptable, compare `count` in the result of `explain analyze` and the number of `row` in `execution info`. If a large difference is found in the `TableScan/IndexScan` row, it is likely that the statistics is incorrect. If a large difference is found in other rows, the problem might not be in the statistics.
- `select count(*)`. When the execution plan contains a `join` operation, `explain analyze` might take a long time. You can check whether the problem is in the statistics by executing `select count(*)` for the conditions on `TableScan/IndexScan` and comparing the `row count` information in the `explain` result.

- 3.3.3 Mitigation
  - For v3.0 and later versions, use the `SQL Bind` feature to bind the execution plan.
  - Update the statistics. If you are roughly sure that the problem is caused by the statistics, dump the statistics. If the cause is outdated statistics, such as the `modify count/row count` in `show stats_meta` is greater than a certain value (for example, 0.3), or the table has an index of time column, you can try recovering by using `analyze table`. If `auto analyze` is configured, check whether the `tidb_auto_analyze_ratio` system variable is too large (for example, greater than 0.3), and whether the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`.
  - For other situations, report a bug.

10.1.1.3.4 3.4 SQL execution error

- 3.4.1 The client reports the `ERROR 1265(01000)Data Truncated` error. This is because the way TiDB internally calculates the precision of `Decimal` type is incompatible with that of MySQL. This issue has been fixed in v3.0.10 (#14438).
  - Cause:

    In MySQL, if two large-precision `Decimal` are divided and the result exceeds the maximum decimal precision (`30`), only `30` digits are reserved and no error is reported;

    In TiDB, the calculation result is the same as in MySQL, but inside the data structure that represents `Decimal`, a field for decimal precision still retains the actual precision.

    Take `(0.1^30)/ 10` as an example. The results in TiDB and MySQL are both `0`, because the precision is `30` at most. However, in TiDB, the field for decimal precision is still `31`.

    After multiple `Decimal` divisions, even though the result is correct, this precision field could grow larger and larger, and eventually exceeds the threshold in TiDB (`72`), and the `Data Truncated` error is reported.

    The multiplication of `Decimal` does not have this issue, because the out-of-bounds is bypassed, and the precision is set to the maximum precision limit.

- Solution: You can bypass this issue by manually adding `Cast(xx as decimal(a , b))`, in which `a` and `b` are the target precisions.

10.1.1.3.5 3.5 Slow query issues

To identify slow queries, see Identify slow queries. To analyze and handle slow queries, see Analyze slow queries.

10.1.1.3.6 3.6 Hotspot issues

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency. For detailed solutions, see Troubleshoot Hotspot Issues.

10.1.1.3.7 3.7 High disk I/O usage

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck. For how to locate and handle the issue of high I/O usage in TiDB, see Troubleshoot High Disk I/O Usage.

10.1.1.3.8 3.8 Lock conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. To learn how to troubleshoot lock-related issues and how to handle optimistic and pessimistic lock conflicts, see Troubleshoot Lock Conflicts.

10.1.1.3.9 3.9 Inconsistency between data and indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

To learn more about the inconsistency error and how to bypass the check, see Troubleshoot Inconsistency Between Data and Indexes.

10.1.1.4 4. TiKV issues

10.1.1.4.1 4.1 TiKV panics and fails to start

- 4.1.1 `sync-log = false`. The `unexpected raft log index: last_index X < applied_index Y` error is returned after the machine is powered off.

  This issue is expected. You can restore the Region using `tikv-ctl`.

- 4.1.2 If TiKV is deployed on a virtual machine, when the virtual machine is killed or the physical machine is powered off, the `entries[X, Y] is unavailable from storage` error is reported.

  This issue is expected. The `fsync` of virtual machines is not reliable, so you need to restore the Region using `tikv-ctl`.

- 4.1.3 For other unexpected causes, report a bug.

10.1.1.4.2 4.2 TiKV OOM

- 4.2.1 If the `block-cache` configuration is too large, it might cause OOM.

  To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana -> TiKV-details**.

  Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"` parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- 4.2.2 Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM.

  To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana -> TiKV-details -> coprocessor overview**.

- 4.2.3 Other components occupy too much memory.

  This issue is unexpected. You can report a bug.

10.1.1.4.3 4.3 The client reports the `server is busy` error

Check the specific cause for busy by viewing the monitor **Grafana -> TiKV -> errors**. `server is busy` is caused by the flow control mechanism of TiKV, which informs `tidb/ti -client` that TiKV is currently under too much pressure and will retry later.

- 4.3.1 TiKV RocksDB encounters `write stall`.

  A TiKV instance has two RocksDB instances, one in `data/raft` to store the Raft log, and the other in `data/db` to store the real data. You can check the specific cause for the stall by running `grep "Stalling" RocksDB` in the log. The RocksDB log is a file starting with `LOG`, and `LOG` is the current log. `write stall` is a performance degradation mechanism natively built in RocksDB. When `write stall` occurs in RocksDB, the system performance drops significantly. In versions before v5.2.0, TiDB tries to block all write requests by returning a `ServerIsBusy` error directly to the client when encountering `write stall`, but this could lead to a sharp decrease in QPS performance. Starting from v5.2.0, TiKV introduces a new flow control mechanism that suppresses writes by delaying write requests dynamically in the scheduling layer, which replaces the previous mechanism of returning `server is busy` to clients when `write stall` occurs. The new flow control mechanism is enabled by default, and TiKV automatically disables the `write stall` mechanism for `KvDB` and `RaftDB` (except for memtables). However, when the number of pending requests exceeds a certain threshold, the flow control mechanism still takes effect, beginning to reject some or all write requests and returning a `server is busy` error to clients. For detailed explanations and thresholds, see Flow control configuration.

  - If the `server is busy` error is triggered by too many pending compaction bytes, you can alleviate this issue by increasing the values of the `soft-pending-compaction-bytes-limit` and `hard-pending-compaction-bytes-limit` parameters.
    - When pending compaction bytes reach the value of the `soft-pending-compaction-bytes-limit` parameter (`192GiB` by default), the flow control mechanism begins to reject some write requests (by returning `ServerIsBusy` to clients). In this case, you can increase the value of this parameter, for example, `[storage.flow-control] soft-pending-compaction-bytes-limit = "384GiB"`.
    - When pending compaction bytes reach the value of the `hard-pending-compaction-bytes-limit` parameter (`1024GiB` by default), the flow control mechanism begins to reject all write requests (by returning `ServerIsBusy` to clients). This scenario is less likely to occur because the flow control mechanism intervenes to slow down write speed after reaching the threshold of `soft-pending-compaction-bytes-limit`. If it occurs, you can increase the value of this parameter, for example, `[storage.flow-control] hard-pending-compaction-bytes-limit = "2048GiB"`.
    - If the disk I/O capacity fails to keep up with the write for a long time, it is recommended to scale up your disk. If the disk throughput reaches the upper limit and causes write stall (for example, the SATA SSD is much lower than NVME SSD), while the CPU resources is sufficient, you may apply a compression algorithm of higher compression ratio. This way, the CPU resources is traded for disk resources, and the pressure on the disk is eased.

    - If the default CF compaction sees a high pressure, change the `[rocksdb.defaultcf] compression-per-level` parameter from `["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.
  - Too many memtables causes stall. This usually occurs when the amount of instant writes is large and the memtables flush to the disk slowly. If the disk write speed cannot be improved, and this issue only occurs during business peaks, you can mitigate it by increasing the `max-write-buffer-number` of the corresponding CF.
    - For example, set `[rocksdb.defaultcf] max-write-buffer-number` to `8` (`5` by default). Note that this might cause more memory usage in the peak, because more memtables might be in the memory.

- 4.3.2 `scheduler too busy`

  - Serious write conflict. `latch wait duration` is high. You can view `latch wait duration` in the monitor **Grafana -> TiKV-details -> scheduler prewrite/scheduler commit**. When the write tasks pile up in the scheduler, the pending write tasks exceed the threshold set in `[storage] scheduler-pending-write-threshold` (100MB). You can verify the cause by viewing the metric corresponding to `MVCC_CONFLICT_COUNTER`.
  - Slow write causes write tasks to pile up. The data being written to TiKV exceeds the threshold set by `[storage] scheduler-pending-write-threshold` (100MB). Refer to 4.5.

- 4.3.3 `raftstore is busy`. The processing of messages is slower than the receiving of messages. The short-term `channel full` status does not affect the service, but if the error persists for a long time, it might cause Leader switch.

  - `append log` encounters stall. Refer to 4.3.1.
  - `append log duration` is high, which causes slow processing of messages. You can refer to 4.5 to analyze why `append log duration` is high.
  - raftstore receives a large batch of messages in an instant (check in the TiKV Raft messages dashboard), and fails to process them. Usually the short-term `channel full` status does not affect the service.

- 4.3.4 TiKV coprocessor is in a queue. The number of piled up tasks exceeds `coprocessor threads * readpool.coprocessor.max-tasks-per-worker-[normal|low|high]`. Too many large queries leads to the tasks piling up in coprocessor. You need to check whether a execution plan change causes a large number of table scan operations. Refer to 3.3.

10.1.1.4.4 4.4 Some TiKV nodes drop Leader frequently

- 4.4.1 Re-election because TiKV is restarted

  - After TiKV panics, it is pulled up by systemd and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
  - TiKV is stopped or killed by a third party and then pulled up by systemd. Check the cause by viewing `dmesg` and the TiKV log.
  - TiKV is OOM, which causes restart. Refer to 4.2.
  - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage). See case case-500 in Chinese.

- 4.4.2 TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`. Refer to 4.3.1.

- 4.4.3 Re-election because of network isolation.

10.1.1.4.5 4.5 TiKV write is slow

- 4.5.1 Check whether the TiKV write is low by viewing the `prewrite/commit/raw-put` duration of TiKV gRPC (only for RawKV clusters). Generally, you can locate the slow phase according to the performance-map. Some common situations are listed as follows.

- 4.5.2 The scheduler CPU is busy (only for transaction kv).

  The `scheduler command duration` of prewrite/commit is longer than the sum of `scheduler latch wait duration` and `storage async write duration`. The scheduler worker has a high CPU demand, such as over 80% of `scheduler-worker-pool-size` * 100%, or the CPU resources of the entire machine are relatively limited. If the write workload is large, check if `[storage] scheduler-worker-pool-size` is set too small.

  For other situations, report a bug.

- 4.5.3 Append log is slow.

  The **Raft IO**/`append log duration` in TiKV Grafana is high, usually because the disk write operation is slow. You can verify the cause by checking the `WAL Sync Duration max` value of RocksDB - raft.

  For other situations, report a bug.

- 4.5.4 The raftstore thread is busy.

  The **Raft Propose**/`propose wait duration` is significantly larger than the append log duration in TiKV Grafana. Take the following methods:

  - Check whether the `[raftstore] store-pool-size` configuration value is too small. It is recommended to set the value between `1` and `5` and not too large.

- Check whether the CPU resources on the machine are insufficient.

- 4.5.5 Apply is slow.

  The **Raft IO**/`apply log duration` in TiKV Grafana is high, which usually comes with a high **Raft Propose**/`apply wait duration`. The possible causes are as follows:

  - `[raftstore] apply-pool-size` is too small (it is recommended to set the value between `1` and `5` and not too large), and the **Thread CPU**/`apply CPU` is large.
  - The CPU resources on the machine are insufficient.
  - Region write hot spot. A single apply thread has high CPU usage. Currently, we cannot properly address the hot spot problem on a single Region, which is being improved. To view the CPU usage of each thread, modify the Grafana expression and add `by (instance, name)`.
  - RocksDB write is slow. **RocksDB kv**/`max write duration` is high. A single Raft log might contain multiple KVs. When writing into RocksDB, 128 KVs are written into RocksDB in a write batch. Therefore, an apply log might be associated with multiple writes in RocksDB.
  - For other situations, report a bug.

- 4.5.6 Raft commit log is slow.

  The **Raft IO**/`commit log duration` in TiKV Grafana is high (this metric is only supported in Grafana after v4.x). Every Region corresponds to an independent Raft group. Raft has a flow control mechanism, similar to the sliding window mechanism of TCP. You can control the size of the sliding window by configuring the `[raftstore]` ↪ `raft-max-inflight-msgs = 256` parameter. If there is a write hot spot and the `commit log duration` is high, you can adjust the parameter, such as increasing it to `1024`.

- 4.5.7 For other situations, refer to the write path on performance-map and analyze the cause.

10.1.1.5 5. PD issues

10.1.1.5.1 5.1 PD scheduling

- 5.1.1 Merge

  - Empty Regions across tables cannot be merged. You need to modify the `[` ↪ `coprocessor] split-region-on-table` parameter in TiKV, which is set to `false` in v4.x by default. See case-896 in Chinese.
  - Region merge is slow. You can check whether the merged operator is generated by accessing the monitor dashboard in **Grafana** -> **PD** -> **operator**. To accelerate the merge, increase the value of `merge-schedule-limit`.

- 5.1.2 Add replicas or take replicas online/offline

    - The TiKV disk uses 80% of the capacity, and PD does not add replicas. In this situation, the number of miss peers increases, so TiKV needs to be scaled out. See case-801 in Chinese.
    - When a TiKV node is taken offline, some Region cannot be migrated to other nodes. This issue has been fixed in v3.0.4 (#5526). See case-870 in Chinese.

- 5.1.3 Balance

    - The Leader/Region count is not evenly distributed. See case-394 and case-759 in Chinese. The major cause is that the balance performs scheduling based on the size of Region/Leader, so this might result in the uneven distribution of the count. In TiDB 4.0, the `[leader-schedule-policy]` parameter is introduced, which enables you to set the scheduling policy of Leader to be `count`-based or `size`-based.

10.1.1.5.2 5.2 PD election

- 5.2.1 PD switches Leader.

    - Cause 1: Disk. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana** -> **disk performance** -> **latency/load**. You can also use the FIO tool to run a check on the disk if necessary. See case-292 in Chinese.
    - Cause 2: Network. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana** -> **PD** -> **etcd**. See case-177 in Chinese.
    - Cause 3: High system load. The log shows `server is likely overloaded`. See case-214 in Chinese.

- 5.2.2 PD cannot elect a Leader or the election is slow.

    - PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19. See case-875 in Chinese.
    - The election is slow: The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region -storage` to `true`, which significantly reduce the Region loading duration. See case-429 in Chinese.

- 5.2.3 PD timed out when TiDB executes SQL statements.
  - PD doesn't have a Leader or switches Leader. Refer to 5.2.1 and 5.2.2.
  - Network issue. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana -> blackbox_exporter -> ping latency**.
  - PD panics. Report a bug.
  - PD is OOM. Refer to 5.3.
  - If the issue has other causes, get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.
- 5.2.4 Other issues
  - PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040). For details, see case-947 in Chinese.
  - For other situations, report a bug.

10.1.1.5.3 5.3 PD OOM

- 5.3.1 When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- 5.3.2 PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that TCP InSegs is relatively large. This issue has been fixed in v3.0.6 (#1952).

10.1.1.5.4 5.4 Grafana display

- 5.4.1 The monitor in **Grafana -> PD -> cluster -> role** displays follower. The Grafana expression issue has been fixed in v3.0.8.

10.1.1.6 6. Ecosystem tools

10.1.1.6.1 6.1 Data Migration

- 6.1.1 TiDB Data Migration (DM) is a migration tool that supports data migration from MySQL/MariaDB into TiDB. For details, see DM overview.
- 6.1.2 `Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you run `query status` or check the log.

    - The database related passwords in all the DM configuration files should be encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt the password. Cleartext passwords can be used since v1.0.6.
    - During DM operation, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data replication task.
    - To deploy different versions of DM-worker/DM-master/dmctl in a DM cluster, see the case study on AskTUG in Chinese.

- 6.1.3 A replication task is interrupted with the `driver: bad connection` error returned.

    - The `driver: bad connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure and TiDB restart), and that the data of the current request has not yet been sent to TiDB.
        - For versions earlier than DM 1.0.0 GA, stop the task by running `stop-task` and then restart the task by running `start-task`.
        - For DM 1.0.0 GA or later versions, an automatic retry mechanism for this type of error is added. See #265.

- 6.1.4 A replication task is interrupted with the `invalid connection` error.

    - The `invalid connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy), and that a part of the data for the current request has been sent to TiDB. Because DM has the feature of concurrently replicating data to the downstream in replication tasks, several errors might occur when a task is interrupted. You can check these errors by running `query-status` or `query-error`.
        - If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
        - If DM does not retry or fails to retry automatically because of version problems (automatic retry is introduced in v1.0.0-rc.1), use `stop-task` to stop the task and then use `start-task` to restart the task.

- 6.1.5 The relay unit reports the error `event from * in * diff from passed-in` ↪ `event *`, or a replication task is interrupted with an error that fails to get or parse binlog, such as `get binlog error ERROR 1236 (HY000)and binlog checksum` ↪ `mismatch, data may be corrupted returned`

    - During the process that DM pulls relay log or the incremental replication, this two errors might occur if the size of the upstream binlog file exceeds 4 GB.

- Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the binlog file size, and store the replicated binlog positions as checkpoints. However, the official MySQL uses uint32 to store binlog positions, which means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.
- Solution:
  - For relay processing units, manually recover replication.
  - For binlog replication processing units, manually recover replication.

- 6.1.6 The DM replication is interrupted, and the log returns `ERROR 1236 (HY000) ↪ The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION ↪ = 1, but the master has purged binary logs containing GTIDs that the ↪ slave requires.`
  - Check whether the master binlog is purged.
  - Check the position information recorded in `relay.meta`.
    - `relay.meta` has recorded the empty GTID information. DM-worker saves the GTID information in memory to `relay.meta` when it exits or in every 30s. When DM-worker does not obtain the upstream GTID information, it saves the empty GTID information to `relay.meta`. See case-772 in Chinese.
    - The binlog event recorded in `relay.meta` triggers the incomplete recover process and records the wrong GTID information. This issue is fixed in v1.0.2, and might occur in earlier versions.

- 6.1.7 The DM replication process returns an error `Error 1366: incorrect utf8 ↪ value eda0bdedb29d(\ufffd\ufffd\ufffd\ufffd\ufffd\ufffd)`.
  - This value cannot be successfully written into MySQL 8.0 or TiDB, but can be written into MySQL 5.7. You can skip the data format check by enabling the `tidb_skip_utf8_check` parameter.

10.1.1.6.2 6.2 TiDB Lightning

- 6.2.1 TiDB Lightning is a tool for fast full import of large amounts of data into a TiDB cluster. See TiDB Lightning on GitHub.

- 6.2.2 Import speed is too slow.
  - `region-concurrency` is set too high, which causes thread contention and reduces performance. Three ways to troubleshoot:
    - The setting can be found from the start of the log by searching `region- ↪ concurrency`.

    - If TiDB Lightning shares a server with other services (for example, Importer), you must manually set `region-concurrency` to 75% of the total number of CPU cores on that server.
    - If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning might not be able to read this out. In this case, `region-concurrency` must also be manually reduced.
  - Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Dumpling output. If the indices are negligible, you may first remove them from the schema, and add them back via `CREATE INDEX` after the import is complete.
  - The version of TiDB Lightning is old. Try the latest version, which might improve the import speed.

- 6.2.3 `checksum failed: checksum mismatched remote vs local`.

  - Cause 1: The table might already have data. These old data can affect the final checksum.
  - Cause 2: If the checksum of the target database is 0, which means nothing is imported, it is possible that the cluster is too hot and fails to take in any data.
  - Cause 3: If the data source is generated by the machine and not backed up by Dumpling, ensure it respects the constrains of the table. For example:
    - `AUTO_INCREMENT` columns need to be positive, and do not contain the value "0".
    - UNIQUE and PRIMARY KEYs must not have duplicate entries.
  - Solution: See Troubleshooting Solution.

- 6.2.4 `Checkpoint for ··· has invalid status:(error code)`

  - Cause: Checkpoint is enabled, and Lightning/Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed. The error code is an integer less than 25, with possible values as `0, 3, 6, 9, 12, 14, 15, 17, 18, 20 and 21`. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later the exit occurs.
  - Solution: See Troubleshooting Solution.

- 6.2.5 `cannot guess encoding for input file, please convert to UTF-8 manually`

  - Cause: TiDB Lightning only supports the UTF-8 and GB-18030 encodings. This error means the file is not in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical ALTER TABLE executions.

- Solution: See Troubleshooting Solution.

- 6.2.6 `[sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 0 45 0 0}'`

  - Cause: A timestamp type entry has a time value that does not exist. This is either because of DST changes or because the time value has exceeded the supported range (from Jan 1, 1970 to Jan 19, 2038).
  - Solution: See Troubleshooting Solution.

10.1.1.7 7. Common log analysis

10.1.1.7.1 7.1 TiDB

- 7.1.1 `GC life time is shorter than transaction duration`.

  The transaction duration exceeds the GC lifetime (10 minutes by default).

  You can increase the GC lifetime by modifying the `tidb_gc_life_time` system variable. Generally, it is not recommended to modify this parameter, because changing it might cause many old versions to pile up if this transaction has a large number of `UPDATE` and `DELETE` statements.

- 7.1.2 `txn takes too much time`.

  This error is returned when you commit a transaction that has not been committed for a long time (over 590 seconds).

  If your application needs to execute a transaction of such a long time, you can increase the `[tikv-client] max-txn-time-use = 590` parameter and the GC lifetime to avoid this issue. It is recommended to check whether your application needs such a long transaction time.

- 7.1.3 `coprocessor.go` reports `request outdated`.

  This error is returned when the coprocessor request sent to TiKV waits in a queue at TiKV for over 60 seconds.

  You need to investigate why the TiKV coprocessor is in a long queue.

- 7.1.4 `region_cache.go` reports a large number of `switch region peer to next due to send request fail`, and the error message is `context deadline exceeded`.

  The request for TiKV timed out and triggers the region cache to switch the request to other nodes. You can continue to run the `grep "<addr> cancelled` command on the `addr` field in the log and take the following steps according to the `grep` results:

  - `send request is cancelled`: The request timed out during the sending phase. You can investigate the monitoring **Grafana** -> **TiDB** -> **Batch Client**/`Pending Request Count by TiKV` and see whether the Pending Request Count is greater than 128:

  - If the value is greater than 128, the sending goes beyond the processing capacity of KV, so the sending piles up.
  - If the value is not greater than 128, check the log to see if the report is caused by the operation and maintenance changes of the corresponding KV; otherwise, this error is unexpected, and you need to report a bug.
- `wait response is cancelled`: The request timed out after it is sent to TiKV. You need to check the response time of the corresponding TiKV address and the Region logs in PD and KV at that time.

- 7.1.5 `distsql.go` reports `inconsistent index`.

  The data index seems to be inconsistent. Run the `admin check table <TableName>` command on the table where the reported index is. If the check fails, disable garbage collection by running the following command, and report a bug:

```
SET GLOBAL tidb_gc_enable = 0;
```

10.1.1.7.2 7.2 TiKV

- 7.2.1 `key is locked`.

  The read and write have conflict. The read request encounters data that has not been committed and needs to wait until the data is committed.

  A small number of this error has no impact on the business, but a large number of this error indicates that the read-write conflict is severe in your business.

- 7.2.2 `write conflict`.

  This is the write-write conflict in optimistic transactions. If multiple transactions modify the same key, only one transaction succeed and other transactions automatically obtain the timestamp again and retry the operation, with no impact on the business.

  If the conflict is severe, it might cause transaction failure after multiple retries. In this case, it is recommended to use the pessimistic lock. For more details about the error and the solution, see Troubleshoot Write Conflicts in Optimistic Transactions.

- 7.2.3 `TxnLockNotFound`.

  This transaction commit is too slow, causing it to be rolled back by other transactions after Time To Live (TTL). This transaction will automatically retry, so the business is usually not affected. For a transaction with a size of 0.25 MB or smaller, the default TTL is 3 seconds. For more details, see the `LockNotFound` error.

- 7.2.4 `PessimisticLockNotFound`.

  Similar to `TxnLockNotFound`. The pessimistic transaction commit is too slow and thus rolled back by other transactions.

- 7.2.5 `stale_epoch`.

  The request epoch is outdated, so TiDB re-sends the request after updating the routing. The business is not affected. Epoch changes when Region has a split/merge operation or a replica is migrated.

- 7.2.6 `peer is not leader`.

  The request is sent to a replica that is not Leader. If the error response indicates which replica is the latest Leader, TiDB updates the local routing according the error and sends a new request to the latest Leader. Usually, the business is not affected.

  In v3.0 and later versions, TiDB tries other peers if the request to the previous Leader fails, which might lead to frequent `peer is not leader` in TiKV log. You can check the `switch region peer to next due to send request fail` log of the corresponding Region in TiDB to determine the root cause of the sending failure. For details, refer to 7.1.4.

  This error might also be returned if a Region has no Leader due to other reasons. For details, see 4.4.

10.1.2 TiDB Cluster Troubleshooting Guide

You can use this guide to help you diagnose and solve basic problems while using TiDB. If your problem is not resolved, please collect the following information and you can report a bug:

- The exact error message and the operations while the error occurs
- The state of all the components
- The `error/fatal/panic` information in the log of the component that reports the error
- The configuration and deployment topology
- The TiDB component related issue in `dmesg`

For other information, see Frequently Asked Questions (FAQ).

10.1.2.1 Cannot connect to the database

1. Make sure all the services are started, including `tidb-server`, `pd-server`, and `tikv-server`.

2. Use the `ps` command to check if all the processes are running.

   - If a certain process is not running, see the following corresponding sections to diagnose and solve the issue.
   - If all the processes are running, check the `tidb-server` log to see if the following messages are displayed:

- InformationSchema is out of date: This message is displayed if the `tikv-server` cannot be connected. Check the state and log of `pd-server` and `tikv-server`.
- panic: This message is displayed if there is an issue with the program. Please provide the detailed panic log and you can report a bug.

3. If the data is cleared and the services are re-deployed, make sure that:

    - All the data in `tikv-server` and `pd-server` are cleared. The specific data is stored in `tikv-server` and the metadata is stored in `pd-server`. If only one of the two servers is cleared, the data will be inconsistent.
    - After the data in `pd-server` and `tikv-server` are cleared and the `pd-server` and `tikv-server` are restarted, the `tidb-server` must be restarted too. The cluster ID is randomly allocated when the `pd-server` is initialized. So when the cluster is re-deployed, the cluster ID changes and you need to restart the `tidb-server` to get the new cluster ID.

10.1.2.2 Cannot start `tidb-server`

See the following for the situations when the `tidb-server` cannot be started:

- Error in the startup parameters.

  See the TiDB configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tidb-server` is not occupied.

- Cannot connect to `pd-server`.

    - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
    - If there is no issue with the network, check the state and log of the `pd-server` process.

10.1.2.3 Cannot start `tikv-server`

See the following for the situations when the `tikv-server` cannot be started:

- Error in the startup parameters: See the TiKV configuration and options.
- The port is occupied: Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tikv-server` is not occupied.
- Cannot connect to `pd-server`.

- Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
- If there is no issue with the network, check the state and log of the `pd-server` process.

- The file is occupied.

  Do not open two TiKV files on one database file directory.

10.1.2.4 Cannot start `pd-server`

See the following for the situations when the `pd-server` cannot be started:

- Error in the startup parameters.

  See the PD configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `pd-server` is not occupied.

10.1.2.5 The TiDB/TiKV/PD process aborts unexpectedly

- Is the process started on the foreground? The process might exit because the client aborts.
- Is `nohup+&` run in the command line? This might cause the process to abort because it receives the hup signal. It is recommended to write and run the startup command in a script.

10.1.2.6 TiDB panic

Please provide the panic log and you can report a bug.

10.1.2.7 The connection is rejected

Make sure the network parameters of the operating system are correct, including but not limited to:

- The port in the connection string is consistent with the `tidb-server` starting port.
- The firewall is configured correctly.

10.1.2.8 Open too many files

Before starting the process, make sure the result of `ulimit -n` is large enough. It is recommended to set the value to `unlimited` or larger than `1000000`.

10.1.2.9 Database access times out and the system load is too high

First, check the slow query log and see if it is because of some inappropriate SQL statement.

If you failed to solve the problem, provide the following information:

- The deployment topology
    - How many `tidb-server`/`pd-server`/`tikv-server` instances are deployed?
    - How are these instances distributed in the machines?
- The hardware configuration of the machines where these instances are deployed:
    - The number of CPU cores
    - The size of the memory
    - The type of the disk (SSD or Hard Drive Disk)
    - Are they physical machines or virtual machines?
- Are there other services besides the TiDB cluster?
- Are the `pd-server`s and `tikv-server`s deployed separately?
- What is the current operation?
- Check the CPU thread name using the `top -H` command.
- Are there any exceptions in the network or IO monitoring data recently?

10.1.3 Troubleshoot a TiFlash Cluster

This section describes some commonly encountered issues when using TiFlash, the reasons, and the solutions.

10.1.3.1 TiFlash fails to start

The issue might occur due to different reasons. It is recommended that you troubleshoot it following the steps below:

1. Check whether your system is RedHat Enterprise Linux 8.

   RedHat Enterprise Linux 8 does not have the `libnsl.so` system library. You can manually install it via the following command:

   ```
   dnf install libnsl
   ```

2. Check your system's `ulimit` parameter setting.

   ```
   ulimit -n 1000000
   ```

3. Use the PD Control tool to check whether there is any TiFlash instance that failed to go offline on the node (same IP and Port) and force the instance(s) to go offline. For detailed steps, refer to Scale in a TiFlash cluster.

If the above methods cannot resolve your issue, save the TiFlash log files and get support from PingCAP or the community.

10.1.3.2 TiFlash replica is always unavailable

This is because TiFlash is in an abnormal state caused by configuration errors or environment issues. Take the following steps to identify the faulty component:

1. Check whether PD enables the `Placement Rules` feature:

```
echo 'config show replication' | /path/to/pd-ctl -u http://${pd-ip}:${
    ↪ pd-port}
```

   - If `true` is returned, go to the next step.
   - If `false` is returned, enable the Placement Rules feature and go to the next step.

2. Check whether the TiFlash process is working correctly by viewing `UpTime` on the TiFlash-Summary monitoring panel.

3. Check whether the TiFlash proxy status is normal through `pd-ctl`.

```
echo "store" | /path/to/pd-ctl -u http://${pd-ip}:${pd-port}
```

   The TiFlash proxy's `store.labels` includes information such as `{"key": "engine ↪ ", "value": "tiflash"}`. You can check this information to confirm a TiFlash proxy.

4. Check whether `pd buddy` can correctly print the logs (the log path is the value of `log` in the [flash.flash_cluster] configuration item; the default log path is under the `tmp` directory configured in the TiFlash configuration file).

5. Check whether the number of configured replicas is less than or equal to the number of TiKV nodes in the cluster. If not, PD cannot replicate data to TiFlash:

```
echo 'config placement-rules show' | /path/to/pd-ctl -u http://${pd-ip
    ↪ }:${pd-port}
```

   Reconfirm the value of `default: count`.

Note:

- When Placement Rules are enabled and multiple rules exist, the previously configured `max-replicas`, `location-labels`, and `isolation-level` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.
- When Placement Rules are enabled and only one default rule exists, TiDB will automatically update this default rule when `max-replicas`, `location-labels`, or `isolation-level` configurations are changed.

6. Check whether the remaining disk space of the machine (where `store` of the TiFlash node is) is sufficient. By default, when the remaining disk space is less than 20% of the `store` capacity (which is controlled by the `low-space-ratio` parameter), PD cannot schedule data to this TiFlash node.

10.1.3.3 Some queries return the `Region Unavailable` error

If the load pressure on TiFlash is too heavy and it causes that TiFlash data replication falls behind, some queries might return the `Region Unavailable` error.

In this case, you can balance the load pressure by adding more TiFlash nodes.

10.1.3.4 Data file corruption

Take the following steps to handle the data file corruption:

1. Refer to Take a TiFlash node down to take the corresponding TiFlash node down.
2. Delete the related data of the TiFlash node.
3. Redeploy the TiFlash node in the cluster.

10.1.3.5 TiFlash analysis is slow

If a statement contains operators or functions not supported in the MPP mode, TiDB does not select the MPP mode. Therefore, the analysis of the statement is slow. In this case, you can execute the `EXPLAIN` statement to check for operators or functions not supported in the MPP mode.

```
create table t(a datetime);
alter table t set tiflash replica 1;
insert into t values('2022-01-13');
set @@session.tidb_enforce_mpp=1;
explain select count(*) from t where subtime(a, '12:00:00') > '2022-01-01'
    ↪ group by a;
show warnings;
```

In this example, the warning message shows that TiDB does not select the MPP mode because TiDB 5.4 and earlier versions do not support the `subtime` function.

```
+---------+------+-------------------------------------------------------------------------
   ↪
> | Level   | Code | Message
   ↪                                                                    |
+---------+------+-------------------------------------------------------------------------
   ↪
| Warning | 1105 | Scalar function 'subtime'(signature: SubDatetimeAndString
   ↪ , return type: datetime) is not supported to push down to tiflash now
   ↪ . |
+---------+------+-------------------------------------------------------------------------
   ↪
```

10.1.3.6 Data is not replicated to TiFlash

After deploying a TiFlash node and starting replication (by performing the ALTER operation), no data is replicated to it. In this case, you can identify and address the problem by following the steps below:

1. Check whether the replication is successful by running the `ALTER table <tbl_name>` ↪ `set tiflash replica <num>` command and check the output.

    - If there is output, go to the next step.
    - If there is no output, run the `SELECT * FROM information_schema.tiflash` ↪ `_replica` command to check whether TiFlash replicas have been created. If not, run the `ALTER table ${tbl_name} set tiflash replica ${num}` command again, check whether other statements (for example, `add index`) have been executed, or check whether DDL executions are successful.

2. Check whether TiFlash Region replication runs correctly.

    Check whether there is any change in `progress`:

    - If yes, TiFlash replication runs correctly.
    - If no, TiFlash replication is abnormal. In `tidb.log`, search the log saying `Tiflash` ↪ `replica is not available`. Check whether `progress` of the corresponding table is updated. If not, check the `tiflash log` for further information. For example, search `lag_region_info` in `tiflash log` to find out which Region lags behind.

3. Check whether the Placement Rules function has been enabled by using pd-ctl:

    ```
    echo 'config show replication' | /path/to/pd-ctl -u http://<pd-ip>:<pd-
       ↪ port>
    ```

- If `true` is returned, go to the next step.
- If `false` is returned, enable the Placement Rules feature and go to the next step.

4. Check whether the `max-replicas` configuration is correct:

    - If the value of `max-replicas` does not exceed the number of TiKV nodes in the cluster, go to the next step.
    - If the value of `max-replicas` is greater than the number of TiKV nodes in the cluster, the PD does not replicate data to the TiFlash node. To address this issue, change `max-replicas` to an integer fewer than or equal to the number of TiKV nodes in the cluster.

> **Note:**
>
> `max-replicas` is defaulted to 3. In production environments, the value is usually fewer than the number of TiKV nodes. In test environments, the value can be 1.

```
curl -X POST -d '{
    "group_id": "pd",
    "id": "default",
    "start_key": "",
    "end_key": "",
    "role": "voter",
    "count": 3,
    "location_labels": [
    "host"
    ]
}' <http://172.16.x.xxx:2379/pd/api/v1/config/rule>
```

5. Check whether TiDB has created any placement rule for tables.

    Search the logs of TiDB DDL Owner and check whether TiDB has notified PD to add placement rules. For non-partitioned tables, search `ConfigureTiFlashPDForTable`. For partitioned tables, search `ConfigureTiFlashPDForPartitions`.

    - If the keyword is found, go to the next step.
    - If not, collect logs of the corresponding component for troubleshooting.

6. Check whether PD has configured any placement rule for tables.

    Run the `curl http://<pd-ip>:<pd-port>/pd/api/v1/config/rules/group/tiflash` command to view all TiFlash placement rules on the current PD. If a rule with the ID being `table-<table_id>-r` is found, the PD has configured a placement rule successfully.

7. Check whether the PD schedules properly.

   Search the `pd.log` file for the `table-<table_id>-r` keyword and scheduling behaviors like `add operator`.

   - If the keyword is found, the PD schedules properly.
   - If not, the PD does not schedule properly.

10.1.3.7 Data replication gets stuck

If data replication on TiFlash starts normally but then all or some data fails to be replicated after a period of time, you can confirm or resolve the issue by performing the following steps:

1. Check the disk space.

   Check whether the disk space ratio is higher than the value of `low-space-ratio` (defaulted to 0.8. When the space usage of a node exceeds 80%, the PD stops migrating data to this node to avoid exhaustion of disk space).

   - If the disk usage ratio is greater than or equal to the value of `low-space-ratio`, the disk space is insufficient. To relieve the disk space, remove unnecessary files, such as `space_placeholder_file` (if necessary, set `reserve-space` to 0MB after removing the file) under the `${data}/flash/` folder.
   - If the disk usage ratio is less than the value of `low-space-ratio`, the disk space is sufficient. Go to the next step.

2. Check whether there is any `down peer` (a `down peer` might cause the replication to get stuck).

   Run the `pd-ctl region check-down-peer` command to check whether there is any `down peer`. If any, run the `pd-ctl operator add remove-peer <region-id> <tiflash-store-id>` command to remove it.

10.1.3.8 Data replication is slow

The causes may vary. You can address the problem by performing the following steps.

1. Increase `store limit` to accelerate replication.

2. Adjust the load on TiFlash.

   Excessively high load on TiFlash can also result in slow replication. You can check the load of TiFlash indicators on the **TiFlash-Summary** panel on Grafana:

   - `Applying snapshots Count`: `TiFlash-summary` > `raft` > `Applying snapshots Count`

- Snapshot Predecode Duration: TiFlash-summary > raft > Snapshot Predecode Duration
- Snapshot Flush Duration: TiFlash-summary > raft > Snapshot Flush Duration
- Write Stall Duration: TiFlash-summary > Storage Write Stall > Write Stall Duration
- generate snapshot CPU: TiFlash-Proxy-Details > Thread CPU > Region task worker pre-handle/generate snapshot CPU

Based on your service priorities, adjust the load accordingly to achieve optimal performance.

10.2 Issue Scenarios

10.2.1 Slow Queries

10.2.1.1 Identify Slow Queries

To help users identify slow queries, analyze and improve the performance of SQL execution, TiDB outputs the statements whose execution time exceeds tidb_slow_log_threshold (The default value is 300 milliseconds) to slow-query-file (The default value is "tidb-slow.log").

TiDB enables the slow query log by default. You can enable or disable the feature by modifying the system variable tidb_enable_slow_log.

10.2.1.1.1 Usage example

```
#### Time: 2019-08-14T09:26:59.487776265+08:00

```

10.2.1.1.2 Fields description

> **Note:**
>
> The unit of all the following time fields in the slow query log is **"second"**.

Slow query basics:

- `Time`: The print time of log.
- `Query_time`: The execution time of a statement.
- `Parse_time`: The parsing time for the statement.

- `Compile_time`: The duration of the query optimization.
- `Optimize_time`: The time consumed for optimizing the execution plan.
- `Wait_TS`: The waiting time of the statement to get transaction timestamps.
- `Query`: A SQL statement. `Query` is not printed in the slow log, but the corresponding field is called `Query` after the slow log is mapped to the memory table.
- `Digest`: The fingerprint of the SQL statement.
- `Txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `Is_internal`: Whether a SQL statement is TiDB internal. `true` indicates that a SQL statement is executed internally in TiDB and `false` indicates that a SQL statement is executed by the user.
- `Index_names`: The index names used by the statement.
- `Stats`: The health state, internal version, total row count, modified row count, and load state of statistics that are used during this query. `pseudo` indicates that the statistics information is unhealthy. If the optimizer attempts to use some statistics that are not fully loaded, the internal state is also printed. For example, the meaning of `t1:439478225786634241[105000;5000][col1:allEvicted][idx1:allEvicted]` can be understood as follows:
    - `t1`: statistics on table `t1` are used during query optimization.
    - `439478225786634241`: the internal version.
    - `105000`: the total row count in the statistics.
    - `5000`: the number of rows modified since the last statistics collection.
    - `col1:allEvicted`: statistics on the column `col1` are not fully loaded.
    - `idx1:allEvicted`: statistics on the index `idx1` are not fully loaded.
- `Succ`: Whether a statement is executed successfully.
- `Backoff_time`: The waiting time before retry when a statement encounters errors that require a retry. The common errors as such include: `lock occurs`, `Region split`, and `tikv server is busy`.
- `Plan`: The execution plan of a statement. Execute the `SELECT tidb_decode_plan('xxx...')` statement to parse the specific execution plan.
- `Binary_plan`: The execution plan of a binary-encoded statement. Execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan. The `Plan` and `Binary_plan` fields carry the same information. However, the format of execution plans parsed from the two fields are different.
- `Prepared`: Whether this statement is a `Prepare` or `Execute` request or not.
- `Plan_from_cache`: Whether this statement hits the execution plan cache.
- `Plan_from_binding`: Whether this statement uses the bound execution plans.
- `Has_more_results`: Whether this statement has more results to be fetched by users.
- `Rewrite_time`: The time consumed for rewriting the query of this statement.
- `Preproc_subqueries`: The number of subqueries (in the statement) that are executed in advance. For example, the `where id in (select if from t)` subquery might be executed in advance.
- `Preproc_subqueries_time`: The time consumed for executing the subquery of this statement in advance.

- `Exec_retry_count`: The retry times of this statement. This field is usually for pessimistic transactions in which the statement is retried when the lock is failed.
- `Exec_retry_time`: The execution retry duration of this statement. For example, if a statement has been executed three times in total (failed for the first two times), `Exec_retry_time` means the total duration of the first two executions. The duration of the last execution is `Query_time` minus `Exec_retry_time`.
- `KV_total`: The time spent on all the RPC requests on TiKV or TiFlash by this statement.
- `PD_total`: The time spent on all the RPC requests on PD by this statement.
- `Backoff_total`: The time spent on all the backoff during the execution of this statement.
- `Write_sql_response_total`: The time consumed for sending the results back to the client by this statement.
- `Result_rows`: The row count of the query results.
- `IsExplicitTxn`: Whether this statement is in an explicit transaction. If the value is `false`, the transaction is `autocommit=1` and the statement is automatically committed after execution.
- `Warnings`: The JSON-formatted warnings that are generated during the execution of this statement. These warnings are generally consistent with the output of the `SHOW WARNINGS` statement, but might include extra warnings that provide more diagnostic information. These extra warnings are marked as `IsExtra: true`.

The following fields are related to transaction execution:

- `Prewrite_time`: The duration of the first phase (prewrite) of the two-phase transaction commit.
- `Commit_time`: The duration of the second phase (commit) of the two-phase transaction commit.
- `Get_commit_ts_time`: The time spent on getting `commit_ts` during the second phase (commit) of the two-phase transaction commit.
- `Local_latch_wait_time`: The time that TiDB spends on waiting for the lock before the second phase (commit) of the two-phase transaction commit.
- `Write_keys`: The count of keys that the transaction writes to the Write CF in TiKV.
- `Write_size`: The total size of the keys or values to be written when the transaction commits.
- `Prewrite_region`: The number of TiKV Regions involved in the first phase (prewrite) of the two-phase transaction commit. Each Region triggers a remote procedure call.
- `Wait_prewrite_binlog_time`: The time used to write binlogs when a transaction is committed. Starting from v8.4.0, TiDB Binlog is removed, and this field has no value.
- `Resolve_lock_time`: The time to resolve or wait for the lock to be expired after a lock is encountered during a transaction commit.

Memory usage fields:

- `Mem_max`: The maximum memory space used during the execution period of a SQL statement (the unit is byte).

Hard disk fields:

- `Disk_max`: The maximum disk space used during the execution period of a SQL statement (the unit is byte).

User fields:

- `User`: The name of the user who executes this statement.
- `Host`: The host name of this statement.
- `Conn_ID`: The Connection ID (session ID). For example, you can use the keyword `con:3` to search for the log whose session ID is `3`.
- `DB`: The current database.

TiKV Coprocessor Task fields:

- `Request_count`: The number of Coprocessor requests that a statement sends.
- `Total_keys`: The number of keys that Coprocessor has scanned.
- `Process_time`: The total processing time of a SQL statement in TiKV. Because data is sent to TiKV concurrently, this value might exceed `Query_time`.
- `Wait_time`: The total waiting time of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `Process_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `Num_cop_tasks`: The number of Coprocessor tasks sent by this statement.
- `Cop_proc_avg`: The average execution time of cop-tasks, including some waiting time that cannot be counted, such as the mutex in RocksDB.
- `Cop_proc_p90`: The P90 execution time of cop-tasks.
- `Cop_proc_max`: The maximum execution time of cop-tasks.
- `Cop_proc_addr`: The address of the cop-task with the longest execution time.
- `Cop_wait_avg`: The average waiting time of cop-tasks, including the time of request queueing and getting snapshots.
- `Cop_wait_p90`: The P90 waiting time of cop-tasks.
- `Cop_wait_max`: The maximum waiting time of cop-tasks.
- `Cop_wait_addr`: The address of the cop-task whose waiting time is the longest.
- `Rocksdb_delete_skipped_count`: The number of scans on deleted keys during RocksDB reads.

- `Rocksdb_key_skipped_count`: The number of deleted (tombstone) keys that RocksDB encounters when scanning data.
- `Rocksdb_block_cache_hit_count`: The number of times RocksDB reads data from the block cache.
- `Rocksdb_block_read_count`: The number of times RocksDB reads data from the file system.
- `Rocksdb_block_read_byte`: The amount of data RocksDB reads from the file system.
- `Rocksdb_block_read_time`: The time RocksDB takes to read data from the file system.
- `Cop_backoff_{backoff-type}_total_times`: The total times of backoff caused by an error.
- `Cop_backoff_{backoff-type}_total_time`: The total time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_time`: The longest time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_addr`: The address of the cop-task that has the longest backoff time caused by an error.
- `Cop_backoff_{backoff-type}_avg_time`: The average time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_p90_time`: The P90 percentile backoff time caused by an error.

`backoff-type` generally includes the following types:

- `tikvRPC`: The backoff caused by failing to send RPC requests to TiKV.
- `tiflashRPC`: The backoff caused by failing to send RPC requests to TiFlash.
- `pdRPC`: The backoff caused by failing to send RPC requests to PD.
- `txnLock`: The backoff caused by lock conflicts.
- `regionMiss`: The backoff caused by that processing requests fails when the TiDB Region cache information is outdated after Regions are split or merged.
- `regionScheduling`: The backoff caused by that TiDB cannot process requests when Regions are being scheduled and the Leader is not selected.
- `tikvServerBusy`: The backoff caused by that the TiKV load is too high to handle new requests.
- `tiflashServerBusy`: The backoff caused by that the TiFlash load is too high to handle new requests.
- `tikvDiskFull`: The backoff caused by that the TiKV disk is full.
- `txnLockFast`: The backoff caused by that locks are encountered during data reads.

Fields related to Resource Control:

- `Resource_group`: the resource group that the statement is bound to.
- `Request_unit_read`: the total read RUs consumed by the statement.
- `Request_unit_write`: the total write RUs consumed by the statement.
- `Time_queued_by_rc`: the total time that the statement waits for available resources.

10.2.1.1.3 Related system variables

- tidb_slow_log_threshold: Sets the threshold for the slow log. The SQL statement whose execution time exceeds this threshold is recorded in the slow log. The default value is 300 (ms).
- tidb_query_log_max_len: Sets the maximum length of the SQL statement recorded in the slow log. The default value is 4096 (byte).
- tidb_redact_log: Determines whether to desensitize user data using ? in the SQL statement recorded in the slow log. The default value is 0, which means to disable the feature.
- tidb_enable_collect_execution_info: Determines whether to record the physical execution information of each operator in the execution plan. The default value is 1. This feature impacts the performance by approximately 3%. After enabling this feature, you can view the Plan information as follows:

```
> select tidb_decode_plan('
    ↪ jAOIMAk1XzE3CTAJMQlmdW5jczpjb3VudChDb2x1bW4jNyktPkMJC/

```

If you are conducting a performance test, you can disable the feature of automatically collecting the execution information of operators:

```
set @@tidb_enable_collect_execution_info=0;
```

The returned result of the `Plan` field has roughly the same format with that of `EXPLAIN` or `EXPLAIN ANALYZE`. For more details of the execution plan, see `EXPLAIN` or `EXPLAIN ANALYZE`.

For more information, see TiDB specific variables and syntax.

10.2.1.1.4 Memory mapping in slow log

You can query the content of the slow query log by querying the `INFORMATION_SCHEMA.` ↪ `SLOW_QUERY` table. Each column name in the table corresponds to one field name in the slow log. For table structure, see the introduction to the `SLOW_QUERY` table in Information Schema.

> **Note:**
>
> Every time you query the `SLOW_QUERY` table, TiDB reads and parses the current slow query log.

For TiDB 4.0, `SLOW_QUERY` supports querying the slow log of any period of time, including the rotated slow log file. You need to specify the `TIME` range to locate the slow log files that need to be parsed. If you don't specify the `TIME` range, TiDB only parses the current slow log file. For example:

- If you don't specify the time range, TiDB only parses the slow query data that TiDB is writing to the slow log file:

```
select count(*),
     min(time),
     max(time)
from slow_query;
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 122492   | 2020-03-11 23:35:20.908574 | 2020-03-25 19:16:38.229035 |
+----------+----------------------------+----------------------------+
```

- If you specify the time range, for example, from `2020-03-10 00:00:00` to `2020-03-11 00:00:00`, TiDB first locates the slow log files of the specified time range, and then parses the slow query information:

```
select count(*),
     min(time),
     max(time)
from slow_query
where time > '2020-03-10 00:00:00'
  and time < '2020-03-11 00:00:00';
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 2618049 | 2020-03-10 00:00:00.427138 | 2020-03-10 23:00:22.716728 |
+----------+----------------------------+----------------------------+
```

> **Note:**
>
> If the slow log files of the specified time range are removed, or there is no slow query, the query returns NULL.

TiDB 4.0 adds the `CLUSTER_SLOW_QUERY` system table to query the slow query information of all TiDB nodes. The table schema of the `CLUSTER_SLOW_QUERY` table differs from that of the `SLOW_QUERY` table in that an `INSTANCE` column is added to `CLUSTER_SLOW_QUERY`. The `INSTANCE` column represents the TiDB node address of the row information on the slow query. You can use `CLUSTER_SLOW_QUERY` the way you do with `SLOW_QUERY`.

When you query the `CLUSTER_SLOW_QUERY` table, TiDB pushes the computation and the judgment down to other nodes, instead of retrieving all slow query information from other nodes and executing the operations on one TiDB node.

10.2.1.1.5 `SLOW_QUERY` / `CLUSTER_SLOW_QUERY` usage examples

Top-N slow queries

Query the Top 2 slow queries of users. `Is_internal=false` means excluding slow queries inside TiDB and only querying slow queries of users.

```
select query_time, query
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 2;
```

Output example:

```
+--------------+-----------------------------------------------------------------------+
   ↪
| query_time | query                                                                  |
+--------------+-----------------------------------------------------------------------+
   ↪
| 12.77583857 | select * from t_slim, t_wide where t_slim.c0=t_wide.c0; |
|  0.734982725 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=
   ↪ t1.c0; |
+--------------+-----------------------------------------------------------------------+
   ↪
```

Query the Top-N slow queries of the `test` user

In the following example, the slow queries executed by the `test` user are queried, and the first two results are displayed in reverse order of execution time.

```
select query_time, query, user
from information_schema.slow_query
where is_internal = false
  and user = "test"
order by query_time desc
limit 2;
```

Output example:

```
+-------------+-------------------------------------------------------------------------+------
   ↪
| Query_time | query                                                                   |
   ↪ user         |
+-------------+-------------------------------------------------------------------------+------
   ↪
| 0.676408014 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=t1
   ↪ .c1; | test |
+-------------+-------------------------------------------------------------------------+------
   ↪
```

Query similar slow queries with the same SQL fingerprints

After querying the Top-N SQL statements, continue to query similar slow queries using the same fingerprints.

1. Acquire Top-N slow queries and the corresponding SQL fingerprints.

```
select query_time, query, digest
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 1;
```

Output example:

```
+-------------+-----------------------------+-----------------------------------
    ↪
| query_time | query                      | digest
    ↪                                                        |
+-------------+-----------------------------+-----------------------------------
    ↪
| 0.302558006 | select * from t1 where a=1; | 4751
    ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa |
+-------------+-----------------------------+-----------------------------------
    ↪
```

2. Query similar slow queries with the fingerprints.

```
select query, query_time
from information_schema.slow_query
where digest = "4751
    ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa";
```

Output example:

```
+-----------------------------+-------------+
| query                      | query_time |
+-----------------------------+-------------+
| select * from t1 where a=1; | 0.302558006 |
| select * from t1 where a=2; | 0.401313532 |
+-----------------------------+-------------+
```

10.2.1.1.6 Query slow queries with pseudo stats

```
select query, query_time, stats
from information_schema.slow_query
where is_internal = false
  and stats like '%pseudo%';
```

Output example:

```
+----------------------------+------------+--------------------------------+
   ↪
| query                      | query_time | stats                          |
+----------------------------+------------+--------------------------------+
   ↪
| select * from t1 where a=1; | 0.302558006 | t1:pseudo                     |
| select * from t1 where a=2; | 0.401313532 | t1:pseudo                     |
| select * from t1 where a>2; | 0.602011247 | t1:pseudo                     |
| select * from t1 where a>3; | 0.50077719 | t1:pseudo                      |
| select * from t1 join t2; | 0.931260518 | t1:407872303825682445,t2:pseudo
   ↪ |
+----------------------------+------------+--------------------------------+
   ↪
```

Query slow queries whose execution plan is changed

When the execution plan of SQL statements of the same category is changed, the execution slows down, because the statistics is outdated, or the statistics is not accurate enough to reflect the real data distribution. You can use the following SQL statement to query SQL statements with different execution plans.

```
select count(distinct plan_digest) as count,
      digest,
      min(query)
from cluster_slow_query
group by digest
having count > 1
limit 3\G
```

Output example:

```
***************************[ 1. row ]***************************
count     | 2
digest    | 17b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94
min(query) | SELECT DISTINCT c FROM sbtest25 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (291638, 291737)];
***************************[ 2. row ]***************************
count     | 2
digest    | 9337865f3e2ee71c1c2e740e773b6dd85f23ad00f8fa1f11a795e62e15fc9b23
min(query) | SELECT DISTINCT c FROM sbtest22 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (215420, 215519)];
***************************[ 3. row ]***************************
count     | 2
digest    | db705c89ca2dfc1d39d10e0f30f285cbbadec7e24da4f15af461b148d8ffb020
min(query) | SELECT DISTINCT c FROM sbtest11 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (303359, 303458)];
```

Then you can query the different plans using the SQL fingerprint in the query result above:

```
select min(plan),
      plan_digest
from cluster_slow_query
where digest='17
    ↪ b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94'
group by plan_digest\G
```

Output example:

```
*************************** 1. row ***************************
  min(plan):  Sort_6               root   100.00131380758702   sbtest.
     ↪ sbtest25.c:asc
        ─HashAgg_10          root   100.00131380758702   group by:sbtest.
          ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
          ↪ .c
          ─TableReader_15    root   100.00131380758702   data:TableRangeScan
            ↪ _14
            ─TableScan_14    cop    100.00131380758702   table:sbtest25,
              ↪ range:[502791,502890], keep order:false
plan_digest: 6
    ↪ afbbd21f60ca6c6fdf3d3cd94f7c7a49dd93c00fcf8774646da492e50e204ee
*************************** 2. row ***************************
  min(plan):  Sort_6               root   1                    sbtest.
     ↪ sbtest25.c:asc
        ─HashAgg_12          root   1                    group by:sbtest.
          ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
          ↪ .c
          ─TableReader_13    root   1                    data:HashAgg_8
            ─HashAgg_8       cop    1                    group by:sbtest.
              ↪ sbtest25.c,
              ─TableScan_11  cop    1.2440069558121831   table:sbtest25,
                ↪ range:[472745,472844], keep order:false
```

Query the number of slow queries for each TiDB node in a cluster

```
select instance, count(*) from information_schema.cluster_slow_query where
    ↪ time >= "2020-03-06 00:00:00" and time < now() group by instance;
```

Output example:

```
+---------------+----------+
| instance      | count(*) |
```

```
+---------------+----------+
| 0.0.0.0:10081 | 124      |
| 0.0.0.0:10080 | 119771   |
+---------------+----------+
```

Query slow logs occurring only in abnormal time period

If you find problems such as decreased QPS or increased latency for the time period from `2020-03-10 13:24:00` to `2020-03-10 13:27:00`, the reason might be that a large query crops up. Run the following SQL statement to query slow logs that occur only in abnormal time period. The time range from `2020-03-10 13:20:00` to `2020-03-10 13:23:00` refers to the normal time period.

```
SELECT * FROM
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ count(*),
        min(time),
        sum(query_time) AS sum_query_time,
        sum(Process_time) AS sum_process_time,
        sum(Wait_time) AS sum_wait_time,
        sum(Commit_time),
        sum(Request_count),
        sum(process_keys),
        sum(Write_keys),
        max(Cop_proc_max),
        min(query),min(prev_stmt),
        digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:24:00'
           AND time < '2020-03-10 13:27:00'
           AND Is_internal = false
    GROUP BY digest) AS t1
WHERE t1.digest NOT IN
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:20:00'
           AND time < '2020-03-10 13:23:00'
    GROUP BY digest)
ORDER BY t1.sum_query_time DESC limit 10\G
```

Output example:

```
***************************[ 1. row ]***************************
count(*)         | 200
min(time)        | 2020-03-10 13:24:27.216186
sum_query_time   | 50.114126194
sum_process_time | 268.351
```

```
sum_wait_time    | 8.476
sum(Commit_time) | 1.044304306
sum(Request_count) | 6077
sum(process_keys) | 202871950
sum(Write_keys)  | 319500
max(Cop_proc_max) | 0.263
min(query)       | delete from test.tcs2 limit 5000;
min(prev_stmt)   |
digest           | 24
   ↪ bd6d8a9b238086c9b8c3d240ad4ef32f79ce94cf5a468c0b8fe1eb5f8d03df
```

Parse other TiDB slow log files

TiDB uses the session variable `tidb_slow_query_file` to control the files to be read and parsed when querying `INFORMATION_SCHEMA.SLOW_QUERY`. You can query the content of other slow query log files by modifying the value of the session variable.

```
set tidb_slow_query_file = "/path-to-log/tidb-slow.log"
```

Parse TiDB slow logs with `pt-query-digest`

Use `pt-query-digest` to parse TiDB slow logs.

> **Note:**
>
> It is recommended to use `pt-query-digest` 3.0.13 or later versions.

For example:

```
pt-query-digest --report tidb-slow.log
```

Output example:

```
#### 320ms user time, 20ms system time, 27.00M rss, 221.32M vsz
#### Current date: Mon Mar 18 13:18:51 2019

10.2.1.1.7 Identify problematic SQL statements

Not all of the `SLOW_QUERY` statements are problematic. Only those whose `process_time` is very large increase the pressure on the entire cluster.

The statements whose `wait_time` is very large and `process_time` is very small are usually not problematic. This is because the statement is blocked by real problematic statements and it has to wait in the execution queue, which leads to a much longer response time.

`ADMIN SHOW SLOW` command

In addition to the TiDB log file, you can identify slow queries by running the `ADMIN SHOW SLOW` command:

```
ADMIN SHOW SLOW recent N
ADMIN SHOW SLOW TOP [internal | all] N
```

`recent N` shows the recent N slow query records, for example:

```
ADMIN SHOW SLOW recent 10
```

`top N` shows the slowest N query records recently (within a few days). If the `internal` option is provided, the returned results would be the inner SQL executed by the system; If the `all` option is provided, the returned results would be the user's SQL combinated with inner SQL; Otherwise, this command would only return the slow query records from the user's SQL.

```
ADMIN SHOW SLOW top 3
ADMIN SHOW SLOW top internal 3
ADMIN SHOW SLOW top all 5
```

TiDB stores only a limited number of slow query records because of the limited memory. If the value of `N` in the query command is greater than the records count, the number of returned records is smaller than `N`.

The following table shows output details:

Column name	Description
start	The starting time of the SQL execution
duration	The duration of the SQL execution
details	The details of the SQL execution
succ	Whether the SQL statement is executed successfully. `1` means success and `0` means failure.

Column name	Description
conn_id	The connection ID for the session
transaction_ts	The `start ↪ ↪ ts` of the transaction
user	The user name for the execution of the statement
db	The database involved when the statement is executed

Column name	Description
table_ids	The ID of the table involved when the SQL statement is executed
index_ids	The ID of the index involved when the SQL statement is executed
internal	This is a TiDB internal SQL statement
digest	The fingerprint of the SQL statement

Column name	Description
sql	The SQL statement that is being executed or has been executed

10.2.1.2 Analyze Slow Queries

To address the issue of slow queries, you need to take the following two steps:

1. Among many queries, identify which type of queries are slow.
2. Analyze why this type of queries are slow.

You can easily perform step 1 using the slow query log and the statement summary table features. It is recommended to use TiDB Dashboard, which integrates the two features and directly displays the slow queries in your browser.

This document focuses on how to perform step 2 - analyze why this type of queries are slow.

Generally, slow queries have the following major causes:

- Optimizer issues, such as wrong index selected, wrong join type or sequence selected.
- System issues. All issues not caused by the optimizer are system issues. For example, a busy TiKV instance processes requests slowly; outdated Region information causes slow queries.

In actual situations, optimizer issues might cause system issues. For example, for a certain type of queries, the optimizer uses a full table scan instead of the index. As a result, the SQL queries consume many resources, which causes the CPU usage of some TiKV instances to soar. This seems like a system issue, but in essence, it is an optimizer issue.

To identify system issues is relatively simple. To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. Therefore, it is recommended to analyze slow queries by following these procedures:

1. Identify the performance bottleneck of the query, that is, the time-consuming part of the query process.
2. Analyze the system issues: analyze the possible causes according to the query bottleneck and the monitoring/log information of that time.
3. Analyze the optimizer issues: analyze whether there is a better execution plan.

The procedures above are explained in the following sections.

10.2.1.2.1 Identify the performance bottleneck of the query

First, you need to have a general understanding of the query process. The key stages of the query execution process in TiDB are illustrated in TiDB performance map.

You can get the duration information using the following methods:

- Slow log. It is recommended to view the slow log in TiDB Dashboard.
- `EXPLAIN ANALYZE` statement.

The methods above are different in the following aspects:

- The slow log records the duration of almost all stages of a SQL execution, from parsing to returning results, and is relatively comprehensive (you can query and analyze the slow log in TiDB Dashboard in an intuitive way).
- By executing `EXPLAIN ANALYZE`, you can learn the time consumption of each operator in an actual SQL execution. The results have more detailed statistics of the execution duration.

In summary, the slow log and `EXPLAIN ANALYZE` statements help you determine the SQL query is slow in which component (TiDB or TiKV) at which stage of the execution. Therefore, you can accurately identify the performance bottleneck of the query.

In addition, since v4.0.3, the `Plan` field in the slow log also includes the SQL execution information, which is the result of `EXPLAIN ANALYZE`. So you can find all information of SQL duration in the slow log.

10.2.1.2.2 Analyze system issues

System issues can be divided into the following types according to different execution stages of a SQL statement:

1. TiKV is slow in data processing. For example, the TiKV coprocessor processes data slowly.
2. TiDB is slow in execution. For example, a `Join` operator processes data slowly.
3. Other key stages are slow. For example, getting the timestamp takes a long time.

For each slow query, first determine to which type the query belongs, and then analyze it in detail.

TiKV is slow in data processing

If TiKV is slow in data processing, you can easily identify it in the result of `EXPLAIN ANALYZE`. In the following example, `StreamAgg_8` and `TableFullScan_15`, two `tikv-tasks` (as indicated by `cop[tikv]` in the `task` column), take `170ms` to execute. After subtracting `170ms`, the execution time of TiDB operators account for a very small proportion of the total execution time. This indicates that the bottleneck is in TiKV.

```
+--
   ↪ -------------------------+---------+---------+-----------+---------------+-----
   ↪
| id                        | estRows | actRows | task   | access object |
   ↪ execution info                                                          |
   ↪ operator info                | memory   | disk |
+--
   ↪ -------------------------+---------+---------+-----------+---------------+-----
   ↪
| StreamAgg_16              | 1.00    | 1       | root      |               | time
   ↪ :170.08572ms, loops:2                                                   |
   ↪ funcs:count(Column#5)->Column#3 | 372 Bytes | N/A |
|  ─TableReader_17          | 1.00    | 1       | root      |               | time
   ↪ :170.080369ms, loops:2, rpc num: 1, rpc time:17.023347ms, proc keys
   ↪ :28672 | data:StreamAgg_8  | 202 Bytes | N/A |
|    ─StreamAgg_8           | 1.00    | 1       | cop[tikv] |               | time
   ↪ :170ms, loops:29                                                        |
   ↪ funcs:count(1)->Column#5    | N/A       | N/A |
|      ─TableFullScan_15    | 7.00    | 28672   | cop[tikv] | table:t       | time
   ↪ :170ms, loops:29                                                        |
   ↪ keep order:false, stats:pseudo | N/A    | N/A |
+--
   ↪ -------------------------+---------+---------+-----------+---------------+-----
   ↪
```

In addition, the `Cop_process` and `Cop_wait` fields in the slow log can also help your analysis. In the following example, the total duration of the query is around `180.85ms`, and the largest `coptask` takes `171ms`. This indicates that the bottleneck of this query is on the TiKV side.

For the description of each field in the slow log, see fields description.

```
#### Query_time: 0.18085
...
#### Num_cop_tasks: 1
#### Cop_process: Avg_time: 170ms P90_time: 170ms Max_time: 170ms Max_addr:
   ↪ 10.6.131.78
```

```
#### Cop_wait: Avg_time: 1ms P90_time: 1ms Max_time: 1ms Max_Addr:
    ↪ 10.6.131.78
```

After identifying that TiKV is the bottleneck, you can find out the cause as described in the following sections.

TiKV instance is busy

During the execution of a SQL statement, TiDB might fetch data from multiple TiKV instances. If one TiKV instance responds slowly, the overall SQL execution speed is slowed down.

The `Cop_wait` field in the slow log can help you determine this cause.

```
#### Cop_wait: Avg_time: 1ms P90_time: 2ms Max_time: 110ms Max_Addr:
    ↪ 10.6.131.78
```

The log above shows that a `cop-task` sent to the `10.6.131.78` instance waits `110ms` ↪ before being executed. It indicates that this instance is busy. You can check the CPU monitoring of that time to confirm the cause.

Too many outdated keys

A TiKV instance has much outdated data, which needs to be cleaned up for data scan. This impacts the processing speed.

Check `Total_keys` and `Processed_keys`. If they are greatly different, the TiKV instance has too many keys of the older versions.

```
...
#### Total_keys: 2215187529 Processed_keys: 1108056368
...
```

Other key stages are slow

Slow in getting timestamps

You can compare `Wait_TS` and `Query_time` in the slow log. The timestamps are prefetched, so generally `Wait_TS` should be low.

```
#### Query_time: 0.0300000
...
#### Wait_TS: 0.02500000
```

Outdated Region information

Region information on the TiDB side might be outdated. In this situation, TiKV might return the `regionMiss` error. Then TiDB gets the Region information from PD again, which is reflected in the `Cop_backoff` information. Both the failed times and the total duration are recorded.

```
#### Cop_backoff_regionMiss_total_times: 200 Cop_backoff_regionMiss_total_
    ↪ time: 0.2 Cop_backoff_regionMiss_max_time: 0.2 Cop_backoff_regionMiss
    ↪ _max_addr: 127.0.0.1 Cop_backoff_regionMiss_avg_time: 0.2 Cop_backoff
    ↪ _regionMiss_p90_time: 0.2
#### Cop_backoff_rpcPD_total_times: 200 Cop_backoff_rpcPD_total_time: 0.2
    ↪ Cop_backoff_rpcPD_max_time: 0.2 Cop_backoff_rpcPD_max_addr: 127.0.0.1
    ↪  Cop_backoff_rpcPD_avg_time: 0.2 Cop_backoff_rpcPD_p90_time: 0.2
```

Subqueries are executed in advance

For statements with non-correlated subqueries, the subquery part might be executed in advance. For example, in `select * from t1 where a = (select max(a)from t2)`, the `select max(a)from t2` part might be executed in advance in the optimization stage. The result of `EXPLAIN ANALYZE` does not show the duration of this type of subqueries.

```
mysql> explain analyze select count(*) from t where a=(select max(t1.a)
    ↪ from t t1, t t2 where t1.a=t2.a);
+--
    ↪ ---------------------------+----------+---------+-----------+---------------+--
    ↪
| id                          | estRows | actRows | task    | access object |
    ↪ execution info      | operator info                 | memory   | disk |
+--
    ↪ ---------------------------+----------+---------+-----------+---------------+--
    ↪
| StreamAgg_59                | 1.00    | 1       | root      |               | time
    ↪ :4.69267ms, loops:2 | funcs:count(Column#10)->Column#8 | 372 Bytes |
    ↪ N/A |
|  ─TableReader_60            | 1.00    | 1       | root      |               |
    ↪ time:4.690428ms, loops:2 | data:StreamAgg_48          | 141 Bytes | N/A
    ↪  |
|    ─StreamAgg_48            | 1.00    |         | cop[tikv] |               |
    ↪ time:0ns, loops:0     | funcs:count(1)->Column#10    | N/A      | N/A
    ↪ |
|      ─Selection_58          | 16384.00 |       | cop[tikv] |               |
    ↪ time:0ns, loops:0     | eq(test.t.a, 1)              | N/A      | N/A
    ↪ |
|        ─TableFullScan_57    | 16384.00 | -1    | cop[tikv] | table:t       |
    ↪ time:0s, loops:0      | keep order:false             | N/A      | N/A
    ↪ |
+--
    ↪ ---------------------------+----------+---------+-----------+---------------+--
    ↪
5 rows in set (7.77 sec)
```

But you can identify this type of subquery execution in the slow log:

```
#### Query_time: 7.770634843
...
#### Rewrite_time: 7.765673663 Preproc_subqueries: 1 Preproc_subqueries_time
    ↪ : 7.765231874
```

From log record above, you can see that a subquery is executed in advance and takes `7.76s`.

TiDB is slow in execution

Assume that the execution plan in TiDB is correct but the execution is slow. To solve this type of issue, you can adjust parameters or use the hint according to the result of `EXPLAIN ANALYZE` for the SQL statement.

If the execution plan is incorrect, see the Analyze optimizer issues section.

Low concurrency

If the bottleneck is in the operator with concurrency, speed up the execution by adjusting the concurrency. For example:

```
mysql> explain analyze select sum(t1.a) from t t1, t t2 where t1.a=t2.a;
+--
    ↪ ------------------------------+-------------+----------+----------+--------
    ↪
| id                            | estRows     | actRows  | task     | access
    ↪ object | execution info
    ↪                                                                | operator
    ↪ info                                | memory         | disk   |
+--
    ↪ ------------------------------+-------------+----------+----------+--------
    ↪
| HashAgg_11                    | 1.00        | 1        | root     |

    ↪            | time:0ns, loops:0
    ↪                                                                | not(isnull(
    ↪ test.t.a))                      | N/A            | N/A    |
|         └─TableFullScan_16     | 16384.00   | -1       | cop[tikv] | table:
    ↪ t1   | time:0s, loops:0
    ↪                                                                 | keep order:
    ↪ false                           | N/A            | N/A    |
+--
    ↪ ------------------------------+-------------+----------+-----------+--------
    ↪
9 rows in set (9.67 sec)
```

As shown above, `HashJoin_14` and `Projection_24` consume much of the execution time. Consider increasing their concurrency using SQL variables to speed up execution.

All system variables are documented in system-variables. To increase the concurrency of `HashJoin_14`, you can modify the `tidb_hash_join_concurrency` system variable.

Data is spilled to disk

Another cause of slow execution is disk spill that occurs during execution if the memory limit is reached. You can find out this cause in the execution plan and the slow log:

```
+--
    ↪ ----------------------+----------+---------+----------+---------------+------
    ↪
| id                    | estRows  | actRows | task    | access object |

```
...
#### Disk_max: 229974016
...
```

Join operations with Cartesian product

Join operations with Cartesian product generate data volume as large as `left child row count * right child row count`. This is inefficient and should be avoided.

This type of join operations is marked `CARTESIAN` in the execution plan. For example:

```
mysql> explain select * from t t1, t t2 where t1.a>t2.a;
+--
   ↪ ---------------------------+------------+----------+--------------+---------
   ↪
| id                          | estRows    | task     | access object | operator
   ↪  info                                  |
+--
   ↪ ---------------------------+------------+----------+--------------+---------
   ↪
| HashJoin_8                  | 99800100.00 | root   |              | CARTESIAN

10.2.1.2.3 Analyze optimizer issues

To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. You need to have some understanding of the optimization process and each operator.

For the following examples, assume that the table schema is `create table t (id int ↪ , a int, b int, c int, primary key(id), key(a), key(b, c))`.

1. `select * from t`: There is no filter condition and a full table scan is performed. So the `TableFullScan` operator is used to read data.
2. `select a from t where a=2`: There is a filter condition and only the index columns are read, so the `IndexReader` operator is used to read data.
3. `select * from t where a=2`: There is a filter condition for `a` but the `a` index cannot fully cover the data to be read, so the `IndexLookup` operator is used.
4. `select b from t where c=3`: Without the prefix condition, the multi-column index cannot be used. So the `IndexFullScan` is used.
5. …

The examples above are operators used for data reads. For more operators, see Understand TiDB Execution Plan.

In addition, reading SQL Tuning Overview helps you better understand the TiDB optimizer and determine whether the execution plan is reasonable or not.

Most optimizer issues are explained in SQL Tuning Overview. For the solutions, see the following documents:

1. Wrong Index Solution
2. Wrong join order
3. Expressions are not pushed down

10.2.2 Troubleshoot TiDB OOM Issues

This document describes how to troubleshoot TiDB OOM (Out of Memory) issues, including phenomena, causes, solutions, and diagnostic information.

10.2.2.1 Typical OOM phenomena

The following are some typical OOM phenomena:

- The client side reports the following error: `SQL error, errno = 2013, state = '
  ↪ HY000': Lost connection to MySQL server during query`.
- The Grafana dashboard shows:
  - **TiDB** > **Server** > **Memory Usage** shows that the `process/heapInUse` metric keeps rising, and suddenly drops to zero after reaching the threshold.
  - **TiDB** > **Server** > **Uptime** suddenly drops to zero.
  - **TiDB-Runtime** > **Memory Usage** shows that the `estimate-inuse` metric keeps rising.
- Check `tidb.log`, and you can find the following log entries:
  - An alarm about OOM: `[WARN] [memory_usage_alarm.go:139] ["tidb-
    ↪ server has the risk of OOM because of memory usage exceeds alarm
    ↪ ratio. Running SQLs and heap profile will be recorded in record
    ↪ path"]`. For more information, see memory-usage-alarm-ratio.
  - A log entry about restart: `[INFO] [printer.go:33] ["Welcome to TiDB."]`.

10.2.2.2 Overall troubleshooting process

When you troubleshoot OOM issues, follow this process:

1. Confirm whether it is an OOM issue.

   Execute the following command to check the operating system logs. If there is an `oom-killer` log near the time when the problem occurs, you can confirm that it is an OOM issue.

   ```
   dmesg -T | grep tidb-server
   ```

   The following is an example of the log that contains `oom-killer`:

   ```
   ......
   Mar 14 16:55:03 localhost kernel: tidb-server invoked oom-killer: gfp_
      ↪ mask=0x201da, order=0, oom_score_adj=0
   Mar 14 16:55:03 localhost kernel: tidb-server cpuset=/ mems_allowed=0
   Mar 14 16:55:03 localhost kernel: CPU: 14 PID: 21966 Comm: tidb-server
      ↪ Kdump: loaded Not tainted 3.10.0-1160.el7.x86_64 #1
   Mar 14 16:55:03 localhost kernel: Hardware name: QEMU Standard PC (
      ↪ i440FX + PIIX, 1996), BIOS rel-1.14.0-0-g155821a1990b-prebuilt.
      ↪ qemu.org 04/01/2014
   ......
   Mar 14 16:55:03 localhost kernel: Out of memory: Kill process 21945 (
      ↪ tidb-server) score 956 or sacrifice child
   Mar 14 16:55:03 localhost kernel: Killed process 21945 (tidb-server),
      ↪ UID 1000, total-vm:33027492kB, anon-rss:31303276kB, file-rss:0kB,
      ↪  shmem-rss:0kB
   ```

```
Mar 14 16:55:07 localhost systemd: tidb-4000.service: main process
    ↪ exited, code=killed, status=9/KILL
......
```

2. After confirming that it is an OOM issue, you can further investigate whether the OOM is caused by deployment or the database.

    - If the OOM is caused by a deployment issue, you need to investigate the resource configuration and impact of hybrid deployment.
    - If the OOM is caused by a database issue, the following are some possible causes:
        - TiDB handles large data traffic, such as large queries, large writes, and data import.
        - TiDB is in a high concurrency scenario, where multiple SQL statements consume resources concurrently or operator concurrency is high.
        - TiDB has a memory leak and resources are not released.

    Refer to the following sections for specific troubleshooting methods.

10.2.2.3 Typical causes and solutions

OOM issues are usually caused by the following:

- Deployment issues
- Database issues
- Client side issues

10.2.2.3.1 Deployment issues

The following are some causes of OOM due to improper deployment:

- The memory capacity of the operating system is too small.
- The TiUP configuration `resource_control` is not appropriate.
- In the case of hybrid deployments (meaning that TiDB and other applications are deployed on the same server), TiDB is killed accidentally by `oom-killer` due to lack of resources.

10.2.2.3.2 Database issues

This section describes the causes and solutions for OOM caused by database issues.

> **Note:**
>
> If you have configured `tidb_mem_quota_query`, an error occurs: `ERROR 1105 (HY000): Out Of Memory Quota![conn_id=54]`. It is caused by the memory usage control behavior of the database. It is a normal behavior.

Executing SQL statements consumes too much memory

You can take the following measures to reduce the memory usage of SQL statements, depending on the different causes of OOM issues.

- If the execution plan of SQL is not optimal, for example, due to lack of proper indexes, outdated statistics, or optimizer bugs, a wrong execution plan of SQL might be selected. A huge intermediate result set will then be accumulated in the memory. In this case, consider the following measures:
    - Add appropriate indexes.
    - Use the disk spill feature for execution operators.
    - Adjust the JOIN order between tables.
    - Use hints to optimize SQL statements.
- Some operators and functions are not supported to be pushed down to the storage level, resulting in a huge accumulation of intermediate result sets. In this case, you need to refine the SQL statements or use hints to optimize, and use the functions or operators that support pushing down.
- The execution plan contains the operator HashAgg. HashAgg is executed concurrently by multiple threads, which is faster but consumes more memory. Instead, you can use `STREAM_AGG()`.
- Reduce the number of Regions to be read simultaneously or reduce the concurrency of operators to avoid memory problems caused by high concurrency. The corresponding system variables include:
    - `tidb_distsql_scan_concurrency`
    - `tidb_index_serial_scan_concurrency`
    - `tidb_executor_concurrency`
- The concurrency of sessions is too high near the time point when the problem occurs. In this case, consider scaling out the TiDB cluster by adding more TiDB nodes.

Large transactions or large writes consume too much memory

You need to plan for memory capacity. When a transaction is executed, the memory usage of the TiDB process is scaled up comparing with the transaction size, up to two to three times or more of the transaction size.

You can split a single large transaction to multiple smaller transactions.

The process of collecting and loading statistical information consumes too much memory

A TiDB node needs to load statistics into memory after it starts. TiDB consumes memory when collecting statistical information. You can control memory usage in the following ways:

- Specify a sampling rate, only collect statistics for specific columns, and reduce `ANALYZE` concurrency.
- Since TiDB v6.1.0, you can use the system variable `tidb_stats_cache_mem_quota` to control the memory usage for statistical information.
- Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the maximum memory usage when TiDB updates statistics.

For more information, see Introduction to Statistics.

Prepared statements are overused

The client side keeps creating prepared statements but does not execute `deallocate prepare stmt`, which causes memory consumption to continue to rise and eventually triggers TiDB OOM. The reason is that the memory occupied by a prepared statement is not released until the session is closed. This is especially important for long-time connection sessions.

To solve the problem, consider the following measures:

- Adjust the session lifecycle.
- Adjust the `wait_timeout` and `max_execution_time` of the connection pool.
- Use the system variable `max_prepared_stmt_count` to control the maximum number of prepared statements in a session.

`tidb_enable_rate_limit_action` is not configured properly

The system variable `tidb_enable_rate_limit_action` controls memory usage effectively when an SQL statement only reads data. When this variable is enabled and computing operations (such as join or aggregation operations) are required, memory usage might not be under the control of `tidb_mem_quota_query`, which increases the risk of OOM.

It is recommended that you disable this system variable. Since TiDB v6.3.0, this system variable is disabled by default.

10.2.2.3.3 Client side issues

If OOM occurs on the client side, investigate the following:

- Check the trend and speed on **Grafana TiDB Details > Server > Client Data Traffic** to see if there is a network blockage.
- Check whether there is an application OOM caused by wrong JDBC configuration parameters. For example, if the `defaultFetchSize` parameter for streaming read is incorrectly configured, it can cause data to be heavily accumulated on the client side.

10.2.2.4 Diagnostic information to be collected to troubleshoot OOM issues

To locate the root cause of an OOM issue, you need to collect the following information:

- Collect the memory-related configurations of the operating system:
    - TiUP configuration: `resource_control.memory_limit`
    - Operating system configurations:
        - Memory information: `cat /proc/meminfo`
        - Kernel parameters: `vm.overcommit_memory`
    - NUMA information:
        - `numactl --hardware`
        - `numactl --show`
- Collect the version information and the memory-related configurations of the database:
    - TiDB version
    - `tidb_mem_quota_query`
    - `memory-usage-alarm-ratio`
    - `mem-quota-query`
    - `oom-action`
    - `tidb_enable_rate_limit_action`
    - `tidb_server_memory_limit`
    - `oom-use-tmp-storage`
    - `tmp-storage-path`
    - `tmp-storage-quota`
    - `tidb_analyze_version`
- Check the daily usage of TiDB memory on the Grafana dashboard: **TiDB** > **Server** > **Memory Usage**.
- Check the SQL statements that consume more memory.
    - View SQL statement analysis, slow queries, and memory usage on the TiDB Dashboard.
    - Check `SLOW_QUERY` and `CLUSTER_SLOW_QUERY` in `INFORMATION_SCHEMA`.
    - Check `tidb_slow_query.log` on each TiDB node.
    - Run `grep "expensive_query" tidb.log` to check the corresponding log entries.
    - Run `EXPLAIN ANALYZE` to check the memory usage of operators.
    - Run `SELECT * FROM information_schema.processlist;` to check the value of the `MEM` column.
- Run the following command to collect the TiDB Profile information when memory usage is high:

```
curl -G "http://{TiDBIP}:10080/debug/zip?seconds=10" > profile.zip
```

- Run `grep "tidb-server has the risk of OOM" tidb.log` to check the path of the alert file collected by TiDB Server. The following is an example output:

```
["tidb-server has the risk of OOM because of memory usage exceeds alarm
    ↪  ratio. Running SQLs and heap profile will be recorded in record
    ↪ path"] ["is tidb_server_memory_limit set"=false] ["system memory
    ↪ total"=14388137984] ["system memory usage"=11897434112] ["tidb-
    ↪ server memory usage"=11223572312] [memory-usage-alarm-ratio=0.8]
    ↪ ["record path"="/tmp/0_tidb/MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA=/
    ↪ tmp-storage/record"]
```

10.2.3 Troubleshoot Hotspot Issues

This document describes how to locate and resolve the problem of read and write hotspots.

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency.

10.2.3.1 Common hotspots

This section describes TiDB encoding rules, table hotspots, and index hotspots.

10.2.3.1.1 TiDB encoding rules

TiDB assigns a TableID to each table, an IndexID to each index, and a RowID to each row. By default, if the table uses an integer primary key, the value of the primary key is treated as the RowID. Among these IDs, TableID is unique in the entire cluster, while IndexID and RowID are unique in the table. The type of all these IDs is int64.

Each row of data is encoded as a key-value pair according to the following rule:

```
Key: tablePrefix{tableID}_recordPrefixSep{rowID}
Value: [col1, col2, col3, col4]
```

The `tablePrefix` and `recordPrefixSep` of the key are specific string constants, used to distinguish from other data in the KV space.

For Index data, the key-value pair is encoded according to the following rule:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: rowID
```

Index data has two types: the unique index and the non-unique index.

- For unique indexes, you can follow the coding rules above.
- For non-unique indexes, a unique key cannot be constructed through this encoding, because the `tablePrefix{tableID}_indexPrefixSep{indexID}` of the same index is the same and the `ColumnsValue` of multiple rows might be the same. The encoding rule for non-unique indexes is as follows:

  ```
  Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue_
      ↪ rowID
  Value: null
  ```

10.2.3.1.2 Table hotspots

According to TiDB coding rules, the data of the same table is in a range prefixed by the beginning of the TableID, and the data is arranged in the order of RowID values. When RowID values are incremented during table inserting, the inserted line can only be appended to the end. The Region will split after it reaches a certain size, and then it still can only be appended to the end of the range. The `INSERT` operation can only be executed on one Region, forming a hotspot.

The common auto-increment primary key is sequentially increasing. When the primary key is of the integer type, the value of the primary key is used as the RowID by default. At this time, the RowID is sequentially increasing, and a write hotspot of the table forms when a large number of `INSERT` operations exist.

Meanwhile, the RowID in TiDB is also sequentially auto-incremental by default. When the primary key is not an integer type, you might also encounter the problem of write hotspots.

In addition, when hotspots occur during the process of data writes (on a newly created table or partition) or data reads (periodic read hotspots in read-only scenarios), you can control the Region merge behavior using table attributes. For details, see Control the Region merge behavior using table attributes.

10.2.3.1.3 Index hotspots

Index hotspots are similar to table hotspots. Common index hotspots appear in fields that are monotonously increasing in time order, or `INSERT` scenarios with a large number of repeated values.

10.2.3.2 Identify hotspot issues

Performance problems are not necessarily caused by hotspots and might be caused by multiple factors. Before troubleshooting issues, confirm whether it is related to hotspots.

- To judge write hotspots, open **Hot Write** in the **TiKV-Trouble-Shooting** monitoring panel to check whether the Raftstore CPU metric value of any TiKV node is significantly higher than that of other nodes.
- To judge read hotspots, open **Thread_CPU** in the **TiKV-Details** monitoring panel to check whether the coprocessor CPU metric value of any TiKV node is particularly high.

10.2.3.2.1 Use TiDB Dashboard to locate hotspot tables

The **Key Visualizer** feature in TiDB Dashboard helps users narrow down hotspot troubleshooting scope to the table level. The following is an example of the thermal diagram shown by **Key Visualizer**. The horizontal axis of the graph is time, and the vertical axis are various tables and indexes. The brighter the color, the greater the load. You can switch the read or write flow in the toolbar.

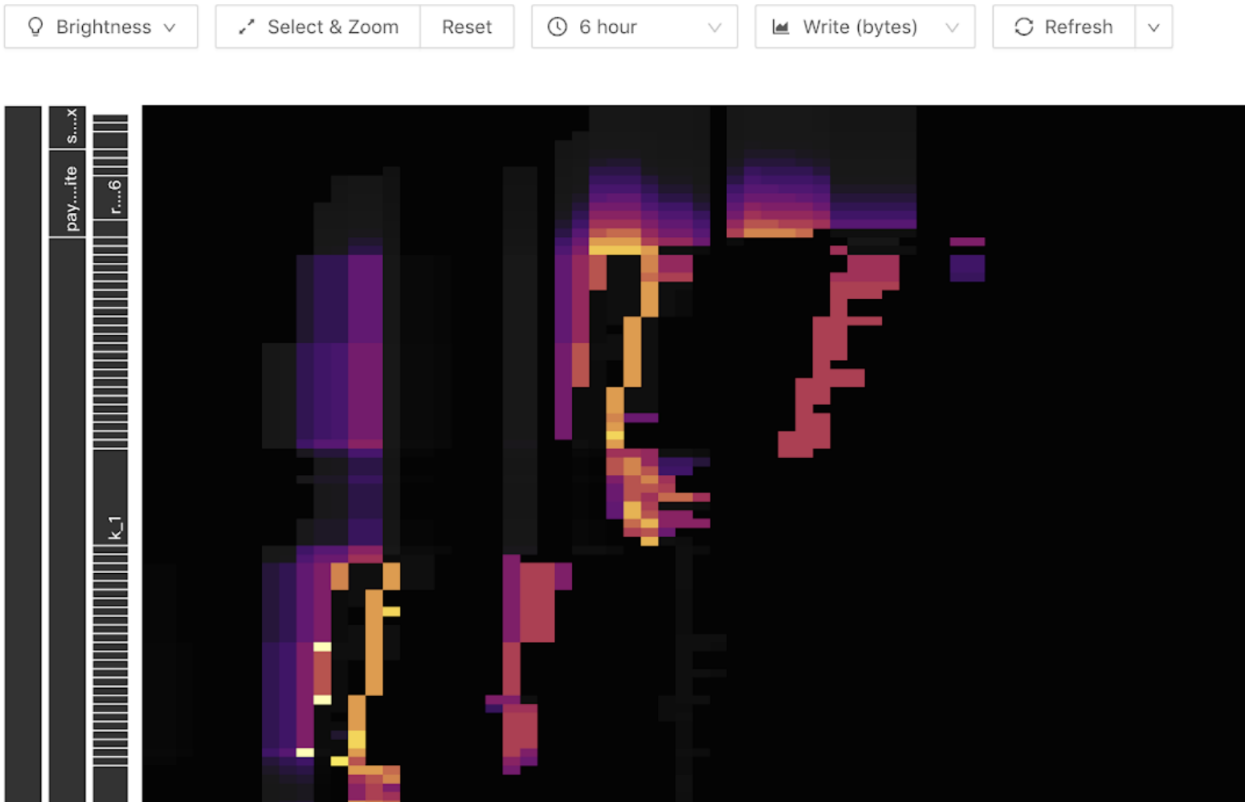

Figure 301: Dashboard Example 1

The following bright diagonal lines (oblique upward or downward) can appear in the write flow graph. Because the write only appears at the end, as the number of table Regions becomes larger, it appears as a ladder. This indicates that a write hotspot shows in this table:

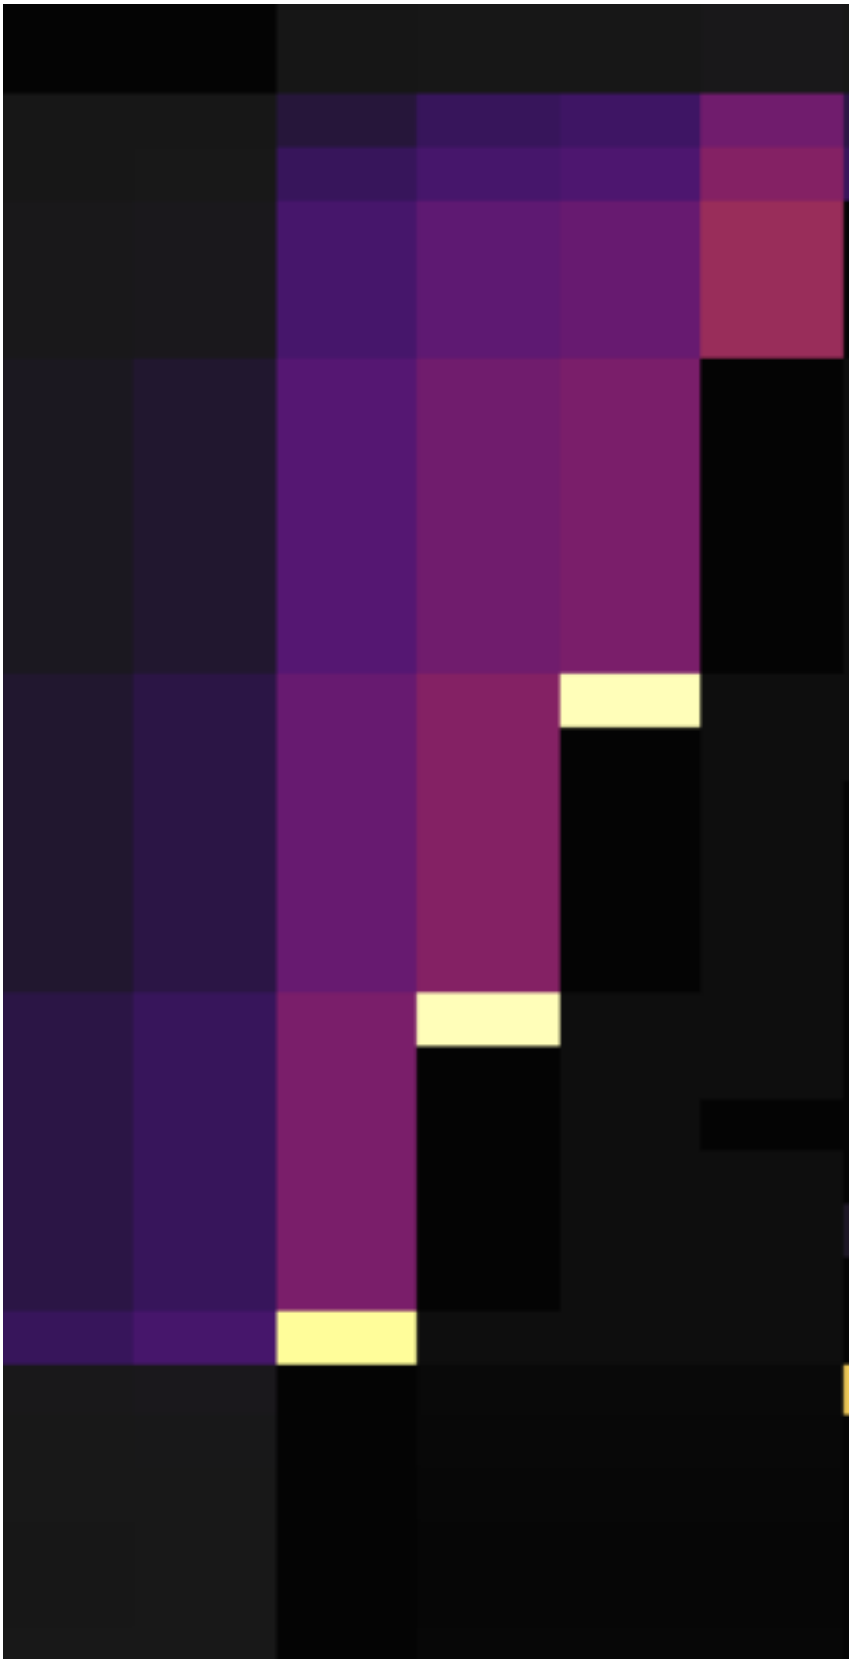

Figure 302: Dashboard Example 2

For read hotspots, a bright horizontal line is generally shown in the thermal diagram. Usually these are caused by small tables with a large number of accesses, shown as follows:

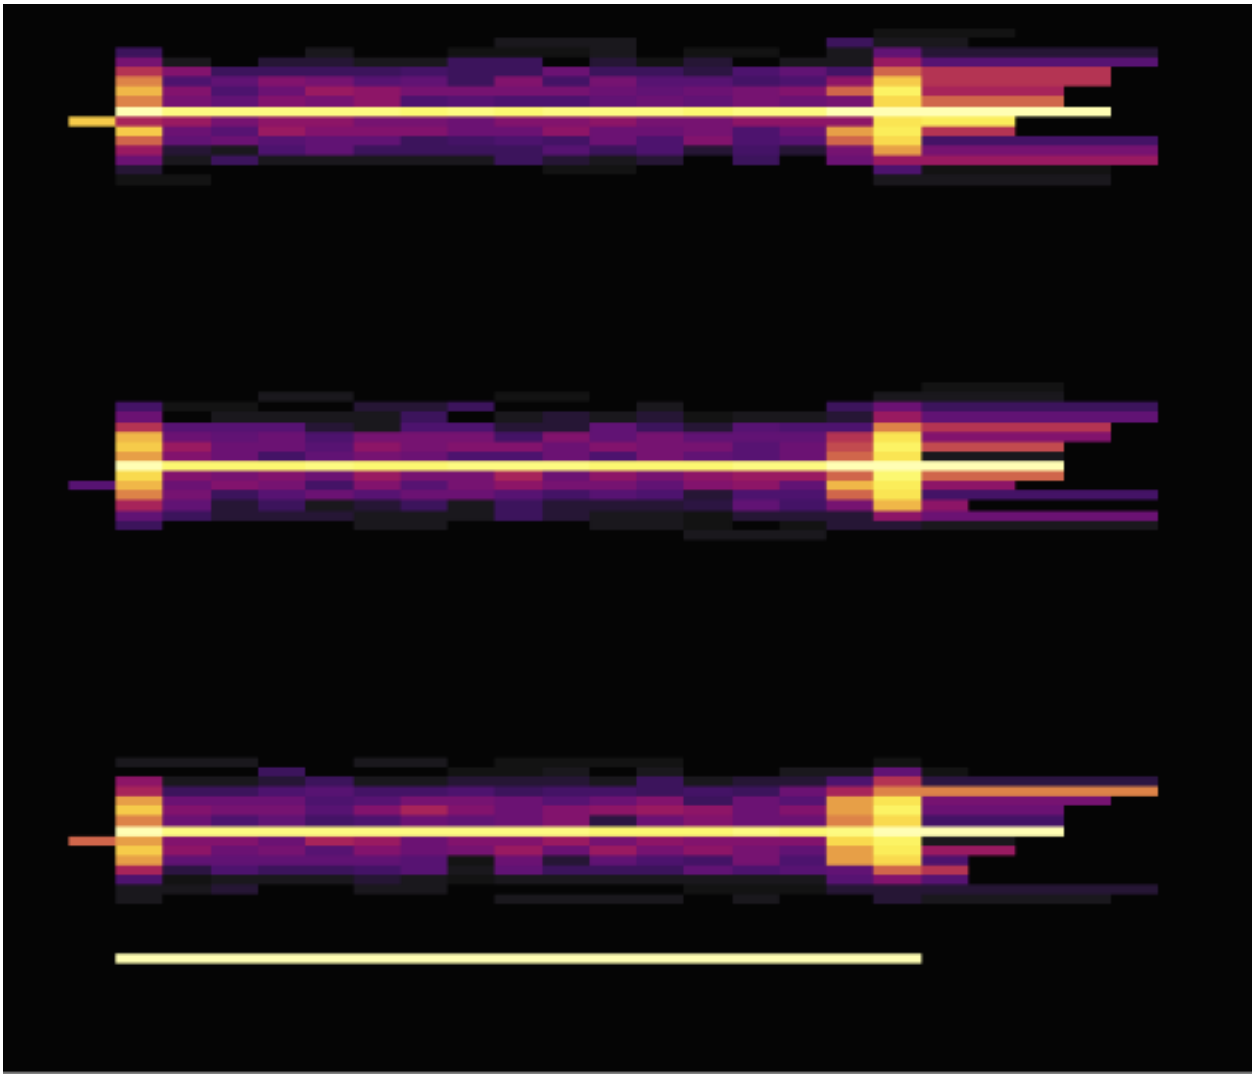

Figure 303: Dashboard Example 3

Hover over the bright block, you can see what table or index has a heavy load. For example:

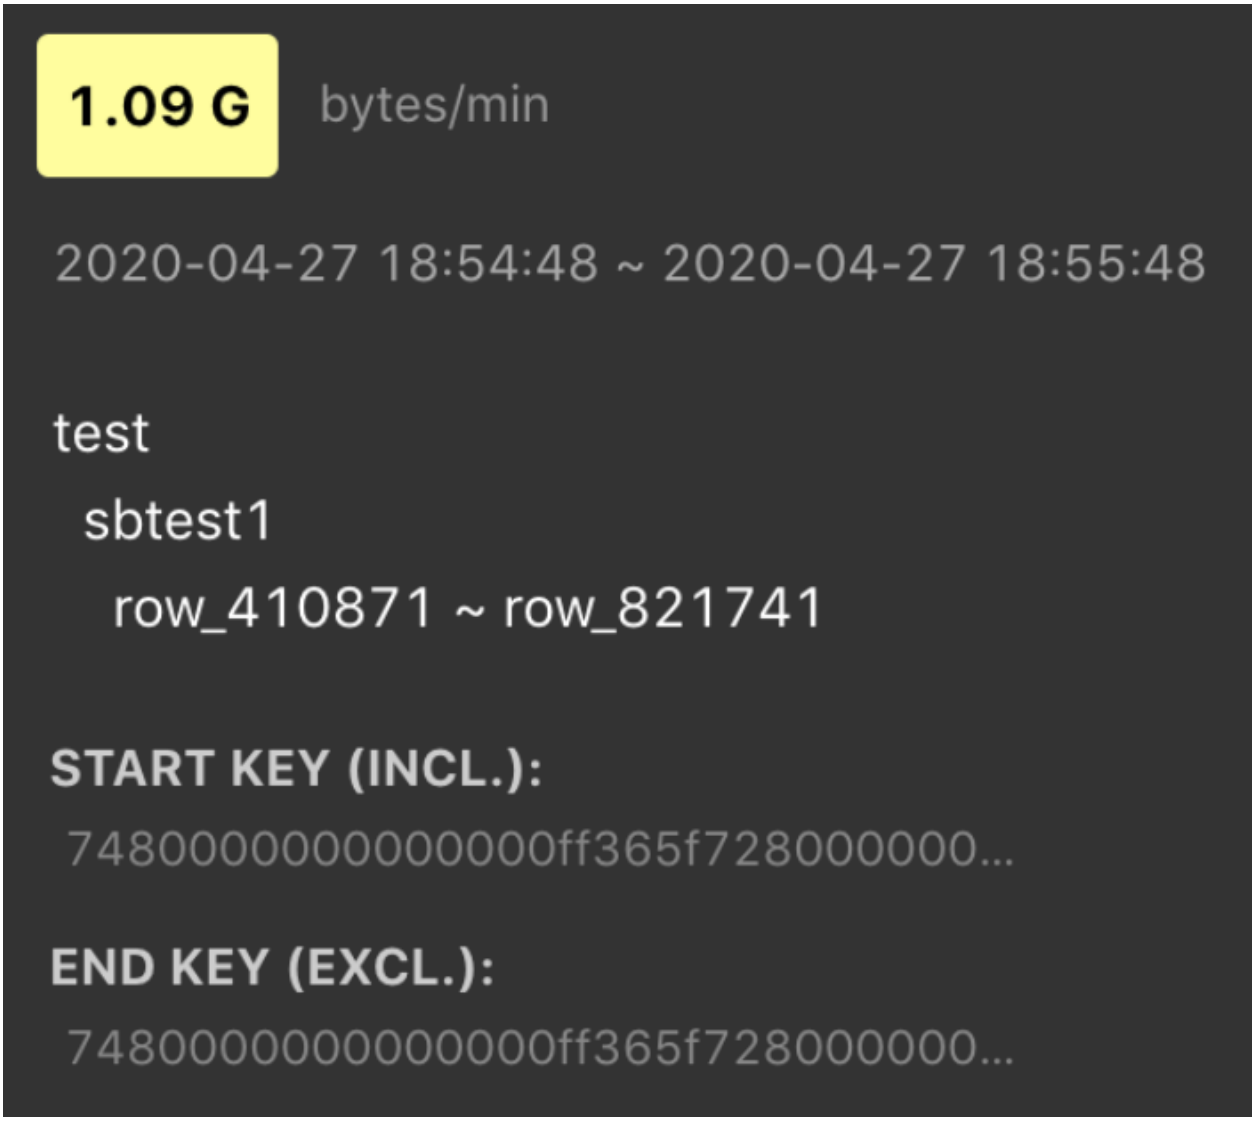

Figure 304: Dashboard Example 4

10.2.3.3 Use `SHARD_ROW_ID_BITS` to process hotspots

For a non-clustered primary key or a table without a primary key, TiDB uses an implicit auto-increment RowID. When a large number of `INSERT` operations exist, the data is written into a single Region, resulting in a write hotspot.

By setting `SHARD_ROW_ID_BITS`, row IDs are scattered and written into multiple Regions, which can alleviate the write hotspot issue.

```
SHARD_ROW_ID_BITS = 4 # Represents 16 shards.
SHARD_ROW_ID_BITS = 6 # Represents 64 shards.
SHARD_ROW_ID_BITS = 0 # Represents the default 1 shard.
```

Statement example:

```
CREATE TABLE: CREATE TABLE t (c int) SHARD_ROW_ID_BITS = 4;
ALTER TABLE: ALTER TABLE t SHARD_ROW_ID_BITS = 4;
```

The value of `SHARD_ROW_ID_BITS` can be dynamically modified. The modified value only takes effect for newly written data.

For the table with a primary key of the `CLUSTERED` type, TiDB uses the primary key of the table as the RowID. At this time, the `SHARD_ROW_ID_BITS` option cannot be used because it changes the RowID generation rules. For the table with the primary key of the `NONCLUSTERED` type, TiDB uses an automatically allocated 64-bit integer as the RowID. In this case, you can use the `SHARD_ROW_ID_BITS` feature. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

The following two load diagrams shows the case where two tables without primary keys use `SHARD_ROW_ID_BITS` to scatter hotspots. The first diagram shows the situation before scattering hotspots, while the second one shows the situation after scattering hotspots.

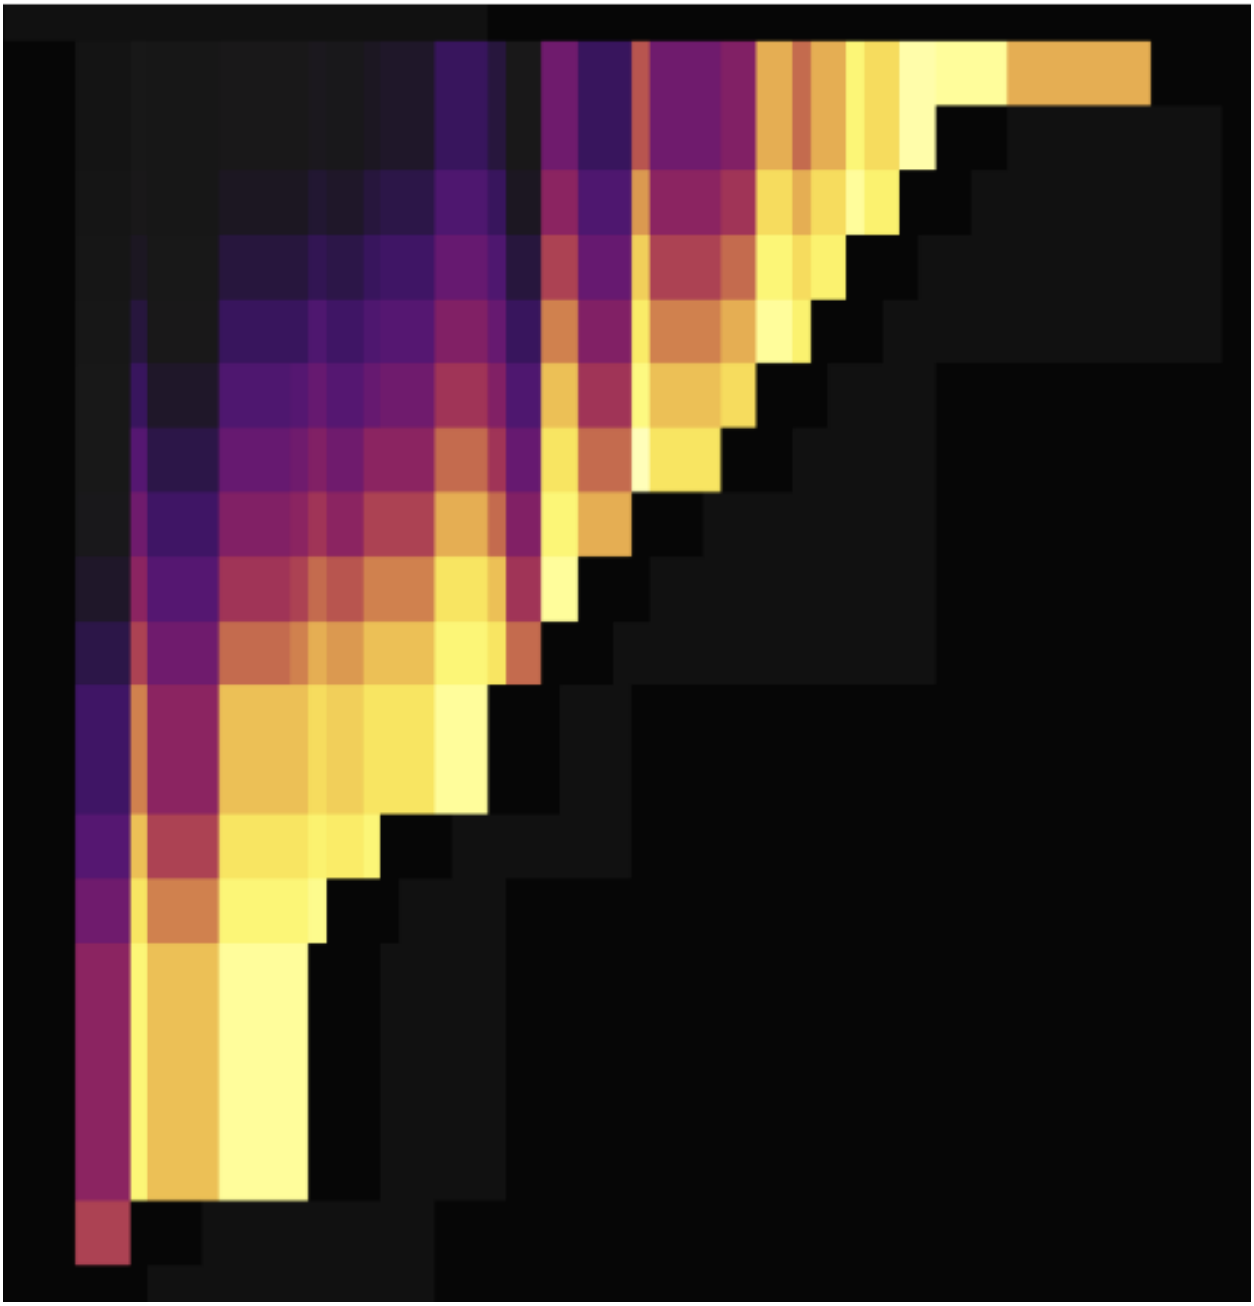

Figure 305: Dashboard Example 5

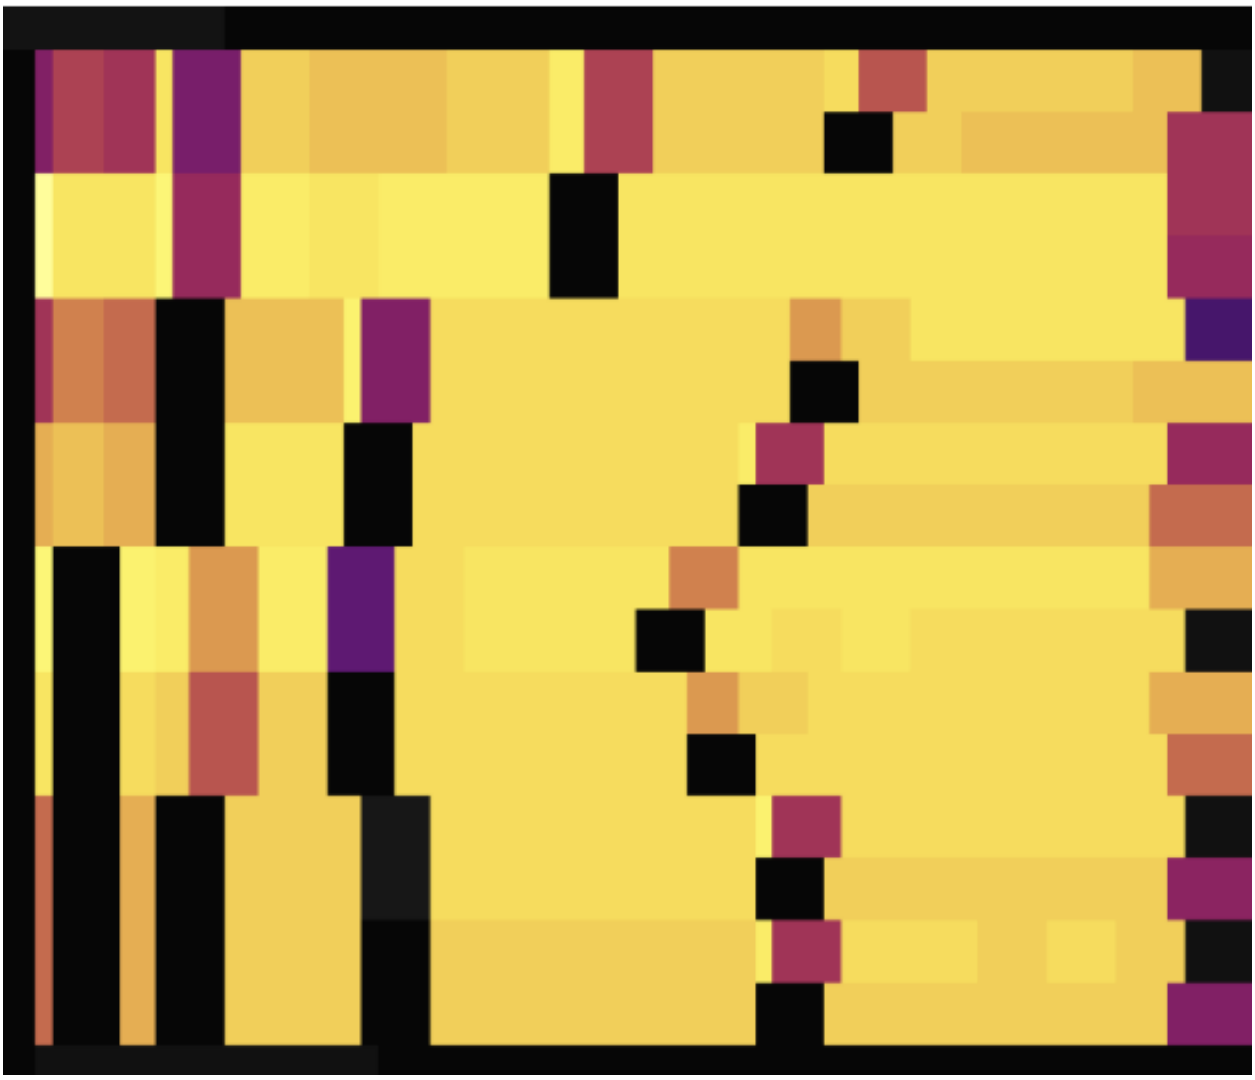

Figure 306: Dashboard Example 6

As shown in the load diagrams above, before setting `SHARD_ROW_ID_BITS`, load hotspots are concentrated on a single Region. After setting `SHARD_ROW_ID_BITS`, load hotspots become scattered.

10.2.3.4 Handle auto-increment primary key hotspot tables using `AUTO_RANDOM`

To resolve the write hotspots brought by auto-increment primary keys, use `AUTO_RANDOM` to handle hotspot tables that have auto-increment primary keys.

If this feature is enabled, TiDB generates randomly distributed and non-repeated (before the space is used up) primary keys to achieve the purpose of scattering write hotspots.

Note that the primary keys generated by TiDB are no longer auto-increment primary

keys and you can use `LAST_INSERT_ID()` to obtain the primary key value assigned last time.

To use this feature, modify `AUTO_INCREMENT` to `AUTO_RANDOM` in the `CREATE TABLE` statement. This feature is suitable for non-application scenarios where the primary keys only need to guarantee uniqueness.

For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b varchar(255));
INSERT INTO t (b) VALUES ("foo");
SELECT * FROM t;
```

```
+------------+---+
| a          | b |
+------------+---+
| 1073741825 | b |
+------------+---+
```

```
SELECT LAST_INSERT_ID();
```

```
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1073741825       |
+------------------+
```

The following two load diagrams shows the situations both before and after modifying `AUTO_INCREMENT` to `AUTO_RANDOM` to scatter hotspots. The first one uses `AUTO_INCREMENT`, while the second one uses `AUTO_RANDOM`.

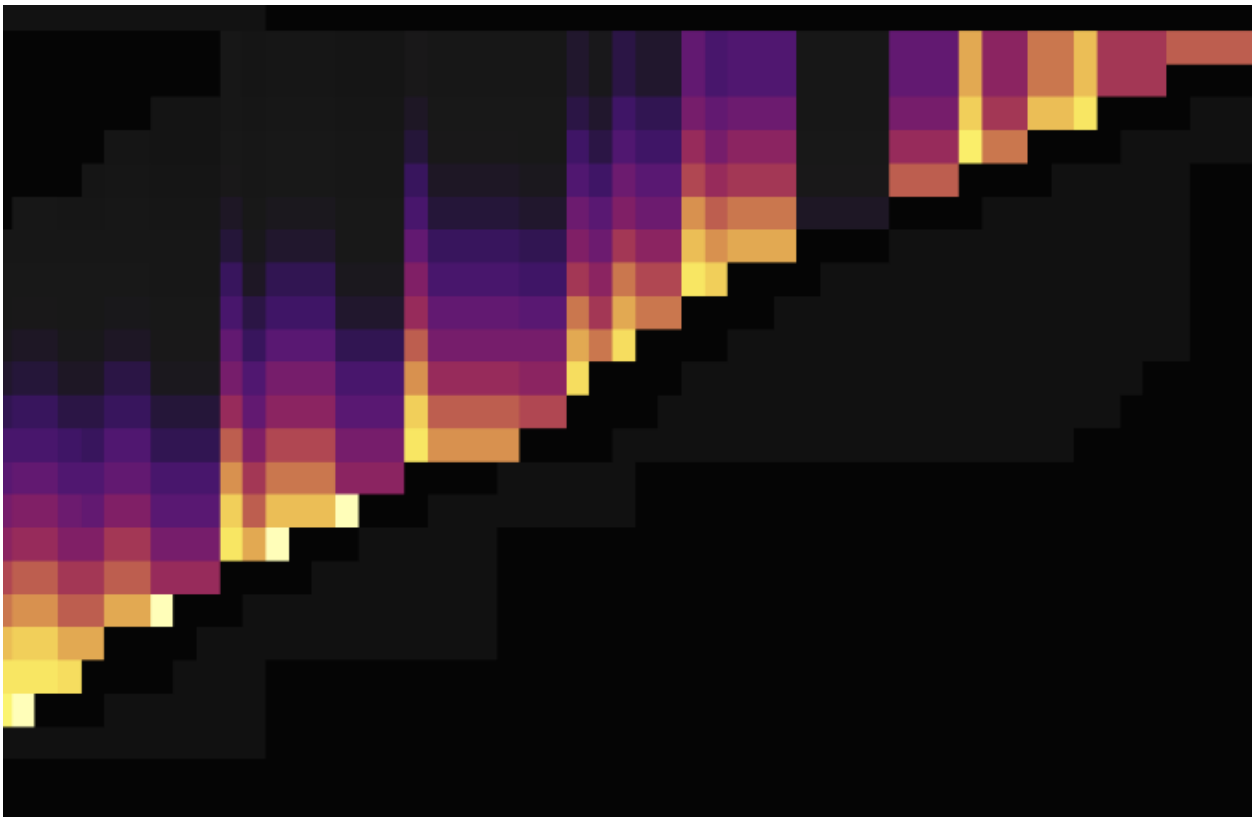

Figure 307: Dashboard Example 7

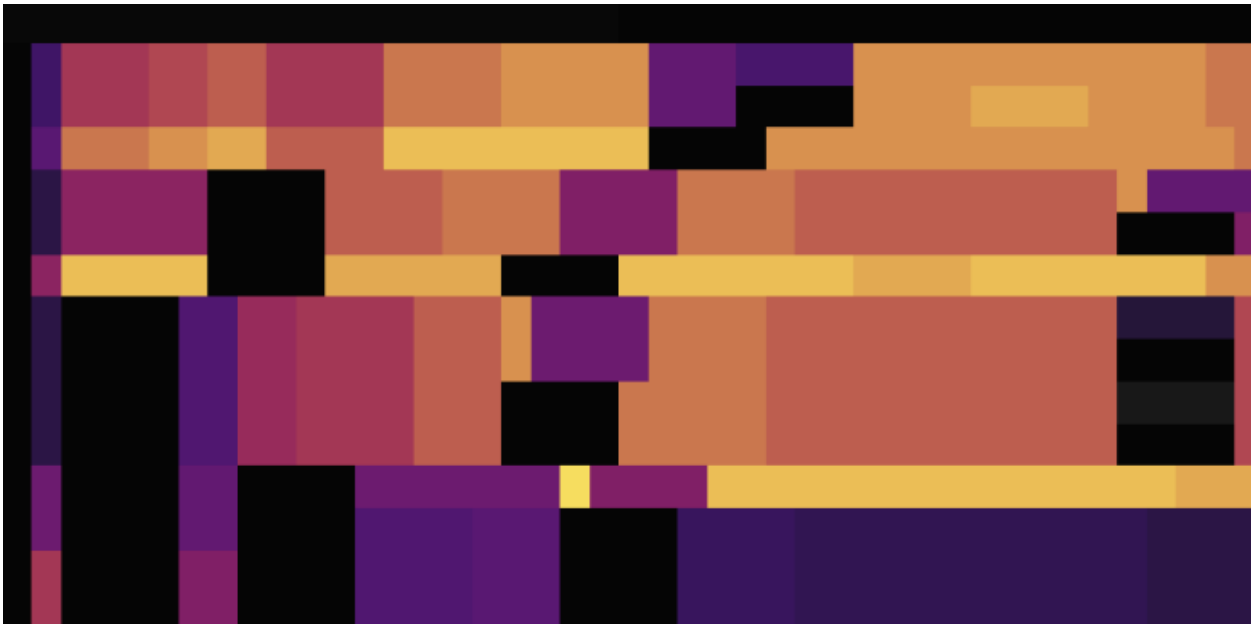

Figure 308: Dashboard Example 8

As shown in the load diagrams above, using `AUTO_RANDOM` to replace `AUTO_INCREMENT` can well scatter hotspots.

For more details, see AUTO_RANDOM.

10.2.3.5 Optimization of small table hotspots

The Coprocessor Cache feature of TiDB supports pushing down computing result caches. After this feature is enabled, TiDB caches the computing results that will be pushed down to TiKV. This feature works well for read hotspots of small tables.

For more details, see Coprocessor Cache.

See also:

- Highly Concurrent Write Best Practices
- Split Region

10.2.3.6 Scatter read hotspots

In a read hotspot scenario, the hotspot TiKV node cannot process read requests in time, resulting in the read requests queuing. However, not all TiKV resources are exhausted at this time. To reduce latency, TiDB v7.1.0 introduces the load-based replica read feature, which allows TiDB to read data from other TiKV nodes without queuing on the hotspot TiKV node. You can control the queue length of read requests using the `tidb_load_based_replica_read_threshold` system variable. When the estimated queue time of the leader node exceeds this threshold, TiDB prioritizes reading data from follower nodes. This feature can improve read throughput by 70% to 200% in a read hotspot scenario compared to not scattering read hotspots.

10.2.4 Troubleshoot Increased Read and Write Latency

This document introduces the possible causes of read and write latency and jitters, and how to troubleshoot these issues.

10.2.4.1 Common causes

10.2.4.1.1 Incorrect TiDB execution plan

The execution plan of queries is unstable and might select the incorrect index, which causes higher latency.

Phenomenon

- If the query execution plan is output in the slow log, you can directly view the plan. Execute the `select tidb_decode_plan('xxx...')` statement to parse the detailed execution plan.

- The number of scanned keys in the monitor abnormally increases; in the slow log, the number of `Scan Keys` are large.
- The SQL execution duration in TiDB is greatly different than that in other databases such as MySQL. You can compare the execution plan of other databases (for example, whether `Join Order` is different).

Possible reason

The statistics is inaccurate.

Troubleshooting methods

- Update the statistical information
  - Execute `analyze table` manually and execute `analyze` periodically with the `crontab` command to keep the statistics accurate.
  - Execute `auto analyze` automatically. Lower the threshold value of `analyze ratio`, increase the frequency of information collection, and set the start and end time of the execution. See the following examples:
    - `set global tidb_auto_analyze_ratio=0.2;`
    - `set global tidb_auto_analyze_start_time='00:00 +0800';`
    - `set global tidb_auto_analyze_end_time='06:00 +0800';`
- Bind the execution plan
  - Modify the application SQL statements and execute `use index` to consistently use the index of the column.
  - In 3.0 versions, you do not need to modify the application SQL statements. Use `create global binding` to create the binding SQL statement of `force index`.
  - In 4.0 versions, SQL Plan Management is supported, which avoids the performance decrease caused by unstable execution plans.

10.2.4.1.2 PD anomalies

Phenomenon

There is an abnormal increase of the `wait duration` metric for the PD TSO. This metric represents the duration of waiting for PD to return requests.

Possible reasons

- Disk issue. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana -> disk performance -> latency/load**. You can also use the FIO tool to run a check on the disk if necessary.

- Network issues between PD peers. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana -> PD -> etcd**.
- High server load. The log shows `server is likely overloaded`.
- PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19.
- The leader election is slow. The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region-storage` to `true`, which significantly reduce the Region loading duration.
- The network issue between TiDB and PD. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana -> black-box_exporter -> ping latency**.
- PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040).
- When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that `TCP InSegs` is relatively large. This issue has been fixed in v3.0.6 (#1952).
- PD panics. Report a bug.
- Other causes. Get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

10.2.4.1.3 TiKV anomalies

Phenomenon

The `KV Cmd Duration` metric in the monitor increases abnormally. This metric represents the duration between the time that TiDB sends a request to TiKV and the time that TiDB receives the response.

Possible reasons

- Check the `gRPC duration` metric. This metric represents the total duration of a gRPC request in TiKV. You can find out the potential network issue by comparing `gRPC duration` of TiKV and `KV duration` of TiDB. For example, the gRPC duration is short but the KV duration of TiDB is long, which indicates that the network latency

between TiDB and TiKV might be high, or that the NIC bandwidth between TiDB and TiKV is fully occupied.

- Re-election because TiKV is restarted.

    - After TiKV panics, it is pulled up by `systemd` and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
    - TiKV is stopped or killed by a third party and then pulled up by `systemd`. Check the cause by viewing `dmesg` and the TiKV log.
    - TiKV is OOM, which causes restart.
    - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage).

- Check monitor: TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`.

- Re-election because of network isolation.

- If the `block-cache` configuration is too large, it might cause TiKV OOM. To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**. Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"`parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM. To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana** -> **TiKV-details** -> **coprocessor overview**.

10.2.4.1.4 Bottleneck of a single TiKV thread

There are some single threads in TiKV that might become the bottleneck.

- Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana** -> **TiKV-details** -> **Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue.
- For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana** -> **TiKV-details** -> **Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.

10.2.4.1.5 CPU load increases

Phenomenon

The usage of CPU resources becomes the bottleneck.

Possible reasons

- Hotspot issue
- High overall load. Check the slow queries and expensive queries of TiDB. Optimize the executing queries by adding indexes or executing queries in batches. Another solution is to scale out the cluster.

10.2.4.2 Other causes

10.2.4.2.1 Cluster maintenance

Most of each online cluster has three or five nodes. If the machine to be maintained has the PD component, you need to determine whether the node is the leader or the follower. Disabling a follower has no impact on the cluster operation. Before disabling a leader, you need to switch the leadership. During the leadership change, performance jitter of about 3 seconds will occur.

10.2.4.2.2 Minority of replicas are offline

By default, each TiDB cluster has three replicas, so each Region has three replicas in the cluster. These Regions elect the leader and replicate data through the Raft protocol. The Raft protocol ensures that TiDB can still provide services without data loss even when the nodes (that are fewer than half of replicas) fail or are isolated. For the cluster with three replicas, the failure of one node might cause performance jitter but the usability and correctness in theory are not affected.

10.2.4.2.3 New indexes

Creating indexes consumes a huge amount of resources when TiDB scans tables and backfills indexes. Index creation might even conflict with the frequently updated fields, which affects the application. Creating indexes on a large table often takes a long time, so you must try to balance the index creation time and the cluster performance (for example, creating indexes at the off-peak time).

Parameter adjustment:

Currently, you can use `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` ↪ to dynamically adjust the speed of index creation. Usually, the smaller the values, the smaller the impact on the system, with longer execution time though.

In general cases, you can first keep their default values (`4` and `256`), observe the resource usage and response speed of the cluster, and then increase the value of `tidb_ddl_reorg_` ↪ `worker_cnt` to increase the concurrency. If no obvious jitter is observed in the monitor,

increase the value of `tidb_ddl_reorg_batch_size`. If the columns involved in the index creation are frequently updated, the many resulting conflicts will cause the index creation to fail and be retried.

In addition, you can also set the value of `tidb_ddl_reorg_priority` to `PRIORITY_HIGH` to prioritize the index creation and speed up the process. But in the general OLTP system, it is recommended to keep its default value.

10.2.4.2.4 High GC pressure

The transaction of TiDB adopts the Multi-Version Concurrency Control (MVCC) mechanism. When the newly written data overwrites the old data, the old data is not replaced, and both versions of data are stored. Timestamps are used to mark different versions. The task of GC is to clear the obsolete data.

- In the phase of Resolve Locks, a large amount of `scan_lock` requests are created in TiKV, which can be observed in the gRPC-related metrics. These `scan_lock` requests call all Regions.
- In the phase of Delete Ranges, a few (or no) `unsafe_destroy_range` requests are sent to TiKV, which can be observed in the gRPC-related metrics and the **GC tasks** panel.
- In the phase of Do GC, each TiKV by default scans the leader Regions on the machine and performs GC to each leader, which can be observed in the **GC tasks** panel.

10.2.5 Troubleshoot Write Conflicts in Optimistic Transactions

This document introduces the reason of and solutions to write conflicts in optimistic transactions.

Before TiDB v3.0.8, TiDB uses the optimistic transaction model by default. In this model, TiDB does not check conflicts during transaction execution. Instead, while the transaction is finally committed, the two-phase commit (2PC) is triggered and TiDB checks write conflicts. If a write conflict exists and the auto-retry mechanism is enabled, then TiDB retries the transaction within limited times. If the retry succeeds or has reached the upper limit on retry times, TiDB returns the result of transaction execution to the client. Therefore, if a lot of write conflicts exist in the TiDB cluster, the duration can be longer.

10.2.5.1 The reason of write conflicts

TiDB implements its transactions by using the Percolator transaction model. `percolator` is generally an implementation of 2PC. For the detailed 2PC process, see TiDB Optimistic Transaction Model.

After the client sends a `COMMIT` request to TiDB, TiDB starts the 2PC process:

1. TiDB chooses one key from all keys in the transaction as the primary key of the transaction.

2. TiDB sends the `prewrite` request to all the TiKV Regions involved in this commit. TiKV judges whether all keys can preview successfully.
3. TiDB receives the result that all `prewrite` requests are successful.
4. TiDB gets the `commit_ts` from PD.
5. TiDB sends the `commit` request to the TiKV Region that contains the primary key of the transaction. After TiKV receives the `commit` request, it checks the validity of the data and clears the locks left in the `prewrite` stage.
6. After the `commit` request returns successfully, TiDB returns success to the client.

The write conflict occurs in the `prewrite` stage. When the transaction finds that another transaction is writing the current key (`data.commit_ts` > `txn.start_ts`), a write conflict occurs.

10.2.5.2 Detect write conflicts

In the TiDB Grafana panel, check the following monitoring metrics under **KV Errors**:

- **KV Backoff OPS** indicates the count of error messages per second returned by TiKV.

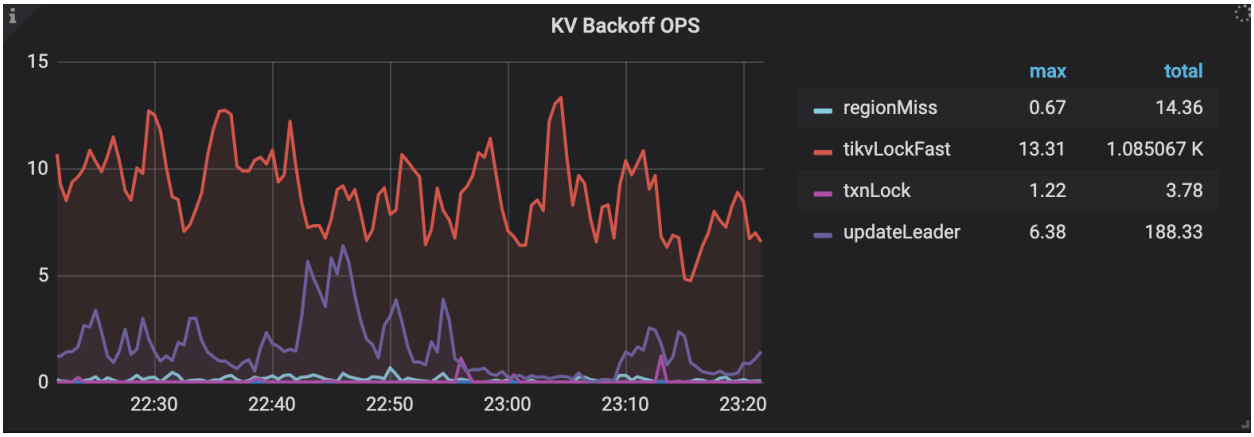

Figure 309: kv-backoff-ops

The `txnlock` metric indicates the write-write conflict. The `txnLockFast` metric indicates the read-write conflict.

- **Lock Resolve OPS** indicates the count of items related to transaction conflicts per second:

Figure 310: lock-resolve-ops

- `not_expired` indicates the TTL of the lock was not expired. The conflict transaction cannot resolve locks until the TTL is expired.
- `wait_expired` indicates that the transaction needs to wait the lock to expire.
- `expired` indicates the TTL of the lock was expired. Then the conflict transaction can resolve this lock.

- **KV Retry Duration** indicates the duration of re-sends the KV request:

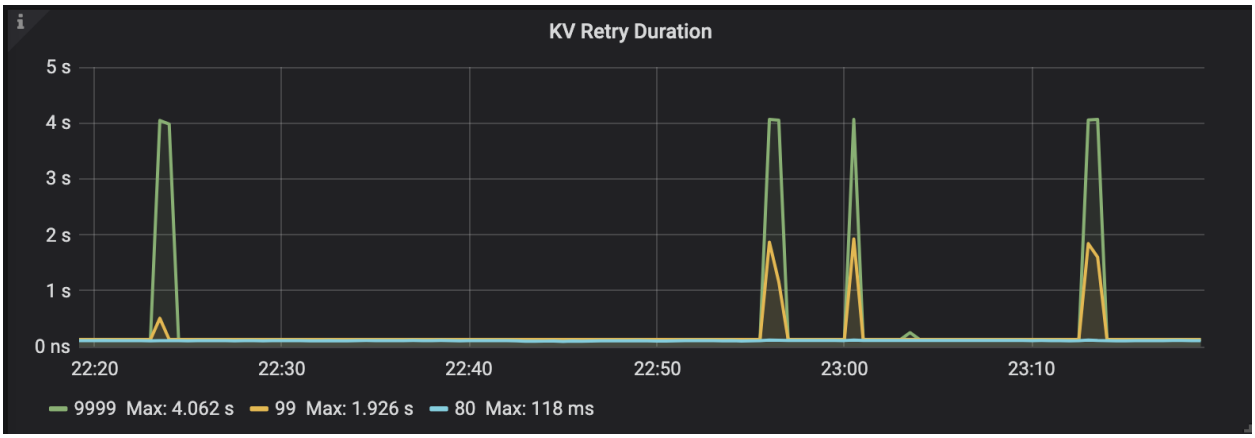

Figure 311: kv-retry-duration

You can also use `[kv:9007]Write conflict` as the keywords to search in the TiDB log. The keywords also indicate the write conflict exists in the cluster.

10.2.5.3 Resolve write conflicts

If many write conflicts exist in the cluster, it is recommended to find out the write conflict key and the reason, and then try to change the application logic to avoid write conflicts.

When the write conflict exists in the cluster, you can see the log similar to the following one in the TiDB log file:

```
[2020/05/12 15:17:01.568 +08:00] [WARN] [session.go:446] ["commit failed"] [
    ↪ conn=3] ["finished txn"="Txn{state=invalid}"] [error="[kv:9007]Write
    ↪ conflict, txnStartTS=416617006551793665, conflictStartTS
    ↪ =416617018650001409, conflictCommitTS=416617023093080065, key={
    ↪ tableID=47, indexID=1, indexValues={string, }} primary={tableID=47,
    ↪ indexID=1, indexValues={string, }} [try again later]"]
```

The explanation of the log above is as follows:

- `[kv:9007]Write conflict`: indicates the write-write conflict.
- `txnStartTS=416617006551793665`: indicates the `start_ts` of the current transaction. You can use the `pd-ctl` tool to convert `start_ts` to physical time.
- `conflictStartTS=416617018650001409`: indicates the `start_ts` of the write conflict transaction.
- `conflictCommitTS=416617023093080065`: indicates the `commit_ts` of the write conflict transaction.
- `key={tableID=47, indexID=1, indexValues={string, }}`: indicates the write conflict key. `tableID` indicates the ID of the write conflict table. `indexID` indicates the ID of write conflict index. If the write conflict key is a record key, the log prints `handle=x`, indicating which record(row) has a conflict. `indexValues` indicates the value of the index that has a conflict.
- `primary={tableID=47, indexID=1, indexValues={string, }}`: indicates the primary key information of the current transaction.

You can use the `pd-ctl` tool to convert the timestamp to readable time:

```
tiup ctl:v<CLUSTER_VERSION> pd -u https://127.0.0.1:2379 tso {TIMESTAMP}
```

You can use `tableID` to find the name of the related table:

```
curl http://{TiDBIP}:10080/db-table/{tableID}
```

You can use `indexID` and the table name to find the name of the related index:

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE TABLE_SCHEMA='{db_name}
    ↪ ' AND TABLE_NAME='{table_name}' AND INDEX_ID={indexID};
```

In addition, in TiDB v3.0.8 and later versions, the pessimistic transaction becomes the default mode. The pessimistic transaction mode can avoid write conflicts during the transaction prewrite stage, so you do not need to modify the application any more. In the pessimistic transaction mode, each DML statement writes a pessimistic lock to the related keys during execution. This pessimistic lock can prevent other transactions from modifying the same keys, thus ensuring no write conflicts exist in the `prewrite` stage of the transaction 2PC.

10.2.6 Troubleshoot High Disk I/O Usage in TiDB

This document introduces how to locate and address the issue of high disk I/O usage in TiDB.

10.2.6.1 Check the current I/O metrics

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck.

10.2.6.1.1 Locate I/O issues from monitor

The quickest way to locate I/O issues is to view the overall I/O status from the monitor, such as the Grafana dashboard which is deployed by default by TiUP. The dashboard panels related to I/O include **Overview**, **Node_exporter**, and **Disk-Performance**.

The first type of monitoring panels

In **Overview> System Info> IO Util**, you can see the I/O status of each machine in the cluster. This metric is similar to `util` in the Linux `iostat` monitor. The higher percentage represents higher disk I/O usage:

- If there is only one machine with high I/O usage in the monitor, currently there might be read and write hotspots on this machine.
- If the I/O usage of most machines in the monitor is high, the cluster now has high I/O loads.

For the first situation above (only one machine with high I/O usage), you can further observe I/O metrics from the **Disk-Performance Dashboard** such as `Disk Latency` and `Disk Load` to determine whether any anomaly exists. If necessary, use the fio tool to check the disk.

The second type of monitoring panels

The main storage component of the TiDB cluster is TiKV. One TiKV instance contains two RocksDB instances: one for storing Raft logs, located in `data/raft`, and the other for storing real data, located in `data/db`.

In **TiKV-Details > Raft IO**, you can see the metrics related to disk writes of these two instances:

- `Append log duration`: This metric indicates the response time of writes into RockDB that stores Raft logs. The `.99` response time should be within 50 ms.
- `Apply log duration`: This metric indicates the response time of writes into RockDB that stores real data. The `.99` response should be within 100 ms.

These two metrics also have the **.. per server** monitoring panel to help you view the write hotspots.

The third type of monitoring panels

In **TiKV-Details** > **Storage**, there are monitoring metrics related to storage:

- `Storage command total`: Indicates the number of different commands received.
- `Storage async write duration`: Includes monitoring metrics such as `disk sync duration`, which might be related to Raft I/O. If you encounter an abnormal situation, check the working statuses of related components by checking logs.

Other panels

In addition, some other panel metrics might help you determine whether the bottleneck is I/O, and you can try to set some parameters. By checking the prewrite/commit/raw-put (for raw key-value clusters only) of TiKV gRPC duration, you can determine that the bottleneck is indeed the slow TiKV write. The common situations of slow TiKV writes are as follows:

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which is often due to slow disk writes. You can check the value of `WAL Sync Duration max` in **RocksDB-raft** to determine the cause of slow `append log`. Otherwise, you might need to report a bug.
- The `raftstore` thread is busy. In TiKV Grafana, `Raft Propose/propose wait duration` is significantly higher than `append log duration`. Check the following aspects for troubleshooting:
  - Whether the value of `store-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1,5]` and not too large.
  - Whether the CPU resource of the machine is insufficient.
- `apply log` is slow. TiKV Grafana's `Raft I/O` and `apply log duration` metrics are relatively high, which might usually occur along with relatively high `Raft Propose /apply wait duration`. The possible causes are as follows:
  - The value of `apply-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1, 5]` and not too large. The value of `Thread CPU /apply cpu` is also relatively high.
  - Insufficient CPU resources on the machine.
  - Write hotspot issue of a single Region (Currently, the solution to this issue is still on the way). The CPU usage of a single `apply` thread is high (which can be viewed by modifying the Grafana expression, appended with `by (instance, name)`).
  - Slow write into RocksDB, and `RocksDB kv/max write duration` is high. A single Raft log might contain multiple key-value pairs (kv). 128 kvs are written to RocksDB in a batch, so one `apply` log might involve multiple RocksDB writes.

    - For other causes, report them as bugs.

- `raft commit log` is slow. In TiKV Grafana, `Raft I/O` and `commit log duration` (only available in Grafana 4.x) metrics are relatively high. Each Region corresponds to an independent Raft group. Raft has a flow control mechanism similar to the sliding window mechanism of TCP. To control the size of a sliding window, adjust the `[raftstore] raft-max-inflight-msgs` parameter. If there is a write hotspot and `commit log duration` is high, you can properly set this parameter to a larger value, such as `1024`.

10.2.6.1.2 Locate I/O issues from log

- If the client reports errors such as `server is busy` or especially `raftstore is busy`, the errors might be related to I/O issues.

  You can check the monitoring panel (**Grafana** -> **TiKV** -> **errors**) to confirm the specific cause of the `busy` error. `server is busy` is TiKV's flow control mechanism. In this way, TiKV informs `tidb/ti-client` that the current pressure of TiKV is too high, and the client should try later.

- `Write stall` appears in TiKV RocksDB logs.

  It might be that too many level-0 SST files cause the write stall. To address the issue, you can add the `[rocksdb] max-sub-compactions = 2 (or 3)` parameter to speed up the compaction of level-0 SST files. This parameter means that the compaction tasks of level-0 to level-1 can be divided into `max-sub-compactions` subtasks for multi-threaded concurrent execution.

  If the disk's I/O capability fails to keep up with the write, it is recommended to scale up the disk. If the throughput of the disk reaches the upper limit (for example, the throughput of SATA SSD is much lower than that of NVMe SSD), which results in write stall, but the CPU resource is relatively sufficient, you can try to use a compression algorithm of higher compression ratio to relieve the pressure on the disk, that is, use CPU resources to make up for disk resources.

  For example, when the pressure of `default cf compaction` is relatively high, you can change the parameter `[rocksdb.defaultcf] compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `compression-per-level = ["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

10.2.6.1.3 I/O issues found in alerts

The cluster deployment tool (TiUP) deploys the cluster with alert components by default that have built-in alert items and thresholds. The following alert items are related to I/O:

- TiKV_write_stall
- TiKV_raft_log_lag

- TiKV_async_request_snapshot_duration_seconds
- TiKV_async_request_write_duration_seconds
- TiKV_raft_append_log_duration_secs
- TiKV_raft_apply_log_duration_secs

10.2.6.2 Handle I/O issues

- When an I/O hotspot issue is confirmed to occur, you need to refer to Handle TiDB Hotspot Issues to eliminate the I/O hotspots.
- When it is confirmed that the overall I/O performance has become the bottleneck, and you can determine that the I/O performance will keep falling behind in the application side, then you can take advantage of the distributed database's capability of scaling and increase the number of TiKV nodes to have greater overall I/O throughput.
- Adjust some of the parameters as described above, and use computing/memory resources to make up for disk storage resources.

10.2.7 Troubleshoot Lock Conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. This document describes how to use Lock View to troubleshoot lock issues and how to deal with common lock conflict issues in optimistic and pessimistic transactions.

10.2.7.1 Use Lock View to troubleshoot lock issues

Since v5.1, TiDB supports the Lock View feature. This feature has several system tables built in `information_schema` that provide more information about the lock conflicts and lock waitings.

> **Note:**
>
> Currently, the Lock View feature provides conflict and waiting information for pessimistic locks only.

For the detailed introduction of these tables, see the following documents:

- `TIDB_TRX` and `CLUSTER_TIDB_TRX`: Provides information of all running transactions on the current TiDB node or in the entire cluster, including whether the transaction is in the lock-waiting state, the lock-waiting time, and the digests of statements that have been executed in the transaction.

- DATA_LOCK_WAITS: Provides the pessimistic lock-waiting information in TiKV, including the `start_ts` of the blocking and blocked transaction, the digest of the blocked SQL statement, and the key on which the waiting occurs.
- DEADLOCKS and CLUSTER_DEADLOCKS: Provides the information of several deadlock events that have recently occurred on the current TiDB node or in the entire cluster, including the waiting relationship among transactions in the deadlock loops, the digest of the statement currently being executed in the transaction, and the key on which the waiting occurs.

> **Note:**
>
> The SQL statements shown in the Lock View-related system tables are normalized SQL statements (that is, SQL statements without formats and arguments), which are obtained by internal queries according to SQL digests, so the tables cannot obtain the complete statements that include the format and arguments. For the detailed description of SQL digests and normalized SQL statement, see Statement Summary Tables.

The following sections show the examples of troubleshooting some issues using these tables.

10.2.7.1.1 Deadlock errors

To get the information of the recent deadlock errors, you can query the `DEADLOCKS` or `CLUSTER_DEADLOCKS` table.

For example, to query the `DEADLOCKS` table, you can execute the following SQL statement:

```
select * from information_schema.deadlocks;
```

The following is an example output:

```
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
| DEADLOCK_ID | OCCUR_TIME                 | RETRYABLE | TRY_LOCK_TRX_ID |
    ↪ CURRENT_SQL_DIGEST                                  | CURRENT_SQL_
    ↪ DIGEST_TEXT            | KEY                           | KEY_INFO
    ↪
    ↪ | TRX_HOLDING_LOCK |
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
```

```
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406216 |
   ↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
   ↪ update `t` set `v` = ? where `id` = ? ; | 7480000000000000355
   ↪ F728000000000000002 | {"db_id":1,"db_name":"test","table_id":53,"
   ↪ table_name":"t","handle_type":"int","handle_value":"2"} |
   ↪ 426812829645406217 |
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406217 |
   ↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
   ↪ update `t` set `v` = ? where `id` = ? ; | 7480000000000000355
   ↪ F728000000000000001 | {"db_id":1,"db_name":"test","table_id":53,"
   ↪ table_name":"t","handle_type":"int","handle_value":"1"} |
   ↪ 426812829645406216 |
+--
   ↪ ----------+--------------------------+----------+------------------+------
   ↪
```

The query result above shows the waiting relationship among multiple transactions in the deadlock error, the normalized form of the SQL statements currently being executed in each transaction (statements without formats and arguments), the key on which the conflict occurs, and the information of the key.

For example, in the above example, the first row means that the transaction with the ID of `426812829645406216` is executing a statement like `update `t` set `v` =? Where `id ↪ ` =? ;` but is blocked by another transaction with the ID of `426812829645406217`. The transaction with the ID of `426812829645406217` is also executing a statement that is in the form of `update `t` set `v` =? Where `id` =? ;` but is blocked by the transaction with the ID of `426812829645406216`. The two transactions thus form a deadlock.

10.2.7.1.2 A few hot keys cause queueing locks

The `DATA_LOCK_WAITS` system table provides the lock-waiting status on the TiKV nodes. When you query this table, TiDB automatically obtains the real-time lock-waiting information from all TiKV nodes. If a few hot keys are frequently locked and block many transactions, you can query the `DATA_LOCK_WAITS` table and aggregate the results by key to try to find the keys on which issues frequently occur:

```
select `key`, count(*) as `count` from information_schema.data_lock_waits
   ↪ group by `key` order by `count` desc;
```

The following is an example output:

```
+----------------------------------------+-------+
| key                                    | count |
+----------------------------------------+-------+
| 748000000000000415F728000000000000001 | 2 |
| 748000000000000415F728000000000000002 | 1 |
+----------------------------------------+-------+
```

To avoid contingency, you might need to make multiple queries.

If you know the key that frequently has issues occurred, you can try to get the information of the transaction that tries to lock the key from the `TIDB_TRX` or `CLUSTER_TIDB_TRX` table.

Note that the information displayed in the `TIDB_TRX` and `CLUSTER_TIDB_TRX` tables is also the information of the transactions that are running at the time the query is performed. These tables do not display the information of the completed transactions. If there is a large number of concurrent transactions, the result set of the query might also be large. You can use the `limit` clause or the `where` clause to filter transactions with a long lock-waiting time. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

For example, to filter transactions with a long lock-waiting time using the `where` clause, you can execute the following SQL statement:

```
select trx.* from information_schema.data_lock_waits as l left join
    ↪ information_schema.cluster_tidb_trx as trx on l.trx_id = trx.id where
    ↪  l.key = "74800000000000000415F72800000000000000001"\G
```

The following is an example output:

```
*************************** 1. row ***************************
              INSTANCE: 127.0.0.1:10080

10.2.7.1.3 A transaction is blocked for a long time

If a transaction is known to be blocked by another transaction (or multiple transactions) and the `start_ts` (transaction ID) of the current transaction is known, you can use the following method to obtain the information of the blocking transaction. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```
select l.key, trx.*, tidb_decode_sql_digests(trx.all_sql_digests) as sqls
   ↪ from information_schema.data_lock_waits as l join information_schema.
   ↪ cluster_tidb_trx as trx on l.current_holding_trx_id = trx.id where l.
   ↪ trx_id = 426831965449355272\G
```

The following is an example output:

```
*************************** 1. row ***************************
                   key: 74800000000000004D5F728000000000000001

1 row in set (0.01 sec)
```

In the above query, the TIDB_DECODE_SQL_DIGESTS function is used on the ALL_SQL ↪ _DIGESTS column of the CLUSTER_TIDB_TRX table. This function tries to convert this column (the value is a set of SQL digests) to the normalized SQL statements, which improves readability.

If the start_ts of the current transaction is unknown, you can try to find it out from the information in the TIDB_TRX / CLUSTER_TIDB_TRX table or in the PROCESSLIST / CLUSTER_ ↪ PROCESSLIST table.

10.2.7.2 Troubleshoot optimistic lock conflicts

This section provides the solutions of common lock conflict issues in the optimistic transaction mode.

10.2.7.2.1 Read-write conflicts

As the TiDB server receives a read request from a client, it gets a globally unique and increasing timestamp at the physical time as the start_ts of the current transaction. The transaction needs to read the latest data before start_ts, that is, the target key of the latest commit_ts that is smaller than start_ts. When the transaction finds that the target key is locked by another transaction, and it cannot know which phase the other transaction is in, a read-write conflict happens. The diagram is as follows:

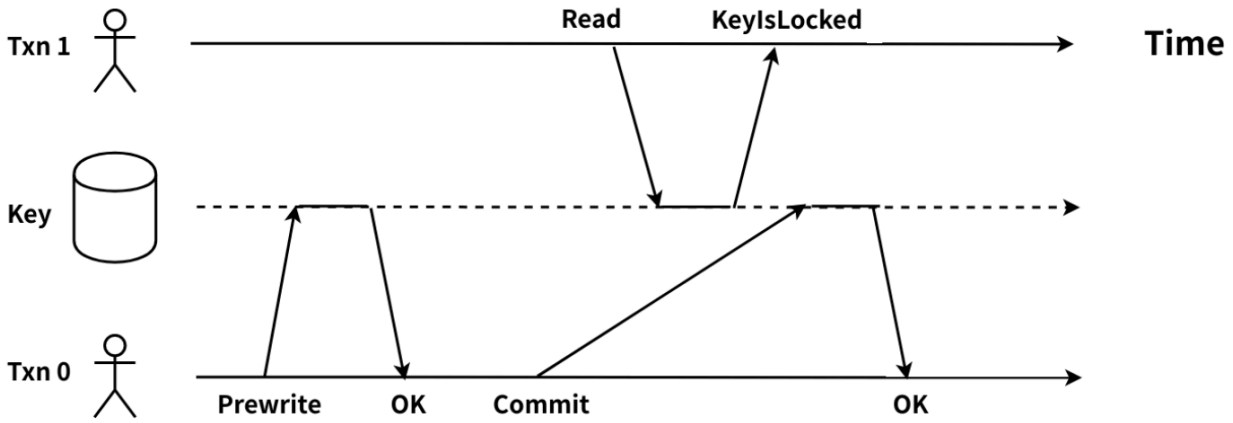

Figure 312: read-write conflict

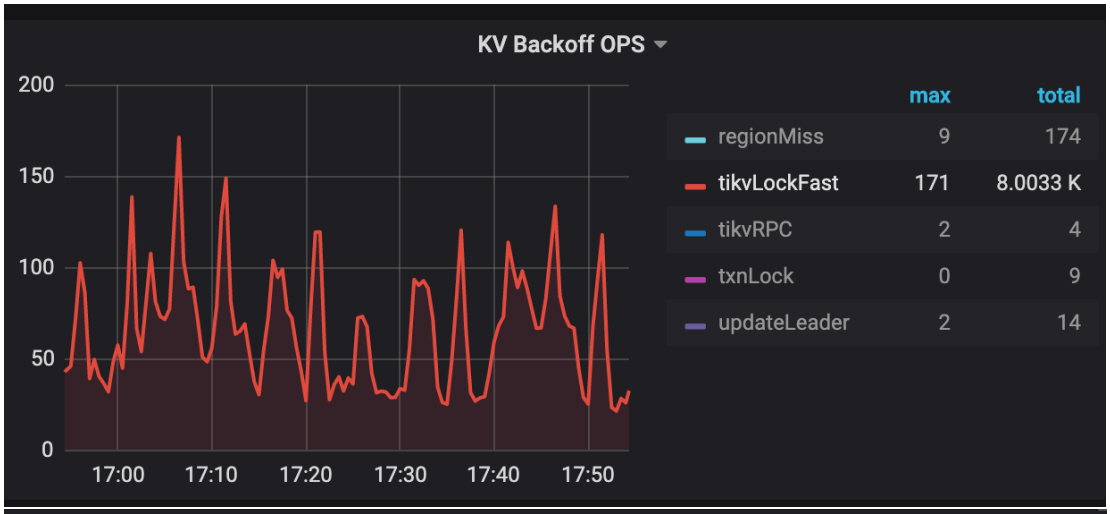
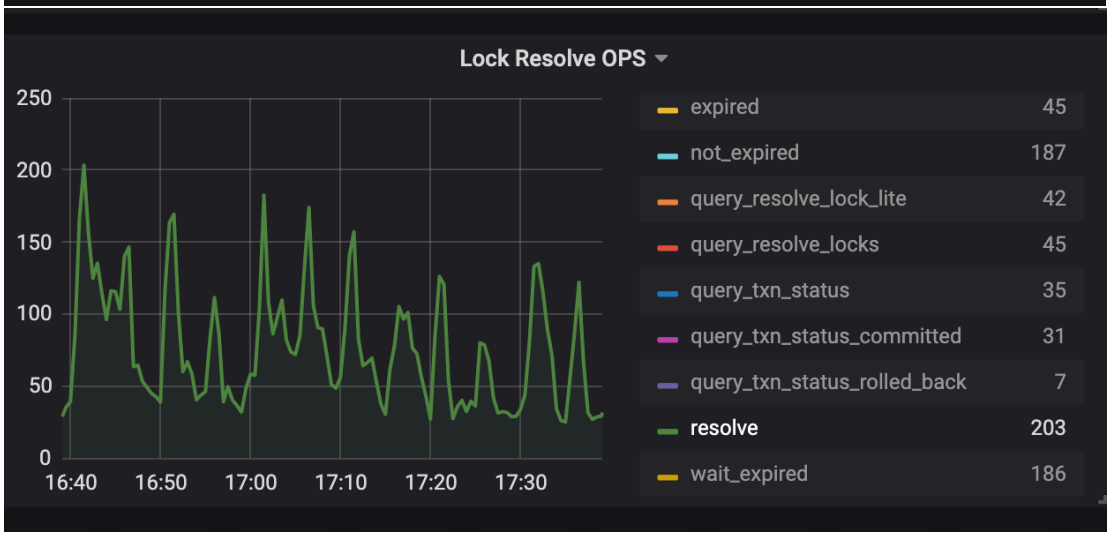


Txn0 completes the Prewrite phase and enters the Commit phase. At this time, Txn1 requests to read the same target key. Txn1 needs to read the target key of the latest commit_ts that is smaller than its start_ts. Because Txn1's start_ts is larger than Txn0's lock_ts, Txn1 must wait for the target key's lock to be cleared, but it hasn't been done. As a result, Txn1 cannot confirm whether Txn0 has been committed or not. Thus, a read-write conflict between Txn1 and Txn0 happens.



You can detect the read-write conflict in your TiDB cluster by the following ways:

1. Monitoring metrics and logs of the TiDB server

    - Monitoring data through Grafana

      In the `KV Errors` panel in the TiDB dashboard, `not_expired/resolve` in `Lock Resolve OPS` and `tikvLockFast` in `KV Backoff OPS` are monitoring metrics that can be used to check read-write conflicts in transactions. If the values of all the metrics increase, there might be many read-write conflicts. The `not_expired` item means that the transaction's lock has not timed out. The `resolve` item means that the other transaction tries to clean up the locks. The `tikvLockFast` item means that read-write conflicts occur.

- Logs of the TiDB server

  If there is any read-write conflict, you can see the following message in the TiDB log:

```
[INFO] [coprocessor.go:743] ["[TIME_COP_PROCESS] resp_time
    ↪ :406.038899ms txnStartTS:416643508703592451 region_id:8297
    ↪ store_addr:10.8.1.208:20160 backoff_ms:255 backoff_types:[
    ↪ txnLockFast,txnLockFast] kv_process_ms:333 scan_total_write
    ↪ :0 scan_processed_write:0 scan_total_data:0 scan_processed_
    ↪ data:0 scan_total_lock:0 scan_processed_lock:0"]
```

  - txnStartTS: The start_ts of the transaction that is sending the read request. In the above log, `416643508703592451` is the start_ts.
  - backoff_types: If a read-write conflict happens, and the read request performs backoff and retry, the type of retry is `TxnLockFast`.
  - backoff_ms: The time that the read request spends in the backoff and retry, and the unit is milliseconds. In the above log, the read request spends 255 milliseconds in the backoff and retry.

- region_id: Region ID corresponding to the target key of the read request.

2. Logs of the TiKV server

   If there is any read-write conflict, you can see the following message in the TiKV log:

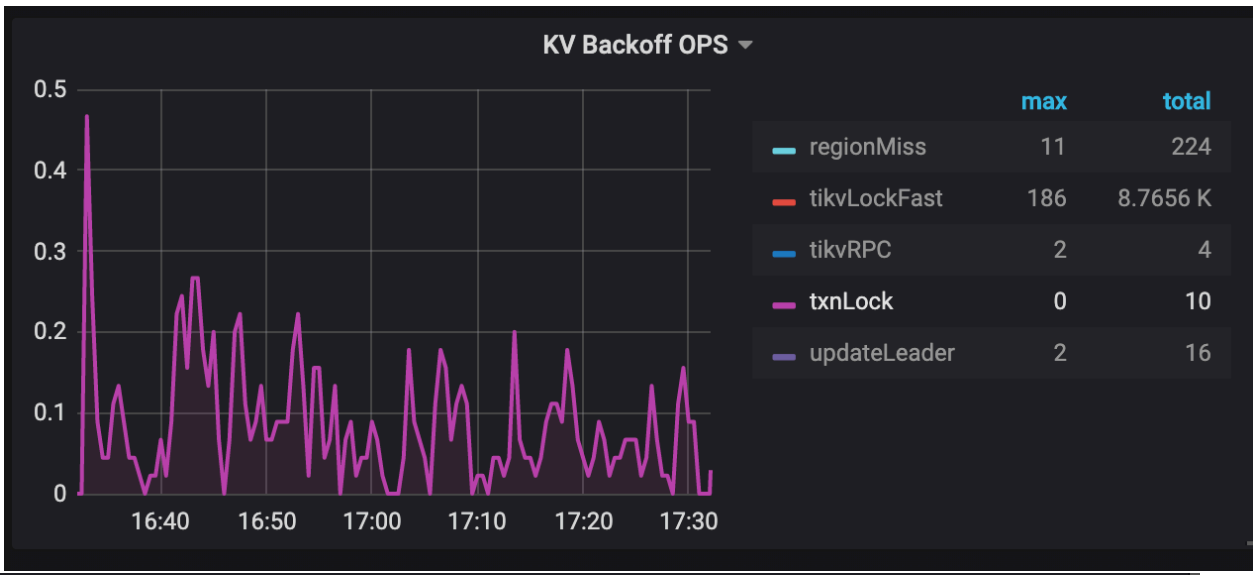
```
[ERROR] [endpoint.rs:454] [error-response] [err=""locked primary_lock
    ↪ :7480000000000004
    ↪ D35F6980000000000000010380000000004C788E0380000000004C0748 lock_
    ↪ version: 411402933858205712 key: 7480000000000004
    ↪ D35F7280000000004C0748 lock_ttl: 3008 txn_size: 1""]
```

   This message indicates that a read-write conflict occurs in TiDB. The target key of the read request has been locked by another transaction. The locks are from the uncommitted optimistic transaction and the uncommitted pessimistic transaction after the prewrite phase.

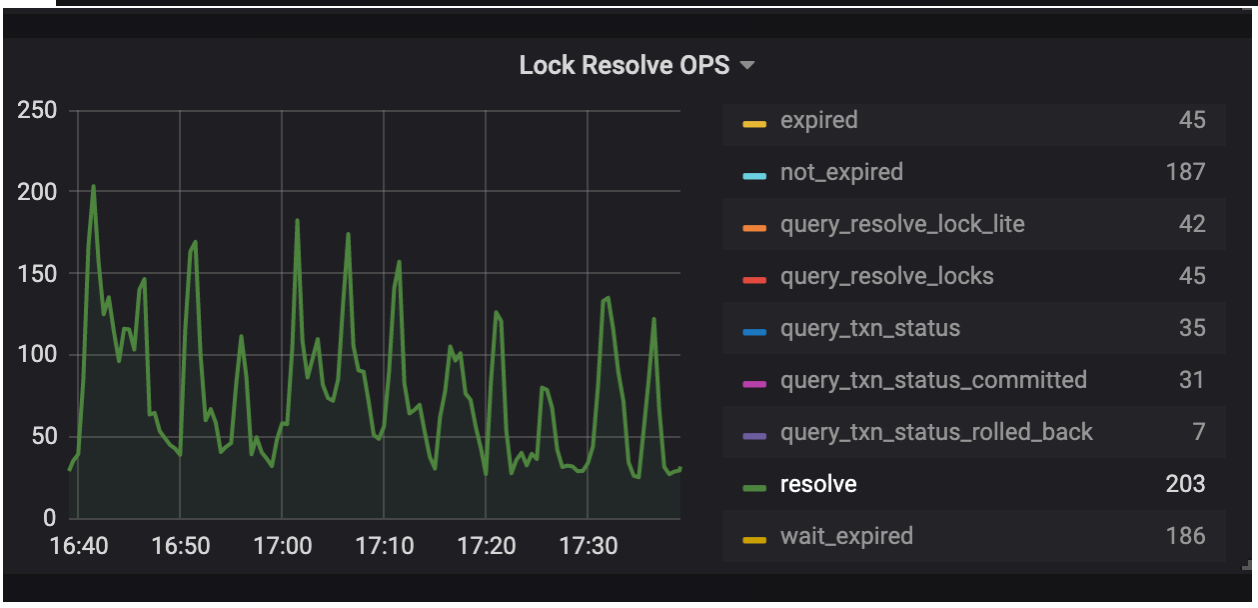
   - primary_lock: Indicates that the target key is locked by the primary lock.
   - lock_version: The start_ts of the transaction that owns the lock.
   - key: The target key that is locked.
   - lock_ttl: The lock's TTL (Time To Live)
   - txn_size: The number of keys that are in the Region of the transaction that owns the lock.

Solutions:

- A read-write conflict triggers an automatic backoff and retry. As in the above example, Txn1 has a backoff and retry. The first time of the retry is 10 ms, the longest retry is 3000 ms, and the total time is 20000 ms at maximum.
- You can use the sub-command `decoder` of TiDB Control to view the table id and rowid of the row corresponding to the specified key:



```
./tidb-ctl decoder "t\x00\x00\x00\x00\x00\x00\x1c_r\x00\x00\x00\x00
    ↪ \x00\x00\x00\xfa"
format: table_row
table_id: -9223372036854775780
row_id: -9223372036854775558
```



10.2.7.2.2 KeyIsLocked error

In the Prewrite phase of a transaction, TiDB checks whether there is any write-write conflict, and then checks whether the target key has been locked by another transaction. If the key is locked, the TiKV server outputs a "KeyIsLocked" error. At present, the error message is not printed in the logs of TiDB and TiKV. Same as read-write conflicts, when "KeyIsLocked" occurs, TiDB automatically performs backoff and retry for the transaction.

You can check whether there's any "KeyIsLocked" error in the TiDB monitoring on Grafana:

The `KV Errors` panel in the TiDB dashboard has two monitoring metrics `Lock Resolve OPS` and `KV Backoff OPS` which can be used to check write-write conflicts caused by a transaction. If the `resolve` item under `Lock Resolve OPS` and the `txnLock` item under `KV Backoff OPS` have a clear upward trend, a "KeyIsLocked" error occurs. `resolve` refers to the operation that attempts to clear the lock, and `txnLock` represents a write conflict.

Solutions:

- If there is a small amount of txnLock in the monitoring, no need to pay too much attention. The backoff and retry is automatically performed in the background. The first time of the retry is 100 ms and the maximum time is 3000 ms for a single retry.

- If there are too many "txnLock" operations in the `KV Backoff OPS`, it is recommended that you analyze the reasons to the write conflicts from the application side.
- If your application is a write-write conflict scenario, it is strongly recommended to use the pessimistic transaction mode.

10.2.7.2.3 LockNotFound error

The error log of "TxnLockNotFound" means that transaction commit time is longer than the TTL time, and when the transaction is going to commit, its lock has been rolled back by other transactions. If the TiDB server enables transaction commit retry, this transaction is re-executed according to tidb_retry_limit. (Note about the difference between explicit and implicit transactions.)

You can check whether there is any "LockNotFound" error in the following ways:

1. View the logs of the TiDB server

   If a "TxnLockNotFound" error occurs, the TiDB log message is like this:

```
[WARN] [session.go:446] ["commit failed"] [conn=149370] ["finished txn
    ↪ "="Txn{state=invalid}"] [error="[kv:6]Error: KV error safe to
    ↪ retry tikv restarts txn: Txn(Mvcc(TxnLockNotFound{ start_ts:
    ↪ 412720515987275779, commit_ts: 412720519984971777, key: [116,
    ↪ 128, 0, 0, 0, 0, 1, 111, 16, 95, 114, 128, 0, 0, 0, 0, 0, 0, 2]
    ↪ })) [try again later]"]
```

   - start_ts: The start_ts of the transaction that outputs the `TxnLockNotFound` error because its lock has been rolled back by other transactions. In the above log, `412720515987275779` is the start_ts.
   - commit_ts: The commit_ts of the transaction that outputs the `TxnLockNotFound` ↪ error. In the above log, `412720519984971777` is the commit_ts.

2. View the logs of the TiKV server

   If a "TxnLockNotFound" error occurs, the TiKV log message is like this:

```
Error: KV error safe to retry restarts txn: Txn(Mvcc(TxnLockNotFound))
    ↪ [ERROR [Kv.rs:708] ["KvService::batch_raft send response fail"] [
    ↪ err=RemoteStoped]
```

   Solutions:

- By checking the time interval between start_ts and commit_ts, you can confirm whether the commit time exceeds the TTL time.

  Checking the time interval using the PD control tool:

```
tiup ctl:v<CLUSTER_VERSION> pd tso [start_ts]
tiup ctl:v<CLUSTER_VERSION> pd tso [commit_ts]
```

- It is recommended to check whether the write performance is slow, which might cause that the efficiency of transaction commit is poor, and thus the lock is cleared.
- In the case of disabling the TiDB transaction retry, you need to catch the exception on the application side and try again.

10.2.7.3 Troubleshoot pessimistic lock conflicts

This section provides the solutions of common lock conflict issues in the pessimistic transaction mode.

> **Note:**
>
> Even if the pessimistic transaction mode is set, autocommit transactions still try to commit using the optimistic mode first. If a conflict occurs, the transactions will switch to the pessimistic transaction mode during automatic retry.

10.2.7.3.1 Read-write conflicts

The error messages and solutions are the same as Read-write conflict for optimistic lock conflict.

10.2.7.3.2 Pessimistic lock retry limit reached

When the transaction conflict is very serious or a write conflict occurs, the optimistic transaction will be terminated directly, and the pessimistic transaction will retry the statement with the latest data from storage until there is no write conflict.

Because TiDB's locking operation is a write operation, and the process of the operation is to read first and then write, there are two RPC requests. If a write conflict occurs in the middle of a transaction, TiDB will try again to lock the target keys, and each retry will be printed to the TiDB log. The number of retries is determined by pessimistic-txn.max-retry-count.

In the pessimistic transaction mode, if a write conflict occurs and the number of retries reaches the upper limit, an error message containing the following keywords appears in the TiDB log:

```
err="pessimistic lock retry limit reached"
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust from the application side.
- If your business contains high concurrent locking on the same row (the same key) and encounters frequent conflicts, you can try to enable the system variable `tidb_pessimistic_txn_fair_locking`. Note that enabling this variable might bring some cost of throughput reduction (average latency increase) for transactions with lock conflicts. For newly deployed clusters, this variable is enabled (`ON`) by default.

10.2.7.3.3 Lock wait timeout exceeded

In the pessimistic transaction mode, transactions wait for locks of each other. The timeout for waiting a lock is defined by the innodb_lock_wait_timeout parameter of TiDB. This is the maximum wait lock time at the SQL statement level, which is the expectation of a SQL statement Locking, but the lock has never been acquired. After this time, TiDB will not try to lock again and will return the corresponding error message to the client.

When a wait lock timeout occurs, the following error message will be returned to the client:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust the application logic.

10.2.7.3.4 TTL manager has timed out

The transaction execution time cannot exceed the GC time limit. In addition, the TTL time of pessimistic transactions has an upper limit, whose default value is 1 hour. Therefore, a pessimistic transaction executed for more than 1 hour will fail to commit. This timeout threshold is controlled by the TiDB parameter `performance.max-txn-ttl`.

When the execution time of a pessimistic transaction exceeds the TTL time, the following error message occurs in the TiDB log:

```
TTL manager has timed out, pessimistic locks may expire, please commit or
    ↪ rollback this transaction
```

Solutions:

- First, confirm whether the application logic can be optimized. For example, large transactions may trigger TiDB's transaction size limit, which can be split into multiple small transactions.
- Also, you can adjust the related parameters properly to meet the application transaction logic.

10.2.7.3.5 Deadlock found when trying to get lock

Due to resource competition between two or more transactions, a deadlock occurs. If you do not handle it manually, transactions that block each other cannot be executed successfully and will wait for each other forever. To resolve dead locks, you need to manually terminate one of the transactions to resume other transaction requests.

When a pessimistic transaction has a deadlock, one of the transactions must be terminated to unlock the deadlock. The client will return the same `Error 1213` error as in MySQL, for example:

```
[err="[executor:1213]Deadlock found when trying to get lock; try restarting
    ↪ transaction"]
```

Solutions:

- If it is difficult to confirm the cause of the deadlock, for v5.1 and later versions, you are recommended to try to query the `INFORMATION_SCHEMA.DEADLOCKS` or `INFORMATION_SCHEMA.CLUSTER_DEADLOCKS` system table to get the information of deadlock waiting chain. For details, see the Deadlock errors section and the `DEADLOCKS` table document.
- If the deadlock occurs frequently, you need to adjust the transaction query logic in your application to reduce such occurrences.

10.2.8 Troubleshoot Inconsistency Between Data and Indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

This document describes the meanings of data inconsistency errors and provides some methods to bypass the consistency check. If a data consistency error occurs, you can get support from PingCAP or the community.

10.2.8.1 Error explanation

When inconsistency between data and indexes occurs, you can check TiDB error messages to know which item is inconsistent between row data and index data, or check the related error logs for further investigation.

10.2.8.1.1 Errors reported during transaction execution

This section lists the data inconsistency errors reported when TiDB executes transactions and explains the meanings of these errors with examples.

Error 8133

```
ERROR 8133 (HY000): data inconsistency in table: t, index: k2, index-
↪ count:1 != record-count:0
```

This error indicates that for the `k2` index in table `t`, the number of indexes in the table is 1 and the number of row records is 0. The number is inconsistent.

Error 8138

```
ERROR 8138 (HY000): writing inconsistent data in table: t, expected-
↪ values:{KindString green} != record-values:{KindString GREEN}
```

This error indicates that the transaction was attempting to write an incorrect row value. For the data to be written, the encoded row data does not match the original data before encoding.

Error 8139

```
ERROR 8139 (HY000): writing inconsistent data in table: t, index: i1,
↪ index-handle:4 != record-handle:3, index: tables.mutation{key:kv.Key{0
↪ x74, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x69, 0x80, 0x0, 0
↪ x0, 0x0, 0x0, 0x0, 0x0, 0x1, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0,
↪  0x0, 0xfc, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0, 0x0, 0xfc, 0x3,
↪  0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x4}, flags:0x0, value:[]uint8{0x30
↪ }, indexID:1}, record: tables.mutation{key:kv.Key{0x74, 0x80, 0x0, 0x0,
↪ 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x72, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0
↪ , 0x3}, flags:0xd, value:[]uint8{0x80, 0x0, 0x2, 0x0, 0x0, 0x0, 0x1, 0x2
↪ , 0x5, 0x0, 0xa, 0x0, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x68, 0x65, 0x6c, 0
↪ x6c, 0x6f}, indexID:0}
```

This error indicates that the handle (that is, the key of the row data) of the data to be written is inconsistent. For index `i1` in table `t`, the row to be written by the transaction has a handle of 4 in the index key-value pair and a handle of 3 in the row record key-value pair. The data of this row will not be written.

Error 8140

```
ERROR 8140 (HY000): writing inconsistent data in table: t, index: i2,
↪ col: c1, indexed-value:{KindString hellp} != record-value:{KindString
↪ hello}
```

This error indicates that the data in a row to be written by the transaction does not match the data in the index. For index `i2` in table `t`, a row to be written by the transaction has data `hellp` in the index key-value pair and data `hello` in the record key-value pair. The data of this row will not be written.

Error 8141

```
ERROR 8141 (HY000): assertion failed: key: 748000000000000405f7201330000000000000f8
↪ , assertion: NotExist, start_ts: 430590532931813377, existing start ts:
↪ 430590532931551233, existing commit ts: 430590532931551234
```

This error indicates that the assertion failed when a transaction was being committed. Assuming that data and indexes are consistent, TiDB asserted that the key `748000000000000405f7201330000000000000000f8` did not exist. When the transaction was being committed, TiDB found the key did exist, written by the transaction with the `start ts` `430590532931551233`. TiDB will print the Multi-Version Concurrency Control (MVCC) history of this key to logs.

10.2.8.1.2 Errors reported in admin check

This section lists the data inconsistency errors that might occur in TiDB when you execute the `ADMIN CHECK [TABLE|INDEX]` statement, and explains the meanings of these errors with examples.

Error 8003

```
ERROR 8003 (HY000): table count 3 != index(idx)count 2
```

This error indicates that the table on which the `ADMIN CHECK` statement is executed has 3 row key-value pairs but only 2 index key-value pairs.

Error 8134

```
ERROR 8134 (HY000): data inconsistency in table: t, index: c2, col: c2
↪ , handle: "2", index-values:"KindInt64 13" != record-values:"KindInt64
↪ 12", compare err:<nil>
```

This error indicates that for index `c2` in table `t`, the value of column `c2` has the following inconsistency:

- In the index key-value pair of the row whose handle is `2`, the value of column `c2` is `13`.
- In the row record key-value pair, the value of column `c2` is `12`.

Error 8223

```
ERROR 8223 (HY000): data inconsistency in table: t2, index: i1, handle:
↪  {hello, hello}, index-values:"" != record-values:"handle: {hello, hello
↪ }, values: [KindString hello KindString hello]"
```

This error indicates that `index-values` are null and `record-values` are not null, meaning that there is no corresponding index for the row.

10.2.8.2 Solutions

If you encounter a data inconsistency error, get support from PingCAP for troubleshooting immediately instead of dealing with the error by yourself. If your application needs to skip such errors urgently, you can use the following methods to bypass the check.

10.2.8.2.1 Rewrite SQL

If the data inconsistency error occurs in a particular SQL statement only, you can bypass this error by rewriting the SQL statement to another equivalent form using different execution operators.

10.2.8.2.2 Disable error checks

For the following errors reported in transaction execution, you can bypass the corresponding checks:

- To bypass the checks of errors 8138, 8139, and 8140, configure `set @@tidb_enable_mutation_checker=0`.
- To bypass the checks of error 8141, configure `set @@tidb_txn_assertion_level=OFF`.

> **Note:**
>
> Disabling `tidb_enable_mutation_checker` and `tidb_txn_assertion_level` will bypass the corresponding checks of all SQL statements.

For other errors reported in transaction execution and all errors reported during the execution of the `ADMIN CHECK [TABLE|INDEX]` statement, you cannot bypass the corresponding check, because the data is already inconsistent.

10.3 Diagnostic Methods

10.3.1 SQL Diagnostics

SQL diagnostics is a feature introduced in TiDB v4.0. You can use this feature to locate problems in TiDB with higher efficiency. Before TiDB v4.0, you need to use different tools to obtain different information.

The SQL diagnostic system has the following advantages:

- It integrates information from all components of the system as a whole.
- It provides a consistent interface to the upper layer through system tables.
- It provides monitoring summaries and automatic diagnostics.
- You will find it easier to query cluster information.

10.3.1.1 Overview

The SQL diagnostic system consists of three major parts:

- **Cluster information table**: The SQL diagnostics system introduces cluster information tables that provide a unified way to get the discrete information of each instance. This system fully integrates the cluster topology, hardware information, software information, kernel parameters, monitoring, system information, slow queries, statements, and logs of the entire cluster into the table. So you can query these information using SQL statements.

- **Cluster monitoring table**: The SQL diagnostic system introduces cluster monitoring tables. All of these tables are in `metrics_schema`, and you can query monitoring information using SQL statements. Compared to the visualized monitoring before v4.0, you can use this SQL-based method to perform correlated queries on all the monitoring information of the entire cluster, and compare the results of different time periods to quickly identify performance bottlenecks. Because the TiDB cluster has many monitoring metrics, the SQL diagnostic system also provides monitoring summary tables, so you can find abnormal monitoring items more easily.

Automatic diagnostics: Although you can manually execute SQL statements to query cluster information tables, cluster monitoring tables, and summary tables to locate issues, the automatic diagnostics allows you to quickly locate common issues. The SQL diagnostic system performs automatic diagnostics based on the existing cluster information tables and monitoring tables, and provides relevant diagnostic result tables and diagnostic summary tables.

10.3.1.2 Cluster information tables

The cluster information tables bring together the information of all instances and instances in a cluster. With these tables, you can query all cluster information using only one SQL statement. The following is a list of cluster information tables:

- From the cluster topology table `information_schema.cluster_info`, you can get the current topology information of the cluster, the version of each instance, the Git Hash corresponding to the version, the starting time of each instance, and the running time of each instance.
- From the cluster configuration table `information_schema.cluster_config`, you can get the configuration of all instances in the cluster. For versions earlier than 4.0, you need to access the HTTP API of each instance one by one to get these configuration information.
- On the cluster hardware table `information_schema.cluster_hardware`, you can quickly query the cluster hardware information.
- On the cluster load table `information_schema.cluster_load`, you can query the load information of different instances and hardware types of the cluster.
- On the kernel parameter table `information_schema.cluster_systeminfo`, you can query the kernel configuration information of different instances in the cluster. Currently, TiDB supports querying the sysctl information.
- On the cluster log table `information_schema.cluster_log`, you can query cluster logs. By pushing down query conditions to each instance, the impact of the query on cluster performance is less than that of the `grep` command.

On the system tables earlier than TiDB v4.0, you can only view the current instance. TiDB v4.0 introduces the corresponding cluster tables and you can have a global view of the entire cluster on a single TiDB instance. These tables are currently in `information_schema`, and the query method is the same as other `information_schema` system tables.

10.3.1.3 Cluster monitoring tables

To dynamically observe and compare cluster conditions in different time periods, the SQL diagnostic system introduces cluster monitoring system tables. All monitoring tables are in `metrics_schema`, and you can query the monitoring information using SQL statements. Using this method, you can perform correlated queries on all monitoring information of the entire cluster and compare the results of different time periods to quickly identify performance bottlenecks.

- `information_schema.metrics_tables`: Because many system tables exist now, you can query meta-information of these monitoring tables on the `information_schema.metrics_tables` table.

Because the TiDB cluster has many monitoring metrics, TiDB provides the following monitoring summary tables in v4.0:

- The monitoring summary table `information_schema.metrics_summary` summarizes all monitoring data to for you to check each monitoring metric with higher efficiency.
- `information_schema.metrics_summary_by_label` also summarizes all monitoring data. Particularly, this table aggregates statistics using different labels of each monitoring metric.

10.3.1.4 Automatic diagnostics

On the cluster information tables and cluster monitoring tables above, you need to manually execute SQL statements to troubleshoot the cluster. TiDB v4.0 supports the automatic diagnostics. You can use diagnostic-related system tables based on the existing basic information tables, so that the diagnostics is automatically executed. The following are the system tables related to the automatic diagnostics:

- The diagnostic result table `information_schema.inspection_result` displays the diagnostic result of the system. The diagnostics is passively triggered. Executing `select * from inspection_result` triggers all diagnostic rules to diagnose the system, and the faults or risks in the system are displayed in the results.
- The diagnostic summary table `information_schema.inspection_summary` summarizes the monitoring information of a specific link or module. You can troubleshoot and locate problems based on the context of the entire module or link.

10.3.2 Statement Summary Tables

To better handle SQL performance issues, MySQL has provided statement summary tables in `performance_schema` to monitor SQL with statistics. Among these tables, `events_statements_summary_by_digest` is very useful in locating SQL problems with its abundant fields such as latency, execution times, rows scanned, and full table scans.

Therefore, starting from v4.0.0-rc.1, TiDB provides system tables in `information_schema` (*not* `performance_schema`) that are similar to `events_statements_summary_by_digest` in terms of features.

- `statements_summary`
- `statements_summary_history`
- `cluster_statements_summary`
- `cluster_statements_summary_history`
- `statements_summary_evicted`

> **Note:**
>
> The preceding tables are not available on TiDB Cloud Serverless clusters.

This document details these tables and introduces how to use them to troubleshoot SQL performance issues.

10.3.2.1 `statements_summary`

`statements_summary` is a system table in `information_schema`. `statements_summary` groups the SQL statements by the resource group, the SQL digest and the plan digest, and provides statistics for each SQL category.

The "SQL digest" here means the same as used in slow logs, which is a unique identifier calculated through normalized SQL statements. The normalization process ignores constant, blank characters, and is case insensitive. Therefore, statements with consistent syntaxes have the same digest. For example:

```
SELECT * FROM employee WHERE id IN (1, 2, 3) AND salary BETWEEN 1000 AND
    ↪ 2000;
select * from EMPLOYEE where ID in (4, 5) and SALARY between 3000 and 4000;
```

After normalization, they are both of the following category:

```
select * from employee where id in (...) and salary between ? and ?;
```

The "plan digest" here refers to the unique identifier calculated through normalized execution plan. The normalization process ignores constants. The same SQL statements might be grouped into different categories because the same statements might have different execution plans. SQL statements of the same category have the same execution plan.

`statements_summary` stores the aggregated results of SQL monitoring metrics. In general, each of the monitoring metrics includes the maximum value and average value. For

example, the execution latency metric corresponds to two fields: `AVG_LATENCY` (average latency) and `MAX_LATENCY` (maximum latency).

To make sure that the monitoring metrics are up to date, data in the `statements_summary` table is periodically cleared, and only recent aggregated results are retained and displayed. The periodical data clearing is controlled by the `tidb_stmt_summary_refresh_interval` system variable. If you happen to make a query right after the clearing, the data displayed might be very little.

The following is a sample output of querying `statements_summary`:

```
  SUMMARY_BEGIN_TIME: 2020-01-02 11:00:00
    SUMMARY_END_TIME: 2020-01-02 11:30:00
          STMT_TYPE: Select
        SCHEMA_NAME: test
             DIGEST: 0611
                 ↪ cc2fe792f8c146cc97d39b31d9562014cf15f8d41f23a4938ca341f54182
                 ↪
        DIGEST_TEXT: select * from employee where id = ?
        TABLE_NAMES: test.employee
        INDEX_NAMES: NULL
        SAMPLE_USER: root
         EXEC_COUNT: 3
        SUM_LATENCY: 1035161
        MAX_LATENCY: 399594
        MIN_LATENCY: 301353
        AVG_LATENCY: 345053
    AVG_PARSE_LATENCY: 57000
    MAX_PARSE_LATENCY: 57000
  AVG_COMPILE_LATENCY: 175458
  MAX_COMPILE_LATENCY: 175458
  ............
              AVG_MEM: 103
              MAX_MEM: 103
              AVG_DISK: 65535
              MAX_DISK: 65535
    AVG_AFFECTED_ROWS: 0
          FIRST_SEEN: 2020-01-02 11:12:54
           LAST_SEEN: 2020-01-02 11:25:24
    QUERY_SAMPLE_TEXT: select * from employee where id=3100
     PREV_SAMPLE_TEXT:
          PLAN_DIGEST:
             ↪ f415b8d52640b535b9b12a9c148a8630d2c6d59e419aad29397842e32e8e5de3
             ↪
                PLAN: Point_Get_1   root    1       table:employee, handle:3100
```

Note:

- In TiDB, the time unit of fields in statement summary tables is nanosecond (ns), whereas in MySQL the time unit is picosecond (ps).
- Starting from v7.5.1 and v7.6.0, for clusters with resource control enabled, `statements_summary` will be aggregated by resource group, for example, the same statements executed in different resource groups will be collected as different records.

10.3.2.2 `statements_summary_history`

The table schema of `statements_summary_history` is identical to that of `statements_summary`. `statements_summary_history` saves the history data of a time range. By checking history data, you can troubleshoot anomalies and compare monitoring metrics of different time ranges.

The fields `SUMMARY_BEGIN_TIME` and `SUMMARY_END_TIME` represent the start time and the end time of the historical time range.

10.3.2.3 `statements_summary_evicted`

The `tidb_stmt_summary_max_stmt_count` variable controls the maximum number of statements that the `statement_summary` table stores in memory. The `statement_summary` table uses the LRU algorithm. Once the number of SQL statements exceeds the `tidb_stmt_summary_max_stmt_count` value, the longest unused record is evicted from the table. The number of evicted SQL statements during each period is recorded in the `statements_summary_evicted` table.

The `statements_summary_evicted` table is updated only when a SQL record is evicted from the `statement_summary` table. The `statements_summary_evicted` only records the period during which the eviction occurs and the number of evicted SQL statements.

10.3.2.4 The `cluster` tables for statement summary

The `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` tables only show the statement summary of a single TiDB server. To query the data of the entire cluster, you need to query the `cluster_statements_summary`, `cluster_statements_summary_history`, or `cluster_statements_summary_evicted` tables.

`cluster_statements_summary` displays the `statements_summary` data of each TiDB server. `cluster_statements_summary_history` displays the `statements_summary_history` data of each TiDB server. `cluster_statements_summary_evicted` displays the `statements_summary_evicted` data of each TiDB server. These tables use the `INSTANCE` field to represent the address of the TiDB server. The other fields are the same as

those in `statements_summary`, `statements_summary_history`, and `statements_summary_evicted`.

10.3.2.5 Parameter configuration

The following system variables are used to control the statement summary:

- `tidb_enable_stmt_summary`: Determines whether to enable the statement summary feature. `1` represents `enable`, and `0` means `disable`. The feature is enabled by default. The statistics in the system table are cleared if this feature is disabled. The statistics are re-calculated next time this feature is enabled. Tests have shown that enabling this feature has little impact on performance.
- `tidb_stmt_summary_refresh_interval`: The interval at which the `statements_summary` table is refreshed. The time unit is second (s). The default value is `1800`.
- `tidb_stmt_summary_history_size`: The size of each SQL statement category stored in the `statements_summary_history` table, which is also the maximum number of records in the `statements_summary_evicted` table. The default value is `24`.

- `tidb_stmt_summary_max_stmt_count`: Limits the number of SQL statements that can be stored in statement summary tables. The default value is `3000`. If the limit is exceeded, TiDB clears the SQL statements that recently remain unused. These cleared SQL statements are represented as rows with `DIGEST` set to `NULL` and recorded in the `statements_summary_evicted` table. On the SQL statements page of TiDB Dashboard, the information of these rows is displayed as `Others`.

- `tidb_stmt_summary_max_sql_length`: Specifies the longest display length of `DIGEST_TEXT` and `QUERY_SAMPLE_TEXT`. The default value is `4096`.
- `tidb_stmt_summary_internal_query`: Determines whether to count the TiDB SQL statements. `1` means to count, and `0` means not to count. The default value is `0`.

Note:

When a category of SQL statement needs to be removed because the `tidb_stmt_summary_max_stmt_count` limit is exceeded, TiDB removes the data of that SQL statement category of all time ranges from the `statement_summary_history` table. Therefore, even if the number of SQL statement categories in a certain time range does not reach the limit, the number of SQL statements stored in the `statement_summary_history` table is less than the actual number of SQL statements. If this situation occurs and affects performance, you are recommended to increase the value of `tidb_stmt_summary_max_stmt_count`.

An example of the statement summary configuration is shown as follows:

```
set global tidb_stmt_summary_max_stmt_count = 3000;
set global tidb_enable_stmt_summary = true;
set global tidb_stmt_summary_refresh_interval = 1800;
set global tidb_stmt_summary_history_size = 24;
```

After the preceding configuration takes effect, the `statements_summary` table is cleared every 30 minutes and the `statements_summary_history` table stores up to 3000 types of SQL statements. For each type, the `statements_summary_history` table stores data for the recent 24 periods. The `statements_summary_evicted` table records the recent 24 periods during which SQL statements are evicted from the statement summary. The `statements_summary_evicted` table is updated every 30 minutes.

Note:

- If a SQL type appears every minute, the `statements_summary_history` stores data for the most recent 12 hours. If a SQL type only appears from 00:00 to 00:30 every day, the `statements_summary_history` stores data for the most recent 24 periods, with each period being 1 day. Therefore, the `statements_summary_history` stores the most recent 24 days of data for this SQL type.
- The `tidb_stmt_summary_history_size`, `tidb_stmt_summary_max_stmt_count`, and `tidb_stmt_summary_max_sql_length` configuration items affect memory usage. It is recommended that you adjust these configurations based on your needs, the SQL size, SQL count, and machine configuration. It is not recommended to set them too large values. You can calculate the memory usage using `tidb_stmt_summary_history_size * tidb_stmt_summary_max_stmt_count * tidb_stmt_summary_max_sql_length * 3`.

10.3.2.5.1 Set a proper size for statement summary

After the system has run for a period of time (depending on the system load), you can check the `statement_summary` table to see whether SQL eviction has occurred. For example:

```
select @@global.tidb_stmt_summary_max_stmt_count;
select count(*) from information_schema.statements_summary;
```

```
+-----------------------------------------+
| @@global.tidb_stmt_summary_max_stmt_count |
+-----------------------------------------+
| 3000                                    |
```

```
+--------------------------------------------+
1 row in set (0.001 sec)

+----------+
| count(*) |
+----------+
|     3001 |
+----------+
1 row in set (0.001 sec)
```

You can see that the `statements_summary` table is full of records. Then check the evicted data from the `statements_summary_evicted` table:

```
select * from information_schema.statements_summary_evicted;
```

```
+--------------------+---------------------+--------------+
| BEGIN_TIME         | END_TIME            | EVICTED_COUNT |
+--------------------+---------------------+--------------+
| 2020-01-02 16:30:00 | 2020-01-02 17:00:00 |     59 |
+--------------------+---------------------+--------------+
| 2020-01-02 16:00:00 | 2020-01-02 16:30:00 |     45 |
+--------------------+---------------------+--------------+
2 row in set (0.001 sec)
```

From the preceding result, you can see that a maximum of 59 SQL categories are evicted. In this case, it is recommended that you increase the size of the `statement_summary` table by at least 59 records, which means increasing the size to at least 3059 records.

10.3.2.6 Limitation

By default, statements summary tables are saved in memory. When a TiDB server restarts, all data will be lost.

To address this issue, TiDB v6.6.0 experimentally introduces the statement summary persistence feature, which is disabled by default. After this feature is enabled, the history data is no longer saved in memory, but directly written to disks. In this way, the history data is still available if a TiDB server restarts.

10.3.2.7 Persist statements summary

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be

changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

As described in the Limitation section, statements summary tables are saved in memory by default. Once a TiDB server restarts, all the statements summary will be lost. Starting from v6.6.0, TiDB experimentally provides the configuration item `tidb_stmt_summary_enable_persistent` to allow users to enable or disable statements summary persistence.

To enable statements summary persistence, you can add the following configuration items to the TiDB configuration file:

```
[instance]
tidb_stmt_summary_enable_persistent = true
### The following entries use the default values, which can be modified as needed.
### tidb_stmt_summary_filename = "tidb-statements.log"
### tidb_stmt_summary_file_max_days = 3
### tidb_stmt_summary_file_max_size = 64 # MiB
### tidb_stmt_summary_file_max_backups = 0
```

After statements summary persistence is enabled, the memory keeps only the current real-time data and no history data. Once the real-time data is refreshed as history data, the history data is written to the disk at an interval of `tidb_stmt_summary_refresh_interval` described in the Parameter configuration section. Queries on the `statements_summary_history` or `cluster_statements_summary_history` table will return results combining both in-memory and on-disk data.

Note:

- When statements summary persistence is enabled, the `tidb_stmt_summary_history_size` configuration described in the Parameter configuration section will no longer take effect because the memory does not keep the history data. Instead, the following three configurations will be used to control the retention period and size of history data for persistence: `tidb_stmt_summary_file_max_days`, `tidb_stmt_summary_file_max_size`, and `tidb_stmt_summary_file_max_backups`.
- The smaller the value of `tidb_stmt_summary_refresh_interval`, the more immediate data is written to the disk. However, this also means more redundant data is written to the disk.

10.3.2.8 Troubleshooting examples

This section provides two examples to show how to use the statement summary feature to troubleshoot SQL performance issues.

10.3.2.8.1 Could high SQL latency be caused by the server end?

In this example, the client shows slow performance with point queries on the `employee` table. You can perform a fuzzy search on SQL texts:

```
SELECT avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary
    WHERE digest_text LIKE 'select * from employee%';
```

`1ms` and `0.3ms` are considered within the normal range of `avg_latency`. Therefore, it can be concluded that the server end is not the cause. You can troubleshoot with the client or the network.

```
+-------------+-----------+-----------------------------------------+
| avg_latency | exec_count | query_sample_text                      |
+-------------+-----------+-----------------------------------------+
|     1042040 |         2 | select * from employee where name='eric' |
|      345053 |         3 | select * from employee where id=3100 |
+-------------+-----------+-----------------------------------------+
2 rows in set (0.00 sec)
```

10.3.2.8.2 Which categories of SQL statements consume the longest total time?

If the QPS decrease significantly from 10:00 to 10:30, you can find out the three categories of SQL statements with the longest time consumption from the history table:

```
SELECT sum_latency, avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary_history
    WHERE summary_begin_time='2020-01-02 10:00:00'
    ORDER BY sum_latency DESC LIMIT 3;
```

The result shows that the following three categories of SQL statements consume the longest time in total, which need to be optimized with high priority.

```
+--
    ↪ -----------+-------------+-----------+-----------------------------------------
    ↪
| sum_latency | avg_latency | exec_count | query_sample_text
    ↪                                       |
+--
    ↪ -----------+-------------+-----------+-----------------------------------------
    ↪
```

```
|    7855660 |   1122237 |       7 | select avg(salary) from employee
    ↪ where company_id=2013      |
|    7241960 |   1448392 |       5 | select * from employee join company
    ↪ on employee.company_id=company.id |
|    2084081 |   1042040 |       2 | select * from employee where name='
    ↪ eric'                     |
+--
    ↪ ----------+-------------+-----------+-----------------------------------
    ↪
3 rows in set (0.00 sec)
```

10.3.2.9 Fields description

10.3.2.9.1 `statements_summary` fields description

The following are descriptions of fields in the `statements_summary` table.

Basic fields:

- `STMT_TYPE`: SQL statement type.
- `SCHEMA_NAME`: The current schema in which SQL statements of this category are executed.
- `DIGEST`: The digest of SQL statements of this category.
- `DIGEST_TEXT`: The normalized SQL statement.
- `QUERY_SAMPLE_TEXT`: The original SQL statements of the SQL category. Only one original statement is taken.
- `TABLE_NAMES`: All tables involved in SQL statements. If there is more than one table, each is separated by a comma.
- `INDEX_NAMES`: All SQL indexes used in SQL statements. If there is more than one index, each is separated by a comma.
- `SAMPLE_USER`: The users who execute SQL statements of this category. Only one user is taken.
- `PLAN_DIGEST`: The digest of the execution plan.
- `PLAN`: The original execution plan. If there are multiple statements, the plan of only one statement is taken.
- `BINARY_PLAN`: The original execution plan encoded in binary format. If there are multiple statements, the plan of only one statement is taken. Execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan.
- `PLAN_CACHE_HITS`: The total number of times that SQL statements of this category hit the plan cache.
- `PLAN_IN_CACHE`: Indicates whether the previous execution of SQL statements of this category hit the plan cache.
- `PLAN_CACHE_UNQUALIFIED`: The number of times that the SQL statements of this category fail to hit the plan cache.

- `PLAN_CACHE_UNQUALIFIED_LAST_REASON`: The reason why the SQL statements of this category fail to hit the plan cache last time.

Fields related to execution time:

- `SUMMARY_BEGIN_TIME`: The beginning time of the current summary period.
- `SUMMARY_END_TIME`: The ending time of the current summary period.
- `FIRST_SEEN`: The time when SQL statements of this category are seen for the first time.
- `LAST_SEEN`: The time when SQL statements of this category are seen for the last time.

Fields related to TiDB server:

- `EXEC_COUNT`: Total execution times of SQL statements of this category.
- `SUM_ERRORS`: The sum of errors occurred during execution.
- `SUM_WARNINGS`: The sum of warnings occurred during execution.
- `SUM_LATENCY`: The total execution latency of SQL statements of this category.
- `MAX_LATENCY`: The maximum execution latency of SQL statements of this category.
- `MIN_LATENCY`: The minimum execution latency of SQL statements of this category.
- `AVG_LATENCY`: The average execution latency of SQL statements of this category.
- `AVG_PARSE_LATENCY`: The average latency of the parser.
- `MAX_PARSE_LATENCY`: The maximum latency of the parser.
- `AVG_COMPILE_LATENCY`: The average latency of the compiler.
- `MAX_COMPILE_LATENCY`: The maximum latency of the compiler.
- `AVG_MEM`: The average memory (byte) used.
- `MAX_MEM`: The maximum memory (byte) used.
- `AVG_DISK`: The average disk space (byte) used.
- `MAX_DISK`: The maximum disk space (byte) used.
- `AVG_TIDB_CPU_TIME`: The average TiDB server CPU time that SQL statements of this category consume. It shows meaningful values only when the Top SQL feature is enabled. Otherwise the value is always `0`.

Fields related to TiKV Coprocessor task:

- `SUM_COP_TASK_NUM`: The total number of Coprocessor requests sent.
- `MAX_COP_PROCESS_TIME`: The maximum execution time of Coprocessor tasks.
- `MAX_COP_PROCESS_ADDRESS`: The address of the Coprocessor task with the maximum execution time.
- `MAX_COP_WAIT_TIME`: The maximum waiting time of Coprocessor tasks.
- `MAX_COP_WAIT_ADDRESS`: The address of the Coprocessor task with the maximum waiting time.
- `AVG_PROCESS_TIME`: The average processing time of SQL statements in TiKV.
- `MAX_PROCESS_TIME`: The maximum processing time of SQL statements in TiKV.

- `AVG_WAIT_TIME`: The average waiting time of SQL statements in TiKV.
- `MAX_WAIT_TIME`: The maximum waiting time of SQL statements in TiKV.
- `AVG_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry.
- `MAX_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry.
- `AVG_TOTAL_KEYS`: The average number of keys that Coprocessor has scanned.
- `MAX_TOTAL_KEYS`: The maximum number of keys that Coprocessor has scanned.
- `AVG_PROCESSED_KEYS`: The average number of keys that Coprocessor has processed. Compared with `avg_total_keys`, `avg_processed_keys` does not include the old versions of MVCC. A great difference between `avg_total_keys` and `avg_processed_keys` indicates that many old versions exist.
- `MAX_PROCESSED_KEYS`: The maximum number of keys that Coprocessor has processed.
- `AVG_TIKV_CPU_TIME`: The average TiKV server CPU time that SQL statements of this category consume.

Transaction-related fields:

- `AVG_PREWRITE_TIME`: The average time of the prewrite phase.
- `MAX_PREWRITE_TIME`: The longest time of the prewrite phase.
- `AVG_COMMIT_TIME`: The average time of the commit phase.
- `MAX_COMMIT_TIME`: The longest time of the commit phase.
- `AVG_GET_COMMIT_TS_TIME`: The average time of getting `commit_ts`.
- `MAX_GET_COMMIT_TS_TIME`: The longest time of getting `commit_ts`.
- `AVG_COMMIT_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `MAX_COMMIT_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `AVG_RESOLVE_LOCK_TIME`: The average time for resolving lock conflicts occurred between transactions.
- `MAX_RESOLVE_LOCK_TIME`: The longest time for resolving lock conflicts occurred between transactions.
- `AVG_LOCAL_LATCH_WAIT_TIME`: The average waiting time of the local transaction.
- `MAX_LOCAL_LATCH_WAIT_TIME`: The maximum waiting time of the local transaction.
- `AVG_WRITE_KEYS`: The average count of written keys.
- `MAX_WRITE_KEYS`: The maximum count of written keys.
- `AVG_WRITE_SIZE`: The average amount of written data (in byte).
- `MAX_WRITE_SIZE`: The maximum amount of written data (in byte).
- `AVG_PREWRITE_REGIONS`: The average number of Regions involved in the prewrite phase.
- `MAX_PREWRITE_REGIONS`: The maximum number of Regions during the prewrite phase.
- `AVG_TXN_RETRY`: The average number of transaction retries.
- `MAX_TXN_RETRY`: The maximum number of transaction retries.
- `SUM_BACKOFF_TIMES`: The sum of retries when SQL statements of this category encounter errors that require a retry.

- `BACKOFF_TYPES`: All types of errors that require retries and the number of retries for each type. The format of the field is `type:number`. If there is more than one error type, each is separated by a comma, like `txnLock:2,pdRPC:1`.
- `AVG_AFFECTED_ROWS`: The average number of rows affected.
- `PREV_SAMPLE_TEXT`: When the current SQL statement is `COMMIT`, `PREV_SAMPLE_TEXT` is the previous statement to `COMMIT`. In this case, SQL statements are grouped by the digest and `prev_sample_text`. This means that `COMMIT` statements with different `prev_sample_text` are grouped to different rows. When the current SQL statement is not `COMMIT`, the `PREV_SAMPLE_TEXT` field is an empty string.

Fields related to Resource Control:

- `AVG_REQUEST_UNIT_WRITE`: the average number of write RUs consumed by SQL statements.
- `MAX_REQUEST_UNIT_WRITE`: the maximum number of write RUs consumed by SQL statements.
- `AVG_REQUEST_UNIT_READ`: the average number of read RUs consumed by SQL statements.
- `MAX_REQUEST_UNIT_READ`: the maximum number of read RUs consumed by SQL statements.
- `AVG_QUEUED_RC_TIME`: the average waiting time for available RU when executing SQL statements.
- `MAX_QUEUED_RC_TIME`: the maximum waiting time for available RU when executing SQL statements.
- `RESOURCE_GROUP`: the resource group bound to SQL statements.

10.3.2.9.2 `statements_summary_evicted` fields description

- `BEGIN_TIME`: Records the starting time.
- `END_TIME`: Records the ending time.
- `EVICTED_COUNT`: The number of SQL categories that are evicted during the record period.

10.3.3 Identify Expensive Queries

TiDB allows you to identify expensive queries during SQL execution, so you can diagnose and improve the performance of SQL execution. Specifically, TiDB prints the information about statements whose execution time exceeds `tidb_expensive_query_time_threshold` (60 seconds by default) or memory usage exceeds `tidb_mem_quota_query` (1 GB by default) to the tidb-server log file ("tidb.log" by default).

Note:

The expensive query log differs from the slow query log in this way: TiDB prints statement information to the expensive query log **as soon as** the statement exceeds the threshold of resource usage (execution time or memory usage); while TiDB prints statement information to the slow query log **after** the statement execution.

10.3.3.1 Expensive query log example

```
[expensivequery.go:145] [expensive_query] [cost_time=60.021998785s] [cop_
    ↪ time=0.022540151s] [process_time=28.448316643s] [wait_time
    ↪ =0.045507163s] [request_count=430] [total_keys=3538276] [process_keys
    ↪ =3537846] [num_cop_tasks=430] [process_avg_time=0.066158875s] [
    ↪ process_p90_time=0.140427865s] [process_max_time=0.27903656s] [
    ↪ process_max_addr=tikv-1-peer:20160] [wait_avg_time=0.00010583s] [wait
    ↪ _p90_time=0.000358794s] [wait_max_time=0.001218721s] [wait_max_addr=
    ↪ tikv-1-peer:20160] [stats=usertable:451469035823955972] [conn
    ↪ =1621098504] [user=root] [database=test] [table_ids="[104]"] [txn_
    ↪ start_ts=451469037501677571] [mem_max="621043469 Bytes (592.3 MB)"] [
    ↪ sql="insert /*+ SET_VAR(tidb_dml_type=bulk) */ into usertable_2
    ↪ select * from usertable limit 5000000"] [session_alias=] ["affected
    ↪ rows"=3505282]]
```

10.3.3.2 Fields description

Basic fields:

- `cost_time`: The execution time of a statement when the log is printed.
- `stats`: The version of statistics used by the tables or indexes involved in a statement. If the value is `pseudo`, it means that there are no available statistics. In this case, you need to analyze the tables or indexes.
- `table_ids`: The IDs of the tables involved in a statement.
- `txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `sql`: The sql statement.
- `session_alias`: The alias of the current session.
- `affected rows`: The number of rows currently affected by the statement.

Memory usage related fields:

- `mem_max`: Memory usage of a statement when the log is printed. This field has two kinds of units to measure memory usage: byte and other readable and adaptable units (such as MB and GB).

User related fields:

- `user`: The name of the user who executes the statement.
- `conn_id`: The connection ID (session ID). For example, you can use the keyword `con:60026` to search for the log whose session ID is `60026`.
- `database`: The database where the statement is executed.

TiKV Coprocessor task related fields:

- `wait_time`: The total waiting time of all Coprocessor requests of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `request_count`: The number of Coprocessor requests that a statement sends.
- `total_keys`: The number of keys that Coprocessor has scanned.
- `processed_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `num_cop_tasks`: The number of Coprocessor requests that a statement sends.
- `process_avg_time`: The average execution time of Coprocessor tasks.
- `process_p90_time`: The P90 execution time of Coprocessor tasks.
- `process_max_time`: The maximum execution time of Coprocessor tasks.
- `process_max_addr`: The address of the Coprocessor task with the longest execution time.
- `wait_avg_time`: The average waiting time of Coprocessor tasks.
- `wait_p90_time`: The P90 waiting time of Coprocessor tasks.
- `wait_max_time`: The maximum waiting time of Coprocessor tasks.
- `wait_max_addr`: The address of the Coprocessor task with the longest waiting time.

10.3.4 Use PLAN REPLAYER to Save and Restore the On-Site Information of a Cluster

When you locate and troubleshoot the issues of a TiDB cluster, you often need to provide information on the system and the execution plan. To help you get the information and troubleshoot cluster issues in a more convenient and efficient way, the `PLAN REPLAYER` ↪ command is introduced in TiDB v5.3.0. This command enables you to easily save and restore the on-site information of a cluster, improves the efficiency of troubleshooting, and helps you more easily archive the issue for management.

The features of `PLAN REPLAYER` are as follows:

- Exports the information of a TiDB cluster at an on-site troubleshooting to a ZIP-formatted file for storage.
- Imports into a cluster the ZIP-formatted file exported from another TiDB cluster. This file contains the information of the latter TiDB cluster at an on-site troubleshooting.

10.3.4.1 Use `PLAN REPLAYER` to export cluster information

You can use `PLAN REPLAYER` to save the on-site information of a TiDB cluster. The export interface is as follows:

```
PLAN REPLAYER DUMP EXPLAIN [ANALYZE] [WITH STATS AS OF TIMESTAMP expression
    ↪ ] sql-statement;
```

Based on `sql-statement`, TiDB sorts out and exports the following on-site information:

- TiDB version
- TiDB configuration
- TiDB session variables
- TiDB SQL bindings
- The table schema in `sql-statement`
- The statistics of the table in `sql-statement`
- The result of `EXPLAIN [ANALYZE] sql-statement`
- Some internal procedures of query optimization

If historical statistics are enabled, you can specify a time in the `PLAN REPLAYER` statement to get the historical statistics for the corresponding time. You can directly specify a time and date or specify a timestamp. TiDB looks for the historical statistics before the specified time and exports the latest one among them.

If there are no historical statistics before the specified time, TiDB exports the latest statistics, which is consistent with the behavior when no time is specified. In addition, TiDB prints the error messages in the `errors.txt` file within the exported `ZIP` file.

> **Note:**
>
> `PLAN REPLAYER` **DOES NOT** export any table data.

10.3.4.1.1 Examples of exporting cluster information

```
use test;
create table t(a int, b int);
insert into t values(1,1), (2, 2), (3, 3);
analyze table t;

plan replayer dump explain select * from t;
plan replayer dump with stats as of timestamp '2023-07-17 12:00:00' explain
    ↪  select * from t;
plan replayer dump with stats as of timestamp '442012134592479233' explain
    ↪ select * from t;
```

`PLAN REPLAYER DUMP` packages the table information above into a `ZIP` file and returns the file identifier as the execution result.

> **Note:**
>
> The `ZIP` file is stored in a TiDB cluster for at most one hour. After one hour, TiDB will delete it.

```
MySQL [test]> plan replayer dump explain select * from t;
```

```
+-----------------------------------------------------------------+
| Dump_link                                                       |
+-----------------------------------------------------------------+
| replayer_JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip |
+-----------------------------------------------------------------+
1 row in set (0.015 sec)
```

Alternatively, you can use the session variable `tidb_last_plan_replayer_token` to obtain the result of the last `PLAN REPLAYER DUMP` execution.

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_Fdamsm3C7ZiPJ-LQqgVjkA==_1663304195885090000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

When there are multiple SQL statements, you can obtain the result of the `PLAN REPLAYER DUMP` execution using a file. The results of multiple SQL statements are separated by `;` in this file.

```
plan replayer dump explain 'sqls.txt';
```

```
Query OK, 0 rows affected (0.03 sec)
```

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_LEDKg8sb-K0u24QesiH8ig==_1663226556509182000.zip |
```

```
+-------------------------------------------------------------+
1 row in set (0.00 sec)
```

Because the file cannot be downloaded on MySQL Client, you need to use the TiDB HTTP interface and the file identifier to download the file:

```
http://${tidb-server-ip}:${tidb-server-status-port}/plan_replayer/dump/${
    ↪ file_token}
```

`${tidb-server-ip}:${tidb-server-status-port}` is the address of any TiDB server in the cluster. For example:

```
curl http://127.0.0.1:10080/plan_replayer/dump/replayer_
    ↪ JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip > plan_replayer.zip
```

10.3.4.2 Use `PLAN REPLAYER` to import cluster information

> **Warning:**
>
> When you import the on-site information of a TiDB cluster to another cluster, the TiDB session variables, SQL bindings, table schemas and statistics of the latter cluster are modified.

With an existing `ZIP` file exported using `PLAN REPLAYER`, you can use the `PLAN REPLAYER` import interface to restore the on-site information of a cluster to any other TiDB cluster. The syntax is as follows:

```
PLAN REPLAYER LOAD 'file_name';
```

In the statement above, `file_name` is the name of the `ZIP` file to be imported.

For example:

```
PLAN REPLAYER LOAD 'plan_replayer.zip';
```

> **Note:**
>
> You need to disable auto analyze. Otherwise the imported statistics will be overwritten by analyze.

You can disable auto analyze by setting the `tidb_enable_auto_analyze` system variable to `OFF`:

```
set @@global.tidb_enable_auto_analyze = OFF;
```

After the cluster information is imported, the TiDB cluster is loaded with the required table schema, statistics and other information that affects the construction of the execution plan. You can view the execution plan and verify statistics in the following way:

```
mysql> desc t;
+-------+---------+------+------+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+------+---------+-------+
| a     | int(11) | YES |     | NULL    |       |
| b     | int(11) | YES |     | NULL    |       |
+-------+---------+------+------+---------+-------+
2 rows in set (0.01 sec)

mysql> explain select * from t where a = 1 or b =1;
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| id                   | estRows | task    | access object | operator info
    ↪                  |
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| TableReader_7        | 0.01    | root     |               | data:Selection_6
    ↪                |
|  -Selection_6        | 0.01    | cop[tikv] |               | or(eq(test.t.a,
    ↪ 1), eq(test.t.b, 1)) |
|    -TableFullScan_5  | 6.00    | cop[tikv] | table:t     | keep order:false,
    ↪  stats:pseudo  |
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
3 rows in set (0.00 sec)

mysql> show stats_meta;
+--
    ↪ ------+-----------+---------------+--------------------+-------------+-----
    ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count | Row_
    ↪ count |
+--
    ↪ ------+-----------+---------------+--------------------+-------------+-----
    ↪
| test   | t         |               | 2022-08-26 15:52:07 |        3 |
```

```
    ↪        6 |
+--
    ↪ -------+------------+---------------+--------------------+-------------+-----
    ↪
1 row in set (0.04 sec)
```

After the scene is loaded and restored, you can diagnose and improve the execution plan for the cluster.

> **Note:**
>
> If you use the `mysql` command-line client and encounter `ERROR 2068 (HY000): LOAD DATA LOCAL INFILE file request rejected due to restrictions on access.`, you can add `--local-infile=true` in the connection string.

10.3.4.3 Use `PLAN REPLAYER CAPTURE` to capture target plans

When you locate the execution plan of TiDB in some scenarios, the target SQL statement and the target execution plan might only appear occasionally in the query, so you cannot directly capture the statement and the plan using `PLAN REPLAYER`. In such cases, you can use `PLAN REPLAYER CAPTURE` to help you capture the optimizer information of the target SQL statement and the target plan.

`PLAN REPLAYER CAPTURE` has the following main features:

- Registers the target SQL statement and the digest of the target execution plan in the TiDB cluster in advance, and starts matching the target query.
- When the target query is matched successfully, directly captures its optimizer-related information and exports it as a ZIP file.
- For each matched SQL and execution plan, the information is only captured once.
- Displays the ongoing matching tasks and generated files through the system table.
- Periodically cleans up historical files.

10.3.4.3.1 Enable `PLAN REPLAYER CAPTURE`

`PLAN REPLAYER CAPTURE` is controlled by the system variable `tidb_enable_plan_replayer_capture`. To enable `PLAN REPLAYER CAPTURE`, set the value of the system variable to `ON`.

10.3.4.3.2 Use `PLAN REPLAYER CAPTURE`

You can register the digest of the target SQL statement and execution plan in the TiDB cluster using the following statement:

```
PLAN REPLAYER CAPTURE 'sql_digest' 'plan_digest';
```

If the target SQL statement has multiple execution plans and you want to capture all execution plans, you can register all the execution plans at once using the following statement:

```
PLAN REPLAYER CAPTURE 'sql_digest' '*';
```

10.3.4.3.3 View the capture tasks

You can view the ongoing capture tasks of `PLAN REPLAYER CAPTURE` in the TiDB cluster using the following statement:

```
mysql> PLAN REPLAYER CAPTURE 'example_sql' 'example_plan';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
+-------------+--------------+---------------------+
| sql_digest | plan_digest | update_time     |
+-------------+--------------+---------------------+
| example_sql | example_plan | 2023-01-28 11:58:22 |
+-------------+--------------+---------------------+
1 row in set (0.01 sec)
```

10.3.4.3.4 View the capture results

After `PLAN REPLAYER CAPTURE` successfully captures the result, you can view the token used for file download using the following SQL statement:

```
mysql> SELECT * FROM mysql.plan_replayer_status;
+--
   ↪ ------------------------------------------------------------------+--------------
   ↪
| sql_digest                                                         | plan_digest
   ↪                                                                | origin_sql | token
   ↪                                                                | update_time      | fail_
   ↪ reason | instance    |
+--
   ↪ ------------------------------------------------------------------+--------------
   ↪
| 086e3fbd2732f7671c17f299d4320689deeeb87ba031240e1e598a0ca14f808c | 042
   ↪ de2a6652a6d20afc629ff90b8507b7587a1c7e1eb122c3e0b808b1d80cc02 | |
   ↪ replayer_Utah4nkz2sIEzkks7tIRog==_1668746293523179156.zip |
   ↪ 2022-11-18 12:38:13 | NULL | 172.16.4.4:4022 |
```

```
| b5b38322b7be560edb04f33f15b15a885e7c6209a22b56b0804622e397199b54 | 1770

    ↪ replayer_RZcRHJB7BaCccxFfOIAhWg==_1668746293578282450.zip |
    ↪ 2022-11-18 12:38:13 | NULL | 172.16.4.4:4022 |
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
3 rows in set (0.00 sec)
```

The method of downloading the file of `PLAN REPLAYER CAPTURE` is the same as that of `PLAN REPLAYER`. For details, see Examples of exporting cluster information.

> **Note:**
>
> The result file of `PLAN REPLAYER CAPTURE` is kept in the TiDB cluster for up to one week. After one week, TiDB deletes the file.

10.3.4.3.5 Remove the capture tasks

If a capture task is no longer needed, you can remove it using the `PLAN REPLAYER ↪ CAPTURE REMOVE` statement. For example:

```
mysql> PLAN REPLAYER CAPTURE '077
    ↪ a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0' '4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
| sql_digest                                                       | plan_digest
    ↪                                                  | update_time      |
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
| 077a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0 | 4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce |
    ↪ 2024-05-21 11:26:10 |
```

```
+--
    ↪ ------------------------------------------------------------------+--------------
    ↪
1 row in set (0.01 sec)

mysql> PLAN REPLAYER CAPTURE REMOVE '077
    ↪ a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0' '4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
Empty set (0.01 sec)
```

10.3.4.4 Use `PLAN REPLAYER CONTINUOUS CAPTURE`

After `PLAN REPLAYER CONTINUOUS CAPTURE` is enabled, TiDB asynchronously records the applications' SQL statements with the `PLAN REPLAYER` method according to their `SQL DIGEST` and `PLAN DIGEST`. For SQL statements and execution plans that share the same DIGEST, `PLAN REPLAYER CONTINUOUS CAPTURE` does not record them repeatedly.

10.3.4.4.1 Enable `PLAN REPLAYER CONTINUOUS CAPTURE`

`PLAN REPLAYER CONTINUOUS CAPTURE` is controlled by the system variable `tidb_enable_plan_replayer_continuous_capture`. To enable `PLAN REPLAYER CONTINUOUS CAPTURE`, set the value of the system variable to `ON`.

10.3.4.4.2 View the capture results

The method of viewing the capture results of `PLAN REPLAYER CONTINUOUS CAPTURE` is the same as that of Viewing the capture results of `PLAN REPLAYER CAPTURE`.

10.3.5 Understanding Stale Read and safe-ts in TiKV

In this guide, you can learn about Stale Read and safe-ts in TiKV and how to diagnose common issues related to Stale Read.

10.3.5.1 Overview of Stale Read and safe-ts

Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. In TiKV, Stale Read relies on safe-ts. If a read request on a Region peer has a timestamp (ts) that is less than or equal to the Region's safe-ts, TiDB can safely read the data from the peer. TiKV implements this safety guarantee by ensuring that safe-ts is always less than or equal to resolved-ts.

10.3.5.2 Understand safe-ts and resolved-ts

This section explains the concepts and maintenance of safe-ts and resolved-ts.

10.3.5.2.1 What is safe-ts?

The safe-ts is a timestamp that each peer in a Region maintains. It ensures that all transactions with a timestamp less than this value have been applied locally, which enables local Stale Read.

10.3.5.2.2 What is resolved-ts?

The resolved-ts is a timestamp that guarantees all transactions with a timestamp less than this value have been applied by the leader. Unlike safe-ts, which is a peer concept, resolved-ts is only maintained by the Region leader. Followers might have a smaller apply index than the leader, so resolved-ts cannot be directly treated as safe-ts in followers.

10.3.5.2.3 The maintenance of safe-ts

The `RegionReadProgress` module maintains safe-ts. The Region leader maintains resolved-ts and periodically sends its resolved-ts, the minimum required apply index (which validates this resolved-ts), and the Region itself to the `RegionReadProgerss` modules of all replicas via the CheckLeader RPC.

When a peer applies data, it updates the apply index and checks if any pending resolved-ts can become the new safe-ts.

10.3.5.2.4 The maintenance of resolved-ts

The Region leader uses a resolver to manage resolved-ts. This resolver tracks locks in the LOCK CF (Column Family) by receiving change logs when Raft applies. When initialized, the resolver scans the entire Region to track locks.

10.3.5.3 Diagnose Stale Read issues

This section introduces how to diagnose Stale Read issues using Grafana, `tikv-ctl`, and logs.

10.3.5.3.1 Identify issues

In the Grafana > TiDB dashboard > **KV Request** dashboard, the following panels show the hit rate, OPS, and traffic of Stale Read:

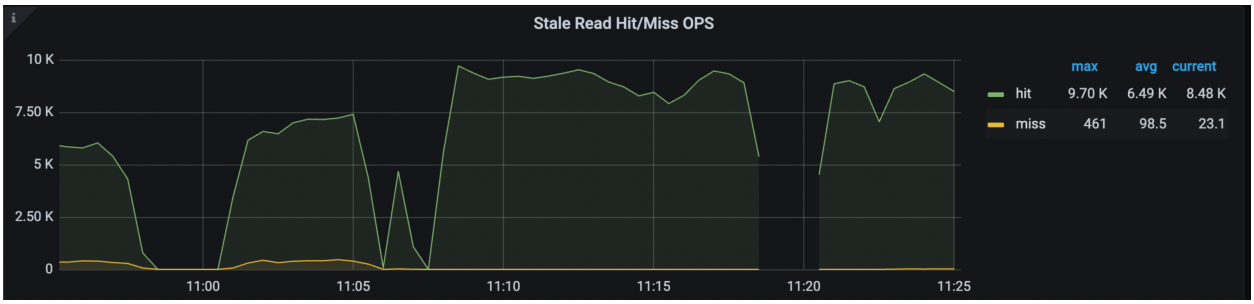

Figure 313: Stale Read Hit/Miss OPS

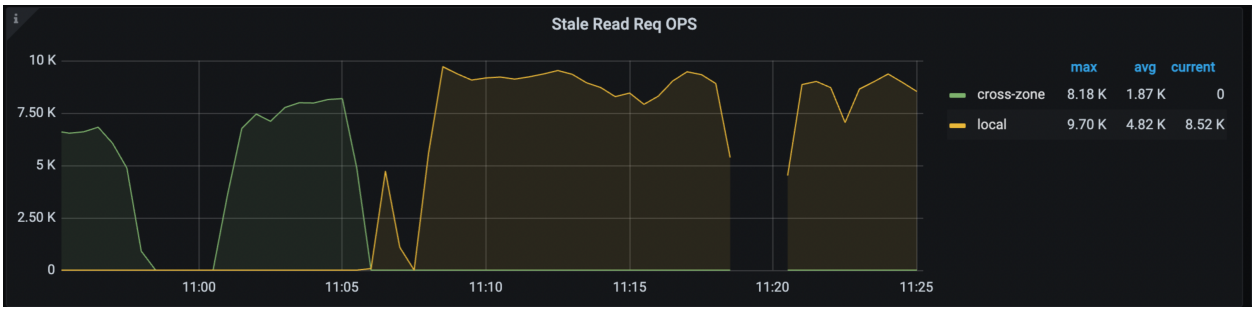

Figure 314: Stale Read Req OPS

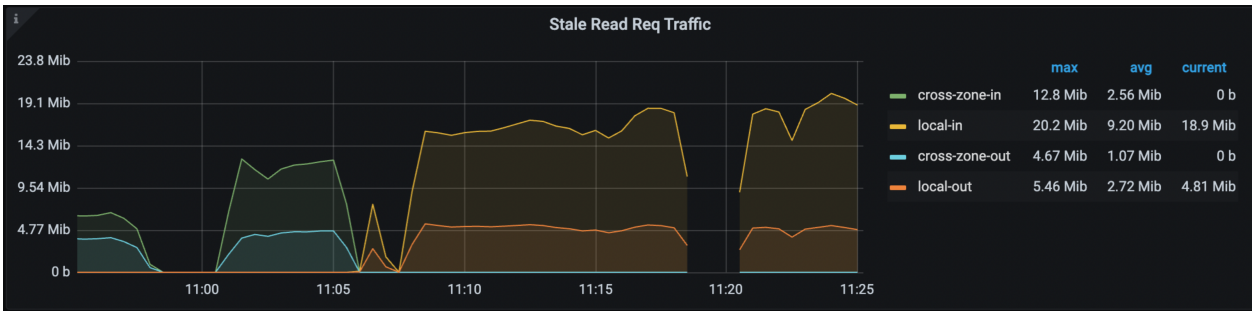

Figure 315: Stale Read Req Traffic

For more information about the preceding metrics, see TiDB monitoring metrics.

When Stale Read issues occur, you might notice changes in the preceding metrics. The most direct indicator is a WARN log from TiDB, which reports `DataIsNotReady` with a Region ID and the `safe-ts` it encounters.

10.3.5.3.2 Common causes

The most common causes that can impact the effectiveness of Stale Read are as follows:

- Transactions that take long time to commit.
- Transactions live too long before they commit.
- Delays in pushing the information of CheckLeader from the leader to the follower.

10.3.5.3.3 Use Grafana to diagnose

In the **TiKV-Details > Resolved-TS** dashboard, you can identify the Region with the smallest resolved-ts and safe-ts for each TiKV. If these timestamps are significantly behind real-time, you need to check the details of these Regions using `tikv-ctl`.

10.3.5.3.4 Use `tikv-ctl` to diagnose

`tikv-ctl` provides up-to-date details of the resolver and `RegionReadProgress`. For more details, see Get the state of a Region's `RegionReadProgress`.

The following is an example:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 14 --log --
    ↪ min-start-ts 0
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 0,
    applied_index: 92,
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
    pending back item (latest) applied index: 0,
    paused: false,
Resolver:
    exist: true,
    resolved_ts: 0,
    tracked index: 92,
    number of locks: 0,
    number of transactions: 0,
    stopped: false,
```

The preceding output helps you determine:

- Whether locks are blocking resolved-ts.
- Whether the apply index is too small to update safe-ts.
- Whether the leader is sending a sufficiently updated resolved-ts when a follower peer exists.

10.3.5.3.5 Use logs to diagnose

Every 10 seconds, TiKV checks the following metrics:

- The Region leader whose resolved-ts is the minimal
- The Region follower whose safe-ts is the minimal
- The Region follower whose resolved-ts is the minimal

If any of these timestamps is abnormally small, TiKV prints a log.

These logs are especially useful when you want to diagnose a historical problem that is no longer present.

The following shows an example of the logs:

```
[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:505] ["the max gap of
   ↪ leader resolved-ts is large"] [last_resolve_attempt="Some(LastAttempt
   ↪  { success: false, ts: TimeStamp(443888082736381953), reason: \"lock
   ↪ \", lock: Some(748000000000000625F728000000002512B5C) })"] [duration
   ↪ _to_last_update_safe_ts=10648ms] [min_memory_lock=None] [txn_num=0] [
   ↪ lock_num=0] [min_lock=None] [safe_ts=443888117326544897] [gap=110705
   ↪ ms] [region_id=291]

[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:526] ["the max gap of
   ↪ follower safe-ts is large"] [oldest_candidate=None] [latest_candidate
   ↪ =None] [applied_index=3276] [duration_to_last_consume_leader=11460ms]
   ↪  [resolved_ts=443888117117353985] [safe_ts=443888117117353985] [gap
   ↪ =111503ms] [region_id=273]

[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:547] ["the max gap of
   ↪ follower resolved-ts is large; it's the same region that has the min
   ↪ safe-ts"]
```

10.3.5.4 Troubleshooting tips

10.3.5.4.1 Handle slow transaction commit

A transaction that takes a long time to commit is often a large transaction. The prewrite phase of this slow transaction leaves some locks, but it takes too long before the commit phase clean the locks. To troubleshoot this issue, you can try to identify the transaction to which the locks belong and try to pinpoint the reason they exist, such as using logs.

The following list some actions you can take:

- Specify the `--log` option in the `tikv-ctl` command and check TiKV logs to find the specific locks with their start_ts.

- Search the start_ts in both TiDB and TiKV logs to identify issues with the transaction.

  If a query takes over 60 seconds, an `expensive_query` log is printed with the SQL statement. You can use the start_ts value to match the log. The following is an example:

```
[2023/07/17 19:32:09.403 +08:00] [WARN] [expensivequery.go:145] [
    ↪ expensive_query] [cost_time=60.025022732s] [cop_time=0.00346666s]
    ↪  [process_time=8.358409508s] [wait_time=0.013582596s] [request_
    ↪ count=278] [total_keys=9943616] [process_keys=9943360] [num_cop_
    ↪ tasks=278] [process_avg_time=0.030066221s] [process_p90_time
    ↪ =0.045296042s] [process_max_time=0.052828934s] [process_max_addr
    ↪ =192.168.31.244:20160] [wait_avg_time=0.000048858s] [wait_p90_
    ↪ time=0.00006057s] [wait_max_time=0.00040991s] [wait_max_addr
    ↪ =192.168.31.244:20160] [stats=t:4429166669135872O1] [conn
    ↪ =2826881778407440457] [user=root] [database=test] [table_ids
    ↪ ="[100]"] [**txn_start_ts**=442916790435840001] [mem_max
    ↪ ="2514229289 Bytes (2.34 GB)"] [sql="update t set b = b + 1"]
```

- Use the `CLUSTER_TIDB_TRX` table to find active transactions if you cannot get enough information about the locks from logs.
- Execute `SHOW PROCESSLIST` to view the current sessions connected to the same TiDB server and their time spent on the current statement. But it does not show start_ts.

If the locks exist due to ongoing large transactions, consider modifying your application logic as these locks can hinder the progress of resolve-ts.

If the locks do not belong to any ongoing transactions, it might be due to a coordinator (TiDB) crashing after it prewrites the locks. In this case, TiDB will automatically resolve the locks. No action is required unless the problem persists.

10.3.5.4.2 Handle long-lived transactions

Transactions that remain active for a long time could possibly block the advance of resolved-ts, even if they eventually commit quickly. This is because it is the start-ts of these long-lived transactions that are used to calculate the resolved-ts.

To address this issue:

- Identify the Transaction: Begin by pinpointing the transaction associated with the locks. It is crucial to understand the reason behind their existence. Leveraging logs can be particularly helpful.
- Examine Application Logic: If the prolonged transaction duration is a result of your application's logic, consider revising it to prevent such occurrences.
- Address Slow Queries: If the transaction's duration is extended due to slow queries, prioritize resolving these queries to alleviate the issue.

10.3.5.4.3 Address CheckLeader issues

To address CheckLeader issues, you can check the network and the **Check Leader Duration** metric in **TiKV-Details > Resolved-TS** dashboard.

10.3.5.5 Example

If you observe an increasing miss rate of **Stale Read OPS** as follows:

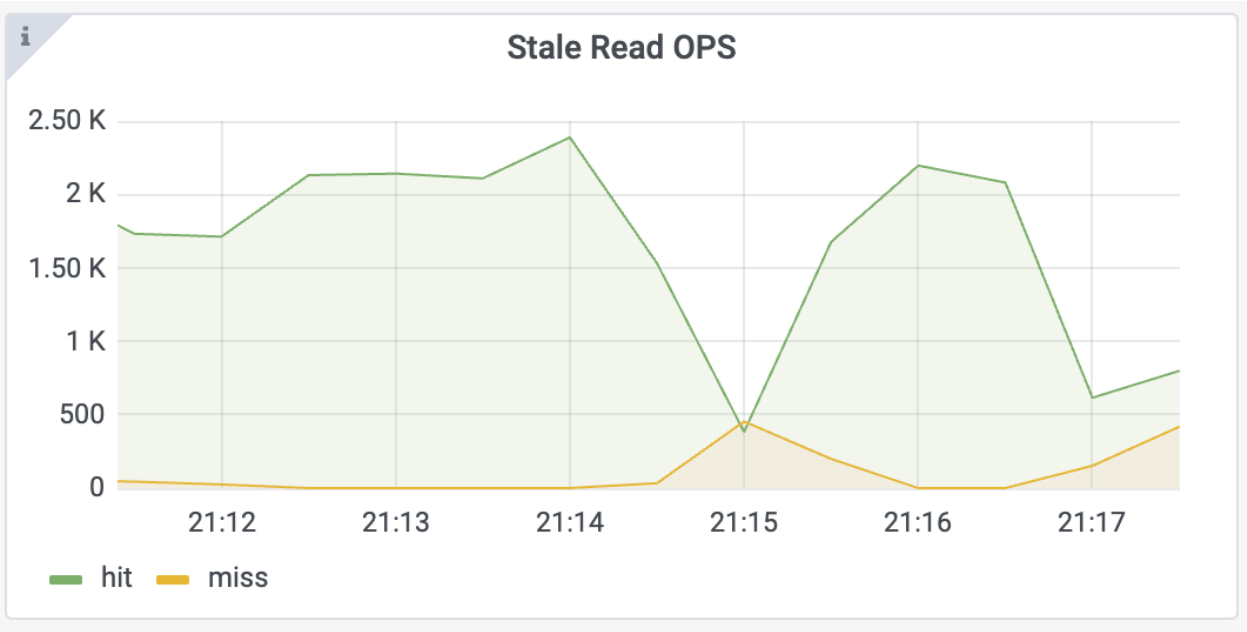

Figure 316: Example: Stale Read OPS

You can first check the **Max Resolved TS gap** and **Min Resolved TS Region** metrics in the **TiKV-Details > Resolved-TS** dashboard:

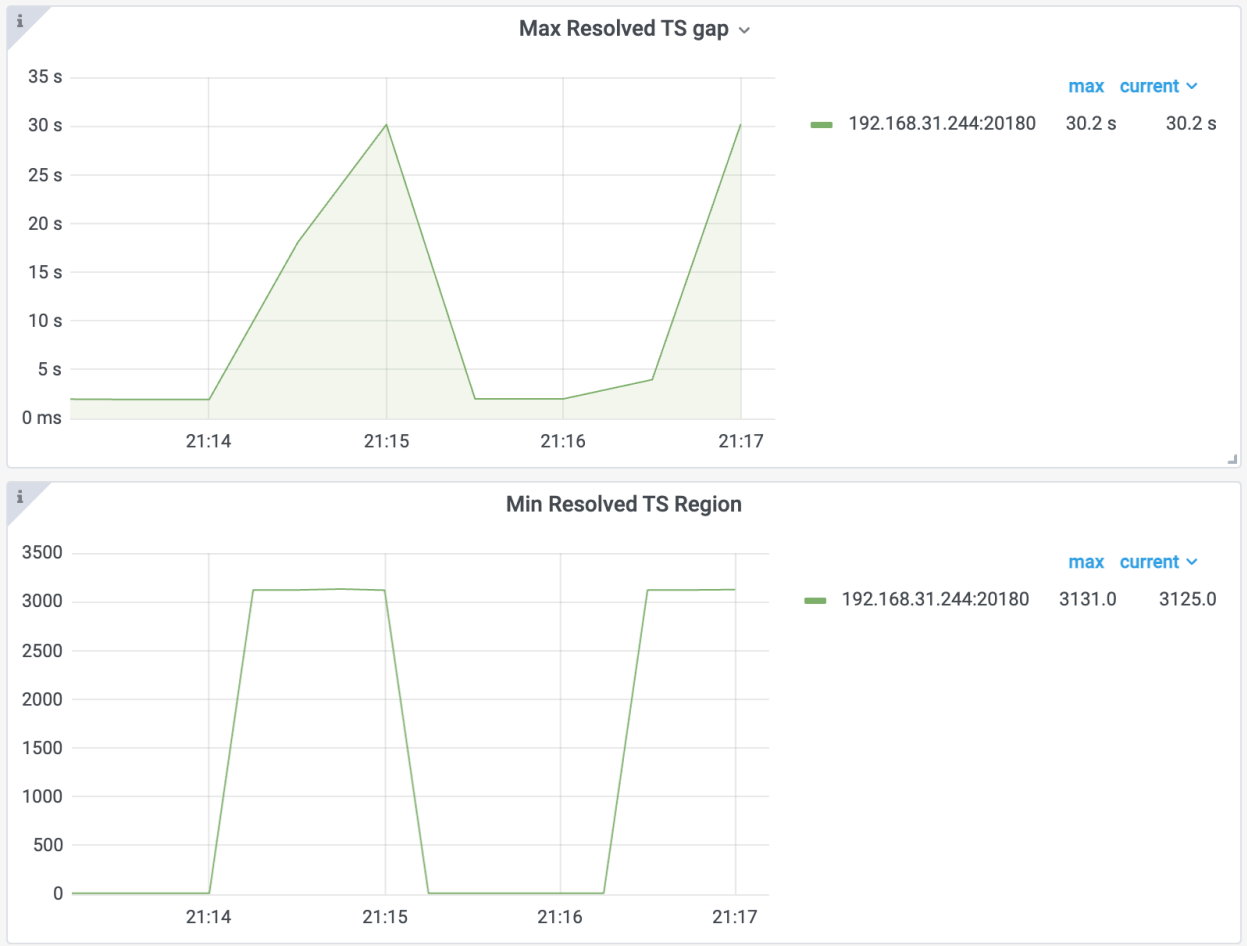

Figure 317: Example: Max Resolved TS gap

From the preceding metrics, you can find that Region `3121` and some other Regions have not updated their resolved-ts in time.

To get more details about the state of Region `3121`, you can run the following command:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 3121 --log
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 442918444145049601,
    applied_index: 2477,
    read_state.ts: 442918444145049601,
    read_state.apply_index: 1532,
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
```

```
    pending back item (latest) applied index: 0,
    paused: false,
    discarding: false,
Resolver:
    exist: true,
    resolved_ts: 442918444145049601,
    tracked index: 2477,
    number of locks: 480000,
    number of transactions: 1,
    stopped: false,
```

A notable observation here is that the `applied_index` equals to the `tracked index` in resolver. Therefore, the resolver appears to be the root of this issue. You can also see that there is 1 transaction that leaves 480000 locks in this Region, which might be the cause.

To get the exact transaction and the keys of some of the locks, you can check TiKV logs and grep `locks with`. The output is as follows:

```
[2023/07/17 21:16:44.257 +08:00] [INFO] [resolver.rs:213] ["locks with the
    ↪ minimum start_ts in resolver"] [keys="[74800000000000006
    ↪ A5F7280000000000405F6, ... , 748000000000000006A5F72800000000000EFF6,
    ↪ 748000000000000006A5F7280000000000721D9, 74800000000000006
    ↪ A5F72800000000002F691]"] [start_ts=442918429687808001] [region_id
    ↪ =3121]
```

From the TiKV log, you can get the start_ts of the transaction, that is `442918429687808001` ↪ . To get more information about the statement and transaction, you can grep this timestamp in TiDB logs. The output is as follows:

```
[2023/07/17 21:16:18.287 +08:00] [INFO] [2pc.go:685] ["[BIG_TXN]"] [session
    ↪ =2826881778407440457] ["key sample"=74800000000000006
    ↪ a5f728000000000000000] [size=319967171] [keys=10000000] [puts
    ↪ =10000000] [dels=0] [locks=0] [checks=0] [txnStartTS
    ↪ =442918429687808001]

[2023/07/17 21:16:22.703 +08:00] [WARN] [expensivequery.go:145] [expensive_
    ↪ query] [cost_time=60.047172498s] [cop_time=0.004575113s] [process_
    ↪ time=15.356963423s] [wait_time=0.017093811s] [request_count=397] [
    ↪ total_keys=20000398] [process_keys=10000000] [num_cop_tasks=397] [
    ↪ process_avg_time=0.038682527s] [process_p90_time=0.082608262s] [
    ↪ process_max_time=0.116321331s] [process_max_addr
    ↪ =192.168.31.244:20160] [wait_avg_time=0.000043057s] [wait_p90_time
    ↪ =0.00004007s] [wait_max_time=0.00075014s] [wait_max_addr
    ↪ =192.168.31.244:20160] [stats=t:442918428521267201] [conn
    ↪ =2826881778407440457] [user=root] [database=test] [table_ids="[106]"]
    ↪  [txn_start_ts=442918429687808001] [mem_max="2513773983 Bytes (2.34
    ↪ GB)"] [sql="update t set b = b + 1"]
```

Then, you can basically locate the statement that caused the problem. To further check it, you can execute the `SHOW PROCESSLIST` statement. The output is as follows:

```
+--
    ↪ ------------------+------+---------------------+--------+---------+------+-----
    ↪
| Id                  | User | Host                | db     | Command | Time |
    ↪ State   | Info                    |
+--
    ↪ ------------------+------+---------------------+--------+---------+------+-----
    ↪
| 2826881778407440457 | root | 192.168.31.43:58641 | test | Query | 48 |
    ↪ autocommit | update t set b = b + 1 |
| 2826881778407440613 | root | 127.0.0.1:45952 | test | Execute | 0 |
    ↪ autocommit | select * from t where a=? |
| 2826881778407440619 | root | 192.168.31.43:60428 | <null> | Query | 0 |
    ↪ autocommit | show processlist |
+--
    ↪ ------------------+------+---------------------+--------+---------+------+-----
    ↪
```

The output shows that someone is executing an unexpected `UPDATE` statement (`update t set b = b + 1`), which results in a large transaction and hinders Stale Read.

To resolve this issue, you can stop the application that is running this `UPDATE` statement.

10.4 Support Resources

If you encounter a problem when you use TiDB, you can reach out for support from PingCAP or the TiDB community via the following methods:

- Get support from PingCAP for TiDB Enterprise Edition:
    - Submit a request
- Get support from PingCAP for TiDB Cloud:
    - Report an issue directly from the TiDB Cloud console
    - Documentation for TiDB Cloud support
- Seek help from the TiDB community:
    - Discord channels
    - Slack channels: #everyone (English), #tidb-japan (Japanese)

    - Stack Overflow (questions tagged with #tidb)
    - TiDB Forum

- Report a bug

    - Submit an issue on GitHub

- Learn TiDB's implementation and design

    - TiDB development guide
    - Discussions on GitHub

11 Performance Tuning

11.1 Tuning Guide

11.1.1 TiDB Performance Tuning Overview

This document introduces the basic concepts of performance tuning, such as user response time, throughput, and database time, and also provides a general process for performance tuning.

11.1.1.1 User response time and database time

11.1.1.1.1 User response time

User response time indicates how long an application takes to return the results of a request to users. As you can see from the following sequential timing diagram, the time of a typical user request contains the following:

- The network latency between the user and the application
- The processing time of the application
- The network latency during the interaction between the application and the database
- The service time of the database

The user response time is affected by various subsystems on the request chain, such as network latency and bandwidth, number and request types of concurrent users, and resource usage of server CPU and I/O. To optimize the entire system effectively, you need to first identify the bottlenecks in user response time.

To get a total user response time within a specified time range (`ΔT`), you can use the following formula:

Total user response time in `ΔT` = Average TPS (Transactions Per Second) x Average user response time x `ΔT`.

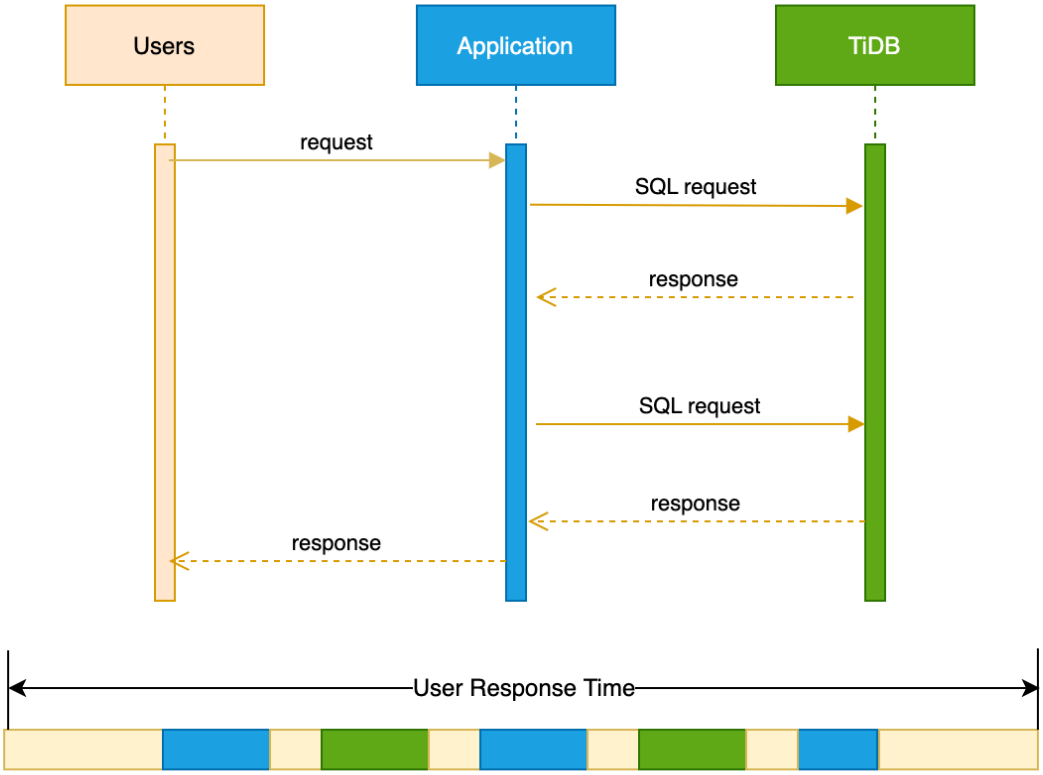

Figure 318: user_response_time

11.1.1.1.2 Database time

Database time indicates the total service time provided by a database. The database time in ΔT is the sum of the time that a database takes to process all application requests concurrently.

To get the database time, you can use any of the following methods:

- Method 1: Multiply the average query latency by QPS and by ΔT, that is, `DB Time in ΔT = QPS × avg latency × ΔT`
- Method 2: Multiply the average number of active sessions by ΔT, that is, `DB Time in ΔT = avg active connections × ΔT`
- Method 3: Calculate the time based on the TiDB internal Prometheus metric `tidb_server_tokens`, that is. `ΔT DB Time = rate(tidb_server_tokens)× ΔT`

11.1.1.2 Relationship between user response time and system throughput

User response time consists of service time, queuing time, and concurrent waiting time to complete a user request.

```
User Response time = Service time + Queuing delay + Coherency delay
```

- Service time: the time a system consumes on certain resources when processing a request, for example, the CPU time that a database consumes to complete a SQL request.
- Queuing delay: the time a system waits in a queue for service of certain resources when processing a request.
- Coherency delay: the time a system communicates and collaborates with other concurrent tasks, so that it can access shared resources when processing a request.

System throughput indicates the number of requests that can be completed by a system per second. User response time and throughput are usually inverse of each other. When the throughput increases, the system resource utilization and the queuing latency for a requested service increase accordingly. Once resource utilization exceeds a certain inflection point, the queuing latency will increase dramatically.

For example, for a database system running OLTP loads, after its CPU utilization exceeds 65%, the CPU queueing scheduling latency increases significantly. This is because concurrent requests of a system are not completely independent, which means that these requests can collaborate and compete for shared resources. For example, requests from different users might perform mutually exclusive locking operations on the same data. When the resource utilization increases, the queuing and scheduling latency increases too, which causes that the shared resources cannot be released in time and in turn prolongs the waiting time for shared resources by other tasks.

11.1.1.3 Performance tuning process

The performance tuning process consists of the following 6 steps:

1. Define a tuning objective.
2. Establish a performance baseline.
3. Identify bottlenecks in user response time.
4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution.
5. Implement tuning solutions.
6. Evaluate tuning results.

To achieve the tuning objective of a performance tuning project, you usually need to repeat Step 2 to Step 6 multiple times.

11.1.1.3.1 Step 1. Define a tuning objective

For different types of systems, tuning objectives are different too. For example, for a financial core OLTP system, the tuning objective might be to reduce the long-tail latency of

transactions; for a financial settlement system, the tuning objective might be to make better use of hardware resources and reduce the time of batch settlement tasks.

A good tuning objective should be easily quantifiable. For example:

- Good tuning objective: The p99 latency for transfer transactions needs to be less than 200 ms during peak business hours of 9 am to 10 am.
- Poor tuning objective: The system is too slow to respond so it needs to be optimized.

Defining a clear tuning objective helps guide the subsequent performance tuning steps.

11.1.1.3.2 Step 2. Establish a performance baseline

To tune performance efficiently, you need to capture the current performance data to establish a performance baseline. The performance data to be captured typically includes the following:

- Mean and long-tail values of user response time, and throughput of your application
- Database performance data such as database time, query latency, and QPS

  TiDB measures and stores performance data thoroughly in different dimensions, such as slow query logs, Top SQL, Continuous Performance Profiling, and traffic visualizer. In addition, you can perform historical backtracking and comparison of the timing metrics data stored in Prometheus.
- Resource utilization, including resources such as CPU, IO, and network
- Configuration information, such as application configurations, database configurations, and operating system configurations

11.1.1.3.3 Step 3. Identify bottlenecks in user response time

Identify or speculate on bottlenecks in user response times based on data from the performance baseline.

Applications usually do not measure and record the full chain of user requests, so you cannot effectively break down user response time from top to bottom through the application.

In contrast, databases have a complete record of performance metrics such as query latency and throughput. Based on database time, you can determine if the bottleneck in user response time is in a database.

- If the bottleneck is not in databases, you need to rely on the resource utilization collected outside databases or profile the application to identify the bottleneck outside databases. Common scenarios include insufficient resources of an application or proxy server, and insufficient usage of hardware resources caused by serial points in an application.

- If bottlenecks are in databases, you can analyze and diagnose the database performances using comprehensive tuning tools. Common scenarios include the presence of slow SQL, unreasonable usage of a database by an application, and the presence of read and write hotspots in databases.

For more information about the analysis and diagnostic methods and tools, see Performance Analysis and Tuning.

11.1.1.3.4 Step 4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution

After identifying the bottleneck of a system through performance analysis, you can propose a tuning solution that is cost-effective, has low risks, and provides the maximum benefit based on the actual situation.

According to Amdahl's Law, the maximum gain from performance tuning depends on the percentage of the optimized part in the overall system. Therefore, you need to identify the system bottlenecks and the corresponding percentage based on the performance data, and then predict the gains after the bottleneck is resolved or optimized.

Note that even if a solution can bring the greatest potential benefits by tuning the largest bottleneck, you still need to evaluate the risks and costs of this solution. For example:

- The most straightforward tuning objective solution for a resource-overloaded system is to expand its capacity, but in practice, the expansion solution might be too costly to be adopted.
- When a slow query in a business module causes a slow response of the entire module, upgrading to a new version of the database can solve the slow query issue, but it might also affect modules that did not have this issue. Therefore, this solution might have a potentially high risk. A low-risk solution is to skip the database version upgrade and rewrite the existing slow queries for the current database version.

11.1.1.3.5 Step 5. Implement tuning solutions

Considering the benefits, risks, and costs, choose one or more tuning solutions for implementation. In the implementation process, you need to make thorough preparation for changes to the production system and record the changes in detail.

To mitigate risks and validate the benefits of a tuning solution, it is recommended that you perform validation and complete regression of changes in both test and staging environments. For example, if the selected tuning solution of a slow query is to create a new index to optimize the query access path, you need to ensure that the new index does not introduce any obvious write hotspots to the existing data insertion workload and slows down other modules.

11.1.1.3.6 Step 6. Evaluate tuning results

After applying the tuning solution, you need to evaluate the results:

- If the tuning objective is reached, the entire tuning project is completed successfully.
- If the tuning objective is not reached, you need to repeat Step 2 to Step 6 in this document until the tuning objective is reached.

After reaching your tuning objectives, you might need to further plan your system capacity to meet your business growth.

11.1.2 Configure TiDB for Optimal Performance

This guide describes how to optimize the performance of TiDB, including:

- Best practices for common workloads.
- Strategies for handling challenging performance scenarios.

> **Note:**
>
> The optimization techniques in this guide can help achieve optimal performance in TiDB. However, performance tuning often involves balancing multiple factors, and no single solution addresses all performance needs. Some techniques in this guide use experimental features, which are marked accordingly. Although these optimizations can significantly improve performance, they might not be suitable for production environments and require careful evaluation before implementation.

11.1.3 Overview

Optimizing TiDB for peak performance requires careful tuning of various settings. In many cases, achieving optimal performance involves adjusting configurations beyond their default values.

The default settings prioritize stability over performance. To maximize performance, you might need to use more aggressive configurations and, in some cases, experimental features. These recommendations are based on production deployment experience and performance optimization research.

This guide describes the non-default settings, including their benefits and potential trade-offs. Use this information to optimize TiDB settings for your workload requirements.

11.1.4 Key settings for common workloads

The following settings are commonly used to optimize TiDB performance:

- Enhance execution plan cache, such as SQL Prepared Execution Plan Cache, Non-prepared plan cache, and Instance-level execution plan cache.
- Optimize the behavior of the TiDB optimizer by using Optimizer Fix Controls.
- Use the Titan storage engine more aggressively.

These settings can significantly improve performance for many workloads. However, as with any optimization, thoroughly test them in your environment before deploying to production.

11.1.4.1 System variables

Execute the following SQL commands to apply the recommended settings:

```
SET GLOBAL tidb_enable_instance_plan_cache=on;
SET GLOBAL tidb_instance_plan_cache_max_size=2GiB;
SET GLOBAL tidb_enable_non_prepared_plan_cache=on;
SET GLOBAL tidb_ignore_prepared_cache_close_stmt=on;
SET GLOBAL tidb_analyze_column_options='ALL';
SET GLOBAL tidb_stats_load_sync_wait=2000;
SET GLOBAL tidb_opt_derive_topn=on;
SET GLOBAL tidb_runtime_filter_mode=LOCAL;
SET GLOBAL tidb_opt_enable_mpp_shared_cte_execution=on;
SET GLOBAL tidb_rc_read_check_ts=on;
SET GLOBAL tidb_guarantee_linearizability=off;
SET GLOBAL pd_enable_follower_handle_region=on;
SET GLOBAL tidb_opt_fix_control = '44262:ON,44389:ON,44823:10000,44830:ON
    ↪ ,44855:ON,52869:ON';
```

The following table outlines the impact of specific system variable configurations:

System variable	Description	Note
tidb_enable_instance_plan_cache	Use instance-level plan cache instead of session-level caching. This significantly improves performance for workloads with high connection counts or frequent prepared statement usage.	This is an experimental feature. Test in non-production environments first and monitor memory usage as the plan cache size increases.
tidb_instance_plan_cache_max_size		

System variable	Description	Note
tidb_ ↪ enable ↪ _non_ ↪ prepared ↪ _plan ↪ _ ↪ cache	Enable the Non-prepared plan cache feature to reduce compile costs for applications that do not use prepared statements.	N/A

System variable	Description	Note
tidb_ ↪ ignore ↪ _ ↪ prepared ↪ _ ↪ cache ↪ _ ↪ close ↪ _stmt	Cache plans for applications that use prepared statements but close the plan after each execution.	N/A

System variable	Description	Note
tidb_analyze_column_options	Collect statistics for all columns to avoid sub-optimal execution plans due to missing column statistics. By default, TiDB only collects statistics for predicate columns.	Setting this variable to 'ALL' can cause more resource usage for the ANALYZE TABLE operation compared with the default value 'PREDICATE'.

System variable	Description	Note
tidb_ ↪ stats ↪ _load ↪ _sync ↪ _wait	Increase the time-out for syn-chronously load-ing statis-tics from the de-fault 100 mil-lisec-onds to 2 sec-onds. This en-sures TiDB loads the nec-es-sary statis-tics be-fore query com-pila-tion.	Increasing this value leads to a longer syn-chro-niza-tion wait time be-fore query com-pila-tion.

System variable	Description	Note
tidb_opt ↪ _ ↪ derive ↪ _topn	Enable the optimization rule of Deriving TopN or Limit from window functions.	This is limited to the ROW_ ↪ NUMBER ↪ () ↪ window function.
tidb_ ↪ runtime ↪ _ ↪ filter ↪ _mode	Enable Runtime Filter in the local mode to improve hash join efficiency.	The variable is introduced in v7.2.0 and is disabled by default for safety.

System variable	Description	Note
tidb_opt ↪ _ ↪ enable ↪ _mpp_ ↪ shared ↪ _cte_ ↪ execution ↪	Enable non-recursive Common Table Expressions (CTE) push-down to TiFlash.	This is an experimental feature.

System variable	Description	Note
tidb_rc_ ↪ read_ ↪ check ↪ _ts	For the read-committed isolation level, enabling this variable avoids the latency and cost of getting the global timestamp and optimizes transaction-level read latency.	This feature is incompatible with the Repeatable Read isolation level.

System variable	Description	Note
tidb_guarantee_linearizability	Improve performance by skipping the commit timestamp fetch from the PD server.	This sacrifices linearizability in favor of performance. Only causal consistency is guaranteed. It is not suitable for scenarios requiring strict linearizability.

System variable	Description	Note
pd_enable_follower_handle_region	Activate the PD Follower feature, allowing PD followers to process Region requests. This helps distribute load evenly across all PD servers and reduces CPU pressure on the PD leader.	This is an experimental feature. Test in non-production environments.

System variable	Description	Note
tidb_opt ↪ _fix_ ↪ control ↪	Enable advanced query optimization strategies to improve performance through additional optimization rules and heuristics.	Test thoroughly in your environment, as performance improvements vary by workload.

The following describes the optimizer control configurations that enable additional optimizations:

- 44262:ON: Use Dynamic pruning mode to access the partitioned table when the GlobalStats are missing.
- 44389:ON: For filters such as `c = 10 and (a = 'xx' or (a = 'kk' and b = 1))`, build more comprehensive scan ranges for `IndexRangeScan`.
- 44823:10000: To save memory, plan cache does not cache queries with parameters exceeding the specified number of this variable. Increase plan cache parameter limit from 200 to 10000 to make plan cache available for query with long in-lists.
- 44830:ON: Plan cache is allowed to cache execution plans with the `PointGet` operator generated during physical optimization.
- 44855:ON: The optimizer selects `IndexJoin` when the `Probe` side of an `IndexJoin` operator contains a `Selection` operator.
- 52869:ON: The optimizer chooses index merge automatically if the optimizer can choose the single index scan method (other than full table scan) for a query plan.

11.1.4.2 TiKV configurations

Add the following configuration items to the TiKV configuration file:

```
[server]
concurrent-send-snap-limit = 64
concurrent-recv-snap-limit = 64
snap-io-max-bytes-per-sec = "400MiB"

[pessimistic-txn]
in-memory-peer-size-limit = "32MiB"
in-memory-instance-size-limit = "512MiB"

[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"

[storage.flow-control]
l0-files-threshold = 60
```

Configuration item	Description	Note
concurrent ↪ -send ↪ -snap ↪ - ↪ limit ↪ , concurrent ↪ -recv ↪ -snap ↪ - ↪ limit ↪ , and snap-io- ↪ max- ↪ bytes ↪ -per- ↪ sec	Set limits for concurrent snapshot transfer and I/O bandwidth during TiKV scaling operations. Higher limits reduce scaling time by allowing faster data migration.	Adjusting these limits affects the trade-off between scaling and online transaction performance.

Configuration item	Description	Note
`in-memory-peer-size-limit` and `in-memory-instance-size-limit`	Control the memory allocation for pessimistic lock caching at the Region and TiKV instance levels. Storing locks in memory reduces disk I/O and improves transaction performance.	Monitor memory usage carefully. Higher limits improve performance but increase memory consumption.

Configuration item	Description	Note
rocksdb.titan, rocksdb.defaultcf.titan, min-blob-size, and blob-file-compression	Enable the Titan storage engine to reduce write amplification and alleviate disk I/O bottlenecks. Particularly useful when RocksDB compaction cannot keep up with write workloads, resulting in accumulated	Enable it when write amplification is the primary bottleneck. Trade-offs include: 1. Potential performance impact on primary key range scans. 2. Increased space amplification (up to 2x in the worst case). 3.

Configuration item	Description	Note
storage. ↪ flow- ↪ control ↪ .l0- ↪ files ↪ - ↪ threshold ↪	Control when write flow control is triggered based on the number of kvDB L0 files. Increasing the threshold reduces write stalls during high write workloads.	Higher thresholds might lead to more aggressive compactions when many L0 files exist.

11.1.4.3 TiFlash configurations

Add the following configuration items to the TiFlash configuration file:

```
[raftstore-proxy.server]
snap-io-max-bytes-per-sec = "300MiB"
```

Configuration item	Description	Note
snap-io-max-bytes-per-sec	Control the maximum allowable disk bandwidth for data replication from TiKV to TiFlash. Higher limits accelerate initial data loading and catch-up replication.	Higher bandwidth consumption might impact online transaction performance. Balance between replication speed and system stability.

11.1.5 Benchmark

This section compares performance between default settings (baseline) and optimized settings based on the preceding key settings for common loads.

11.1.5.1 Sysbench workloads on 1000 tables

11.1.5.1.1 Test environment

The test environment is as follows:

- 3 TiDB servers (16 cores, 64 GiB)
- 3 TiKV servers (16 cores, 64 GiB)
- TiDB version: v8.4.0
- Workload: sysbench oltp_read_only

11.1.5.1.2 Performance comparison

The following table compares throughput, latency, and plan cache hit ratio between baseline and optimized settings.

Metric	Baseline	Optimized	Improvement
QPS	89,100	100,128	+12.38%
Average latency (ms)	35.87	31.92	-11.01%
P95 latency (ms)	58.92	51.02	-13.41%
Plan cache hit ratio (%)	56.89%	87.51%	+53.82%
Plan cache memory usage (MiB)	95.3	70.2	-26.34%

11.1.5.1.3 Key benefits

The instance plan cache demonstrates significant performance improvements over the baseline configuration:

- Higher hit ratio: increases by 53.82% (from 56.89% to 87.51%).
- Lower memory usage: decreases by 26.34% (from 95.3 MiB to 70.2 MiB).
- Better performance:
  - QPS increases by 12.38%.
  - Average latency decreases by 11.01%.
  - P95 latency decreases by 13.41%.

11.1.5.1.4 How it works

Instance plan cache improves performance through these mechanisms:

- Cache execution plans for `SELECT` statements in memory.
- Share cached plans across all connections (up to 200) on the same TiDB instance.
- Can effectively store plans for up to 5,000 `SELECT` statements across 1,000 tables.
- Cache misses primarily occur only for `BEGIN` and `COMMIT` statements.

11.1.5.1.5 Real-world benefits

Although the benchmark using simple sysbench `oltp_read_only` queries (14 KB per plan) shows modest improvements, you can expect greater benefits in real-word applications:

- Complex queries can run up to 20 times faster.
- Memory usage is more efficient compared to session-level plan cache.

Instance plan cache is particularly effective for systems with:

- Large tables with many columns.
- Complex SQL queries.
- High concurrent connections.
- Diverse query patterns.

11.1.5.1.6 Memory efficiency

Instance plan cache provides better memory efficiency than session-level plan cache because:

- Plans are shared across all connections
- No need to duplicate plans for each session
- More efficient memory utilization while maintaining higher hit ratios

In scenarios with multiple connections and complex queries, session-level plan cache would require significantly more memory to achieve similar hit ratios, making instance plan cache the more efficient choice.

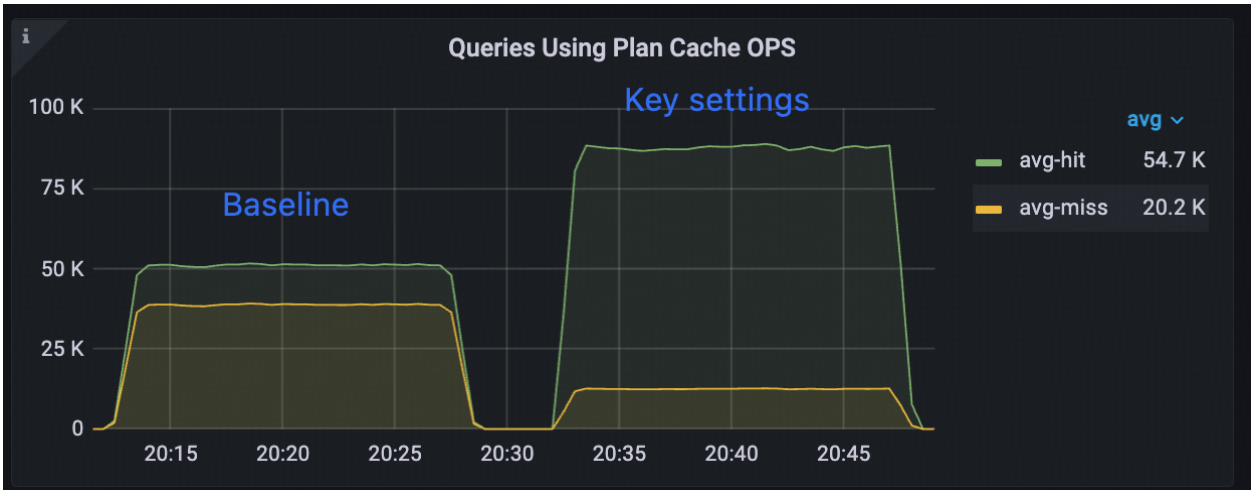

Figure 319: Instance plan cache: Queries Using Plan Cache OPS

11.1.5.1.7 Test workload

The following `sysbench oltp_read_only prepare` command loads data:

```
sysbench oltp_read_only prepare --mysql-host={host} --mysql-port={port} --
    ↪ mysql-user=root --db-driver=mysql --mysql-db=test --threads=100 --
    ↪ time=900 --report-interval=10 --tables=1000 --table-size=10000
```

The following `sysbench oltp_read_only run` command runs workload:

```
sysbench oltp_read_only run --mysql-host={host} --mysql-port={port} --mysql
    ↪ -user=root --db-driver=mysql --mysql-db=test --threads=200 --time=900
    ↪  --report-interval=10 --tables=1000 --table-size=10000
```

For more information, see How to Test TiDB Using Sysbench.

11.1.5.2 YCSB workloads on large record value

11.1.5.2.1 Test environment

The test environment is as follows:

- 3 TiDB servers (16 cores, 64 GiB)
- 3 TiKV servers (16 cores, 64 GiB)
- TiDB version: v8.4.0
- Workload: go-ycsb workloada

11.1.5.2.2 Performance comparison

The following table compares throughput (operations per second) between the baseline and optimized settings.

Item	Baseline (OPS)	Optimized (OPS)	Improvement
load data	2858.5	5074.3	+77.59%
workloada	2243.0	12804.3	+470.86%

11.1.5.2.3 Performance analysis

Titan is enabled by default starting from v7.6.0 and the default `min-blob-size` of Titan in TiDB v8.4.0 is `32KiB`. The baseline configuration uses a record size of `31KiB` to ensure data is stored in RocksDB. In contrast, for the key settings configuration, set `min-blob-size` to `1KiB`, causing data to be stored in Titan.

The performance improvement observed in the key settings is primarily attributed to Titan's ability to reduce RocksDB compactions. As shown in the following figures:

- Baseline: The total throughput of RocksDB compaction exceeds 1 GiB/s, with peaks over 3 GiB/s.
- Key settings: The peak throughput of RocksDB compaction remains below 100 MiB/s.

This significant reduction in compaction overhead contributes to the overall throughput improvement seen in the key settings configuration.

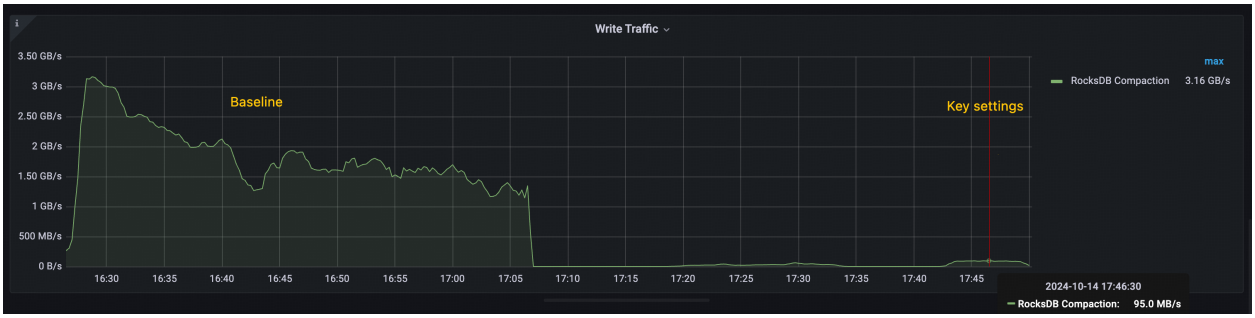

Figure 320: Titan RocksDB compaction:

11.1.5.2.4 Test workload

The following `go-ycsb load` command loads data:

```
go-ycsb load mysql -P /ycsb/workloads/workloada -p {host} -p mysql.port={
    ↪ port} -p threadcount=100 -p recordcount=5000000 -p operationcount
    ↪ =5000000 -p workload=core -p requestdistribution=uniform -pfieldcount
    ↪ =31 -p fieldlength=1024
```

The following `go-ycsb run` command runs workload:

```
go-ycsb run mysql -P /ycsb/workloads/workloada -p {host} -p mysql.port={port
    ↪ } -p mysql.db=test -p threadcount=100 -p recordcount=5000000 -p
    ↪ operationcount=5000000 -p workload=core -prequestdistribution=uniform
    ↪  -p fieldcount=31 -p fieldlength=1024
```

11.1.6 Edge cases and optimizations

This section shows you how to optimize TiDB for specific scenarios that need targeted adjustments beyond basic optimizations. You will learn how to tune TiDB for your particular use cases.

11.1.6.1 Identify edge cases

To identify edge cases, perform the following steps:

1. Analyze query patterns and workload characteristics.
2. Monitor system metrics to identify performance bottlenecks.
3. Gather feedback from application teams about specific issues.

11.1.6.2 Common edge cases

The following lists some common edge cases:

- High TSO wait for high-frequency small queries
- Choose the proper max chunk size for different workloads
- Tune coprocessor cache for read-heavy workloads
- Optimize chunk size for workload characteristics
- Optimize transaction mode and DML type for different workloads
- Optimize `GROUP BY` and `DISTINCT` operations with TiKV pushdown
- Mitigate MVCC version accumulation using in-memory engine
- Optimize statistics collection during batch operations
- Optimize thread pool settings for different instance types

The following sections explain how to handle each of these cases. You need to adjust different parameters or use specific TiDB features for each scenario.

> **Note:**
>
> Apply these optimizations carefully and test thoroughly, as their effectiveness might vary based on your use case and data patterns.

11.1.6.3 High TSO wait for high-frequency small queries

11.1.6.3.1 Troubleshooting

If your workload involves frequent small transactions or queries that frequently request timestamps, TSO (Timestamp Oracle) can become a performance bottleneck. To check if TSO wait time is impacting your system, check the **Performance Overview > SQL Execute Time Overview** panel. If TSO wait time constitutes a large portion of your SQL execution time, consider the following optimizations:

- Use low-precision TSO (enable `tidb_low_resolution_tso`) for read operations that do not need strict consistency. For more information, see Solution 1: use low-precision TSO.
- Combine small transactions into larger ones where possible. For more information, see Solution 2: parallel mode for TSO requests.

11.1.6.3.2 Solution 1: low-precision TSO

You can reduce TSO wait time by enabling the low-precision TSO feature (`tidb_low_resolution_tso`). After this feature is enabled, TiDB uses the cached timestamp to read data, reducing TSO wait time at the expense of potentially stale reads.

This optimization is particularly effective in the following scenarios:

- Read-heavy workloads where slight staleness is acceptable.
- Scenarios where reducing query latency is more important than absolute consistency.
- Applications that can tolerate reads that are a few seconds behind the latest committed state.

Benefits and trade-offs:

- Reduce query latency by enabling stale reads with a cached TSO, eliminating the need to request new timestamps.
- Balance performance against data consistency: this feature is only suitable for scenarios where stale reads are acceptable. It is not recommended to use it when strict data consistency is required.

To enable this optimization:

```
SET GLOBAL tidb_low_resolution_tso=ON;
```

11.1.6.3.3 Solution 2: parallel mode for TSO requests

The `tidb_tso_client_rpc_mode` system variable switches the mode in which TiDB sends TSO RPC requests to PD. The default value is `DEFAULT`. When the following conditions are met, you can consider switching this variable to `PARALLEL` or `PARALLEL-FAST` for potential performance improvements:

- TSO waiting time constitutes a significant portion of the total execution time of SQL queries.
- The TSO allocation in PD has not reached its bottleneck.
- PD and TiDB nodes have sufficient CPU resources.
- The network latency between TiDB and PD is significantly higher than the time PD takes to allocate TSO (that is, network latency accounts for the majority of TSO RPC duration).
    - To get the duration of TSO RPC requests, check the **PD TSO RPC Duration** panel in the PD Client section of the Grafana TiDB dashboard.
    - To get the duration of PD TSO allocation, check the **PD server TSO handle duration** panel in the TiDB section of the Grafana PD dashboard.

- The additional network traffic resulting from more TSO RPC requests between TiDB and PD (twice for `PARALLEL` or four times for `PARALLEL-FAST`) is acceptable.

To switch the parallel mode, execute the following command:

```
-- Use the PARALLEL mode
SET GLOBAL tidb_tso_client_rpc_mode=PARALLEL;

-- Use the PARALLEL-FAST mode
SET GLOBAL tidb_tso_client_rpc_mode=PARALLEL-FAST;
```

11.1.6.4 Tune coprocessor cache for read-heavy workloads

You can improve query performance for read-heavy workloads by optimizing the coprocessor cache. This cache stores the results of coprocessor requests, reducing repeated computations of frequently accessed data. To optimize cache performance, perform the following steps:

1. Monitor the cache hit ratio using the metrics described in Coprocessor Cache.
2. Increase the cache size to improve hit rates for larger working sets.
3. Adjust the admission threshold based on query patterns.

The following lists some recommended settings for a read-heavy workload:

```
[tikv-client.copr-cache]
capacity-mb = 4096
admission-max-ranges = 5000
admission-max-result-mb = 10
admission-min-process-ms = 0
```

11.1.6.5 Optimize chunk size for workload characteristics

The `tidb_max_chunk_size` system variable sets the maximum number of rows in a chunk during the execution process. Adjusting this value based on your workload can improve performance.

- For OLTP workloads with large concurrency and small transactions:
  - Set the value between `128` and `256` rows (the default value is `1024`).
  - This reduces memory usage and makes limit queries faster.
  - Use case: point queries, small range scans.

```
SET GLOBAL tidb_max_chunk_size = 128;
```

- For OLAP or analytical workloads with complex queries and large result sets:
    - Set the value between `1024` and `4096` rows.
    - This increases throughput when scanning large amounts of data.
    - Use case: aggregations, large table scans.

```
SET GLOBAL tidb_max_chunk_size = 4096;
```

11.1.6.6 Optimize transaction mode and DML type for different workloads

TiDB provides different transaction modes and DML execution types to optimize performance for various workload patterns.

11.1.6.6.1 Transaction modes

You can set the transaction mode using the `tidb_txn_mode` system variable.

- Pessimistic transaction mode (default):
    - Suitable for general workloads with potential write conflicts.
    - Provides stronger consistency guarantees.

```
sql  SET SESSION tidb_txn_mode = "pessimistic";
```

- Optimistic transaction mode:
    - Suitable for workloads with minimal write conflicts.
    - Better performance for multi-statement transactions.
    - Example: `BEGIN; INSERT...; INSERT...; COMMIT;`.

```
sql  SET SESSION tidb_txn_mode = "optimistic";
```

11.1.6.6.2 DML types

You can control the execution mode of DML statements using the `tidb_dml_type` system variable, which is introduced in v8.0.0.

To use the bulk DML execution mode, set `tidb_dml_type` to `"bulk"`. This mode optimizes bulk data loading without conflicts and reduces memory usage during large write operations. Before using this mode, ensure that:

- Auto-commit is enabled.
- The `pessimistic-auto-commit` configuration item is set to `false`.

```
SET SESSION tidb_dml_type = "bulk";
```

11.1.6.7 Optimize `GROUP BY` and `DISTINCT` operations with TiKV pushdown

TiDB pushes down aggregation operations to TiKV to reduce data transfer and processing overhead. The performance improvement varies based on your data characteristics.

11.1.6.7.1 Usage scenarios

- **Ideal scenarios** (high performance gain):
  - Columns containing few distinct values (low NDV).
  - Data containing frequent duplicate values.
  - Example: status columns, category codes, date parts.
- **Non-ideal scenarios** (potential performance loss):
  - Columns containing mostly unique values (high NDV).
  - Unique identifiers or timestamps.
  - Example: User IDs, transaction IDs.

11.1.6.7.2 Configuration

Enable pushdown optimizations at the session or global level:

```
-- Enable regular aggregation pushdown
SET GLOBAL tidb_opt_agg_push_down = ON;

-- Enable distinct aggregation pushdown
SET GLOBAL tidb_opt_distinct_agg_push_down = ON;
```

11.1.6.8 Mitigate MVCC version accumulation using in-memory engine

Excessive MVCC versions can cause performance bottlenecks, particularly in high read-/write areas or due to issues with garbage collection and compaction. You can use the in-memory engine introduced in v8.5.0 to mitigate this issue. To enable it, add the following configuration to your TiKV configuration file.

> **Note:**
>
> The in-memory engine helps reduce the impact of excessive MVCC versions but might increase memory usage. Monitor your system after enabling this feature.

```
[in-memory-engine]
enable = true
```

11.1.6.9 Optimize statistics collection during batch operations

You can optimize performance during batch operations while maintaining query optimization by managing statistics collection. This section describes how to manage this process effectively.

11.1.6.9.1 When to disable auto analyze

You can disable auto analyze by setting the `tidb_enable_auto_analyze` system variable to `OFF` in the following scenarios:

- During large data imports.
- During bulk update operations.
- For time-sensitive batch processing.
- When you need full control over the timing of statistics collection.

11.1.6.9.2 Best practices

- Before the batch operation:

```
sql   -- Disable auto analyze SET GLOBAL tidb_enable_auto_analyze = OFF;
```

- After the batch operation:

“‘sql – Manually collect statistics ANALYZE TABLE your_table;

– Re-enable auto analyze SET GLOBAL tidb_enable_auto_analyze = ON; “‘

11.1.6.10 Optimize thread pool settings for different instance types

To improve TiKV performance, configure the thread pools based on your instance's CPU resources. The following guidelines help you optimize these settings:

- For instances with 8 to 16 cores, the default settings are typically sufficient.
- For instances with 32 or more cores, increase the pool sizes for better resource utilization. Adjust the settings as follows:

```
[server]
# Increase gRPC thread pool
grpc-concurrency = 10

[raftstore]
# Optimize for write-intensive workloads
apply-pool-size = 4
store-pool-size = 4
store-io-pool-size = 2
```

11.1.7 A Practical Guide for SQL Tuning

This guide is designed for TiDB SQL tuning beginners. It focuses on the following key principles:

- Low entry barrier: introducing tuning concepts and methods step by step.
- Practice-oriented: providing specific steps and examples for each optimization tip.
- Quick start: prioritizing the most common and effective optimization methods.
- Gentle learning curve: emphasizing practical techniques rather than complex theory.
- Scenario-based: using real-world business cases to demonstrate optimization effects.

11.1.7.1 Introduction to SQL tuning

SQL tuning is crucial for optimizing database performance. It involves systematically improving the efficiency of SQL queries through the following typical steps:

1. Identify high-impact SQL statements:

    - Review the SQL execution history to find statements that consume significant system resources or contribute heavily to the application workload.
    - Use monitoring tools and performance metrics to identify resource-intensive queries.

2. Analyze execution plans:

    - Examine the execution plans generated by the query optimizer for the identified statements.
    - Verify whether these plans are reasonably efficient and use appropriate indexes and join methods.

3. Implement optimizations:

    Implement optimizations to inefficient SQL statements. Optimizations might include rewriting SQL statements, adding or modifying indexes, updating statistics, or adjusting database parameters.

Repeat these steps until:

- The system performance meets target requirements.
- No further improvements can be made to the remaining statements.

SQL tuning is an ongoing process. As your data volume grows and query patterns change, you should:

- Regularly monitor query performance.
- Re-evaluate your optimization strategies.
- Adapt your approach to address new performance challenges.

By consistently applying these practices, you can maintain optimal database performance over time.

11.1.7.2 Goals of SQL tuning

The primary goals of SQL tuning are the following:

- Reduce response time for end users.
- Minimize resource consumption during query execution.

To achieve these goals, you can use the following strategies.

11.1.7.2.1 Optimize query execution

SQL tuning focuses on finding more efficient ways to process the same workload without changing query functionality. You can optimize query execution as follows:

1. Improving execution plans:
    - Analyze and modify query structures for more efficient processing.
    - Use appropriate indexes to reduce data access and processing time.
    - Enable TiFlash for analytical queries on large datasets and leverage the Massively Parallel Processing (MPP) engine for complex aggregations and joins.
2. Enhancing data access methods:
    - Use covering indexes to satisfy queries directly from the index, avoiding full table scans.
    - Implement partitioning strategies to limit data scans to relevant partitions.

Examples:

- Create indexes on frequently queried columns to significantly reduce resource usage, particularly for queries that access small portions of the table.
- Use index-only scans for queries that return a limited number of sorted results to avoid full table scans and sorting operations.

11.1.7.2.2 Balance workload distribution

In a distributed architecture like TiDB, balancing workloads across TiKV nodes is essential for optimal performance. To identify and resolve read and write hotspots, see Troubleshoot hotspot issues.

By implementing these strategies, you can ensure that your TiDB cluster efficiently utilizes all available resources and avoids bottlenecks caused by uneven workload distribution or serialization on individual TiKV nodes.

11.1.7.3 Identify high-load SQL

The most efficient way to identify resource-intensive SQL statements is by using TiDB Dashboard. You can also use other tools, such as views and logs, to identify high-load SQL statements.

11.1.7.3.1 Monitor SQL statements using TiDB Dashboard

SQL Statements page

In TiDB Dashboard, navigate to the **SQL Statements** page to identify the following:

- The SQL statement with the highest total latency, which is the statement that takes the longest time to execute across multiple executions.
- The number of times each SQL statement has been executed, which helps identify statements with the highest execution frequency.
- Execution details of each SQL statement by clicking it to view `EXPLAIN ANALYZE` results.

TiDB normalizes SQL statements into templates by replacing literals and bind variables with `?`. This normalization and sorting process helps you quickly identify the most resource-intensive queries that might require optimization.

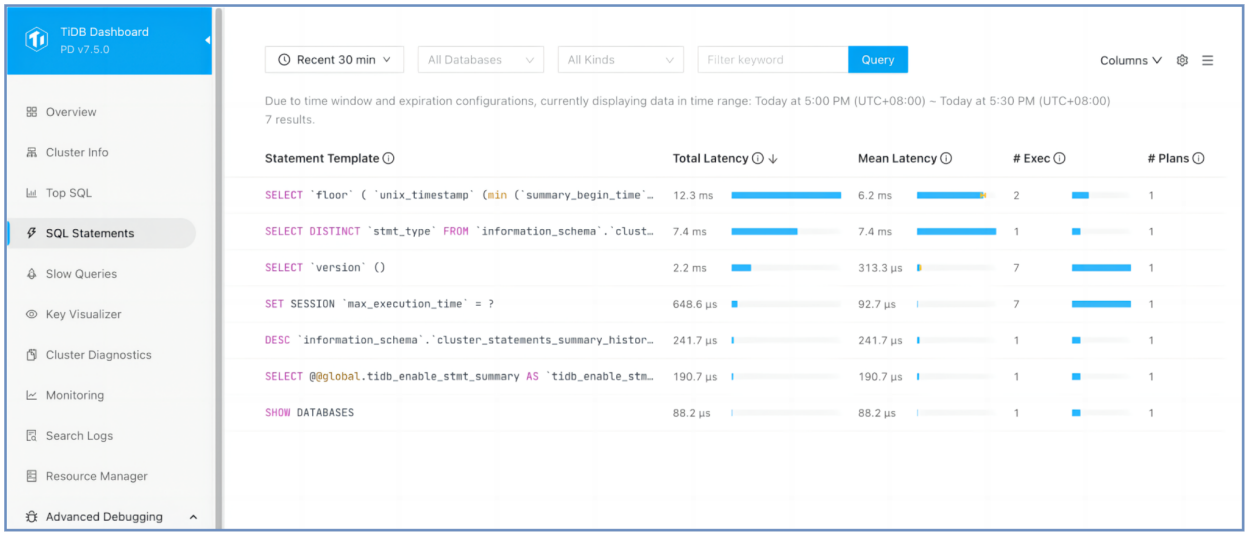

Figure 321: sql-statements-default

Slow Queries page

In TiDB Dashboard, navigate to the **Slow Queries** page to find the following:

- The slowest SQL queries.
- The SQL query that reads the most data from TiKV.
- The `EXPLAIN ANALYZE` output by clicking a query for detailed execution analysis.

The **Slow Queries** page does not display SQL execution frequency. A query appears on this page if its execution time exceeds the `tidb_slow_log_threshold` configuration item for a single instance.

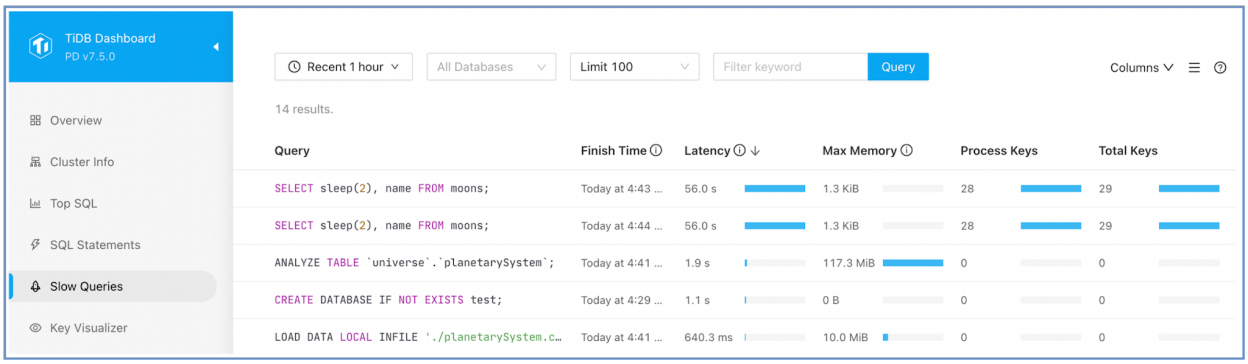

Figure 322: slow-query-default

11.1.7.3.2 Use other tools to identify Top SQL

In addition to TiDB Dashboard, you can use other tools to identify resource-intensive SQL queries. Each tool offers unique insights and can be valuable for different analysis scenarios. Using a combination of these tools helps ensure comprehensive SQL performance monitoring and optimization.

- TiDB Dashboard Top SQL Page
- Logs: slow query log and expensive queries in TiDB log
- Views: `cluster_statements_summary` view and `cluster_processlist` view

11.1.7.3.3 Gather data on identified SQL statements

For the top SQL statements identified, you can use `PLAN REPLAYER` to capture and save SQL execution information from a TiDB cluster. This tool helps recreate the execution environment for further analysis. To export SQL execution information, use the following syntax:

```
PLAN REPLAYER DUMP EXPLAIN [ANALYZE] [WITH STATS AS OF TIMESTAMP expression
    ↪ ] sql-statement;
```

Use `EXPLAIN ANALYZE` whenever possible, as it provides both the execution plan and actual performance metrics for more accurate insights into query performance.

11.1.7.4 SQL tuning guide

This guide provides practical advice for beginners on optimizing SQL queries in TiDB. By following these best practices, you can improve query performance and streamline SQL tuning. This guide covers the following topics:

- Understand query processing
    - Query processing workflow

    - Optimizer fundamentals
    - Statistics management
- Understand execution plans
    - How TiDB builds an execution plan
    - Generate and display execution plans
    - Read execution plans: first child first
    - Identify bottlenecks in execution plans
- Index strategy in TiDB
    - Composite index strategy guidelines
    - The cost of indexing
    - SQL tuning with a covering index
    - SQL tuning with a composite index involving sorting
    - SQL tuning with composite indexes for efficient filtering and sorting#sql-tuning-with-composite-indexes-for-efficient-filtering-and-sorting
- When to use TiFlash
    - Analytical query
    - SaaS arbitrary filtering workloads

11.1.7.4.1 Understand query processing

This section introduces the query processing workflow, optimizer fundamentals, and statistics management.

Query processing workflow

When a client sends a SQL statement to TiDB, the statement passes through the protocol layer of the TiDB server. This layer manages the connection between the TiDB server and the client, receives SQL statements, and returns data to the client.

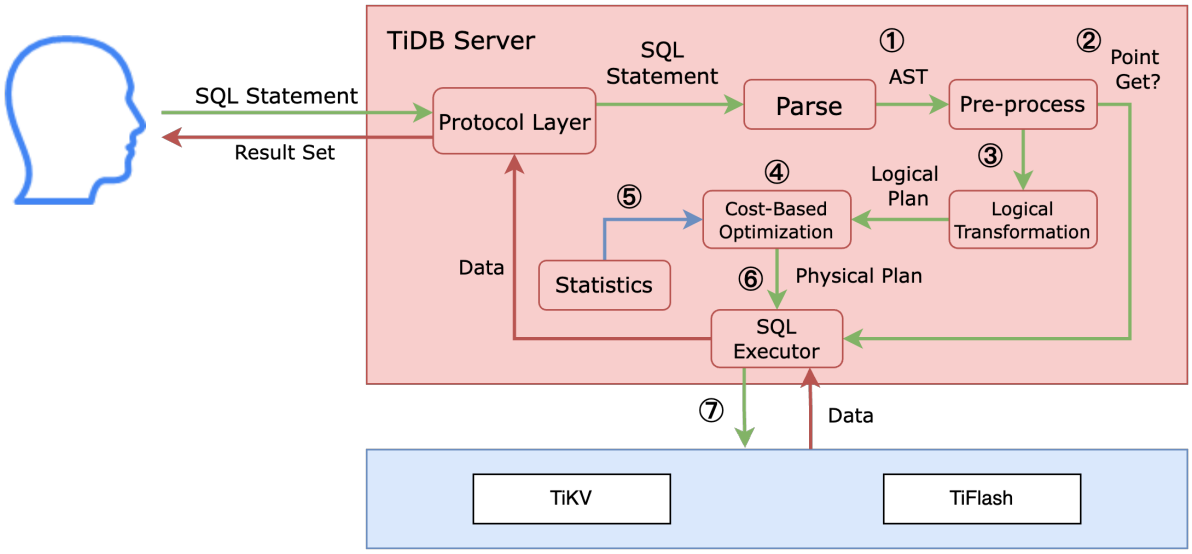

Figure 323: workflow

In the preceding figure, to the right of the protocol layer is the optimizer of the TiDB server, which processes SQL statements as follows:

1. The SQL statement arrives at the SQL optimizer through the protocol layer and is parsed into an abstract syntax tree (AST).
2. TiDB identifies whether it is a Point Get statement, which involves a simple one-table lookup through a primary or unique key, such as `SELECT * FROM t WHERE pk_col = 1` or `SELECT * FROM t WHERE uk_col IN (1,2,3)`. For `Point Get` statements, TiDB skips subsequent optimization steps and proceeds directly to execution in the SQL executor.
3. If the query is not a `Point Get`, the AST undergoes logical transformation, where TiDB rewrites the SQL logically based on specific rules.
4. After logical transformation, TiDB processes the AST through cost-based optimization.
5. During cost-based optimization, the optimizer uses statistics to select appropriate operators and generates a physical execution plan.
6. The generated physical execution plan is sent to the SQL executor of the TiDB node for execution.
7. Unlike traditional single-node databases, TiDB pushes down operators or coprocessors to TiKV and/or TiFlash nodes containing the data. This approach processes parts of the execution plan where the data is stored, efficiently utilizing the distributed architecture, using resources in parallel, and reducing network data transfer. The TiDB node executor then assembles the final result and returns it to the client.

Optimizer fundamentals

TiDB uses a cost-based optimizer (CBO) to determine the most efficient execution plan for a SQL statement. The optimizer evaluates different execution strategies and selects the one with the lowest estimated cost. The cost depends on factors such as:

- The SQL statement
- Schema design
- Statistics, including:
    - Table statistics
    - Index statistics
    - Column statistics

Based on these inputs, the cost model generates an execution plan that details how TiDB will execute the SQL statement, including:

- Access method
- Join method
- Join order

The effectiveness of the optimizer depends on the quality of the information it receives. To achieve optimal performance, ensure that statistics are up to date and indexes are well-designed.

Statistics management

Statistics are essential for the TiDB optimizer. TiDB uses statistics as the input of the optimizer to estimate the number of rows processed in each step of a SQL execution plan.

Statistics are divided into two levels:

- **Table-level statistics**: include the total number of rows in the table and the number of rows modified since the last statistics collection.
- **Index/column-level statistics**: include detailed information such as histograms, Count-Min Sketch, Top-N (values or indexes with the highest occurrences), distribution and quantity of different values, and the number of NULL values.

To check the accuracy and health of your statistics, you can use the following SQL statements:

- `SHOW STATS_META`: shows metadata about table statistics.

```
SHOW STATS_META WHERE table_name='T2'\G;
```

```
*************************** 1. row ***************************
         Db_name: test
      Table_name: T2
   Partition_name:
     Update_time: 2023-05-11 02:16:50
    Modify_count: 10000
       Row_count: 20000
1 row in set (0.03 sec)
```

- SHOW STATS_HEALTHY: shows the health status of table statistics.

```
SHOW STATS_HEALTHY WHERE table_name='T2'\G;
```

```
*************************** 1. row ***************************
      Db_name: test
   Table_name: T2
Partition_name:
      Healthy: 50
1 row in set (0.00 sec)
```

TiDB provides two methods for collecting statistics: automatic and manual collection. In most cases, automatic collection is sufficient. TiDB triggers automatic collection when certain conditions are met. Some common triggering conditions include:

- tidb_auto_analyze_ratio: the healthiness trigger.
- tidb_auto_analyze_start_time and tidb_auto_analyze_end_time: the time window for automatic statistics collection.

```
SHOW VARIABLES LIKE 'tidb\_auto\_analyze%';
```

```
+----------------------------------------+-------------+
| Variable_name                          | Value       |
+----------------------------------------+-------------+
| tidb_auto_analyze_ratio                | 0.5         |
| tidb_auto_analyze_start_time           | 00:00 +0000 |
| tidb_auto_analyze_end_time             | 23:59 +0000 |
+----------------------------------------+-------------+
```

In some cases, automatic collection might not meet your needs. By default, it occurs between 00:00 and 23:59, meaning the analyze job can run at any time. To minimize performance impact on your online business, you can set specific start and end times for statistics collection.

You can manually collect statistics using the `ANALYZE TABLE table_name` statement. This lets you adjust settings such as the sample rate, the number of Top-N values, or collect statistics for specific columns only.

Note that after manual collection, subsequent automatic collection jobs inherit the new settings. This means that any customizations made during manual collection will apply to future automatic analyses.

Locking table statistics is useful in the following scenarios:

- The statistics on the table already represent the data well.
- The table is very large, and statistics collection is time-consuming.
- You want to maintain statistics only during specific time windows.

To lock statistics for a table, you can use the `LOCK STATS table_name` statement.

For more information, see Statistics.

11.1.7.4.2 Understand execution plans

An execution plan details the steps that TiDB will follow to execute a SQL query. This section explains how TiDB builds an execution plan and how to generate, display, and interpret execution plans.

How TiDB builds an execution plan

A SQL statement undergoes three main optimization stages in the TiDB optimizer:

1. Pre-processing
2. Logical transformation
3. Cost-based optimization

1. Pre-processing

During pre-processing, TiDB determines whether the SQL statement can be executed using `Point_Get` or `Batch_Point_Get`. These operations use a primary or unique key to read directly from TiKV through an exact key lookup. If a plan qualifies for `Point_Get` or `Batch_Point_Get`, the optimizer skips the logical transformation and cost-based optimization steps because direct key lookup is the most efficient way to access the row.

The following is an example of a `Point_Get` query:

```
EXPLAIN SELECT id, name FROM emp WHERE id = 901;
```

```
+-------------+---------+------+---------------+---------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+---------------+---------------+
| Point_Get_1 | 1.00    | root | table:emp     | handle:901    |
+-------------+---------+------+---------------+---------------+
```

2. Logical transformation

During logical transformation, TiDB optimizes SQL statements based on the `SELECT` list, `WHERE` predicates, and other conditions. It generates a logical execution plan to annotate and rewrite the query. This logical plan is used in the next stage, cost-based optimization. The transformation applies rule-based optimizations such as column pruning, partition pruning, and join reordering. Because this process is rule-based and automatic, manual adjustments are usually unnecessary.

For more information, see SQL Logical Optimization.

3. Cost-based optimization

The TiDB optimizer uses statistics to estimate the number of rows processed in each step of a SQL statement and assigns a cost to each step. During cost-based optimization, the optimizer evaluates all possible plan choices, including index accesses and join methods, and calculates the total cost for each plan. The optimizer then selects the execution plan with the minimal total cost.

The following figure illustrates various data access paths and row set operations considered during cost-based optimization. For data retrieval paths, the optimizer determines the most efficient method between index scans and full table scans, and decides whether to retrieve data from row-based TiKV storage or columnar TiFlash storage.

The optimizer also evaluates operations that manipulate row sets, such as aggregation, join, and sorting. For example, the aggregation operator might use either `HashAgg` or `StreamAgg`, while the join method can select from `HashJoin`, `MergeJoin`, or `IndexJoin`.

Additionally, the physical optimization phase includes pushing down expressions and operators to the physical storage engines. The physical plan is distributed to different components based on the underlying storage engines as follows:

- Root tasks are executed on the TiDB server.
- Cop (Coprocessor) tasks are executed on TiKV.
- MPP tasks are executed on TiFlash.

This distribution enables cross-component collaboration for efficient query processing.

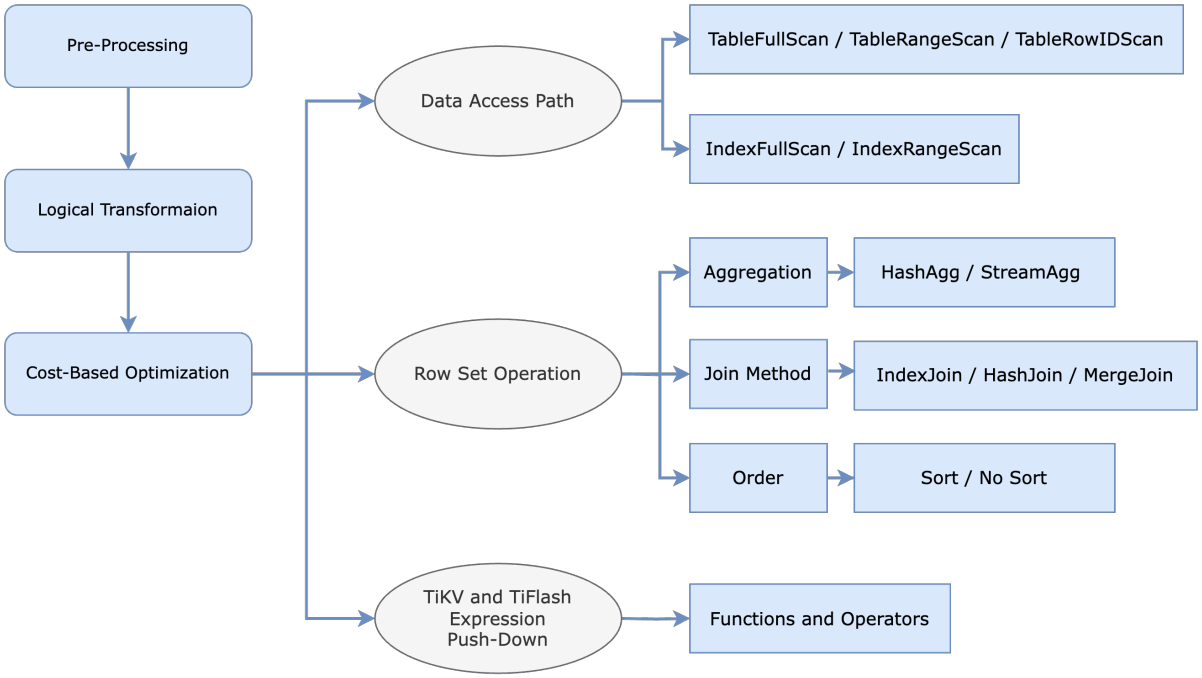

Figure 324: cost-based-optimization

For more information, see SQL Physical Optimization.

Generate and display execution plans

Besides accessing execution plan information through TiDB Dashboard, you can use the `EXPLAIN` statement to display the execution plan for a SQL query. The `EXPLAIN` output includes the following columns:

- `id`: the operator name and a unique identifier of the step.
- `estRows`: the estimated number of rows from the particular step.
- `task`: indicates the layer where the operator is executed. For example, `root` indicates execution on the TiDB server, `cop[tikv]` indicates execution on TiKV, and `mpp[tiflash]` indicates execution on TiFlash.
- `access object`: the object where row sources are located.
- `operator info`: additional details about the operator in the step.

```
EXPLAIN SELECT COUNT(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+-------------------------+-------------+-------------+--------------------+-----------
    ↪
```

```
| id                    | estRows    | task         | access object   |
   ↪ operator info
   ↪
   ↪ |
+-------------------------+------------+-------------+-------------------+-----------
   ↪
| StreamAgg_20          | 1.00       | root         |                 | funcs:
   ↪ count(Column#13)->Column#11
   ↪                                                          |
|  ─TableReader_21       | 1.00       | root         |                 | data:
   ↪ StreamAgg_9
   ↪
   ↪ |
|    ─StreamAgg_9        | 1.00       | cop[tikv]    |                 | funcs:
   ↪ count(1)->Column#13
   ↪                                                                   |
|      ─Selection_19     | 250.00     | cop[tikv]    |                 | ge(
   ↪ trips.start_date, 2017-07-01 00:00:00.000000), le(trips.start_date,
   ↪ 2017-07-01 23:59:59.000000) |
|        ─TableFullScan_18 | 10000.00 | cop[tikv] | table:trips     | keep
   ↪ order:false, stats:pseudo
   ↪                                                                 |
+-------------------------+------------+-------------+-------------------+-----------
   ↪
5 rows in set (0.00 sec)
```

Different from `EXPLAIN`, `EXPLAIN ANALYZE` executes the corresponding SQL statement, records its runtime information, and returns the runtime information together with the execution plan. This runtime information is crucial for debugging query execution. For more information, see EXPLAIN ANALYZE.

The `EXPLAIN ANALYZE` output includes:

- `actRows`: the number of rows output by the operator.
- `execution info`: detailed execution information of the operator. `time` represents the total `wall time`, including the total execution time of all sub-operators. If the operator is called many times by the parent operator, then the time refers to the accumulated time.
- `memory`: the memory used by the operator.
- `disk`: the disk space used by the operator.

The following is an example. Some attributes and table columns are omitted to improve formatting.

```
EXPLAIN ANALYZE
```

```
SELECT SUM(pm.m_count) / COUNT(*)
FROM (
    SELECT COUNT(m.name) m_count
    FROM universe.moons m
    RIGHT JOIN (
        SELECT p.id, p.name
        FROM universe.planet_categories c
        JOIN universe.planets p
            ON c.id = p.category_id
            AND c.name = 'Jovian'
    ) pc ON m.planet_id = pc.id
    GROUP BY pc.name
) pm;
```

```

```

Read execution plans: first child first

To diagnose slow SQL queries, you need to understand how to read execution plans. The key principle is **"first child first – recursive descent"**. Each operator in the plan generates a set of rows, and the execution order determines how these rows flow through the plan tree.

The "first child first" rule means that an operator must retrieve rows from all its child operators before producing output. For example, a join operator requires rows from both its child operators to perform the join. The "recursive descent" rule means you analyze the plan from top to bottom, although actual data flows from bottom to top, as each operator depends on its children's output.

Consider these two important concepts when reading execution plans:

- Parent-child interaction: a parent operator calls its child operators sequentially but might cycle through them multiple times. For example, in an index lookup or nested loop join, the parent fetches a batch of rows from the first child, then retrieves zero or more rows from the second child. This process repeats until the first child's result set is fully processed.
- Blocking vs. non-blocking operators: operators can be either blocking or non-blocking:
    - Blocking operators, such as `TopN` and `HashAgg`, must create their entire result set before passing data to their parent.
    - Non-blocking operators, such as `IndexLookup` and `IndexJoin`, produce and pass rows incrementally as needed.

When reading an execution plan, start from the top and work downward. In the following example, the leaf node of the plan tree is `TableFullScan_18`, which performs a full table scan. The rows from this scan are consumed by the `Selection_19` operator, which filters the

data based on `ge(trips.start_date, 2017-07-01 00:00:00.000000)`, `le(trips.start_date, 2017-07-01 23:59:59.000000)`. Then, the group-by operator `StreamAgg_9` performs the final aggregation `COUNT(*)`.

These three operators (`TableFullScan_18`, `Selection_19`, and `StreamAgg_9`) are pushed down to TiKV (marked as `cop[tikv]`), enabling early filtering and aggregation in TiKV to reduce data transfer between TiKV and TiDB. Finally, `TableReader_21` reads the data from `StreamAgg_9`, and `StreamAgg_20` performs the final aggregation `count(*)`.

```
EXPLAIN SELECT COUNT(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```

|        ─TableFullScan_18 | 10000.00 | cop[tikv] | table:trips        | keep
    ↪ order:false, stats:pseudo
    ↪                                                                      |
+-------------------------+------------+-------------+--------------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In the following example, start by examining `IndexRangeScan_47`, the first leaf node of the plan tree. The optimizer selects only the `name` and `id` columns from the `stars` table, which can be retrieved from the `name(name)` index. As a result, the root reader for `stars` is `IndexReader_48`, not `TableReader`.

The join between `stars` and `planets` is a hash join (`HashJoin_44`). The `planets` table is accessed using a full table scan (`TableFullScan_45`). After the join, `TopN_26` and `TopN_19`

apply the `ORDER BY` and `LIMIT` clauses, respectively. The final operator, `Projection_16`, selects the final column `t5.name`.

```
EXPLAIN
SELECT t5.name
FROM (
    SELECT p.name, p.gravity, p.distance_from_sun
    FROM universe.planets p
    JOIN universe.stars s
        ON s.id = p.sun_id
        AND s.name = 'Sun'
    ORDER BY p.distance_from_sun ASC
    LIMIT 5
) t5
ORDER BY t5.gravity DESC
LIMIT 3;
```

```

   ↪
```

The following figure illustrates the plan tree for the second execution plan:

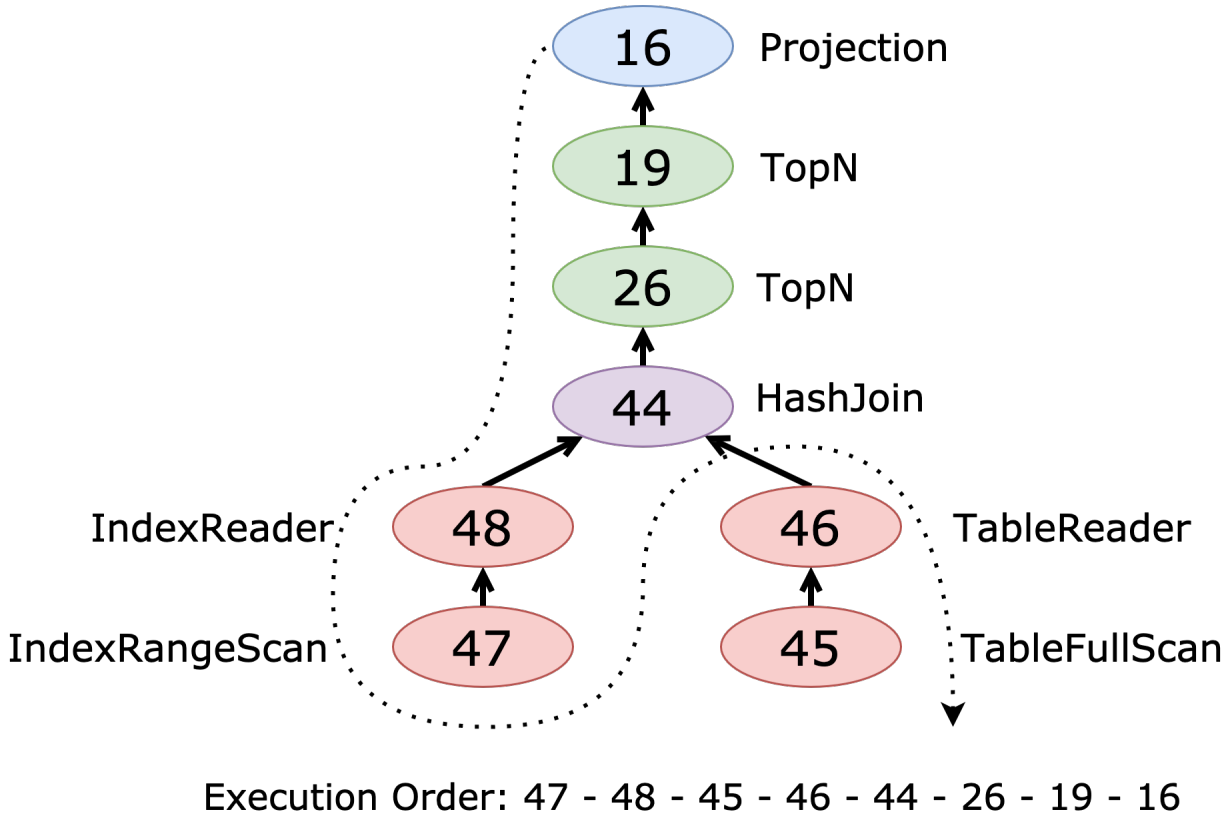

Figure 325: execution-plan-traverse

The execution plan follows a top-to-bottom, first-child-first traversal, corresponding to a postorder traversal (Left, Right, Root) of the plan tree.

You can read this plan in the following order:

1. Start at the top with `Projection_16`.
2. Move to its child, `TopN_19`.
3. Continue to `TopN_26`.
4. Proceed to `HashJoin_44`.
5. For `HashJoin_44`, process its left (Build) child first:
    - `IndexReader_48`
    - `IndexRangeScan_47`
6. For `HashJoin_44`, process its right (Probe) child:
    - `TableReader_46`
    - `TableFullScan_45`

This traversal ensures that each operator's inputs are processed before the operator itself, enabling efficient query execution.

Identify bottlenecks in execution plans

When analyzing execution plans, compare `actRows` (actual rows) with `estRows` (estimated rows) to evaluate the accuracy of the optimizer's estimations. A significant difference between these values might indicate outdated or inaccurate statistics, which can lead to suboptimal query plans.

To identify bottlenecks in a slow query, perform the following steps:

1. Review the `execution info` section from top to bottom, focusing on operators with high execution time.
2. For the first child operator that consumes significant time:
    - Compare `actRows` with `estRows` to assess estimation accuracy.
    - Analyze detailed metrics in `execution info`, such as high execution time or other metrics.
    - Check `memory` and `disk` usage for potential resource constraints.
3. Correlate these factors to determine the root cause of the performance issue. For example, if a `TableFullScan` operation has a high `actRows` count and long execution time in `execution info`, consider creating an index. If a `HashJoin` operation shows high memory usage and execution time, consider optimizing the join order or using an alternative join method.

In the following execution plan, the query runs for 5 minutes and 51 seconds before being canceled. The key issues include:

1. Severe underestimation: The first leaf node `IndexReader_76` reads data from the `index_orders_on_adjustment_id(adjustment_id)` index. The actual number of rows (`actRows`) is 256,811,189, which is significantly higher than the estimated 1 row (`estRows`).
2. Memory overflow: This underestimation causes the hash join operator `HashJoin_69` to build a hash table with far more data than expected, consuming excessive memory (22.6 GB) and disk space (7.65 GB).
3. Query termination: The `actRows` value of `0` for `HashJoin_69` and operators above it indicate either no matching rows or query termination due to resource constraints. In this case, the hash join consumes too much memory, triggering memory control mechanisms to terminate the query.
4. Incorrect join order: The root cause of this inefficient plan is the severe underestimation of `estRows` for `IndexRangeScan_75`, leading the optimizer to choose an incorrect join order.

To address these issues, ensure that table statistics are up to date, particularly for the `orders` table and the `index_orders_on_adjustment_id` index.

```
+-------------------
```

```
   ↪                                                                                                  | tikv_
   ↪ task:{proc...| N/A   | N/A     |
|    ─TableReader_28(Probe)       | 0.00     | 43.64       | 0         | root
   ↪     |
   ↪
   ↪ |               ...| N/A     | N/A     |
|      ─Selection_27              | 0.00     | 653.96      | 0         | cop[
   ↪ tikv] |
   ↪
   ↪ |               ...| N/A     | N/A     |
|        ─TableRangeScan_26       | 1.01     | 454.36      | 0         | cop[
   ↪ tikv] | table:labels
   ↪                                                                                                  |
   ↪               ...| N/A     | N/A     |
+-------------------------------------------------------------------------------------------------------
   ↪
```

The following execution plan shows the expected results after fixing the incorrect estimation on the `orders` table. The query now takes 1.96 seconds to run, which is a significant improvement from the previous 5 minutes and 51 seconds:

- Accurate estimation: The `estRows` values now closely match the `actRows`, indicating that the statistics are updated and more accurate.
- Efficient join order: The query now starts with a `TableReader` on the `labels` table, followed by an `IndexJoin` with the `rates` table, and another `IndexJoin` with the `orders` table. This join order works more efficiently with the actual data distribution.
- No memory overflow: Unlike the previous plan, this execution shows no signs of excessive memory or disk usage, indicating that the query runs within expected resource limits.

This optimized plan demonstrates the importance of accurate statistics and proper join order in query performance. The execution time reduction (from 351 seconds to 1.96 seconds) shows the impact of addressing estimation errors.

11.1.7.4.3 Index strategy in TiDB

TiDB is a distributed SQL database that separates the SQL layer (TiDB Server) from the storage layer (TiKV). Unlike traditional databases, TiDB does not use a buffer pool to cache data on compute nodes. As a result, SQL query performance and overall cluster performance depend on the number of key-value (KV) RPC requests that need to be processed. Common KV RPC requests include `Point_Get`, `Batch_Point_Get`, and Coprocessor.

To optimize performance in TiDB, it is essential to use indexes effectively, as they can significantly reduce the number of KV RPC requests. Fewer KV RPC requests improve query performance and system efficiency. The following lists some key strategies that help optimize indexing:

- Avoid full table scans.
- Avoid sorting operations.
- Use covering indexes or exclude unnecessary columns to reduce row lookups.

This section explains general indexing strategies and indexing costs. It also provides three practical examples of effective indexing in TiDB, with a focus on composite and covering indexes for SQL tuning.

Composite index strategy guidelines

To create an efficient composite index, order your columns strategically. The column order directly affects how efficiently the index filters and sorts data.

Follow these recommended column order guidelines for a composite index:

1. Start with index prefix columns for direct access:
    - Columns with equivalent conditions
    - Columns with `IS NULL` conditions
2. Add columns for sorting next:
    - Let the index handle sorting operations
    - Enable sort and limit pushdown to TiKV
    - Preserve the sorted order
3. Include additional filtering columns to reduce row lookups:
    - Time range conditions on datetime columns
    - Other non-equivalent conditions, such as `!=`, `<>`, and `IS NOT NULL`
4. Add columns from the `SELECT` list or used in aggregation to fully utilize a covering index.

The cost of indexing

While indexes can improve query performance, they also introduce costs you should consider:

- Performance impact on writes:
  - A non-clustered index reduces the chance of single-phase commit optimization.
  - Each additional index slows down write operations (such as `INSERT`, `UPDATE`, and `DELETE`).
  - When data is modified, all affected indexes must be updated.
  - The more indexes a table has, the greater the write performance impact.
- Resource consumption:
  - Indexes require additional disk space.
  - More memory is needed to cache frequently accessed indexes.
  - Backup and recovery operations take longer.
- Write hotspot risk:
  - Secondary indexes can create write hotspots. For example, a monotonically increasing datetime index will cause hotspots on table writes.
  - Hotspots can lead to significant performance degradation.

The following lists some best practices:

- Create indexes only when they provide clear performance benefits.
- Regularly review index usage statistics using `TIDB_INDEX_USAGE`.
- Consider the write/read ratio of your workload when designing indexes.

SQL tuning with a covering index

A covering index includes all columns referenced in the `WHERE` and `SELECT` clauses. Using a covering index can eliminate the need for additional index lookups, significantly improving query performance.

The following query requires an index lookup of 2,597,411 rows and takes 46.4 seconds to execute. TiDB dispatches 67 cop tasks for the index range scan on `logs_idx` (`IndexRangeScan_11`) and 301 cop tasks for table access (`TableRowIDScan_12`).

```
SELECT
  SUM(`logs`.`amount`)
FROM
  `logs`
WHERE
  `logs`.`user_id` = 1111
  AND `logs`.`snapshot_id` IS NULL
  AND `logs`.`status` IN ('complete', 'failure')
```

```
  AND `logs`.`source_type` != 'online'
  AND (
    `logs`.`source_type` IN ('user', 'payment')
    OR `logs`.`source_type` IN (
      'bank_account',
    )
    AND `logs`.`target_type` IN ('bank_account')
  );
```

The original execution plan is as follows:

```
+------------------------------+-----------+---------+----------+-------------------
   ↪
| id                           | estRows   | actRows | task     | access object
   ↪                                                  | execution info
   ↪                                        |
+------------------------------+-----------+---------+----------+-------------------
   ↪
| HashAgg_18                   | 1.00      | 2571625.22 | 1     | root     |
   ↪                                                    | time:46.4s,
   ↪ loops:2, partial_worker:{wall_time:46.37, ...|
|  ─IndexLookUp_19             | 1.00      | 2570096.68 | 301   | root     |
   ↪                                                    | time:46.4s,
   ↪ loops:2, index_task: {total_time: 45.8s, ...|
|    ─IndexRangeScan_11(Build) | 1309.50 | 317033.98 | 2597411 | cop[tikv]
   ↪ | table:logs, index:logs_idx(snapshot_id, user_id, status) | time:228
   ↪ ms, loops:2547, cop_task: {num: 67, max: 2.17s, ...|
|    ─HashAgg_7(Probe)         | 1.00      | 588434.48 | 301    | cop[tikv] |
   ↪                                                      | time:3m46.7s,
   ↪ loops:260, cop_task: {num: 301,    ...|
|      ─Selection_13           | 1271.37   | 561549.27 | 2566562 | cop[tikv] |
   ↪                                                     | tikv_task:{proc
   ↪ max:10s, min:0s, avg: 915.3ms,   ...|
|        ─TableRowIDScan_12    | 1309.50   | 430861.31 | 2597411 | cop[tikv] |
   ↪ table:logs                                          | tikv_task:{proc
   ↪ max:10s, min:0s, avg: 908.7ms,   ...|
+------------------------------+-----------+---------+----------+-------------------
   ↪
```

To improve query performance, you can create a covering index that includes `source_type`, `target_type`, and `amount` columns. This optimization eliminates the need for additional table lookups, reducing execution time to 90 milliseconds, and TiDB only needs to send one cop task to TiKV for data scanning.

After creating the index, execute the `ANALYZE TABLE` statement to collect statistics. In TiDB, index creation does not automatically update statistics, so analyzing the table ensures

that the optimizer selects the new index.

```
CREATE INDEX logs_covered ON logs(snapshot_id, user_id, status, source_type
    ↪ , target_type, amount);
ANALYZE TABLE logs INDEX logs_covered;
```

The new execution plan is as follows:

```
+------------------------------+-----------+---------+----------+-------------------
    ↪
| id                           | estRows   | actRows | task     | access object
    ↪
    ↪ | execution info                          |
+------------------------------+-----------+---------+----------+-------------------
    ↪
| HashAgg_13                   | 1.00      | 1       | root     |
    ↪
    ↪ | time:90ms, loops:2, RU:158.885311,  ...|
|  ─IndexReader_14             | 1.00      | 1       | root     |
    ↪
    ↪ | time:89.8ms, loops:2, cop_task: {num: 1, ...|
|    ─HashAgg_6                | 1.00      | 1       | cop[tikv] |
    ↪
    ↪ | tikv_task:{time:88ms, loops:52},    ...|
|      ─Selection_12           | 5245632.33 | 52863 | cop[tikv] |
    ↪
    ↪ | tikv_task:{time:80ms, loops:52}     ...|
|        ─IndexRangeScan_11    | 5245632.33 | 52863 | cop[tikv] | table:logs,
    ↪ index:logs_covered(snapshot_id, user_id, status, source_type, target_
    ↪ type, amount)                 | tikv_task:{time:60ms, loops:52}     ...|
+------------------------------+-----------+---------+----------+-------------------
    ↪
```

SQL tuning with a composite index involving sorting

You can optimize queries with `ORDER BY` clauses by creating composite indexes that include both filtering and sorting columns. This approach helps TiDB access data efficiently while maintaining the desired order.

For example, consider the following query that retrieves data from `test` based on specific conditions:

```
EXPLAIN ANALYZE SELECT
test.*
FROM
  test
WHERE
  test.snapshot_id = 459840
```

```
  AND test.id > 998464
ORDER BY
  test.id ASC
LIMIT
  1000
```

The execution plan shows a duration of 170 ms. TiDB uses the `test_index` to perform an `IndexRangeScan_20` with the filter `snapshot_id = 459840`. It then retrieves all columns from the table, returning 5,715 rows to TiDB after `IndexLookUp_23`. TiDB sorts these rows and returns 1,000 rows.

The `id` column is the primary key, which means it is implicitly included in the `test_idx` index. However, `IndexRangeScan_20` does not guarantee order because `test_idx` includes two additional columns (`user_id` and `status`) after the index prefix column `snapshot_id`. As a result, the ordering of `id` is not preserved.

The original plan is as follows:

```
+-----------------------------+---------+---------+-----------+-----------------------
   ↪
| id                          | estRows | actRows | task  | access object
   ↪                                     | execution info
   ↪                             | operator info                           |
+-----------------------------+---------+---------+-----------+-----------------------
   ↪
| id                          | estRows | actRows | task  | access object
   ↪                                     | execution info
   ↪                           ...| test.id, offset:0, count:1000        |
| TopN_10                     | 19.98  | 1000   | root     |
   ↪                                                | time:170.6ms,
   ↪ loops:2                    ...|                                       |
|  ─IndexLookUp_23            | 19.98  | 5715   | root     |
   ↪                                                | time:166.6ms,
   ↪ loops:7                    ...|                                       |
|    ─Selection_22(Build)     | 19.98  | 5715   | cop[tikv] |
   ↪                                                   | time:18.6ms, loops
   ↪ :9, cop_task: {num: 3, ...| gt(test.id, 998464)                 |
|      ─IndexRangeScan_20     | 433.47 | 7715   | cop[tikv] | table:test,
   ↪ index:test_idx(snapshot_id, user_id, status) | tikv_task:{proc max:4
   ↪ ms, min:4ms, avg: 4ms ...| range:[459840,459840], keep order:false |
|    ─TableRowIDScan_21(Probe) | 19.98 | 5715 | cop[tikv] | table:test
   ↪                                      | time:301.6ms, loops:10, cop_
   ↪ task: {num: 3, ...| keep order:false                  |
+-----------------------------+---------+---------+-----------+-----------------------
   ↪
```

To optimize the query, you can create a new index on `(snapshot_id)`. This ensures that `id` is sorted within each `snapshot_id` group. With this index, execution time drops to 96 ms. The `keep order` property becomes `true` for `IndexRangeScan_33`, and `TopN` is replaced with `Limit`. As a result, `IndexLookUp_35` returns only 1,000 rows to TiDB, eliminating the need for additional sorting operations.

The following is the query statement with the optimized index:

```
CREATE INDEX test_new ON test(snapshot_id);
ANALYZE TABLE test INDEX test_new;
```

The new plan is as follows:

```
+---------------------------------+---------+---------+-----------+--------------------
   ↪
| id                              | estRows | actRows | task  | access object
   ↪                               | execution info                          |
   ↪ operator info                                  |
+---------------------------------+---------+---------+-----------+--------------------
   ↪
| Limit_14                        | 17.59  | 1000   | root     |
   ↪                                                | time:96.1ms, loops:2, RU

SQL tuning with composite indexes for efficient filtering and sorting

The following query takes 11 minutes and 9 seconds to execute, which is excessively long for a query that returns only 101 rows. The slow performance is caused by several factors:

- Inefficient index usage: The optimizer selects the index on `created_at`, resulting in a scan of 25,147,450 rows.
- Large intermediate result set: After applying the date range filter, 12,082,311 rows still require processing.
- Late filtering: The most selective predicates `(mode, user_id, and label_id)` are applied after accessing the table, resulting in 16,604 rows.

- Sorting overhead: The final sort operation on 16,604 rows adds additional processing time.

The following is the query statement:

```
SELECT `orders`.*
FROM `orders`
WHERE
    `orders`.`mode` = 'production'
    AND `orders`.`user_id` = 11111
    AND orders.label_id IS NOT NULL
    AND orders.created_at >= '2024-04-07 18:07:52'
    AND orders.created_at <= '2024-05-11 18:07:52'
    AND orders.id >= 1000000000
    AND orders.id < 1500000000
ORDER BY orders.id DESC
LIMIT 101;
```

The following are the existing indexes on `orders`:

```
PRIMARY KEY (`id`),
UNIQUE KEY `index_orders_on_adjustment_id` (`adjustment_id`),
KEY `index_orders_on_user_id` (`user_id`),
KEY `index_orders_on_label_id` (`label_id`),
KEY `index_orders_on_created_at` (`created_at`)
```

The original execution plan is as follows:

```
+-------------------------------+----------+--------+----------+--------------------
   ↪
| id                            | estRows  | actRows | task    | access object

11.1.7.4.4 When to use TiFlash

This section explains when to use TiFlash in TiDB. TiFlash is optimized for analytical queries that involve complex calculations, aggregations, and large dataset scans. Its columnar storage format and MPP mode significantly improve performance in these scenarios.

Use TiFlash in the following scenarios:

- Large-scale data analysis: TiFlash delivers faster performance for OLAP workloads that require extensive data scans. Its columnar storage and MPP execution mode optimize query efficiency compared to TiKV.
- Complex scans, aggregations, and joins: TiFlash processes queries with heavy aggregations and joins more efficiently by reading only the necessary columns.
- Mixed workloads: in hybrid environments where both transactional (OLTP) and analytical (OLAP) workloads run simultaneously, TiFlash handles analytical queries without affecting TiKV's performance for transactional queries.
- SaaS applications with arbitrary filtering requirements: queries often involve filtering across many columns. Indexing all columns is impractical, especially when queries include a tenant ID as part of the primary key. TiFlash sorts and clusters data by primary key, making it well suited for these workloads. With the late materialization feature, TiFlash enables efficient table range scans, improving query performance without the overhead of maintaining multiple indexes.

Using TiFlash strategically enhances query performance and optimizes resource usage in TiDB for data-intensive analytical queries. The following sections provide examples of TiFlash use cases.

Analytical query

This section compares the execution performance of TPC-H Query 14 on TiKV and TiFlash storage engines.

TPC-H Query 14 involves joining the `order_line` and `item` tables. The query takes **21.1 seconds** on TiKV but only **1.41 seconds** using TiFlash MPP mode, making it 15 times faster.

- TiKV plan: TiDB fetches 3,864,397 rows from the `lineitem` table and 10 million rows from the `part` table. The hash join operation (`HashJoin_21`), along with the subsequent projection (`Projection_38`) and aggregation (`HashAgg_9`) operations, are performed in TiDB.
- TiFlash plan: The optimizer detects TiFlash replicas for both `order_line` and `item` tables. Based on cost estimation, TiDB automatically selects the MPP mode, executing the entire query within the TiFlash columnar storage engine. This includes table scans, hash joins, column projections, and aggregations, significantly improving performance compared to the TiKV plan.

The following is the query:

```
select 100.00 * sum(case when i_data like 'PR%' then ol_amount else 0 end)
    ↪ / (1+sum(ol_amount)) as promo_revenue
from order_line, item
where ol_i_id = i_id and ol_delivery_d >= '2007-01-02 00:00:00.000000' and
    ↪ ol_delivery_d < '2030-01-02 00:00:00.000000';
```

The execution plan on TiKV is as follows:

```
+------------------------------+-------------+----------+----------+---------------
   ↪
| ID                           | ESTROWS     | ACTROWS  | TASK     | ACCESS

```

SaaS arbitrary filtering workloads

In SaaS applications, tables often use composite primary keys that include tenant identification. The following example demonstrates how TiFlash can significantly improve query performance in these scenarios.

Case study: multi-tenant data access

Consider a table with a composite primary key: `(tenantId, objectTypeId, objectId ↪ )`. A typical query pattern for this table involves:

- Retrieving the first N records for a specific tenant and object type while applying random filters across hundreds or thousands of columns. This makes creating indexes for all possible filter combinations impractical. The query might also include a sort operation after filtering.
- Calculating the total count of records that match the filter criteria.

Performance comparison

When running the same query on different storage engines, you can observe significant performance differences:

- TiKV plan: The query takes 2 minutes 38.6 seconds on TiKV. `TableRangeScan` sends 5,121 cop tasks because the data is distributed across 5,121 Regions.

- TiFlash plan: The same query takes only 3.44 seconds on TiFlash MPP engine—nearly 46 times faster. TiFlash stores data sorted by primary key, so queries filtered by the primary key's prefix use `TableRangeScan` instead of a full table scan. TiFlash requires only 2 MPP tasks compared to TiKV's 5,121 tasks.

The following is the query statement:

```
WITH `results` AS (
  SELECT field1, field2, field3, field4
  FROM usertable
  where tenantId = 1234 and objectTypeId = 6789
),
`limited_results` AS (
  SELECT field1, field2, field3, field4
  FROM `results` LIMIT 100
)
SELECT field1, field2, field3, field4
FROM
  (
    SELECT 100 `__total__`, field1, field2, field3, field4
    FROM `limited_results`
    UNION ALL
    SELECT count(*) `__total__`, field1, field2, field3, field4
    FROM `results`
  ) `result_and_count`;
```

The execution plan on TiKV is as follows:

```
+--------------------------------+-----------+---------+-----------+--------------------
   ↪

Query routing between TiKV and TiFlash

After enabling TiFlash replicas for tables with large amounts of multi-tenant data, the optimizer routes queries to either TiKV or TiFlash based on the row count:

- Small tenants: TiKV is more suitable for tenants with small data size, as it provides high concurrency for small queries with table range scans.
- Large tenants: For tenants with large datasets (such as 10 million rows in this case), TiFlash is more efficient for the following advantages:
    - TiFlash handles dynamic filtering conditions without requiring specific indexes.
    - TiDB can push down `COUNT`, `SORT`, and `LIMIT` operations to TiFlash.
    - TiFlash scans only the required columns using columnar storage.

11.1.8 Tuning by Metrics

11.1.8.1 Performance Analysis and Tuning

This document describes a tuning approach by database time, and illustrates how to use the TiDB Performance Overview dashboard for performance analysis and tuning.

With the methods described in this document, you can analyze user response time and database time from a global and top-down perspective, to confirm whether the bottleneck in user response time is caused by database issues. If the bottleneck is in the database, you can use the database time overview and SQL latency breakdowns to identify the bottleneck and tune performance.

11.1.8.1.1 Performance tuning based on database time

TiDB is constantly measuring and collecting SQL processing paths and database time. Therefore, it is easy to identify database performance bottlenecks in TiDB. Based on database time metrics, you can achieve the following two goals even without data on user response time:

- Determine whether the bottleneck is in TiDB by comparing the average SQL processing latency with the idle time of a TiDB connection in a transaction.
- If the bottleneck is in TiDB, further identify the exact module in the distributed system based on database time overview, color-based performance data, key metrics, resource utilization, and top-down latency breakdowns.

Is TiDB the bottleneck?

- If the average idle time of TiDB connections in transactions is higher than the average SQL processing latency, the database is not to blame for the transaction latency of applications. The database time takes only a small part of the user response time, indicating that the bottleneck is outside the database.

  In this case, check the external components of the database. For example, determine whether there are sufficient hardware resources in the application server, and whether the network latency from the application to the database is excessively high.

- If the average SQL processing latency is higher than the average idle time of TiDB connections in transactions, the bottleneck in transactions is in TiDB, and the database time takes a large percentage of the user response time.

If the bottleneck is in TiDB, how to identify it?

The following figure shows a typical SQL process. You can see that most SQL processing paths are covered in TiDB performance metrics. The database time is broken down into different dimensions, which are colored accordingly. You can quickly understand the workload characteristics and catch the bottlenecks inside the database if any.

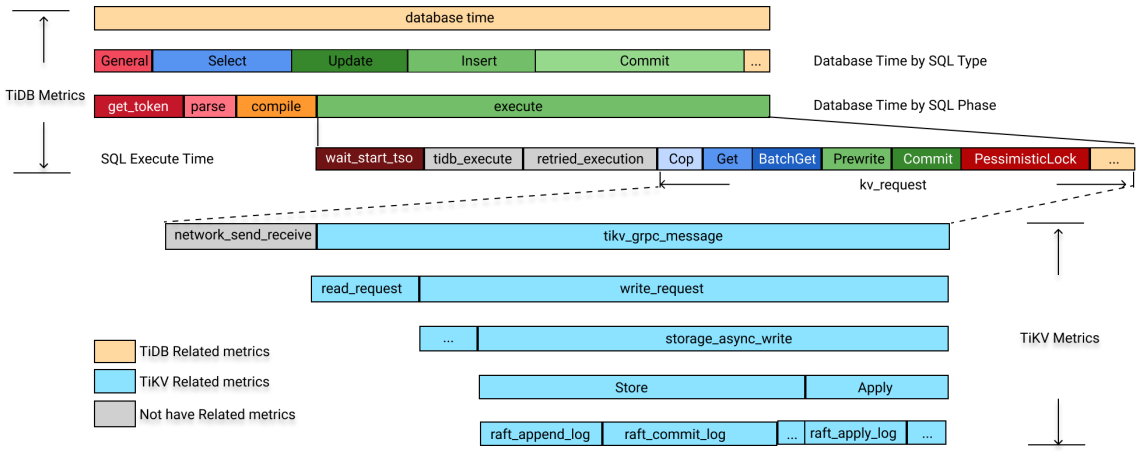

Figure 326: database time decomposition chart

Database time is the sum of all SQL processing time. A breakdown of the database time into the following three dimensions helps you quickly identify bottlenecks in TiDB:

- By SQL processing type: Determine which type of SQL statements consumes the most database time. The formula is:

  ```
  DB Time = Select Time + Insert Time + Update Time + Delete Time +
  ↪ Commit Time + ...
  ```

- By the 4 steps of SQL processing (get_token/parse/compile/execute): Determine which step consumes the most time. The formula is:

  ```
  DB Time = Get Token Time + Parse Time + Compile Time + Execute Time
  ```

- By executor time, TSO wait time, KV request time, and execution retry time: Determine which execution step constitutes the bottleneck. The formula is:

  ```
  Execute Time ~= TiDB Executor Time + KV Request Time + PD TSO Wait Time
  ↪  + Retried execution time
  ```

11.1.8.1.2 Performance analysis and tuning using the Performance Overview dashboard

This section describes how to perform performance analysis and tuning based on database time using the Performance Overview dashboard in Grafana.

The Performance Overview dashboard orchestrates the metrics of TiDB, PD, and TiKV, and presents each of them in the following sections:

- Database time and SQL execution time overview: Color-coded SQL types, database time by SQL execution phase, and database time of different requests help you quickly identify database workload characteristics and performance bottlenecks.
- Key metrics and resource utilization: Contains database QPS, connection information, request command types between the applications and the database, database internal TSO and KV request OPS, and TiDB/TiKV resource usage.
- Top-down latency breakdown: Contains a comparison of query latency and connection idle time, breakdown of query latency, latency of TSO requests and KV requests in SQL execution, and breakdown of TiKV internal write latency.

Database time and SQL execution time overview

The database time metric is the sum of the latency that TiDB processes SQL per second, which is also the total time that TiDB concurrently processes application SQL requests per second (equal to the number of active connections).

The Performance Overview dashboard provides the following three stacked area graphs. They help you understand database workload profile and quickly identify the bottleneck causes in terms of statements, sql phase, and TiKV or PD request type during SQL execution.

- Database Time By SQL Type
- Database Time By SQL Phase
- SQL Execute Time Overview

Tune by color

The diagrams of database time breakdown and execution time overview present both expected and unexpected time consumption intuitively. Therefore, you can quickly identify

performance bottleneck and learn the workload profile. Green and blue areas stand for normal time consumption and requests. If non-green or non-blue areas occupy a significant proportion in these two diagrams, the database time distribution is inappropriate.

- Database Time By SQL Type:
  - Blue: `Select` statement
  - Green: `Update`, `Insert`, `Commit` and other DML statements
  - Red: General SQL types, including `StmtPrepare`, `StmtReset`, `StmtFetch`, and `StmtClose`
- Database Time By SQL Phase: The SQL execution phase is in green and other phases are in red on general. If non-green areas are large, it means much database time is consumed in other phases than the execution phase and further cause analysis is required. A common scenario is that the compile phase shown in orange takes a large area due to unavailability of prepared plan cache.
- SQL Execute Time Overview: Green metrics stand for common KV write requests (such as `Prewrite` and `Commit`), blue metrics stand for common KV read requests (such as Cop and Get), purple metrics stand for TiFlash MPP requests, and metrics in other colors stand for unexpected situations which you need to pay attention. For example, pessimistic lock KV requests are marked red and TSO waiting is marked dark brown. If non-blue or non-green areas are large, it means there is bottleneck during SQL execution. For example:
  - If serious lock conflicts occur, the red area will take a large proportion.
  - If excessive time is consumed in waiting TSO, the dark brown area will take a large proportion.

Example 1: TPC-C workload

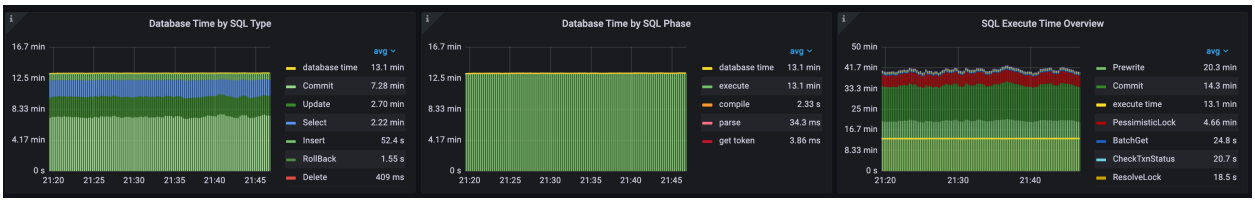

Figure 327: TPC-C

- Database Time by SQL Type: Most time-consuming statements are `commit`, `update`, `select`, and `insert` statements.
- Database Time by SQL Phase: The most time-consuming phase is SQL execution in green.

- SQL Execute Time Overview: The most time-consuming KV requests in SQL execution are `Prewrite` and `Commit` in green.

> **Note:**
>
> It is normal that the total KV request time is greater than the execute time. Because the TiDB executor may send KV requests to multiple TiKVs concurrently, causing the total KV request wait time to be greater than the execute time. In the preceding TPC-C workload, TiDB sends `Prewrite` and `Commit` requests concurrently to multiple TiKVs when a transaction is committed. Therefore, the total time for `Prewrite`, `Commit` , and `PessimisticLock` requests in this example is obviously longer than the execute time.
>
> - The `execute` time may also be significantly greater than the total time of the KV request plus the `tso_wait` time. This means that the SQL execution time is spent mostly inside the TiDB executor. Here are two common examples:

```
> - Example 1: After TiDB executor reads a large amount of data from
    ↪ TiKV, it needs to do complex join and aggregation inside TiDB,
    ↪ which consumes a lot of time.
> - Example 2: The application experiences serious write statement lock
    ↪  conflicts. Frequent lock retries result in long `Retried
    ↪ execution time`.
```

Example 2: OLTP read-heavy workload

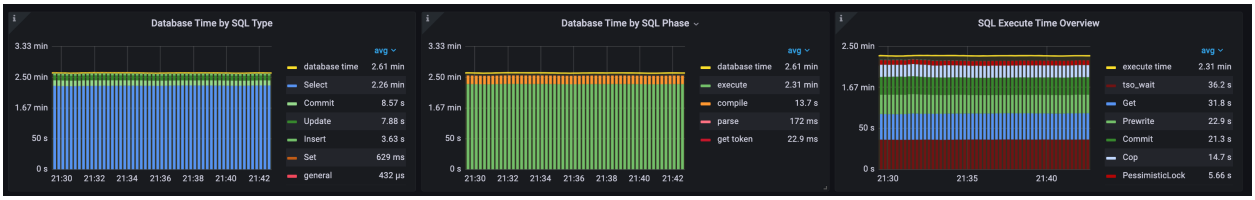

Figure 328: OLTP

- Database Time by SQL Type: Major time-consuming statements are `SELECT`, `COMMIT`, `UPDATE`, and `INSERT`, among which `SELECT` consumes most database time.
- Database Time by SQL Phase: Most time is consumed in the `execute` phase in green.
- SQL Execute Time Overview: In SQL execution phase, `pd tso_wait` in dark brown, `KV Get` in blue, and `Prewrite` and `Commit` in green are time-consuming.

Example 3: Read-only OLTP workload

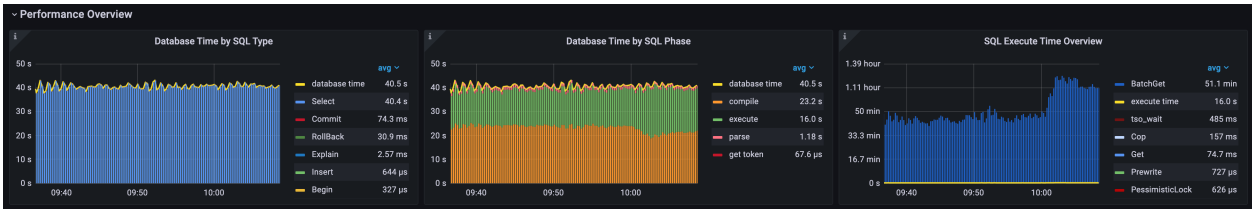

Figure 329: OLTP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Major time-consuming phases are `compile` in orange and `execute` in green. Latency in the `compile` phase is the highest, indicating that TiDB is taking too long to generate execution plans and the root cause needs to be further determined based on the subsequent performance data.
- SQL Execute Time Overview: The KV BatchGet requests in blue consume the most time during SQL execution.

> **Note:**
>
> In example 3, `SELECT` statements need to read thousands of rows concurrently from multiple TiKVs. Therefore, the total time of the `BatchGet` request is much longer than the execution time.

Example 4: Lock contention workload

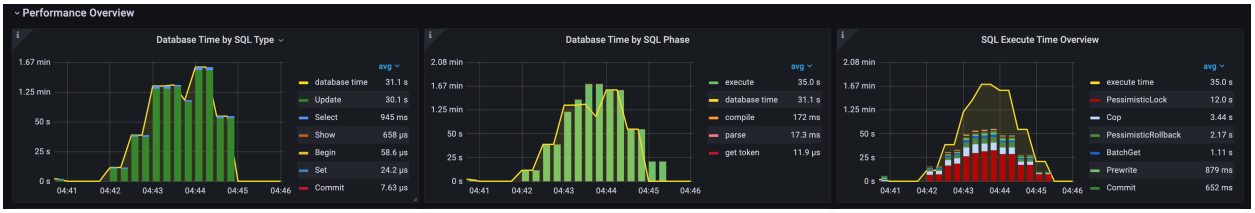

Figure 330: OLTP

- Database Time by SQL Type: Mainly are `UPDATE` statements.
- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The KV request PessimisticLock shown in red consumes the most time during SQL execution, and the execution time is obviously longer than

the total time of KV requests. This is caused by serious lock conflicts in write statements and frequent lock retries prolong `Retried execution time`. Currently, TiDB does not measure `Retried execution time`.

Example 5: HTAP CH-Benchmark workload

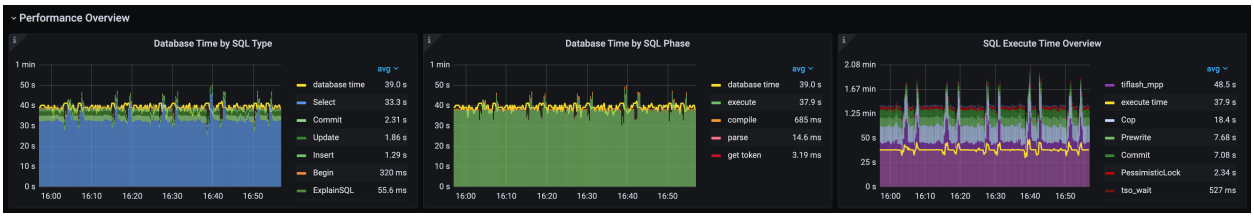

Figure 331: HTAP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The `tiflash_mpp` requests shown in purple consume the most time during SQL execution, followed by the KV requests, including the `Cop` requests in blue, and the `Prewrite` and `Commit` requests in green.

TiDB key metrics and cluster resource utilization

Query Per Second, Command Per Second, and Prepared-Plan-Cache

By checking the following three panels in Performance Overview, you can learn the application workload type, how the application interacts with TiDB, and whether the application fully utilizes TiDB prepared plan cache.

- QPS: Short for Query Per Second. It shows the count of SQL statements executed by the application.
- CPS By Type: Short for Command Per Second. Command indicates MySQL protocol-specific commands. A query statement can be sent to TiDB either by a query command or a prepared statement.
- Queries Using Plan Cache OPS: `avg-hit` is the number of queries using the execution plan cache per second in a TiDB cluster, and `avg-miss` is the number of queries not using the execution plan cache per second in a TiDB cluster.

  `avg-hit + avg-miss` is equal to `StmtExecute`, which is the number of all queries executed per second. When prepared plan cache is enabled in TiDB, the following three scenarios will occur:

  - No prepared plan cache is hit: `avg-hit` (the number of hits per second) is 0, and `avg-miss` is equal to the number of `StmtExecute` commands per second. The possible reasons include:

- The application is using the query interface.
- The cached plans are cleaned up because the application calls the `StmtClose` command after each `StmtExecute` execution.
- All statements executed by `StmtExecute` do not meet the cache conditions so the execution plan cache cannot be hit.

- All prepared plan cache is hit: `avg-hit` (the number of hits per second) is equal to the number of `StmtExecute` commands per second, and `avg-miss` (the number without hits per second) is 0.
- Some prepared plan cache is hit: `avg-hit` (the number of hits per second) is fewer than the number of `StmtExecute` commands per second. Prepared plan cache has known limitations. For example, it does not support subqueries, so SQL statements with subqueries cannot use prepared plan cache.

Example 1: TPC-C workload

The TPC-C workload are mainly `UPDATE`, `SELECT`, and `INSERT` statements. The total QPS is equal to the number of `StmtExecute` commands per second and the latter is almost equal to `avg-hit` on the Queries Using Plan Cache OPS panel. Ideally, the client caches the object of the prepared statement. In this way, the cached statement is called directly when a SQL statement is executed. All SQL executions hit the prepared plan cache, and there is no need to recompile to generate execution plans.

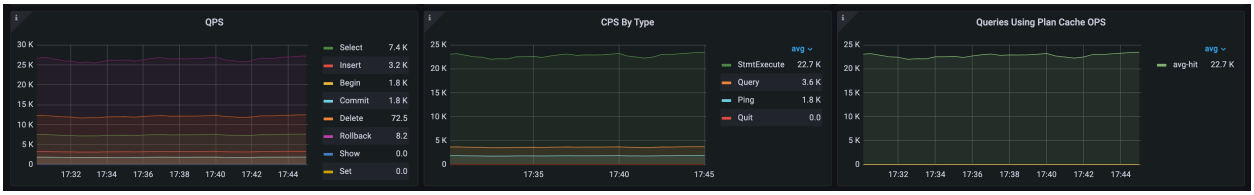

Figure 332: TPC-C

Example 2: Prepared plan cache unavailable for query commands in read-only OLTP workload

In this workload, `Commit QPS` = `Rollback QPS` = `Select QPS`. The application has enabled auto-commit concurrency, and rollback is performed every time a connection is fetched from the connection pool. As a result, these three statements are executed the same number of times.

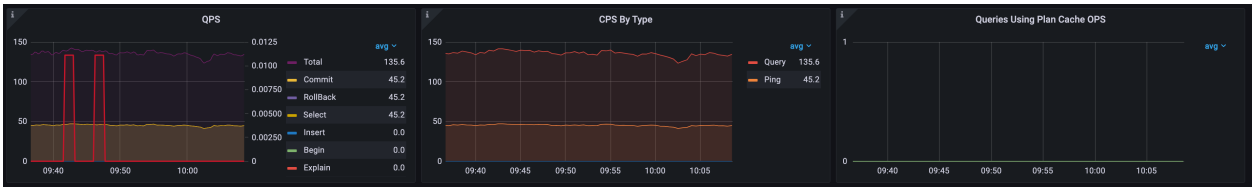

Figure 333: OLTP-Query

- The red bold line in the QPS panel stands for failed queries, and the Y-axis on the right shows the number of failed queries. A value other than 0 means the presence of failed queries.
- The total QPS is equal to the number of queries in the CPS By Type panel, the query command has been used by the application.
- The Queries Using Plan Cache OPS panel has no data, because prepared plan cache is unavailable for query command. This means that TiDB needs to parse and generate an execution plan for every query execution. As a result, the compile time is longer with increasing CPU consumption by TiDB.

Example 3: Prepared plan cache unavailable with prepared statement enabled for OLTP workload

`StmtPrepare` times = `StmtExecute` times = `StmtClose` times ~= `StmtFetch` times. The application uses the prepare > execute > fetch > close loop. To prevent prepared statement object leak, many application frameworks call `close` after the `execute` phase. This creates two problems.

- A SQL execution requires four commands and four network round trips.
- Queries Using Plan Cache OPS is 0, indicating zero hit of prepared plan cache. The `StmtClose` command clears cached execution plans by default and the next `StmtPrepare` command needs to generate the execution plan again.

> **Note:**
>
> Starting from TiDB v6.0.0, you can prevent the `StmtClose` command from clearing cached execution plans via the global variable (`set global tidb _ignore_prepared_cache_close_stmt=on;`). In this way, subsequent executions can hit the prepared plan cache.

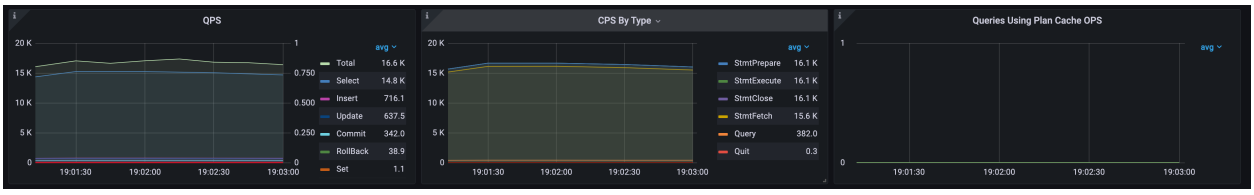

Figure 334: OLTP-Prepared

Example 4: Prepared statements have a resource leak

The number of `StmtPrepare` commands per second is much greater than that of `StmtClose` per second, which indicates that the application has an object leak for prepared statements.

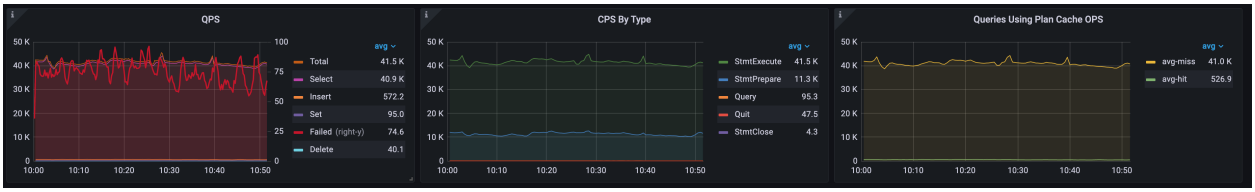

Figure 335: OLTP-Query

- In the QPS panel, the red bold line indicates the number of failed queries, and the Y axis on the right indicates the coordinate value of the number. In this example, the number of failed queries per second is 74.6.
- In the CPS By Type panel, the number of `StmtPrepare` commands per second is much greater than that of `StmtClose` per second, which indicates that an object leak occurs in the application for prepared statements.
- In the Queries Using Plan Cache OPS panel, `avg-miss` is almost equal to `StmtExecute` in the CPS By Type panel, which indicates that almost all SQL executions miss the execution plan cache.

KV/TSO Request OPS and KV Request Time By Source

- In the KV/TSO Request OPS panel, you can view the statistics of KV and TSO requests per second. Among the statistics, `kv request total` represents the sum of all requests from TiDB to TiKV. By observing the types of requests from TiDB to PD and TiKV, you can get an idea of the workload profile within the cluster.
- In the KV Request Time By Source panel, you can view the time ratio of each KV request type and all request sources.
    - kv request total time: The total time of processing KV and TiFlash requests per second.
    - Each KV request and the corresponding request source form a stacked bar chart, in which `external` identifies normal business requests and `internal` identifies internal activity requests (such as DDL and auto analyze requests).

Example 1: Busy workload

Figure 336: TPC-C

In this TPC-C workload:

- The total number of KV requests per second is 79,700. The top request types are `Prewrite`, `Commit`, `PessimisticLock`, and `BatchGet` in order of number of requests.
- Most of the KV processing time is spent on `Commit-external_Commit` and `Prewrite-external_Commit`, which indicates that the most time-consuming KV requests are `Commit` and `Prewrite` from external commit statements.

Example 2: Analyze workload

Figure 337: OLTP

In this workload, only `ANALYZE` statements are running in the cluster:

- The total number of KV requests per second is 35.5 and the number of Cop requests per second is 9.3.
- Most of the KV processing time is spent on `Cop-internal_stats`, which indicates that the most time-consuming KV request is `Cop` from internal `ANALYZE` operations.

CPU and memory usage

In the CPU/Memory panels of TiDB, TiKV, and PD, you can monitor their respective logical CPU usage and memory consumption, such as average CPU, maximum CPU, delta CPU (maximum CPU usage minus minimum CPU usage), CPU quota, and maximum memory usage. Based on these metrics, you can determine the overall resource usage of TiDB, TiKV, and PD.

- Based on the `delta` value, you can determine if CPU usage in TiDB or TiKV is unbalanced. For TiDB, a high `delta` usually means unbalanced application connections among the TiDB instances; For TiKV, a high `delta` usually means there are read/write hot spots in the cluster.
- With an overview of TiDB, TiKV, and PD resource usage, you can quickly determine if there are resource bottlenecks in your cluster and whether TiKV, TiDB, or PD needs scale-out or scale-up.

Example 1: High TiKV resource usage

In the following TPC-C workload, each TiDB and TiKV is configured with 16 CPUs. PD is configured with 4 CPUs.

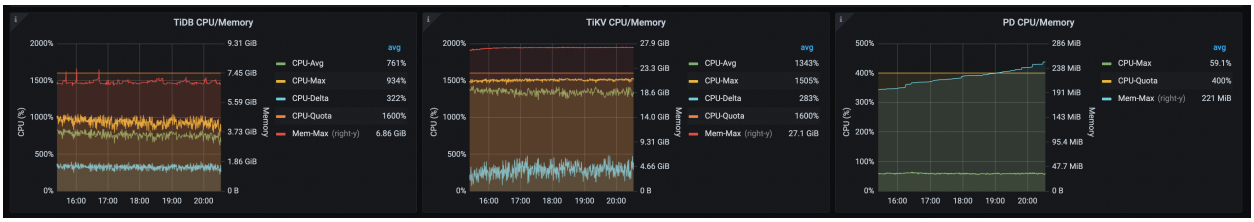

Figure 338: TPC-C

- The average, maximum, and delta CPU usage of TiDB are 761%, 934%, and 322%, respectively. The maximum memory usage is 6.86 GiB.
- The average, maximum, and delta CPU usage of TiKV are 1343%, 1505%, and 283%, respectively. The maximum memory usage is 27.1 GiB.
- The maximum CPU usage of PD is 59.1%. The maximum memory usage is 221 MiB.

Obviously, TiKV consumes more CPU, which is expected because TPC-C is a write-heavy scenario. To improve performance, it is recommended to scale out TiKV.

Data traffic

The read and write traffic panels offer insights into traffic patterns within your TiDB cluster, allowing you to monitor data flow from clients to the database and between internal components comprehensively.

- Read traffic
    - `TiDB -> Client`: the outbound traffic statistics from TiDB to the client
    - `Rocksdb -> TiKV`: the data flow that TiKV retrieves from RocksDB during read operations within the storage layer
- Write traffic
    - `Client -> TiDB`: the inbound traffic statistics from the client to TiDB

- `TiDB -> TiKV: general`: the rate at which foreground transactions are written from TiDB to TiKV
- `TiDB -> TiKV: internal`: the rate at which internal transactions are written from TiDB to TiKV
- `TiKV -> Rocksdb`: the flow of write operations from TiKV to RocksDB
- `RocksDB Compaction`: the total read and write I/O flow generated by RocksDB compaction operations. If `RocksDB Compaction` is significantly higher than `TiKV -> Rocksdb`, and your average row size is larger than 512 bytes, you can enable Titan to reduce the compaction I/O flow as follows, with min-blob-size set to `"512B"` or `"1KB"` and blob-file-compression set to `"zstd"`.

```
[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"
```

Example 1: Read and write traffic in the TPC-C workload

The following is an example of read and write traffic in the TPC-C workload.

- Read traffic
  - `TiDB -> Client`: 14.2 MB/s
  - `Rocksdb -> TiKV`: 469 MB/s. Note that both read operations (`SELECT` statements) and write operations (`INSERT`, `UPDATE`, and `DELETE` statements) require reading data from RocksDB into TiKV before committing a transaction.
- Write traffic
  - `Client -> TiDB`: 5.05 MB/s
  - `TiDB -> TiKV: general`: 13.1 MB/s
  - `TiDB -> TiKV`: internal: 5.07 KB/s
  - `TiKV -> Rocksdb`: 109 MB/s
  - `RocksDB Compaction`: 567 MB/s

Figure 339: TPC-C

Example 2: Write traffic before and after Titan is enabled

The following example shows the performance changes before and after Titan is enabled. For an insert workload with 6 KB records, Titan significantly reduces write traffic and compaction I/O, enhancing overall performance and resource utilization of TiKV.

- Write traffic before Titan is enabled
    - `Client -> TiDB`: 510 MB/s
    - `TiDB -> TiKV: general`: 187 MB/s
    - `TiDB -> TiKV: internal`: 3.2 KB/s
    - `TiKV -> Rocksdb`: 753 MB/s
    - `RocksDB Compaction`: 10.6 GB/s

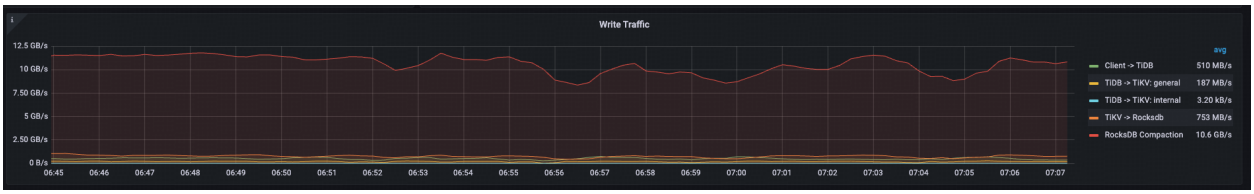

Figure 340: Titan Disable

- Write traffic after Titan is enabled
    - `Client -> TiDB`: 586 MB/s
    - `TiDB -> TiKV: general`: 295 MB/s
    - `TiDB -> TiKV: internal`: 3.66 KB/s
    - `TiKV -> Rocksdb`: 1.21 GB/s
    - `RocksDB Compaction`: 4.68 MB/s

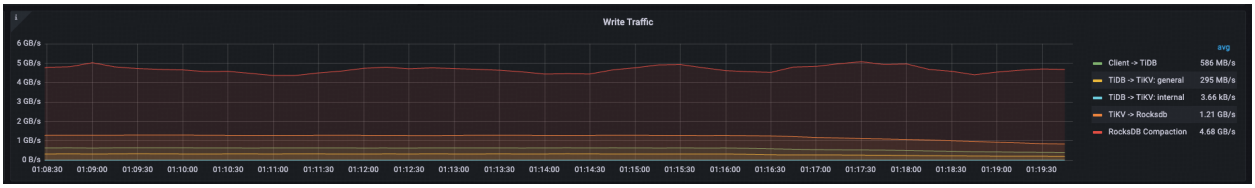

Figure 341: Titan Enable

Query latency breakdown and key latency metrics

The latency panel provides average values and 99th percentile. The average values help identify the overall bottleneck, while the 99th or 999th percentile or 999th helps determine whether there is a significant latency jitter.

Duration, Connection Idle Duration, and Connection Count

The Duration panel contains the average and P99 latency of all statements, and the average latency of each SQL type. The Connection Idle Duration panel contains the average and the P99 connection idle duration. Connection idle duration includes the following two states:

- in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is within a transaction.
- not-in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is not within a transaction.

An applications perform transactions with the same database connection. By comparing the average query latency with the connection idle duration, you can determine if TiDB is the bottleneck for overall system, or if user response time jitter is caused by TiDB.

- If the application workload is not read-only and contains transactions, by comparing the average query latency with `avg-in-txn`, you can determine the proportion in processing transactions inside and outside the database, and identify the bottleneck in user response time.
- If the application workload is read-only or autocommit mode is on, you can compare the average query latency with `avg-not-in-txn`.

In real customer scenarios, it is not rare that the bottleneck is outside the database, for example:

- The client server configuration is too low and the CPU resources are exhausted.
- HAProxy is used as a TiDB cluster proxy, and the HAProxy CPU resource is exhausted.
- HAProxy is used as a TiDB cluster proxy, and the network bandwidth of the HAProxy server is used up under high workload.
- The network latency from the application server to the database is high. For example, the network latency is high because in public-cloud deployments the applications and the TiDB cluster are not in the same region, or the dns workload balancer and the TiDB cluster are not in the same region.
- The bottleneck is in client applications. The application server's CPU cores and Numa resources cannot be fully utilized. For example, only one JVM is used to establish thousands of JDBC connections to TiDB.

In the Connection Count panel, you can check the total number of connections and also the number of connections on each TiDB node, which helps you determine whether the total number of connections is normal and whether the number of connections on each TiDB node is unbalanced. `active connections` indicates the number of active connections, which is equal to the database time per second. The Y axis on the right (`disconnection/s`) indicates

the number of disconnections per second in a cluster, which can be used to determine whether the application uses short connections.

Example 1: The number of disconnection/s is too high

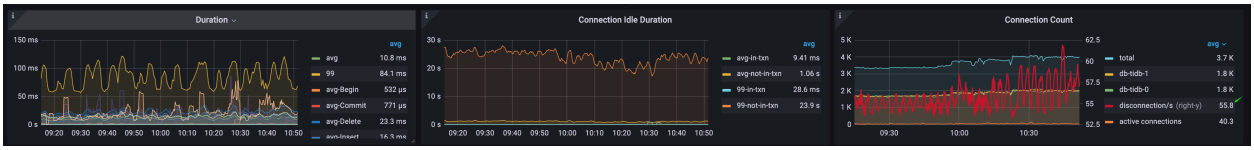

Figure 342: high disconnection/s

In this workload:

- The average latency and P99 latency of all SQL statements are 10.8 ms and 84.1 ms, respectively.
- The average connection idle time in transactions `avg-in-txn` is 9.4 ms.
- The total number of connections to the cluster is 3,700, and the number of connections to each TiDB node is 1,800. The average number of active connections is 40.3, which indicates that most of the connections are idle. The average number of `disconnection /s` is 55.8, which indicates that the application is connecting and disconnecting frequently. The behavior of short connections will have a certain impact on TiDB resources and response time.

Example 2: TiDB is the bottleneck of user response time

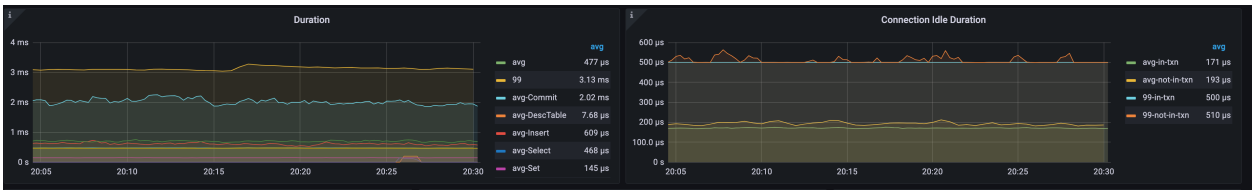

Figure 343: TiDB is the Bottleneck

In this TPC-C workload:

- The average latency and P99 latency of all SQL statements are 477 us and 3.13 ms, respectively. The average latencies of the commit statement, insert statement, and query statement are 2.02 ms, 609 us, and 468 us, respectively.
- The average connection idle time in transactions `avg-in-txn` is 171 us.

The average query latency is significantly greater than `avg-in-txn`, which means the main bottleneck in transactions is inside the database.

Example 3: TiDB is not the bottleneck of user response time

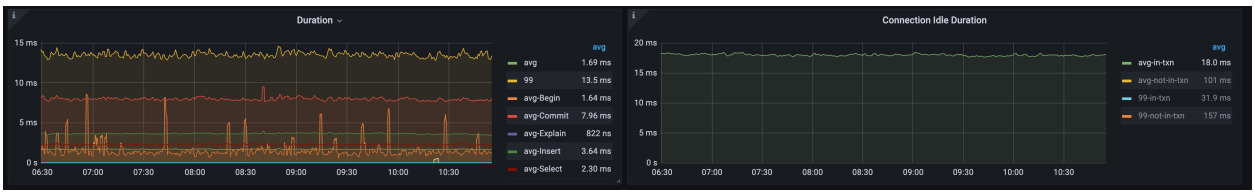

Figure 344: TiDB is not Bottleneck

In this workload, the average query latency is 1.69 ms and `avg-in-txn` is 18 ms, indicating that TiDB spends 1.69 ms on average to process a SQL statement in transactions, and then needs to wait for 18 ms to receive the next statement.

The average query latency is significantly lower than `avg-in-txn`. The bottleneck of user response time is not in TiDB. This example is in a public cloud environment, where high network latency between the application and the database results in extremely high connection idle time, because the application and the database are not in the same region.

Parse, Compile, and Execute Duration

In TiDB, there is a typical processing flow from sending query statements to returning results.

SQL processing in TiDB consists of four phases, `get token`, `parse`, `compile`, and `execute`.

- `get token`: Usually only a few microseconds and can be ignored. The token is limited only when the number of connections to a single TiDB instance reaches the token-limit limit.
- `parse`: The query statements are parsed into abstract syntax tree (AST).
- `compile`: Execution plans are compiled based on the AST from the `parse` phase and statistics. The `compile` phase contains logical optimization and physical optimization. Logical optimization optimizes query plans by rules, such as column pruning based on relational algebra. Physical optimization estimates the cost of the execution plans by statistics by a cost-based optimizer and selects a physical execution plan with the lowest cost.
- `execute`: The time consumption to execute a SQL statement. TiDB first waits for the globally unique timestamp TSO. Then the executor constructs the TiKV API request based on the Key range of the operator in the execution plan and distributes it to TiKV. `execute` time includes the TSO wait time, the KV request time, and the time spent by TiDB executor in processing data.

If an application uses the `query` or `StmtExecute` MySQL command interface only, you can use the following formula to identify the bottleneck in average latency.

```
avg Query Duration = avg Get Token + avg Parse Duration + avg Compile
    ↪ Duration + avg Execute Duration
```

Usually, the `execute` phase accounts for the most of the `query` latency. However, the `parse` and `compile` phases can also take a large part in the following cases:

- Long latency in the `parse` phase: For example, when the `query` statement is long, much CPU will be consumed to parse the SQL text.
- Long latency in the `compile` phase: If the prepared plan cache is not hit, TiDB needs to compile an execution plan for every SQL execution. The latency in the `compile` phase can be several or tens of milliseconds or even higher. If prepared plan cache is not hit, logical and physical optimization are done in the `compile` phase, which consumes a lot of CPU and memory, makes Go Runtime (TiDB is written in Go) under pressure, and affects the performance of other TiDB components. Prepared plan cache is important for efficient processing of OLTP workload in TiDB.

Example 1: Database bottleneck in the `compile` phase

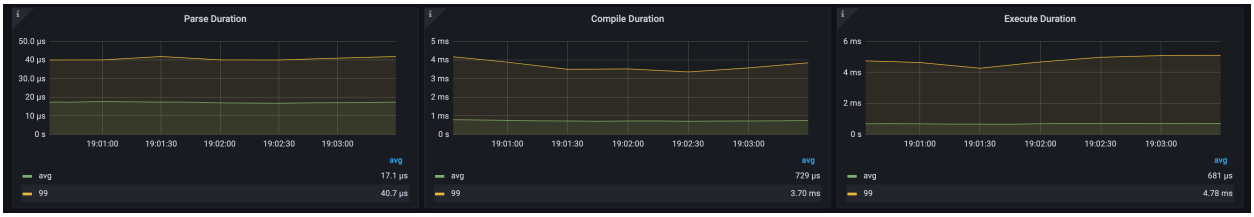

Figure 345: Compile

In the preceding figure, the average time of the `parse`, `compile`, and `execute` phases are 17.1 us, 729 us, and 681 us, respectively. The `compile` latency is high because the application uses the `query` command interface and cannot use prepared plan cache.

Example 2: Database bottleneck in the `execute` phase

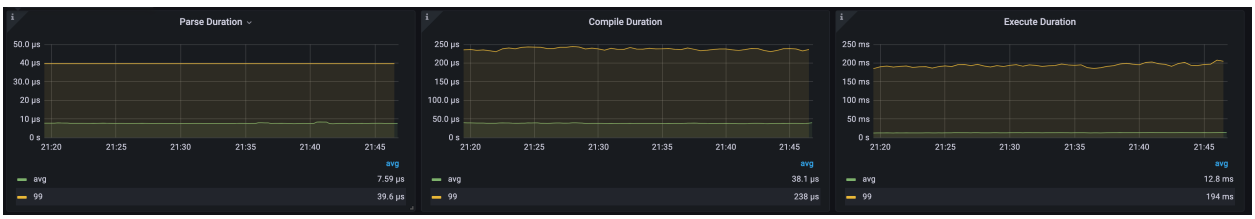

Figure 346: Execute

In this TPC-C workload, the average time of `parse`, `compile` and `execute` phases are 7.39 us, 38.1 us, and 12.8 ms, respectively. The `execute` phase is the bottleneck of the `query` latency.

KV and TSO Request Duration

TiDB interacts with PD and TiKV in the `execute` phase. As shown in the following figure, when processing SQL request, TiDB requests TSOs before entering the `parse` and `compile` phases. The PD Client does not block the caller, but returns a `TSFuture` and asynchronously sends and receives the TSO requests in the background. Once the PD client finishes handling the TSO requests, it returns `TSFuture`. The holder of the `TSFuture` needs to call the Wait method to get the final TSOs. After TiDB finishes the `parse` and `compile` phases, it enters the `execute` phase, where two situations might occur:

- If the TSO request has completed, the Wait method immediately returns an available TSO or an error
- If the TSO request has not yet completed, the Wait method is blocked until a TSO is available or an error appears (the gRPC request has been sent but no result is returned, and the network latency is high)

The TSO wait time is recorded as `TSO WAIT` and the network time of the TSO request is recorded as `TSO RPC`. After the TSO wait is complete, TiDB executor usually sends read or write requests to TiKV.

- Common KV read requests: `Get`, `BatchGet`, and `Cop`
- Common KV write requests: `PessimisticLock`, `Prewrite` and `Commit` for two-phase commits

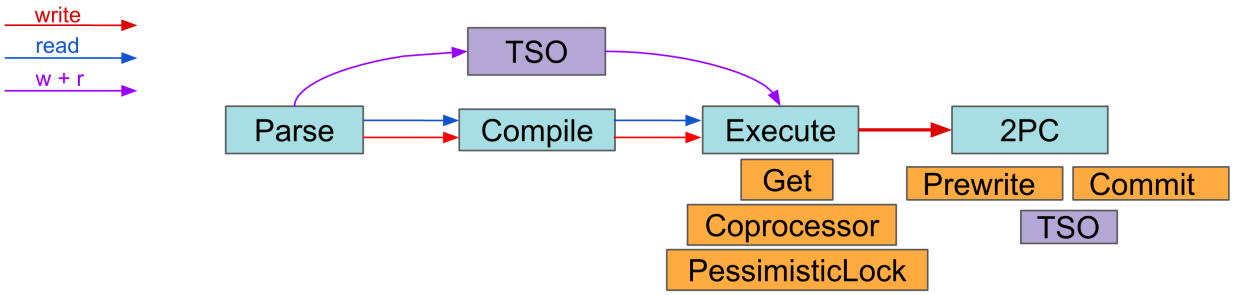

Figure 347: Execute

The indicators in this section correspond to the following three panels.

- Avg TiDB KV Request Duration: The average latency of KV requests measured by TiDB

- Avg TiKV GRPC Duration: The average latency in processing gPRC messages in TiKV
- PD TSO Wait/RPC Duration: TiDB executor TSO wait time and network latency for TSO requests (RPC)

The relationship between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is as follows:

```
Avg TiDB KV Request Duration = Avg TiKV GRPC Duration + Network latency between TiDB and TiKV + TiKV gRPC processing time + TiDB gRPC processing time and scheduling latency
```

The difference between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is closely related to the network traffic, network latency, and resource usage by TiDB and TiKV.

- In the same data center: The difference is generally less than 2 ms.
- In different availability zones in the same region: The difference is generally less than 5 ms.

Example 1: Low workload of clusters deployed on the same data center

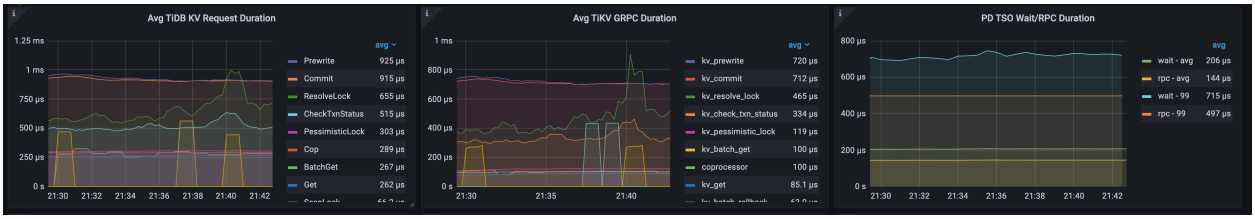

Figure 348: Same Data Center

In this workload, the average `Prewrite` latency on TiDB is 925 us, and the average `kv_prewrite` processing latency inside TiKV is 720 us. The difference is about 200 us, which is normal in the same data center. The average TSO wait latency is 206 us, and the RPC time is 144 us.

Example 2: Normal workload on public cloud clusters

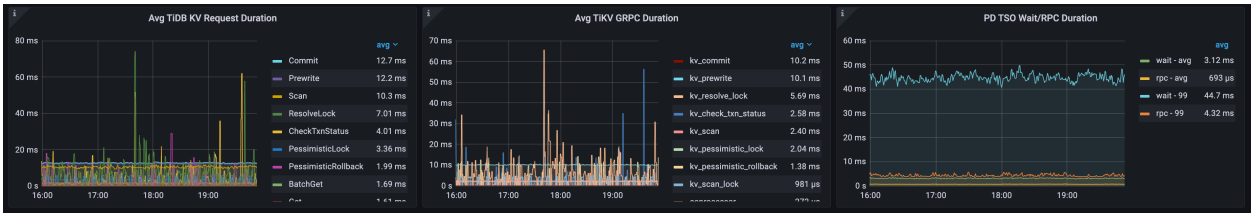

Figure 349: Cloud Env

In this example, TiDB clusters are deployed in different data centers in the same region. The average `commit` latency on TiDB is 12.7 ms, and the average `kv_commit` processing latency inside TiKV is 10.2 ms, a difference of about 2.5 ms. The average TSO wait latency is 3.12 ms, and the RPC time is 693 us.

Example 3: Resource overloaded on public cloud clusters

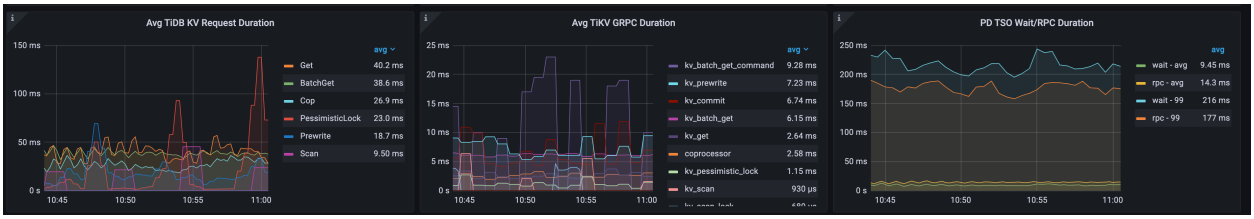

Figure 350: Cloud Env, TiDB Overloaded

In this example, the TiDB clusters are deployed in different data centers in the same region, and TiDB network and CPU resources are severely overloaded. The average `BatchGet` latency on TiDB is 38.6 ms, and the average `kv_batch_get` processing latency inside TiKV is 6.15 ms. The difference is more than 32 ms, which is much higher than the normal value. The average TSO wait latency is 9.45 ms and the RPC time is 14.3 ms.

Storage Async Write Duration, Store Duration, and Apply Duration

TiKV processes a write request in the following procedure:

- `scheduler worker` processes the write request, performs a transaction consistency check, and converts the write request into a key-value pair to be sent to the `raftstore` module.
- The TiKV consensus module `raftstore` applies the Raft consensus algorithm to make the storage layer (composed of multiple TiKVs) fault-tolerant.

  Raftstore consists of a `Store` thread and an `Apply` thread:

  - The `Store` thread processes Raft messages and new `proposals`. When a new `proposals` is received, the `Store` thread of the leader node writes to the local Raft DB and copies the message to multiple follower nodes. When this `proposals` is successfully persisted in most instances, the `proposals` is successfully committed.
  - The `Apply` thread writes the committed `proposals` to the KV DB. When the data is successfully written to the KV DB, the `Apply` thread notifies externally that the write request has completed.

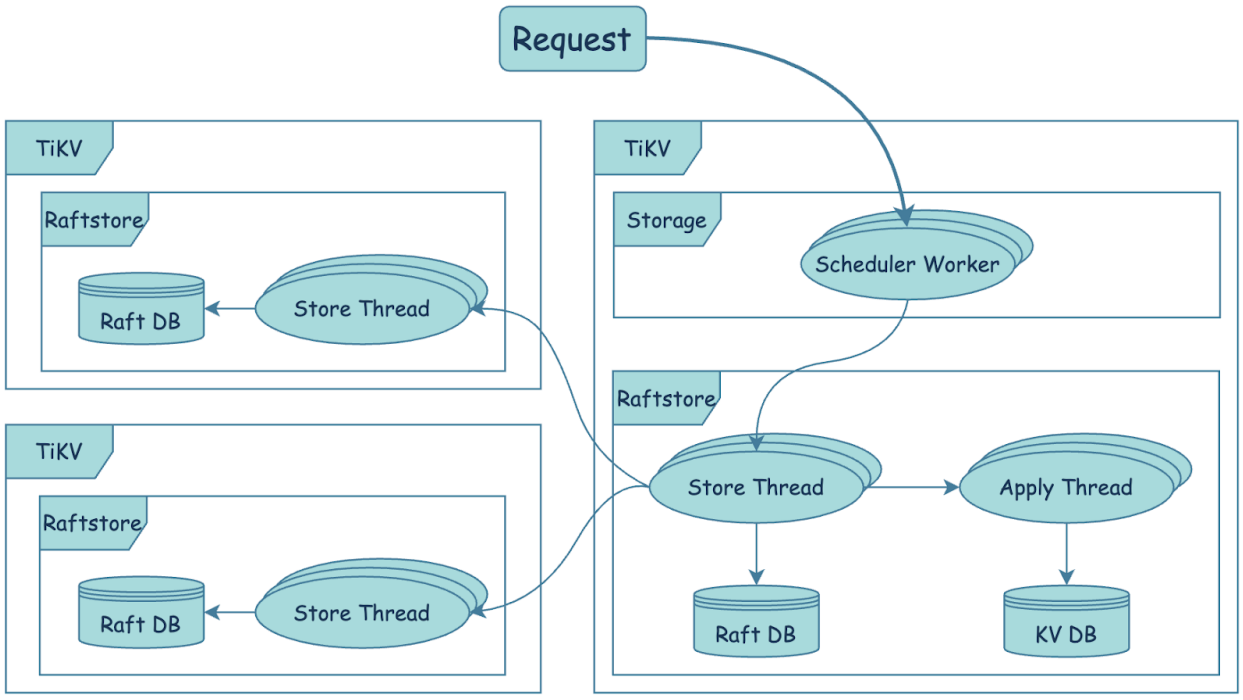

Figure 351: TiKV Write

The `Storage Async Write Duration` metric records the latency after a write request enters raftstore. The data is collected on a basis of per request.

The `Storage Async Write Duration` metric contains two parts, `Store Duration` and `Apply Duration`. You can use the following formula to determine whether the bottleneck for write requests is in the `Store` or `Apply` step.

```
avg Storage Async Write Duration = avg Store Duration + avg Apply Duration
```

> **Note:**
>
> `Store Duration` and `Apply Duration` are supported since v5.3.0.

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

According to the preceding formula, the QPS of a write-heavy OLTP workload in v5.4.0 is 14% higher than that in v5.3.0:

- v5.3.0: 24.4 ms ~= 17.7 ms + 6.59 ms
- v5.4.0: 21.4 ms ~= 14.0 ms + 7.33 ms

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Store Duration` compared with v5.3.0.

v5.3.0:

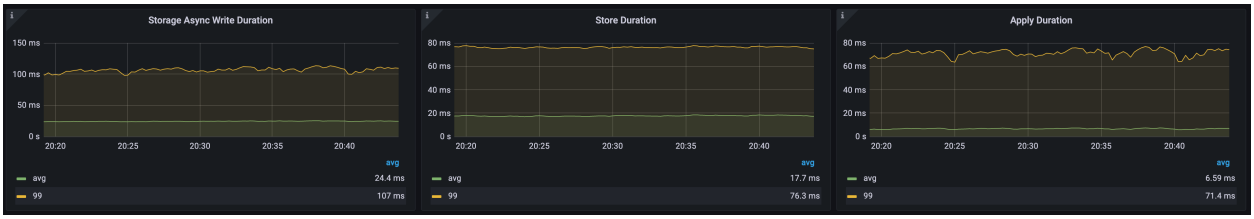

Figure 352: v5.3.0

v5.4.0:

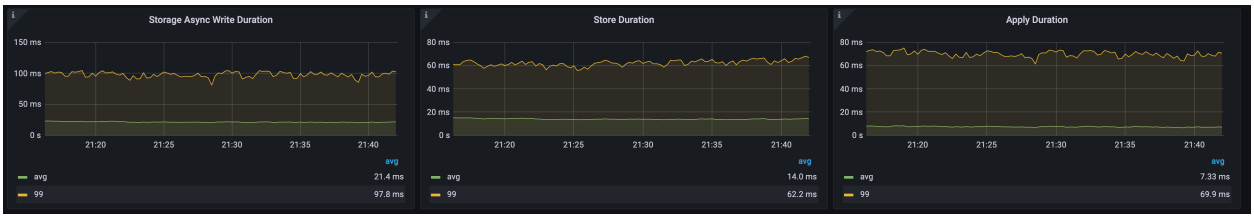

Figure 353: v5.4.0

Example 2: Store Duration is a bottleneck

Apply the preceding formula: 10.1 ms ~= 9.81 ms + 0.304 ms. The result indicates that the latency bottleneck for write requests is in `Store Duration`.

Figure 354: Store

Commit Log Duration, Append Log Duration, and Apply Log Duration

`Commit Log Duration`, `Append Log Duration`, and `Apply Log Duration` are latency metrics for key operations within raftstore. These latencies are captured at the batch operation level, with each operation combining multiple write requests. Therefore, the latencies do not directly correspond to the `Store Duration` and `Apply Duration` mentioned above.

- `Commit Log Duration` and `Append Log Duration` record time of operations performed in the `Store` thread. `Commit Log Duration` includes the time of copying Raft logs to other TiKV nodes (to ensure raft-log persistence). `Commit Log Duration` usually contains two `Append Log Duration` operations, one for the leader and the other for the follower. `Commit Log Duration` is usually significantly higher than `Append Log Duration`, because the former includes the time of copying Raft logs to other TiKV nodes through network.
- `Apply Log Duration` records the latency of `apply` Raft logs by the `Apply` thread.

Common scenarios where `Commit Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.store-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high, resulting in high `Append Log Duration` latency
- The network latency between TiKV nodes is high
- The number of the gRPC threads are too small, CPU usage is uneven among the GRPC threads.

Common scenarios where `Apply Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.apply-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

The QPS of a write-heavy OLTP workload in v5.4.0 is improved by 14% compared with that in v5.3.0. The following table compares the three key latencies.

Avg Duration	v5.3.0 (ms)	v5.4.0 (ms)
Append Log Duration	0.27	0.303
Commit Log Duration	13	8.68
Apply Log Duration	0.457	0.514

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Commit Log Duration` and `Store Duration` compared with v5.3.0.

v5.3.0:

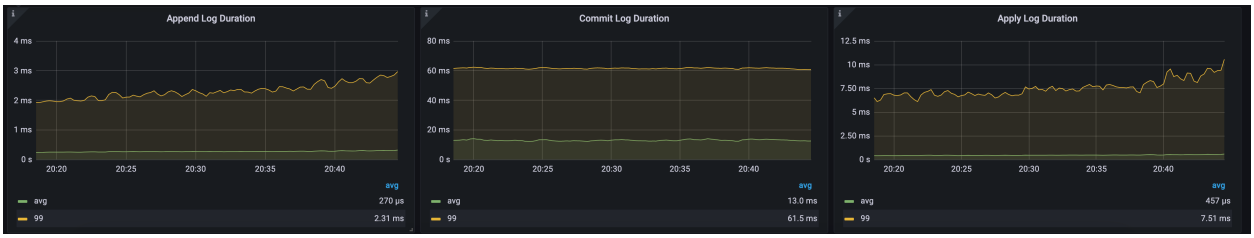

Figure 355: v5.3.0

v5.4.0:

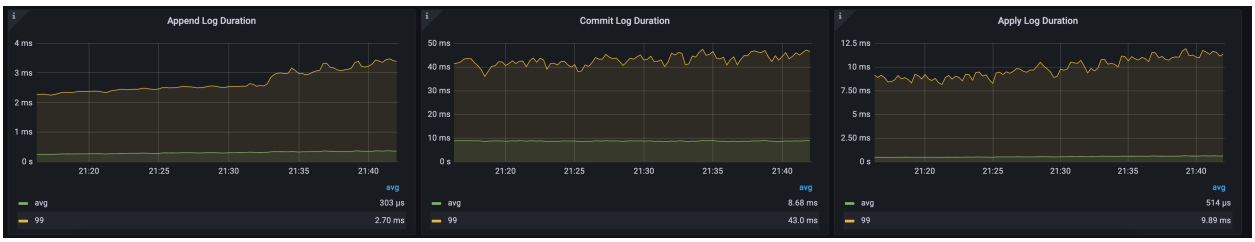

Figure 356: v5.4.0

Example 2: Commit Log Duration is a bottleneck

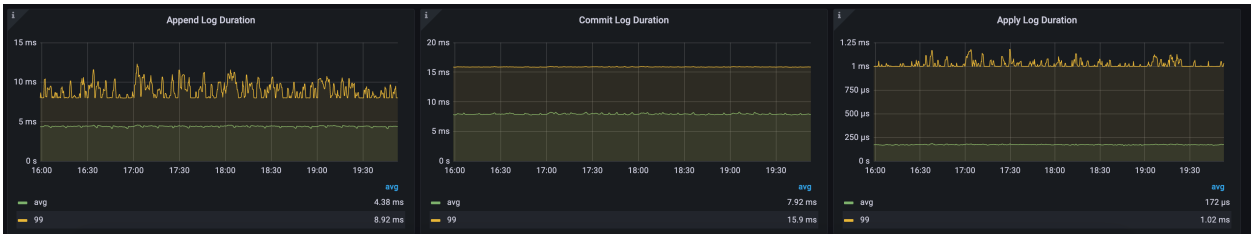

Figure 357: Store

- Average `Append Log Duration` = 4.38 ms
- Average `Commit Log Duration` = 7.92 ms
- Average `Apply Log Duration` = 172 us

For the `Store` thread, `Commit Log Duration` is obviously higher than `Apply Log Duration`. Meanwhile, `Append Log Duration` is significantly higher than `Apply Log Duration`, indicating that the `Store` thread might suffer from bottlenecks in both CPU and I/O. Possible ways to reduce `Commit Log Duration` and `Append Log Duration` are as follows:

- If TiKV CPU resources are sufficient, consider adding `Store` threads by increasing the value of `raftstore.store-pool-size`.
- If TiDB is v5.4.0 or later, consider enabling `Raft Engine` by setting `raft-engine.enable: true`. Raft Engine has a light execution path. This helps reduce I/O writes and long-tail latency of writes in some scenarios.
- If TiKV CPU resources are sufficient and TiDB is v5.3.0 or later, consider enabling `StoreWriter` by setting `raftstore.store-io-pool-size: 1`.

11.1.8.1.3 If my TiDB version is earlier than v6.1.0, what should I do to use the Performance Overview dashboard?

Starting from v6.1.0, Grafana has a built-in Performance Overview dashboard by default. This dashboard is compatible with TiDB v4.x and v5.x versions. If your TiDB is earlier than v6.1.0, you need to manually import `performance_overview.json`, as shown in the following figure:

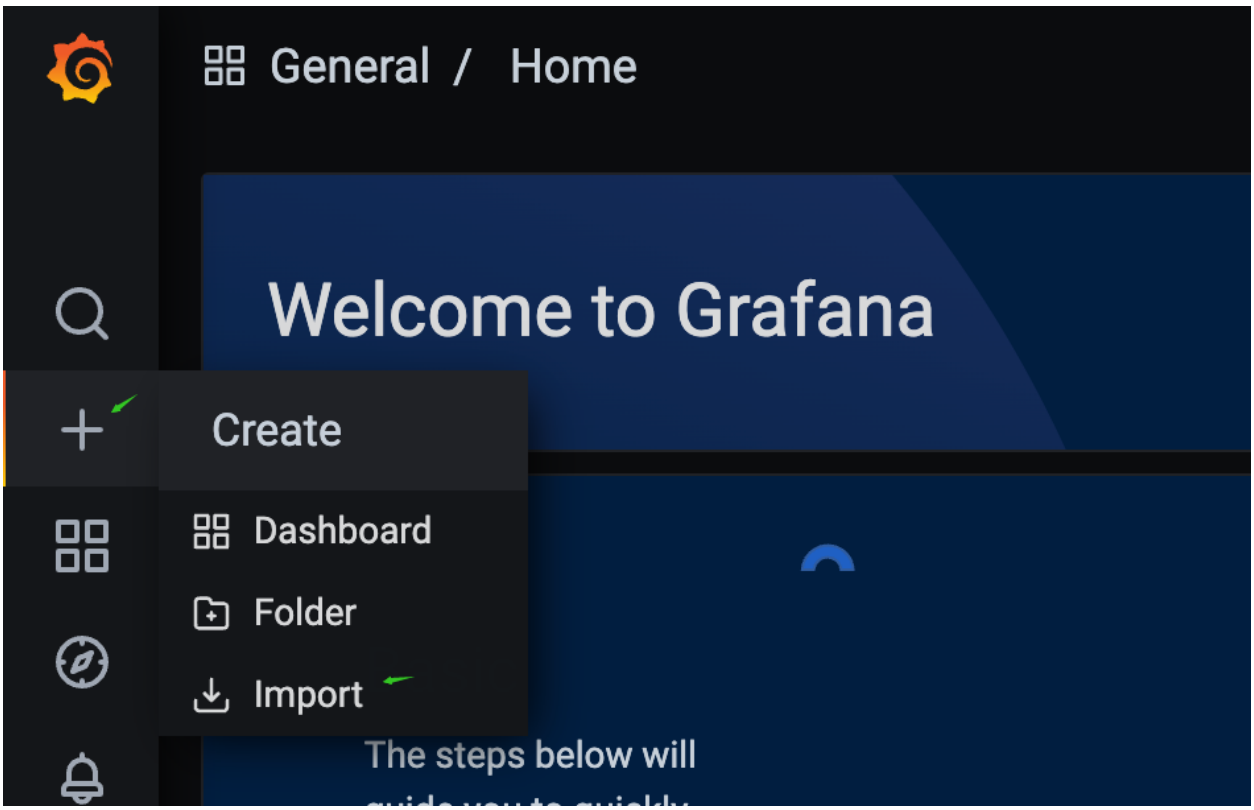

Figure 358: Store

11.1.8.2 Performance Tuning Practices for OLTP Scenarios

TiDB provides comprehensive performance diagnostics and analysis features, such as Top SQL and Continuous Profiling features on the TiDB Dashboard, and TiDB Performance Overview Dashboard.

This document describes how to use these features together to analyze and compare the performance of the same OLTP workload in seven different runtime scenarios, which demonstrates a performance tuning process to help you analyze and tune TiDB performance efficiently.

> **Note:**
>
> Top SQL and Continuous Profiling are not enabled by default. You need to enable them in advance.

By running the same application with different JDBC configurations in these scenarios, this document shows you how the overall system performance is affected by different interactions between applications and databases, so that you can apply Best Practices for Developing Java Applications with TiDB for better performance.

11.1.8.2.1 Environment description

This document takes a core banking OLTP workload for demonstration. The configurations of the simulation environment are as follows:

- Application development language for the workload: JAVA
- SQL statements used in business: 200 statements in total, 90% of which are SELECT statements. It is a typical read-heavy OLTP workload.
- Tables used in transactions: 60 tables in total. 12 tables involve update operations, and the rest 48 tables are read-only.
- Isolation level used by the application: `read committed`.
- TiDB cluster configuration: 3 TiDB nodes and 3 TiKV nodes, with 16 CPUs allocated to each node.
- Client server configuration: 36 CPUs.

11.1.8.2.2 Scenario 1. Use the Query interface

Application configuration

The application uses the following JDBC configuration to connect to the database through the Query interface.

```
useServerPrepStmts=false
```

Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that the non-business SQL type `SELECT @@session.tx_isolation` consumes the most resources. Although TiDB

processes these types of SQL statements quickly, these types of SQL statements have the highest number of executions that result in the highest overall CPU time consumption.

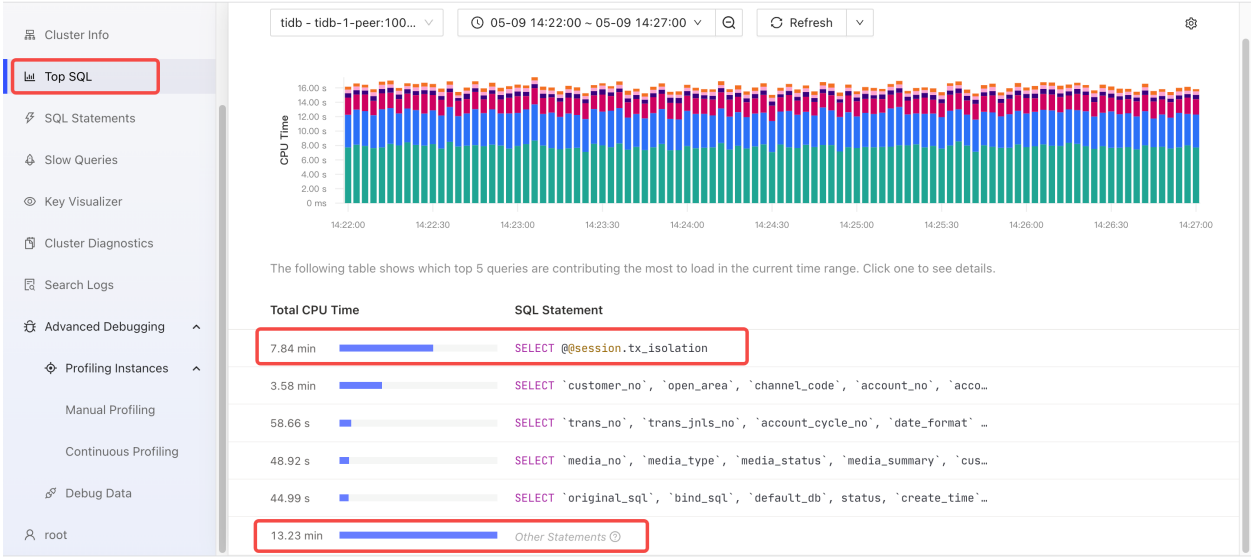

Figure 359: dashboard-for-query-interface

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is significant during the SQL execution. Because the application uses the Query interface, TiDB cannot use the execution plan cache. TiDB needs to compile and generate an execution plan for each SQL statement.

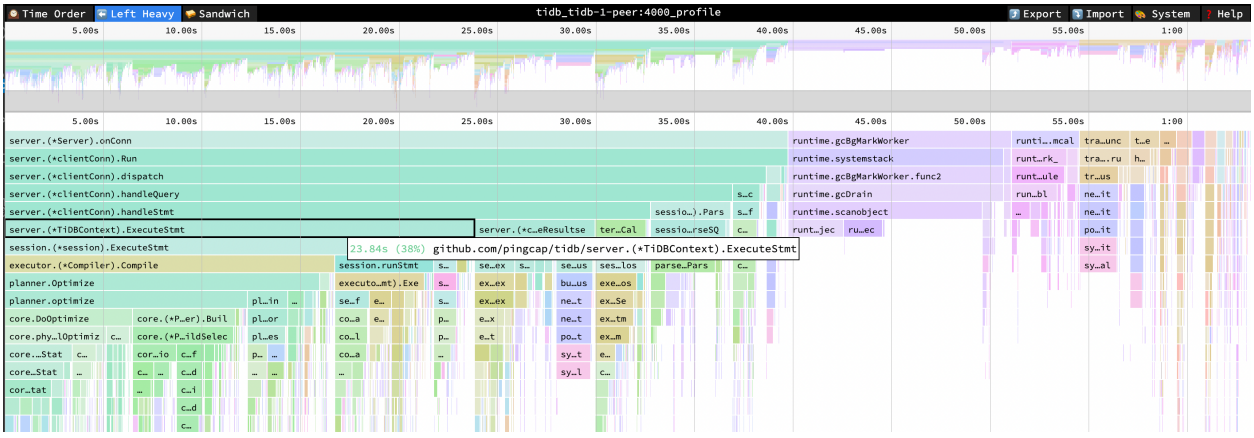

Figure 360: flame-graph-for-query-interface

- ExecuteStmt cpu = 38% cpu time = 23.84s
- Compile cpu = 27% cpu time = 17.17s
- Optimize cpu = 26% cpu time = 16.41s

Performance Overview dashboard

Check the database time overview and QPS in the following Performance Overview dashboard.

Figure 361: performance-overview-1-for-query-interface

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `tso wait` take most of the time.
- CPS By Type: only the `Query` command is used.
- Queries Using Plan Cache OPS: no data indicates that the execution plan cache is not hit.
- In the query duration, the latency of `execute` and `compile` takes the highest percentage.
- avg QPS = 56.8k

Check the resource consumption of the cluster: the average utilization of TiDB CPU is 925%, the average utilization of TiKV CPU is 201%, and the average throughput of TiKV IO is 18.7 MB/s. The resource consumption of TiDB is significantly higher.

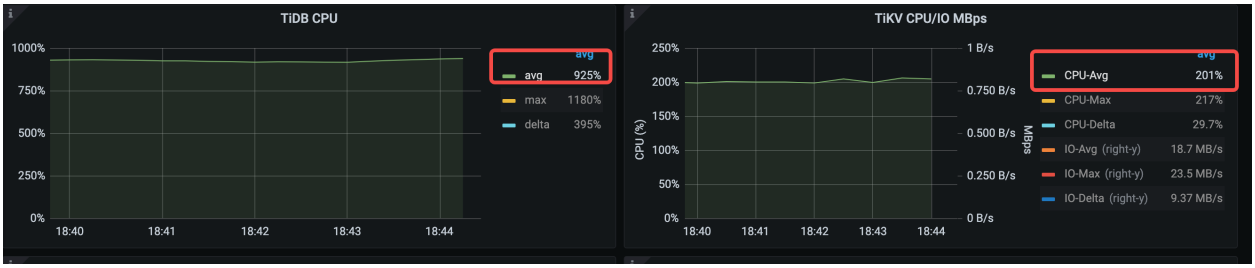

Figure 362: performance-overview-2-for-query-interface

Analysis conclusion

We need to eliminate these useless non-business SQL statements, which have a large number of executions and contribute to the high TiDB CPU usage.

11.1.8.2.3 Scenario 2. Use the maxPerformance configuration

Application configuration

The application adds a new parameter `useConfigs=maxPerformance` to the JDBC connection string in Scenario 1. This parameter can be used to eliminate the SQL statements sent from JDBC to the database (for example, `select @@session.transaction_read_only` ↪). The full configuration is as follows:

```
useServerPrepStmts=false&useConfigs=maxPerformance
```

Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that `SELECT` ↪ `@@session.tx_isolation`, which consumed the most resources, has disappeared.

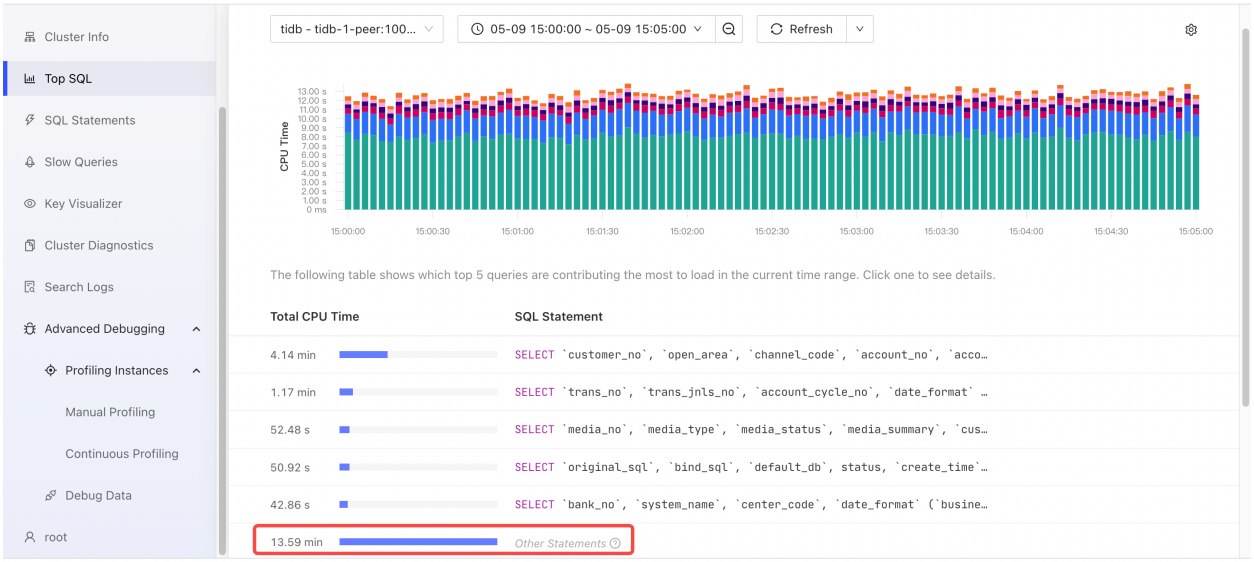

Figure 363: dashboard-for-maxPerformance

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is still significant during the SQL execution.

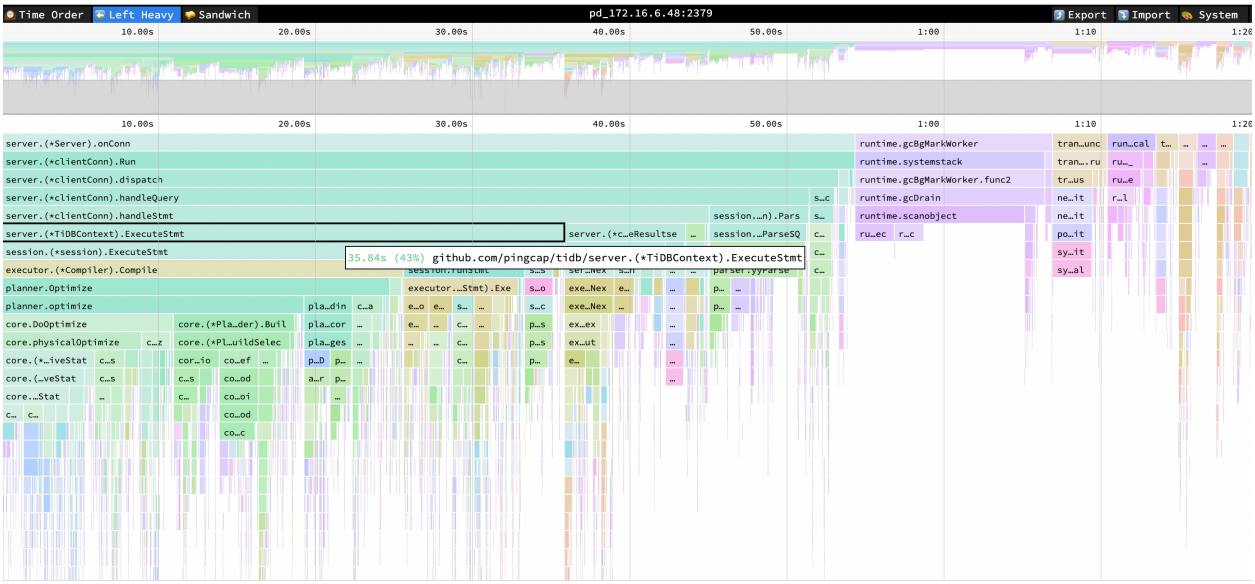

Figure 364: flame-graph-for-maxPerformance

- ExecuteStmt cpu = 43% cpu time =35.84s
- Compile cpu = 31% cpu time =25.61s
- Optimize cpu = 30% cpu time = 24.74s

Performance Overview dashboard

The data of the database time overview and QPS is as follows:

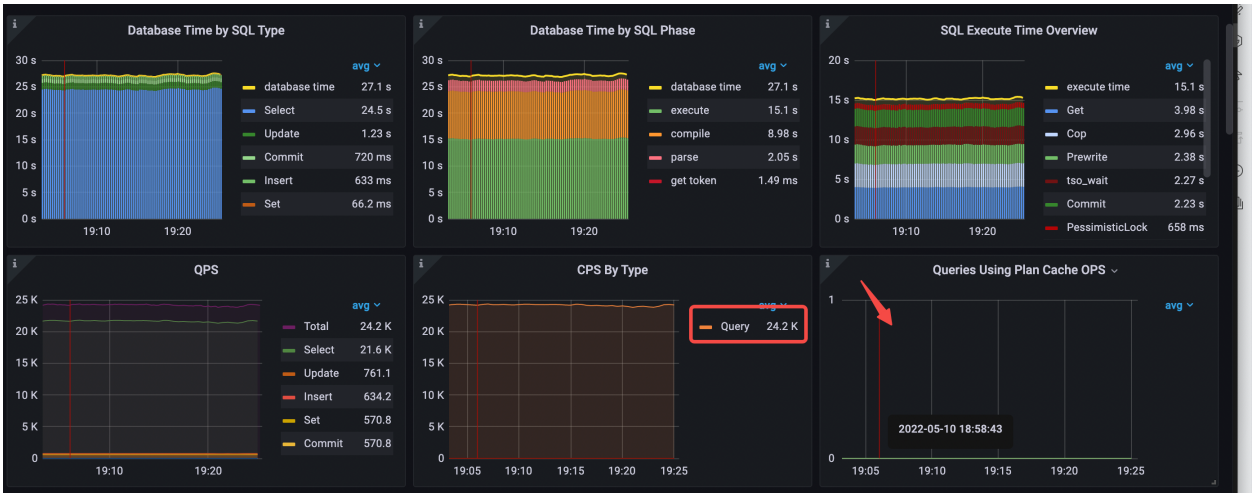

Figure 365: performance-overview-1-for-maxPerformance

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- In the database time, the latency of `execute` and `compile` takes the highest percentage.
- CPS By Type: only the `Query` command is used.
- avg QPS = 24.2k (from 56.3k to 24.2k)
- The execution plan cache is not hit.

From Scenario 1 to Scenario 2, the average TiDB CPU utilization drops from 925% to 874%, and the average TiKV CPU utilization increases from 201% to about 250%.

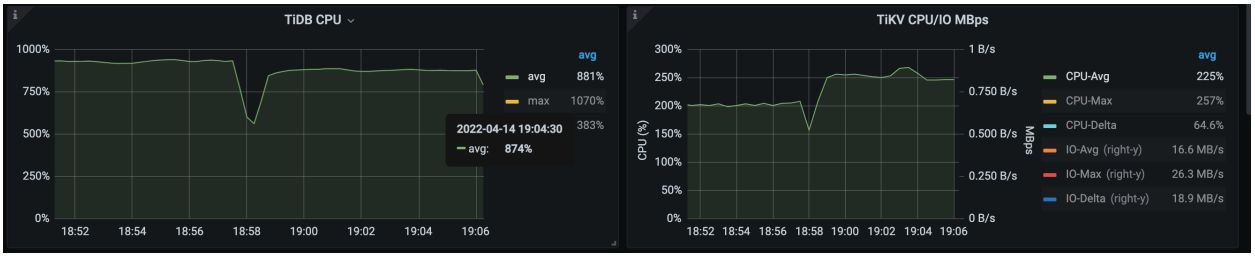

Figure 366: performance-overview-2-for-maxPerformance

The changes in key latency metrics are as follows:

Figure 367: performance-overview-3-for-maxPerformance

- avg query duration = 1.12ms (from 479 s to 1.12ms)
- avg parse duration = 84.7 s (from 37.2 s to 84.7 s)
- avg compile duration = 370 s (from 166 s to 370 s)
- avg execution duration = 626 s (from 251 s to 626 s)

Analysis conclusion

Compared with Scenario 1, the QPS of Scenario 2 has significantly decreased. The average query duration and average `parse`, `compile`, and `execute` durations have significantly increased. This is because SQL statements such as `select @@session.transaction_read_only` in Scenario 1, which are executed many times and have fast processing time, lower the average performance data. After Scenario 2 blocks such statements, only business-related SQL statements remain, so the average duration increases.

When the application uses the Query interface, TiDB cannot use the execution plan cache, which results in TiDB consuming high resources to compile execution plans. In this case, it is recommended that you use the Prepared Statement interface, which uses the execution plan cache of TiDB to reduce the TiDB CPU consumption caused by execution plan compiling and decrease the latency.

11.1.8.2.4 Scenario 3. Use the Prepared Statement interface with execution plan caching not enabled

Application configuration

The application uses the following connection configuration. Compared with Scenario 2, the value of the JDBC parameter `useServerPrepStmts` is modified to `true`, indicating that the Prepared Statement interface is enabled.

```
useServerPrepStmts=true&useConfigs=maxPerformance"
```

Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the CPU consumption of `CompileExecutePreparedStmt` and `Optimize` is still significant after the Prepared Statement interface is enabled.

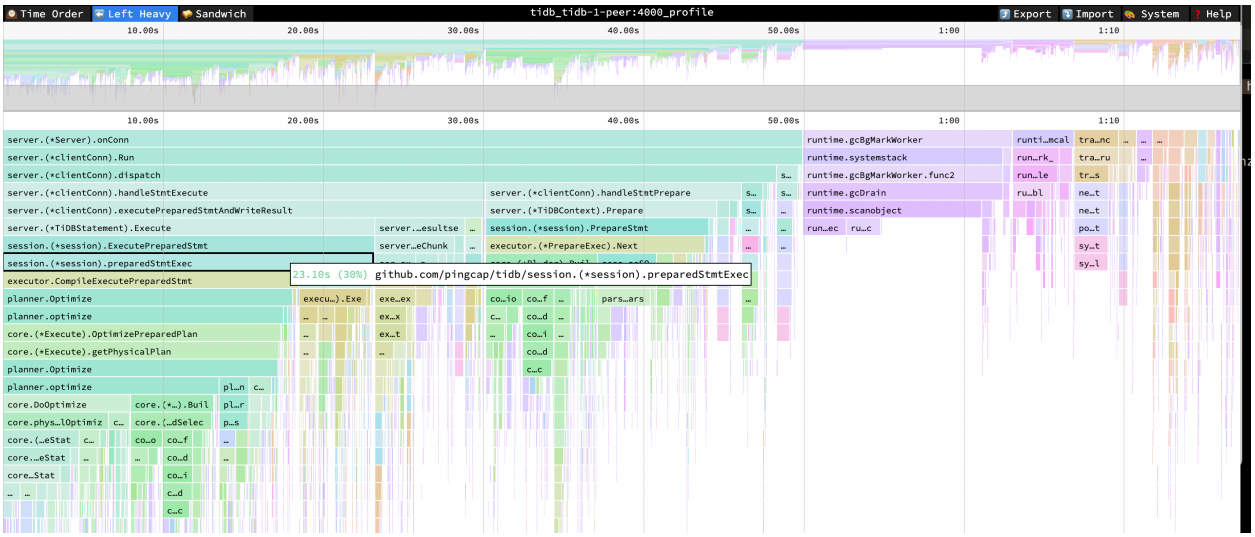

Figure 368: flame-graph-for-PrepStmts

- ExecutePreparedStmt cpu = 31% cpu time = 23.10s
- preparedStmtExec cpu = 30% cpu time = 22.92s
- CompileExecutePreparedStmt cpu = 24% cpu time = 17.83s
- Optimize cpu = 23% cpu time = 17.29s

Performance Overview dashboard

After the Prepared Statement interface is used, the data of database time overview and QPS is as follows:

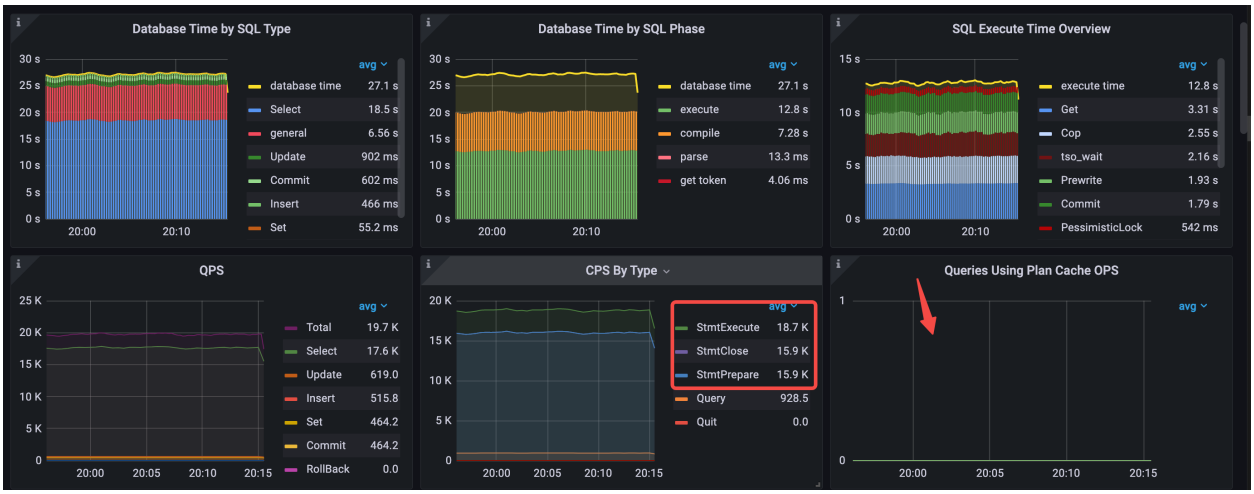

Figure 369: performance-overview-1-for-PrepStmts

The QPS drops from 24.4k to 19.7k. From the Database Time Overview, you can see that the application uses three types of Prepared commands, and the `general` statement type (which includes the execution time of commands such as `StmtPrepare` and `StmtClose`) takes the second place in Database Time by SQL Type. This indicates that even when the Prepared Statement interface is used, the execution plan cache is not hit. The reason is that, when the `StmtClose` command is executed, TiDB clears the execution plan cache of SQL statements in the internal processing.

- Database Time by SQL Type: the `Select` statement type takes most of the time, followed by `general` statements.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- CPS By Type: 3 types of commands (`StmtPrepare`, `StmtExecute`, `StmtClose`) are used.
- avg QPS = 19.7k (from 24.4k to 19.7k)
- The execution plan cache is not hit.

The TiDB average CPU utilization increases from 874% to 936%.

Figure 370: performance-overview-1-for-PrepStmts

The key latency metrics are as follows:

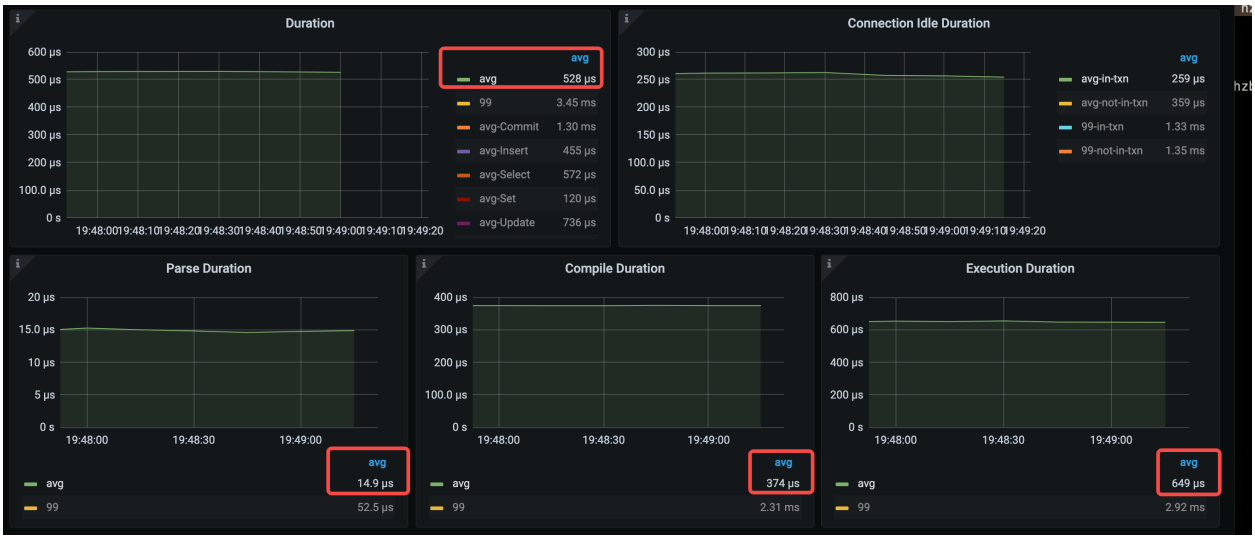

Figure 371: performance-overview-2-for-PrepStmts

- avg query duration = 528 s (from 1.12ms to 528 s)
- avg parse duration = 14.9 s (from 84.7 s to 14.9 s)
- avg compile duration = 374 s (from 370 s to 374 s)
- avg execution duration = 649 s (from 626 s to 649 s)

Analysis conclusion

Unlike Scenario 2, the application in Scenario 3 enables the Prepared Statement interface but still fails to hit the cache. In addition, Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). Compared with Scenario 2, Scenario 3 has two more network round-trip delays.

- Analysis for the decrease in QPS: From the **CPS By Type** pane, you can see that Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has

three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). `StmtPrepare` and `StmtClose` are non-conventional commands that are not counted by QPS, so QPS is reduced. The non-conventional commands `StmtPrepare` and `StmtClose` are counted in the `general` SQL type, so `general` time is displayed in the database overview of Scenario 3, and it accounts for more than a quarter of the database time.

- Analysis for the significant decrease in average query duration: for the `StmtPrepare` and `StmtClose` command types newly added in Scenario 3, their query duration is calculated separately in the TiDB internal processing. TiDB executes these two types of commands very quickly, so the average query duration is significantly reduced.

Although Scenario 3 uses the Prepared Statement interface, the execution plan cache is still not hit, because many application frameworks call the `StmtClose` method after `StmtExecute` to prevent memory leaks. Starting from v6.0.0, you can set the global variable `tidb_ignore_prepared_cache_close_stmt=on;`. After that, TiDB will not clear the cached execution plans even if the application calls the `StmtClose` method, so the next SQL execution can reuse the existing execution plan and avoid compiling the execution plan repeatedly.

11.1.8.2.5 Scenario 4. Use the Prepared Statement interface and enable execution plan caching

Application configuration

The application configuration remains the same as that of Scenario 3. To resolve the issue of not hitting the cache even if the application triggers `StmtClose`, the following parameters are configured.

- Set the TiDB global variable `set global tidb_ignore_prepared_cache_close_stmt=on;` (introduced since TiDB v6.0.0, `off` by default).
- Set the TiDB configuration item `prepared-plan-cache: {enabled: true}` to enable the plan cache feature.

Performance analysis

TiDB Dashboard

From the flame chart of the TiDB CPU usage, you can see that `CompileExecutePreparedStmt` and `Optimize` have no significant CPU consumption. 25% of the CPU is consumed by the `Prepare` command, which contains parsing-related functions of Prepare such as `PlanBuilder` and `parseSQL`.

PreparseStmt cpu = 25% cpu time = 12.75s

Figure 372: flame-graph-for-3-commands

Performance Overview dashboard

In the Performance Overview dashboard, the most significant change is the average time of the `compile` phase, which is reduced from 8.95 seconds per second in Scenario 3 to 1.18 seconds per second. The number of queries using the execution plan cache is roughly equal to the value of `StmtExecute`. With the increase in QPS, the database time consumed by `Select` statements per second decreases, and the database time consumed by `general` statements per second type increases.

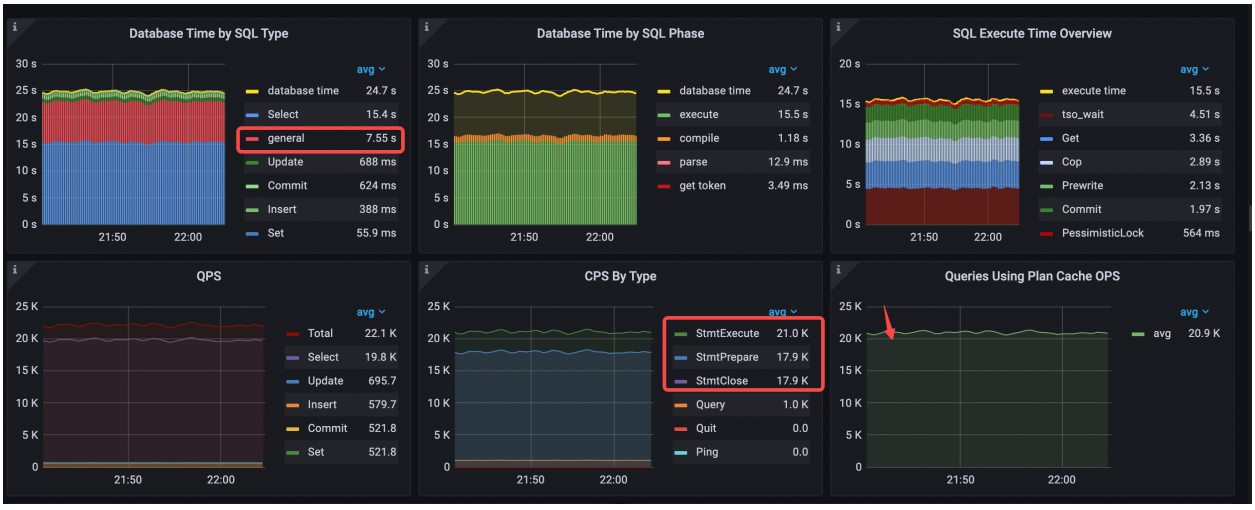

Figure 373: performance-overview-1-for-3-commands

- Database Time by SQL Type: the `Select` statement type takes the most time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.

- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: 3 types of commands (same as Scenario 3)
- Compared with scenario 3, the time consumed by `general` statements is longer because the QPS is increased.
- avg QPS = 22.1k (from 19.7k to 22.1k)

The average TiDB CPU utilization drops from 936% to 827%.

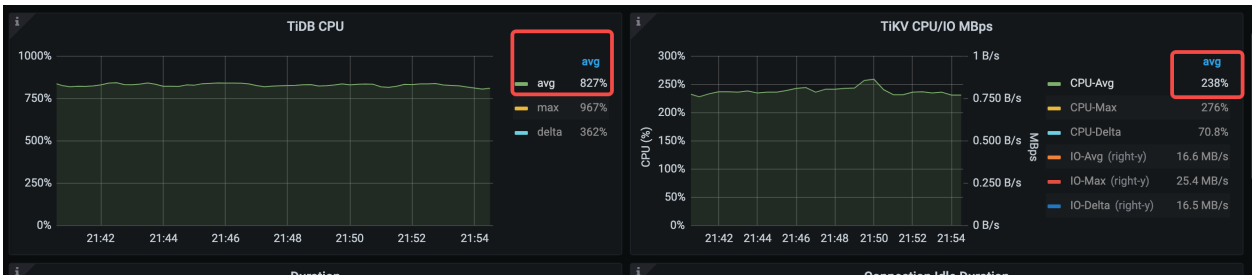

Figure 374: performance-overview-2-for-3-commands

The average `compile` time drops significantly, from 374 us to 53.3 us. Because the QPS increases, the average `execute` time increases too.

Figure 375: performance-overview-3-for-3-commands

- avg query duration = 426 s (from 528 s to 426 s)
- avg parse duration = 12.3 s (from 14.8 s to 12.3 s)

- avg compile duration = 53.3 s (from 374 s to 53.3 s)
- avg execution duration = 699 s (from 649 s to 699us)

Analysis conclusion

Compared with Scenario 3, Scenario 4 also uses 3 command types. The difference is that Scenario 4 hits the execution plan cache, which reduces compile duration greatly, reduces the query duration, and improves QPS.

Because the `StmtPrepare` and `StmtClose` commands consume significant database time and increase the number of interactions between the application and TiDB each time the application executes a SQL statement. The next scenario will further tune the performance by eliminating the calls of these two commands through JDBC configurations.

11.1.8.2.6 Scenario 5. Cache prepared objects on the client side

Application configuration

Compared with Scenario 4, 3 new JDBC parameters `cachePrepStmts=true&` ↪ `prepStmtCacheSize=1000&prepStmtCacheSqlLimit=20480` are configured, as explained below.

- `cachePrepStmts = true`: caches Prepared Statement objects on the client side, which eliminates the calls of StmtPrepare and StmtClose.
- `prepStmtCacheSize`: the value must be greater than 0.
- `prepStmtCacheSqlLimit`: the value must be greater than the length of the SQL text.

In Scenario 5, the complete JDBC configurations are as follows.

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the high CPU consumption of the `Prepare` command is no longer present.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

Figure 376: flame-graph-for-1-command

Performance Overview dashboard

In the Performance Overview dashboard, the most notable changes are that the three Stmt command types in the **CPS By Type** pane drop to one type, the `general` statement type in the **Database Time by SQL Type** pane is disappeared, and the QPS in the **QPS** pane increases to 30.9k.

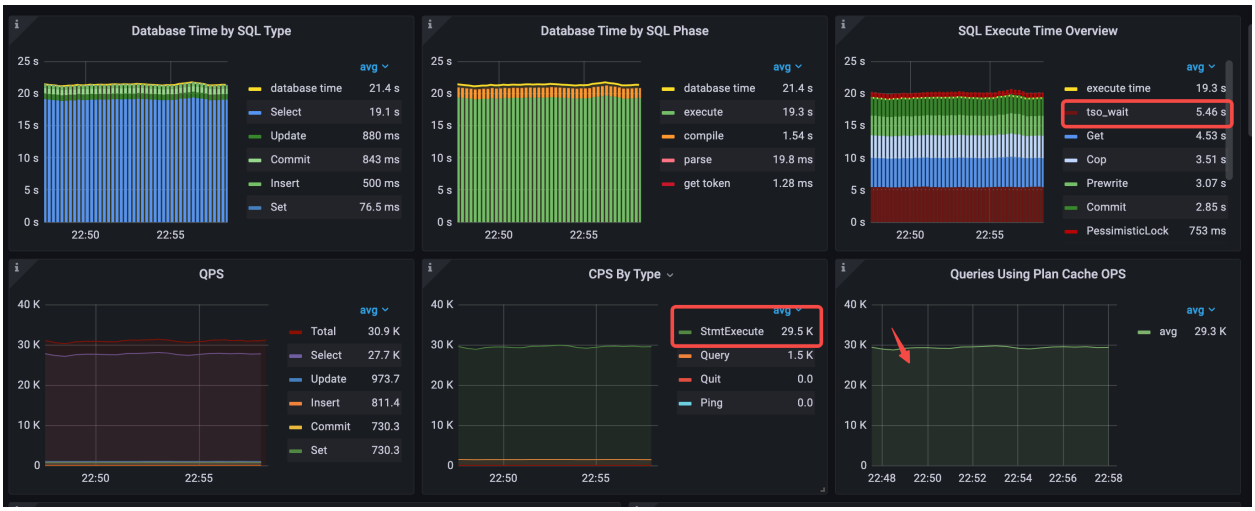

Figure 377: performance-overview-for-1-command

- Database Time by SQL Type: the `Select` statement type takes most of the time and the `general` statement type disappears.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.

- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 30.9k (from 22.1k to 30.9k)

The average TiDB CPU utilization drops from 827% to 577%. As the QPS increases, the average TiKV CPU utilization increases to 313%.

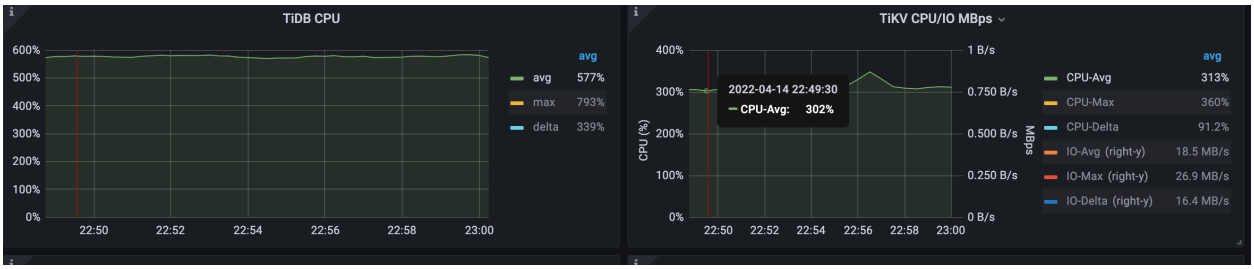

Figure 378: performance-overview-for-2-command

The key latency metrics are as follows:

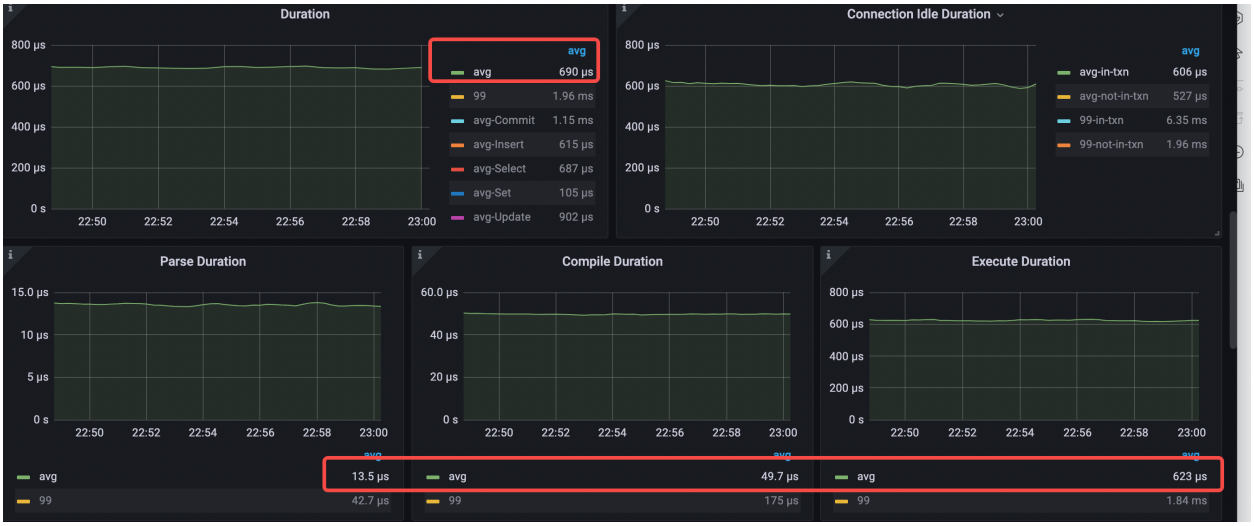

Figure 379: performance-overview-for-3-command

- avg query duration = 690 s (from 426 s to 690 s)
- avg parse duration = 13.5 s (from 12.3 s to 13.5 s)
- avg compile duration = 49.7 s (from 53.3 s to 49.7 s)
- avg execution duration = 623 s (from 699us to 623 s)
- avg pd tso wait duration = 196 s (from 224 s to 196 s)
- connection idle duration avg-in-txn = 608 s (from 250 s to 608 s)

Analysis conclusion

- Compared with Scenario 4, the **CPS By Type** pane in Scenario 5 has the `StmtExecute` command only, which avoids two network round trips and increases the overall system QPS.
- In the case of QPS increase, the latency decreases in terms of parse duration, compile duration, and execution duration, but the query duration increases instead. This is because TiDB processes `StmtPrepare` and `StmtClose` very quickly, and eliminating these two command types increases the average query duration.
- In Database Time by SQL Phase, `execute` takes the most time and is close to the database time. While in SQL Execute Time Overview, `tso wait` takes most of the time, and more than a quarter of `execute` time is taken to wait for TSO.
- The total `tso wait` time per second is 5.46s. The average `tso wait` time is 196 us, and the number of `tso cmd` times per second is 28k, which is very close to the QPS of 30.9k. This is because according to the implementation of the `read committed` isolation level in TiDB, every SQL statement in a transaction needs to request TSO from PD.

TiDB v6.0 provides `rc read`, which optimizes the `read committed` isolation level by reducing `tso cmd`. This feature is controlled by the global variable `set global tidb_rc_read_check_ts=on;`. When this variable is enabled, the default behavior of TiDB acts the same as the `repeatable-read` isolation level, at which only `start-ts` and `commit-ts` need to be obtained from the PD. The statements in a transaction use the `start-ts` to read data from TiKV first. If the data read from TiKV is earlier than `start-ts`, the data is returned directly. If the data read from TiKV is later than `start-ts`, the data is discarded. TiDB requests TSO from PD, and then retries the read. The `for update ts` of subsequent statements uses the latest PD TSO.

11.1.8.2.7 Scenario 6: Enable the `tidb_rc_read_check_ts` variable to reduce TSO requests

Application configuration

Compared with Scenario 5, the application configuration remains the same. The only difference is that the `set global tidb_rc_read_check_ts=on;` variable is configured to reduce TSO requests.

Performance analysis

Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

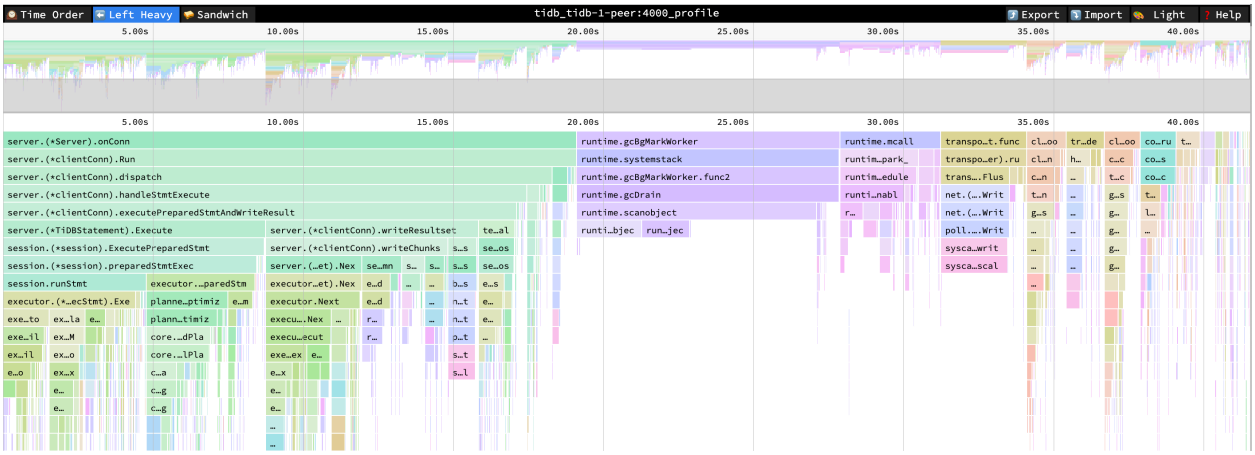

Figure 380: flame-graph-for-rc-read

Performance Overview dashboard

After using RC read, QPS increases from 30.9k to 34.9k, and the `tso wait` time consumed per second decreases from 5.46 s to 456 ms.

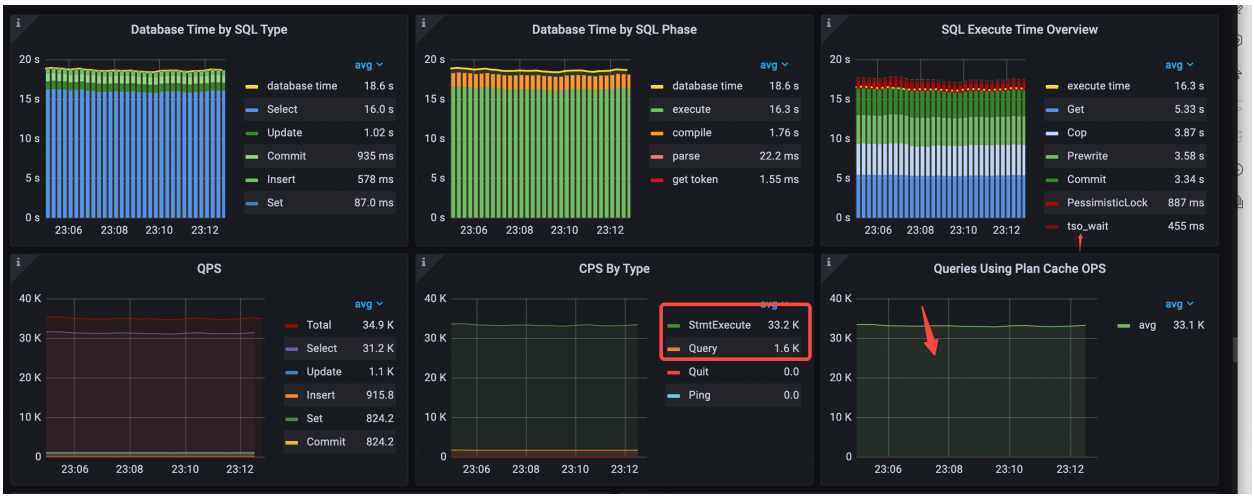

Figure 381: performance-overview-1-for-rc-read

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `Prewrite` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 34.9k (from 30.9k to 34.9k)

The `tso cmd` per second drops from 28.3k to 2.7k.

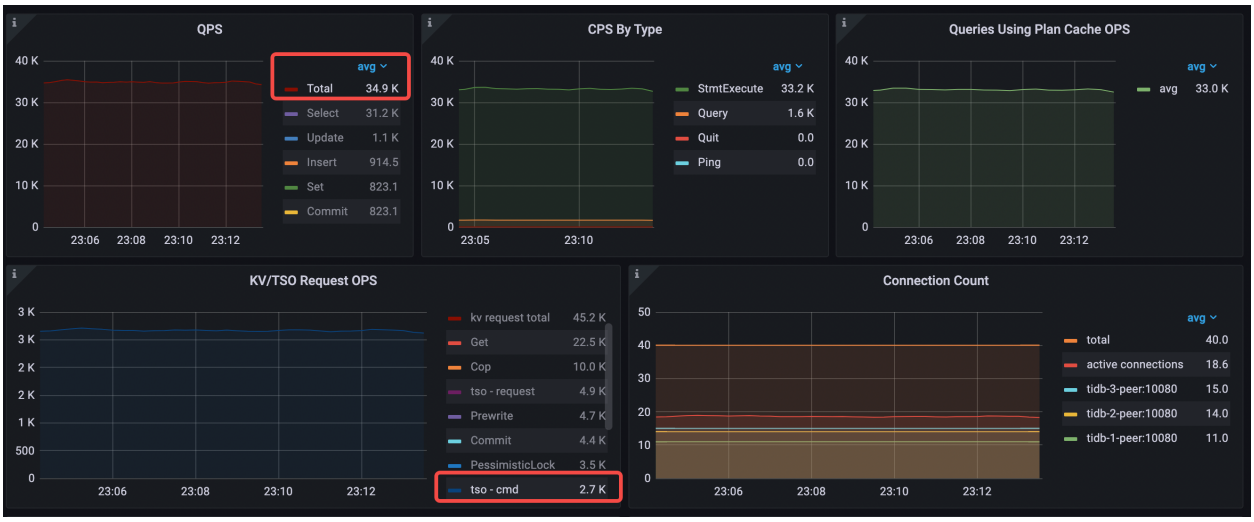

Figure 382: performance-overview-2-for-rc-read

The average TiDB CPU increases to 603% (from 577% to 603%).

Figure 383: performance-overview-3-for-rc-read

The key latency metrics are as follows:

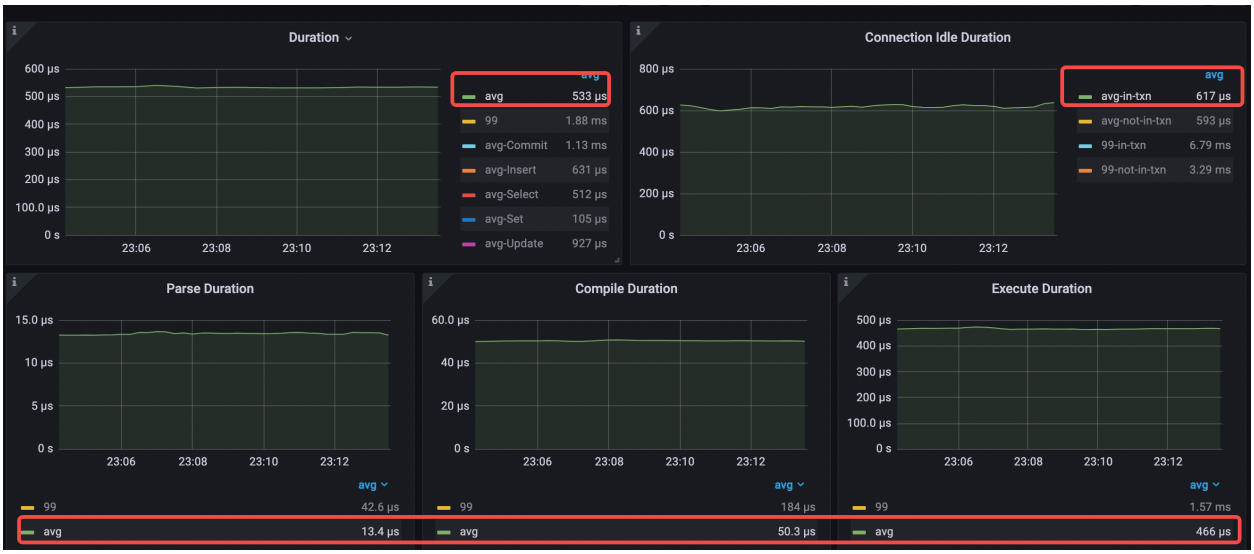

Figure 384: performance-overview-4-for-rc-read

- avg query duration = 533 s (from 690 s to 533 s)
- avg parse duration = 13.4 s (from 13.5 s to 13.4 s)
- avg compile duration = 50.3 s (from 49.7 s to 50.3 s)
- avg execution duration = 466 s (from 623 s to 466 s)
- avg pd tso wait duration = 171 s (from 196 s to 171 s)

Analysis conclusion

After enabling RC Read by `set global tidb_rc_read_check_ts=on;`, RC Read significantly reduces the times of `tso cmd`, thus reducing `tso wait` and average query duration, and improving QPS.

The bottlenecks of both current database time and latency are in the `execute` phase, in which the `Get` and `Cop` read requests take the highest percentage. Most of the tables in this workload are read-only or rarely modified, so you can use the small table caching feature supported since TiDB v6.0.0 to cache the data of these small tables and reduce the waiting time and resource consumption of KV read requests.

11.1.8.2.8 Scenario 7: Use the small table cache

Application configuration

Compared with Scenario 6, the application configuration remains the same. The only difference is that Scenario 7 uses SQL statements such as `alter table t1 cache;` to cache those read-only tables for the business.

Performance analysis

TiDB Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

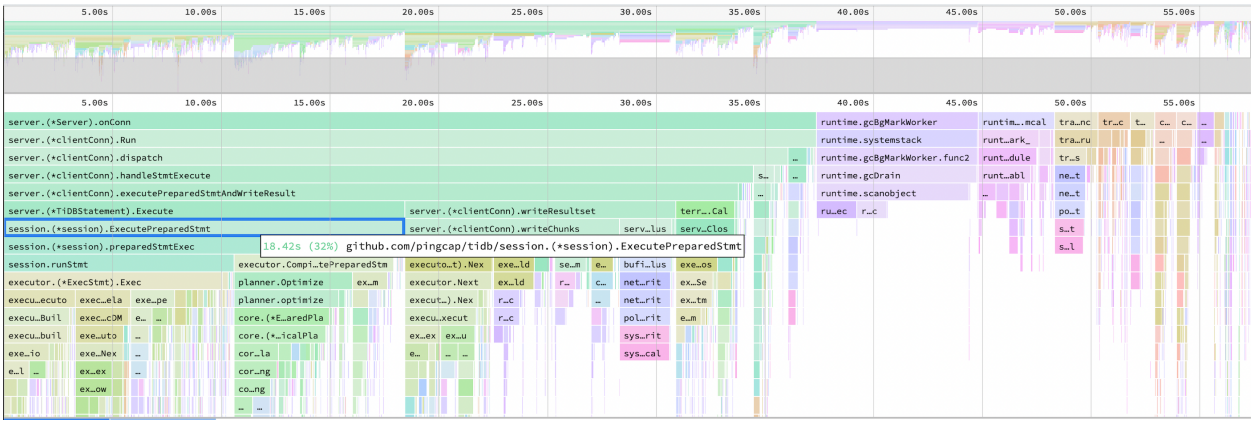

Figure 385: flame-graph-for-table-cache

Performance Overview dashboard

The QPS increases from 34.9k to 40.9k, and the KV request types take the most time in the `execute` phase change to `Prewrite` and `Commit`. The database time consumed by `Get` per second decreases from 5.33 seconds to 1.75 seconds, and the database time consumed by `Cop` per second decreases from 3.87 seconds to 1.09 seconds.

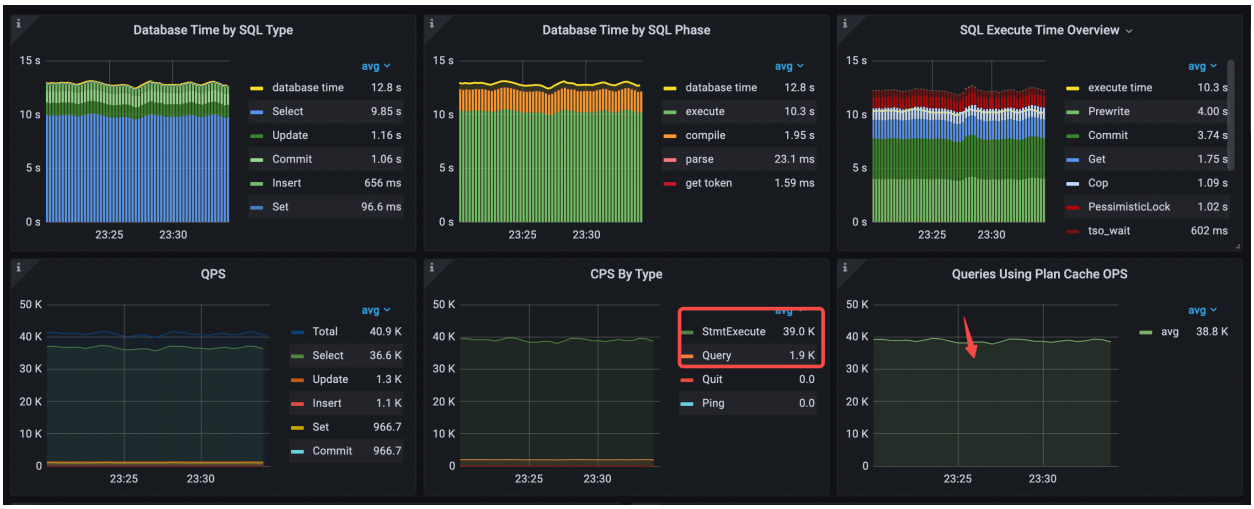

Figure 386: performance-overview-1-for-table-cache

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Prewrite`, `Commit`, and `Get` take most of the time.

- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 40.9k (from 34.9k to 40.9k)

The average TiDB CPU utilization drops from 603% to 478% and the average TiKV CPU utilization drops from 346% to 256%.

Figure 387: performance-overview-2-for-table-cache

The average query latency drops from 533 us to 313 us. The average `execute` latency drops from 466 us to 250 us.

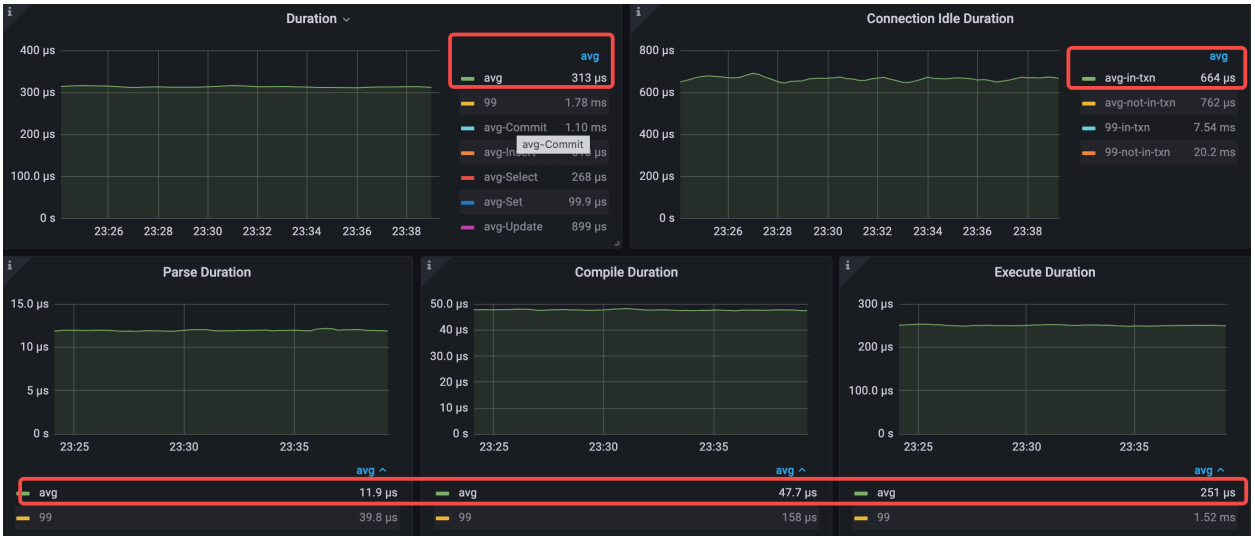

Figure 388: performance-overview-3-for-table-cache

- avg query duration = 313 s (from 533 s to 313 s)
- avg parse duration = 11.9 s (from 13.4 s to 11.9 s)
- avg compile duration = 47.7 s (from 50.3 s to 47.7 s)
- avg execution duration = 251 s (from 466 s to 251 s)

Analysis conclusion

After caching all read-only tables, the `Execute Duration` drops significantly because all read-only tables are cached in TiDB and there is no need to query data in TiKV for those tables, so the query duration drops and the QPS increases.

This is an optimistic result because data of read-only tables in actual business might be too large for TiDB to cache them all. Another limitation is that although the small table caching feature supports write operations, the write operation requires a default wait of 3 seconds to ensure that the cache of all TiDB nodes is invalidated first, which might not be feasible to applications with strict latency requirements.

11.1.8.2.9 Summary

The following table lists the performance of seven different scenarios.

Metrics	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6	Scenario 7	Comparing Scenario 5 with Scenario 2 (%)	Comparing Scenario 7 with Scenario 3 (%)
query duration	479 s	1120 s	528 s	426 s	690 s	533 s	313 s	-38%	-41%
QPS	56.3k	24.2k	19.7k	22.1k	30.9k	34.9k	40.9k	+28%	+108%

In these scenarios, Scenario 2 is a common scenario where applications use the Query interface, and Scenario 5 is an ideal scenario where applications use the Prepared Statement interface.

- Comparing Scenario 5 with Scenario 2, you can see that by using best practices for Java application development and caching Prepared Statement objects on the client side, each SQL statement requires only one command and database interaction to hit the execution plan cache, which results in a 38% drop in query latency and a 28% increase in QPS, while the average TiDB CPU utilization drops from 936% to 577%.
- Comparing Scenario 7 with Scenario 3, you can see that with the latest TiDB optimization features such as RC Read and small table cache on top of Scenario 5, latency is reduced by 41% and QPS is increased by 108%, while the average TiDB CPU utilization drops from 936% to 478%.

By comparing the performance of each scenario, we can draw the following conclusions:

- The execution plan cache of TiDB plays a critical role in the OLTP performance tuning. The RC Read and small table cache features introduced from v6.0.0 also play an important role in the further performance tuning of this workload.

- TiDB is compatible with different commands of the MySQL protocol. When using the Prepared Statement interface and setting the following JDBC connection parameters, the application can achieve its best performance:

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

- It is recommended that you use TiDB Dashboard (for example, the Top SQL feature and Continuous Profiling feature) and Performance Overview dashboard for performance analysis and tuning.

    - With the Top SQL feature, you can visually monitor and explore the CPU consumption of each SQL statement in your database during execution to troubleshoot database performance issues.
    - With Continuous Profiling, you can continuously collect performance data from each instance of TiDB, TiKV, and PD. When applications use different interfaces to interact with TiDB, the difference in the CPU consumption of TiDB is huge.
    - With Performance Overview Dashboard, you can get an overview of database time and SQL execution time breakdown information. You can analyze and diagnose performance based on database time to determine whether the performance bottleneck of the entire system is in TiDB or not. If the bottleneck is in TiDB, you can use the database time and latency breakdowns, along with load profile and resource usage, to identify performance bottlenecks within TiDB and tune the performance accordingly.

With a combination usage of these features, you can analyze and tune performance for real-world applications efficiently.

11.1.8.3 TiFlash Performance Analysis and Tuning Methods

This document introduces TiFlash resource utilization and key performance metrics. You can monitor and evaluate the TiFlash cluster performance through the TiFlash panel on the Performance Overview dashboard.

11.1.8.3.1 Resource utilization of a TiFlash cluster

With the following three metrics, you can quickly get the resource utilization of a TiFlash cluster:

- CPU: the CPU utilization per TiFlash instance.
- Memory: the memory usage per TiFlash instance.

- IO utilization: the IO utilization per TiFlash instance.

Example: Resource utilization during CH-benCHmark workload

This TiFlash cluster consists of two nodes, each node configured with 16 cores and 48 GB of memory. During the CH-benCHmark workload, CPU utilization can reach up to 1500%, memory usage can reach up to 20 GB, and IO utilization can reach up to 91%. These metrics indicate that TiFlash node resources are approaching saturation.

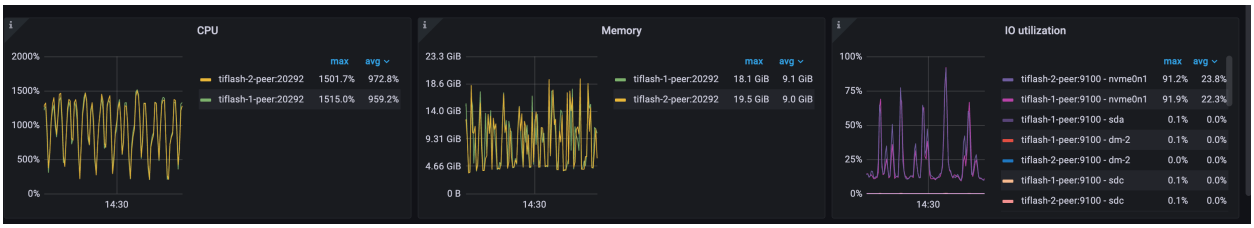

Figure 389: CH-TiFlash-MPP

11.1.8.3.2 Key metrics for TiFlash performance

Throughput metrics

With the following metrics, you can get the throughput of TiFlash:

- MPP Query count: the instant value of MPP query count for each TiFlash instance, reflecting the current number of MPP queries that need to be processed by the TiFlash instance (including those being processed and those awaiting scheduling).
- Request QPS: the number of coprocessor requests received by all TiFlash instances.
    - `run_mpp_task`, `dispatch_mpp_task`, and `mpp_establish_conn` are MPP requests.
    - `batch`: the number of batch requests.
    - `cop`: the number of coprocessor requests that are sent directly via the coprocessor interface.
    - `cop_execution`: the number of coprocessor requests currently being executed.
    - `remote_read`, `remote_read_constructed`, and `remote_read_sent` are remote read-related metrics. An increase in remote reads usually indicates an issue in the system.
- Executor QPS: the number of each type of dag operators in the requests received by all TiFlash instances, where `table_scan` is the table scan operator, `selection` is the selection operator, `aggregation` is the aggregation operator, `top_n` is the TopN operator, `limit` is the limit operator, `join` is a join operator, `exchange_sender` is a data sending operator, and `exchange_receiver` is a data receiving operator.

Latency metrics

With the following metrics, you can get the latency of TiFlash:

- Request Duration Overview: provides a stacked chart of the total processing duration for all request types in all TiFlash instances per second.

    - If the type of a request is `run_mpp_task`, `dispatch_mpp_task`, or `mpp_establish_conn`, it indicates that the SQL statement execution has been partially or fully pushed down to TiFlash, typically involving join and data distribution operations. This is the most common request type in TiFlash.
    - If the type of a request is `cop`, it indicates that the statement related to this request has not been fully pushed down to TiFlash. Typically, TiDB pushes down the table full scan operator to TiFlash for data access and filtering. If `cop` becomes the most common request type in the stacked chart, you need to check if it is reasonable.
        - If the amount of data queried by a SQL statement is large, the optimizer might estimate that TiFlash full table scans are more cost-effective according to the cost model.
        - If the schema of a queried table lacks suitable indexes, the optimizer can only push the query down to TiFlash for a full table scan, even if the amount of data to be queried is small. In this case, it is more efficient to create proper indexes and access the data through TiKV.

- Request Duration: the total processing duration for each MPP and coprocessor request type in all TiFlash instances, which includes the average latency and p99 latency.

- Request Handle Duration: the time from the start of executing the `cop` and `batch cop` requests to the completion of the execution, excluding waiting time. This metric is only applicable to the `cop` and `batch cop` types of requests, including average and P99 latency.

Example 1: Processing duration overview of TiFlash MPP requests

In the workload of the following diagram, `run_mpp_task` and `mpp_establish_conn` requests constitute the majority of the total processing duration, indicating that most of the requests are MPP tasks that are fully pushed down to TiFlash for execution.

The processing duration of `cop` requests is relatively small, indicating that some of the requests are pushed down to TiFlash for data access and filtering through the coprocessor.

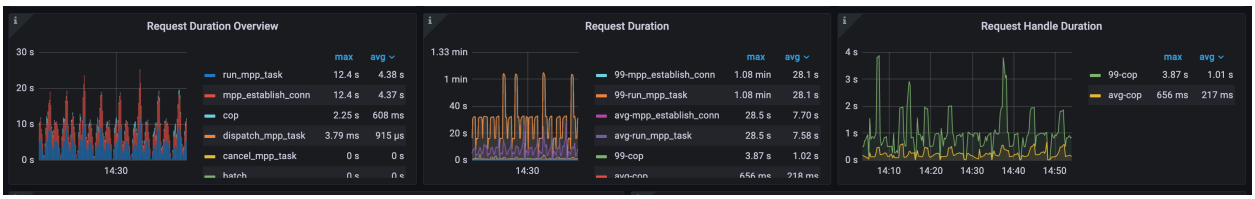

Figure 390: CH-TiFlash-MPP

Example 2: TiFlash `cop` requests constitute the majority of the total processing duration

In the workload of the following diagram, `cop` requests constitute the majority of the total processing duration. In this case, you can check the SQL execution plan to see why these `cop` requests are generated.

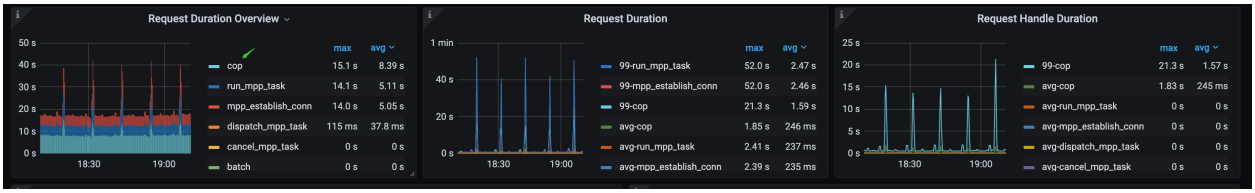

Figure 391: Cop

Raft-related metrics

With the following metrics, you can get the Raft replication status of TiFlash:

- Raft Wait Index Duration: the duration of waiting until the local Region index >= `read_index` for all TiFlash instances, which represents the latency of the `wait_index` operation. If this metric is too high, it indicates that data replication from TiKV to TiFlash has a significant latency. Possible reasons include the following:
    - TiKV resource is overloaded.
    - TiFlash resource is overloaded, especially IO resources.
    - There is a network bottleneck between TiKV and TiFlash.
- Raft Batch Read Index Duration: the latency of `read_index` for all TiFlash instances. If this metric is too high, it indicates that the interaction between TiFlash and TiKV is slow. Possible reasons include the following:
    - TiFlash resource is overloaded.
    - TiKV resource is overloaded.
    - There is a network bottleneck between TiFlash and TiKV.

IO throughput metrics

With the following metrics, you can get the IO throughput of TiFlash:

- Write Throughput By Instance: the throughput of data written by each TiFlash instance. It includes the throughput by applying the Raft data logs and Raft snapshots.
- Write flow: the traffic of disk writes by all TiFlash instances.
    - File Descriptor: the stable layer of the DeltaTree storage engine used by TiFlash.

    - Page: refers to Pagestore, the Delta change layer of the DeltaTree storage engine used by TiFlash.

- Read flow: traffic of disk read operations for all TiFlash instances.

    - File Descriptor: the stable layer of the DeltaTree storage engine used by TiFlash.
    - Page: refers to Pagestore, the Delta change layer of the DeltaTree storage engine used by TiFlash.

You can calculate the write amplification factor of the entire TiFlash cluster using the `(Read flow + Write flow)÷ total Write Throughput By Instance` formula.

Example 1: Raft and IO metrics of the CH-benCHmark workload in a self-hosted environment

As shown in the following diagram, the `Raft Wait Index Duration` and the 99th percentile of `Raft Batch Read Index Duration` for this TiFlash cluster are relatively high, at 3.24 seconds and 753 milliseconds respectively. This is because the TiFlash workload in this cluster is high and latency occurs in data replication.

In this cluster, there are two TiFlash nodes. The incremental data replication speed from TiKV to TiFlash is approximately 28 MB per second. The maximum write throughput of the stable layer (File Descriptor) is 939 MB/s, and the maximum read throughput is 1.1 GiB/s. Meanwhile, the maximum write throughput of the Delta layer (Page) is 74 MB/s, and the maximum read throughput is 111 MB/s. In this environment, TiFlash uses dedicated NVME disks, which have strong IO throughput capabilities.

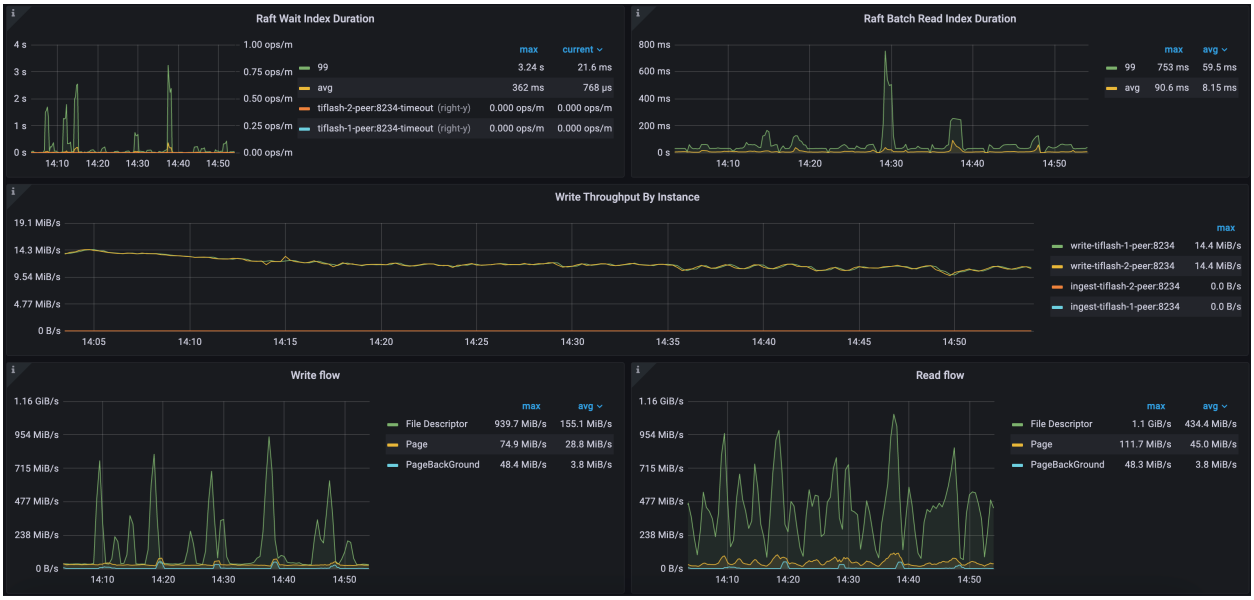

Figure 392: CH-2TiFlash-OP

Example 2: Raft and IO metrics of the CH-benCHmark workload in a public cloud deployment environment

As shown in the following diagram, the 99th percentile of `Raft Wait Index Duration` is up to 438 milliseconds, and 99th percentile of the `Raft Batch Read Index Duration` is up to 125 milliseconds. This cluster has only one TiFlash node. TiKV replicates about 5 MB of incremental data to TiFlash per second. The maximum write traffic of the stable layer (File Descriptor) is 78 MB/s and the maximum read traffic is 221 MB/s. In the meantime, the maximum write traffic of the Delta layer (Page) is 8 MB/s and the maximum read traffic is 18 MB/s. In this environment, TiFlash uses an AWS EBS cloud disk, which has relatively weak IO throughput.

Figure 393: CH-TiFlash-MPP

11.1.8.4 TiCDC Performance Analysis and Tuning Methods

This document introduces TiCDC resource utilization and key performance metrics. You can monitor and evaluate TiCDC performance on data replication through the CDC panel on the Performance Overview dashboard.

11.1.8.4.1 Resource utilization of a TiCDC cluster

With the following three metrics, you can quickly get the resource utilization of a TiCDC cluster:

- CPU usage: the CPU usage per TiCDC node.
- Memory usage: the memory usage per TiCDC node.
- Goroutine count: the number of goroutines per TiCDC node.

11.1.8.4.2 Key metrics for TiCDC data replication

TiCDC overall metrics

With the following metrics, you can get an overview of TiCDC data replication:

- Changefeed checkpoint lag: the progress lag of data replication between the upstream and the downstream, measured in seconds.

  If the speed at which TiCDC consumes data and writes downstream keeps up with upstream data changes, this metric remains within a small latency range, typically within 10 seconds. Otherwise, this metric will continue to increase.

  When this metric (that is, `Changefeed checkpoint lag`) increases, common reasons are as follows:

  - Insufficient system resources: if the CPU, memory, or disk space of TiCDC is insufficient, it might cause data processing to be too slow, which results in a long checkpoint of the TiCDC changefeed.
  - Network issues: if network interruptions, lags, or insufficient bandwidth occur in TiCDC, it might affect data transfer speed, which results in a long checkpoint of the TiCDC changefeed.
  - High QPS in the upstream: if the data to be processed by TiCDC is excessively large, it might cause data processing timeouts, which results in an increased checkpoint of the TiCDC changefeed. Typically, a single TiCDC node can handle a maximum QPS of around 60K.
  - Database issues:
    - The gap between the `min resolved ts` of the upstream TiKV cluster and the latest PD TSO is significant. This issue usually occurs because TiKV fails to advance the resolved ts in time when the write workload of the upstream is excessively heavy.
    - The write latency in downstream databases is high, blocking TiCDC from replicating data to the downstream timely.

- Changefeed resolved ts lag: the progress lag between the internal replication status of a TiCDC node and the upstream, measured in seconds. If this metric is high, it indicates that the data processing capability of the TiCDC Puller or Sorter module might be insufficient, or there might be network latency or slow disk read/write speed issues. In such cases, to ensure the efficient and stable operation of TiCDC, you need to take appropriate measures, such as increasing the number of TiCDC nodes or optimizing the network configuration.

- The status of changefeeds: for status explanations of changefeeds, see Changefeed state transfer.

Example 1: High checkpoint lag due to high upstream QPS in the case of a single TiCDC node

As shown in the following diagram, because the upstream QPS is excessively high and there is only a single TiCDC node in the cluster, the TiCDC node is overloaded, the CPU usage is high, and both `Changefeed checkpoint lag` and `Changefeed resolved ts lag` keep increasing. The changefeed status intermittently transitions from `0` to `1`, indicating that the changefeed keeps getting errors. You can try resolving this issue by adding more resources as follows:

- Add more TiCDC nodes: scale out the TiCDC cluster to multiple nodes to increase processing capacity.
- Optimize TiCDC node resources: increase CPU and memory configurations of the TiCDC node to improve performance.

Figure 394: TiCDC overview

Data flow throughput metrics and downstream latency

With the following metrics, you can learn the data flow throughput and downstream latency of TiCDC:

- Puller output events/s: the number of rows that the Puller module of TiCDC nodes sends to the Sorter module per second.
- Sorter output events/s: the number of rows that the Sorter module of TiCDC nodes sends to the Mounter module per second.
- Mounter output events/s: the number of rows that the Mounter module of TiCDC nodes sends to the Sink module per second.
- Table sink output events/s: the number of rows that the Table Sorter module of the TiCDC nodes sends to the Sink module per second.
- SinkV2 - Sink flush rows/s: the number of rows that the Sink module in the TiCDC node sends to the downstream per second.
- Transaction Sink Full Flush Duration: the average latency and p999 latency of writing downstream transactions by the MySQL Sink of TiCDC nodes.

- MQ Worker Send Message Duration Percentile: the latency of sending messages by MQ worker when the downstream is Kafka.
- Kafka Outgoing Bytes: the traffic of writing downstream transactions in MQ Workload.

Example 2: Impact of downstream database write speed on TiCDC data replication performance

As shown in the following diagram, both upstream and downstream are TiDB clusters. The TiCDC `Puller output events/s` metric indicates the QPS of the upstream database. The `Transaction Sink Full Flush Duration` metric indicates the average write latency of the downstream database, which is high during the first workload and low during the second workload.

- During the first workload, because the downstream TiDB cluster writes data slowly, TiCDC consumes data at a speed that falls behind the upstream QPS, leading to a continuous increase in `Changefeed checkpoint lag`. However, `Changefeed resolved ts lag` remains within 300 milliseconds, indicating that replication lag and throughput bottlenecks are not caused by the puller and sorter modules but caused by the downstream sink module.
- During the second workload, because the downstream TiDB cluster writes data faster, TiCDC replicates data at a speed that completely catches up with the upstream, the `Changefeed checkpoint lag` and `Changefeed resolved ts lag` remain within 500 milliseconds, which is a relatively ideal replication speed for TiCDC.

Figure 395: TiCDC overview

Figure 396: data flow and txn latency

11.1.8.5 Latency Breakdown

This document breaks down the latency into metrics and then analyzes it from the user's perspective from the following aspects:

- General SQL layer
- Read queries
- Write queries
- Batch client
- TiKV snapshot
- Async write

These analyses provide you with a deep insight into time cost during TiDB SQL queries. This is a guide to TiDB's critical path diagnosis. Besides, the Diagnosis use cases section introduces how to analyze latency in real use cases.

It's better to read Performance Analysis and Tuning before this document. Note that when breaking down latency into metrics, the average value of duration or latency is calculated instead of some specific slow queries. Many metrics are shown as histogram, which is a distribution of the duration or latency. To calculate the average latency, you need to use the following sum and count counter.

```
avg = ${metric_name}_sum / ${metric_name}_count
```

Metrics described in this document can be read directly from the Prometheus dashboard of TiDB.

11.1.8.5.1 General SQL layer

This general SQL layer latency exists on the top level of TiDB and is shared by all SQL queries. The following is the time cost diagram of general SQL layer operation:

```
Diagram(
    NonTerminal("Token wait duration"),
    Choice(
        0,
        Comment("Prepared statement"),
        NonTerminal("Parse duration"),
    ),
    OneOrMore(
        Sequence(
        Choice(
            0,
            NonTerminal("Optimize prepared plan duration"),
            Sequence(
            Comment("Plan cache miss"),
            NonTerminal("Compile duration"),
            ),
        ),
        NonTerminal("TSO wait duration"),
        NonTerminal("Execution duration"),
        ),
        Comment("Retry"),
    ),
)
```

The general SQL layer latency can be observed as the `e2e duration` metric and is calculated as:

```
e2e duration =
    tidb_server_get_token_duration_seconds +
    tidb_session_parse_duration_seconds +
    tidb_session_compile_duration_seconds +
    tidb_session_execute_duration_seconds{type="general"}
```

- `tidb_server_get_token_duration_seconds` records the duration of Token waiting. This is usually less than 1 millisecond and is small enough to be ignored.
- `tidb_session_parse_duration_seconds` records the duration of parsing SQL queries to an Abstract Syntax Tree (AST), which can be skipped by `PREPARE/EXECUTE` statements.
- `tidb_session_compile_duration_seconds` records the duration of compiling an AST to an execution plan, which can be skipped by SQL prepared execution plan cache.

- `tidb_session_execute_duration_seconds{type="general"}` records the duration of execution, which mixes all types of user queries. This needs to be broken down into fine-grained durations for analyzing performance issues or bottlenecks.

Generally, OLTP (Online Transactional Processing) workload can be divided into read and write queries, which share some critical code. The following sections describe latency in read queries and write queries, which are executed differently.

11.1.8.5.2 Read queries

Read queries have only a single process form.

Point get

The following is the time cost diagram of point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Resolve TSO"),
        Comment("Read by clustered PK in auto-commit-txn mode or snapshot
            ↪ read"),
    ),
    Choice(
        0,
        NonTerminal("Read handle by index key"),
        Comment("Read by clustered PK, encode handle by key"),
    ),
    NonTerminal("Read value by handle"),
)
```

During point get, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handle duration +
    read value duration
```

`pd_client_cmd_handle_cmds_duration_seconds{type="wait"}` records the duration of fetching TSO (Timestamp Oracle) from PD. When reading in an auto-commit transaction mode with a clustered primary index or from a snapshot, the value will be zero.

The `read handle duration` and `read value duration` are calculated as:

```
read handle duration = read value duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="get"} =
    send request duration =
```

```
    tidb_tikvclient_request_seconds{type="Get"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

The `tidb_tikvclient_request_seconds{type="Get"}` records a duration of get requests which are sent directly to TiKV via a batched gRPC wrapper. For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration` ↪ , `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_` ↪ `seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    tikv_engine_seek_micro_seconds{type="seek_average"} +
    read value duration +
    read value duration(non-short value)
```

At this time, requests are in TiKV. TiKV processes get requests by one seek and one or two read actions (short values are encoded in a write column family, and reading it once is enough). TiKV gets a snapshot before processing the read request. For more details about the TiKV snapshot duration, refer to the TiKV snapshot section.

The `read value duration(from disk)` is calculated as:

```
read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="get/
        ↪ batch_get_command"})) / sum(rate(tikv_storage_rocksdb_perf{metric
        ↪ ="block_read_count",req="get/batch_get_command"}))
```

TiKV uses RocksDB as its storage engine. When the required value is missing from the block cache, TiKV needs to load the value from the disk. For `tikv_storage_rocksdb_perf`, the get request can be either `get` or `batch_get_command`.

Batch point get

The following is the time cost diagram of batch point get operations:

```
Diagram(
  NonTerminal("Resolve TSO"),
  Choice(
    0,
    NonTerminal("Read all handles by index keys"),
    Comment("Read by clustered PK, encode handle by keys"),
  ),
  NonTerminal("Read values by handles"),
)
```

During batch point get, the `tidb_session_execute_duration_seconds{type="general"}` is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handles duration +
    read values duration
```

The process of batch point get is almost the same as Point get except that batch point get reads multiple values at the same time.

The `read handles duration` and `read values duration` are calculated as:

```
read handles duration = read values duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} =
    send request duration =
    tidb_tikvclient_request_seconds{type="BatchGet"} =
    tidb_tikvclient_batch_wait_duration(transaction) +
    tidb_tikvclient_batch_send_latency(transaction) +
    tikv_grpc_msg_duration_seconds{type="kv_batch_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}(transaction)
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration(transaction)`, `tidb_tikvclient_batch_send_latency(transaction)`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}(transaction)`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_batch_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_batch_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    n * (
        tikv_engine_seek_micro_seconds{type="seek_max"} +
        read value duration +
        read value duration(non-short value)
    )

read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="batch_
        get"})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_read_
        count",req="batch_get"}))
```

After getting a snapshot, TiKV reads multiple values from the same snapshot. The read duration is the same as Point get. When TiKV loads data from disk, the average duration can be calculated by `tikv_storage_rocksdb_perf` with `req="batch_get"`.

Table scan & Index scan

The following is the time cost diagram of table scan and index scan operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related table/index ranges"),
        OneOrMore(
            NonTerminal("Wait for result"),
            Comment("Next loop: drain the result"),
        ),
    ),
)
```

During table scan and index scan, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )
    tidb_distsql_handle_query_duration_seconds{sql_type="general"} <= send
        ↪ request duration
```

Table scan and index scan are processed in the same way. `req_per_copr` is the distributed task count. Because coprocessor execution and data responding to client are in different threads, `tidb_distsql_handle_query_duration_seconds{sql_type="general"}` is the wait time and it is less than the `send request duration`.

The `send request duration` and `req_per_copr` are calculated as:

```
send request duration =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="coprocessor"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tikv_grpc_msg_duration_seconds{type="coprocessor"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} +
    tikv_coprocessor_request_wait_seconds{type="schedule"} +
    tikv_coprocessor_request_handler_build_seconds{type="index/select"} +
    tikv_coprocessor_request_handle_seconds{type="index/select"}

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    ↪ (tidb_distsql_scan_keys_partial_num_count)
```

In TiKV, the table scan type is `select` and the index scan type is `index`. The details of `select` and `index` type duration are the same.

Index look up

The following is the time cost diagram of index look up operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related index ranges"),
        OneOrMore(
            Sequence(
                NonTerminal("Wait for index scan result"),
                NonTerminal("Wait for table scan result"),
            ),
        Comment("Next loop: drain the result"),
        ),
    ),
)
```

During index look up, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    ) +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    (tidb_distsql_scan_keys_partial_num_count)
```

An index look up combines index scan and table scan, which are processed in a pipeline.

11.1.8.5.3 Write queries

Write queries are much more complex than read queries. There are some variants of write queries. The following is the time cost diagram of write queries operations:

```
Diagram(
    NonTerminal("Execute write query"),
    Choice(
        0,
        NonTerminal("Pessimistic lock keys"),
        Comment("bypass in optimistic transaction"),
    ),
```

```
    Choice(
        0,
        NonTerminal("Auto Commit Transaction"),
        Comment("bypass in non-auto-commit or explicit transaction"),
    ),
)
```

	Pessimistic transaction	Optimistic transaction
Auto-commit	execute + lock + commit	execute + commit
Non-auto-commit	execute + lock	execute

A write query is divided into the following three phases:

- execute phase: execute and write mutation into the memory of TiDB.
- lock phase: acquire pessimistic locks for the execution result.
- commit phase: commit the transaction via the two-phase commit protocol (2PC).

In the execute phase, TiDB manipulates data in memory and the main latency comes from reading the required data. For update and delete queries, TiDB reads data from TiKV first, and then updates or deletes the row in memory.

The exception is lock-time read operations (`SELECT FOR UPDATE`) with point get and batch point get, which perform read and lock in a single Remote Procedure Call (RPC).

Lock-time point get

The following is the time cost diagram of lock-time point get operations:

```
Diagram(
    Choice(
        0,
        Sequence(
            NonTerminal("Read handle key by index key"),
            NonTerminal("Lock index key"),
        ),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock handle key"),
    NonTerminal("Read value from pessimistic lock cache"),
)
```

During lock-time point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    2 * tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

Lock-time point get locks the key and returns its value. Compared with the lock phase after execution, this saves 1 round trip. The duration of the lock-time point get can be treated the same as Lock duration.

Lock-time batch point get

The following is the time cost diagram of lock-time batch point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Read handle keys by index keys"),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock index and handle keys"),
    NonTerminal("Read values from pessimistic lock cache"),
)
```

During lock-time batch point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} +
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

The execution of the lock-time batch point get is similar to the Lock-time point get except that the lock-time batch point get reads multiple values in a single RPC. For more details about the `tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"}` duration, refer to the Batch point get section.

Lock

This section describes the lock duration.

```
round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_pessimistic_lock
        ↪ "})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_pessimistic_
        ↪ lock"})) /
    committer-concurrency
)
```

```
lock = tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"} =
    round * tidb_tikvclient_request_seconds{type="PessimisticLock"}
```

Locks are acquired through the 2PC structure, which has a flow control mechanism. The flow control limits concurrent on-the-fly requests by `committer-concurrency` (default value is 128). For simplicity, the flow control can be treated as an amplification of request latency (`round`).

The `tidb_tikvclient_request_seconds{type="PessimisticLock"}` is calculated as:

```
tidb_tikvclient_request_seconds{type="PessimisticLock"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration`, `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} =
    tikv_scheduler_latch_wait_duration_seconds{type="acquire_pessimistic_lock"} +
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    (lock in-mem key count + lock on-disk key count) * lock read duration +
    lock on-disk key count / (lock in-mem key count + lock on-disk key count ) *
    lock write duration
```

- Since TiDB v6.0, TiKV uses in-memory pessimistic lock by default. In-memory pessimistic lock bypass the async write process.
- `tikv_storage_engine_async_request_duration_seconds{type="snapshot"}` is a snapshot type duration. For more details, refer to the TiKV Snapshot section.
- The `lock in-mem key count` and `lock on-disk key count` are calculated as:

```
lock in-mem key count =
    sum(rate(tikv_in_memory_pessimistic_locking{result="success"})) /
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="kv_pessimistic_lock"}))

lock on-disk key count =
```

```
    sum(rate(tikv_in_memory_pessimistic_locking{result="full"})) /
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="kv_pessimistic_
        ↪ lock"}}))
```

The count of in-memory and on-disk locked keys can be calculated by the in-memory lock counter. TiKV reads the keys' values before acquiring locks, and the read duration can be calculated by RocksDB performance context.

```
lock read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ acquire_pessimistic_lock"})) / sum(rate(tikv_storage_rocksdb_
        ↪ perf{metric="block_read_count",req="acquire_pessimistic_lock
        ↪ "}))
```

- `lock write duration` is the duration of writing on-disk lock. For more details, refer to the Async write section.

Commit

This section describes the commit duration. The following is the time cost diagram of commit operations:

```
Diagram(
    Stack(
        Sequence(
            Choice(
                0,
                Comment("use 2pc or causal consistency"),
                NonTerminal("Get min-commit-ts"),
            ),
            Optional("Async prewrite binlog"),
            NonTerminal("Prewrite mutations"),
            Optional("Wait prewrite binlog result"),
        ),
        Sequence(
            Choice(
                1,
                Comment("1pc"),
                Sequence(
                    Comment("2pc"),
                    NonTerminal("Get commit-ts"),
                    NonTerminal("Check schema"),
                    NonTerminal("Commit PK mutation"),
                ),
                Sequence(
                    Comment("async-commit"),
```

```
                NonTerminal("Commit mutations asynchronously"),
            ),
        ),
        Choice(
            0,
            Comment("committed"),
            NonTerminal("Async cleanup"),
        ),
        Optional("Commit binlog"),
    ),
),
)
```

The duration of the commit phase is calculated as:

```
commit =
    Get_latest_ts_time +
    Prewrite_time +
    Get_commit_ts_time +
    Commit_time

Get_latest_ts_time = Get_commit_ts_time =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"}

prewrite_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_prewrite"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_prewrite"})) /
    committer-concurrency
)

commit_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_commit"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_commit"})) /
    committer-concurrency
)

Prewrite_time =
    prewrite_round * tidb_tikvclient_request_seconds{type="Prewrite"}

Commit_time =
    commit_round * tidb_tikvclient_request_seconds{type="Commit"}
```

The commit duration can be broken down into four metrics:

- `Get_latest_ts_time` records the duration of getting latest TSO in async-commit or single-phase commit (1PC) transaction.

- `Prewrite_time` records the duration of the prewrite phase.
- `Get_commit_ts_time` records the duration of common 2PC transaction.
- `Commit_time` records the duration of the commit phase. Note that an async-commit or 1PC transaction does not have this phase.

Like pessimistic lock, flow control acts as an amplification of latency (`prewrite_round` and `commit_round` in the preceding formula).

The `tidb_tikvclient_request_seconds{type="Prewrite"}` and `tidb_tikvclient_request_seconds{type="Commit"}` duration are calculated as:

```
tidb_tikvclient_request_seconds{type="Prewrite"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_prewrite"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tidb_tikvclient_request_seconds{type="Commit"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_commit"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration`, `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_prewrite"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_prewrite"} =
    prewrite key count * prewrite read duration +
    prewrite write duration

prewrite key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="prewrite"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="prewrite"}))

prewrite read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ prewrite"})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_
        ↪ read_count",req="prewrite"}))
```

Like locks in TiKV, prewrite is processed in read and write phases. The read duration can be calculated from the RocksDB performance context. For more details about the write duration, refer to the Async write section.

The `tikv_grpc_msg_duration_seconds{type="kv_commit"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_commit"} =
    commit key count * commit read duration +
    commit write duration

commit key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="commit"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="commit"}))

commit read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="commit
        ↪ "})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_read_count
        ↪ ",req="commit"})) (storage)
```

The duration of `kv_commit` is almost the same as `kv_prewrite`. For more details about the write duration, refer to the Async write section.

11.1.8.5.4 Batch client

The following is the time cost diagram of the batch client:

```
Diagram(
    NonTerminal("Get conn pool to the target store"),
    Choice(
        0,
        Sequence(
            Comment("Batch enabled"),
                NonTerminal("Push request to channel"),
                NonTerminal("Wait response"),
            ),
            Sequence(
            NonTerminal("Get conn from pool"),
            NonTerminal("Call RPC"),
            Choice(
                0,
                Comment("Unary call"),
                NonTerminal("Recv first"),
            ),
        ),
    ),
)
```

- The overall duration of sending a request is observed as `tidb_tikvclient_request_seconds`.

- RPC client maintains connection pools (named ConnArray) to each store, and each pool has a BatchConn with a batch request (send) channel.
- Batch is enabled when the store is TiKV and batch size is positive, which is true in most cases.
- The size of batch request channel is `tikv-client.max-batch-size` (default is `128`), the duration of enqueue is observed as `tidb_tikvclient_batch_wait_duration`.
- There are three kinds of stream requests: `CmdBatchCop`, `CmdCopStream`, and `CmdMPPConn`, which involve an additional `recv()` call to fetch the first response from the stream.

Though there is still some latency missed observed, the `tidb_tikvclient_request_seconds` can be calculated approximately as:

```
tidb_tikvclient_request_seconds{type="?"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_?"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

- `tidb_tikvclient_batch_wait_duration` records the waiting duration in the batch system.
- `tidb_tikvclient_batch_send_latency` records the encode duration in the batch system.
- `tikv_grpc_msg_duration_seconds{type="kv_?"}` is the TiKV processing duration.
- `tidb_tikvclient_rpc_net_latency_seconds` records the network latency.

11.1.8.5.5 TiKV snapshot

The following is the time cost diagram of TiKV snapshot operations:

```
Diagram(
    Choice(
        0,
        Comment("Local Read"),
        Sequence(
            NonTerminal("Propose Wait"),
            NonTerminal("Read index Read Wait"),
        ),
    ),
    NonTerminal("Fetch A Snapshot From KV Engine"),
)
```

The overall duration of a TiKV snapshot is observed as `tikv_storage_engine_async_request_duration_seconds{type="snapshot"}` and is calculated as:

```
tikv_storage_engine_async_request_duration_seconds{type="snapshot"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} =
    tikv_raftstore_request_wait_time_duration_secs +
    tikv_raftstore_commit_log_duration_seconds +
    get snapshot from rocksdb duration
```

When leader lease is expired, TiKV proposes a read index command before getting a snapshot from RocksDB. `tikv_raftstore_request_wait_time_duration_secs` and `tikv_raftstore_commit_log_duration_seconds` are the duration of committing read index command.

Since getting a snapshot from RocksDB is usually a fast operation, the `get snapshot from rocksdb duration` is ignored.

11.1.8.5.6 Async write

Async write is the process that TiKV writes data into the Raft-based replicated state machine asynchronously with a callback.

- The following is the time cost diagram of async write operations when the asynchronous IO is disabled:

```
Diagram(
    NonTerminal("Propose Wait"),
    NonTerminal("Process Command"),
    Choice(
        0,
        Sequence(
            NonTerminal("Wait Current Batch"),
            NonTerminal("Write to Log Engine"),
        ),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

- The following is the time cost diagram of async write operations when the asynchronous IO is enabled:

```
Diagram(
    NonTerminal("Propose Wait"),
```

```
    NonTerminal("Process Command"),
    Choice(
        0,
        NonTerminal("Wait Until Persisted by Write Worker"),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

The async write duration is calculated as:

```
async write duration(async io disabled) =
    propose +
    async io disabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds

async write duration(async io enabled) =
    propose +
    async io enabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds
```

Async write can be broken down into the following three phases:

- Propose
- Commit
- Apply: `tikv_raftstore_apply_wait_time_duration_secs + tikv_raftstore_apply_log_duration_seconds` in the preceding formula

The duration of the propose phase is calculated as:

```
propose =
    propose wait duration +
    propose duration

propose wait duration =
    tikv_raftstore_store_wf_batch_wait_duration_seconds

propose duration =
    tikv_raftstore_store_wf_send_to_queue_duration_seconds -
    tikv_raftstore_store_wf_batch_wait_duration_seconds
```

The Raft process is recorded in a waterfall manner. So the propose duration is calculated from the difference between the two metrics.

The duration of the commit phase is calculated as:

```
async io disabled commit = max(
    persist log locally duration,
    replicate log duration
)

async io enabled commit = max(
    wait by write worker duration,
    replicate log duration
)
```

Since v5.3.0, TiKV supports Async IO Raft (write Raft log by a StoreWriter thread pool). The Async IO Raft is only enabled when the `store-io-pool-size` is set to a positive value, which changes the process of commit. The `persist log locally duration` and `wait by write worker duration` are calculated as:

```
persist log locally duration =
    batch wait duration +
    write to raft db duration

batch wait duration =
    tikv_raftstore_store_wf_before_write_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

write to raft db duration =
    tikv_raftstore_store_wf_write_end_duration_seconds -
    tikv_raftstore_store_wf_before_write_duration_seconds

wait by write worker duration =
    tikv_raftstore_store_wf_persist_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds
```

The difference between with and without Async IO is the duration of persisting logs locally. With Async IO, the duration of persisting log locally can be calculated from the waterfall metrics directly (skip the batch wait duration).

The replicate log duration records the duration of log persisted in quorum peers, which contains an RPC duration and the duration of log persisting in the majority. The `replicate log duration` is calculated as:

```
replicate log duration =
    raftmsg send wait duration +
    commit log wait duration
```

```
raftmsg send wait duration =
    tikv_raftstore_store_wf_send_proposal_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

commit log wait duration =
    tikv_raftstore_store_wf_commit_log_duration -
    tikv_raftstore_store_wf_send_proposal_duration_seconds
```

Raft DB

The following is the time cost diagram of Raft DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
    NonTerminal("Write and Sync Log"),
    NonTerminal("Apply Log to Memtable"),
)
```

```
write to raft db duration = raft db write duration
commit log wait duration >= raft db write duration

raft db write duration(raft engine enabled) =
    raft_engine_write_preprocess_duration_seconds +
    raft_engine_write_leader_duration_seconds +
    raft_engine_write_apply_duration_seconds

raft db write duration(raft engine disabled) =
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_thread_
       ↪ wait"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_
       ↪ scheduling_flushes_compactions_time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_wal_
       ↪ time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_
       ↪ memtable_time"}
```

Because `commit log wait duration` is the longest duration of quorum peers, it might be larger than `raft db write duration`.

Since v6.1.0, TiKV uses Raft Engine as its default log storage engine, which changes the process of writing log.

KV DB

The following is the time cost diagram of KV DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
```

```
    NonTerminal("Preprocess"),
    Choice(
        0,
        Comment("No Need to Switch"),
        NonTerminal("Switch WAL or Memtable"),
    ),
    NonTerminal("Write and Sync WAL"),
    NonTerminal("Apply to Memtable"),
)
```

```
tikv_raftstore_apply_log_duration_seconds =
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_thread_
        ↪ wait"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_
        ↪ scheduling_flushes_compactions_time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_wal_
        ↪ time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_
        ↪ memtable_time"}
```

In the async write process, committed logs need to be applied to the KV DB. The applying duration can be calculated from the RocksDB performance context.

11.1.8.5.7 Diagnosis use cases

The preceding sections explain the details about time cost metrics during querying. This section introduces common procedures of metrics analysis when you encounter slow read or write queries. All metrics can be checked in the Database Time panel of Performance Overview Dashboard.

Slow read queries

If `SELECT` statements account for a significant portion of the database time, you can assume that TiDB is slow at read queries.

The execution plans of slow queries can be found in the Top SQL statements panel of TiDB Dashboard. To investigate the time costs of slow read queries, you can analyze Point get, Batch point get and some simple coprocessor queries according to the preceding descriptions.

Slow write queries

Before investigating slow writes, you need to troubleshoot the cause of the conflicts by checking `tikv_scheduler_latch_wait_duration_seconds_sum{type="acquire_pessimistic_lock"} by (instance)`:

- If this metric is high in some specific TiKV instances, there might be conflicts in hot Regions.

- If this metric is high across all instances, there might be conflicts in the application.

After confirming the cause of conflicts from the application, you can investigate slow write queries by analyzing the duration of Lock and Commit.

11.1.9 TiDB Best Practices on Public Cloud

Public cloud infrastructure has become an increasingly popular choice for deploying and managing TiDB. However, deploying TiDB on public cloud requires careful consideration of several critical factors, including performance tuning, cost optimization, reliability, and scalability.

This document covers various essential best practices for deploying TiDB on public cloud, such as reducing compaction I/O flow in KV RocksDB, using a dedicated disk for Raft Engine, optimizing costs for cross-AZ traffic, mitigating Google Cloud live migration events, and fine-tuning the PD server in large clusters. By following these best practices, you can maximize the performance, cost efficiency, reliability, and scalability of your TiDB deployment on public cloud.

11.1.9.1 Reduce compaction I/O flow in KV RocksDB

As the storage engine of TiKV, RocksDB is used to store user data. Because the provisioned IO throughput on cloud EBS is usually limited due to cost considerations, RocksDB might exhibit high write amplification, and the disk throughput might become the bottleneck for the workload. As a result, the total number of pending compaction bytes grows over time and triggers flow control, which indicates that TiKV lacks sufficient disk bandwidth to keep up with the foreground write flow.

To alleviate the bottleneck caused by limited disk throughput, you can improve performance by enabling Titan. If your average row size is smaller than 512 bytes, Titan is not applicable. In this case, you can improve performance by increasing all the compression levels.

11.1.9.1.1 Enable Titan

Titan is a high-performance RocksDB plugin for key-value separation, which can reduce write amplification in RocksDB when large values are used.

If your average row size is larger than 512 bytes, you can enable Titan to reduce the compaction I/O flow as follows, with `min-blob-size` set to `"512B"` or `"1KB"` and `blob-file-compression` set to `"zstd"`:

```
[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"
```

Note:

When Titan is enabled, there might be a slight performance degradation for range scans on the primary key. For more information, see Impact of `min-blob-size` on performance.

11.1.9.1.2 Increase all the compression levels

If your average row size is smaller than 512 bytes, you can increase all the compression levels of the default column family to `"zstd"` as follows:

```
[rocksdb.defaultcf]
compression-per-level = ["zstd", "zstd", "zstd", "zstd", "zstd", "zstd", "
    ↪ zstd"]
```

11.1.9.2 Use a dedicated disk for Raft Engine

The Raft Engine in TiKV plays a critical role similar to that of a write-ahead log (WAL) in traditional databases. To achieve optimal performance and stability, it is crucial to allocate a dedicated disk for the Raft Engine when you deploy TiDB on public cloud. The following `iostat` shows the I/O characteristics on a TiKV node with a write-heavy workload.

```
Device            r/s     rkB/s       w/s     wkB/s     f/s  aqu-sz %util
sdb          1649.00 209030.67 1293.33 304644.00 13.33   5.09 48.37
sdd          1033.00  4132.00  1141.33 31685.33  571.00   0.94 100.00
```

The device `sdb` is used for KV RocksDB, while `sdd` is used to restore Raft Engine logs. Note that `sdd` has a significantly higher `f/s` value, which represents the number of flush requests completed per second for the device. In Raft Engine, when a write in a batch is marked synchronous, the batch leader will call `fdatasync()` after writing, guaranteeing that buffered data is flushed to the storage. By using a dedicated disk for Raft Engine, TiKV reduces the average queue length of requests, thereby ensuring optimal and stable write latency.

Different cloud providers offer various disk types with different performance characteristics, such as IOPS and MBPS. Therefore, it is important to choose an appropriate cloud provider, disk type, and disk size based on your workload.

11.1.9.2.1 Choose appropriate disks for Raft Engine on public clouds

This section outlines best practices for choosing appropriate disks for Raft Engine on different public clouds. Depending on performance requirements, two types of recommended disks are available.

Middle-range disk

The following are recommended middle-range disks for different public clouds:

- On AWS, gp3 is recommended. The gp3 volume offers a free allocation of 3000 IOPS and 125 MB/s throughput, regardless of the volume size, which is usually sufficient for the Raft Engine.
- On Google Cloud, pd-ssd is recommended. The IOPS and MBPS vary depending on the allocated disk size. To meet performance requirements, it is recommended to allocate 200 GB for Raft Engine. Although Raft Engine does not require such a large space, it ensures optimal performance.
- On Azure, Premium SSD v2 is recommended. Similar to AWS gp3, Premium SSD v2 provides a free allocation of 3000 IOPS and 125 MB/s throughput, regardless of the volume size, which is usually sufficient for Raft Engine.

High-end disk

If you expect an even lower latency for Raft Engine, consider using high-end disks. The following are recommended high-end disks for different public clouds:

- On AWS, io2 is recommended. Disk size and IOPS can be provisioned according to your specific requirements.
- On Google Cloud, pd-extreme is recommended. Disk size, IOPS, and MBPS can be provisioned, but it is only available on instances with more than 64 CPU cores.
- On Azure, ultra disk is recommended. Disk size, IOPS, and MBPS can be provisioned according to your specific requirements.

11.1.9.2.2 Example 1: Run a social network workload on AWS

AWS offers 3000 IOPS and 125 MBPS/s for a 20 GB gp3 volume.

By using a dedicated 20 GB gp3 Raft Engine disk on AWS for a write-intensive social network application workload, the following improvements are observed but the estimated cost only increases by 0.4%:

- a 17.5% increase in QPS (queries per second)
- an 18.7% decrease in average latency for insert statements
- a 45.6% decrease in p99 latency for insert statements.

Metric	Shared Raft Engine disk	Dedicated Raft Engine disk	Difference (%)
QPS (K/s)	8.0	9.4	17.5
AVG Insert Latency (ms)	11.3	9.2	-18.7
P99 Insert Latency (ms)	29.4	16.0	-45.6

11.1.9.2.3 Example 2: Run TPC-C/Sysbench workload on Azure

By using a dedicated 32 GB ultra disk for Raft Engine on Azure, the following improvements are observed:

- Sysbench `oltp_read_write` workload: a 17.8% increase in QPS and a 15.6% decrease in average latency.
- TPC-C workload: a 27.6% increase in QPS and a 23.1% decrease in average latency.

Metric	Workload	Shared Raft Engine disk	Dedicated Raft Engine disk
QPS (K/s)	Sysbench `oltp_read_write`	60.7	71.5
QPS (K/s)	TPC-C	23.9	30.5
AVG Latency (ms)	Sysbench `oltp_read_write`	4.5	3.8
AVG Latency (ms)	TPC-C	3.9	3.0

11.1.9.2.4 Example 3: Attach a dedicated pd-ssd disk on Google Cloud for Raft Engine on TiKV manifest

The following TiKV configuration example shows how to attach an additional 512 GB pd-ssd disk to a cluster on Google Cloud deployed by TiDB Operator, with `raft-engine.dir` configured to store Raft Engine logs to this specific disk.

```
tikv:
    config: |
      [raft-engine]
        dir = "/var/lib/raft-pv-ssd/raft-engine"
        enable = true
        enable-log-recycle = true
    requests:
      storage: 4Ti
    storageClassName: pd-ssd
    storageVolumes:
    - mountPath: /var/lib/raft-pv-ssd
      name: raft-pv-ssd
      storageSize: 512Gi
```

11.1.9.3 Optimize cost for cross-AZ network traffic

Deploying TiDB across multiple availability zones (AZs) can lead to increased costs due to cross-AZ data transfer fees. To optimize costs, it is important to reduce cross-AZ network traffic.

To reduce cross-AZ read traffic, you can enable the Follower Read feature, which allows TiDB to prioritize selecting replicas in the same availability zone. To enable this feature, set the `tidb_replica_read` variable to `closest-replicas` or `closest-adaptive`.

To reduce cross-AZ write traffic in TiKV instances, you can enable the gRPC compression feature, which compresses data before transmitting it over the network. The following configuration example shows how to enable gzip gRPC compression for TiKV.

```
server_configs:
  tikv:
    server.grpc-compression-type: gzip
```

To reduce network traffic caused by the data shuffle of TiFlash MPP tasks, it is recommended to deploy multiple TiFlash instances in the same availability zones (AZs). Starting from v6.6.0, compression exchange is enabled by default, which reduces the network traffic caused by MPP data shuffle.

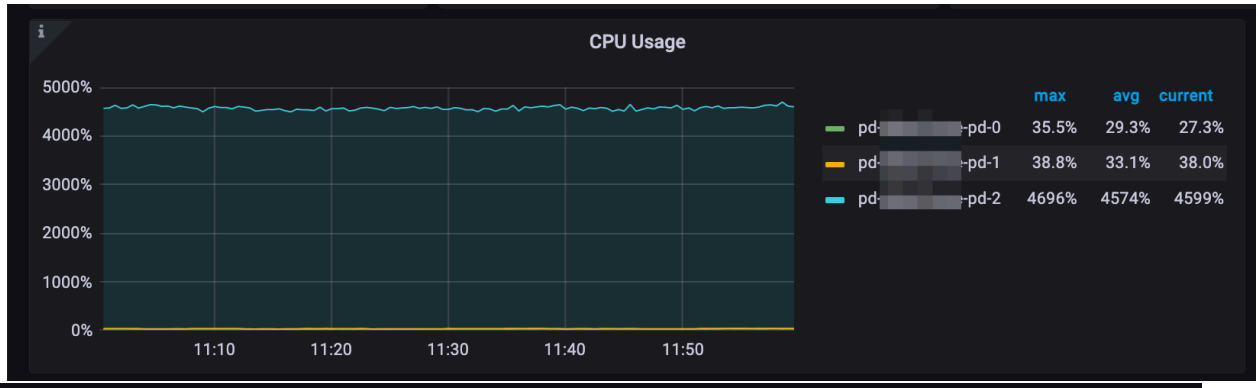
11.1.9.4 Mitigate live migration maintenance events on Google Cloud

The Live Migration feature of Google Cloud enables VMs to be seamlessly migrated between hosts without causing downtime. However, these migration events, although infrequent, can significantly impact the performance of VMs, including those running in a TiDB cluster. During such events, affected VMs might experience reduced performance, leading to longer query processing times in the TiDB cluster.

To detect live migration events initiated by Google Cloud and mitigate the performance impact of these events, TiDB provides a watching script based on Google's metadata example. You can deploy this script on TiDB, TiKV, and PD nodes to detect maintenance events. When a maintenance event is detected, appropriate actions can be taken automatically as follows to minimize disruption and optimize the cluster behavior:

- TiDB: Takes the TiDB node offline by cordoning it and deleting the TiDB pod. This assumes that the node pool of the TiDB instance is set to auto-scale and dedicated to TiDB. Other pods running on the node might experience interruptions, and the cordoned node is expected to be reclaimed by the auto-scaler.
- TiKV: Evicts leaders on the affected TiKV store during maintenance.
- PD: Resigns a leader if the current PD instance is the PD leader.

It is important to note that this watching script is specifically designed for TiDB clusters deployed using TiDB Operator, which offers enhanced management functionalities for TiDB in Kubernetes environments.



By utilizing the watching script and taking necessary actions during maintenance events, TiDB clusters can better handle live migration events on Google Cloud and ensure smoother operations with minimal impact on query processing and response times.

11.1.9.5 Tune PD for a large-scale TiDB cluster with high QPS

In a TiDB cluster, a single active Placement Driver (PD) server is used to handle crucial tasks such as serving the TSO (Timestamp Oracle) and processing requests. However, relying on a single active PD server can limit the scalability of TiDB clusters.

11.1.9.5.1 Symptoms of PD limitation

The following diagrams show the symptoms of a large-scale TiDB cluster consisting of three PD servers, each equipped with 56 CPUs. From these diagrams, it is observed that when the query per second (QPS) exceeds 1 million and the TSO (Timestamp Oracle) requests per second exceed 162,000, the CPU utilization reaches approximately 4,600%. This high CPU utilization indicates that the PD leader is experiencing a significant load and is running out of available CPU resources.

11.1.9.5.2 Tune PD performance

To address the high CPU utilization issue in the PD server, you can make the following tuning adjustments:

Adjust PD configuration

`tso-update-physical-interval`: This parameter controls the interval at which the PD server updates the physical TSO batch. By reducing the interval, the PD server can allocate TSO batches more frequently, thereby reducing the waiting time for the next allocation.

```
tso-update-physical-interval = "10ms" # default: 50ms
```

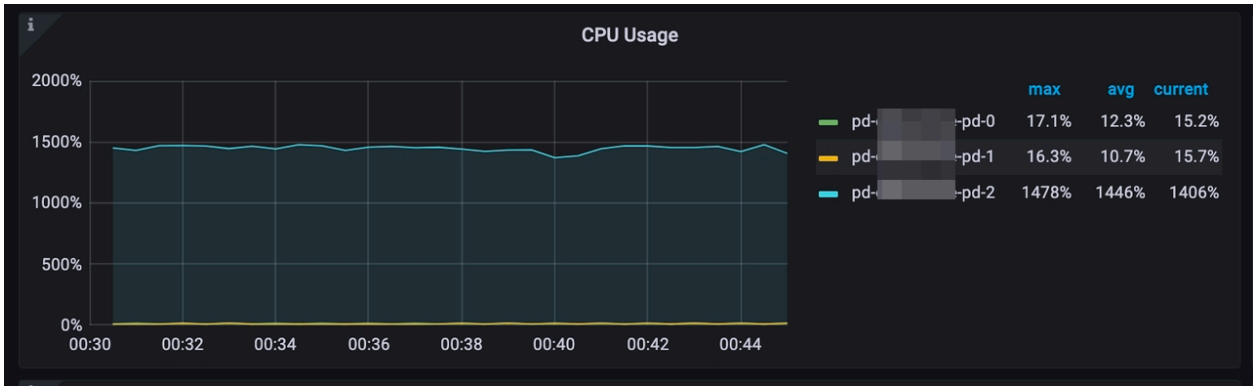
Adjust a TiDB global variable

In addition to the PD configuration, enabling the TSO client batch wait feature can further optimize the TSO client's behavior. To enable this feature, you can set the global variable `tidb_tso_client_batch_max_wait_time` to a non-zero value.

```
set global tidb_tso_client_batch_max_wait_time = 2; # default: 0
```

Adjust TiKV configuration

To reduce the number of Regions and alleviate the heartbeat overhead on the system, you can refer to Adjust Region size to moderately increase the size of the Region in TiKV configuration.



```
[coprocessor]
  region-split-size = "288MiB"
```

11.1.9.5.3 After tuning

After the tuning, the following effects can be observed:

- The TSO requests per second are decreased to 64,800.
- The CPU utilization is significantly reduced from approximately 4,600% to 1,400%.
- The P999 value of `PD server TSO handle time` is decreased from 2ms to 0.5ms.

These improvements indicate that the tuning adjustments have successfully reduced the CPU utilization of the PD server while maintaining stable TSO handling performance.

11.2 Configuration Tuning

11.2.1 Tune Operating System Performance

This document introduces how to tune each subsystem of CentOS 7.

Note:

- The default configuration of the CentOS 7 operating system is suitable for most services running under moderate workloads. Adjusting the performance of a particular subsystem might negatively affects other subsystems. Therefore, before tuning the system, back up all the user data and configuration information.
- Fully test all the changes in the test environment before applying them to the production environment.

11.2.1.1 Performance analysis methods

System tuning must be based on the results of system performance analysis. This section lists common methods for performance analysis.

11.2.1.1.1 In 60 seconds

Linux Performance Analysis in 60,000 Milliseconds is published by the author Brendan Gregg and the Netflix Performance Engineering team. All tools used can be obtained from the official release of Linux. You can analyze outputs of the following list items to troubleshoot most common performance issues.

- `uptime`
- `dmesg | tail`
- `vmstat 1`
- `mpstat -P ALL 1`
- `pidstat 1`
- `iostat -xz 1`
- `free -m`
- `sar -n DEV 1`
- `sar -n TCP,ETCP 1`
- `top`

For detailed usage, see the corresponding `man` instructions.

11.2.1.1.2 perf

perf is an important performance analysis tool provided by the Linux kernel, which covers hardware level (CPU/PMU, performance monitoring unit) features and software features (software counters, trace points). For detailed usage, see perf Examples.

11.2.1.1.3 BCC/bpftrace

Starting from CentOS 7.6, the Linux kernel has supported Berkeley Packet Filter (BPF). Therefore, you can choose proper tools to conduct an in-depth analysis based on the results in In 60 seconds. Compared with perf/ftrace, BPF provides programmability and smaller performance overhead. Compared with kprobe, BPF provides higher security and is more suitable for the production environments. For detailed usage of the BCC toolkit, see BPF Compiler Collection (BCC).

11.2.1.2 Performance tuning

This section introduces performance tuning based on the classified kernel subsystems.

11.2.1.2.1 CPU—frequency scaling

cpufreq is a module that dynamically adjusts the CPU frequency. It supports five modes. To ensure service performance, select the performance mode and fix the CPU frequency at the highest supported operating frequency without dynamic adjustment. The command for this operation is `cpupower frequency-set --governor performance`.

11.2.1.2.2 CPU—interrupt affinity

- Automatic balance can be implemented through the `irqbalance` service.
- Manual balance:

- Identify the devices that need to balance interrupts. Starting from CentOS 7.5, the system automatically configures the best interrupt affinity for certain devices and their drivers, such as devices that use the `be2iscsi` driver and NVMe settings. You can no longer manually configure interrupt affinity for such devices.
- For other devices, check the chip manual to see whether these devices support distributing interrupts.
    - If they do not, all interrupts of these devices are routed to the same CPU and cannot be modified.
    - If they do, calculate the `smp_affinity` mask and set the corresponding configuration file. For details, see the kernel document.

11.2.1.2.3 NUMA CPU binding

To avoid accessing memory across Non-Uniform Memory Access (NUMA) nodes as much as possible, you can bind a thread/process to certain CPU cores by setting the CPU affinity of the thread. For ordinary programs, you can use the `numactl` command for the CPU binding. For detailed usage, see the Linux manual pages. For network interface card (NIC) interrupts, see tune network.

11.2.1.2.4 Memory—transparent huge page (THP)

It is **NOT** recommended to use THP for database applications, because databases often have sparse rather than continuous memory access patterns. If high-level memory fragmentation is serious, a higher latency will occur when THP pages are allocated. If the direct compaction is enabled for THP, the CPU usage will surge. Therefore, it is recommended to disable THP.

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

11.2.1.2.5 Memory—virtual memory parameters

- `dirty_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to use the `pdflush` operation to write the dirty page caches to disk. The default value of `dirty_ratio` is 20% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, lowering this value helps improve the efficiency of memory reclamation.
- `dirty_background_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to write the dirty page caches to the disk in the background. The default value of `dirty_background_ratio` is 10% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, setting a lower value helps improve the efficiency of memory reclamation.

11.2.1.2.6 Storage and file system

The core I/O stack link is long, including the file system layer, the block device layer, and the driver layer.

I/O scheduler

The I/O scheduler determines when and how long I/O operations run on the storage device. It is also called I/O elevator. For SSD devices, it is recommended to set the I/O scheduling policy to `noop`.

```
echo noop > /sys/block/${SSD_DEV_NAME}/queue/scheduler
```

Formatting parameters—block size

Blocks are the working units of the file system. The block size determines how much data can be stored in a single block, and thus determines the minimum amount of data to be written or read each time.

The default block size is suitable for most scenarios. However, if the block size (or the size of multiple blocks) is the same or slightly larger than the amount of data normally read or written each time, the file system performs better and the data storage efficiency is higher. Small files still use the entire block. Files can be distributed among multiple blocks, but this will increase runtime overhead.

When using the `mkfs` command to format a device, specify the block size as a part of the file system options. The parameters that specify the block size vary with the file system. For details, see the corresponding `mkfs` manual pages, such as using `man mkfs.ext4`.

`mount` parameters

If the `noatime` option is enabled in the `mount` command, the update of metadata is disabled when files are read. If the `nodiratime` behavior is enabled, the update of metadata is disabled when the directory is read.

11.2.1.2.7 Network tuning

The network subsystem consists of many different parts with sensitive connections. The CentOS 7 network subsystem is designed to provide the best performance for most workloads and automatically optimizes the performance of these workloads. Therefore, usually you do not need to manually adjust network performance.

Network issues are usually caused by issues of hardware or related devices. So before tuning the protocol stack, rule out hardware issues.

Although the network stack is largely self-optimizing, the following aspects in the network packet processing might become the bottleneck and affect performance:

- NIC hardware cache: To correctly observe the packet loss at the hardware level, use the `ethtool -S ${NIC_DEV_NAME}` command to observe the `drops` field. When packet loss occurs, it might be that the processing speed of the hard/soft interrupts cannot

catch up with the receiving speed of NIC. If the received buffer size is less than the upper limit, you can also try to increase the RX buffer to avoid packet loss. The query command is: `ethtool -g ${NIC_DEV_NAME}`, and the modification command is `ethtool -G ${NIC_DEV_NAME}`.

- Hardware interrupts: If the NIC supports the Receive-Side Scaling (RSS, also called multi-NIC receiving) feature, observe the `/proc/interrupts` NIC interrupts. If the interrupts are uneven, see CPU—frequency scaling, CPU—interrupt affinity, and NUMA CPU binding. If the NIC does not support RSS or the number of RSS is much smaller than the number of physical CPU cores, configure Receive Packet Steering (RPS, which can be regarded as the software implementation of RSS), and the RPS extension Receive Flow Steering (RFS). For detailed configuration, see the kernel document.

- Software interrupts: Observe the monitoring of `/proc/net/softnet_stat`. If the values of the other columns except the third column are increasing, properly adjust the value of `net.core.netdev_budget` or `net.core.dev_weight` for `softirq` to get more CPU time. In addition, you also need to check the CPU usage to determine which tasks are frequently using the CPU and whether they can be optimized.

- Receive queue of application sockets: Monitor the `Resv-q` column of `ss -nmp`. If the queue is full, consider increasing the size of the application socket cache or use the automatic cache adjustment method. In addition, consider whether you can optimize the architecture of the application layer and reduce the interval between reading sockets.

- Ethernet flow control: If the NIC and switch support the flow control feature, you can use this feature to leave some time for the kernel to process the data in the NIC queue, to avoid the issue of NIC buffer overflow.

- Interrupts coalescing: Too frequent hardware interrupts reduces system performance, and too late hardware interrupts causes packet loss. Newer NICs support the interrupt coalescing feature and allow the driver to automatically adjust the number of hardware interrupts. You can execute `ethtool -c ${NIC_DEV_NAME}` to check and `ethtool -C ${NIC_DEV_NAME}` to enable this feature. The adaptive mode allows the NIC to automatically adjust the interrupt coalescing. In this mode, the driver checks the traffic mode and kernel receiving mode, and evaluates the coalescing settings in real time to prevent packet loss. NICs of different brands have different features and default configurations. For details, see the NIC manuals.

- Adapter queue: Before processing the protocol stack, the kernel uses this queue to buffer the data received by the NIC, and each CPU has its own backlog queue. The maximum number of packets that can be cached in this queue is `netdev_max_backlog`. Observe the second column of `/proc/net/softnet_stat`. When the second column of a row continues to increase, it means that the CPU [row-1] queue is full and the data packet is lost. To resolve this problem, continue to double the `net.core.netdev_max_backlog` value.

- Send queue: The length value of a send queue determines the number of packets that can be queued before sending. The default value is `1000`, which is sufficient for 10 Gbps. But if you have observed the value of TX errors from the output of `ip -s link`, you can try to double it: `ip link set dev ${NIC_DEV_NAME} txqueuelen 2000`.
- Driver: NIC drivers usually provide tuning parameters. See the device hardware manual and its driver documentation.

11.2.2 TiDB Memory Control

Currently, TiDB can track the memory quota of a single SQL query and take actions to prevent OOM (out of memory) or troubleshoot OOM when the memory usage exceeds a specific threshold value. The system variable `tidb_mem_oom_action` specifies the action to take when a query reaches the memory limit:

- A value of `LOG` means that queries will continue to execute when the `tidb_mem_quota_query` limit is reached, but TiDB will print an entry to the log.
- A value of `CANCEL` means TiDB stops executing the SQL query immediately after the `tidb_mem_quota_query` limit is reached, and returns an error to the client. The error information clearly shows the memory usage of each physical execution operator that consumes memory in the SQL execution process.

11.2.2.1 Configure the memory quota of a query

The system variable `tidb_mem_quota_query` sets the limit for a query in bytes. Some usage examples:

```
-- Set the threshold value of memory quota for a single SQL query to 8GB:
SET tidb_mem_quota_query = 8 << 30;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8MB:
SET tidb_mem_quota_query = 8 << 20;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8KB:
SET tidb_mem_quota_query = 8 << 10;
```

11.2.2.2 Configure the memory usage threshold of a tidb-server instance

Since v6.5.0, you can use the system variable `tidb_server_memory_limit` to set the threshold for the memory usage of a tidb-server instance.

For example, set the total memory usage of a tidb-server instance to 32 GB:

```
SET GLOBAL tidb_server_memory_limit = "32GB";
```

After you set this variable, when the memory usage of a tidb-server instance reaches 32 GB, TiDB will terminate the SQL operation with the largest memory usage among all running SQL operations in order, until the memory usage of the instance drops below 32 GB. The forcibly terminated SQL operation will return the `Out Of Memory Quota!` error to the client.

Currently, the memory limit set by `tidb_server_memory_limit` **DOES NOT** terminate the following SQL operations:

- DDL operations
- SQL operations that contain window functions and common table expressions

> **Warning:**
>
> - During the startup process, TiDB does not guarantee that the `tidb_server_memory_limit` limit is enforced. If the free memory of the operating system is insufficient, TiDB might still encounter OOM. You need to ensure that the TiDB instance has enough available memory.
> - In the process of memory control, the total memory usage of TiDB might slightly exceed the limit set by `tidb_server_memory_limit`.
> - Since v6.5.0, the configuration item `server-memory-quota` is deprecated. To ensure compatibility, after you upgrade your cluster to v6.5.0 or a later version, `tidb_server_memory_limit` will inherit the value of `server-memory-quota`. If you have not configured `server-memory-quota` before the upgrade, the default value of `tidb_server_memory_limit` is used, which is `80%`.

When the memory usage of a tidb-server instance reaches a certain proportion of the total memory (the proportion is controlled by the system variable `tidb_server_memory_limit_gc_trigger`), tidb-server will try to trigger a Golang GC to relieve memory stress. To avoid frequent GCs that cause performance issues due to the instance memory fluctuating around the threshold, this GC method will trigger GC at most once every minute.

> **Note:**
>
> In a hybrid deployment scenario, `tidb_server_memory_limit` is the memory usage threshold for a single tidb-server instance, instead of the total memory threshold for the whole physical machine.

11.2.2.3 View the memory usage of the current tidb-server instance using the INFORMATION_SCHEMA system table

To view the memory usage of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE`.

To view the memory-related operations and execution basis of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE_OPS_HISTORY`. For each instance, this table retains the latest 50 records.

11.2.2.4 Trigger the alarm of excessive memory usage

When the memory usage of a tidb-server instance exceeds its memory threshold (70% of its total memory by default) and any of the following conditions is met, TiDB records the related status files and prints an alarm log.

- It is the first time the memory usage exceeds the memory threshold.
- The memory usage exceeds the memory threshold and it has been more than 60 seconds since the last alarm.
- The memory usage exceeds the memory threshold and `(Current memory usage - Memory usage at the last alarm)/ Total memory > 10%`.

You can control the memory threshold that triggers the alarm by modifying the memory usage ratio via the system variable `tidb_memory_usage_alarm_ratio`.

When the alarm of excessive memory usage is triggered, TiDB takes the following actions:

- TiDB records the following information in the directory where the TiDB log file `filename` is located.
    - The information about the top 10 SQL statements with the highest memory usage and the top 10 SQL statements with the longest running time among all SQL statements currently being executed
    - The goroutine stack information
    - The usage status of heap memory
- TiDB prints an alarm log containing the keyword `tidb-server has the risk of OOM` and the values of the following memory-related system variables.
    - `tidb_mem_oom_action`
    - `tidb_mem_quota_query`
    - `tidb_server_memory_limit`
    - `tidb_analyze_version`
    - `tidb_enable_rate_limit_action`

To avoid accumulating too many status files for alarms, TiDB only retains the status files generated during the recent five alarms by default. You can adjust this number by configuring the system variable tidb_memory_usage_alarm_keep_record_num.

The following example constructs a memory-intensive SQL statement that triggers the alarm:

1. Set tidb_memory_usage_alarm_ratio to 0.85:

```
SET GLOBAL tidb_memory_usage_alarm_ratio = 0.85;
```

2. Execute CREATE TABLE t(a int); and insert 1000 rows of data.

3. Execute select * from t t1 join t t2 join t t3 order by t1.a. This SQL statement outputs one billion records, which consumes a large amount of memory and therefore triggers the alarm.

4. Check the tidb.log file which records the total system memory, current system memory usage, memory usage of the tidb-server instance, and the directory of status files.

```
[2022/10/11 16:39:02.281 +08:00] [WARN] [memoryusagealarm.go:212] ["
    ↪ tidb-server has the risk of OOM because of memory usage exceeds
    ↪ alarm ratio. Running SQLs and heap profile will be recorded in
    ↪ record path"] ["is tidb_server_memory_limit set"=false] ["system
    ↪ memory total"=33682427904] ["system memory usage"=22120655360] ["
    ↪ tidb-server memory usage"=21468556992] [memory-usage-alarm-ratio
    ↪ =0.85] ["record path"=/tiup/deploy/tidb-4000/log/oom_record]
```

   The fields of the example log file above are described as follows:

   - is tidb_server_memory_limit set indicates whether tidb_server_memory_
     ↪ limit is set.
   - system memory total indicates the total memory of the current system.
   - system memory usage indicates the current system memory usage.
   - tidb-server memory usage indicates the memory usage of the tidb-server instance.
   - memory-usage-alarm-ratio indicates the value of the system variable tidb_
     ↪ memory_usage_alarm_ratio.
   - record path indicates the directory of status files.

5. By checking the directory of status files (In the preceding example, the directory is /tiup/deploy/tidb-4000/log/oom_record), you can see a record directory with the corresponding timestamp (for example, record2022-10-09T17:18:38+08:00). The record directory includes three files: goroutinue, heap, and running_sql. These three files are suffixed with the time when status files are logged. They respectively record goroutine stack information, the usage status of heap memory, and the running SQL information when the alarm is triggered. For the content in running_sql, refer to expensive-queries.

11.2.2.5 Reduce the memory usage for write transactions in tidb-server

The transaction model used by TiDB requires that all write operations of transactions are first cached in memory before being committed. When TiDB writes large transactions, memory usage might increase and become a bottleneck. To reduce or avoid high memory usage by large transactions under various constraints, you can adjust the `tidb_dml_type` system variable to `"bulk"` or use Non-transactional DML statements.

11.2.2.6 Other memory control behaviors of tidb-server

11.2.2.6.1 Flow control

- TiDB supports dynamic memory control for the operator that reads data. By default, this operator uses the maximum number of threads that `tidb_distsql_scan_concurrency` allows to read data. When the memory usage of a single SQL execution exceeds `tidb_mem_quota_query` each time, the operator that reads data stops one thread.
- This flow control behavior is controlled by the system variable `tidb_enable_rate_limit_action`.
- When the flow control behavior is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, destroy one token now`.

11.2.2.6.2 Disk spill

TiDB supports disk spill for execution operators. When the memory usage of a SQL execution exceeds the memory quota, tidb-server can spill the intermediate data of execution operators to the disk to relieve memory pressure. Operators supporting disk spill include Sort, MergeJoin, HashJoin, and HashAgg.

- The disk spill behavior is jointly controlled by the following parameters: `tidb_mem_quota_query`, `tidb_enable_tmp_storage_on_oom`, `tmp-storage-path`, and `tmp-storage-quota`.
- When the disk spill is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, spill to disk now` or `memory exceeds quota, set aggregate mode to spill-mode`.
- Disk spill for the Sort, MergeJoin, and HashJoin operators is introduced in v4.0.0. Disk spill for the non-parallel algorithm of the HashAgg operator is introduced in v5.2.0. Disk spill for the parallel algorithm of the HashAgg operator is introduced in v8.0.0 as an experimental feature and becomes generally available (GA) in v8.2.0. Disk spill for the TopN operator is introduced in v8.3.0.
- You can control whether to enable the parallel HashAgg algorithm that supports disk spill using the `tidb_enable_parallel_hashagg_spill` system variable. This variable will be deprecated in a future release.

- When the SQL executions containing Sort, MergeJoin, HashJoin, HashAgg, or TopN cause OOM, TiDB triggers disk spill by default.

> **Note:**
>
> The disk spill for HashAgg does not support SQL executions containing the `DISTINCT` aggregate function. When a SQL execution containing a `DISTINCT` aggregate function uses too much memory, the disk spill does not apply.

The following example uses a memory-consuming SQL statement to demonstrate the disk spill feature for HashAgg:

1. Configure the memory quota of a SQL statement to 1GB (1 GB by default):

```
SET tidb_mem_quota_query = 1 << 30;
```

2. Create a single table `CREATE TABLE t(a int);` and insert 256 rows of different data.

3. Execute the following SQL statement:

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

   Because executing this SQL statement occupies too much memory, the following "Out of Memory Quota" error message is returned:

```
ERROR 1105 (HY000): Out Of Memory Quota![conn_id=3]
```

4. Execute the same SQL statement. You can find that this time, the statement is successfully executed and no error message is returned. From the following detailed execution plan, you can see that HashAgg has used 600 MB of hard disk space.

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

```

11.2.2.7 Others

11.2.2.7.1 Mitigate OOM issues by configuring GOMEMLIMIT

GO 1.19 introduces an environment variable GOMEMLIMIT to set the memory limit that triggers GC.

For v6.1.3 <= TiDB < v6.5.0, you can mitigate a typical category of OOM issues by manually setting GOMEMLIMIT. The typical category of OOM issues is: before OOM occurs, the estimated memory in use on Grafana occupies only half of the entire memory (TiDB-Runtime > Memory Usage > estimate-inuse), as shown in the following figure:

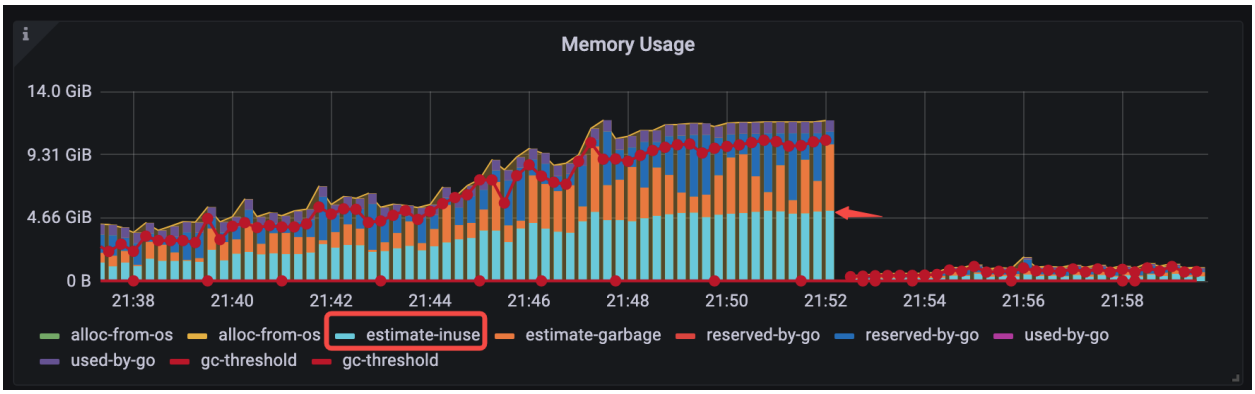

Figure 397: normal OOM case example

To verify the performance of GOMEMLIMIT, a test is performed to compare the specific memory usage with and without GOMEMLIMIT configuration.

- In TiDB v6.1.2, the TiDB server encounters OOM (system memory: about 48 GiB) after the simulated workload runs for several minutes:

Figure 398: v6.1.2 workload oom

- In TiDB v6.1.3, `GOMEMLIMIT` is set to 40000 MiB. It is found that the simulated workload runs stably for a long time, OOM does not occur in the TiDB server, and the maximum memory usage of the process is stable at around 40.8 GiB:

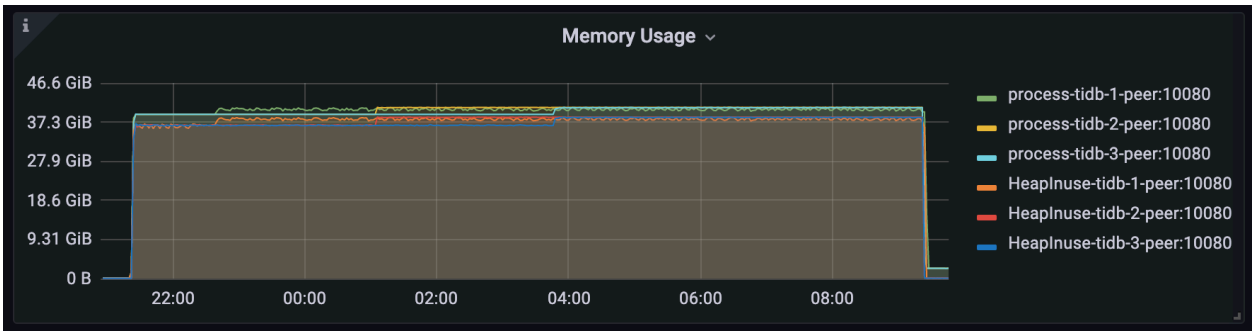

Figure 399: v6.1.3 workload no oom with GOMEMLIMIT

11.2.3 Tune TiKV Thread Pool Performance

This document introduces TiKV internal thread pools and how to tune their performance.

11.2.3.1 Thread pool introduction

The TiKV thread pool is mainly composed of gRPC, Scheduler, UnifyReadPool, Raftstore, StoreWriter, Apply, RocksDB, and some scheduled tasks and detection components that do not consume much CPU. This document mainly introduces a few CPU-intensive thread pools that affect the performance of read and write requests.

- The gRPC thread pool: it handles all network requests and forwards requests of different task types to different thread pools.

- The Scheduler thread pool: it detects write transaction conflicts, converts requests like the two-phase commit, pessimistic locking, and transaction rollbacks into key-value pair arrays, and then sends them to the Raftstore thread for Raft log replication.
- The Raftstore thread pool:
    - It processes all Raft messages and the proposal to add a new log.
    - It writes Raft logs to the disk. If the value of `store-io-pool-size` is `0`, the Raftstore thread writes the logs to the disk; if the value is not `0`, the Raftstore thread sends the logs to the StoreWriter thread.
    - When Raft logs in the majority of replicas are consistent, the Raftstore thread sends the logs to the Apply thread.
- The StoreWriter thread pool: it writes all Raft logs to the disk and returns the result to the Raftstore thread.
- The Apply thread pool: it receives the submitted log sent from the Raftstore thread pool, parses it as a key-value request, then writes it to RocksDB, calls the callback function to notify the gRPC thread pool that the write request is complete, and returns the result to the client.
- The RocksDB thread pool: it is a thread pool for RocksDB to compact and flush tasks. For RocksDB's architecture and `Compact` operation, refer to RocksDB: A Persistent Key-Value Store for Flash and RAM Storage.
- The UnifyReadPool thread pool: it is a combination of the Coprocessor thread pool and Storage Read Pool. All read requests such as kv get, kv batch get, raw kv get, and coprocessor are executed in this thread pool.

11.2.3.2 TiKV read-only requests

TiKV's read requests are divided into the following types:

- Simple queries that specify a certain row or several rows, running in the Storage Read Pool.
- Complex aggregate calculation and range queries, running in the Coprocessor Read Pool.

Starting from TiKV v5.0, all read requests use the unified thread pool for queries by default. If your TiKV cluster is upgraded from TiKV v4.0 and the `use-unified-pool` configuration of `readpool.storage` was set to `false` before the upgrade, all read requests continue using different thread pools after the upgrade. In this scenario, to make all read requests use the unified thread pool for queries, you can set the value of `readpool.storage` ↪ `.use-unified-pool` to `true`.

11.2.3.3 Performance tuning for TiKV thread pools

- The gRPC thread pool.

  The default size (configured by `server.grpc-concurrency`) of the gRPC thread pool is `5`. This thread pool has almost no computing overhead and is mainly responsible for network I/O and deserialization requests, so generally you do not need to adjust the default configuration.

  - If the machine deployed with TiKV has a small number (less than or equal to 8) of CPU cores, consider setting the `server.grpc-concurrency` configuration item to `2`.
  - If the machine deployed with TiKV has very high configuration, TiKV undertakes a large number of read and write requests, and the value of `gRPC poll CPU` that monitors Thread CPU on Grafana exceeds 80% of `server.grpc-concurrency` ↪ , then consider increasing the value of `server.grpc-concurrency` to keep the thread pool usage rate below 80% (that is, the metric on Grafana is lower than `80% * server.grpc-concurrency`).

- The Scheduler thread pool.

  When TiKV detects that the number of machine CPU cores is larger than or equal to 16, the default size (configured by `storage.scheduler-worker-pool-size`) of the Scheduler thread pool is `8`; when TiKV detects that the number of machine CPU cores is smaller than 16, the default size is `4`.

  This thread pool is mainly used to convert complex transaction requests into simple key-value read and write requests. However, **the Scheduler thread pool itself does not perform any write operation**.

  - If it detects a transaction conflict, then this thread pool returns the conflict result to the client in advance.
  - If no conflict is detected, then this thread pool merges the key-value requests that perform write operations into a Raft log and sends it to the Raftstore thread for Raft log replication.

  Generally speaking, to avoid excessive thread switching, it is best to ensure that the utilization rate of the Scheduler thread pool is between 50% and 75%. If the thread pool size is `8`, then it is recommended to keep `TiKV-Details.Thread CPU.scheduler` ↪ `worker CPU` on Grafana between 400% and 600%.

- The Raftstore thread pool.

  The Raftstore thread pool is the most complex thread pool in TiKV. The default size (configured by `raftstore.store-pool-size`) of this thread pool is `2`. For the StoreWriter thread pool, the default size (configured by `raftstore.store-io-pool-` ↪ `size`) is `1`.

- When the size of the StoreWriter thread pool is 0, all write requests are written into RocksDB in the way of `fsync` by the Raftstore thread. In this case, it is recommended to tune the performance as follows:
  - Keep the overall CPU usage of the Raftstore thread below 60%. When the number of Raftstore threads is 2, keep the **TiKV-Details**, **Thread CPU**, **Raft store CPU** on Grafana below 120%. Due to I/O requests, the CPU usage of Raftstore threads in theory is always lower than 100%.
  - Do not increase the size of the Raftstore thread pool to improve write performance without careful consideration, because this might increase the disk burden and degrade performance.
- When the size of the StoreWriter thread pool is not 0, all write requests are written into RocksDB in the way of `fsync` by the StoreWriter thread. In this case, it is recommended to tune the performance as follows:
  - Enable the StoreWriter thread pool ONLY when the overall CPU resources are sufficient. When the StoreWriter thread pool is enabled, keep the CPU usage of the StoreWriter thread and the Raftstore thread below 80%.

  Compared with the case that the write requests are processed by the Raftstore thread, in theory, when the write requests are processed by the StoreWriter thread, write latency and the tail latency of data read are significantly reduced. However, as the write speed grows faster, the number of Raft logs increases accordingly. This can cause the CPU overhead of the Raftstore threads, the Apply threads, and the gRPC threads to increase. In this case, insufficient CPU resources might offset the tuning effect, and as a result, the write speed might become slower than before. Therefore, if the CPU resources are not sufficient, it is not recommended to enable the StoreWriter thread. Because the Raftstore thread sends most of the I/O requests to the StoreWriter thread, you need to keep the CPU usage of the Raftstore thread below 80%.
- In most cases, set the size of the StoreWriter thread pool to 1 or 2. This is because the size of the StoreWriter thread pool affects the number of Raft logs, so the value of the thread pool size should not be too large. If the CPU usage is higher than 80%, consider increasing the thread pool size.
- Pay attention to the impact of increasing Raft logs on the CPU overhead of other thread pools. If necessary, you need to increase the number of Raftstore threads, Apply threads, and gRPC threads accordingly.

- The UnifyReadPool thread pool.

  The UnifyReadPool is responsible for handling all read requests. The default size (configured by `readpool.unified.max-thread-count`) is 80% of the number of the machine's CPU cores. For example, if the machine CPU has 16 cores, the default thread pool size is 12. It is recommended to adjust the CPU usage rate according to the application workloads and keep it between 60% and 90% of the thread pool size.

If the peak value of the `TiKV-Details.Thread CPU.Unified read pool CPU` on Grafana does not exceed 800%, then it is recommended to set `readpool.unified.max-thread-count` to `10`. Too many threads can cause more frequent thread switching, and take up resources of other thread pools.

Since v6.3.0, TiKV supports automatically adjusting the UnifyReadPool thread pool size based on the current CPU usage. To enable this feature, you can set the `readpool.unified.auto-adjust-pool-size = true`. It is recommended to automatically adjust the thread pool size for clusters that are reread and whose maximum CPU usage exceeds 80%.

- The RocksDB thread pool.

  The RocksDB thread pool is a thread pool for RocksDB to compact and flush tasks. Usually, you do not need to configure it.

  - If the machine has a small number of CPU cores, set both `rocksdb.max-background-jobs` and `raftdb.max-background-jobs` to `4`.
  - If you encounter write stall, go to Write Stall Reason in **RocksDB-kv** on Grafana and check on the metrics that are not `0`.
    - If it is caused by reasons related to pending compaction bytes, set `rocksdb.max-sub-compactions` to `2` or `3`. This configuration item indicates the number of sub-threads allowed for a single compaction job. Its default value is `3` in TiKV 4.0 and `1` in TiKV 3.0.
    - If the reason is related to memtable count, it is recommended to increase the `max-write-buffer-number` of all columns (`5` by default).
    - If the reason is related to the level0 file limit, it is recommended to increase values of the following parameters to `64` or a larger number:

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

11.2.4 Tune TiKV Memory Parameter Performance

This document describes how to tune the TiKV parameters for optimal performance. You can find the default configuration file in etc/config-template.toml. To modify the configuration, you can use TiUP or modify TiKV dynamically for a limited set of configuration items. For the complete configuration, see TiKV configuration file.

TiKV uses RocksDB for persistent storage at the bottom level of the TiKV architecture. Therefore, many of the performance parameters are related to RocksDB. TiKV uses

two RocksDB instances: the default RocksDB instance stores KV data, the Raft RocksDB instance (RaftDB) stores Raft logs.

TiKV implements `Column Families` (CF) from RocksDB.

- The default RocksDB instance stores KV data in the `default`, `write` and `lock` CFs.
    - The `default` CF stores the actual data. The corresponding parameters are in `[rocksdb.defaultcf]`.
    - The `write` CF stores the version information in Multi-Version Concurrency Control (MVCC) and index-related data. The corresponding parameters are in `[rocksdb.writecf]`.
    - The `lock` CF stores the lock information. The system uses the default parameters.
- The Raft RocksDB (RaftDB) instance stores Raft logs.
    - The `default` CF stores the Raft log. The corresponding parameters are in `[raftdb.defaultcf]`.

After TiKV 3.0, by default, all CFs share one block cache instance. You can configure the size of the cache by setting the `capacity` parameter under `[storage.block-cache]`. The bigger the block cache, the more hot data can be cached, and the easier to read data, in the meantime, the more system memory is occupied.

Before TiKV 3.0, shared block cache is not supported, and you need to configure block cache for each CF individually.

Each CF also has a separate `write buffer`. You can configure the size by setting the `write-buffer-size` parameter.

11.2.4.1 Parameter specification

```
### Log level: trace, debug, warn, error, info, off.
log-level = "info"

[server]
### Set listening address
### addr = "127.0.0.1:20160"

### Size of thread pool for gRPC
### grpc-concurrency = 4
### The number of gRPC connections between each TiKV instance
### grpc-raft-conn-num = 10

### Most read requests from TiDB are sent to the coprocessor of TiKV. This
   ↪ parameter is used to set the number of threads
```

```
### of the coprocessor. If many read requests exist, add the number of
   ↪ threads and keep the number within that of the
### system CPU cores. For example, for a 32-core machine deployed with TiKV,
   ↪  you can even set this parameter to 30 in
### repeatable read scenarios. If this parameter is not set, TiKV
   ↪ automatically sets it to CPU cores * 0.8.
### end-point-concurrency = 8

### Tag the TiKV instances to schedule replicas.
### labels = {zone = "cn-east-1", host = "118", disk = "ssd"}

[storage]
### The data directory
### data-dir = "/tmp/tikv/store"

### In most cases, you can use the default value. When importing data, it is
   ↪  recommended to set the parameter to 1024000.
### scheduler-concurrency = 102400
### This parameter controls the number of write threads. When write
   ↪ operations occur frequently, set this parameter value
### higher. Run `top -H -p tikv-pid` and if the threads named `sched-worker-
   ↪ pool` are busy, set the value of parameter
### `scheduler-worker-pool-size` higher and increase the number of write
   ↪ threads.
### scheduler-worker-pool-size = 4

[storage.block-cache]
#### Whether to create a shared block cache for all RocksDB column families.
#### ## Block cache is used by RocksDB to cache uncompressed blocks. Big
   ↪ block cache can speed up read.
#### It is recommended to turn on shared block cache. Since only the total
   ↪ cache size need to be
#### set, it is easier to configure. In most cases, it should be able to
   ↪ auto-balance cache usage
#### between column families with standard LRU algorithm.
#### ## The rest of config in the storage.block-cache session is effective
   ↪ only when shared block cache
#### is on.
#### Starting from v6.6.0, the `shared` option is always enabled and cannot
   ↪ be disabled.
### shared = true

#### Size of the shared block cache. Normally it should be tuned to 30%-50%
   ↪ of system's total memory.
#### When the config is not set, it is decided by the sum of the following
```

```
   ↪ fields or their default
#### value:
####  * rocksdb.defaultcf.block-cache-size or 25% of system's total memory
####  * rocksdb.writecf.block-cache-size or 15% of system's total memory
####  * rocksdb.lockcf.block-cache-size or 2% of system's total memory
####  * raftdb.defaultcf.block-cache-size or 2% of system's total memory
#### ## To deploy multiple TiKV nodes on a single physical machine,
   ↪ configure this parameter explicitly.
#### Otherwise, the OOM problem might occur in TiKV.
### capacity = "1GiB"

[pd]
### PD address
### endpoints = ["127.0.0.1:2379","127.0.0.2:2379","127.0.0.3:2379"]

[metric]
### The interval of pushing metrics to Prometheus Pushgateway
interval = "15s"
### Prometheus Pushgateway address
address = ""
job = "tikv"

[raftstore]
### Raft RocksDB directory. The default value is Raft subdirectory of [
   ↪ storage.data-dir].
### If there are multiple disks on the machine, store the data of Raft
   ↪ RocksDB on different disks to improve TiKV performance.
### raftdb-path = "/tmp/tikv/store/raft"

### When the data size change in a Region is larger than the threshold value
   ↪ , TiKV checks whether this Region needs split.
### To reduce the costs of scanning data in the checking process, set the
   ↪ value to 32 MiB during the data import process. In the normal
   ↪ operation status, set it to the default value.
region-split-check-diff = "32MiB"

[coprocessor]
#### If the size of a Region with the range of [a,e) is larger than the
   ↪ value of `region_max_size`, TiKV tries to split the Region to several
   ↪  Regions, for example, the Regions with the ranges of [a,b), [b,c), [
   ↪ c,d), and [d,e).
#### After the Region split, the size of the split Regions is equal to the
   ↪ value of `region_split_size` (or slightly larger than the value of `
   ↪ region_split_size`).
### region-max-size = "144MiB"
```

```
### region-split-size = "96MiB"

[rocksdb]
### The maximum number of threads of RocksDB background tasks. The
   ↪ background tasks include compaction and flush.
### For detailed information why RocksDB needs to implement compaction, see
   ↪ RocksDB-related materials. When write
### traffic (like the importing data size) is big, it is recommended to
   ↪ enable more threads. But set the number of the enabled
### threads smaller than that of CPU cores. For example, when importing data
   ↪ , for a machine with a 32-core CPU,
### set the value to 28.
### max-background-jobs = 8

### The maximum number of file handles RocksDB can open
### max-open-files = 40960

### The file size limit of RocksDB MANIFEST. For more details, see https://
   ↪ github.com/facebook/rocksdb/wiki/MANIFEST
max-manifest-file-size = "20MiB"

### The directory of RocksDB write-ahead logs. If there are two disks on the
   ↪  machine, store the RocksDB data and WAL logs
### on different disks to improve TiKV performance.
### wal-dir = "/tmp/tikv/store"

### Use the following two parameters to deal with RocksDB archiving WAL.
### For more details, see https://github.com/facebook/rocksdb/wiki/How-to-
   ↪ persist-in-memory-RocksDB-database%3F
### wal-ttl-seconds = 0
### wal-size-limit = 0

### In most cases, set the maximum total size of RocksDB WAL logs to the
   ↪ default value.
### max-total-wal-size = "4GiB"

### Use this parameter to enable the readahead feature during RocksDB
   ↪ compaction. If you are using mechanical disks, it is recommended to
   ↪ set the value to 2MiB at least.
### compaction-readahead-size = "2MiB"

[rocksdb.defaultcf]
### The data block size. RocksDB compresses data based on the unit of block.
### Similar to page in other databases, block is the smallest unit cached in
   ↪  block-cache.
```

```
block-size = "64KB"

### The compaction mode of each layer of RocksDB data. The optional values
    ↪ include no, snappy, zlib,
### bzip2, lz4, lz4hc, and zstd. Note that the Snappy compressed file must
    ↪ be in the [official Snappy format](https://github.com/google/snappy).
    ↪  Other variants of Snappy compression are not supported.
### "no:no:lz4:lz4:lz4:zstd:zstd" indicates there is no compaction of level0
    ↪  and level1; lz4 compaction algorithm is used
### from level2 to level4; zstd compaction algorithm is used from level5 to
    ↪ level6.
### "no" means no compaction. "lz4" is a compaction algorithm with moderate
    ↪ speed and compaction ratio. The
### compaction ratio of zlib is high. It is friendly to the storage space,
    ↪ but its compaction speed is slow. This
### compaction occupies many CPU resources. Different machines deploy
    ↪ compaction modes according to CPU and I/O resources.
### For example, if you use the compaction mode of "no:no:lz4:lz4:lz4:zstd:
    ↪ zstd" and find much I/O pressure of the
### system (run the iostat command to find %util lasts 100%, or run the top
    ↪ command to find many iowaits) when writing
### (importing) a lot of data while the CPU resources are adequate, you can
    ↪ compress level0 and level1 and exchange CPU
### resources for I/O resources. If you use the compaction mode of "no:no:
    ↪ lz4:lz4:lz4:zstd:zstd" and you find the I/O
### pressure of the system is not big when writing a lot of data, but CPU
    ↪ resources are inadequate. Then run the top
### command and choose the -H option. If you find a lot of bg threads (
    ↪ namely the compaction thread of RocksDB) are
### running, you can exchange I/O resources for CPU resources and change the
    ↪  compaction mode to "no:no:no:lz4:lz4:zstd:zstd".
### In a word, it aims at making full use of the existing resources of the
    ↪ system and improving TiKV performance
### in terms of the current resources.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### The RocksDB memtable size
write-buffer-size = "128MiB"

### The maximum number of the memtables. The data written into RocksDB is
    ↪ first recorded in the WAL log, and then inserted
### into memtables. When the memtable reaches the size limit of `write-
    ↪ buffer-size`, it turns into read only and generates
### a new memtable receiving new write operations. The flush threads of
    ↪ RocksDB will flush the read only memtable to the
```

```
### disks to become an sst file of level0. `max-background-flushes` controls
    ↪  the maximum number of flush threads. When the
### flush threads are busy, resulting in the number of the memtables waiting
    ↪  to be flushed to the disks reaching the limit
### of `max-write-buffer-number`, RocksDB stalls the new operation.
### "Stall" is a flow control mechanism of RocksDB. When importing data, you
    ↪  can set the `max-write-buffer-number` value
### higher, like 10.
max-write-buffer-number = 5

### When the number of sst files of level0 reaches the limit of `level0-
    ↪ slowdown-writes-trigger`, RocksDB
### tries to slow down the write operation, because too many sst files of
    ↪ level0 can cause higher read pressure of
### RocksDB. `level0-slowdown-writes-trigger` and `level0-stop-writes-
    ↪ trigger` are for the flow control of RocksDB.
### When the number of sst files of level0 reaches 4 (the default value),
    ↪ the sst files of level0 and the sst files
### of level1 which overlap those of level0 implement compaction to relieve
    ↪ the read pressure.
level0-slowdown-writes-trigger = 20

### When the number of sst files of level0 reaches the limit of `level0-stop
    ↪ -writes-trigger`, RocksDB stalls the new
### write operation.
level0-stop-writes-trigger = 36

### When the level1 data size reaches the limit value of `max-bytes-for-
    ↪ level-base`, the sst files of level1
### and their overlap sst files of level2 implement compaction. The golden
    ↪ rule: the first reference principle
### of setting `max-bytes-for-level-base` is guaranteeing that the `max-
    ↪ bytes-for-level-base` value is roughly equal to the
### data volume of level0. Thus unnecessary compaction is reduced. For
    ↪ example, if the compaction mode is
### "no:no:lz4:lz4:lz4:lz4:lz4", the `max-bytes-for-level-base` value is
    ↪ write-buffer-size * 4, because there is no
### compaction of level0 and level1 and the trigger condition of compaction
    ↪ for level0 is that the number of the
### sst files reaches 4 (the default value). When both level0 and level1
    ↪ adopt compaction, it is necessary to analyze
### RocksDB logs to know the size of an sst file compressed from an mentable
    ↪ . For example, if the file size is 32MB,
### the proposed value of `max-bytes-for-level-base` is 32MiB * 4 = 128MiB.
max-bytes-for-level-base = "512MiB"
```

```
### The sst file size. The sst file size of level0 is influenced by the
    ↪ compaction algorithm of `write-buffer-size`
### and level0. `target-file-size-base` is used to control the size of a
    ↪ single sst file of level1-level6.
target-file-size-base = "32MiB"

[rocksdb.writecf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MiB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MiB"
target-file-size-base = "32MiB"

[raftdb]
### The maximum number of the file handles RaftDB can open
### max-open-files = 40960

### Enable the readahead feature in RaftDB compaction. If you are using
    ↪ mechanical disks, it is recommended to set
### this value to 2MB at least.
### compaction-readahead-size = "2MiB"

[raftdb.defaultcf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MiB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MiB"
target-file-size-base = "32MiB"
```

11.2.4.2 TiKV memory usage

Besides `block cache` and `write buffer` which occupy the system memory, the system memory is occupied in the following scenarios:

- Some of the memory is reserved as the system's page cache.
- When TiKV processes large queries such as `select * from ...`, it reads data, generates the corresponding data structure in the memory, and returns this structure to TiDB. During this process, TiKV occupies some of the memory.

11.2.4.3 Recommended configuration of TiKV

- In production environments, it is not recommended to deploy TiKV on the machine whose CPU cores are less than 8 or the memory is less than 32GiB.
- If you demand a high write throughput, it is recommended to use a disk with good throughput capacity.
- If you demand a very low read-write latency, it is recommended to use SSD with high IOPS.

11.2.5 Follower Read

When a read hotspot appears in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader, and improve the throughput of the whole system by balancing the load among multiple followers. This document introduces the use and implementation mechanism of Follower Read.

11.2.5.1 Overview

The Follower Read feature refers to using any follower replica of a Region to serve a read request under the premise of strongly consistent reads. This feature improves the throughput of the TiDB cluster and reduces the load of the leader. It contains a series of load balancing mechanisms that offload TiKV read loads from the leader replica to the follower replica in a Region. TiKV's Follower Read implementation provides users with strongly consistent reads.

> **Note:**
>
> To achieve strongly consistent reads, the follower node currently needs to request the current execution progress from the leader node (that is `ReadIndex`), which causes an additional network request overhead. Therefore, the main benefits of Follower Read are to isolate read requests from write requests in the cluster and to increase overall read throughput.

11.2.5.2 Usage

To enable TiDB's Follower Read feature, modify the value of the `tidb_replica_read` variable as follows:

```
set [session | global] tidb_replica_read = '<target value>';
```

Scope: SESSION | GLOBAL

Default: leader

This variable is used to set the expected data read mode.

- When the value of `tidb_replica_read` is set to `leader` or an empty string, TiDB maintains its default behavior and sends all read operations to the leader replica to perform.
- When the value of `tidb_replica_read` is set to `follower`, TiDB selects a follower replica of the Region to perform all read operations.
- When the value of `tidb_replica_read` is set to `leader-and-follower`, TiDB can select any replicas to perform read operations. In this mode, read requests are load balanced between the leader and follower.
- When the value of `tidb_replica_read` is set to `prefer-leader`, TiDB prefers to select the leader replica to perform read operations. If the leader replica is obviously slow in processing read operations (such as caused by disk or network performance jitter), TiDB will select other available follower replicas to perform read operations.
- When the value of `tidb_replica_read` is set to `closest-replicas`, TiDB prefers to select a replica in the same availability zone to perform read operations, which can be a leader or a follower. If there is no replica in the same availability zone, TiDB reads from the leader replica.
- When the value of `tidb_replica_read` is set to `closest-adaptive`:
    - If the estimated result of a read request is greater than or equal to the value of `tidb_adaptive_closest_read_threshold`, TiDB prefers to select a replica in the same availability zone for read operations. To avoid unbalanced distribution of read traffic across availability zones, TiDB dynamically detects the distribution of availability zones for all online TiDB and TiKV nodes. In each availability zone, the number of TiDB nodes whose `closest-adaptive` configuration takes effect is limited, which is always the same as the number of TiDB nodes in the availability zone with the fewest TiDB nodes, and the other TiDB nodes automatically read from the leader replica. For example, if TiDB nodes are distributed across 3 availability zones (A, B, and C), where A and B each contains 3 TiDB nodes and C contains only 2 TiDB nodes, the number of TiDB nodes whose `closest-adaptive` configuration takes effect in each availability zone is 2, and the other TiDB node in each of the A and B availability zones automatically selects the leader replica for read operations.

- If the estimated result of a read request is less than the value of `tidb_adaptive_closest_read_threshold`, TiDB can only select the leader replica for read operations.

- When the value of `tidb_replica_read` is set to `learner`, TiDB reads data from the learner replica. If there is no learner replica in the Region, TiDB returns an error.

> **Note:**
>
> When the value of `tidb_replica_read` is set to `closest-replicas` or `closest-adaptive`, you need to configure the cluster to ensure that replicas are distributed across availability zones according to the specified configuration. To configure `location-labels` for PD and set the correct `labels` for TiDB and TiKV, refer to Schedule replicas by topology labels. TiDB depends on the `zone` label to match TiKV nodes in the same availability zone, so you need to make sure that the `zone` label is included in the `location-labels` of PD and `zone` is included in the configuration of each TiDB and TiKV node. If your cluster is deployed using TiDB Operator, refer to High availability of data.

11.2.5.3 Implementation mechanism

Before the Follower Read feature was introduced, TiDB applied the strong leader principle and submitted all read and write requests to the leader node of a Region to handle. Although TiKV can distribute Regions evenly on multiple physical nodes, for each Region, only the leader can provide external services. The other followers can do nothing to handle read requests but receive the data replicated from the leader at all times and prepare for voting to elect a leader in case of a failover.

To allow data reading in the follower node without violating linearizability or affecting Snapshot Isolation in TiDB, the follower node needs to use `ReadIndex` of the Raft protocol to ensure that the read request can read the latest data that has been committed on the leader. At the TiDB level, the Follower Read feature simply needs to send the read request of a Region to a follower replica based on the load balancing policy.

11.2.5.3.1 Strongly consistent reads

When the follower node processes a read request, it first uses `ReadIndex` of the Raft protocol to interact with the leader of the Region, to obtain the latest commit index of the current Raft group. After the latest commit index of the leader is applied locally to the follower, the processing of a read request starts.

11.2.5.3.2 Follower replica selection strategy

Because the Follower Read feature does not affect TiDB's Snapshot Isolation transaction isolation level, TiDB adopts the round-robin strategy to select the follower replica. Currently, for the coprocessor requests, the granularity of the Follower Read load balancing policy is at the connection level. For a TiDB client connected to a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

However, for the non-coprocessor requests, such as a point query, the granularity of the Follower Read load balancing policy is at the transaction level. For a TiDB transaction on a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted. If a transaction contains both point queries and coprocessor requests, the two types of requests are scheduled for reading separately according to the preceding scheduling policy. In this case, even if a coprocessor request and a point query are for the same Region, TiDB processes them as independent events.

11.2.6 Tune Region Performance

This document introduces how to tune Region performance by adjusting the Region size and how to use bucket to optimize concurrent queries when the Region size is large. In addition, this document introduces how to enhance the ability of PD to provide Region information to TiDB nodes by enabling the Active PD Follower feature.

11.2.6.1 Overview

TiKV automatically shards bottom-layered data. Data is split into multiple Regions based on the key ranges. When the size of a Region exceeds a threshold, TiKV splits it into two or more Regions.

In scenarios involving large datasets, if the Region size is relatively small, TiKV might have too many Regions, which causes more resource consumption and performance regression.

> **Note:**
>
> - In v6.1.0, TiDB supports customizing Region size as an experimental feature.
> - Starting from v6.5.0, this feature becomes generally available (GA).
> - Starting from v8.4.0, the default size of the Region is resized from 96 MiB to 256 MiB. Increasing the Region size can reduce the number of Regions.

To reduce the performance overhead of many Regions, you can also enable Hibernate Region or `Region Merge`.

11.2.6.2 Use `region-split-size` to adjust Region size

> **Note:**
>
> The recommended range for the Region size is [48 MiB, 256 MiB]. Commonly used sizes include 96 MiB, 128 MiB, and 256 MiB. It is NOT recommended to set the Region size beyond 1 GiB. Avoid setting the size to more than 10 GiB. An excessively large Region size might result in the following side effects:
>
> - Performance jitters
> - Decreased query performance, especially for queries that deal with a large range of data
> - Slower Region scheduling

To adjust the Region size, you can use the `coprocessor.region-split-size` configuration item. When TiFlash or the Dumpling tool is used, the Region size should not exceed 1 GiB. After increasing the Region size, you need to reduce the concurrency if the Dumpling tool is used; otherwise, TiDB might run out of memory.

11.2.6.3 Use bucket to increase concurrency

> **Warning:**
>
> Currently, this is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

After Regions are set to a larger size, if you want to further improve the query concurrency, you can set `coprocessor.enable-region-bucket` to `true`. When you use this configuration, Regions are divided into buckets. Buckets are smaller ranges within a Region and are used as the unit of concurrent query to improve the scan concurrency. You can control the bucket size using `coprocessor.region-bucket-size`.

11.2.6.4 Use the Active PD Follower feature to enhance the scalability of PD's Region information query service

> **Warning:**

> The Active PD Follower feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

In a TiDB cluster with a large number of Regions, the PD leader might experience high CPU load due to the increased overhead of handling heartbeats and scheduling tasks. If the cluster has many TiDB instances, and there is a high concurrency of requests for Region information, the CPU pressure on the PD leader increases further and might cause PD services to become unavailable.

To ensure high availability, the PD leader synchronizes Region information with its followers in real time. PD followers maintain and store Region information in memory, enabling them to process Region information requests. You can enable the Active PD Follower feature by setting the system variable `pd_enable_follower_handle_region` to `ON`. After this feature is enabled, TiDB evenly distributes Region information requests to all PD servers, and PD followers can also directly handle Region requests, thereby reducing the CPU pressure on the PD leader.

PD ensures that the Region information in TiDB is always up-to-date by maintaining the status of Region synchronization streams and using the fallback mechanism of TiKV client-go.

- When the network between the PD leader and a follower is unstable or a follower is unavailable, the Region synchronization stream is disconnected, and the PD follower rejects Region information requests. In this case, TiDB automatically retries the request to the PD leader and temporarily marks the follower as unavailable.
- When the network is stable, because there might be a delay in the synchronization between the leader and the follower, some Region information obtained from the follower might be outdated. In this case, if the KV request corresponding to the Region fails, TiDB automatically re-requests the latest Region information from the PD leader and sends the KV request to TiKV again.

11.2.7 Tune TiFlash Performance

This document introduces how to tune the performance of TiFlash by properly planning machine resources and tuning TiDB parameters. By following these methods, your TiFlash cluster can achieve optimal performance.

11.2.7.1 Plan resources

If you want to save machine resources and have no requirement on isolation, you can use the method that combines the deployment of both TiKV and TiFlash. It is recommended that you save enough resources for TiKV and TiFlash respectively, and do not share disks.

11.2.7.2 Tune TiDB parameters

This section describes how to improve TiFlash performance by tuning TiDB parameters, including:

- Forcibly enable the MPP mode
- Push down aggregate functions to a position before `Join` or `Union`
- Enable `Distinct` optimization
- Compact data using the `ALTER TABLE ... COMPACT` statement
- Replace Shuffled Hash Join with Broadcast Hash Join
- Set a greater execution concurrency
- Configure `tiflash_fine_grained_shuffle_stream_count`

11.2.7.2.1 Forcibly enable the MPP mode

MPP execution plans can fully utilize distributed computing resources, thereby significantly improving the efficiency of batch data queries. When the optimizer does not generate an MPP execution plan for a query, you can forcibly enable the MPP mode:

The variable `tidb_enforce_mpp` controls whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution. To enable MPP mode forcibly, run the following command:

```
set @@tidb_enforce_mpp = ON;
```

The following example shows the query result before and after `tidb_enforce_mpp` is enabled. Before this variable is enabled, TiDB needs to read data from TiKV and execute `Join` and `Aggregation` in TiDB. After `tidb_enforce_mpp` is enabled, `Join` and `Aggregation` are pushed down to TiFlash. In addition, because the optimizer does not necessarily generate MPP execution plans, by enabling `tidb_enforce_mpp`, you can force the optimizer to generate MPP execution plans.

Before MPP mode is enabled:

```
mysql> explain analyze select o_orderpriority, count(*) as order_count from
    ↪  orders where o_orderdate >= '1995-01-01' and o_orderdate < date_add(

11.2.7.2.2 Push down aggregate functions to a position before `Join` or `Union`

By pushing down aggregate operations to the position before `Join` or `Union`, you can reduce the data to be processed in the `Join` or `Union` operation, thereby improving performance.

The variable `tidb_opt_agg_push_down` controls whether the optimizer executes the optimization operation of pushing down the aggregate function to the position before `Join` or `Union`. When the aggregate operations are quite slow in the query, you can set this variable to `ON`.

```
set @@tidb_opt_agg_push_down = ON;
```

The following example shows the query result before and after the `tidb_opt_agg_push_down` variable is enabled. Before this variable is enabled, the `HashAgg_58` operation is executed following the `HashJoin_41` operation. After this variable is enabled, newly generated `HashAgg_21` and `HashAgg_32` operations are executed before the `HashJoin_76` operation. This significantly reduces the data to be processed by the `Join` operation.

Before `tidb_opt_agg_push_down` is enabled:

```

18 rows in set (0.46 sec)
```

11.2.7.2.3 Enable `Distinct` optimization

TiFlash does not support some aggregate functions that accept the `Distinct` column, such as `Sum`. By default, the entire aggregate function is calculated in TiDB. By enabling the `Distinct` optimization, some operations can be pushed down to TiFlash, thereby improving query performance.

If the aggregate function with the `distinct` operation is slow in a query, you can enable the optimization operation of pushing down the aggregate function with `Distinct` (such as `select sum(distinct a)from t`) to Coprocessor by setting the value of the `tidb_opt_distinct_agg_push_down` variable to `ON`.

```
set @@tidb_opt_distinct_agg_push_down = ON;
```

The following example shows the query result before and after the `tidb_opt_distinct_agg_push_down` variable is enabled. Before this variable is enabled, TiDB needs to read all data from TiFlash and execute `distinct` in TiDB. After this variable is enabled, `distinct a` is pushed down to TiFlash, and a new `group by` column `test.t.a` is added in `HashAgg_6`. The two warnings in the query result indicate that the aggregate function cannot be fully pushed down to TiFlash.

Before `tidb_opt_distinct_agg_push_down` is enabled:

```

11.2.7.2.4 Compact data using the `ALTER TABLE ... COMPACT` statement

Executing the `ALTER TABLE ... COMPACT` statement can initiate compaction for a specific table or partition on a TiFlash node. During the compaction, the physical data on the node is rewritten, including cleaning up deleted rows and merging multiple versions of data caused by updates. This helps enhance access performance and reduce disk usage. The

following are examples:

```
ALTER TABLE employees COMPACT TIFLASH REPLICA;
```

```
ALTER TABLE employees COMPACT PARTITION pNorth, pEast TIFLASH REPLICA;
```

11.2.7.2.5 Replace Shuffled Hash Join with Broadcast Hash Join

For `Join` operations with small tables, the Broadcast Hash Join algorithm can avoid transferring large tables, thereby improving the computing performance.

- The `tidb_broadcast_join_threshold_size` variable controls whether to use the Broadcast Hash Join algorithm. If the table size (unit: byte) is smaller than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

  ```
  set @@tidb_broadcast_join_threshold_size = 2000000;
  ```

- The `tidb_broadcast_join_threshold_count` variable also controls whether to use the Broadcast Hash Join algorithm. If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set. In this situation, the size is determined by the number of rows in the result set. If the estimated number of rows for the subquery is fewer than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

  ```
  set @@tidb_broadcast_join_threshold_count = 100000;
  ```

The following example shows the query result before and after `tidb_broadcast_join_threshold_size` is re-configured. Before the re-configuration, the `ExchangeType` of `ExchangeSender_29` is `HashPartition`. After the value of this variable changes to `10000000`, the `ExchangeType` of `ExchangeSender_29` changes to `Broadcast`.

Before `tidb_broadcast_join_threshold_size` is re-configured:

```

11.2.7.2.6 Set a greater execution concurrency

A greater execution concurrency allows TiFlash to occupy more CPU resources of the system, thereby improving query performance.

The `tidb_max_tiflash_threads` variable is used to set the maximum concurrency for TiFlash to execute a request. The unit is threads.

```
set @@tidb_max_tiflash_threads = 20;
```

The following example shows the query result before and after `tidb_max_tiflash_threads` is re-configured. Before `tidb_max_tiflash_threads` is set, the concurrency of request execution for a single TiFlash instance is 8 threads. Since the cluster has a total of 3 TiFlash instances, the total number of threads for request execution on all TiFlash instances is 24 (8×3). After `tidb_max_tiflash_threads` is set to 20, the total number of threads for request execution on all TiFlash instances is 60 (20×3).

Before `tidb_max_tiflash_threads` is re-configured:

```
mysql> explain analyze select a, count(*) from t group by a;

11.2.7.2.7 Configure `tiflash_fine_grained_shuffle_stream_count`

You can increase the concurrency for executing window functions by configuring `tiflash ↪ _fine_grained_shuffle_stream_count` of the Fine Grained Shuffle feature. In this way, the execution of window functions can occupy more system resources, which improves query performance.

When a window function is pushed down to TiFlash for execution, you can use this variable to control the concurrency level of the window function execution. The unit is threads.

```
set @@tiflash_fine_grained_shuffle_stream_count = 20;
```

The following example shows the query result before and after the `tiflash_fine_ ↪ grained_shuffle_stream_count` variable is re-configured. Before the re-configuration, the `stream_count` of `[ExchangeSender_11, ExchangeReceiver_12, Sort_13, Window_ ↪ 22]` is 8. After the re-configuration, the `stream_count` becomes 20.

Before `tiflash_fine_grained_shuffle_stream_count` is re-configured:

```
mysql> explain analyze select *, row_number() over (partition by a) from t;

11.2.8 Coprocessor Cache

Starting from v4.0, the TiDB instance supports caching the results of the calculation that is pushed down to TiKV (the Coprocessor Cache feature), which can accelerate the calculation process in some scenarios.

11.2.8.1 Configuration

You can configure Coprocessor Cache via the `tikv-client.copr-cache` configuration items in the TiDB configuration file. For details about how to enable and configure Coprocessor Cache, see TiDB Configuration File.

11.2.8.2 Feature description

- When a SQL statement is executed on a single TiDB instance for the first time, the execution result is not cached.
- Calculation results are cached in the memory of TiDB. If the TiDB instance is restarted, the cache becomes invalid.
- The cache is not shared among TiDB instances.
- Only push-down calculation result is cached. Even if cache is hit, TiDB still need to perform subsequent calculation.
- The cache is in the unit of Region. Writing data to a Region causes the Region cache to be invalid. For this reason, the Coprocessor Cache feature mainly takes effect on the data that rarely changes.
- When push-down calculation requests are the same, the cache is hit. Usually in the following scenarios, the push-down calculation requests are the same or partially the same:
    - The SQL statements are the same. For example, the same SQL statement is executed repeatedly.

      In this scenario, all the push-down calculation requests are consistent, and all requests can use the push-down calculation cache.
    - The SQL statements contain a changing condition, and the other parts are consistent. The changing condition is the primary key of the table or the partition.

      In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
    - The SQL statements contain multiple changing conditions and the other parts are consistent. The changing conditions exactly match a compound index column.

      In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
- This feature is transparent to users. Enabling or disabling this feature does not affect the calculation result and only affects the SQL execution time.

11.2.8.3 Check the cache effect

You can check the cache effect of Coprocessor by executing `EXPLAIN ANALYZE` or viewing the Grafana monitoring panel.

11.2.8.3.1 Use `EXPLAIN ANALYZE`

You can view the cache hit rate in Operators for accessing tables by using the `EXPLAIN ANALYZE` statement. See the following example:

```
EXPLAIN ANALYZE SELECT * FROM t USE INDEX(a);
+--
   ↪ ----------------------------+----------+--------+----------+---------------
   ↪
| id                          | estRows  | actRows | task    | access object
   ↪       | execution info
   ↪
   ↪ | operator info               | memory             | disk |

   ↪ 4, max: 5.530817ms, min: 1.51829ms, avg: 2.70883ms, p95: 5.530817ms,
   ↪ max_proc_keys: 2480, p95_proc_keys: 2480, tot_proc: 1ms, tot_wait: 1
   ↪ ms, rpc_num: 4, rpc_time: 10.816328ms, copr_cache_hit_rate: 0.75} | |
   ↪  6.685169219970703 MB | N/A |
|  ─IndexFullScan_4(Build)   | 262400.00 | 262400 | cop[tikv] | table:t,
   ↪ index:a(a, c) | proc max:93ms, min:1ms, p80:93ms, p95:93ms, iters
   ↪ :275, tasks:4
   ↪
   ↪ | keep order:false, stats:pseudo | 1.7549400329589844 MB | N/A |
|  ─TableRowIDScan_5(Probe)  | 262400.00 | 0     | cop[tikv] | table:t
   ↪            | time:0ns, loops:0
   ↪
   ↪ | keep order:false, stats:pseudo | N/A            | N/A |
+--
   ↪ ----------------------------+----------+--------+----------+---------------
   ↪
3 rows in set (0.62 sec)
```

The column `execution info` of the execution result gives the `copr_cache_hit_ratio` information, which indicates the hit rate of the Coprocessor Cache. The `0.75` in the above example means that the hit rate is about 75%.

11.2.8.3.2 View the Grafana monitoring panel

In Grafana, you can see the **copr-cache** panel in the `distsql` subsystem under the `tidb` namespace. This panel monitors the number of hits, misses, and cache discards of the Coprocessor Cache in the entire cluster.

11.2.9 Garbage Collection (GC)

11.2.9.1 GC Overview

TiDB uses MVCC to control transaction concurrency. When you update the data, the original data is not deleted immediately but is kept together with the new data, with a timestamp to distinguish the version. The goal of Garbage Collection (GC) is to clear the obsolete data.

11.2.9.1.1 GC process

Each TiDB cluster contains a TiDB instance that is selected as the GC leader, which controls the GC process.

GC runs periodically on TiDB. For each GC, TiDB firstly calculates a timestamp called "safe point". Then, TiDB clears the obsolete data under the premise that all the snapshots after the safe point retain the integrity of the data. Specifically, there are three steps involved in each GC process:

1. Resolve Locks. During this step, TiDB scans locks before the safe point on all Regions and clears these locks.
2. Delete Ranges. During this step, the obsolete data of the entire range generated from the `DROP TABLE/DROP INDEX` operation is quickly cleared.
3. Do GC. During this step, each TiKV node scans data on it and deletes unneeded old versions of each key.

In the default configuration, GC is triggered every 10 minutes. Each GC retains data of the recent 10 minutes, which means that the GC life time is 10 minutes by default (safe point = the current time - GC life time). If one round of GC has been running for too long, before this round of GC is completed, the next round of GC will not start even if it is time to trigger the next GC. In addition, for long-duration transactions to run properly after exceeding the GC life time, the safe point does not exceed the start time (start_ts) of the ongoing transactions.

11.2.9.1.2 Implementation details

Resolve Locks

The TiDB transaction model is implemented based on Google's Percolator. It's mainly a two-phase commit protocol with some practical optimizations. When the first phase is finished, all the related keys are locked. Among these locks, one is the primary lock and the others are secondary locks which contain a pointer to the primary lock; in the second phase, the key with the primary lock gets a write record and its lock is removed. The write record indicates the write or delete operation in the history or the transactional rollback record of this key. The type of write record that replaces the primary lock indicates whether the corresponding transaction is committed successfully. Then all the secondary locks are replaced successively. If, for some reason such as failure, these secondary locks are retained and not replaced, you can still find the primary key based on the information in the secondary locks and determines whether the entire transaction is committed based on whether the primary key is committed. However, if the primary key information is cleared by GC and

this transaction has uncommitted secondary locks, you will never learn whether these locks can be committed. As a result, data integrity cannot be guaranteed.

The Resolve Locks step clears the locks before the safe point. This means that if the primary key of a lock is committed, this lock needs to be committed; otherwise, it needs to be rolled back. If the primary key is still locked (not committed or rolled back), this transaction is seen as timing out and rolled back.

The Resolve Locks step is implemented in either of the following two ways, which can be configured using the system variable `tidb_gc_scan_lock_mode`:

> **Warning:**
>
> Currently, `PHYSICAL` (Green GC) is an experimental feature. It is not recommended that you use it in the production environment.

- `LEGACY` (default): The GC leader sends requests to all Regions to scan obsolete locks, checks the primary key statuses of scanned locks, and sends requests to commit or roll back the corresponding transaction.
- `PHYSICAL`: TiDB bypasses the Raft layer and directly scans data on each TiKV node.

Delete Ranges

A great amount of data with consecutive keys is removed during operations such as `DROP TABLE/INDEX`. Removing each key and performing GC later for them can result in low execution efficiency on storage reclaiming. In such scenarios, TiDB actually does not delete each key. Instead, it only records the range to be removed and the timestamp of the deletion. Then the Delete Ranges step performs a fast physical deletion on the ranges whose timestamp is before the safe point.

Do GC

The Do GC step clears the outdated versions for all keys. To guarantee that all timestamps after the safe point have consistent snapshots, this step deletes the data committed before the safe point, but retains the last write for each key before the safe point as long as it is not a deletion.

In this step, TiDB only needs to send the safe point to PD, and then the whole round of GC is completed. TiKV automatically detects the change of safe point and performs GC for all Region leaders on the current node. At the same time, the GC leader can continue to trigger the next round of GC.

Note:

Starting with TiDB 5.0, the Do GC step will always use the `DISTRIBUTED` gc mode. This replaces the earlier `CENTRAL` gc mode, which was implemented by TiDB servers sending GC requests to each Region.

11.2.9.2 Garbage Collection Configuration

You can configure garbage collection (GC) using the following system variables:

- `tidb_gc_enable`: controls whether to enable garbage collection for TiKV.
- `tidb_gc_run_interval`: specifies the GC interval.
- `tidb_gc_life_time`: specifies the time limit during which data is retained for each GC.
- `tidb_gc_concurrency`: specifies the number of threads in the Resolve Locks step of GC.
- `tidb_gc_scan_lock_mode`: specifies the way of scanning locks in the Resolve Locks step of GC.
- `tidb_gc_max_wait_time`: specifies the maximum time that active transactions block the GC safe point.

For more information about how to modify the value of a system variable, see System variables.

11.2.9.2.1 GC I/O limit

TiKV supports the GC I/O limit. You can configure `gc.max-write-bytes-per-sec` to limit writes of a GC worker per second, and thus to reduce the impact on normal requests.

`0` indicates disabling this feature.

You can dynamically modify this configuration using tikv-ctl:

```
tikv-ctl --host=ip:port modify-tikv-config -n gc.max-write-bytes-per-sec -v
    ↪ 10MB
```

11.2.9.2.2 Changes in TiDB 5.0

In previous releases of TiDB, garbage collection was configured via the `mysql.tidb` system table. While changes to this table continue to be supported, it is recommended to use the system variables provided. This helps ensure that any changes to configuration can be validated, and prevent unexpected behavior (#20655).

The `CENTRAL` garbage collection mode is no longer supported. The `DISTRIBUTED` GC mode (which has been the default since TiDB 3.0) will automatically be used in its place.

This mode is more efficient, since TiDB no longer needs to send requests to each TiKV region to trigger garbage collection.

For information on changes in previous releases, refer to earlier versions of this document using the *TIDB version selector* in the left hand menu.

11.2.9.2.3 Changes in TiDB 6.1.0

Before TiDB v6.1.0, the transaction in TiDB does not affect the GC safe point. Starting from v6.1.0, TiDB considers the startTS of the transaction when calculating the GC safe point, to resolve the problem that the data to be accessed has been cleared. If the transaction is too long, the safe point will be blocked for a long time, which affects the application performance.

In TiDB v6.1.0, the system variable `tidb_gc_max_wait_time` is introduced to control the maximum time that active transactions block the GC safe point. After the value is exceeded, the GC safe point is forwarded forcefully.

GC in Compaction Filter

Based on the `DISTRIBUTED` GC mode, the mechanism of GC in Compaction Filter uses the compaction process of RocksDB, instead of a separate GC worker thread, to run GC. This new GC mechanism helps to avoid extra disk read caused by GC. Also, after clearing the obsolete data, it avoids a large number of left tombstone marks which degrade the sequential scan performance.

The following example shows how to enable the mechanism in the TiKV configuration file:

```
[gc]
enable-compaction-filter = true
```

You can also enable this GC mechanism by modifying the configuration dynamically. See the following example:

```
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | false |
+------+------------------+-----------------------------+-------+
```

```
set config tikv gc.enable-compaction-filter = true;
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | true |
+------+------------------+-----------------------------+-------+
```

11.3 SQL Tuning

11.3.1 SQL Tuning Overview

SQL is a declarative language. That is, an SQL statement describes *what the final result should look like* and not a set of steps to execute in sequence. TiDB will optimize the execution, and is semantically permitted to execute parts of the query in any order provided that it correctly returns the final result as described.

A useful comparison to SQL optimization, is to describe what happens when you use GPS navigation. From your provided address, *2955 Campus Drive San Mateo CA 94403*, the GPS software plans the most time-efficient way to route you. It may make use of various statistics such as previous trips, meta data such as speed limits, and in modern cases, a live feed of traffic information. Several of these analogies translate to TiDB.

This section introduces several concepts about query execution:

- Understanding the Query Execution Plan introduces how to use the `EXPLAIN` statement to understand how TiDB has decided to execute a statement.
- SQL Optimization Process introduces what optimizations TiDB is capable of using to improve query execution performance.
- Control Execution Plans introduces ways to control the generation of the execution plan. This can be useful in cases where the execution plan decided by TiDB is suboptimal.

11.3.2 Understanding the Query Execution Plan

11.3.2.1 TiDB Query Execution Plan Overview

> **Note:**
>
> When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less -S` command. Then, after the `EXPLAIN` result is output, you can press

> the right arrow → button on your keyboard to horizontally scroll through the output.

SQL is a declarative language. It describes what the results of a query should look like, **not the methodology** to actually retrieve those results. TiDB considers all the possible ways in which a query could be executed, including using what order to join tables and whether any potential indexes can be used. The process of *considering query execution plans* is known as SQL optimization.

The `EXPLAIN` statement shows the selected execution plan for a given statement. That is, after considering hundreds or thousands of ways in which the query could be executed, TiDB believes that this *plan* will consume the least resources and execute in the shortest amount of time:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a INT NOT NULL,
    ↪  pad1 VARCHAR(255), INDEX(a));
INSERT INTO t VALUES (1, 1, 'aaa'),(2,2, 'bbb');
EXPLAIN SELECT * FROM t WHERE a = 1;
```

```
Query OK, 0 rows affected (0.96 sec)

Query OK, 2 rows affected (0.02 sec)
Records: 2 Duplicates: 0 Warnings: 0

+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
| id                          | estRows | task     | access object     |
    ↪ operator info                           |
+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
| IndexLookUp_10              | 10.00   | root     |                   |
    ↪                                         |
|  ─IndexRangeScan_8(Build)   | 10.00   | cop[tikv] | table:t, index:a(a) |
    ↪ range:[1,1], keep order:false, stats:pseudo |
|  ─TableRowIDScan_9(Probe)   | 10.00   | cop[tikv] | table:t          | keep
    ↪ order:false, stats:pseudo          |
+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
3 rows in set (0.00 sec)
```

`EXPLAIN` does not execute the actual query. `EXPLAIN ANALYZE` can be used to execute the query and show `EXPLAIN` information. This can be useful in diagnosing cases where the execution plan selected is suboptimal. For additional examples of using `EXPLAIN`, see the following documents:

- Indexes
- Joins
- Subqueries
- Aggregation
- Views
- Partitions

11.3.2.1.1 Understand EXPLAIN output

The following describes the output of the `EXPLAIN` statement above:

- `id` describes the name of an operator, or sub-task that is required to execute the SQL statement. See Operator overview for additional details.
- `estRows` shows an estimate of the number of rows TiDB expects to process. This number might be based on dictionary information, such as when the access method is based on a primary or unique key, or it could be based on statistics such as a CMSketch or histogram.
- `task` shows where an operator is performing the work. See Task overview for additional details.
- `access object` shows the table, partition and index that is being accessed. The parts of the index are also shown, as in the case above that the column `a` from the index was used. This can be useful in cases where you have composite indexes.
- `operator info` shows additional details about the access. See Operator info overview for additional details.

> **Note:**
>
> In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0.
>
> Before v6.4.0, `estRows` means the number of estimated rows to be processed by the probe side operators for each row from the build side operators. Since v6.4.0, `estRows` means the **total number** of estimated rows to be processed by the probe side operators. The actual number of rows displayed (indicated by the `actRows` column) in the result of `EXPLAIN ANALYZE` means the total row count, so since v6.4.0 the meanings of `estRows` and `actRows` for the probe side child nodes of `IndexJoin` and `Apply` operators are consistent.
>
> For example:

```
CREATE TABLE t1(a INT, b INT);
CREATE TABLE t2(a INT, b INT, INDEX ia(a));
EXPLAIN SELECT /*+ INL_JOIN(t2) */ * FROM t1 JOIN t2 ON t1.a =
    ↪  t2.a;
EXPLAIN SELECT (SELECT a FROM t2 WHERE t2.a = t1.b LIMIT 1)
    ↪ FROM t1;
```

```

Operator overview

An operator is a particular step that is executed as part of returning query results. The operators that perform table scans (of the disk or the TiKV Block Cache) are listed as follows:

- **TableFullScan**: Full table scan
- **TableRangeScan**: Table scans with the specified range
- **TableRowIDScan**: Scans the table data based on the RowID. Usually follows an index read operation to retrieve the matching data rows.
- **IndexFullScan**: Similar to a "full table scan", except that an index is scanned, rather than the table data.
- **IndexRangeScan**: Index scans with the specified range.

TiDB aggregates the data or calculation results scanned from TiKV/TiFlash. The data aggregation operators can be divided into the following categories:

- **TableReader**: Aggregates the data obtained by the underlying operators like `TableFullScan` or `TableRangeScan` in TiKV.
- **IndexReader**: Aggregates the data obtained by the underlying operators like `IndexFullScan` or `IndexRangeScan` in TiKV.
- **IndexLookUp**: First aggregates the RowID (in TiKV) scanned by the `Build` side. Then at the `Probe` side, accurately reads the data from TiKV based on these RowIDs. At the `Build` side, there are operators like `IndexFullScan` or `IndexRangeScan`; at the `Probe` side, there is the `TableRowIDScan` operator.
- **IndexMerge**: Similar to `IndexLookUp`. `IndexMerge` can be seen as an extension of `IndexLookupReader`. `IndexMerge` supports reading multiple indexes at the same time. There are many `Build`s and one `Probe`. The execution process of `IndexMerge` the same as that of `IndexLookUp`.

While the structure appears as a tree, executing the query does not strictly require the child nodes to be completed before the parent nodes. TiDB supports intra-query parallelism,

so a more accurate way to describe the execution is that the child nodes *flow into* their parent nodes. Parent, child and sibling operators *might* potentially be executing parts of the query in parallel.

In the previous example, the `└─IndexRangeScan_8(Build)` operator finds the internal `RowID` for rows that match the `a(a)` index. The `└─TableRowIDScan_9(Probe)` operator then retrieves these rows from the table.

Range query

In the `WHERE/HAVING/ON` conditions, the TiDB optimizer analyzes the result returned by the primary key query or the index key query. For example, these conditions might include comparison operators of the numeric and date type, such as `>`, `<`, `=`, `>=`, `<=`, and the character type such as `LIKE`.

Note:

- In order to use an index, the condition must be *sargable*. For example, the condition `YEAR(date_column)< 1992` cannot use an index, but `date_column < '1992-01-01'` can.
- It is recommended to compare data of the same type and character set and collation. Mixing types may require additional `cast` operations, or prevent indexes from being used.
- You can also use `AND` (intersection) and `OR` (union) to combine the range query conditions of one column. For a multi-dimensional composite index, you can use conditions in multiple columns. For example, regarding the composite index `(a, b, c)`:
  - When `a` is an equivalent query, continue to figure out the query range of `b`; when `b` is also an equivalent query, continue to figure out the query range of `c`.
  - Otherwise, if `a` is a non-equivalent query, you can only figure out the range of `a`.

Task overview

Currently, calculation tasks of TiDB can be divided into two categories: cop tasks and root tasks. A `cop[tikv]` task indicates that the operator is performed inside the TiKV coprocessor. A `root` task indicates that it will be completed inside of TiDB.

One of the goals of SQL optimization is to push the calculation down to TiKV as much as possible. The Coprocessor in TiKV supports most of the built-in SQL functions (including the aggregate functions and the scalar functions), SQL `LIMIT` operations, index scans, and table scans.

Operator info overview

The `operator info` can show useful information such as which conditions were able to be pushed down:

- `range: [1,1]` shows that the predicate from the where clause of the query (`a = 1`) was pushed right down to TiKV (the task is of `cop[tikv]`).
- `keep order:false` shows that the semantics of this query did not require TiKV to return the results in order. If the query were to be modified to require an order (such as `SELECT * FROM t WHERE a = 1 ORDER BY id`), then this condition would be `keep order:true`.
- `stats:pseudo` shows that the estimates shown in `estRows` might not be accurate. TiDB periodically updates statistics as part of a background operation. A manual update can also be performed by running `ANALYZE TABLE t`.

Different operators output different information after the `EXPLAIN` statement is executed. You can use optimizer hints to control the behavior of the optimizer, and thereby controlling the selection of the physical operators. For example, `/*+ HASH_JOIN(t1, t2)*/` means that the optimizer uses the `Hash Join` algorithm. For more details, see Optimizer Hints.

11.3.2.2 `EXPLAIN` Walkthrough

Because SQL is a declarative language, you cannot automatically tell whether a query is executed efficiently. You must first use the `EXPLAIN` statement to learn the current execution plan.

The following statement from the bikeshare example database counts how many trips were taken on July 1, 2017:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ---------------------------+----------+----------+---------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪
    ↪ |
+--
    ↪ ---------------------------+----------+----------+---------------+-----------
    ↪
| StreamAgg_20                | 1.00    | root     |               | funcs:count(
    ↪ Column#13)->Column#11
    ↪
    ↪ |
```

```
|  └─TableReader_21          | 1.00    | root     |              | data:
    ↪ StreamAgg_9
    ↪
    ↪ |
|    └─StreamAgg_9           | 1.00    | cop[tikv] |              | funcs:count
    ↪ (1)->Column#13
    ↪
    ↪ |
|      └─Selection_19        | 250.00  | cop[tikv] |              | ge(
    ↪ bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(bikeshare
    ↪ .trips.start_date, 2017-07-01 23:59:59.000000) |
|        └─TableFullScan_18  | 10000.00 | cop[tikv] | table:trips | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ---------------------------+---------+----------+--------------+-----------
    ↪
5 rows in set (0.00 sec)
```

From the child operator `└─TableFullScan_18` back, you can see its execution process as follows, which is currently suboptimal:

1. The coprocessor (TiKV) reads the entire `trips` table as a `TableFullScan` operation. It then passes the rows that it reads to the `Selection_19` operator, which is still within TiKV.
2. The `WHERE start_date BETWEEN ..` predicate is then filtered in the `Selection_19` ↪ operator. Approximately `250` rows are estimated to meet this selection. Note that this number is estimated according to the statistics and the operator's logic. The `└─TableFullScan_18` operator shows `stats:pseudo`, which means that the table does not have the actual statistical information. After running `ANALYZE TABLE trips` to collect statistical information, the statistics are expected to be more accurate.
3. The rows that meet the selection criteria then have a `count` function applied to them. This is also completed inside the `StreamAgg_9` operator, which is still inside TiKV (`cop[tikv]`). The TiKV coprocessor can execute a number of MySQL built-in functions, `count` being one of them.
4. The results from `StreamAgg_9` are then sent to the `TableReader_21` operator which is now inside the TiDB server (the task of `root`). The `estRows` column value for this operator is `1`, which means that the operator will receive one row from each of the TiKV Regions to be accessed. For more information about these requests, see `EXPLAIN ANALYZE`.
5. The `StreamAgg_20` operator then applies a `count` function to each of the rows from the `└─TableReader_21` operator, which you can see from `SHOW TABLE REGIONS` and will be about 56 rows. Because this is the root operator, it then returns results to the client.

> **Note:**
>
> For a general view of the Regions that a table contains, execute `SHOW TABLE REGIONS`.

11.3.2.2.1 Assess the current performance

`EXPLAIN` only returns the query execution plan but does not execute the query. To get the actual execution time, you can either execute the query or use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ---------------------------+---------+---------+----------+---------------+-
    ↪
| id                          | estRows | actRows | task     | access object |
    ↪ execution info
    ↪
    ↪ | operator info
    ↪
    ↪ | memory   | disk |
+--
    ↪ ---------------------------+---------+---------+----------+---------------+-
    ↪
| StreamAgg_20                | 1.00    | 1       | root     |               |
    ↪ time:1.031417203s, loops:2
    ↪
    ↪ | funcs:count(Column#13)->Column#11
    ↪
    ↪ | 632 Bytes | N/A |
|  └─TableReader_21           | 1.00    | 56      | root     |               |
    ↪ time:1.031408123s, loops:2, cop_task: {num: 56, max: 782.147269ms,
    ↪ min: 5.759953ms, avg: 252.005927ms, p95: 609.294603ms, max_proc_keys:
    ↪  910371, p95_proc_keys: 704775, tot_proc: 11.524s, tot_wait: 580ms,

    ↪
    ↪ | funcs:count(1)->Column#13
```

```
    ↪
    ↪ | N/A      | N/A |
|     └─Selection_19         | 250.00  | 11409   | cop[tikv] |            |
    ↪ proc max:640ms, min:8ms, p80:276ms, p95:476ms, iters:18695, tasks:56
    ↪
    ↪ | ge(bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(
    ↪ bikeshare.trips.start_date, 2017-07-01 23:59:59.000000) | N/A | N/A |
|       └─TableFullScan_18   | 10000.00 | 19117643 | cop[tikv] | table:trips
    ↪  | proc max:612ms, min:8ms, p80:248ms, p95:460ms, iters:18695, tasks
    ↪ :56
    ↪
    ↪ | keep order:false, stats:pseudo
    ↪
    ↪ | N/A      | N/A |
+--
    ↪ ----------------------------+----------+----------+-----------+---------------+-
    ↪
5 rows in set (1.03 sec)
```

The example query above takes `1.03` seconds to execute, which is an ideal performance.

From the result of `EXPLAIN ANALYZE` above, `actRows` indicates that some of the estimates (`estRows`) are inaccurate (expecting 10 thousand rows but finding 19 million rows), which is already indicated in the `operator info` (`stats:pseudo`) of `└─TableFullScan_18`. If you run `ANALYZE TABLE` first and then `EXPLAIN ANALYZE` again, you can see that the estimates are much closer:

```
ANALYZE TABLE trips;
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
Query OK, 0 rows affected (10.22 sec)

+--

   ↪
   ↪ | N/A      | N/A |
+--
   ↪ ---------------------------+------------+---------+-----------+--------------
   ↪
5 rows in set (0.93 sec)
```

After `ANALYZE TABLE` is executed, you can see that the estimated rows for the `─TableFullScan_18` operator is accurate and the estimate for `─Selection_19` is now also much closer. In the two cases above, although the execution plan (the set of operators TiDB uses to execute this query) has not changed, quite frequently sub-optimal plans are caused by outdated statistics.

In addition to `ANALYZE TABLE`, TiDB automatically regenerates statistics as a back-

ground operation after the threshold of `tidb_auto_analyze_ratio` is reached. You can see how close TiDB is to this threshold (how healthy TiDB considers the statistics to be) by executing the `SHOW STATS_HEALTHY` statement:

```
SHOW STATS_HEALTHY;
```

```
+----------+------------+----------------+---------+
| Db_name  | Table_name | Partition_name | Healthy |
+----------+------------+----------------+---------+
| bikeshare | trips   |                |     100 |
+----------+------------+----------------+---------+
1 row in set (0.00 sec)
```

11.3.2.2.2 Identify optimizations

The current execution plan is efficient in the following aspects:

- Most of the work is handled inside the TiKV coprocessor. Only 56 rows need to be sent across the network back to TiDB for processing. Each of these rows is short and contains only the count that matches the selection.
- Aggregating the count of rows both in TiDB (`StreamAgg_20`) and in TiKV (`StreamAgg_9`) uses the stream aggregation, which is very efficient in its memory usage.

The biggest issue with the current execution plan is that the predicate `start_date BETWEEN '2017-07-01 00:00:00' AND '2017-07-01 23:59:59'` does not apply immediately. All rows are read first with a `TableFullScan` operator, and then a selection is applied afterwards. You can find out the cause from the output of `SHOW CREATE TABLE trips`:

```
SHOW CREATE TABLE trips\G
```

```
*************************** 1. row ***************************
       Table: trips
Create Table: CREATE TABLE `trips` (
  `trip_id` bigint(20) NOT NULL AUTO_INCREMENT,
  `duration` int(11) NOT NULL,
  `start_date` datetime DEFAULT NULL,
  `end_date` datetime DEFAULT NULL,
  `start_station_number` int(11) DEFAULT NULL,
  `start_station` varchar(255) DEFAULT NULL,
  `end_station_number` int(11) DEFAULT NULL,
  `end_station` varchar(255) DEFAULT NULL,
  `bike_number` varchar(255) DEFAULT NULL,
  `member_type` varchar(255) DEFAULT NULL,
```

```
  PRIMARY KEY (`trip_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =20477318
1 row in set (0.00 sec)
```

There is **NO** index on `start_date`. You would need an index in order to push this predicate into an index reader operator. Add an index as follows:

```
ALTER TABLE trips ADD INDEX (start_date);
```

```
Query OK, 0 rows affected (2 min 10.23 sec)
```

Note:

You can monitor the progress of DDL jobs using the `ADMIN SHOW DDL JOBS` command. The defaults in TiDB are carefully chosen so that adding an index does not impact production workloads too much. For testing environments, consider increasing the `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` values. On a reference system, a batch size of `10240` and worker count of `32` can achieve a 10x performance improvement over the defaults.

After adding an index, you can then repeat the query in `EXPLAIN`. In the following output, you can see that a new execution plan is chosen, and the `TableFullScan` and `Selection` operators have been eliminated:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ---------------------------+---------+-----------+-------------------------
    ↪
| id                          | estRows | task      | access object
    ↪                           | operator info
    ↪                                                 |
+--
    ↪ ---------------------------+---------+-----------+-------------------------
    ↪
| StreamAgg_17                | 1.00    | root      |
    ↪                                                 | funcs:count(Column#13)->Column
    ↪ #11                             |
```

```
|  └─IndexReader_18         | 1.00   | root     |
   ↪                                        | index:StreamAgg_9
   ↪                                         |
|    └─StreamAgg_9          | 1.00   | cop[tikv] |
   ↪                                            | funcs:count(1)->Column#13
   ↪                                       |
|      └─IndexRangeScan_16  | 8471.88 | cop[tikv] | table:trips, index:start
   ↪ _date(start_date) | range:[2017-07-01 00:00:00,2017-07-01 23:59:59],
   ↪ keep order:false |
+--
   ↪ -------------------------+---------+-----------+-------------------------
   ↪
4 rows in set (0.00 sec)
```

To compare the actual execution time, you can again use EXPLAIN ANALYZE:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
   ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
   ↪ -------------------------+---------+---------+-----------+-----------------
   ↪
| id                        | estRows | actRows | task   | access object
   ↪                          | execution info
   ↪
   ↪ | operator info                                          | memory
   ↪   | disk |
+--
   ↪ -------------------------+---------+---------+-----------+-----------------
   ↪
| StreamAgg_17              | 1.00   | 1       | root     |
   ↪                                       | time:4.516728ms, loops:2
   ↪
   ↪ | funcs:count(Column#13)->Column#11                        | 372
   ↪ Bytes | N/A |
|  └─IndexReader_18         | 1.00   | 1       | root     |
   ↪                                       | time:4.514278ms, loops:2, cop_
   ↪ task: {num: 1, max:4.462288ms, proc_keys: 11409, rpc_num: 1, rpc_time
   ↪ : 4.457148ms} | index:StreamAgg_9                       | 238 Bytes
   ↪   | N/A |
|    └─StreamAgg_9          | 1.00   | 1       | cop[tikv] |
   ↪                                      | time:4ms, loops:12
   ↪
   ↪ | funcs:count(1)->Column#13                              | N/A
   ↪      | N/A |
```

```
|     └─IndexRangeScan_16   | 8471.88 | 11409 | cop[tikv] | table:trips,
    ↪ index:start_date(start_date) | time:4ms, loops:12
    ↪
    ↪ | range:[2017-07-01 00:00:00,2017-07-01 23:59:59], keep order:false |
    ↪  N/A | N/A |
+--
    ↪ -------------------------+---------+---------+-----------+-------------------
    ↪
4 rows in set (0.00 sec)
```

From the result above, the query time has reduced from 1.03 seconds to 0.0 seconds.

> **Note:**
>
> Another optimization that applies here is the coprocessor cache. If you are unable to add indexes, consider enabling the coprocessor cache. When it is enabled, as long as the Region has not been modified since the operator is last executed, TiKV will return the value from the cache. This will also help reduce much of the cost of the expensive `TableFullScan` and `Selection` operators.

11.3.2.2.3 Disable the early execution of subqueries

During query optimization, TiDB pre-executes subqueries that can be directly calculated. For example:

```
CREATE TABLE t1(a int);
INSERT INTO t1 VALUES(1);
CREATE TABLE t2(a int);
EXPLAIN SELECT * FROM t2 WHERE a = (SELECT a FROM t1);
```

```
+--
    ↪ ----------------------+---------+----------+--------------+---------------
    ↪
| id                    | estRows | task     | access object | operator info
    ↪            |
+--

    ↪ ----------------------+----------+-----------+--------------+---------------
    ↪
3 rows in set (0.00 sec)
```

In the preceding example, the `a = (SELECT a FROM t1)` subquery is calculated during optimization and rewritten as `t2.a=1`. This allows more optimizations such as constant propagation and folding during optimization. However, it affects the execution time of the `EXPLAIN` statement. When the subquery itself takes a long time to execute, the `EXPLAIN` statement might not be completed, which could affect online troubleshooting.

Starting from v7.3.0, TiDB introduces the `tidb_opt_enable_non_eval_scalar_subquery` system variable, which controls whether to disable the pre-execution of such subqueries in `EXPLAIN`. The default value of this variable is `OFF`, which means that the subquery is pre-calculated. You can set this variable to `ON` to disable the pre-execution of subqueries:

```
SET @@tidb_opt_enable_non_eval_scalar_subquery = ON;
EXPLAIN SELECT * FROM t2 WHERE a = (SELECT a FROM t1);
```

```
+--
    ↪ ----------------------+----------+-----------+--------------+---------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪              |
+--
    ↪ ----------------------+----------+-----------+--------------+---------------
    ↪
| Selection_13          | 8000.00 | root    |               | eq(test.t2.a,
    ↪ ScalarQueryCol#5) |
|  ─TableReader_15       | 10000.00 | root    |               | data:
    ↪ TableFullScan_14       |
|    ─TableFullScan_14   | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo |
| ScalarSubQuery_10     | N/A     | root    |               | Output:
    ↪ ScalarQueryCol#5    |
|  ─MaxOneRow_6          | 1.00    | root    |               |
    ↪                              |
|    ─TableReader_9      | 1.00    | root    |               | data:
    ↪ TableFullScan_8        |
|      ─TableFullScan_8  | 1.00    | cop[tikv] | table:t1  | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+--------------+---------------
```

```
    ↪
7 rows in set (0.00 sec)
```

As you can see, the scalar subquery is not expanded during the execution, which makes it easier to understand the specific execution process of such SQL.

> **Note:**
>
> tidb_opt_enable_non_eval_scalar_subquery only affects the behavior of the EXPLAIN statement, and the EXPLAIN ANALYZE statement still pre-executes the subquery in advance.

11.3.2.3 Explain Statements That Use Indexes

TiDB supports several operators which make use of indexes to speed up query execution:

- IndexLookup
- IndexReader
- Point_Get and Batch_Point_Get
- IndexFullScan

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 intkey INT NOT NULL,
 pad1 VARBINARY(1024),
 INDEX (intkey)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM
    ↪ dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
```

11.3.2.3.1 IndexLookup

TiDB uses the `IndexLookup` operator when retrieving data from a secondary index. In this case, the following queries will all use the `IndexLookup` operator on the `intkey` index:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT * FROM t1 WHERE intkey < 10;
EXPLAIN SELECT * FROM t1 WHERE intkey BETWEEN 300 AND 310;
EXPLAIN SELECT * FROM t1 WHERE intkey IN (123,29,98);
EXPLAIN SELECT * FROM t1 WHERE intkey >= 99 AND intkey <= 103;
```

```

   ↪                             |                                 |
|  ─IndexRangeScan_8(Build)  | 6.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[99,103], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 6.00    | cop[tikv] | table:t1
   ↪                   | keep order:false              |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator has two child nodes:

- The `─IndexRangeScan_8(Build)` operator performs a range scan on the `intkey` index and retrieves the values of the internal `RowID` (for this table, the primary key).
- The `─TableRowIDScan_9(Probe)` operator then retrieves the full row from the table data.

Because an `IndexLookup` task requires two steps, the SQL Optimizer might choose the `TableFullScan` operator based on statistics in scenarios where a large number of rows match. In the following example, a large number of rows match the condition of `intkey > 100`, and a `TableFullScan` is chosen:

```
EXPLAIN SELECT * FROM t1 WHERE intkey > 100;
```

```
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪      |
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
| TableReader_7         | 898.50 | root     |               | data:Selection_6
   ↪     |
|  ─Selection_6         | 898.50 | cop[tikv] |              | gt(test.t1.intkey
   ↪ , 100) |
|    ─TableFullScan_5   | 1010.00 | cop[tikv] | table:t1 | keep order:false
   ↪     |
```

```
+--
    ↪ ---------------------+---------+----------+--------------+-----------------
    ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator can also be used to efficiently optimize `LIMIT` on an indexed column:

```
EXPLAIN SELECT * FROM t1 ORDER BY intkey DESC LIMIT 10;
```

```
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
| id                           | estRows | task    | access object
    ↪              | operator info                   |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
| IndexLookUp_21               | 10.00   | root     |
    ↪                              | limit embedded(offset:0, count:10) |
|  ─Limit_20(Build)            | 10.00   | cop[tikv] |
    ↪                              | offset:0, count:10              |
|    ─IndexFullScan_18         | 10.00   | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:true, desc    |
|  ─TableRowIDScan_19(Probe)   | 10.00   | cop[tikv] | table:t1
    ↪                   | keep order:false, stats:pseudo |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
4 rows in set (0.00 sec)
```

In the above example, the last 10 rows are read from the index `intkey`. These `RowID` values are then retrieved from the table data.

11.3.2.3.2 IndexReader

TiDB supports the *covering index optimization*. If all rows can be retrieved from an index, TiDB will skip the second step that is usually required in an `IndexLookup`. Consider the following two examples:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT id FROM t1 WHERE intkey = 123;
```

```
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
```

```
| id                          | estRows | task    | access object
    ↪               | operator info                 |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
| IndexLookUp_10              | 1.00    | root     |
    ↪                             |                                |
|  ─IndexRangeScan_8(Build)  | 1.00    | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | range:[123,123], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 1.00    | cop[tikv] | table:t1
    ↪                  | keep order:false              |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
3 rows in set (0.00 sec)

+--
    ↪ ----------------------+---------+----------+-----------------------------+
    ↪
| id                     | estRows | task    | access object               |
    ↪ operator info                |
+--
    ↪ ----------------------+---------+----------+-----------------------------+
    ↪
| Projection_4           | 1.00    | root     |                             |
    ↪ test.t1.id                    |
|  ─IndexReader_6        | 1.00    | root     |                              |
    ↪ index:IndexRangeScan_5        |
|    ─IndexRangeScan_5   | 1.00    | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | range:[123,123], keep order:false |
+--
    ↪ ----------------------+---------+----------+-----------------------------+
    ↪
3 rows in set (0.00 sec)
```

Because `id` is also the internal `RowID`, it is stored in the `intkey` index. After using the `intkey` index as part of `─IndexRangeScan_5`, the value of the `RowID` can be returned directly.

11.3.2.3.3 Point_Get and Batch_Point_Get

TiDB uses the `Point_Get` or `Batch_Point_Get` operator when retrieving data directly from a primary key or unique key. These operators are more efficient than `IndexLookup`. For example:

```
EXPLAIN SELECT * FROM t1 WHERE id = 1234;
EXPLAIN SELECT * FROM t1 WHERE id IN (1234,123);

ALTER TABLE t1 ADD unique_key INT;
UPDATE t1 SET unique_key = id;
ALTER TABLE t1 ADD UNIQUE KEY (unique_key);

EXPLAIN SELECT * FROM t1 WHERE unique_key = 1234;
EXPLAIN SELECT * FROM t1 WHERE unique_key IN (1234, 123);
```

```
+-------------+---------+------+--------------+--------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+--------------+--------------+
| Point_Get_1 | 1.00 | root | table:t1    | handle:1234 |
+-------------+---------+------+--------------+--------------+
1 row in set (0.00 sec)

+--
    ↪ ---------------+--------+------+-------------------------------------+----
    ↪
| id              | estRows | task | access object                       |
    ↪ operator info            |
+--
    ↪ ---------------+--------+------+-------------------------------------+----
    ↪
| Batch_Point_Get_1 | 2.00 | root | table:t1, index:unique_key(unique_key)
    ↪ | keep order:false, desc:false |
+--
    ↪ ---------------+--------+------+-------------------------------------+----
    ↪
1 row in set (0.00 sec)
```

11.3.2.3.4 IndexFullScan

Because indexes are ordered, the `IndexFullScan` operator can be used to optimize common queries such as the `MIN` or `MAX` values for an indexed value:

```
EXPLAIN SELECT MIN(intkey) FROM t1;
EXPLAIN SELECT MAX(intkey) FROM t1;
```

```
+--

    ↪                              | offset:0, count:1             |
|    └─IndexReader_29        | 1.00    | root     |
    ↪                              | index:Limit_28                |
|      └─Limit_28            | 1.00    | cop[tikv] |
    ↪                              | offset:0, count:1             |
|        └─IndexFullScan_27  | 1.00    | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | keep order:true, desc    |
+--
    ↪ ---------------------------+---------+----------+-------------------------
    ↪
5 rows in set (0.00 sec)
```

In the above statements, an `IndexFullScan` task is performed on each TiKV Region. Despite the name `FullScan`, only the first row needs to be read (`└─Limit_28`). Each TiKV Region returns its `MIN` or `MAX` value to TiDB, which then performs Stream Aggregation to filter for a single row. Stream Aggregation with the aggregation function `MAX` or `MIN` also ensures that `NULL` is returned if the table is empty.

By contrast, executing the `MIN` function on an unindexed value will result in `TableFullScan`. The query will require all rows to be scanned in TiKV, but a `TopN` calculation is performed to ensure each TiKV Region only returns one row to TiDB. Although `TopN` prevents excessive rows from being transferred between TiKV and TiDB, this statement is still considered far less efficient than the above example where `MIN` is able

to make use of an index.

```
EXPLAIN SELECT MIN(pad1) FROM t1;
```

```

11.3.2.4 Explain Statements That Use Joins

In TiDB, the SQL Optimizer needs to decide in which order tables should be joined and what is the most efficient join algorithm for a particular SQL statement. The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
SELECT SLEEP(1);
ANALYZE TABLE t1, t2;
```

11.3.2.4.1 Index Join

If the number of estimated rows that need to be joined is small (typically less than 10000 rows), it is preferable to use the index join method. This method of join works similar to the primary method of join used in MySQL. In the following example, the operator `─ ↪ TableReader_29(Build)` first reads the table `t1`. For each row that matches, TiDB will probe the table `t2`:

> **Note:**
>
> In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0. For more details, see TiDB Query Execution Plan Overview.

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.id =
    ↪ t2.t1_id;
```

```

|    ─TableRowIDScan_9(Probe)   | 90000.00 | cop[tikv] | table:t2
    ↪               | keep order:false
    ↪
```

```
    ↪ |
+--
    ↪ ------------------------------+---------+----------+-----------------------
    ↪
```

Index join is efficient in memory usage, but might be slower to execute than other join methods when a large number of probe operations are required. Consider also the following query:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id=t2.t1_id WHERE t1.pad1 = 'value'
    ↪ and t2.pad1='value';
```

In an inner join operation, TiDB implements join reordering and might access either `t1` or `t2` first. Assume that TiDB selects `t1` as the first table to apply the `build` step, and then TiDB is able to filter on the predicate `t1.pad1 = 'value'` before probing the table `t2`. The filter for the predicate `t2.pad1='value'` will be applied on each probe of table `t2`, which might be less efficient than other join methods.

Index join is effective if the build side is small and the probe side is pre-indexed and large. Consider the following query where an index join performs worse than a hash join and is not chosen by the SQL Optimizer:

```
-- DROP previously added index
ALTER TABLE t2 DROP INDEX t1_id;

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```

In the above example, the index join operation is missing an index on `t1.int_col`. Once this index is added, the performance of the operation improves from `0.3 sec` to `0.06 sec`, as the following result shows:

```
-- Re-add index
ALTER TABLE t2 ADD INDEX (t1_id);

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```

Note:

In the above example, the SQL Optimizer selects the hash join plan which performs worse than the index join. Query optimization is an NP-complete problem, and less-than-optimal plans might be chosen. If this is a frequent query, it is recommended to use SQL Plan Management to bind a hint to a query, which can be easier to manage than inserting hints into queries that your application sends to TiDB.

Variations of Index Join

An index join operation using the hint `INL_JOIN` creates a hash table of the intermediate results before joining on the outer table. TiDB also supports creating a hash table on the outer table using the hint `INL_HASH_JOIN`. Each of these variations of index join is automatically selected by the SQL Optimizer.

Configuration

Index join performance is influenced by the following system variables:

- `tidb_index_join_batch_size` (default value: `25000`) - the batch size of `index lookup join` operations.
- `tidb_index_lookup_join_concurrency` (default value: `4`) - the number of concurrent index lookup tasks.

11.3.2.4.2 Hash Join

In a hash join operation, TiDB reads and caches the data on the `Build` side of the join in a hash table, and then reads the data on the `Probe` side of the join, probing the hash table to access required rows. Hash joins require more memory to execute than index joins but execute much faster when there are a lot of rows that need to be joined. The hash join operator is multi-threaded in TiDB and executes in parallel.

An example of hash join is as follows:

```
EXPLAIN SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--

   ↪ equal:[eq(test.t1.id, test.t2.id)] |
| ─TableReader_29(Build)  | 142020.00 | root    |               | data:
   ↪ TableFullScan_28                    |
|   ─TableFullScan_28     | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ false                            |
| ─TableReader_31(Probe)  | 180000.00 | root    |               | data:
   ↪ TableFullScan_30                    |
|   ─TableFullScan_30     | 180000.00 | cop[tikv] | table:t2 | keep order:
   ↪ false                            |
+--
   ↪ ---------------------------+----------+----------+--------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of `HashJoin_27`, TiDB performs the following operations in order:

1. Cache the data of the `Build` side in memory.
2. Construct a Hash Table on the `Build` side based on the cached data.
3. Read the data at the `Probe` side.
4. Use the data of the `Probe` side to probe the Hash Table.
5. Return qualified data to the user.

The `operator info` column in the `EXPLAIN` result table also records other information about `HashJoin_27`, including whether the query is Inner Join or Outer Join, and what are

the conditions of Join. In the above example, the query is an Inner Join, where the Join condition `equal:[eq(test.t1.id, test.t2.id)]` partly corresponds with the query condition `WHERE t1.id = t2.id`. The operator info of the other Join operators in the following examples is similar to this one.

Runtime Statistics

If `tidb_mem_quota_query` (default value: 1 GB) is exceeded, and the `tidb_enable_tmp_storage_on_oom` value is `ON` (default), TiDB will attempt to use temporary storage, and might create the `Build` operator (used as part of the hash join) on disk. Runtime statistics such as memory usage are recorded in the `execution info` of the `EXPLAIN ANALYZE` result table. The following example shows the output of `EXPLAIN ANALYZE` with a 1 GB (default) and a 500 MB quota for `tidb_mem_quota_query`. At 500 MB, disk is used for temporary storage:

```
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
    ↪  t2.id;
SET tidb_mem_quota_query=500 * 1024 * 1024;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
    ↪  t2.id;
```

```

```

Configuration

Hash join performance is influenced by the following system variables:

- `tidb_mem_quota_query` (default value: 1GB) - if the memory quota for a query is exceeded, TiDB will attempt to spill the `Build` operator of a hash join to disk to save memory.
- `tidb_hash_join_concurrency` (default value: `5`) - the number of concurrent hash join tasks.

Related optimizations

TiDB provides the Runtime Filter feature, which optimizes the performance of hash join and greatly improves its execution speed. For specific optimization usage, see Runtime Filter.

11.3.2.4.3 Merge Join

Merge join is a special sort of join that applies when both sides of the join are read in sorted order. It can be described as similar to an *efficient zipper merge*: as data is read on both the `Build` and the `Probe` sides of the join, the join operation works like a streaming operation. Merge joins require far less memory than hash join but do not execute in parallel.

The following is an example:

```
EXPLAIN SELECT /*+ MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
| id                        | estRows  | task     | access object | operator
   ↪ info                                |
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
| MergeJoin_7               | 142020.00 | root    |               | inner join,
   ↪ left key:test.t1.id, right key:test.t2.id |
|  ─TableReader_12(Build)  | 180000.00 | root    |               | data:
   ↪ TableFullScan_11                          |
|    ─TableFullScan_11     | 180000.00 | cop[tikv] | table:t2 | keep order:
   ↪ true                                      |
|  ─TableReader_10(Probe)  | 142020.00 | root    |               | data:
   ↪ TableFullScan_9                           |
|    ─TableFullScan_9      | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ true                                      |
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of the merge join operator, TiDB performs the following operations:

1. Read all the data of a Join Group from the `Build` side into the memory.
2. Read the data of the `Probe` side.
3. Compare whether each row of data on the `Probe` side matches a complete Join Group on the `Build` side. Apart from equivalent conditions, there are non-equivalent conditions. Here "match" mainly refers to checking whether non-equivalent conditions are met. Join Group refers to the data with the same value among all Join Keys.

11.3.2.5 Explain Statements in the MPP Mode

TiDB supports using the MPP mode to execute queries. In the MPP mode, the TiDB optimizer generates execution plans for MPP. Note that the MPP mode is only available for tables that have replicas on TiFlash.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id int, value int);
INSERT INTO t1 values(1,2),(2,3),(1,3);
ALTER TABLE t1 set tiflash replica 1;
ANALYZE TABLE t1;
```

```
SET tidb_allow_mpp = 1;
```

11.3.2.5.1 MPP query fragments and MPP tasks

In the MPP mode, a query is logically sliced into multiple query fragments. Take the following statement as an example:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

This query is divided into two fragments in the MPP mode. One for the first-stage aggregation and the other for the second-stage aggregation, also the final aggregation. When this query is executed, each query fragment is instantiated into one or more MPP tasks.

11.3.2.5.2 Exchange operators

`ExchangeReceiver` and `ExchangeSenderare` two exchange operators specific for MPP execution plans. The `ExchangeReceiver` operator reads data from downstream query fragments and the `ExchangeSender` operator sends data from downstream query fragments to upstream query fragments. In the MPP mode, the root operator of each MPP query fragment is `ExchangeSender`, meaning that query fragments are delimited by the `ExchangeSender` operator.

The following is a simple MPP execution plan:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ----------------------------------+---------+------------------+--------------
   ↪
| id                                | estRows | task              | access object |
   ↪  operator info                                  |

   ↪ ----------------------------------+---------+------------------+--------------
   ↪
| TableReader_31                    | 2.00    | root              |               |
   ↪ data:ExchangeSender_30                          |
|  ─ExchangeSender_30               | 2.00    | batchCop[tiflash] |               |
   ↪ ExchangeType: PassThrough                       |
|    ─Projection_26                 | 2.00    | batchCop[tiflash] |               |
   ↪ Column#4                                        |
|      ─HashAgg_27                  | 2.00    | batchCop[tiflash] |               |
   ↪ group by:test.t1.id, funcs:sum(Column#7)->Column#4 |
|        ─ExchangeReceiver_29       | 2.00    | batchCop[tiflash] |               |
   ↪                                                 |
|          ─ExchangeSender_28       | 2.00    | batchCop[tiflash] |               |
   ↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
```

```
|           └─HashAgg_9            | 2.00   | batchCop[tiflash] |           |
   ↪ group by:test.t1.id, funcs:count(1)->Column#7 |
|             └─TableFullScan_25   | 3.00   | batchCop[tiflash] | table:t1  |
   ↪ keep order:false                             |
+--
   ↪ ---------------------------------+---------+-------------------+-------------
   ↪
```

The above execution plan contains two query fragments:

- The first is `[TableFullScan_25, HashAgg_9, ExchangeSender_28]`, which is mainly responsible for the first-stage aggregation.
- The second is `[ExchangeReceiver_29, HashAgg_27, Projection_26, ExchangeSender ↪ _30]`, which is mainly responsible for the second-stage aggregation.

The `operator info` column of the `ExchangeSender` operator shows the exchange type information. Currently, there are three exchange types. See the following:

- HashPartition: The `ExchangeSender` operator firstly partitions data according to the Hash values and then distributes data to the `ExchangeReceiver` operator of upstream MPP tasks. This exchange type is often used for Hash Aggregation and Shuffle Hash Join algorithms.
- Broadcast: The `ExchangeSender` operator distributes data to upstream MPP tasks through broadcast. This exchange type is often used for Broadcast Join.
- PassThrough: The `ExchangeSender` operator sends data to the only upstream MPP task, which is different from the Broadcast type. This exchange type is often used when returning data to TiDB.

In the example execution plan, the exchange type of the operator `ExchangeSender_28` is HashPartition, meaning that it performs the Hash Aggregation algorithm. The exchange type of the operator `ExchangeSender_30` is PassThrough, meaning that it is used to return data to TiDB.

MPP is also often applied to join operations. The MPP mode in TiDB supports the following two join algorithms:

- Shuffle Hash Join: Shuffle the data input from the join operation using the HashPartition exchange type. Then, upstream MPP tasks join data within the same partition.
- Broadcast Join: Broadcast data of the small table in the join operation to each node, after which each node joins the data separately.

The following is a typical execution plan for Shuffle Hash Join:

```
SET tidb_broadcast_join_threshold_count=0;
SET tidb_broadcast_join_threshold_size=0;
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

   ↪ keep order:false                             |
+--
   ↪ ------------------------------------+--------+-------------+---------------+
   ↪
12 rows in set (0.00 sec)
```

In the above execution plan:

- The query fragment `[TableFullScan_20, Selection_21, ExchangeSender_22]`

reads data from table b and shuffles data to upstream MPP tasks.

- The query fragment `[TableFullScan_16, Selection_17, ExchangeSender_18]` reads data from table a and shuffles data to upstream MPP tasks.
- The query fragment `[ExchangeReceiver_19, ExchangeReceiver_23, HashJoin_44, ExchangeSender_47]` joins all data and returns it to TiDB.

A typical execution plan for Broadcast Join is as follows:

```
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

|        ─ExchangeReceiver_20(Build) | 6.00   | cop[tiflash] |              |
   ↪                                          |
|          ─ExchangeSender_19        | 6.00   | cop[tiflash] |              |
   ↪ ExchangeType: Broadcast                  |
|            ─Selection_18           | 6.00   | cop[tiflash] |              |
   ↪ not(isnull(test.t1.id))                  |
|              ─TableFullScan_17     | 6.00   | cop[tiflash] | table:a      |
   ↪ keep order:false                         |
|        ─Selection_22(Probe)        | 6.00   | cop[tiflash] |              |
   ↪ not(isnull(test.t1.id))                  |
|          ─TableFullScan_21         | 6.00   | cop[tiflash] | table:b      |
   ↪ keep order:false                         |
+--
   ↪ ----------------------------------+--------+-------------+--------------+
   ↪
```

In the above execution plan:

- The query fragment `[TableFullScan_17, Selection_18, ExchangeSender_19]` reads data from the small table (table a) and broadcasts the data to each node that

contains data from the large table (table b).

- The query fragment `[TableFullScan_21, Selection_22, ExchangeReceiver_20, ↪ HashJoin_43, ExchangeSender_46]` joins all data and returns it to TiDB.

11.3.2.5.3 `EXPLAIN ANALYZE` statements in the MPP mode

The `EXPLAIN ANALYZE` statement is similar to `EXPLAIN`, but it also outputs some runtime information.

The following is the output of a simple `EXPLAIN ANALYZE` example:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ---------------------------------+---------+---------+------------------+-----
   ↪
| id                                | estRows | actRows | task         | access
   ↪  object | execution info
   ↪                                                                            |
   ↪  operator info                                                 | memory |

    ↪ scan:{dtfile:{total_scanned_packs:1,...}} | keep order:false
    ↪                             | N/A    | N/A |
+--
    ↪ ---------------------------------+---------+---------+-------------------+-----
    ↪
```

Compared to the output of `EXPLAIN`, the `operator info` column of the operator `ExchangeSender` also shows `tasks`, which records the id of the MPP task that the query fragment instantiates into. In addition, each MPP operator has a `threads` field in the `execution info` column, which records the concurrency of operations when TiDB executes this operator. If the cluster consists of multiple nodes, this concurrency is the result of adding up the concurrency of all nodes.

11.3.2.5.4 MPP version and exchange data compression

Starting from v6.6.0, the new fields `MPPVersion` and `Compression` are added to the MPP execution plan.

- `MppVersion`: The version number of the MPP execution plan, which can be set through the system variable `mpp_version`.
- `Compression`: The data compression mode of the `Exchange` operator, which can be set through the system variable `mpp_exchange_compression_mode`. If data compression is not enabled, this field is not displayed in the execution plan.

See the following example:

```
mysql > EXPLAIN SELECT COUNT(*) AS count_order FROM lineitem GROUP BY l_
    ↪ returnflag, l_linestatus ORDER BY l_returnflag, l_linestatus;

+--
    ↪ ---------------------------------------+-------------+--------------+----------

+--
    ↪ ------------------------------------+--------------+--------------+-----------
    ↪
```

In the preceding execution plan result, TiDB uses an MPP execution plan of version 1 to build `TableReader`. The `ExchangeSender` operator of the `HashPartition` type uses the `FAST` data compression mode. Data compression is not enabled for the `ExchangeSender` operator of the `PassThrough` type.

11.3.2.6 Explain Statements That Use Subqueries

TiDB performs several optimizations to improve the performance of subqueries. This document describes some of these optimizations for common subqueries and how to interpret the output of `EXPLAIN`.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
CREATE TABLE t3 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 t1_id INT NOT NULL,
 UNIQUE (t1_id)
);

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
INSERT INTO t3 SELECT NULL, id FROM t1 WHERE id < 1000;

SELECT SLEEP(1);
ANALYZE TABLE t1, t2, t3;
```

11.3.2.6.1 Inner join (non-unique subquery)

In the following example, the `IN` subquery searches for a list of IDs from the table `t2` ↪ . For semantic correctness, TiDB needs to guarantee that the column `t1_id` is unique. Using `EXPLAIN`, you can see the execution plan used to remove duplicates and perform an `INNER JOIN` operation:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2);
```

```
+--
    ↪ ----------------------------+----------+-----------+-------------------------
    ↪
```

```
| id                           | estRows | task     | access object

+--
    ↪ ------------------------------+---------+----------+-----------------------
    ↪
```

From the query results above, you can see that TiDB uses the index join operation `IndexJoin_15` to join and transform the subquery. In the execution plan, the execution process is as follows:

1. The index scanning operator `─IndexFullScan_26` at the TiKV side reads the values of the `t2.t1_id` column.
2. Some tasks of the `─StreamAgg_34` operator deduplicate the values of `t1_id` in TiKV.

3. Some tasks of the `-StreamAgg_44(Build)` operator deduplicate the values of `t1_id` in TiDB. The deduplication is performed by the aggregate function `firstrow(test.t2.t1_id)`.
4. The operation results are joined with the primary key of the `t1` table. The join condition is `eq(test.t1.id, test.t2.t1_id)`.

11.3.2.6.2 Inner join (unique subquery)

In the previous example, aggregation is required to ensure that the values of `t1_id` are unique before joining against the table `t1`. But in the following example, `t3.t1_id` is already guaranteed unique because of a `UNIQUE` constraint:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t3);
```

```

+--
   ↪ --------------------------+---------+-----------+-------------------------
   ↪
```

Semantically because `t3.t1_id` is guaranteed unique, it can be executed directly as an `INNER JOIN`.

11.3.2.6.3 Semi join (correlated subquery)

In the previous two examples, TiDB is able to perform an `INNER JOIN` operation after the data inside the subquery is made unique (via `StreamAgg`) or guaranteed unique. Both joins are performed using an Index Join.

In this example, TiDB chooses a different execution plan:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2 WHERE t1_id !=
    ↪ t1.int_col);
```

```

    ↪                                                              |
|      ─TableFullScan_20   | 71010.00 | cop[tikv] | table:t1                 |
    ↪  keep order:true
    ↪
    ↪ |
+--
    ↪ -------------------------+---------+----------+-------------------------
```

```
    ↪
```

From the result above, you can see that TiDB uses a `Semi Join` algorithm. Semi-join differs from inner join: semi-join only permits the first value on the right key (`t2.t1_id`), which means that the duplicates are eliminated as a part of the join operator task. The join algorithm is also Merge Join, which is like an efficient zipper-merge as the operator reads data from both the left and the right side in sorted order.

The original statement is considered a *correlated subquery*, because the subquery refers to a column (`t1.int_col`) that exists outside of the subquery. However, the output of `EXPLAIN` shows the execution plan after the subquery decorrelation optimization has been applied. The condition `t1_id != t1.int_col` is rewritten to `t1.id != t1.int_col`. TiDB can perform this in `└─Selection_21` as it is reading data from the table `t1`, so this decorrelation and rewriting make the execution a lot more efficient.

11.3.2.6.4 Anti semi join (`NOT IN` subquery)

In the following example, the query semantically returns all rows from the table `t3` *unless* `t3.t1_id` is in the subquery:

```
EXPLAIN SELECT * FROM t3 WHERE t1_id NOT IN (SELECT id FROM t1 WHERE int_
    ↪ col < 100);
```

```

+--
    ↪ -------------------------+--------+----------+-------------+-------------
    ↪
```

This query starts by reading the table `t3` and then probes the table `t1` based on the `PRIMARY KEY`. The join type is an *anti semi join*; anti because this example is for the non-existence of the value (`NOT IN`) and semi-join because only the first row needs to match before the join is rejected.

11.3.2.6.5 Null-aware semi join (`IN` and `= ANY` subqueries)

The value of the `IN` or `= ANY` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `IN` and `= ANY` operators are converted to semi join and left outer semi join respectively. In the preceding example of Semi join, since columns `test.t1.id` ↪ and `test.t2.t1_id` on both sides of the join key are `not NULL`, the semi join does not need to be considered as null-aware (`NULL` is not processed specially). TiDB processes the null-aware semi join based on the Cartesian product and filter without special optimization. The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a,b) IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a,b) IN (SELECT * FROM s);
```

    ↪
8 rows in set (0.01 sec)
```

In the first query statement `EXPLAIN SELECT (a,b)IN (SELECT * FROM s)FROM t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by the `IN` subquery is null-aware. Specifically, the Cartesian product is calculated first, then the column connected by `IN` or `= ANY` is put into other conditions as a normal equality query for filtering.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a,b)IN (SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the `IN` subquery should have been converted to a null-aware semi join. But TiDB optimizes it by converting semi join to inner join and aggregate. This is because `NULL` and `false` are equivalent in `IN` subqueries for non-scalar output. The `NULL` rows in the push-down filter results in the negative semantics of the `WHERE` clause. Therefore, these rows can be ignored beforehand.

> **Note:**
>
> The `Exists` operator is also converted to semi join, but it is not null-aware.

11.3.2.6.6 Null-aware anti semi join (`NOT IN` and `!= ALL` subqueries)

The value of the `NOT IN` or `!= ALL` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `NOT IN` and `! = ALL` operators are converted to anti semi join and anti left outer semi join respectively. In the preceding example of Anti semi join, since columns `test.t3.t1_id` and `test.t1.id` on both sides of the join key are `not NULL`, the anti semi join does not need to be considered as null-aware (`NULL` is not processed specially).

TiDB v6.3.0 optimizes null-aware anti join (NAAJ) as follows:

- Build hash join using the null-aware equality condition (NA-EQ)

  Set operators introduce the equality condition, which requires a special process for the `NULL` value of operators on both sides of the condition. The equality condition that requires null-aware is called NA-EQ. Different from earlier versions, TiDB v6.3.0 no longer processes NA-EQ as before, but places it in other conditions after join, and then determines the legitimacy of the result set after matching the Cartesian product.

  Since TiDB v6.3.0, NA-EQ, a weakened equality condition, is still used to build hash join. This reduces the matching amount of data that needs to be traversed and speeds up the matching process. The acceleration is more significant when the percentage of total `DISTINCT()` values of the build table is almost 100%.

- Speed up the return of matching results using the special property of `NULL`

  Since anti semi join is a conjunctive normal form (CNF), a `NULL` on either side of the join leads to a definite result. This property can be used to speed up the return of the entire matching process.

The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a, b) NOT IN (SELECT * FROM s);
```

```

+--
    ↪ -------------------------+---------+----------+-------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In the first query statement `EXPLAIN SELECT (a, b)NOT IN (SELECT * FROM s)FROM ↪ t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a, b)NOT IN ( ↪ SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the anti semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

Currently, TiDB can only be null-aware of anti semi join and anti left outer semi join. Only the hash join type is supported and its build table should be fixed to the right table.

> **Note:**
>
> The `Not Exists` operator is also converted to the anti semi join, but it is not null-aware.

11.3.2.6.7 Explain statements using other types of subqueries

- Explain Statements Using Index Merge

11.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB);
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
SELECT SLEEP(1);
ANALYZE TABLE t1;
```

From the output of SHOW TABLE REGIONS, you can see that this table is split into multiple Regions:

```
SHOW TABLE t1 REGIONS;
```

```
+--
    ↪ ---------+-------------+-------------+-----------+-----------------+-------+--
    ↪
| REGION_ID | START_KEY | END_KEY    | LEADER_ID | LEADER_STORE_ID | PEERS |

    ↪ APPROXIMATE_KEYS |
+--
    ↪ ---------+-------------+-------------+-----------+-----------------+-------+--
    ↪
|       64 | t_64_      | t_64_r_31766 |     65 |             1 | 65    |
    ↪         0 |         1325 | 102033520 |                98 |
    ↪ 52797 |
|       66 | t_64_r_31766 | t_64_r_63531 |   67 |             1 | 67    |
    ↪         0 |         1325 |  72522521 |               104 |
    ↪ 78495 |
|       68 | t_64_r_63531 | t_64_r_95296 |   69 |             1 | 69    |
    ↪         0 |         1325 |         0 |               104 |
    ↪ 95433 |
|        2 | t_64_r_95296 |              |        3 |             1 | 3     |
    ↪         0 |         1501 |         0 |                81 |
    ↪ 63211 |
+--
    ↪ ---------+-------------+-------------+-----------+-----------------+-------+--
```

```
    ↪
4 rows in set (0.00 sec)
```

Using `EXPLAIN` with the following aggregation statement, you can see that `-StreamAgg_8` is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in `StreamAgg_16`:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
| id                        | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
| StreamAgg_16              | 1.00     | root     |               | funcs:count(
    ↪ Column#7)->Column#5 |
|  -TableReader_17          | 1.00     | root     |               | data:
    ↪ StreamAgg_8             |
|    -StreamAgg_8           | 1.00     | cop[tikv] |              | funcs:count
    ↪ (1)->Column#7    |
|      -TableFullScan_15    | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
4 rows in set (0.00 sec)
```

This is easiest to observe in `EXPLAIN ANALYZE`, where the `actRows` matches the number of Regions from `SHOW TABLE REGIONS` because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ -------------------------+----------+---------+----------+---------------+---
    ↪
| id                        | estRows  | actRows | task     | access object |
    ↪ execution info
    ↪
    ↪ | operator info               | memory   | disk |
+--
    ↪ -------------------------+----------+---------+----------+---------------+---
    ↪
```

```

    ↪
    ↪ | keep order:false            | N/A      | N/A |
+--
    ↪ -------------------------+----------+--------+----------+---------------+---
    ↪
4 rows in set (0.01 sec)
```

11.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the `HashAgg` operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```
+--
    ↪ -----------------------+----------+----------+--------------+-------------
    ↪
| id                     | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ -----------------------+----------+----------+--------------+-------------
    ↪
| HashAgg_9              | 1.00     | root     |               | funcs:count(
    ↪ Column#6)->Column#5 |
|  ─TableReader_10       | 1.00     | root     |               | data:HashAgg_
    ↪ 5              |
```

```
|   └─HashAgg_5          | 1.00     | cop[tikv] |           | funcs:count
    ↪ (1)->Column#6    |
|     └─TableFullScan_8  | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ ----------------------+----------+----------+--------------+------------
    ↪
4 rows in set (0.00 sec)
```

The `operator info` shows that the hashing function used to aggregate the data is `funcs
↪ :count(1)->Column#6`.

11.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```
CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

+--
    ↪ ---------------------------+----------+----------+--------------+-----------
    ↪
| id                         | estRows | task     | access object | operator
    ↪ info
    ↪ |
+--
    ↪ ---------------------------+----------+----------+--------------+-----------
    ↪
| Projection_4               | 8000.00 | root     |               | test.t2.col1
    ↪ , Column#3                                                              |
|  └─StreamAgg_8             | 8000.00 | root     |               | group by:
    ↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
    ↪ ->test.t2.col1 |
|    └─Sort_13               | 10000.00 | root    |               | test.t2.
    ↪ col1
    ↪                                                                       |
```

```
|     └─TableReader_12      | 10000.00 | root    |              | data:
    ↪ TableFullScan_11
    ↪                                                                |
|       └─TableFullScan_11  | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo
    ↪ |
+--
    ↪ ---------------------------+----------+-----------+---------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In this example, the `└─Sort_13` operator can be eliminated by adding an index on `col1` ↪ . Once the index is added, the data can be read in order and the `└─Sort_13` operator is eliminated:

```
ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.28 sec)

    ↪
5 rows in set (0.00 sec)
```

11.3.2.7.3 Multidimensional data aggregation with ROLLUP

Starting from v7.4.0, the `GROUP BY` clause of TiDB supports the `WITH ROLLUP` modifier.

In the `GROUP BY` clause, you can specify one or more columns as a group list and append the `WITH ROLLUP` modifier after the list. Then, TiDB will conduct multidimensional descending grouping based on the columns in the group list and provide you with summary results for each group in the output.

> **Note:**
>
> Currently, TiDB does not support the Cube syntax.

```
explain SELECT year, month, grouping(year), grouping(month), SUM(profit) AS
    ↪  profit FROM bank GROUP BY year, month WITH ROLLUP;
+--
    ↪ ------------------------------------+---------+-------------+---------------+

    ↪ Column#6,Column#7,gid] |
|               └─Projection_16      | 3.00   | mpp[tiflash] |           |
    ↪ test.bank.profit, test.bank.year->Column#6, test.bank.month->Column#7
    ↪
    ↪
    ↪ |
|                 └─TableFullScan_17 | 3.00   | mpp[tiflash] | table:bank |
    ↪ keep order:false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ----------------------------------+---------+--------------+----------------+
    ↪
10 rows in set (0.05 sec)
```

According to the `GROUP BY year, month WITH ROLLUP` syntax in the preceding statement, the SQL aggregation results for this statement can be calculated and concatenated in three groups: `{year, month}`, `{year}`, and `{}` respectively.

For more information, see GROUP BY modifiers.

11.3.2.8 EXPLAIN Statements Using Views

`EXPLAIN` displays the tables and indexes that a view references, not the name of the view itself. This is because views are only virtual tables and do not store any data themselves.

The definition of the view and the rest of the statement are merged together during SQL optimization.

From the bikeshare example database, you can see that the following two queries are executed in a similar manner:

```
ALTER TABLE trips ADD INDEX (duration);
CREATE OR REPLACE VIEW long_trips AS SELECT * FROM trips WHERE duration >
    ↪ 3600;
EXPLAIN SELECT * FROM long_trips;
EXPLAIN SELECT * FROM trips WHERE duration > 3600;
```

```
Query OK, 0 rows affected (2 min 10.11 sec)

Query OK, 0 rows affected (0.13 sec)

    ↪                                    |                                  |
|  ─IndexRangeScan_10(Build)  | 6372547.67 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_11(Probe)  | 6372547.67 | cop[tikv] | table:trips
    ↪                     | keep order:false                 |
+--
    ↪ ------------------------------+-----------+----------+----------------------
    ↪
3 rows in set (0.00 sec)

+--
    ↪ ------------------------------+----------+----------+----------------------
    ↪
| id                           | estRows  | task     | access object
    ↪                     | operator info                    |
+--
    ↪ ------------------------------+----------+----------+----------------------
    ↪
| IndexLookUp_10               | 833219.37 | root    |
    ↪                                   |                                  |
|  ─IndexRangeScan_8(Build)  | 833219.37 | cop[tikv] | table:trips, index:
```

```
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 833219.37 | cop[tikv] | table:trips
    ↪                    | keep order:false                |
+--
    ↪ ----------------------------+----------+----------+-----------------------
    ↪
3 rows in set (0.00 sec)
```

Similarly, predicates from the view are pushed down to the base table:

```
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪

| id                    | estRows    | task     | access object | operator
    ↪ info                          |
+--
    ↪ ---------------------+------------+----------+--------------+------------
    ↪
```

```
| TableReader_7        | 43.00      | root     |              | data:Selection
    ↪ _6                      |
|  ─Selection_6        | 43.00      | cop[tikv] |              | eq(bikeshare.
    ↪ trips.bike_number, "W00950") |
|    ─TableFullScan_5  | 19117643.00 | cop[tikv] | table:trips | keep order
    ↪ :false                  |
+--
    ↪ ----------------------+------------+----------+--------------+-------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself. Consider the following composite index:

```
ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
Query OK, 0 rows affected (2 min 31.20 sec)

+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
| id                          | estRows | task     | access object
    ↪                                   | operator info
    ↪                                   |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
| IndexLookUp_13              | 63725.48 | root    |
    ↪                                                 |
    ↪                                                 |
|  ─IndexRangeScan_11(Build)  | 63725.48 | cop[tikv] | table:trips, index:
    ↪ bike_number(bike_number, duration) | range:("W00950" 3600,"W00950" +
    ↪ inf], keep order:false |
|  ─TableRowIDScan_12(Probe)  | 63725.48 | cop[tikv] | table:trips
    ↪                                     | keep order:false
    ↪                                   |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
```

```
3 rows in set (0.00 sec)

+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
| id                          | estRows | task     | access object
    ↪                                     | operator info
    ↪                             |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
| IndexLookUp_10              | 19117.64 | root    |
    ↪                                                 |
    ↪                                               |
|  ─IndexRangeScan_8(Build)  | 19117.64 | cop[tikv] | table:trips, index:
    ↪ bike_number(bike_number, duration) | range:["W00950","W00950"], keep
    ↪ order:false |
|  ─TableRowIDScan_9(Probe)  | 19117.64 | cop[tikv] | table:trips
    ↪                                     | keep order:false
    ↪                           |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement, TiDB is able to use both parts of the composite index `(bike_number, duration)`. In the second statement, only the first part which is `bike_number` of the index `(bike_number, duration)` is used.

11.3.2.9 Explain Statements Using Partitions

The `EXPLAIN` statement displays the partitions that TiDB needs to access in order to execute a query. Because of partition pruning, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of `EXPLAIN`.

The sample data used in this document:

```
CREATE TABLE t1 (
 id BIGINT NOT NULL auto_increment,
 d date NOT NULL,
 pad1 BLOB,
 pad2 BLOB,
 pad3 BLOB,
 PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
```

```
 PARTITION p2016 VALUES LESS THAN (2017),
 PARTITION p2017 VALUES LESS THAN (2018),
 PARTITION p2018 VALUES LESS THAN (2019),
 PARTITION p2019 VALUES LESS THAN (2020),
 PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES
 ('2016-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024));

INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

SELECT SLEEP(1);
ANALYZE TABLE t1;
```

The following example shows a statement against the newly created partitioned table:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE d = '2017-06-01';
```

```
+--
   ↪ ----------------------------+---------+-----------+--------------------------+-
   ↪
| id                           | estRows | task      | access object            |
   ↪ operator info                              |
```

```
+--
   ↪ ---------------------------+---------+----------+-------------------------+-
   ↪
| StreamAgg_21                | 1.00    | root     |                         |
   ↪ funcs:count(Column#8)->Column#6      |
|  ─TableReader_22            | 1.00    | root     |                          |
   ↪ data:StreamAgg_10                    |
|    ─StreamAgg_10            | 1.00    | cop[tikv] |                         |
   ↪ funcs:count(1)->Column#8             |
|      ─Selection_20          | 8.87    | cop[tikv] |                         | eq
   ↪ (test.t1.d, 2017-06-01 00:00:00.000000) |
|        ─TableFullScan_19    | 8870.00 | cop[tikv] | table:t1, partition:
   ↪ p2017 | keep order:false               |
+--
   ↪ ---------------------------+---------+----------+-------------------------+-
   ↪
5 rows in set (0.01 sec)
```

Starting from the inner-most (─TableFullScan_19) operator and working back towards the root operator (StreamAgg_21):

- TiDB successfully identified that only one partition (p2017) needed to be accessed. This is noted under access object.
- The partition itself was scanned in the operator ─TableFullScan_19 and then ─ ↪ Selection_20 was applied to filter for rows that have a start date of 2017-06-01 ↪ 00:00:00.000000.
- The rows that match ─Selection_20 are then stream aggregated in the coprocessor, which natively understands the count function.
- Each coprocessor request then sends back one row to ─TableReader_22 inside TiDB, which is then stream aggregated under StreamAgg_21 and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

    ↪                         | funcs:count(1)->Column#17    |
|         └─Selection_111         | 8892.80 | cop[tikv] |
    ↪                        | eq(year(test.t1.d), 2017)    |
|           └─TableFullScan_110   | 11116.00 | cop[tikv] | table:t1,
    ↪ partition:pmax | keep order:false       |
+--
    ↪ ---------------------------------+----------+----------+----------------------
    ↪
27 rows in set (0.00 sec)
```

From the output above:

- TiDB believes that it needs to access all of the partitions (`p2016..pMax`). This is because the predicate `YEAR(d)= 2017` is considered non-sargable. This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.
- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `└─PartitionUnion_21` unions the results from accessing each partition.

11.3.2.10 Explain Statements Using Index Merge

Index merge is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

Index merge in TiDB has two types: the intersection type and the union type. The former applies to the `AND` expression, while the latter applies to the `OR` expression. The union-type index merge is introduced in TiDB v4.0 as an experimental feature and has become GA in v5.4.0. The intersection type is introduced in TiDB v6.5.0, and can be used only when the `USE_INDEX_MERGE` hint is specified.

11.3.2.10.1 Enable index merge

In v5.4.0 or a later TiDB version, index merge is enabled by default. In other situations, if index merge is not enabled, you need to set the variable `tidb_enable_index_merge` to `ON` to enable this feature.

```
SET session tidb_enable_index_merge = ON;
```

11.3.2.10.2 Examples

```
CREATE TABLE t(a int, b int, c int, d int, INDEX idx_a(a), INDEX idx_b(b),
    ↪ INDEX idx_c(c), INDEX idx_d(d));
```

```
EXPLAIN SELECT /*+ NO_INDEX_MERGE() */ * FROM t WHERE a = 1 OR b = 1;

+--

+--
    ↪ ----------------------------+---------+----------+----------------------+--
    ↪
```

In the preceding query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without index merge, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, index merge is introduced in TiDB to access tables.

For the preceding query, the optimizer chooses the union-type index merge to access the table. Index merge allows the optimizer to use multiple indexes per table, to merge the results returned by each index, and to generate the latter execution plan in the preceding output.

In the output, the `type: union` information in `operator info` of the `IndexMerge_8` operator indicates that this operator is a union-type index merge. It has three child nodes. `IndexRangeScan_5` and `IndexRangeScan_6` scan the `RowID`s that meet the condition according to the range, and then the `TableRowIDScan_7` operator accurately reads all the data that meets the condition according to these `RowID`s.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan`/`TableRangeScan`, the `operator info` column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan`/`TableFullScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_5` operator indicates that the operator scans the data from 1 to positive infinity.

```
EXPLAIN SELECT /*+ NO_INDEX_MERGE() */ * FROM t WHERE a > 1 AND b > 1 AND c
    ↪  = 1; -- Does not use index merge

    ↪ ----------------------------+---------+----------+-----------------------+--
    ↪
```

From the preceding example, you can see that the filter condition is a `WHERE` clause that uses `AND` as the connector. Before index merge is enabled, the optimizer can only choose one of the three indexes (`idx_a`, `idx_b`, or `idx_c`).

If one of the filter conditions has a low selectivity, the optimizer directly chooses the corresponding index to achieve the ideal execution efficiency. However, if the data distribution meets all of the following three conditions, you can consider using the intersection-type index merge:

- The data size of the whole table is large, and directly reading the whole table is inefficient.
- For each one of the three filter conditions, the respective selectivity is very high, so the execution efficiency of `IndexLookUp` using a single index is not ideal.
- The overall selectivity of the three filter conditions is low.

When using the intersection-type index merge to access tables, the optimizer can choose to use multiple indexes on a table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the preceding example output. The `type: intersection` information in the `operator info` of the `IndexMerge_9` operator indicates that this operator is an intersection-type index merge. The other parts of the execution plan are similar to the preceding union-type index merge example.

Note:

- The Index Merge feature is enabled by default from v5.4.0. That is, `tidb_enable_index_merge` is `ON`.
- You can use the SQL hint `USE_INDEX_MERGE` to force the optimizer to apply Index Merge, regardless of the setting of `tidb_enable_index_merge`. To enable Index Merge when the filtering conditions contain expressions that cannot be pushed down, you must use the SQL hint `USE_INDEX_MERGE`.
- If the optimizer can choose the single index scan method (other than full table scan) for a query plan, the optimizer will not automatically use index merge. For the optimizer to use index merge, you need to use the optimizer hint. Starting from v8.1.0, you can remove this limitation by setting Optimizer Fix Control 52869. Removing this limitation enables the optimizer to choose index merge automatically in more queries, but might cause the optimizer to ignore the optimal execution plans. Therefore, it is recommended to conduct sufficient tests on actual use cases before removing this limitation to make sure that it will not cause performance regressions.
- Index Merge is not supported in temporary tables for now.
- The intersection-type index merge will not automatically be selected by the optimizer. You must specify the **table name and index name** using the `USE_INDEX_MERGE` hint for it to be selected.

11.3.3 SQL Optimization Process

11.3.3.1 SQL Optimization Process

In TiDB, the process from inputting a query to getting the execution result according to the final execution plan is illustrated as follows:

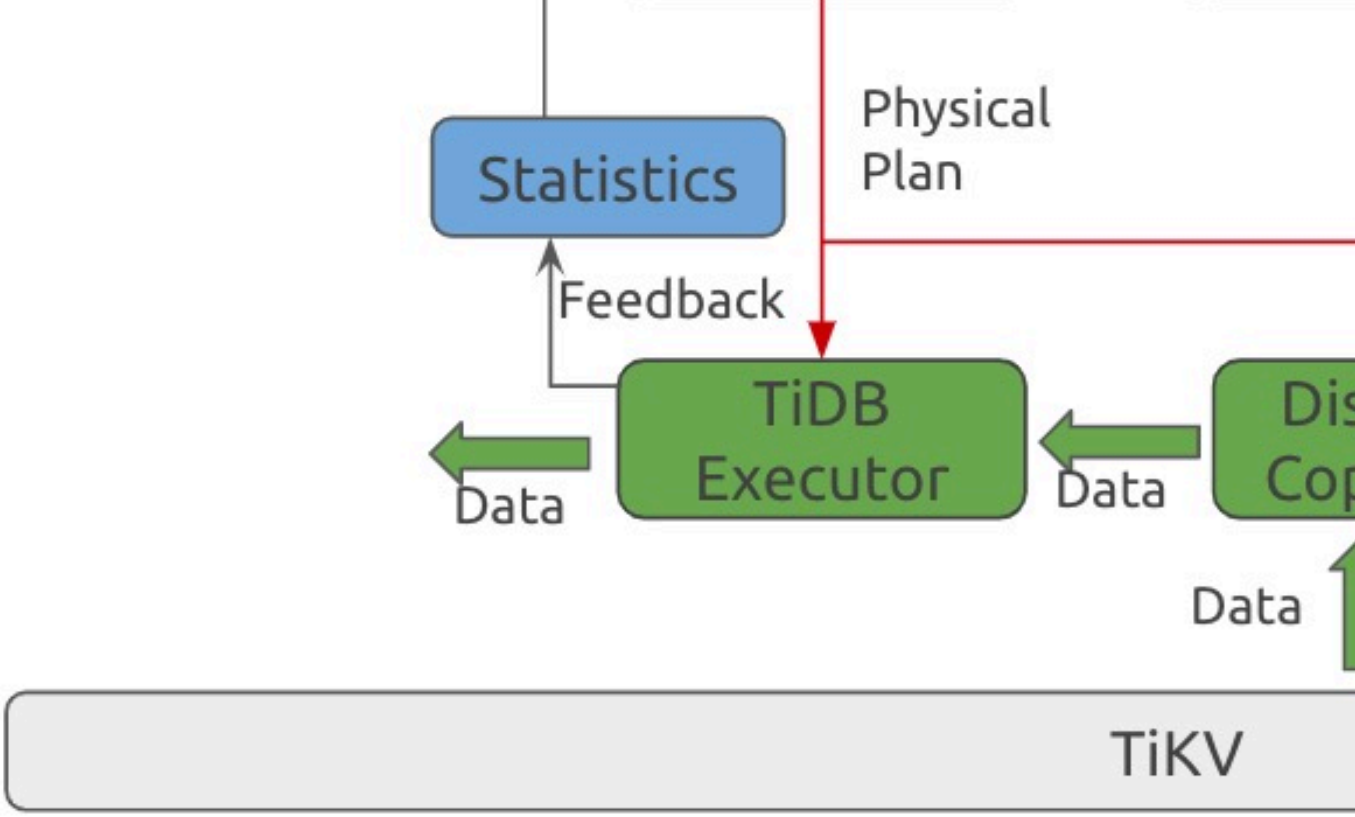

Figure 400: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see SQL Logical Optimization.

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see SQL Physical Optimization.

At the same time, when TiDB executes the `PREPARE` statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see Execution Plan Cache.

11.3.3.2 Logic Optimization

11.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the `IN` sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- Subquery Related Optimizations
- Column Pruning
- Decorrelation of Correlated Subquery
- Eliminate Max/Min
- Predicates Push Down
- Partition Pruning
- TopN and Limit Operator Push Down
- Join Reorder
- Derive TopN or Limit from Window Functions

11.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`
- `IN (SELECT ... FROM ..)`
- `EXISTS (SELECT ... FROM ...)`
- `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

Sometimes a subquery contains non-subquery columns, such as `select * from t where t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of subquery is usually called a "correlated subquery", and the externally introduced column is called a "correlated column". For optimizations about correlated subquery, see Decorrelation of correlated subquery. This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in Understanding TiDB Execution Plan as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

`... < ALL (SELECT ... FROM ...)` or `... > ANY (SELECT ... FROM ...)`

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is NULL. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id)and if(sum(s.id is null)!= 0, null, true)`
- `t.id > any (select s.id from s)` is rewritten as `t.id > max(s.id)or if(sum(s.id is null)!= 0, null, false)`

`... != ANY (SELECT ... FROM ...)`

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s)where (t.id != s.id or cnt_distinct > 1)`

`... = ALL (SELECT ... FROM ...)`

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s )where (t.id = s.id and cnt_distinct <= 1)`

`... IN (SELECT ... FROM ...)`

In this case, the subquery of `IN` is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of `JOIN`.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2. The form of a.` The `DISTINCT` attribute here can be eliminated automatically if `t2.a` has the `UNIQUE` attribute.

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```

    ↪ ---------------------------+---------+-----------+--------------------+----
    ↪
```

This rewrite gets better performance when the `IN` subquery is relatively small and the external query is relatively large, because without rewriting, using `index join` with t2 as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the `t2` table is relatively large, this rewrite affects the performance of the query. Currently, the variable tidb_opt_insubq_to_join_and_agg is used to control this optimization. When this optimization is not suitable, you can manually disable it.

`EXISTS` subquery and `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the `EXISTS` subquery is evaluated to `TRUE` in the optimization stage in advance, so it does not show in the final execution result.

```
create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);
```

```
+--

    ↪  stats:pseudo |
+--
    ↪ ---------------------+----------+-----------+--------------+----------------
    ↪
```

In the preceding optimization, the optimizer automatically optimizes the statement execution. In addition, you can also add the SEMI_JOIN_REWRITE hint to further rewrite the statement.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When SEMI_JOIN_REWRITE() is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

11.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b> 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the Selection operator uses column b. Then the DataSource operator uses columns a and column b. Columns c and column d can be pruned because the DataSource operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called "Column Pruning", corresponding to the columnPruner rule. If you want to disable this rule, refer to The Blocklist of Optimization Rules and Expression Pushdown.

11.3.3.2.4 Decorrelation of Correlated Subquery

Subquery related optimizations describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

Introduction

Take `select * from t1 where t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition t2.b=t1.b, this condition happens to be an equivalent condition, so the query can be rewritten as

`select t1.* from t1, (select b, sum(a)sum_a from t2 group by b)t2 where t1.b = t2.b and t1.a < t2.sum_a;`. In this way, a correlated subquery is rewritten into `JOIN`.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, which might bring better execution performance. In this case, you can disable this optimization by using the `NO_DECORRELATE` optimizer hint or by disabling the "subquery decorrelation" optimization rule in the blocklist of optimization rules and expression pushdown. In most cases, it is recommended to use the optimizer hint along with SQL Plan Management to disable the decorrelation.

Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b = t1.b);
```

```

    ↪ order:false, stats:pseudo
    ↪                                                  |
|   └─TableReader_15(Probe)     | 9990.00 | root    |           | data:
    ↪ Selection_14
    ↪                                                        |
|     └─Selection_14            | 9990.00 | cop[tikv] |           | not(
    ↪ isnull(test.t1.b))
    ↪                                                  |
|       └─TableFullScan_13      | 10000.00 | cop[tikv] | table:t1 | keep
    ↪ order:false, stats:pseudo
    ↪                                                  |
+--
    ↪ ---------------------------------+----------+-----------+--------------+--------
    ↪
```

The above is an example where the optimization takes effect. `HashJoin_11` is a normal `inner join`.

Then, you can use the `NO_DECORRELATE` optimizer hint to tell the optimizer not to perform decorrelation for the subquery:

```
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);
```

```
+--

   ↪                      |
   ↪
   ↪ |
|     ─StreamAgg_20                  | 10000.00 | root    |
   ↪                      | funcs:sum(Column#14)->Column#7
   ↪                                                  |
|       ─Projection_45               | 100000.00 | root   |
   ↪                      | cast(test.t2.a, decimal(10,0) BINARY)->Column
   ↪ #14                           |
|         ─IndexLookUp_44            | 100000.00 | root   |
   ↪                      |
   ↪
   ↪ |
|           ─IndexRangeScan_42(Build) | 100000.00 | cop[tikv] | table:t2,
   ↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
   ↪ order:false, stats:pseudo |
|           ─TableRowIDScan_43(Probe) | 100000.00 | cop[tikv] | table:t2
   ↪          | keep order:false, stats:pseudo
   ↪                                                  |
+--
   ↪ ----------------------------------------+----------+----------+---------------
   ↪
```

Disabling the decorrelation rule can also achieve the same effect:

```
insert into mysql.opt_rule_blacklist values("decorrelate");
admin reload opt_rule_blacklist;
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
   ↪ = t1.b);
```

```

|            ─TableRowIDScan_43(Probe)  | 100000.00 | cop[tikv] | table:t2
    ↪           | keep order:false, stats:pseudo
    ↪                                                  |
+--
    ↪ ---------------------------------------+----------+----------+---------------
    ↪
```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(` ↪ `test.t2.b, test.t1.b)]` in `operator info` of `IndexRangeScan_42(Build)`. It means that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

11.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max/min` functions, the query optimizer tries to convert

the `max`/`min` aggregate functions to the TopN operator by applying the `max`/`min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max`/`min` functions in the `select` statement:

- The statement with only one `max`/`min` function
- The statement with multiple `max`/`min` functions

One `max`/`min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
    ↪ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+--
   ↪ ---------------------------+---------+-----------+----------------------+---
   ↪
| id                          | estRows | task      | access object        |
   ↪ operator info                    |
+--
   ↪ ---------------------------+---------+-----------+----------------------+---
   ↪
| StreamAgg_13                | 1.00    | root      |                      |
   ↪ funcs:max(test.t.a)->Column#4  |
|  ─Limit_17                   | 1.00    | root      |                      |
   ↪ offset:0, count:1                |
|    ─IndexReader_27           | 1.00    | root      |                      |
   ↪ index:Limit_26                   |
|      ─Limit_26               | 1.00    | cop[tikv] |                      |
   ↪ offset:0, count:1                |
```

```
|       └─IndexFullScan_25   | 1.00   | cop[tikv] | table:t, index:idx_a(a) |
    ↪  keep order:true, desc, stats:pseudo |
+--
    ↪ ---------------------------+---------+----------+-----------------------+---
    ↪
5 rows in set (0.00 sec)
```

Multiple `max`/`min` functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max`/`min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
    (select max(a) as max_a from t) t1,
    (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max` ↪ `/min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
    (select max(a) as max_a from (select a from t where a is not null order
       ↪  by a desc limit 1) t) t1,
    (select min(a) as min_a from (select a from t where a is not null order
       ↪  by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+--
   ↪ ---------------------------------+---------+----------+--------------------
   ↪
| id                                | estRows | task     | access object       |

   ↪
12 rows in set (0.01 sec)
```

11.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```
create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| TableReader_7         | 3323.33 | root     |               | data:Selection_6
   ↪           |
| └─Selection_6         | 3323.33 | cop[tikv] |              | lt(test.t.a, 1)
   ↪            |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t  | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

In this query, pushing down the predicate `a < 1` to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```
create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| TableReader_7         | 3323.33 | root     |               | data:Selection_6
   ↪           |
```

```
|  └─Selection_6         | 3323.33 | cop[tikv] |           | lt(test.t.a, 1)
   ↪            |
|    └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+-------------+----------------
   ↪
```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate `a < substring('123', 1, 1)` are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate `a < 1`. After that, TiDB can push `a < 1` down to TiKV.

Case 3: push predicates below join operator

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+--
   ↪ ---------------------------+---------+----------+-------------+-----------
   ↪
| id                          | estRows | task     | access object | operator
   ↪ info                          |
+--
   ↪ ---------------------------+---------+----------+-------------+-----------
   ↪
| HashJoin_8                  | 4154.17 | root     |             | inner join,
   ↪ equal:[eq(test.t.a, test.s.a)] |
|  ├─TableReader_15(Build)    | 3323.33 | root     |             | data:

+--
   ↪ ---------------------------+---------+----------+-------------+-----------
   ↪
7 rows in set (0.00 sec)
```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can

reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the `ON` condition is `t.a = s.a`. The predicate `s.a <1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```
create table t(id int primary key, a varchar(10) not null);
desc select * from t where truncate(a, " ") = '1';
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪                              |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |               | eq(truncate(cast(
   ↪ test.t.a, double BINARY), 0), 1) |
|  ─TableReader_7       | 10000.00 | root    |               | data:
   ↪ TableFullScan_6                          |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo              |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
```

In this query, there is a predicate `truncate(a, " ")= '1'`.

From the `explain` results, you can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `truncate`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
| id                          | estRows | task     | access object | operator
   ↪ info                              |
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
```

```
| Selection_7               | 10000.00 | root    |             | isnull(test
   ↪ .s.a)                          |
|  ─HashJoin_8              | 12500.00 | root    |             | left outer
   ↪  join, equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_13(Build) | 10000.00 | root    |             | data:
   ↪ TableFullScan_12                  |
|      ─TableFullScan_12    | 10000.00 | cop[tikv] | table:s   | keep order:
   ↪ false, stats:pseudo             |
|    ─TableReader_11(Probe) | 10000.00 | root    |             | data:
   ↪ TableFullScan_10                  |
|      ─TableFullScan_10    | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo             |
+--
   ↪ ---------------------------+---------+----------+--------------+----------
   ↪
6 rows in set (0.00 sec)
```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with `NULL` values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```
create table t(id int primary key, a char);
set @a = 1;
explain select * from t where a < @a;
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |               | lt(test.t.a,
   ↪ getvar("a"))  |
|  ─TableReader_7       | 10000.00 | root    |               | data:
   ↪ TableFullScan_6       |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
```

```
3 rows in set (0.00 sec)
```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with `1`, and does not push down it to TiKV.

An example to help you understand is as follows:

```
create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+----+------+----------+
| id | a    | @a:=@a+1 |
+----+------+----------+
|  1 |    1 | 2        |
|  2 |    2 | 3        |
+----+------+----------+
2 rows in set (0.00 sec)
```

As you can see from this query, the value of `@a` will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

11.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (200),
 PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO t1 VALUES (1, 'test1'),(101, 'test2'), (201, 'test3');
```

```
EXPLAIN SELECT * FROM t1 WHERE id BETWEEN 80 AND 120;
```

```
+--
   ↪ ------------------------+---------+-----------+----------------------+------
   ↪
| id                        | estRows | task    | access object       |
   ↪ operator info                                |
+--
   ↪ ------------------------+---------+-----------+----------------------+------

|  ─TableReader_10         | 40.00  | root     |                       | data:
   ↪ TableRangeScan_9                          |
|    ─TableRangeScan_9     | 40.00  | cop[tikv] | table:t1, partition:p0 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
|  ─TableReader_12         | 40.00  | root     |                       | data:
   ↪ TableRangeScan_11                         |
|    ─TableRangeScan_11    | 40.00  | cop[tikv] | table:t1, partition:p1 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
+--
   ↪ ------------------------+---------+-----------+----------------------+------
   ↪
5 rows in set (0.00 sec)
```

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
   ↪ ----------------------+----------+-----------+----------------------+---------
   ↪
| id                    | estRows | task    | access object       | operator
   ↪ info               |
```

```
+--
   ↪ ---------------------+---------+----------+----------------------+--------
   ↪
| TableReader_8         | 10.00   | root     |                      | data:
   ↪ Selection_7           |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
   ↪ .x, 1)              |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ---------------------+---------+----------+----------------------+--------
   ↪
```

In the SQL statement above, it can be known from the condition `x = 1` that all results fall in one partition. The value `1` can be confirmed to be in the `p1` partition after passing through the Hash partition. Therefore, only the `p1` partition needs to be scanned, and there is no need to access the `p2`, `p3`, and `p4` partitions that will not have matching results. From the execution plan, only one `TableFullScan` operator appears and the `p1` partition is specified in `access object`, so it can be confirmed that `partition pruning` takes effect.

Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
   ↪ --------------------------+---------+----------+---------------------+----
   ↪
| id                          | estRows | task     | access object       |
   ↪ operator info               |
+--
   ↪ --------------------------+---------+----------+---------------------+----
   ↪
| Union_10                    | 13333.33 | root    |                     |
   ↪                             |
|  ─TableReader_13            | 3333.33 | root     |                      | data
   ↪ :Selection_12             |
|    ─Selection_12            | 3333.33 | cop[tikv] |                     | gt(
   ↪ test.t.x, 2)              |
```

```
|     └─TableFullScan_11    | 10000.00 | cop[tikv] | table:t, partition:p0
   ↪ | keep order:false, stats:pseudo |
|  └─TableReader_16         | 3333.33 | root    |                   | data
   ↪ :Selection_15          |
|    └─Selection_15         | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)           |
|     └─TableFullScan_14    | 10000.00 | cop[tikv] | table:t, partition:p1
   ↪ | keep order:false, stats:pseudo |
|  └─TableReader_19         | 3333.33 | root    |                   | data
   ↪ :Selection_18          |
|    └─Selection_18         | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)           |
|     └─TableFullScan_17    | 10000.00 | cop[tikv] | table:t, partition:p2
   ↪ | keep order:false, stats:pseudo |
|  └─TableReader_22         | 3333.33 | root    |                   | data
   ↪ :Selection_21          |
|    └─Selection_21         | 3333.33 | cop[tikv] |                   | gt(
   ↪ test.t.x, 2)           |
|     └─TableFullScan_20    | 10000.00 | cop[tikv] | table:t, partition:p3
   ↪ | keep order:false, stats:pseudo |
+--
   ↪ --------------------------+---------+----------+-------------------+----
   ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the `x > 2` condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
   ↪ t2.x < 2);
```

```
+--
   ↪ ----------------------------------+---------+----------+-----------------
   ↪
| id                                  | estRows | task     | access object
   ↪       | operator info                                 |
+--
   ↪ ----------------------------------+---------+----------+-----------------
   ↪
| Projection_13                       | 9990.00 | root     |
   ↪                     | test.t2.x                                 |
```

```
|  ─Apply_15                        | 9990.00 | root    |
   ↪                       | inner join, equal:[eq(test.t2.x, test.t1.x)] |
|    ─TableReader_18(Build)         | 9990.00 | root    |
   ↪                       | data:Selection_17                            |
|      ─Selection_17                | 9990.00 | cop[tikv] |
   ↪                     | not(isnull(test.t2.x))                       |
|        ─TableFullScan_16          | 10000.00 | cop[tikv] | table:t2
   ↪           | keep order:false, stats:pseudo                |
|    ─Selection_19(Probe)           | 0.80    | root    |
   ↪                       | not(isnull(test.t1.x))                       |
|      ─MaxOneRow_20                | 1.00    | root    |
   ↪                       |                                              |
|        ─Union_21                  | 2.00    | root    |
   ↪                       |                                              |
|          ─TableReader_24          | 2.00    | root    |
   ↪                       | data:Selection_23                            |
|            ─Selection_23          | 2.00    | cop[tikv] |
   ↪                     | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
|              ─TableFullScan_22    | 2500.00 | cop[tikv] | table:t1,
   ↪ partition:p0 | keep order:false, stats:pseudo    |
|          ─TableReader_27          | 2.00    | root    |
   ↪                       | data:Selection_26                            |
|            ─Selection_26          | 2.00    | cop[tikv] |
   ↪                     | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
|              ─TableFullScan_25    | 2500.00 | cop[tikv] | table:t1,
   ↪ partition:p1 | keep order:false, stats:pseudo    |
+--
   ↪ ----------------------------------+----------+-----------+--------------------
   ↪
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x = 3;
```

```
+--
    ↪ ----------------------+---------+----------+----------------------+---------
    ↪
| id                    | estRows | task     | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+---------+----------+----------------------+---------
    ↪
| TableReader_8         | 10.00   | root     |                      | data:
    ↪ Selection_7            |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
    ↪ .x, 3)             |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+----------------------+---------
    ↪
```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x in(1,13);
```

```
+--
    ↪ ---------------------------+---------+----------+----------------------+-----
    ↪
| id                         | estRows | task     | access object       |
    ↪ operator info               |
+--
    ↪ ---------------------------+---------+----------+----------------------+-----
    ↪
| Union_8                    | 40.00   | root     |                      |
    ↪                             |
```

```
|  ─TableReader_11         | 20.00   | root     |                       | data:
   ↪ Selection_10          |
|    ─Selection_10         | 20.00   | cop[tikv] |                       | in(
   ↪ test.t.x, 1, 13)        |
|      ─TableFullScan_9    | 10000.00 | cop[tikv] | table:t, partition:p0 |
   ↪  keep order:false, stats:pseudo |
|  ─TableReader_14         | 20.00   | root     |                       | data:
   ↪ Selection_13          |
|    ─Selection_13         | 20.00   | cop[tikv] |                       | in(
   ↪ test.t.x, 1, 13)        |
|      ─TableFullScan_12   | 10000.00 | cop[tikv] | table:t, partition:p2 |
   ↪  keep order:false, stats:pseudo |
+--
   ↪ -------------------------+---------+----------+---------------------+-----
   ↪
```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```
create table t (x int) partition by range (x) (
   partition p0 values less than (5),
   partition p1 values less than (10),
   partition p2 values less than (15)
   );
explain select * from t where x between 7 and 14;
```

```

|     └─TableFullScan_12    | 10000.00 | cop[tikv] | table:t, partition:p2 |
   ↪  keep order:false, stats:pseudo |
+--
   ↪ -------------------------+----------+-----------+----------------------+-----
   ↪
```

Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of `fn(col)`, the query condition is one of `>`, `<`, `=`, `>=`, and `<=`, and the `fn` function is monotonous.

If the `fn` function is monotonous, for any `x` and `y`, if `x > y`, then `fn(x) > fn(y)`. Then this `fn` function can be called strictly monotonous. For any `x` and `y`, if `x > y`, then `fn` ↪ `(x) >= fn(y)`. In this case, `fn` could also be called "monotonous". Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

- `UNIX_TIMESTAMP()`
- `TO_DAYS()`
- `EXTRACT(<time unit> FROM <DATETIME/DATE/TIME column>)`. For `DATE` and `DATETIME` columns, `YEAR` and `YEAR_MONTH` time units are considered monotonous functions. For the `TIME` column, `HOUR`, `HOUR_MINUTE`, `HOUR_SECOND` and `HOUR_MICROSECOND` are considered monotonous functions. Note that `WEEK` is not supported as time unit in `EXTRACT` for partition pruning.

For example, partition pruning takes effect when the partition expression is in the form of `fn(col)`, where the `fn` is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
   partition p0 values less than (to_days('2020-04-01')),
   partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```
+--
   ↪ ----------------------+----------+-----------+----------------------+---------
   ↪
| id                   | estRows | task    | access object      | operator
   ↪ info                        |
```

```
+--
   ↪ ----------------------+---------+----------+-----------------------+--------
   ↪
| TableReader_8         | 3333.33 | root     |                       | data:
   ↪ Selection_7                     |
|  ─Selection_7         | 3333.33 | cop[tikv] |                       | gt(test.t
   ↪ .id, 2020-04-18 00:00:00.000000) |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ----------------------+---------+----------+-----------------------+--------
   ↪
```

Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
   partition p0 values less than (5),
   partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
   ↪ t2.x < 2);
```

```

   ↪                                                     |
|         └─TableReader_24          | 2.00     | root     |
   ↪                       | data:Selection_23
   ↪                                    |
|           └─Selection_23          | 2.00     | cop[tikv] |
   ↪                     | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|             └─TableFullScan_22    | 2.50     | cop[tikv] | table:t1,
   ↪ partition:p0 | keep order:false, stats:pseudo                |
|         └─TableReader_27          | 2.00     | root     |
   ↪                       | data:Selection_26
   ↪                                    |
|           └─Selection_26          | 2.00     | cop[tikv] |
   ↪                     | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|             └─TableFullScan_25    | 2.50     | cop[tikv] | table:t1,
   ↪ partition:p1 | keep order:false, stats:pseudo                |
+--
   ↪ ----------------------------------+----------+-----------+--------------------
   ↪
14 rows in set (0.00 sec)
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the `t1.x> val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

11.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to Optimization Rules and Blocklist for Expression Pushdown.

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```
+-------------------------+---------+----------+--------------+-------------------
   ↪
| id                      | estRows | task     | access object | operator
   ↪ info            |
+-------------------------+---------+----------+--------------+-------------------
   ↪
| TopN_7                  | 10.00   | root     |              | test.t.a,
   ↪ offset:0, count:10 |
| └─TableReader_15        | 10.00   | root     |              | data:TopN_14
   ↪                |
|   └─TopN_14             | 10.00   | cop[tikv] |             | test.t.a,
   ↪ offset:0, count:10 |
|     └─TableFullScan_13  | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo |
+-------------------------+---------+----------+--------------+-------------------
   ↪
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+---------------------------------+---------+----------+--------------+-----------
   ↪
| id                              | estRows | task     | access object |
   ↪ operator info                          |
```

```
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| TopN_12                        | 10.00    | root      |               | test.t.a,
   ↪  offset:0, count:10                |
|  ─HashJoin_17                  | 12.50    | root      |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    ─TopN_18(Build)             | 10.00    | root      |               | test.t.a
   ↪ , offset:0, count:10               |
|      ─TableReader_26           | 10.00    | root      |               | data:
   ↪ TopN_25                            |
|        ─TopN_25                | 10.00    | cop[tikv] |               | test.t.a
   ↪ , offset:0, count:10               |
|          ─TableFullScan_24     | 10000.00 | cop[tikv] | table:t       | keep
   ↪ order:false, stats:pseudo          |
|    ─TableReader_30(Probe)      | 10000.00 | root      |               | data:
   ↪ TableFullScan_29                   |
|      ─TableFullScan_29         | 10000.00 | cop[tikv] | table:s       | keep
   ↪ order:false, stats:pseudo          |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+-------------------------------+----------+-----------+---------------+---------------
   ↪
| id                           | estRows | task      | access object | operator
   ↪ info                           |
+-------------------------------+----------+-----------+---------------+---------------
   ↪
| TopN_12                      | 10.00    | root      |               | test.t.id,
   ↪ offset:0, count:10             |
|  ─HashJoin_16                | 12500.00 | root      |               | inner join,
   ↪  equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_21(Build)    | 10000.00 | root      |               | data:
   ↪ TableFullScan_20                |
```

```
|     └─TableFullScan_20     | 10000.00 | cop[tikv] | table:s  | keep order:
   ↪ false, stats:pseudo       |
|   └─TableReader_19(Probe)  | 10000.00 | root    |             | data:
   ↪ TableFullScan_18                |
|     └─TableFullScan_18     | 10000.00 | cop[tikv] | table:t  | keep order:
   ↪ false, stats:pseudo       |
+-----------------------------+----------+-----------+--------------+---------------
   ↪
6 rows in set (0.00 sec)
```

TopN cannot be pushed down before `Inner Join`. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;
```

```
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| id                            | estRows | task    | access object |
   ↪ operator info                           |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| TopN_12                       | 10.00   | root    |               | test.t.id
   ↪ , offset:0, count:10              |
|  └─HashJoin_17                | 12.50   | root    |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    └─Limit_21(Build)          | 10.00   | root    |               | offset
   ↪ :0, count:10                        |
|      └─TableReader_31         | 10.00   | root    |               | data:
   ↪ Limit_30                            |
|        └─Limit_30             | 10.00   | cop[tikv] |             | offset
   ↪ :0, count:10                        |
|          └─TableFullScan_29   | 10.00   | cop[tikv] | table:t     | keep
   ↪ order:true, stats:pseudo            |
|    └─TableReader_35(Probe)    | 10000.00 | root   |               | data:
   ↪ TableFullScan_34                    |
```

```
|     └─TableFullScan_34        | 10000.00 | cop[tikv] | table:s   | keep
    ↪ order:false, stats:pseudo            |
+-----------------------------------+----------+-----------+---------------+-------------
    ↪
8 rows in set (0.00 sec)
```

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t ↪ .id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

11.3.3.2.9 Introduction to Join Reorder

In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1

As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, the following two Join Reorder algorithms are used in TiDB:

- The greedy algorithm: among all nodes participating in the join, TiDB selects the table with the least rows to estimate its join result with each of the other tables respectively, and then selects the pair with the smallest join result. After that, TiDB continues the similar process to select and join other nodes for the next round, until all the nodes have completed the join.
- The dynamic programming algorithm: among all nodes participating in the join, TiDB enumerates all possible join orders and selects the optimal join order.

Example: the greedy algorithm of Join Reorder

Take the preceding three tables (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

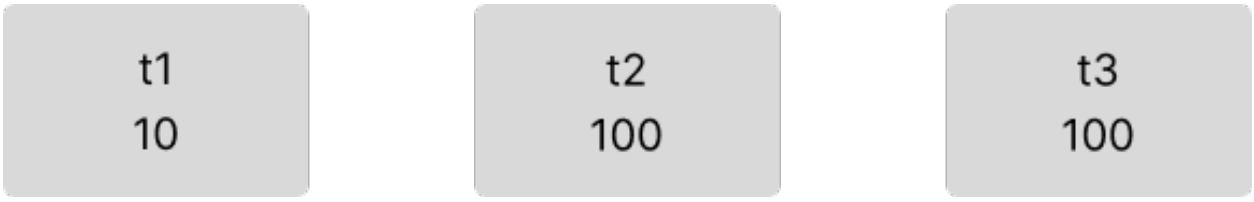

Figure 401: join-reorder-1

After that, the table with the least rows is selected and joined with other two tables respectively. By comparing the sizes of the output result sets, TiDB selects the pair with a smaller result set.

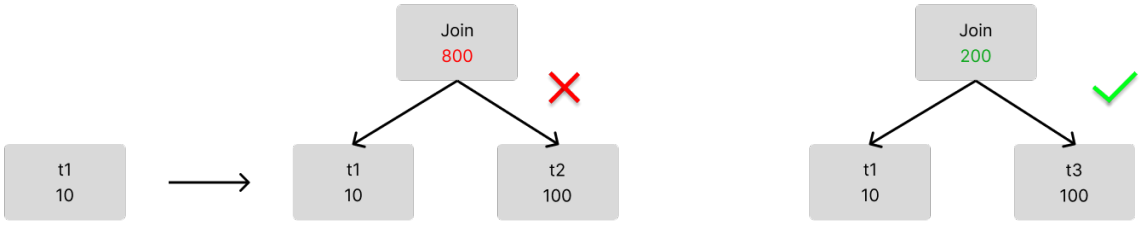

Figure 402: join-reorder-2

Then TiDB enters the next round of selection. If you try to join four tables, TiDB continues to compare the sizes of the output result sets and selects the pair with a smaller result set.

In this case only three tables are joined, so TiDB gets the final join result.

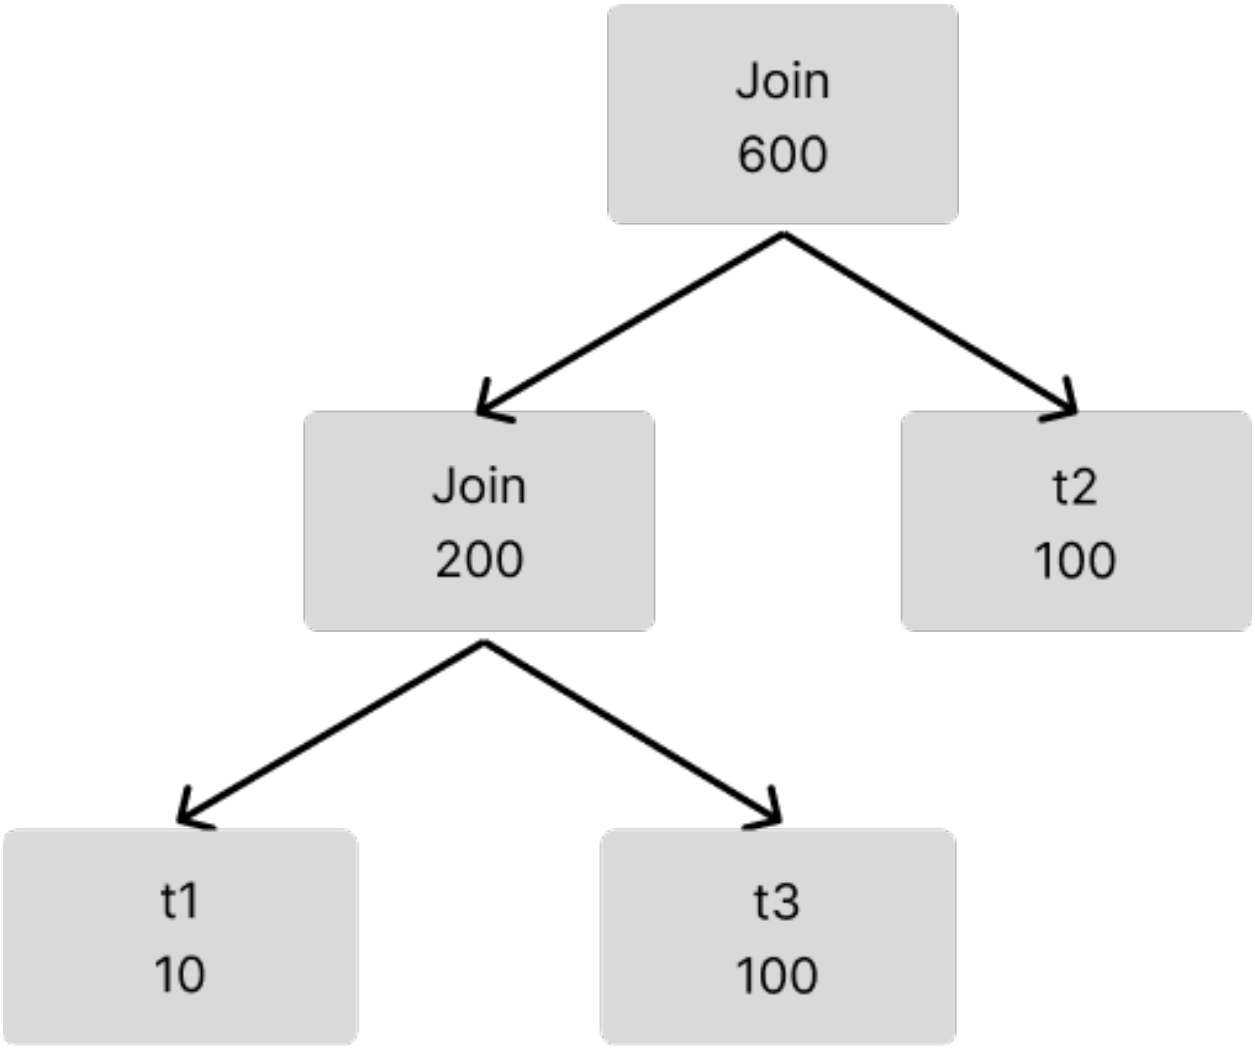

Figure 403: join-reorder-3

Example: the dynamic programming algorithm of Join Reorder

Taking the preceding three tables (t1, t2, and t3) as an example again, the dynamic programming algorithm can enumerate all possibilities. Therefore, comparing with the greedy algorithm, which must start with the `t1` table (the table with the least rows), the dynamic programming algorithm can enumerate a join order as follows:

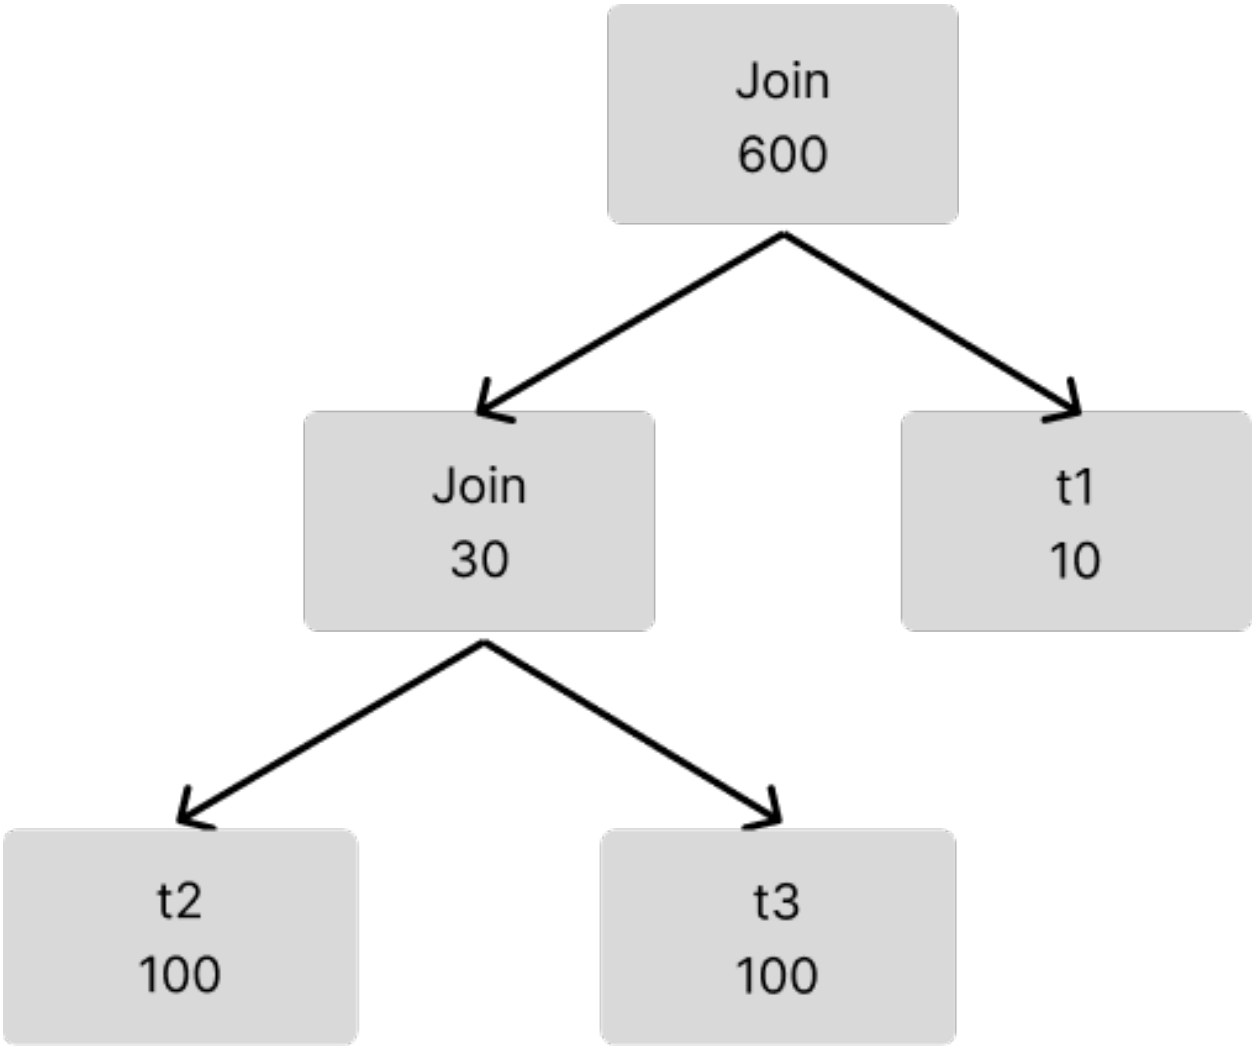

Figure 404: join-reorder-4

When this choice is better than the greedy algorithm, the dynamic programming algorithm can choose a better join order.

Because all possibilities are enumerated, the dynamic programming algorithm consumes more time and is more susceptible to statistics.

Selection of the Join Reorder algorithms

The selection of the TiDB Join Reorder algorithms is controlled by the `tidb_opt_join_reorder_threshold` variable. If the number of nodes participating in Join Reorder is greater than this threshold, TiDB uses the greedy algorithm. Otherwise, TiDB uses the dynamic programming algorithm.

Limitations of Join Reorder algorithms

The current Join Reorder algorithms have the following limitations:

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.
- The Join Reorder algorithm's support for Outer Join is controlled by the `tidb_enable_outer_join_reorder` system variable.
- Currently, the dynamic programming algorithm cannot perform Join Reorder for outer join.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to Description of the syntax elements.

11.3.3.2.10 Derive TopN or Limit from Window Functions

Window Functions are a common type of SQL function. When you use a window function for row numbering, such as `ROW_NUMBER()` or `RANK()`, it is common to filter the results after the window function is evaluated. For example:

```
SELECT * FROM (SELECT ROW_NUMBER() OVER (ORDER BY a) AS rownumber FROM t)
    ↪ dt WHERE rownumber <= 3
```

In a typical SQL execution process, TiDB first sorts all data in the table `t`, then calculates the `ROW_NUMBER()` result for each row, and finally filters with `rownumber <= 3`.

Starting from v7.0.0, TiDB supports deriving the TopN or Limit operator from window functions. With this optimization rule, TiDB can rewrite the original SQL into an equivalent form as follows:

```
WITH t_topN AS (SELECT a FROM t1 ORDER BY a LIMIT 3) SELECT * FROM (SELECT
    ↪ ROW_NUMBER() OVER (ORDER BY a) AS rownumber FROM t_topN) dt WHERE
    ↪ rownumber <= 3
```

After rewriting, TiDB can derive a TopN operator from the window function and the subsequent filter condition. Compared with the Sort operator in the original SQL (`ORDER BY` ↪), the TopN operator has a much higher execution efficiency. In addition, both TiKV and TiFlash support pushing down the TopN operator, which further improves the performance of the rewritten SQL.

Deriving TopN or Limit from window functions is disabled by default. To enable this feature, you can set the session variable tidb_opt_derive_topn to `ON`.

After enabling this feature, you can disable it by performing one of the following operations:

- Set the session variable tidb_opt_derive_topn to `OFF`.
- Follow the steps described in The blocklist of optimization rules and expression pushdown.

Limitations

- Only the `ROW_NUMBER()` window function is supported for SQL rewriting.
- TiDB can only rewrite SQL when filtering on the `ROW_NUMBER()` results and the filter condition is `<` or `<=`.

Usage examples

The following examples demonstrate how to use the optimization rule.

Window functions without PARTITION BY

Example 1: window functions without ORDER BY

```
CREATE TABLE t(id int, value int);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER () AS rownumber FROM t) dt
    ↪ WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+---------+-----------+---------------+--------------
    ↪
| id                              | estRows | task      | access object | operator
    ↪  info                                                |
+---------------------------------+---------+-----------+---------------+--------------
    ↪
| Projection_9                    | 2.40    | root      |               | Column#5
    ↪                                                    |
|  ─Selection_10                   | 2.40    | root      |               | le(Column
    ↪ #5, 3)                                             |
|    ─Window_11                    | 3.00    | root      |               | row_
    ↪ number()->Column#5 over(rows between current row and current row) |
|      ─Limit_15                   | 3.00    | root      |               | offset:0,
    ↪  count:3                                           |
|        ─TableReader_26           | 3.00    | root      |               | data:
    ↪ Limit_25                                                 |
|          ─Limit_25               | 3.00    | cop[tikv] |               | offset:0,
    ↪  count:3                                           |
|            ─TableFullScan_24     | 3.00    | cop[tikv] | table:t       | keep
    ↪ order:false, stats:pseudo                                |
+---------------------------------+---------+-----------+---------------+--------------
    ↪
```

In this query, the optimizer derives the Limit operator from the window function and pushes it down to TiKV.

Example 2: window functions with ORDER BY

```
CREATE TABLE t(id int, value int);
SET tidb_opt_derive_topn=on;
```

```
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (ORDER BY value) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| id                              | estRows | task      | access object |
    ↪ operator info
    ↪                                                                    |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| Projection_10                   | 2.40     | root      |               | Column#5
    ↪
    ↪ |
|  ─Selection_11                  | 2.40     | root      |               | le(
    ↪ Column#5, 3)
    ↪                                                                      |
|    ─Window_12                   | 3.00     | root      |               | row_
    ↪ number()->Column#5 over(order by test.t.value rows between current
    ↪ row and current row) |
|      ─TopN_13                   | 3.00     | root      |               | test.t.
    ↪ value, offset:0, count:3
    ↪                                                        |
|        ─TableReader_25          | 3.00     | root      |               | data:
    ↪ TopN_24
    ↪                                                                          |
|          ─TopN_24               | 3.00     | cop[tikv] |               | test.t.
    ↪ value, offset:0, count:3
    ↪                                                      |
|            ─TableFullScan_23    | 10000.00 | cop[tikv] | table:t       | keep
    ↪ order:false, stats:pseudo
    ↪                                                       |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
```

In this query, the optimizer derives the TopN operator from the window function and pushes it down to TiKV.

Window functions with PARTITION BY

> **Note:**
>
> For a window function containing `PARTITION BY`, the optimization rule only takes effect when the partition column is a prefix of the primary key and the

primary key is a clustered index.

Example 3: window functions without ORDER BY

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+-----------------------------------+---------+-----------+---------------+-----------
    ↪
| id                                | estRows | task      | access object |
    ↪ operator info
    ↪                                                                                 |
+-----------------------------------+---------+-----------+---------------+-----------
    ↪
| Projection_10                     | 2.40    | root      |               | Column#6
    ↪
    ↪
    ↪ |
| └─Selection_11                    | 2.40    | root      |               | le(
    ↪ Column#6, 3)
    ↪                                                                                 |
|   └─Shuffle_26                    | 3.00    | root      |               |
    ↪ execution info: concurrency:2, data sources:[TableReader_24]
    ↪                         |
|     └─Window_12                   | 3.00    | root      |               | row_
    ↪ number()->Column#6 over(partition by test.t.id1 rows between current
    ↪ row and current row) |
|       └─Sort_25                   | 3.00    | root      |               | test.t.
    ↪ id1
    ↪
    ↪ |
|         └─TableReader_24          | 3.00    | root      |               | data:
    ↪ Limit_23
    ↪                                                                                 |
|           └─Limit_23              | 3.00    | cop[tikv] |               |
    ↪ partition by test.t.id1, offset:0, count:3
    ↪                                           |
|             └─TableFullScan_22    | 3.00    | cop[tikv] | table:t       | keep
    ↪ order:false, stats:pseudo
```

```
   ↪                                                                |
+-----------------------------------+---------+----------+--------------+-----------
   ↪                                                                |
```

In this query, the optimizer derives the Limit operator from the window function and pushes it down to TiKV. Note that this Limit is actually a partition Limit, which means that the Limit will be applied to each group of data with the same `id1` value.

Example 4: window functions with ORDER BY

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
   ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1 ORDER BY
   ↪ value1) AS rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+-----------------------------------+---------+----------+--------------+-----------
   ↪
| id                                | estRows | task     | access object |
   ↪ operator info
   ↪
   ↪ |
+-----------------------------------+---------+----------+--------------+-----------
   ↪
| Projection_10                     | 2.40    | root     |              | Column
   ↪ #6
   ↪
   ↪ |
|  ─Selection_11                    | 2.40    | root     |              | le(
   ↪ Column#6, 3)
   ↪
   ↪ |
|    ─Shuffle_23                    | 3.00    | root     |              |
   ↪ execution info: concurrency:3, data sources:[TableReader_21]
   ↪                                                    |
|      ─Window_12                   | 3.00    | root     |              | row_
   ↪ number()->Column#6 over(partition by test.t.id1 order by test.t.
   ↪ value1 rows between current row and current row) |
|        ─Sort_22                   | 3.00    | root     |              | test.t
   ↪ .id1, test.t.value1
   ↪
   ↪ |
|          ─TableReader_21          | 3.00    | root     |              | data:
   ↪ TopN_19
```

```
    ↪
    ↪ |
|          └─TopN_19              | 3.00    | cop[tikv] |            |
    ↪ partition by test.t.id1 order by test.t.value1, offset:0, count:3
    ↪                                          |
|            └─TableFullScan_18   | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
+----------------------------------+----------+-----------+---------------+-----------
    ↪
```

In this query, the optimizer derives the TopN operator from the window function and pushes it down to TiKV. Note that this TopN is actually a partition TopN, which means that the TopN will be applied to each group of data with the same `id1` value.

Example 5: PARTITION BY column is not a prefix of the primary key

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY value1) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+----------------------------------+----------+-----------+---------------+------------
    ↪
| id                               | estRows | task     | access object |
    ↪ operator info
    ↪                                                                    |
+----------------------------------+----------+-----------+---------------+------------
    ↪
| Projection_9                     | 8000.00 | root     |               | Column#6
    ↪
    ↪ |
|  └─Selection_10                   | 8000.00 | root     |               | le(
    ↪ Column#6, 3)
    ↪                                                                    |
|    └─Shuffle_15                   | 10000.00 | root    |               |
    ↪ execution info: concurrency:5, data sources:[TableReader_13]
    ↪                               |
|      └─Window_11                  | 10000.00 | root    |               | row_
    ↪ number()->Column#6 over(partition by test.t.value1 rows between
    ↪ current row and current row) |
|        └─Sort_14                  | 10000.00 | root    |               | test.t.
    ↪ value1
```

```
    ↪
    ↪ |
|         └─TableReader_13       | 10000.00 | root    |               | data:
    ↪ TableFullScan_12
    ↪                                                                    |
|           └─TableFullScan_12   | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪                                                          |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
```

In this query, the SQL is not rewritten because the `PARTITION BY` column is not a prefix of the primary key.

Example 6: PARTITION BY column is a prefix of the primary key but not a clustered index

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) nonclustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1) AS
    ↪ rownumber FROM t use index()) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| id                              | estRows | task     | access object |
    ↪ operator info
    ↪                                                                   |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| Projection_9                    | 8000.00 | root     |               | Column#7
    ↪
    ↪ |
|  └─Selection_10                 | 8000.00 | root     |               | le(
    ↪ Column#7, 3)
    ↪                                                                       |
|    └─Shuffle_15                 | 10000.00 | root    |               |
    ↪ execution info: concurrency:5, data sources:[TableReader_13]
    ↪                          |
|      └─Window_11                | 10000.00 | root    |               | row_
    ↪ number()->Column#7 over(partition by test.t.id1 rows between current
    ↪ row and current row) |
|        └─Sort_14                | 10000.00 | root    |               | test.t.
    ↪ id1
```

```
    ↪

```

In this query, although the `PARTITION BY` column is a prefix of the primary key, the SQL is not rewritten because the primary key is not a clustered index.

11.3.3.3 Physical Optimization

11.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

Understand the Query Execution Plan has introduced some physical operators. This chapter focuses on the following aspects:

- In Index Selection, you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In Introduction to Statistics, you will learn what statistics TiDB collects to obtain the data distribution of a table.
- Wrong Index Solution introduces how to use the right index when you find the index is selected wrongly.
- Distinct Optimization introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.
- Cost Model introduces how to choose a optimal execution plan based on the cost model during physical optimization.

11.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and

different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / BatchPointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	This TableReader operator is for TiKV. It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the `_tidb_rowid` column, or if there are no

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	This TableReader operator is for TiFlash. TiFlash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookupReader	A table has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as IndexReader.	Since the index does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the IndexReader operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexMerge	A table has multiple indexes or a multi-valued index.	When a multi-valued index or multiple indexes are used.	To use the operator, you can specify the optimizer hints, or let the optimizer to automatically select this operator based on cost estimation. For details, see Explain Statements Using Index Merge.

Note:

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection of an operator for accessing tables.

Index selection rules

TiDB selects indexes based on rules or cost. The based rules include pre-rules and skyline-pruning. When selecting an index, TiDB tries the pre-rule first. If an index satisfies a pre-rule, TiDB directly selects this index. Otherwise, TiDB uses skyline-pruning to exclude unsuitable indexes, and then selects the index with the lowest cost based on the cost estimation of each operator that accesses tables.

Rule-based selection

Pre-rules

TiDB uses the following heuristic pre-rules to select indexes:

- Rule 1: If an index satisfies "unique index with full match + no need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)", TiDB directly selects this index.
- Rule 2: If an index satisfies "unique index with full match + the need to retrieve rows from a table (which means that the plan generated by the index is the IndexLookupReader operator)", TiDB selects the index with the smallest number of rows to be retrieved from a table as a candidate index.
- Rule 3: If an index satisfies "ordinary index + no need to retrieve rows from a table + the number of rows to be read is less than the value of a certain threshold", TiDB selects the index with the smallest number of rows to be read as a candidate index.
- Rule 4: If only one candidate index is selected based on rule 2 and 3, select this candidate index. If two candidate indexes are respectively selected based on rule 2 and 3, select the index with the smaller number of rows to be read (the number of rows with index + the number of rows to be retrieved from a table).

The "index with full match" in the above rules means each indexed column has the equal condition. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if the pre-rules match an index, TiDB outputs a NOTE-level warning indicating that the index matches the pre-rule.

In the following example, because the index `idx_b` meets the condition "unique index with full match + the need to retrieve rows from a table" in rule 2, TiDB selects the index `idx_b` as the access path, and `SHOW WARNING` returns a note indicating that the index `idx_b` matches the pre-rule.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, UNIQUE INDEX idx_b(b
    ↪ ));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT b, c FROM t WHERE b = 3 OR b = 6;

Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes, which can reduce the probability of wrong index selection caused by wrong estimation. To judge an index, the following dimensions are needed:

- How many access conditions are covered by the indexed columns. An "access condition" is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.

- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or IndexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do. If both indexes need TiDB to retrieve rows from the table, compare how many filtering conditions are covered by the indexed columns. Filtering conditions mean the `where` condition that can be judged based on the index. If the column set of an index covers more access conditions, the smaller the number of retrieved rows from a table, and the better the index is in this dimension.
- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.
- Whether the index is a global index. In partitioned tables, global indexes can effectively reduce the number of cop tasks for a SQL compared to normal indexes, thus improving overall performance.

For these preceding dimensions, if the index `idx_a` performs no worse than the index `idx_b` in all three dimensions and performs better than `idx_b` in one dimension, then `idx_a` is preferred. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if skyline-pruning excludes some indexes, TiDB outputs a NOTE-level warning listing the remaining indexes after the skyline-pruning exclusion.

In the following example, the indexes `idx_b` and `idx_e` are both inferior to `idx_b_c`, so they are excluded by skyline-pruning. The returned result of `SHOW WARNING` displays the remaining indexes after skyline-pruning.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, d INT, e INT, INDEX
    ↪ idx_b(b), INDEX idx_b_c(b, c), INDEX idx_e(e));
Query OK, 0 rows affected (0.01 sec)

Cost estimation-based selection

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

   This is usually due to stale or inaccurate statistics. You can re-execute the `ANALYZE TABLE` statement or modify the parameters of the `ANALYZE TABLE` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

   At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

3. The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

   In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

Control index selection

The index selection can be controlled by a single query through Optimizer Hints.

- `USE_INDEX` / `IGNORE_INDEX` can force the optimizer to use / not use certain indexes. `FORCE_INDEX` and `USE_INDEX` have the same effect.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

Use multi-valued indexes

Multi-valued indexes are different from normal indexes. TiDB currently only uses IndexMerge to access multi-valued indexes. Therefore, to use multi-valued indexes for data access, make sure that the value of the system variable `tidb_enable_index_merge` is set to `ON`.

For the limitations of multi-valued indexes, refer to `CREATE INDEX`.

Supported scenarios

Currently, TiDB supports accessing multi-valued indexes using IndexMerge that is automatically converted from `json_member_of`, `json_contains`, and `json_overlaps` conditions. You can either rely on the optimizer to automatically select IndexMerge based on cost, or specify the selection of multi-valued indexes through the optimizer hint `use_index_merge` or `use_index`. See the following examples:

```
mysql> CREATE TABLE t1 (j JSON, INDEX idx((CAST(j->'$.path' AS SIGNED ARRAY
    ↪ ))));  -- Uses '$.path' as the path to create a multi-valued index
Query OK, 0 rows affected (0.04 sec)

mysql> EXPLAIN SELECT /*+ use_index_merge(t1, idx) */ * FROM t1 WHERE (1
    ↪ MEMBER OF (j->'$.path'));
+--

```

- All the conditions that are used for the IndexMerge must match the semantics of `OR` or `AND` that connects them.

    - If `json_contains` is connected with `AND`, it matches the semantics. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE json_contains(j->'$.a', '[1]') AND json_contains(j->'$
    ↪ .b', '[2, 3]');
EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE json_contains(j->'$.a', '[1]') OR json_contains(j->'$.
    ↪ b', '[2, 3]');
```

```
> EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE json_contains(j->'$.a', '[1]') AND json_contains(j->'$
    ↪ .b', '[2, 3]');
```

```

- When both `OR` and `AND` are used to connect conditions (essentially nested `OR`

and AND), the conditions that constitute an IndexMerge must either all match the semantics of OR or all match the semantics of AND, not partially match the semantics of OR and partially match the semantics of AND. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE 1 member of (j->'$.a') AND (2 member of (j->'$.b') OR
    ↪ 3 member of (j->'$.a'));
EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE 1 member of (j->'$.a') OR (2 member of (j->'$.b') AND
    ↪ 3 member of (j->'$.a'));
```

```
-- Only 2 member of (j->'$.b') and 3 member of (j->'$.a') that
    ↪ match the semantics of OR constitute the IndexMerge. 1
    ↪ member of (j->'$.a') that matches the semantics of AND is
    ↪ not included.
> EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE 1 member of (j->'$.a') AND (2 member of (j->'$.b') OR

    ↪
```

If conditions contain nested `OR`/`AND`, or if conditions correspond to only indexed columns after transformations, such as expansion, TiDB might not be able to use IndexMerge or make full use of all conditions. It is recommended to verify the behavior of each specific case.

The following are some examples:

```
CREATE TABLE t5 (a INT, j JSON, b INT, k JSON, INDEX idx(a, (CAST(j AS
    ↪ SIGNED ARRAY))), INDEX idx2(b, (CAST(k as SIGNED ARRAY))));
CREATE TABLE t6 (a INT, j JSON, b INT, k JSON, INDEX idx(a, (CAST(j AS
    ↪ SIGNED ARRAY)), b), INDEX idx2(a, (CAST(k as SIGNED ARRAY)), b));
```

If `AND` is nested in conditions connected by `OR` and subconditions connected by `AND` correspond to the exact columns of a multi-column index, TiDB can usually make full use of the conditions. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t5, idx, idx2) */ * FROM t5 WHERE (a=1
    ↪ AND 1 member of (j)) OR (b=2 AND 2 member of (k));
```

```
> EXPLAIN SELECT /*+ use_index_merge(t5, idx, idx2) */ * FROM t5 WHERE (a=1
    ↪  AND 1 member of (j)) OR (b=2 AND 2 member of (k));
+--
    ↪ ----------------------------+---------+-----------+--------------------------
    ↪
| id                          | estRows | task    | access object
    ↪                                 | operator info
    ↪                               |
```

```
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| IndexMerge_8                | 0.20    | root     |
   ↪                                                  | type: union
   ↪                                 |
|  ─IndexRangeScan_5(Build)  | 0.10    | cop[tikv] | table:t5, index:idx(a,

Multi-valued indexes and plan cache

A query plan that uses `member of` to choose multi-valued indexes can be cached. A query plan that uses the `JSON_CONTAINS()` or `JSON_OVERLAPS()` function to choose multi-valued indexes cannot be cached.

The following are some examples that query plans can be cached:

```
mysql> CREATE TABLE t5 (j1 JSON, j2 JSON, INDEX idx1((CAST(j1 AS SIGNED
    ↪ ARRAY))));
Query OK, 0 rows affected (0.04 sec)

mysql> PREPARE st FROM 'SELECT /*+ use_index(t5, idx1) */ * FROM t5 WHERE
    ↪ (? member of (j1))';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @a=1;
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE st USING @a;
Empty set (0.01 sec)

mysql> EXECUTE st USING @a;
Empty set (0.00 sec)
```

```
mysql> SELECT @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)

mysql> PREPARE st FROM 'SELECT /*+ use_index(t5, idx1) */ * FROM t5 WHERE
    ↪ (? member of (j1)) AND JSON_CONTAINS(j2, ?)';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @a=1, @b='[1,2]';
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE st USING @a, @b;
Empty set (0.00 sec)

mysql> EXECUTE st USING @a, @b;
Empty set (0.00 sec)

mysql> SELECT @@LAST_PLAN_FROM_CACHE; -- can hit plan cache if the JSON_
    ↪ CONTAINS doesn't impact index selection

11.3.3.3.3 Introduction to Statistics

TiDB uses statistics as input to the optimizer to estimate the number of rows processed in each plan step for a SQL statement. The optimizer estimates the cost of each available plan choice, including index accesses and the sequence of table joins, and produces a cost for each available plan. The optimizer then picks the execution plan with the lowest overall cost.

Collect statistics

This section describes two ways of collecting statistics: automatic update and manual collection.

Automatic update

For the `INSERT`, `DELETE`, or `UPDATE` statements, TiDB automatically updates the number of rows and modified rows in statistics.

TiDB persists the update information regularly and the update cycle is 20 * `stats-lease`. The default value of `stats-lease` is `3s`. If you specify the value as `0`, TiDB stops updating statistics automatically.

Based upon the number of changes to a table, TiDB will automatically schedule `ANALYZE` to collect statistics on those tables. This is controlled by the following system variables.

System Variable	Default Value	Description
tidb_auto_analyze_end_time	23:59 +0000	The end time in a day when TiDB can perform automatic updates.
tidb_auto_analyze_ratio	0.5	The threshold value of automatic update.
tidb_auto_analyze_start_time	00:00 +0000	The start time in a day when TiDB can perform automatic update.

System Variable	Default Value	Description
tidb_auto_analyze_partition_batch_size	128	The number of partitions that TiDB automatically analyzes when analyzing a partitioned table (that is, when automatically updating statistics on a partitioned table).

System Variable	Default Value	Description
tidb_enable_auto_analyze	ON	Controls whether TiDB automatically executes ANALYZE.

System Variable	Default Value	Description
tidb_enable_auto_analyze_priority_queue	ON	Controls whether to enable the priority queue to schedule the tasks of automatically collecting statistics. When this variable is enabled, TiDB prioritizes collecting statistics for tables that

System Variable	Default Value	Description
tidb_enable_stats_owner	ON	Controls whether the corresponding TiDB instance can run automatic statistics update tasks.

When the ratio of the number of modified rows to the total number of rows of `tbl` in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics on this table.

To avoid the situation that modifying data on a small table frequently triggers the automatic update, when a table has less than 1000 rows, modifications do not trigger the automatic update in TiDB. You can use the `SHOW STATS_META` statement to view the number of rows in a table.

> **Note:**
>
> Currently, the automatic update does not record the configuration items input at manual `ANALYZE`. Therefore, when you use the `WITH` syntax to control the collecting behavior of `ANALYZE`, you need to manually set scheduled tasks to collect statistics.

Manual collection

Currently, TiDB collects statistics as a full collection. You can execute the `ANALYZE TABLE` statement to collect statistics.

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|
    ↪ CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated `TOPN`s.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- `WITH FLOAT_NUM SAMPLERATE` specifies the sampling rate.

`WITH NUM SAMPLES` and `WITH FLOAT_NUM SAMPLERATE` correspond to two different algorithms of collecting samples.

See Histograms, Top-N and CMSketch (Count-Min Sketch) for detailed explanations. For `SAMPLES`/`SAMPLERATE`, see Improve collection performance.

For information on persisting the options for easier reuse, see Persist `ANALYZE` configurations.

Types of statistics

This section describes three types of statistics: histogram, Count-Min Sketch, and Top-N.

Histogram

Histogram statistics are used by the optimizer to estimate selectivity of an interval or range predicate, and might also be used to determine the number of distinct values within a column for estimation of equal/IN predicates in Version 2 of statistics (refer to Versions of Statistics).

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here "equal-depth" means that the number of values falling into each bucket is as equal as possible. For example, for a given set {1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5}, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

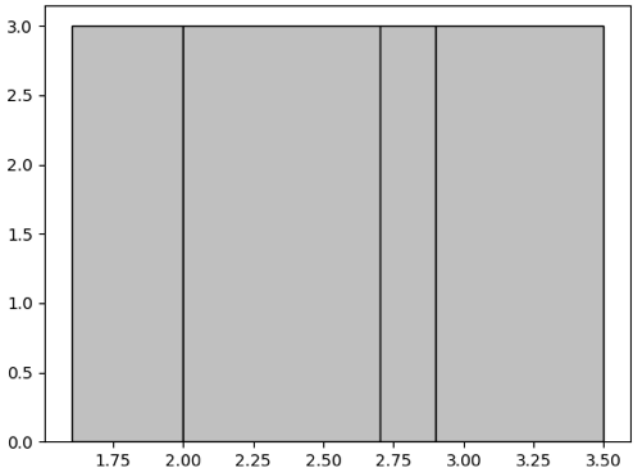

Figure 405: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to Manual Collection. When the number of buckets is larger, the accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage of memory resources. You can adjust this number appropriately according to the actual scenario.

Count-Min Sketch

> **Note:**
>
> Count-Min Sketch is used in statistics Version 1 only for equal/IN predicate selectivity estimation. In Version 2, Histogram statistics are used instead due to challenges in managing Count-Min sketch to avoid collisions as discussed below.

Count-Min Sketch is a hash structure. When processing an equivalence query such as `a = 1` or an `IN` query (for example, `a IN (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it

can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see Manual collection.
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see Manual collection.

Top-N

Top-N values are values with the top N occurrences in a column or index. Top-N statistics are often referred to as frequency statistics or data skew.

TiDB records the values and occurrences of Top-N values. Here `N` is controlled by the `WITH NUM TOPN` parameter. The default value is 20, meaning the top 20 most frequent values are collected. The maximum value is 1024. For details about the parameter, see Manual collection.

Selective statistics collection

This section describes how to collect statistics selectively.

Collect statistics on indexes

To collect statistics on all indexes in `IndexNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

When `IndexNameList` is empty, this syntax collects statistics on all indexes in `TableName` ↪ .

> **Note:**
>
> To ensure that the statistical information before and after the collection is consistent, when `tidb_analyze_version` is `2`, this syntax collects statistics on the indexed columns and all indexes.

Collect statistics on some columns

When TiDB executes SQL statements, the optimizer uses statistics for only a subset of columns in most cases. For example, columns that appear in the `WHERE`, `JOIN`, `ORDER BY`, and `GROUP BY` clauses. These columns are referred to as predicate columns.

If a table has many columns, collecting statistics on all the columns can cause a large overhead. To reduce the overhead, you can collect statistics for only specific columns (that you choose) or `PREDICATE COLUMNS` to be used by the optimizer. To persist the column list of any subset of columns for reuse in future, see Persist column configurations.

Note:

- Collecting statistics on predicate columns is only applicable for `tidb_analyze_version = 2`.
- Starting from TiDB v7.2.0, TiDB also introduces the `tidb_analyze_skip_column_types` system variable, indicating which types of columns are skipped for statistics collection when executing the `ANALYZE` command to collect statistics. The system variable is only applicable for `tidb_analyze_version = 2`.

- To collect statistics on specific columns, use the following syntax:

```
ANALYZE TABLE TableName COLUMNS ColumnNameList [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

  In the syntax, `ColumnNameList` specifies the name list of the target columns. If you need to specify more than one column, use comma `,` to separate the column names. For example, `ANALYZE table t columns a, b`. Besides collecting statistics on the specific columns in a specific table, this syntax collects statistics on the indexed columns and all indexes in that table at the same time.

- To collect statistics on `PREDICATE COLUMNS`, use the following syntax:

```
ANALYZE TABLE TableName PREDICATE COLUMNS [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

  TiDB always writes the `PREDICATE COLUMNS` information to the `mysql.column_stats_usage` system table every 100 * `stats-lease`.

  In addition to collecting statistics on `PREDICATE COLUMNS` in a specific table, this syntax collects statistics on indexed columns and all indexes in that table at the same time.

Note:

- If the mysql.column_stats_usage system table does not contain any PREDICATE COLUMNS recorded for that table, the preceding syntax collects statistics on indexed columns and all indexes in that table.
- Any columns excluded from collection (either by manually listing columns or using PREDICATE COLUMNS) will not have their statistics overwritten. When executing a new type of SQL query, the optimizer will use the old statistics for such columns if it exists, or pseudo column statistics if columns never had statistics collected. The next ANALYZE using PREDICATE COLUMNS will collect the statistics on those columns.

- To collect statistics on all columns and indexes, use the following syntax:

```
ANALYZE TABLE TableName ALL COLUMNS [WITH NUM BUCKETS|TOPN|CMSKETCH
    ↪ DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE
    ↪ ];
```

Collect statistics on partitions

- To collect statistics on all partitions in PartitionNameList in TableName, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

- To collect index statistics on all partitions in PartitionNameList in TableName, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- If you only need to collect statistics on some columns of some partitions in a table, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [COLUMNS
    ↪ ColumnNameList|PREDICATE COLUMNS|ALL COLUMNS] [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

Collect statistics of partitioned tables in dynamic pruning mode

When accessing partitioned tables in dynamic pruning mode (which is the default since v6.3.0), TiDB collects table-level statistics, which is called GlobalStats. Currently, GlobalStats is aggregated from statistics of all partitions. In dynamic pruning mode, a statistics update in any partition of a table can trigger the GlobalStats of that table to be updated.

If statistics of some partitions are empty, or statistics of some columns are missing in some partitions, then the collection behavior is controlled by the `tidb_skip_missing_partition_stats` variable:

- When GlobalStats update is triggered and `tidb_skip_missing_partition_stats` is `OFF`:
    - If some partitions have no statistics (such as a new partition that has never been analyzed), GlobalStats generation is interrupted and a warning message is displayed saying that no statistics are available on partitions.
    - If statistics of some columns are absent in specific partitions (different columns are specified for analyzing in these partitions), GlobalStats generation is interrupted when statistics of these columns are aggregated, and a warning message is displayed saying that statistics of some columns are absent in specific partitions.
- When GlobalStats update is triggered and `tidb_skip_missing_partition_stats` is `ON`:
    - If statistics of all or some columns are missing for some partitions, TiDB skips these missing partition statistics when generating GlobalStats so the generation of GlobalStats is not affected.

In dynamic pruning mode, the `ANALYZE` configurations of partitions and tables should be the same. Therefore, if you specify the `COLUMNS` configuration following the `ANALYZE TABLE TableName PARTITION PartitionNameList` statement or the `OPTIONS` configuration following `WITH`, TiDB will ignore them and return a warning.

Improve collection performance

Note:

- The execution time of `ANALYZE TABLE` in TiDB might be longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while by default in TiDB a comprehensive set of statistics are completely rebuilt.

TiDB provides two options to improve the performance of statistics collection:

- Collecting statistics on a subset of the columns. See Collecting statistics on some columns.
- Sampling.

Statistics sampling

Sampling is available via two separate options of the `ANALYZE` statement - with each corresponding to a different collection algorithm:

- `WITH NUM SAMPLES` specifies the size of the sampling set, which is implemented in the reservoir sampling method in TiDB. When a table is large, it is not recommended to use this method to collect statistics. Because the intermediate result set of the reservoir sampling contains redundant results, it causes additional pressure on resources such as memory.
- `WITH FLOAT_NUM SAMPLERATE` is a sampling method introduced in v5.3.0. With the value range `(0, 1]`, this parameter specifies the sampling rate. It is implemented in the way of Bernoulli sampling in TiDB, which is more suitable for sampling larger tables and performs better in collection efficiency and resource usage.

Before v5.3.0, TiDB uses the reservoir sampling method to collect statistics. Since v5.3.0, the TiDB Version 2 statistics uses the Bernoulli sampling method to collect statistics by default. To re-use the reservoir sampling method, you can use the `WITH NUM SAMPLES` statement.

The current sampling rate is calculated based on an adaptive algorithm. When you can observe the number of rows in a table using `SHOW STATS_META`, you can use this number of rows to calculate the sampling rate corresponding to 100,000 rows. If you cannot observe this number, you can use the sum of all the values in the `APPROXIMATE_KEYS` column in the results of `SHOW TABLE REGIONS` of the table as another reference to calculate the sampling rate.

> **Note:**
>
> Normally, `STATS_META` is more credible than `APPROXIMATE_KEYS`. However, when the result of `STATS_META` is much smaller than the result of `APPROXIMATE_KEYS`, it is recommended that you use `APPROXIMATE_KEYS` to calculate the sampling rate.

The memory quota for collecting statistics

> **Warning:**
>
> Currently, the `ANALYZE` memory quota is an experimental feature, and the memory statistics might be inaccurate in production environments.

Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the memory quota for collecting statistics in TiDB.

To set a proper value of `tidb_mem_quota_analyze`, consider the data size of the cluster. When the default sampling rate is used, the main considerations are the number of columns, the size of column values, and the memory configuration of TiDB. Consider the following suggestions when you configure the maximum and minimum values:

> **Note:**
>
> The following suggestions are for reference only. You need to configure the values based on the real scenario.

- Minimum value: should be greater than the maximum memory usage when TiDB collects statistics from the table with the most columns. An approximate reference: when TiDB collects statistics from a table with 20 columns using the default configuration, the maximum memory usage is about 800 MiB; when TiDB collects statistics from a table with 160 columns using the default configuration, the maximum memory usage is about 5 GiB.
- Maximum value: should be less than the available memory when TiDB is not collecting statistics.

Persist ANALYZE configurations

Since v5.4.0, TiDB supports persisting some `ANALYZE` configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The following are the `ANALYZE` configurations that support persistence:

Configurations	Corresponding ANALYZE syntax
The number of histogram buckets	`WITH NUM BUCKETS`
The number of Top-N	`WITH NUM TOPN`
The number of samples	`WITH NUM SAMPLES`
The sampling rate	`WITH FLOATNUM SAMPLERATE`

Configurations	Corresponding ANALYZE syntax
The `ANALYZE` ↪ column type	AnalyzeColumnOp ::= ('ALL COLUMNS' | 'PREDICATE COLUMNS' | 'COLUMNS' ColumnNameList)
The `ANALYZE` ↪ column	ColumnNameList ::= Identifier (',' Identifier)*

Enable ANALYZE configuration persistence

The `ANALYZE` configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is `2` and `tidb_persist_analyze_options` is `ON` by default).

You can use this feature to record the persistence configurations specified in the `ANALYZE` ↪ statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configuration, TiDB will collect statistics according to the recorded configurations.

To query the configuration persisted on a specific table used for auto analyze operations, you can use the following SQL statement:

```
SELECT sample_num, sample_rate, buckets, topn, column_choice, column_ids
    ↪ FROM mysql.analyze_options opt JOIN information_schema.tables tbl ON
```

```
    ↪ opt.table_id = tbl.tidb_table_id WHERE tbl.table_schema = '{db_name}'
    ↪  AND tbl.table_name = '{table_name}';
```

TiDB will overwrite the previously recorded persistent configuration using the new configurations specified by the latest `ANALYZE` statement. For example, if you run `ANALYZE TABLE t WITH 200 TOPN;`, it will set the top 200 values in the `ANALYZE` statement. Subsequently, executing `ANALYZE TABLE t WITH 0.1 SAMPLERATE;` will set both the top 200 values and a sampling rate of 0.1 for auto `ANALYZE` statements, similar to `ANALYZE TABLE t WITH 200 TOPN, 0.1 SAMPLERATE;`.

Disable ANALYZE configuration persistence

To disable the `ANALYZE` configuration persistence feature, set the `tidb_persist_analyze_options` system variable to `OFF`. Because the `ANALYZE` configuration persistence feature is not applicable to `tidb_analyze_version = 1`, setting `tidb_analyze_version = 1` can also disable the feature.

After disabling the `ANALYZE` configuration persistence feature, TiDB does not clear the persisted configuration records. Therefore, if you enable this feature again, TiDB continues to collect statistics using the previously recorded persistent configurations.

> **Note:**
>
> When you enable the `ANALYZE` configuration persistence feature again, if the previously recorded persistence configurations are no longer applicable to the latest data, you need to execute the `ANALYZE` statement manually and specify the new persistence configurations.

Persist column configurations

If you want to persist the column configuration in the `ANALYZE` statement (including `COLUMNS ColumnNameList`, `PREDICATE COLUMNS`, and `ALL COLUMNS`), set the value of the `tidb_persist_analyze_options` system variable to `ON` to enable the ANALYZE configuration persistence feature. After enabling the ANALYZE configuration persistence feature:

- When TiDB collects statistics automatically or when you manually collect statistics by executing the `ANALYZE` statement without specifying the column configuration, TiDB continues using the previously persisted configuration for statistics collection.
- When you manually execute the `ANALYZE` statement multiple times with column configuration specified, TiDB overwrites the previously recorded persistent configuration using the new configuration specified by the latest `ANALYZE` statement.

To locate `PREDICATE COLUMNS` and columns on which statistics have been collected, use the `SHOW COLUMN_STATS_USAGE` statement.

In the following example, after executing `ANALYZE TABLE t PREDICATE COLUMNS;`, TiDB collects statistics on columns `b`, `c`, and `d`, where column `b` is a `PREDICATE COLUMN` and columns `c` and `d` are index columns.

```
CREATE TABLE t (a INT, b INT, c INT, d INT, INDEX idx_c_d(c, d));
Query OK, 0 rows affected (0.00 sec)

-- The optimizer uses the statistics on column b in this query.
SELECT * FROM t WHERE b > 1;
Empty set (0.00 sec)

-- After waiting for a period of time (100 * stats-lease), TiDB writes the
   ↪  collected `PREDICATE COLUMNS` to mysql.column_stats_usage.
-- Specify `last_used_at IS NOT NULL` to show the `PREDICATE COLUMNS`
   ↪ collected by TiDB.
SHOW COLUMN_STATS_USAGE
WHERE db_name = 'test' AND table_name = 't' AND last_used_at IS NOT NULL;
+--
   ↪ -------+-----------+---------------+------------+-------------------+------
   ↪

```

Versions of statistics

The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`.

- For TiDB Self-Managed, the default value of this variable changes from `1` to `2` starting from v5.3.0.
- For TiDB Cloud, the default value of this variable changes from `1` to `2` starting from v6.5.0.
- If your cluster is upgraded from an earlier version, the default value of `tidb_analyze_version` does not change after the upgrade.

Version 2 is preferred, and will continue to be enhanced to ultimately replace Version 1 completely. Compared to Version 1, Version 2 improves the accuracy of many of the statistics collected for larger data volumes. Version 2 also improves collection performance by removing the need to collect Count-Min sketch statistics for predicate selectivity estimation, and also supporting automated collection only on selected columns (see Collecting statistics on some columns).

The following table lists the information collected by each version for usage in the optimizer estimates:

Information	Version 1	Version 2
The total number of rows in the table		
Equal/IN predicate estimation	(Column/Index Top-N & Count-Min Sketch)	(Column/Index Top-N & Histogram)
Range predicate estimation	(Column/Index Top-N & Histogram)	(Column/Index Top-N & Histogram)
`NULL` ↪ predicate estimation		

Information	Version 1	Version 2
The average length of columns		
The average length of indexes		

Switch between statistics versions

It is recommended to ensure that all tables/indexes (and partitions) utilize statistics collection from the same version. Version 2 is recommended, however, it is not recommended to switch from one version to another without a justifiable reason such as an issue experienced with the version in use. A switch between versions might take a period of time when no statistics are available until all tables have been analyzed with the new version, which might negatively affect the optimizer plan choices if statistics are not available.

Examples of justifications to switch might include - with Version 1, there could be inaccuracies in equal/IN predicate estimation due to hash collisions when collecting Count-Min sketch statistics. Solutions are listed in the Count-Min Sketch section. Alternatively, setting `tidb_analyze_version = 2` and rerunning `ANALYZE` on all objects is also a solution. In the early release of Version 2, there was a risk of memory overflow after `ANALYZE`. This issue is resolved, but initially, one solution was to set `tidb_analyze_version = 1` and rerun `ANALYZE` on all objects.

To prepare `ANALYZE` for switching between versions:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
SELECT DISTINCT(CONCAT('ANALYZE TABLE ', table_schema, '.', table_name
    ↪ , ';'))
FROM information_schema.tables JOIN mysql.stats_histograms
ON table_id = tidb_table_id
WHERE stats_ver = 2;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
SELECT DISTINCT(CONCAT('DROP STATS ', table_schema, '.', table_name, '
    ↪ ;'))
FROM information_schema.tables ON mysql.stats_histograms
ON table_id = tidb_table_id
WHERE stats_ver = 2;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt';
mysql -h ${TiDB_IP} -u user -P ${TIDB_PORT} ... < '/tmp/sql.txt'
```

View statistics

You can view the `ANALYZE` status and statistics information using the following statements.

`ANALYZE` state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using `SHOW ANALYZE STATUS`.

Starting from TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the restart using this statement. Before TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement can only show instance-level tasks, and task records are cleared after a TiDB restart.

`SHOW ANALYZE STATUS` shows the most recent task records only. Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

When `tidb_mem_quota_analyze` is set and an automatic `ANALYZE` task running in the TiDB background uses more memory than this threshold, the task will be retried. You can see failed and retried tasks in the output of the `SHOW ANALYZE STATUS` statement.

When `tidb_max_auto_analyze_time` is greater than 0 and an automatic `ANALYZE` task running in the TiDB background takes more time than this threshold, the task will be terminated.

```
mysql> SHOW ANALYZE STATUS [ShowLikeOrWhere];
+--
    ↪ ------------+------------+----------------+-------------------------------------
    ↪
| Table_schema | Table_name | Partition_name | Job_info
    ↪                                                                  |
    ↪ Processed_rows | Start_time     | End_time          | State   | Fail_
    ↪ reason                                                           |
```

```
+--
   ↪ -----------+-----------+---------------+----------------------------------
   ↪
| test       | sbtest1   |               | retry auto analyze table all
   ↪ columns with 100 topn, 0.055 samplerate          |       2000000 |
   ↪ 2022-05-07 16:41:09 | 2022-05-07 16:41:20 | finished | NULL
   ↪                                                              |
| test       | sbtest1   |               | auto analyze table all columns
   ↪ with 100 topn, 0.5 samplerate                    |            0 |
   ↪ 2022-05-07 16:40:50 | 2022-05-07 16:41:09 | failed | analyze panic
   ↪ due to memory quota exceeds, please try with smaller samplerate |
```

Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

Health state of tables

You can use the `SHOW STATS_HEALTHY` statement to check the health state of tables and roughly estimate the accuracy of the statistics. When `modify_count >= row_count`, the health state is 0; when `modify_count < row_count`, the health state is (1 - `modify_count` ↪ `/row_count`) * 100.

Metadata of columns

You can use the `SHOW STATS_HISTOGRAMS` statement to view the number of different values and the number of `NULL` in all the columns.

Buckets of histogram

You can use the `SHOW STATS_BUCKETS` statement to view each bucket of the histogram.

Top-N information

You can use the `SHOW STATS_TOPN` statement to view the Top-N information currently collected by TiDB.

Delete statistics

You can run the `DROP STATS` statement to delete statistics.

Load statistics

> **Note:**
>
> Loading statistics is not available on TiDB Cloud Serverless clusters.

By default, depending on the size of column statistics, TiDB loads statistics differently as follows:

- For statistics that consume small amounts of memory (such as count, distinctCount, and nullCount), as long as the column data is updated, TiDB automatically loads the corresponding statistics into memory for use in the SQL optimization stage.
- For statistics that consume large amounts of memory (such as histograms, TopN, and Count-Min Sketch), to ensure the performance of SQL execution, TiDB loads the statistics asynchronously on demand. Take histograms as an example. TiDB loads histogram statistics on a column into memory only when the optimizer uses the histogram statistics on that column. On-demand asynchronous statistics loading does not affect the performance of SQL execution but might provide incomplete statistics for SQL optimization.

Since v5.4.0, TiDB introduces the synchronously loading statistics feature. This feature allows TiDB to synchronously load large-sized statistics (such as histograms, TopN, and Count-Min Sketch statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

To enable this feature, set the value of the `tidb_stats_load_sync_wait` system variable to a timeout (in milliseconds) that SQL optimization can wait for at most to synchronously load complete column statistics. The default value of this variable is `100`, indicating that the feature is enabled.

After enabling the synchronously loading statistics feature, you can further configure the feature as follows:

- To control how TiDB behaves when the waiting time of SQL optimization reaches the timeout, modify the value of the `tidb_stats_load_pseudo_timeout` system variable. The default value of this variable is `ON`, indicating that after the timeout, the SQL optimization process does not use any histogram, TopN, or CMSketch statistics on any columns. If this variable is set to `OFF`, after the timeout, SQL execution fails.
- To specify the maximum number of columns that the synchronously loading statistics feature can process concurrently, modify the value of the `stats-load-concurrency` ↪ option in the TiDB configuration file. Starting from v8.2.0, the default value of this option is `0`, indicating that TiDB automatically adjusts concurrency based on the server configuration.
- To specify the maximum number of column requests that the synchronously loading statistics feature can cache, modify the value of the `stats-load-queue-size` option in the TiDB configuration file. The default value is `1000`.

During TiDB startup, SQL statements executed before the initial statistics are fully loaded might have suboptimal execution plans, thus causing performance issues. To avoid such issues, TiDB v7.1.0 introduces the configuration parameter `force-init-stats`. With this option, you can control whether TiDB provides services only after statistics initialization has been finished during startup. Starting from v7.2.0, this parameter is enabled by default.

Starting from v7.1.0, TiDB introduces `lite-init-stats` for lightweight statistics initialization.

- When the value of `lite-init-stats` is `true`, statistics initialization does not load any histogram, TopN, or Count-Min Sketch of indexes or columns into memory.
- When the value of `lite-init-stats` is `false`, statistics initialization loads histograms, TopN, and Count-Min Sketch of indexes and primary keys into memory but does not load any histogram, TopN, or Count-Min Sketch of non-primary key columns into memory. When the optimizer needs the histogram, TopN, and Count-Min Sketch of a specific index or column, the necessary statistics are loaded into memory synchronously or asynchronously.

The default value of `lite-init-stats` is `true`, which means to enable lightweight statistics initialization. Setting `lite-init-stats` to `true` speeds up statistics initialization and reduces TiDB memory usage by avoiding unnecessary statistics loading.

Export and import statistics

This section describes how to export and import statistics.

Export statistics

The interface to export statistics is as follows:

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_
    ↪ name}/${table_name}
```

For example:

```
curl -s http://127.0.0.1:10080/stats/dump/test/t1 -o /tmp/t1.json
```

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database at specific time:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_
    ↪ name}/${table_name}/${yyyyMMddHHmmss}
```

Import statistics

Note:

When you start the MySQL client, use the `--local-infile=1` option.

Generally, the imported statistics refer to the JSON file obtained using the export interface.

Loading statistics can be done with the `LOAD STATS` statement.

For example:

```
LOAD STATS 'file_name';
```

`file_name` is the file name of the statistics to be imported.

Lock statistics

Starting from v6.5.0, TiDB supports locking statistics. After the statistics of a table or a partition are locked, the statistics of the table cannot be modified and the `ANALYZE` statement cannot be executed on the table. For example:

Create table `t`, and insert data into it. When the statistics of table `t` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> SHOW WARNINGS;
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t, reason to use this rate is "Row count in stats_meta is much
    ↪ smaller compared with the row count got by PD, use min(1, 15000/4) as
    ↪  the sample-rate=1" |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Lock the statistics of table `t` and execute `ANALYZE`. The warning message shows that the `ANALYZE` statement has skipped table `t`.

```
mysql> LOCK STATS t;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW STATS_LOCKED;
+---------+------------+----------------+--------+
| Db_name | Table_name | Partition_name | Status |
+---------+------------+----------------+--------+
| test    | t          |                | locked |
+---------+------------+----------------+--------+
1 row in set (0.01 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS;
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
| Level   | Code | Message
   ↪
   ↪ |
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t, reason to use this rate is "use min(1, 110000/8) as the
   ↪ sample-rate=1" |
| Warning | 1105 | skip analyze locked table: test.t
   ↪
   ↪ |
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
2 rows in set (0.00 sec)
```

Unlock the statistics of table `t` and `ANALYZE` can be successfully executed again.

```
mysql> UNLOCK STATS t;
Query OK, 0 rows affected (0.01 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.03 sec)
```

```
mysql> SHOW WARNINGS;
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t, reason to use this rate is "use min(1, 110000/8) as the
    ↪ sample-rate=1" |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

In addition, you can also lock the statistics of a partition using `LOCK STATS`. For example:

Create a partition table `t`, and insert data into it. When the statistics of partition `p1` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT) PARTITION BY RANGE (a) (PARTITION p0
    ↪ VALUES LESS THAN (10), PARTITION p1 VALUES LESS THAN (20), PARTITION
    ↪ p2 VALUES LESS THAN (30));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 6 warning (0.02 sec)

mysql> SHOW WARNINGS;
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | disable dynamic pruning due to t has no global stats
```

```
    ↪
    ↪ |
| Note   | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t's partition p0, reason to use this rate is "Row count in stats
    ↪ _meta is much smaller compared with the row count got by PD, use min
    ↪ (1, 15000/4) as the sample-rate=1" |
| Warning | 1105 | disable dynamic pruning due to t has no global stats
    ↪
    ↪ |
| Note   | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t's partition p1, reason to use this rate is "TiDB assumes that
    ↪ the table is empty, use sample-rate=1"
    ↪                                          |
| Warning | 1105 | disable dynamic pruning due to t has no global stats

    ↪
1 row in set (0.00 sec)
```

Behaviors of locking statistics

- If you lock the statistics on a partitioned table, the statistics of all partitions on the partitioned table are locked.

- If you truncate a table or partition, the statistics lock on the table or partition will be released.

The following table describes the behaviors of locking statistics:

	Delete the whole table	Truncate the whole table	Truncate a partition	Create a new partition	Delete a partition	Reorganize a partition	Exchange a partition
A non-partitioned table is locked	The lock is invalid	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	/	/	/	/	/
A partitioned table and the whole table is locked	The lock is invalid	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	The old partition lock information is invalid, and the new partition is automatically locked	The new partition is automatically locked	The lock information of the deleted partition is cleared, and the lock of the whole table continues to take effect	The lock information of the deleted partition is cleared, and the new partition is automatically locked	The lock information is transferred to the exchanged table, and the new partition is automatically locked

	Delete the whole table	Truncate the whole table	Truncate a partition	Create a new partition	Delete a partition	Reorganize a partition	Exchange a partition
A partitioned table and only some partitions are locked	The lock is invalid	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	/	The deleted partition lock information is cleared	The deleted partition lock information is cleared	The lock information is transferred to the exchanged table

Manage `ANALYZE` tasks and concurrency

This section describes how to terminate background `ANALYZE` tasks and control the `ANALYZE` concurrency.

Terminate background `ANALYZE` tasks

Since TiDB v6.0, TiDB supports using the `KILL` statement to terminate an `ANALYZE` task running in the background. If you find that an `ANALYZE` task running in the background consumes a lot of resources and affects your application, you can terminate the `ANALYZE` task by taking the following steps:

1. Execute the following SQL statement:

   ```
   SHOW ANALYZE STATUS
   ```

   By checking the `instance` column and the `process_id` column in the result, you can get the TiDB instance address and the task `ID` of the background `ANALYZE` task.

2. Terminate the `ANALYZE` task that is running in the background.

   - If `enable-global-kill` is `true` (`true` by default), you can execute the `KILL TIDB ${id};` statement directly, where `${id}` is the `ID` of the background `ANALYZE` task obtained from the previous step.
   - If `enable-global-kill` is `false`, you need to use a client to connect to the TiDB instance that is executing the backend `ANALYZE` task, and then execute the `KILL TIDB ${id};` statement. If you use a client to connect to another TiDB instance, or if there is a proxy between the client and the TiDB cluster, the `KILL` statement cannot terminate the background `ANALYZE` task.

For more information on the `KILL` statement, see KILL.

Control `ANALYZE` concurrency

When you run the `ANALYZE` statement, you can adjust the concurrency using system variables, to control its effect on the system.

The relationships of the relevant system variables are shown below:

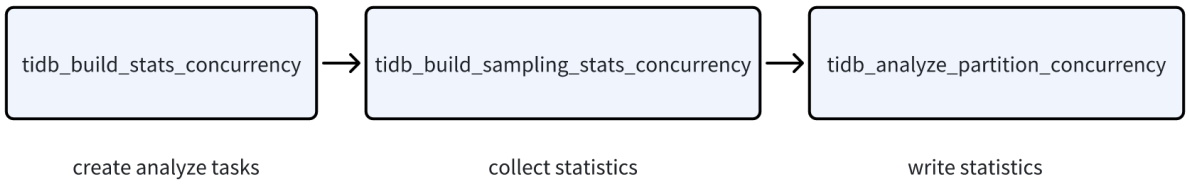

Figure 406: analyze_concurrency

`tidb_build_stats_concurrency`, `tidb_build_sampling_stats_concurrency`, and `tidb_analyze_partition_concurrency` are in an upstream-downstream relationship, as shown in the preceding diagram. The actual total concurrency is: `tidb_build_stats_concurrency` * (`tidb_build_sampling_stats_concurrency` + `tidb_analyze_partition_concurrency`). When modifying these variables, you need to consider their respective values at the same time. It is recommended to adjust them one by one in the order of `tidb_analyze_partition_concurrency`, `tidb_build_sampling_stats_concurrency`, `tidb_build_stats_concurrency`, and observe the impact on the system. The larger the values of these three variables, the greater the resource overhead on the system.

`tidb_build_stats_concurrency`

When you run the `ANALYZE` statement, the task is divided into multiple small tasks. Each task only works on statistics of one column or index. You can use the `tidb_build_stats_concurrency` variable to control the number of simultaneous small tasks. The default value is 2. The default value is 4 for v7.4.0 and earlier versions.

`tidb_build_sampling_stats_concurrency`

When analyzing ordinary columns, you can use `tidb_build_sampling_stats_concurrency` to control the concurrency of executing sampling tasks. The default value is 2.

`tidb_analyze_partition_concurrency`

When running the `ANALYZE` statement, you can use `tidb_analyze_partition_concurrency` to control the concurrency of reading and writing statistics for a partitioned table. The default value is 2. The default value is 1 for v7.4.0 and earlier versions.

`tidb_distsql_scan_concurrency`

When you analyze regular columns, you can use the `tidb_distsql_scan_concurrency` variable to control the number of Regions to be read at one time. The default value is `15`. Note that changing the value will affect query performance. Adjust the value carefully.

`tidb_index_serial_scan_concurrency`

When you analyze index columns, you can use the `tidb_index_serial_scan_concurrency` variable to control the number of Regions to be read at one time. The default value is `1`. Note that changing the value will affect query performance. Adjust the value carefully.

11.3.3.3.4 Introduction to Extended Statistics

TiDB can collect the following two types of statistics. This document describes how to use extended statistics to guide the optimizer. Before reading this document, it is recommended that you read Introduction to Statistics first.

- Basic statistics: statistics such as histograms and Count-Min Sketch, which primarily focus on individual columns. They are essential for the optimizer to estimate the query cost. See Introduction to Statistics for details.
- Extended statistics: statistics that focus on data correlations between specified columns, which guide the optimizer to estimate the query cost more precisely when the queried columns are correlated.

When the `ANALYZE` statement is executed manually or automatically, TiDB by default only collects the basic statistics and does not collect the extended statistics. This is because the extended statistics are only used for optimizer estimates in specific scenarios, and collecting them requires additional overhead.

Extended statistics are disabled by default. To collect extended statistics, you need to first enable extended statistics, and then create your desired extended statistics objects one by one. After the object creation, the next time the `ANALYZE` statement is executed, TiDB collects both the basic statistics and the corresponding extended statistics of the created objects.

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

Limitations

Extended statistics are not collected in the following scenarios:

- Statistics collection on indexes only
- Statistics collection using the `ANALYZE INCREMENTAL` command
- Statistics collection when the value of the system variable `tidb_enable_fast_analyze` is set to `true`

Common operations

Enable extended statistics

To enable extended statistics, set the system variable `tidb_enable_extended_stats` to `ON`:

```
SET GLOBAL tidb_enable_extended_stats = ON;
```

The default value of this variable is `OFF`. The setting of this system variable applies to all extended statistics objects.

Create extended statistics objects

The creation of extended statistics objects is not a one-time task. You need to repeat the creation for each extended statistics object.

To create an extended statistics object, use the SQL statement `ALTER TABLE ADD STATS_EXTENDED`. The syntax is as follows:

```
ALTER TABLE table_name ADD STATS_EXTENDED IF NOT EXISTS stats_name stats_type(column_name, column_name...);
```

In the syntax, you can specify the table name, statistics name, statistics type, and column name of the extended statistics object to be collected.

- `table_name` specifies the name of the table from which the extended statistics are collected.
- `stats_name` specifies the name of the statistics object, which must be unique for each table.
- `stats_type` specifies the type of the statistics. Currently, only the correlation type is supported.

- `column_name` specifies the column group, which might have multiple columns. Currently, you can only specify two column names.

How it works

To improve access performance, each TiDB node maintains a cache in the system table `mysql.stats_extended` for extended statistics. After you create the extended statistics objects, the next time the `ANALYZE` statement is executed, TiDB will collect the extended statistics if the system table `mysql.stats_extended` has the corresponding objects.

Each row in the `mysql.stats_extended` table has a `version` column. Once a row is updated, the value of `version` is increased. In this way, TiDB loads the table into memory incrementally, instead of fully.

TiDB loads `mysql.stats_extended` periodically to ensure that the cache is kept the same as the data in the table.

Warning:

It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can execute the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

Delete extended statistics objects

To delete an extended statistics object, use the following statement:

```
ALTER TABLE table_name DROP STATS_EXTENDED stats_name;
```

How it works

After you execute the statement, TiDB marks the value of the corresponding object in `mysql.stats_extended`'s column `status` to `2`, instead of deleting the object directly.

Other TiDB nodes will read this change and delete the object in their memory cache. The background garbage collection will delete the object eventually.

Warning:

It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can use the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

Export and import extended statistics

The way of exporting or importing extended statistics is the same as exporting or importing basic statistics. See Introduction to Statistics - Import and export statistics for details.

Usage examples for correlation-type extended statistics

Currently, TiDB only supports the correlation-type extended statistics. This type is used to estimate the number of rows in the range query and improve index selection. The following example shows how the correlation-type extended statistics are used to estimate the number of rows in a range query.

Step 1. Define the table

Define a table `t` as follows:

```
CREATE TABLE t(col1 INT, col2 INT, KEY(col1), KEY(col2));
```

Suppose that `col1` and `col2` of table `t` both obey monotonically increasing constraints in row order. This means that the values of `col1` and `col2` are strictly correlated in order, and the correlation factor is `1`.

Step 2. Execute an example query without extended statistics

Execute the following query without using extended statistics:

```
SELECT * FROM t WHERE col1 > 1 ORDER BY col2 LIMIT 1;
```

For the execution of the preceding query, the TiDB optimizer has the following options to access table `t`:

- Uses the index on `col1` to access table `t` and then sorts the result by `col2` to calculate `Top-1`.
- Uses the index on `col2` to meet the first row that satisfies `col1 > 1`. The cost of this access method mainly depends on how many rows are filtered out when TiDB scans the table in `col2`'s order.

Without extended statistics, the TiDB optimizer only supposes that `col1` and `col2` are independent, which **leads to a significant estimation error**.

Step 3. Enable extended statistics

Set `tidb_enable_extended_stats` to `ON`, and create the extended statistics object for `col1` and `col2`:

```
ALTER TABLE t ADD STATS_EXTENDED s1 correlation(col1, col2);
```

When you execute `ANALYZE` after the object creation, TiDB calculates the Pearson correlation coefficient of `col1` and `col2` of table `t`, and writes the object into the `mysql.stats_extended` table.

Step 4. See how extended statistics make a difference

After TiDB has the extended statistics for correlation, the optimizer can estimate how many rows to be scanned more precisely.

At this time, for the query in Stage 2. Execute an example query without extended statistics, `col1` and `col2` are strictly correlated in order. If TiDB accesses table `t` by using the index on `col2` to meet the first row that satisfies `col1 > 1`, the TiDB optimizer will equivalently translate the row count estimation into the following query:

```
SELECT * FROM t WHERE col1 <= 1 OR col1 IS NULL;
```

The preceding query result plus one will be the final estimation for the row count. In this way, you do not need to use the independent assumption and **the significant estimation error is avoided**.

If the correlation factor (`1` in this example) is less than the value of the system variable `tidb_opt_correlation_threshold`, the optimizer will use the independent assumption, but it will also increase the estimation heuristically. The larger the value of `tidb_opt_correlation_exp_factor`, the larger the estimation result. The larger the absolute value of the correlation factor, the larger the estimation result.

11.3.3.3.5 Wrong Index Solution

If you find that the execution speed of some query does not reach the expectation, the optimizer might choose the wrong index to run the query.

You can first view the health state of tables in the statistics, and then solve this issue according to the different health states.

Low health state

The low health state means TiDB has not performed the`ANALYZE` statement for a long time. You can update the statistics by running the `ANALYZE` command. After the update, if the optimizer still uses the wrong index, refer to the next section.

Near 100% health state

The near 100% health state suggests that the `ANALYZE` statement is just completed or was completed a short time ago. In this case, the wrong index issue might be related to TiDB's estimation logic for the number of rows.

For equivalence queries, the cause might be Count-Min Sketch. You can check whether Count-Min Sketch is the cause and take corresponding solutions.

If the cause above does not apply to your problem, you can force-select indexes by using the `USE_INDEX` or `use index` optimzer hint (see USE_INDEX for details). Also, you can change the query behavior by using SQL Plan Management in a non-intrusive way.

Other situations

Apart from the aforementioned situations, the wrong index issue might also be caused by data updates which renders all the indexes no longer applicable. In such cases, you need to perform analysis on the conditions and data distribution to see whether new indexes can speed up the query. If so, you can add new indexes by running the `ADD INDEX` command.

11.3.3.3.6 Distinct Optimization

This document introduces the `distinct` optimization in the TiDB query optimizer, including `SELECT DISTINCT` and `DISTINCT` in the aggregate functions.

`DISTINCT` modifier in `SELECT` statements

The `DISTINCT` modifier specifies removal of duplicate rows from the result set. `SELECT DISTINCT` is transformed to `GROUP BY`, for example:

```
mysql> explain SELECT DISTINCT a from t;
+--
   ↪ ----------------------+---------+-----------+--------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                               |
+--
   ↪ ----------------------+---------+-----------+--------------+----------------
   ↪
| HashAgg_6             | 2.40    | root      |               | group by:test.t.a
   ↪ , funcs:firstrow(test.t.a)->test.t.a |
| └─TableReader_11      | 3.00    | root      |               | data:
   ↪ TableFullScan_10                          |
|   └─TableFullScan_10  | 3.00    | cop[tikv] | table:t       | keep order:false
   ↪ , stats:pseudo                |
+--
   ↪ ----------------------+---------+-----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

`DISTINCT` option in aggregate functions

Usually, aggregate functions with the `DISTINCT` option is executed in the TiDB layer in a single-threaded execution model.

The `tidb_opt_distinct_agg_push_down` system variable or the `distinct-agg-push-down` configuration item in TiDB controls whether to rewrite the distinct aggregate queries and push them to the TiKV or TiFlash Coprocessor.

Take the following queries as an example of this optimization. `tidb_opt_distinct_agg_push_down` is disabled by default, which means the aggregate functions are executed in the TiDB layer. After enabling this optimization by setting its value to `1`, the `distinct a` part of `count(distinct a)` is pushed to TiKV or TiFlash Coprocessor: there is a HashAgg_5 to remove the duplicated values on column a in the TiKV Coprocessor. It might reduce the computation overhead of `HashAgg_8` in the TiDB layer.

```
mysql> desc select count(distinct a) from test.t;
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪                     |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| StreamAgg_6           | 1.00    | root    |               | funcs:count(
    ↪ distinct test.t.a)->Column#4 |
|  ─TableReader_10      | 10000.00 | root    |               | data:
    ↪ TableFullScan_9                |
|    ─TableFullScan_9   | 10000.00 | cop[tikv] | table:t   | keep order:false
    ↪ , stats:pseudo      |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
3 rows in set (0.01 sec)

mysql> set session tidb_opt_distinct_agg_push_down = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> desc select count(distinct a) from test.t;
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| id                     | estRows | task    | access object | operator info
    ↪                      |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| HashAgg_8              | 1.00    | root    |               | funcs:count(
```

```
    ↪ distinct test.t.a)->Column#3 |
|  ─TableReader_9         | 1.00    | root     |              | data:HashAgg_5
    ↪                       |
|    ─HashAgg_5           | 1.00    | cop[tikv] |              | group by:test.
    ↪ t.a,                  |
|      ─TableFullScan_7   | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo      |
+--

11.3.3.3.7 Cost Model

TiDB uses a cost model to choose an index and operator during physical optimization. The process is illustrated in the following diagram:

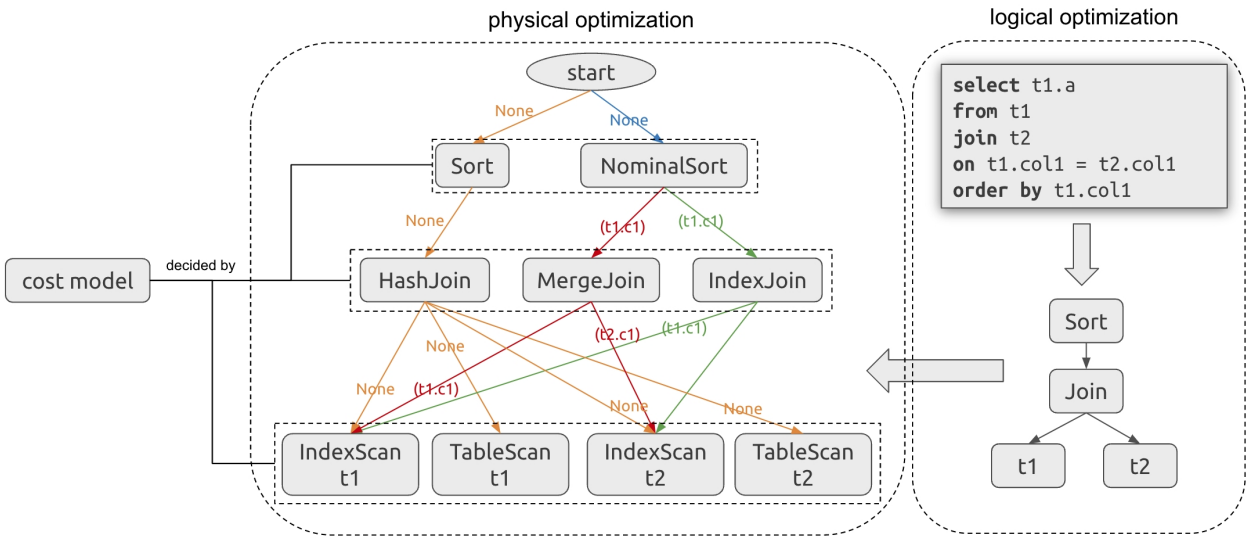

Figure 407: CostModel

TiDB calculates the access cost of each index and the execution cost of each physical operator in plans (such as HashJoin and IndexJoin) and chooses the minimum cost plan.

The following is a simplified example to explain how the cost model works. Suppose that there is a table `t`:

```
mysql> SHOW CREATE TABLE t;
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
```

```
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) DEFAULT NULL,
  KEY `b` (`b`),
  KEY `c` (`c`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

When executing the `SELECT * FROM t WHERE b < 100 and c < 100` statement, suppose that TiDB estimates 20 rows meet the `b < 100` condition and 500 rows meet `c < 100`, and the length of `INT` type indexes is 8. Then TiDB calculates the cost for two indexes:

- The cost of index `b` = row count of `b < 100` * length of index `b` = 20 * 8 = 160
- The cost of index `c` = row count of `c < 100` * length of index `c` = 500 * 8 = 4000

Because the cost of index `b` is lower, TiDB chooses `b` as the index.

The preceding example is simplified and only used to explain the basic principle. In real SQL executions, the TiDB cost model is more complex.

Cost Model Version 2

TiDB v6.2.0 introduces Cost Model Version 2, a new cost model.

Cost Model Version 2 provides a more accurate regression calibration of the cost formula, adjusts some of the cost formulas, and is more accurate than the previous version of the cost formula.

To switch the version of cost model, you can set the `tidb_cost_model_version` variable.

> **Note:**
>
> Switching the version of the cost model might cause changes to query plans.

11.3.3.3.8 Runtime Filter

Runtime Filter is a new feature introduced in TiDB v7.3, which aims to improve the performance of hash join in MPP scenarios. By generating filters dynamically to filter the data of hash join in advance, TiDB can reduce the amount of data scanning and the amount of calculation of hash join at runtime, ultimately improving the query performance.

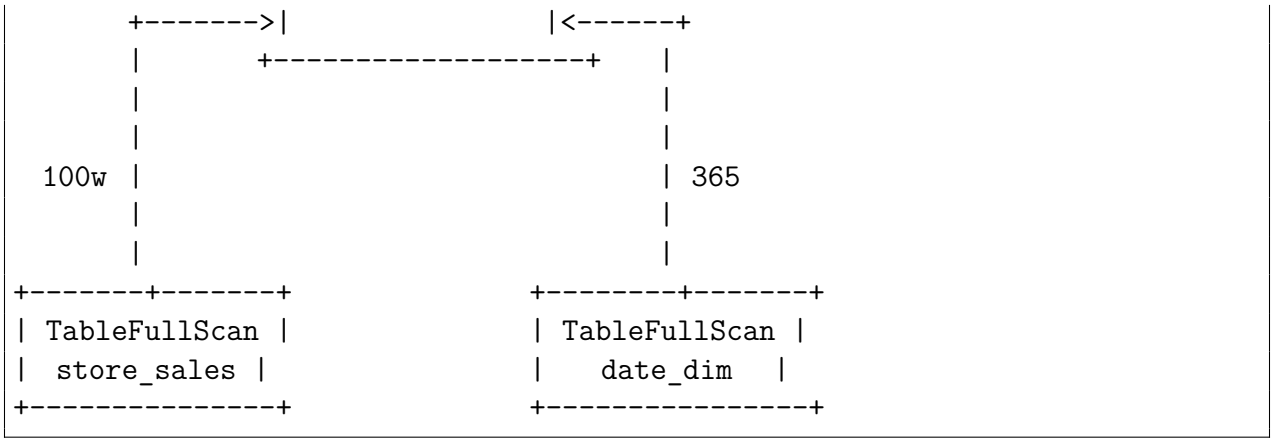
Concepts

- Hash join: a way to implement the join relational algebra. It gets the result of Join by building a hash table on one side and continuously matching the hash table on the other side.
- Build side: one side of hash join used to build a hash table. In this document, the right table of hash join is called the build side by default.
- Probe side: one side of hash join used to continuously match the hash table. In this document, the left table of hash join is called the probe side by default.
- Filter: also known as predicate, which refers to the filter condition in this document.

Working principles of Runtime Filter

Hash join performs the join operation by building a hash table based on the right table and continuously probing the hash table using the left table. If some join key values cannot hit the hash table during the probing process, it means that the data does not exist in the right table and will not appear in the final join result. Therefore, if TiDB can **filter out the join key data in advance** during scanning, it will reduce the scanning time and network overhead, thereby greatly improving the join efficiency.

Runtime Filter is a **dynamic predicate** generated during the query planning phase. This predicate has the same function as other predicates in the TiDB Selection operator. These predicates are all applied to the Table Scan operation to filter out rows that do not match the predicate. The only difference is that the parameter values in Runtime Filter come from the results generated during the hash join build process.

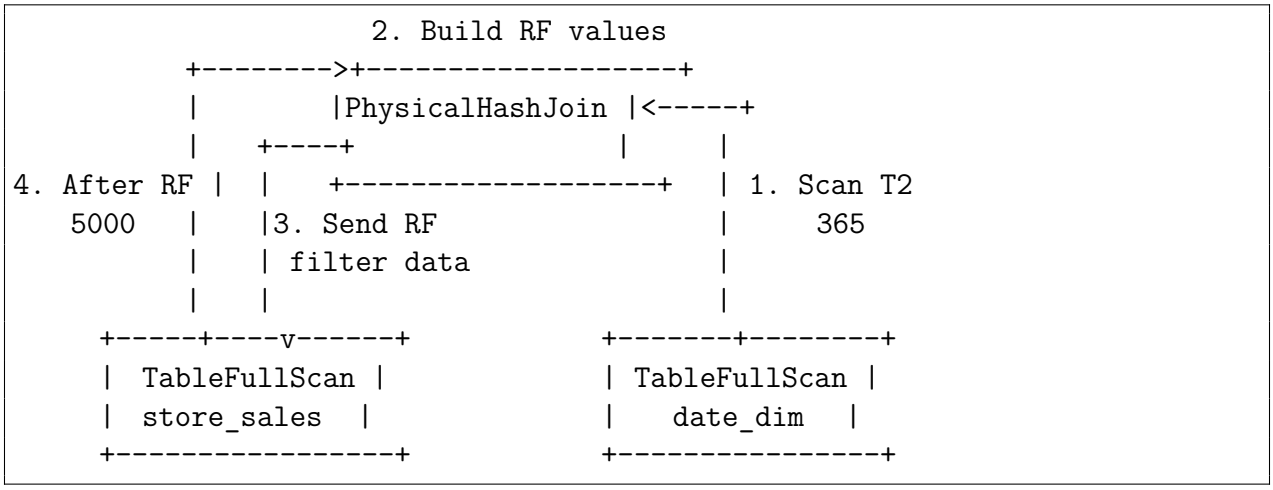


Example

Assume that there is a join query between the `store_sales` table and the `date_dim` table, and the join method is hash join. `store_sales` is a fact table that mainly stores the sales data of stores, and the number of rows is 1 million. `date_dim` is a time dimension table that mainly stores date information. You want to query the sales data of the year 2001, so 365 rows of the `date_dim` table are involved in the join operation.

```
SELECT * FROM store_sales, date_dim
WHERE ss_date_sk = d_date_sk
    AND d_year = 2001;
```

The execution plan of hash join is usually as follows:



```
                +------------------+
                | PhysicalHashJoin |
```

(The above figure omits the exchange node and other nodes.)

The execution process of Runtime Filter is as follows:

1. Scan the data of the `date_dim` table.
2. `PhysicalHashJoin` calculates a filter condition based on the data of the build side, such as `date_dim in (2001/01/01~2001/12/31)`.
3. Send the filter condition to the `TableFullScan` operator that is waiting to scan `store_sales`.
4. The filter condition is applied to `store_sales`, and the filtered data is passed to `PhysicalHashJoin`, thereby reducing the amount of data scanned by the probe side and the amount of calculation of matching the hash table.

(RF is short for Runtime Filter)

From the above two figures, you can see that the amount of data scanned by `store_sales` is reduced from 1 million to 5000. By reducing the amount of data scanned by `TableFullScan`, Runtime Filter can reduce the number of times to match the hash table, avoiding unnecessary I/O and network transmission, thus significantly improving the efficiency of the join operation.

Use Runtime Filter

To use Runtime Filter, you need to create a table with TiFlash replicas and set `tidb_runtime_filter_mode` to `LOCAL`.

Taking the TPC-DS dataset as an example, this section uses the `catalog_sales` table and the `date_dim` table for join operations to illustrate how Runtime Filter improves query efficiency.

Step 1. Create TiFlash replicas for tables to be joined

Add a TiFlash replica to each of the `catalog_sales` table and the `date_dim` table.

```
ALTER TABLE catalog_sales SET tiflash REPLICA 1;
ALTER TABLE date_dim SET tiflash REPLICA 1;
```

Wait until the TiFlash replicas of the two tables are ready, that is, the `AVAILABLE` and `PROGRESS` fields of the replicas are both `1`.

```
SELECT * FROM INFORMATION_SCHEMA.TIFLASH_REPLICA WHERE TABLE_NAME='catalog_
    ↪ sales';
+--
    ↪ ------------+---------------+----------+--------------+----------------+------
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--
    ↪ ------------+---------------+----------+--------------+----------------+------
    ↪
| tpcds50    | catalog_sales |  1055 |           1 |                |
    ↪ 1 |        1 |
+--
    ↪ ------------+---------------+----------+--------------+----------------+------
    ↪

SELECT * FROM INFORMATION_SCHEMA.TIFLASH_REPLICA WHERE TABLE_NAME='date_dim
    ↪ ';
+--
    ↪ ------------+------------+----------+--------------+----------------+---------
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--
    ↪ ------------+------------+----------+--------------+----------------+---------
    ↪
| tpcds50    | date_dim |    1015 |           1 |                |         1 |
    ↪        1 |
+--
    ↪ ------------+------------+----------+--------------+----------------+---------
```

```
    ↪
```

Step 2. Enable Runtime Filter

To enable Runtime Filter, set the value of the system variable `tidb_runtime_filter_mode` to `LOCAL`.

```
SET tidb_runtime_filter_mode="LOCAL";
```

Check whether the change is successful:

```
SHOW VARIABLES LIKE "tidb_runtime_filter_mode";
+--------------------------+--------+
| Variable_name            | Value |
+--------------------------+--------+
| tidb_runtime_filter_mode | LOCAL |
+--------------------------+--------+
```

If the value of the system variable is `LOCAL`, Runtime Filter is enabled.

Step 3. Execute the query

Before executing the query, use the `EXPLAIN` statement to show the execution plan and check whether Runtime Filter has taken effect.

```
EXPLAIN SELECT cs_ship_date_sk FROM catalog_sales, date_dim
WHERE d_date = '2002-2-01' AND
    cs_ship_date_sk = d_date_sk;
```

When Runtime Filter takes effect, the corresponding Runtime Filter is mounted on the `HashJoin` node and the `TableScan` node, indicating that Runtime Filter is applied successfully.

```
TableFullScan: runtime filter:0[IN] -> tpcds50.catalog_sales.cs_ship_date_sk
HashJoin: runtime filter:0[IN] <- tpcds50.date_dim.d_date_sk |
```

The complete query execution plan is as follows:

```
+-----------------------------------------+------------+--------------+-----------------
    ↪
| id                                      | estRows    | task         | access
    ↪ object     | operator info
    ↪
    ↪ |
+-----------------------------------------+------------+--------------+-----------------
    ↪
| TableReader_53                          | 37343.19   | root         |
    ↪                    | MppVersion: 1, data:ExchangeSender_52
    ↪
    ↪ |
```

```
|  ─ExchangeSender_52               | 37343.19   | mpp[tiflash] |
   ↪                 | ExchangeType: PassThrough
   ↪
   ↪ |
|    ─Projection_51                 | 37343.19   | mpp[tiflash] |
   ↪                 | tpcds50.catalog_sales.cs_ship_date_sk
   ↪
   ↪ |
|      ─HashJoin_48                 | 37343.19   | mpp[tiflash] |
   ↪                 | inner join, equal:[eq(tpcds50.date_dim.d_date_sk,
   ↪ tpcds50.catalog_sales.cs_ship_date_sk)], runtime filter:0[IN] <-
   ↪ tpcds50.date_dim.d_date_sk |
|        ─ExchangeReceiver_29(Build) | 1.00       | mpp[tiflash] |
   ↪                 |
   ↪
   ↪ |
|          ─ExchangeSender_28       | 1.00       | mpp[tiflash] |
   ↪                 | ExchangeType: Broadcast, Compression: FAST
   ↪
   ↪ |
|            ─TableFullScan_26      | 1.00       | mpp[tiflash] | table:date
   ↪ _dim | pushed down filter:eq(tpcds50.date_dim.d_date, 2002-02-01
   ↪ 00:00:00.000000), keep order:false                                  |
|        ─Selection_31(Probe)       | 71638034.00 | mpp[tiflash] |
   ↪                 | not(isnull(tpcds50.catalog_sales.cs_ship_date_sk))
   ↪
   ↪ |
|          ─TableFullScan_30        | 71997669.00 | mpp[tiflash] | table:
   ↪ catalog_sales | pushed down filter:empty, keep order:false, runtime
   ↪ filter:0[IN] -> tpcds50.catalog_sales.cs_ship_date_sk             |
+-------------------------------------+------------+--------------+-----------------
   ↪
9 rows in set (0.01 sec)
```

Now, execute the SQL query, and Runtime Filter is applied.

```
SELECT cs_ship_date_sk FROM catalog_sales, date_dim
WHERE d_date = '2002-2-01' AND
    cs_ship_date_sk = d_date_sk;
```

Step 4. Performance comparison

This example uses the 50 GB TPC-DS data. After Runtime Filter is enabled, the query time is reduced from 0.38 seconds to 0.17 seconds, and efficiency is improved by 50%. You can use the `ANALYZE` statement to view the execution time of each operator after Runtime Filter takes effect.

The following is the execution information of the query when Runtime Filter is not enabled:

```
EXPLAIN ANALYZE SELECT cs_ship_date_sk FROM catalog_sales, date_dim WHERE d
    ↪ _date = '2002-2-01' AND cs_ship_date_sk = d_date_sk;
+--
    ↪ ------------------------------------+------------+---------+--------------+-
    ↪
| id                                  | estRows    | actRows | task       |
    ↪ access object     | execution info
    ↪
    ↪ | operator info
    ↪                                                                          |
    ↪ memory | disk |
+--
    ↪ ------------------------------------+------------+---------+--------------+-
    ↪
| TableReader_53                      | 37343.19   | 59574   | root       |
    ↪                   | time:379.7ms, loops:83, RU:0.000000, cop_task: {

    ↪
9 rows in set (0.17 sec)
```

By comparing the execution information of the two queries, you can find the following improvements:

- IO reduction: by comparing the `total_scanned_rows` of the TableFullScan operator, you can see that the scan volume of `TableFullScan` is reduced by 2/3 after Runtime Filter is enabled.

- Hash join performance improvement: the execution duration of the `HashJoin` operator is reduced from 376.1 ms to 157.6 ms.

Best practices

Runtime Filter is applicable to the scenario where a large table and a small table are joined, such as a join query of a fact table and a dimension table. When the dimension table has a small amount of hit data, it means that the filter has fewer values, so the fact table can filter out the data that does not meet the conditions more effectively. Compared with the default scenario where the entire fact table is scanned, this significantly improves the query performance.

The join operation of the `Sales` table and the `date_dim` table in TPC-DS is a typical example.

Configure Runtime Filter

When using Runtime Filter, you can configure the mode and predicate type of Runtime Filter.

Runtime Filter mode

The mode of Runtime Filter is the relationship between the **Filter Sender operator** and **Filter Receiver operator**. There are three modes: `OFF`, `LOCAL`, and `GLOBAL`. In v7.3.0, only `OFF` and `LOCAL` modes are supported. The Runtime Filter mode is controlled by the system variable `tidb_runtime_filter_mode`.

- `OFF`: Runtime Filter is disabled. After it is disabled, the query behavior is the same as in previous versions.
- `LOCAL`: Runtime Filter is enabled in the local mode. In the local mode, the **Filter Sender operator** and **Filter Receiver operator** are in the same MPP task. In other words, Runtime Filter can be applied to the scenario where the HashJoin operator and TableScan operator are in the same task. Currently, Runtime Filter only supports the local mode. To enable this mode, set it to `LOCAL`.
- `GLOBAL`: currently, the global mode is not supported. You cannot set Runtime Filter to this mode.

Runtime Filter type

The type of Runtime Filter is the type of the predicate used by the generated Filter operator. Currently, only one type is supported: `IN`, which means that the generated predicated is similar to `k1 in (xxx)`. The Runtime Filter type is controlled by the system variable `tidb_runtime_filter_type`.

- `IN`: the default type. It means that the generated Runtime Filter uses the `IN` type predicate.

Limitations

- Runtime Filter is an optimization in the MPP architecture and can only be applied to queries pushed down to TiFlash.
- Join type: Left outer, Full outer, and Anti join (when the left table is the probe side) do not support Runtime Filter. Because Runtime Filter filters the data involved in the join in advance, the preceding types of join do not discard the unmatched data, so Runtime Filter cannot be used.
- Equal join expression: When the probe column in the equal join expression is a complex expression, or when the probe column type is JSON, Blob, Array, or other complex data types, Runtime Filter is not generated. The main reason is that the preceding types of columns are rarely used as the join column. Even if the Filter is generated, the filtering rate is usually low.

For the preceding limitations, if you need to confirm whether Runtime Filter is generated correctly, you can use the `EXPLAIN` statement to verify the execution plan.

11.3.3.4 SQL Prepared Execution Plan Cache

TiDB supports execution plan caching for `Prepare` and `Execute` queries. This includes both forms of prepared statements:

- Using the `COM_STMT_PREPARE` and `COM_STMT_EXECUTE` protocol features.
- Using the SQL statements `PREPARE` and `EXECUTE`.

The TiDB optimizer handles these two types of queries in the same way: when preparing, the parameterized query is parsed into an AST (Abstract Syntax Tree) and cached; in later execution, the execution plan is generated based on the stored AST and specific parameter values.

When the execution plan cache is enabled, in the first execution every `Prepare` statement checks whether the current query can use the execution plan cache, and if the query can use it, then put the generated execution plan into a cache implemented by LRU (Least Recently Used) linked list. In the subsequent `Execute` queries, the execution plan is obtained from the cache and checked for availability. If the check succeeds, the step of generating an execution plan is skipped. Otherwise, the execution plan is regenerated and saved in the cache.

TiDB also supports execution plan caching for some non-`PREPARE` statements, similar to the `Prepare`/`Execute` statements. For more details, refer to Non-prepared plan cache.

In the current version of TiDB, if a `Prepare` statement meets any of the following conditions, the query or the plan is not cached:

- The query contains SQL statements other than `SELECT`, `UPDATE`, `INSERT`, `DELETE`, `Union`, `Intersect`, and `Except`.
- The query accesses temporary tables, or a table that contains generated columns, or uses static mode (that is, `tidb_partition_prune_mode` is set to `static`) to access partitioning tables.

- The query contains non-correlated sub-queries, such as `SELECT * FROM t1 WHERE t1 .a > (SELECT 1 FROM t2 WHERE t2.b < 1)`.
- The query contains correlated sub-queries with `PhysicalApply` operators in the execution plan, such as `SELECT * FROM t1 WHERE t1.a > (SELECT a FROM t2 WHERE t1.b > t2.b)`.
- The query contains the `ignore_plan_cache` or `set_var` hint, such as `SELECT /*+ ignore_plan_cache()*/ * FROM t` or `SELECT /*+ set_var(max_execution_time=1)*/ * FROM t`.
- The query contains variables other than `?` (including system variables or user-defined variables), such as `select * from t where a>? and b>@x`.
- The query contains the functions that cannot be cached: `database()`, `current_user`, `current_role`, `user`, `connection_id`, `last_insert_id`, `row_count`, `version`, and `like`.
- The query uses a variable as the `LIMIT` parameter (such as `LIMIT ?` and `LIMIT 10, ?`) and the variable value is greater than 10000.
- The query contains `?` after `Order By`, such as `Order By ?`. Such queries sort data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Order By a+?`, it is cached.
- The query contains `?` after `Group By`, such as `Group By?`. Such queries group data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Group By a+?`, it is cached.
- The query contains `?` in the definition of the `Window Frame` window function, such as `(partition by year order by sale rows ? preceding)`. If `?` appears elsewhere in the window function, the query is cached.
- The query contains parameters for comparing `int` and `string`, such as `c_int >= ?` or `c_int in (?, ?)`, in which `?` indicates the string type, such as `set @x='123'`. To ensure that the query result is compatible with MySQL, parameters need to be adjusted in each query, so such queries are not cached.
- The plan attempts to access `TiFlash`.
- In most cases, the plan that contains `TableDual` is not cached, unless the current `Prepare` statement does not have parameters.
- The query accesses TiDB system views, such as `information_schema.columns`. It is not recommended to use `Prepare` and `Execute` statements to access system views.

TiDB has a limitation on the number of `?` in a query. If a query contains more than 65535 `?`, an error `Prepared statement contains too many placeholders` is reported.

The LRU linked list is designed as a session-level cache because `Prepare`/`Execute` cannot be executed across sessions. Each element of the LRU list is a key-value pair. The value is the execution plan, and the key is composed of the following parts:

- The name of the database where `Execute` is executed
- The identifier of the `Prepare` statement, that is, the name after the `PREPARE` keyword

- The current schema version, which is updated after every successfully executed DDL statement
- The SQL mode when executing `Execute`
- The current time zone, which is the value of the `time_zone` system variable
- The value of the `sql_select_limit` system variable

Any change in the preceding information (for example, switching databases, renaming `Prepare` statement, executing DDL statements, or modifying the value of SQL mode/`time_zone`), or the LRU cache elimination mechanism causes the execution plan cache miss when executing.

After the execution plan cache is obtained from the cache, TiDB first checks whether the execution plan is still valid. If the current `Execute` statement is executed in an explicit transaction, and the referenced table is modified in the transaction pre-order statement, the cached execution plan accessing this table does not contain the `UnionScan` operator, then it cannot be executed.

After the validation test is passed, the scan range of the execution plan is adjusted according to the current parameter values, and then used to perform data querying.

There are several points worth noting about execution plan caching and query performance:

- No matter an execution plan is cached or not, it is affected by SQL bindings. For execution plans that have not been cached (the first `Execute`), these plans are affected by existing SQL bindings. For execution plans that have been cached, if new SQL Bindings are created, these plans become invalid.
- Cached plans are not affected by changes in statistics, optimization rules, and blocklist pushdown by expressions.
- Considering that the parameters of `Execute` are different, the execution plan cache prohibits some aggressive query optimization methods that are closely related to specific parameter values to ensure adaptability. This causes that the query plan may not be optimal for certain parameter values. For example, the filter condition of the query is `where a > ? And a < ?`, the parameters of the first `Execute` statement are `2` and `1` respectively. Considering that these two parameters maybe be `1` and `2` in the next execution time, the optimizer does not generate the optimal `TableDual` execution plan that is specific to current parameter values;
- If cache invalidation and elimination are not considered, an execution plan cache is applied to various parameter values, which in theory also results in non-optimal execution plans for certain values. For example, if the filter condition is `where a < ?` and the parameter value used for the first execution is `1`, then the optimizer generates the optimal `IndexScan` execution plan and puts it into the cache. In the subsequent executions, if the value becomes `10000`, the `TableScan` plan might be the better one. But due to the execution plan cache, the previously generated `IndexScan` is used for execution. Therefore, the execution plan cache is more suitable for application scenarios where the query is simple (the ratio of compilation is high) and the execution plan is relatively fixed.

Starting from v6.1.0, the execution plan cache is enabled by default. You can control prepared plan cache via the system variable `tidb_enable_prepared_plan_cache`.

> **Note:**
>
> The `tidb_enable_prepared_plan_cache` system variable controls the execution plan cache only for `Prepare`/`Execute` queries, not for normal queries. For the execution plan cache for normal queries, see SQL Non-Prepared Execution Plan Cache.

After the execution plan cache feature is enabled, you can use the session-level system variable `last_plan_from_cache` to see whether the previous `Execute` statement used the cached execution plan, for example:

```
MySQL [test]> create table t(a int);
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> prepare stmt from 'select * from t where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)

-- The first execution generates an execution plan and saves it in the
   ↪ cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)

-- The second execution hits the cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 1                      |
+------------------------+
1 row in set (0.00 sec)
```

If you find that a certain set of `Prepare`/`Execute` has unexpected behavior due to the execution plan cache, you can use the `ignore_plan_cache()` SQL hint to skip using the execution plan cache for the current statement. Still, use the preceding statement as an example:

```
MySQL [test]> prepare stmt from 'select /*+ ignore_plan_cache() */ * from t
    ↪  where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
```

11.3.3.4.1 Diagnostics of Prepared Plan Cache

Use `SHOW WARNINGS` to diagnose

Some queries or plans cannot be cached. You can use the `SHOW WARNINGS` statement to check whether the query or plan is cached. If it is not cached, you can check the reason for the failure in the result. For example:

```
mysql> PREPARE st FROM 'SELECT * FROM t WHERE a > (SELECT MAX(a) FROM t)';
    ↪ -- The query contains a subquery and cannot be cached.

Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS; -- Checks the reason why the query plan cannot be
    ↪ cached.

+---------+------+-----------------------------------------------------+
```

```
| Level   | Code | Message                                          |
+---------+------+--------------------------------------------------+
| Warning | 1105 | skip plan-cache: sub-queries are un-cacheable |
+---------+------+--------------------------------------------------+
1 row in set (0.00 sec)

mysql> prepare st from 'select * from t where a<?';

Query OK, 0 rows affected (0.00 sec)

mysql> set @a='1';

Query OK, 0 rows affected (0.00 sec)

mysql> execute st using @a; -- The optimization converts a non-INT type to
    ↪  an INT type, and the execution plan might change with the change of
    ↪  the parameter, so TiDB does not cache the plan.

Empty set, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;

+---------+------+-------------------------------------------------+
| Level   | Code | Message                                         |
+---------+------+-------------------------------------------------+
| Warning | 1105 | skip plan-cache: '1' may be converted to INT |
+---------+------+-------------------------------------------------+
1 row in set (0.00 sec)
```

Use `Statements Summary` to diagnose

The `Statements Summary` table contains two fields, `plan_cache_unqualified` and `plan_cache_unqualified_last_reason`, which respectively indicate the number of times and the reason why the corresponding query is unable to use the plan cache. You can use these two fields for diagnostic purposes:

```
mysql> SELECT digest_text, plan_cache_unqualified, plan_cache_unqualified_
    ↪ last_reason FROM information_schema.statements_summary WHERE plan_
    ↪ cache_unqualified > 0 ORDER BY plan_cache_unqualified DESC
LIMIT 10;

+--
    ↪ ------------------------------+----------------------+----------------------
    ↪
| digest_text                  | plan_cache_unqualified | plan_cache_
    ↪ unqualified_last_reason |
```

```
+--
    ↪ ------------------------------+----------------------+----------------------
    ↪
| select * from `t` where `a` < ? |              10 | '1' may be converted
    ↪ to INT       |
| select * from `t` order by ? |                4 | query has 'order by ?'
    ↪  is un-cacheable |
| select database ( ) from `t` |                2 | query has 'database()'
    ↪  is un-cacheable |
...
+--
    ↪ ------------------------------+----------------------+----------------------
    ↪
10 row in set (0.01 sec)
```

11.3.3.4.2 Memory management of Prepared Plan Cache

Using Prepared Plan Cache incurs memory overhead. To view the total memory consumption by the cached execution plans of all sessions in each TiDB instance, you can use the **Plan Cache Memory Usage** monitoring panel in Grafana.

> **Note:**
>
> Because of the memory reclaim mechanism of Golang and some uncounted memory structures, the memory displayed in Grafana is not equal to the actual heap memory usage. It is tested that there is a deviation of about ±20% between the memory displayed in Grafana and the actual heap memory usage.

To view the total number of execution plans cached in each TiDB instance, you can use the **Plan Cache Plan Num** panel in Grafana.

The following is an example of the **Plan Cache Memory Usage** and **Plan Cache Plan Num** panels in Grafana:

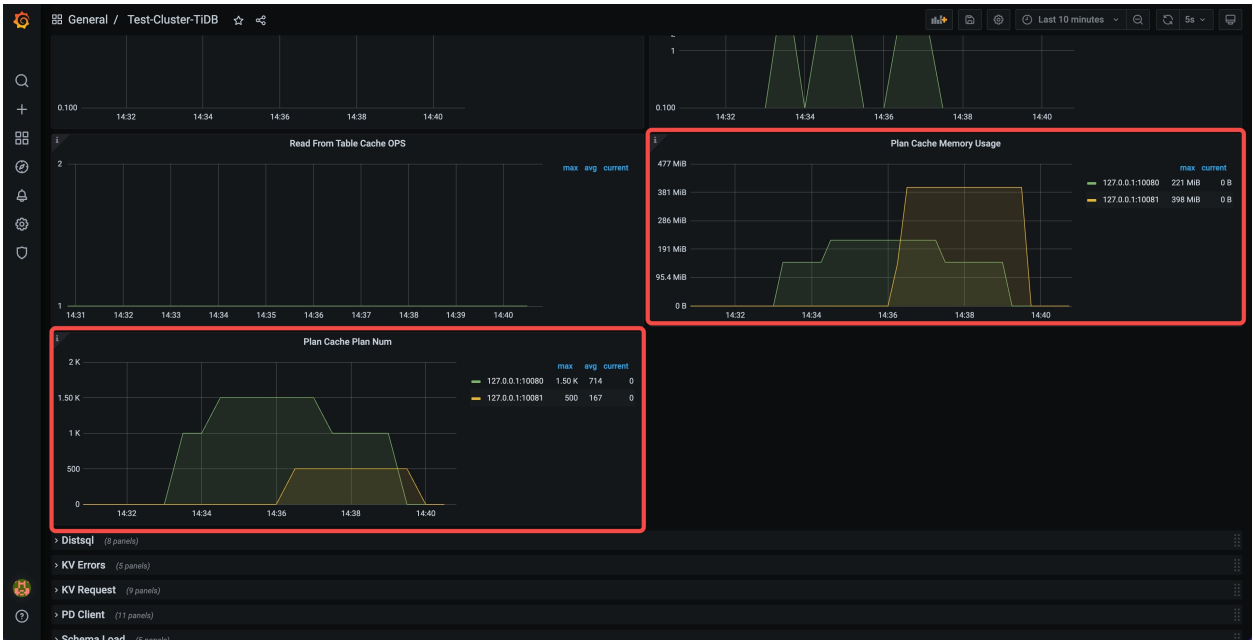

Figure 408: grafana_panels

Starting from v7.1.0, you can control the maximum number of plans that can be cached in each session by configuring the system variable `tidb_session_plan_cache_size`. For different environments, the recommended value is as follows and you can adjust it according to the monitoring panels:

- When the memory threshold of the TiDB server instance is <= 64 GiB, set `tidb_session_plan_cache_size` to 50.
- When the memory threshold of the TiDB server instance is > 64 GiB, set `tidb_session_plan_cache_size` to 100.

Starting from v7.1.0, you can control the maximum size of a plan that can be cached using the system variable `tidb_plan_cache_max_plan_size`. The default value is 2 MB. If the size of a plan exceeds this value, the plan will not be cached.

When the unused memory of the TiDB server is less than a certain threshold, the memory protection mechanism of plan cache is triggered, through which some cached plans will be evicted.

You can control the threshold by configuring the system variable `tidb_prepared_plan_cache_memory_guard_ratio`. The threshold is 0.1 by default, which means when the unused memory of the TiDB server is less than 10% of the total memory (90% of the memory is used), the memory protection mechanism is triggered.

Due to memory limit, plan cache might be missed sometimes. You can check the status by viewing the `Plan Cache Miss OPS` metric in the Grafana dashboard.

11.3.3.4.3 Clear execution plan cache

You can clear execution plan cache by executing the `ADMIN FLUSH [SESSION | INSTANCE] PLAN_CACHE` statement.

In this statement, `[SESSION | INSTANCE]` specifies whether the plan cache is cleared for the current session or the whole TiDB instance. If the scope is not specified, the preceding statement applies to the `SESSION` cache by default.

The following is an example of clearing the `SESSION` execution plan cache:

```
MySQL [test]> create table t (a int);
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> prepare stmt from 'select * from t';
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- Select the cached plan
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)

MySQL [test]> admin flush session plan_cache; -- Clear the cached plan of
    ↪ the current session
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- The cached plan cannot be
    ↪ selected again, because it has been cleared
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      0 |
+------------------------+
1 row in set (0.00 sec)
```

Currently, TiDB does not support clearing `GLOBAL` execution plan cache. That means you cannot clear the cached plan of the whole TiDB cluster. The following error is reported if you try to clear the `GLOBAL` execution plan cache:

```
MySQL [test]> admin flush global plan_cache;
ERROR 1105 (HY000): Do not support the 'admin flush global scope.'
```

11.3.3.4.4 Ignore the `COM_STMT_CLOSE` command and the `DEALLOCATE PREPARE` statement

To reduce the syntax parsing cost of SQL statements, it is recommended that you run `prepare stmt` once, then `execute stmt` multiple times before running `deallocate prepare`:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...; -- Execute once
MySQL [test]> ...
MySQL [test]> execute stmt using ...; -- Execute multiple times
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In real practice, you may be used to running `deallocate prepare` each time after running `execute stmt`, as shown below:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
MySQL [test]> prepare stmt from '...'; -- Prepare twice
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In such practice, the plan obtained by the first executed statement cannot be reused by the second executed statement.

To address the problem, you can set the system variable `tidb_ignore_prepared_cache_close_stmt` to `ON` so TiDB ignores commands to close `prepare stmt`:

```
mysql> set @@tidb_ignore_prepared_cache_close_stmt=1; -- Enable the variable
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare once
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt;                    -- Execute once
Empty set (0.00 sec)

mysql> deallocate prepare stmt;         -- Release after the first execute
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare twice
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt;                        -- Execute twice
Empty set (0.00 sec)

mysql> select @@last_plan_from_cache;  -- Reuse the last plan
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)
```

Monitoring

In the Grafana dashboard on the TiDB page in the **Executor** section, there are the "Queries Using Plan Cache OPS" and "Plan Cache Miss OPS" graphs. These graphs can be used to check if both TiDB and the application are configured correctly to allow the SQL Plan Cache to work correctly. The **Server** section on the same page provides the "Prepared Statement Count" graph. This graph shows a non-zero value if the application uses prepared statements, which is required for the SQL Plan Cache to function correctly.

Figure 409: `sql_plan_cache`

11.3.3.5 SQL Non-Prepared Execution Plan Cache

TiDB supports execution plan caching for some non-`PREPARE` statements, similar to the `Prepare`/`Execute` statements. This feature allows these statements to skip the optimization phase and improve performance.

Enabling the non-prepared plan cache might incur additional memory and CPU overhead and might not be suitable for all situations. To determine whether to enable this feature in

your scenario, refer to the Performance benefits and Memory monitoring sections.

11.3.3.5.1 Principle

The non-prepared plan cache is a session-level feature that shares a cache with the prepared plan cache. The basic principle of the non-prepared plan cache is as follows:

1. After you enable the non-prepared plan cache, TiDB first parameterizes the query based on the abstract syntax tree (AST). For example, `SELECT * FROM t WHERE b < 10 AND a = 1` is parameterized as `SELECT * FROM t WHERE b < ? and a = ?`.
2. Then, TiDB uses the parameterized query to search the plan cache.
3. If a reusable plan is found, it is directly used and the optimization phase is skipped.
4. Otherwise, the optimizer generates a new plan and adds it back into the cache for reuse in the subsequent query.

11.3.3.5.2 Usage

To enable or disable the non-prepared plan cache, you can set the `tidb_enable_non_prepared_plan_cache` system variable. You can also control the size of the non-prepared plan cache using the `tidb_session_plan_cache_size` system variable. When the number of cached plans exceeds `tidb_session_plan_cache_size`, TiDB evicts plans using the least recently used (LRU) strategy.

Starting from v7.1.0, you can control the maximum size of a plan that can be cached using the system variable `tidb_plan_cache_max_plan_size`. The default value is 2 MB. If the size of a plan exceeds this value, the plan will not be cached.

> **Note:**
>
> The memory specified by `tidb_session_plan_cache_size` is shared between the prepared and non-prepared plan cache. If you have enabled the prepared plan cache for the current cluster, enabling the non-prepared plan cache might reduce the hit rate of the original prepared plan cache.

11.3.3.5.3 Example

The following example shows how to use the non-prepared plan cache:

1. Create a table `t` for testing:

```
CREATE TABLE t (a INT, b INT, KEY(b));
```

2. Enable the non-prepared plan cache:

```
SET tidb_enable_non_prepared_plan_cache = ON;
```

3. Execute the following two queries:

```
SELECT * FROM t WHERE b < 10 AND a = 1;
SELECT * FROM t WHERE b < 5 AND a = 2;
```

4. Check whether the second query hits the cache:

```
SELECT @@last_plan_from_cache;
```

If the value of `last_plan_from_cache` in the output is `1`, it means that the execution plan of the second query comes from the cache:

```
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)
```

11.3.3.5.4 Restrictions

Cache suboptimal plans

TiDB only caches one plan for a parameterized query. For example, the queries `SELECT * FROM t WHERE a < 1` and `SELECT * FROM t WHERE a < 100000` share the same parameterized form, `SELECT * FROM t WHERE a < ?`, and thus share the same plan.

If this causes performance issues, you can use the `ignore_plan_cache()` hint to ignore plans in the cache, so that the optimizer generates a new execution plan for the SQL every time. If the SQL cannot be modified, you can create a binding to solve the problem. For example, `CREATE BINDING FOR SELECT ... USING SELECT /*+ ignore_plan_cache()*/ ...`.

Usage restrictions

Due to the preceding risks and the fact that the execution plan cache only provides significant benefits for simple queries (if a query is complex and takes a long time to execute, using the execution plan cache might not be very helpful), TiDB has strict restrictions on the scope of non-prepared plan cache. The restrictions are as follows:

- Queries or plans that are not supported by the Prepared plan cache are also not supported by the non-prepared plan cache.
- Queries that contain complex operators such as `Window` or `Having` are not supported.
- Queries that contain three or more `Join` tables or subqueries are not supported.

- Queries that contain numbers or expressions directly after `ORDER BY` or `GROUP BY` are not supported, such as `ORDER BY 1` and `GROUP BY a+1`. Only `ORDER BY column_name` and `GROUP BY column_name` are supported.
- Queries that filter on columns of `JSON`, `ENUM`, `SET`, or `BIT` type are not supported, such as `SELECT * FROM t WHERE json_col = '{}'`.
- Queries that filter on `NULL` values are not supported, such as `SELECT * FROM t WHERE a is NULL`.
- Queries with more than 200 parameters after parameterization are not supported by default, such as `SELECT * FROM t WHERE a in (1, 2, 3, ... 201)`. Starting from v7.3.0, you can modify this limit by setting the 44823 fix in the `tidb_opt_fix_control` system variable.
- Queries that access virtual columns, temporary tables, views, or memory tables are not supported, such as `SELECT * FROM INFORMATION_SCHEMA.COLUMNS`, where `COLUMNS` is a TiDB memory table.
- Queries with hints or bindings are not supported.
- DML statements or `SELECT` statements with the `FOR UPDATE` clause are not supported by default. To remove this restriction, you can execute `SET tidb_enable_non_prepared_plan_cache_for_dml = ON`.

After you enable this feature, the optimizer quickly evaluates the query. If it does not meet the support conditions for non-prepared plan cache, the query falls back to the regular optimization process.

11.3.3.5.5 Performance benefits

In internal tests, enabling the non-prepared plan cache feature can achieve significant performance benefits in most TP scenarios. For example, a performance improvement of about 4% in TPC-C tests, over 10% in some banking workloads, and 15% in Sysbench RangeScan.

However, this feature also introduces some additional memory and CPU overhead, including determining whether the query is supported, parameterizing the query, and searching for a plan in the cache. If the cache cannot hit the majority of queries in your workload, enabling it might actually adversely affect performance.

In this case, you need to observe the `non-prepared` metric in the **Queries Using Plan Cache OPS** panel and the `non-prepared-unsupported` metric in the **Plan Cache Miss OPS** panel on Grafana. If most queries are not supported and only a few can hit the plan cache, you can disable this feature.

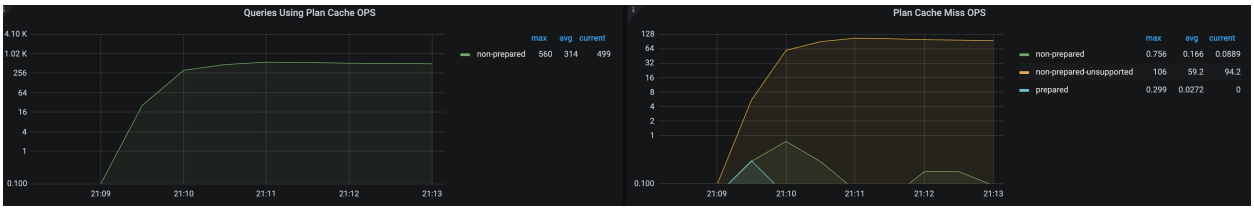

Figure 410: non-prepared-unsupported

11.3.3.5.6 Diagnostics

After enabling the non-prepared plan cache, you can execute the `EXPLAIN FORMAT='plan_cache' SELECT ...` statement to verify whether the query can hit the cache. For queries that cannot hit the cache, the system returns the reason in a warning.

Note that if you do not add `FORMAT='plan_cache'`, the `EXPLAIN` statement will never hit the cache.

To verify whether the query hits the cache, execute the following `EXPLAIN FORMAT='plan_cache'` statement:

```
EXPLAIN FORMAT='plan_cache' SELECT * FROM (SELECT a+1 FROM t) t;
```

The output is as follows:

```
3 rows in set, 1 warning (0.00 sec)
```

To view the queries that cannot hit the cache, execute `SHOW warnings;`:

```
SHOW warnings;
```

The output is as follows:

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                 |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | skip non-prepared plan-cache: queries that have sub-
    ↪ queries are not supported |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

In the preceding example, the query cannot hit the cache because the non-prepared plan cache does not support the + operation.

11.3.3.5.7 Monitoring

After enabling the non-prepared plan cache, you can monitor the memory usage, number of plans in the cache, and cache hit rate in the following panes:

Figure 411: non-prepare-plan-cache

You can also monitor the cache hit rate in the `statements_summary` table and slow query log. The following shows how to view the cache hit rate in the `statements_summary` table:

1. Create a table `t`:

```
CREATE TABLE t (a int);
```

2. Enable the non-prepared plan cache:

```
SET @@tidb_enable_non_prepared_plan_cache=ON;
```

3. Execute the following three queries:

```
SELECT * FROM t WHERE a<1;
SELECT * FROM t WHERE a<2;
SELECT * FROM t WHERE a<3;
```

4. Query the `statements_summary` table to view the cache hit rate:

```
SELECT digest_text, query_sample_text, exec_count, plan_in_cache, plan
    ↪ _cache_hits FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE
    ↪ query_sample_text LIKE '%SELECT * FROM %';
```

The output is as follows:

```
+--
    ↪ ------------------------------+-------------------------------------+
    ↪
| digest_text                   | query_sample_text                     |
    ↪ exec_count | plan_in_cache | plan_cache_hits |
+--
    ↪ ------------------------------+-------------------------------------+
    ↪
| SELECT * FROM `t` WHERE `a` < ? | SELECT * FROM t WHERE a<1      |
    ↪         3 |             1 |              2 |
+--
    ↪ ------------------------------+-------------------------------------+
    ↪
1 row in set (0.01 sec)
```

From the output, you can see that the query was executed three times and hit the cache twice.

11.3.4 Control Execution Plans

11.3.4.1 Control Execution Plan

The first two chapters of SQL Tuning introduce how to understand TiDB's execution plan and how TiDB generates an execution plan. This chapter introduces what methods can be used to control the generation of the execution plan when you determine the problems with the execution plan. This chapter mainly includes the following three aspects:

- In Optimizer Hints, you will learn how to use hints to guide TiDB to generate an execution plan.
- But hints change the SQL statement intrusively. In some scenarios, hints cannot be simply inserted. In SQL Plan Management, you will know how TiDB uses another syntax to non-intrusively control the generation of execution plans, and the methods of automatic execution plan evolution in the background. This method helps address issues such as execution plan instability caused by version upgrades and cluster performance degradation.
- Finally, you will learn how to use the blocklist in Blocklist of Optimization Rules and Expression Pushdown.

Besides the preceding methods, the execution plan is also affected by some system variables. By modifying these variables at the system level or session level, you can control the generation of the execution plan. Starting from v6.5.3 and v7.1.0, TiDB introduces a relatively special variable `tidb_opt_fix_control`. This variable can accept multiple control items to control the behavior of the optimizer in a more fine-grained way, to prevent performance regression caused by behavior changes in the optimizer after cluster upgrade. Refer to Optimizer Fix Controls for a more detailed introduction.

11.3.4.2 Optimizer Hints

TiDB supports optimizer hints, which are based on the comment-like syntax introduced in MySQL 5.7. For example, one of the common syntaxes is `/*+ HINT_NAME([t1_name [, t2_name] ...])*/`. Use of optimizer hints is recommended in cases where the TiDB optimizer selects a less optimal query plan.

If you encounter a situation where hints do not take effect, see Troubleshoot common issues that hints do not take effect.

11.3.4.2.1 Syntax

Optimizer hints are case insensitive and specified within `/*+ ... */` comments following the `SELECT`, `INSERT`, `UPDATE` or `DELETE` keyword in a SQL statement.

Multiple hints can be specified by separating with commas. For example, the following query uses three different hints:

```
SELECT /*+ USE_INDEX(t1, idx1), HASH_AGG(), HASH_JOIN(t1) */ count(*) FROM t t1, t t2 WHERE t1.a = t2.b;
```

How optimizer hints affect query execution plans can be observed in the output of `EXPLAIN` and `EXPLAIN ANALYZE`.

An incorrect or incomplete hint will not result in a statement error. This is because hints are intended to have only a *hint* (suggestion) semantic to query execution. Similarly, TiDB will at most return a warning if a hint is not applicable.

> **Note:**
>
> If the comments do not follow behind the specified keywords, they will be treated as common MySQL comments. The comments do not take effect, and no warning is reported.

Currently, TiDB supports two categories of hints, which are different in scope. The first category of hints takes effect in the scope of query blocks, such as `/*+ HASH_AGG()*/`; the second category of hints takes effect in the whole query, such as `/*+ MEMORY_QUOTA(1024 MB)*/`.

Each query or sub-query in a statement corresponds to a different query block, and each query block has its own name. For example:

```
SELECT * FROM (SELECT * FROM t) t1, (SELECT * FROM t) t2;
```

The above query statement has three query blocks: the outermost `SELECT` corresponds to the first query block, whose name is `sel_1`; the two `SELECT` sub-queries correspond to

the second and the third query block, whose names are `sel_2` and `sel_3`, respectively. The sequence of the numbers is based on the appearance of `SELECT` from left to right. If you replace the first `SELECT` with `DELETE` or `UPDATE`, then the corresponding query block names are `del_1` or `upd_1`.

11.3.4.2.2 Hints that take effect in query blocks

This category of hints can follow behind **any** `SELECT`, `UPDATE` or `DELETE` keywords. To control the effective scope of the hint, use the name of the query block in the hint. You can make the hint parameters clear by accurately identifying each table in the query (in case of duplicated table names or aliases). If no query block is specified in the hint, the hint takes effect in the current block by default.

For example:

```
SELECT /*+ HASH_JOIN(@sel_1 t1@sel_1, t3) */ * FROM (SELECT t1.a, t1.b
    ↪ FROM t t1, t t2 WHERE t1.a = t2.a) t1, t t3 WHERE t1.b = t3.b;
```

This hint takes effect in the `sel_1` query block, and its parameters are the `t1` and `t3` tables in `sel_1` (`sel_2` also contains a `t1` table).

As described above, you can specify the name of the query block in the hint in the following ways:

- Set the query block name as the first parameter of the hint, and separate it from other parameters with a space. In addition to `QB_NAME`, all the hints listed in this section also have another optional hidden parameter `@QB_NAME`. By using this parameter, you can specify the effective scope of this hint.
- Append `@QB_NAME` to a table name in the parameter to explicitly specify which query block this table belongs to.

> **Note:**
>
> You must put the hint in or before the query block where the hint takes effect. If the hint is put after the query block, it cannot take effect.

QB_NAME

If the query statement is a complicated statement that includes multiple nested queries, the ID and name of a certain query block might be mistakenly identified. The hint `QB_NAME` can help us in this regard.

`QB_NAME` means Query Block Name. You can specify a new name to a query block. The specified `QB_NAME` and the previous default name are both valid. For example:

```
SELECT /*+ QB_NAME(QB1) */ * FROM (SELECT * FROM t) t1, (SELECT * FROM t)
    ↪ t2;
```

This hint specifies the outer `SELECT` query block's name to `QB1`, which makes `QB1` and the default name `sel_1` both valid for the query block.

> **Note:**
>
> In the above example, if the hint specifies the `QB_NAME` to `sel_2` and does not specify a new `QB_NAME` for the original second `SELECT` query block, then `sel_2` becomes an invalid name for the second `SELECT` query block.

MERGE_JOIN(t1_name [, tl_name ...])

The `MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the sort-merge join algorithm for the given table(s). Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ MERGE_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_SMJ` is the alias for `MERGE_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_SMJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_SMJ` and `MERGE_JOIN` are both valid names for the hint, but `MERGE_JOIN` is recommended.

NO_MERGE_JOIN(t1_name [, tl_name ...])

The `NO_MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the sort-merge join algorithm for the given table(s). For example:

```
SELECT /*+ NO_MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

INL_JOIN(t1_name [, tl_name ...])

Note:

In some cases, the `INL_JOIN` hint might not take effect. For more information, see `INL_JOIN` hint does not take effect.

The `INL_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the index nested loop join algorithm for the given table(s). This algorithm might consume less system resources and take shorter processing time in some scenarios and might produce an opposite result in other scenarios. If the result set is less than 10,000 rows after the outer table is filtered by the `WHERE` condition, it is recommended to use this hint. For example:

```
SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id AND t2
    ↪ .id = t3.id;
```

In the preceding SQL statement, the `INL_JOIN(t1, t2)` hint tells the optimizer to use the index nested loop join algorithm for `t1` and `t2`. Note that this does not mean that the index nested loop join algorithm is used between `t1` and `t2`. Instead, the hint indicates that `t1` and `t2` each use the index nested loop join algorithm with another table (`t3`).

The parameter(s) given in `INL_JOIN()` is the candidate table for the inner table when you create the query plan. For example, `INL_JOIN(t1)` means that TiDB only considers using `t1` as the inner table to create a query plan. If the candidate table has an alias, you must use the alias as the parameter in `INL_JOIN()`; if it does not have an alias, use the table's original name as the parameter. For example, in the `select /*+ INL_JOIN(t1)*/ * from t t1, t t2 where t1.a = t2.b;` query, you must use the `t` table's alias `t1` or `t2` rather than `t` as `INL_JOIN()`'s parameter.

Note:

`TIDB_INLJ` is the alias for `INL_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_INLJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_INLJ` and `INL_JOIN` are both valid names for the hint, but `INL_JOIN` is recommended.

NO_INDEX_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop join algorithm for the given table(s). For example:

```
SELECT /*+ NO_INDEX_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

INL_HASH_JOIN

The `INL_HASH_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop hash join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm. The difference between the two algorithms is that `INL_JOIN` creates a hash table on the joined inner table, but `INL_HASH_JOIN` creates a hash table on the joined outer table. `INL_HASH_JOIN` has a fixed limit on memory usage, while the memory used by `INL_JOIN` depends on the number of rows matched in the inner table.

NO_INDEX_HASH_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop hash join algorithm for the given table(s).

INL_MERGE_JOIN

The `INL_MERGE_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop merge join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm.

NO_INDEX_MERGE_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop merge join algorithm for the given table(s).

HASH_JOIN(t1_name [, tl_name ...])

The `HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm for the given table(s). This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_HJ` is the alias for `HASH_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_HJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_HJ` and `HASH_JOIN` are both valid names for the hint, but `HASH_JOIN` is recommended.

NO_HASH_JOIN(t1_name [, tl_name ...])

The `NO_HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the hash join algorithm for the given table(s). For example:

```
SELECT /*+ NO_HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

HASH_JOIN_BUILD(t1_name [, tl_name ...])

The `HASH_JOIN_BUILD(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the build side. In this way, you can build hash tables using specific tables. For example:

```
SELECT /*+ HASH_JOIN_BUILD(t1) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

HASH_JOIN_PROBE(t1_name [, tl_name ...])

The `HASH_JOIN_PROBE(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the probe side. In this way, you can execute the hash join algorithm with specific tables as the probe side. For example:

```
SELECT /*+ HASH_JOIN_PROBE(t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

SEMI_JOIN_REWRITE()

The `SEMI_JOIN_REWRITE()` hint tells the optimizer to rewrite the semi-join query to an ordinary join query. Currently, this hint only works for `EXISTS` subqueries.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

```
-- Does not use SEMI_JOIN_REWRITE() to rewrite the query.
EXPLAIN SELECT * FROM t WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t.a);
```

```

    ↪ range: decided by [eq(test.t.a, test.t1.a)], keep order:false, stats:
    ↪ pseudo                  |
+--
    ↪ ---------------------------+---------+-----------+----------------------+----
    ↪
```

From the preceding example, you can see that when using the `SEMI_JOIN_REWRITE()` hint, TiDB can select the execution method of IndexJoin based on the driving table `t1`.

SHUFFLE_JOIN(t1_name [, tl_name ...])

The `SHUFFLE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the Shuffle Join algorithm on specified tables. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ SHUFFLE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

Note:

- Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.
- This hint can be used in combination with the `HASH_JOIN_BUILD` hint and `HASH_JOIN_PROBE` hint to control the Build side and Probe side of the Shuffle Join algorithm.

BROADCAST_JOIN(t1_name [, tl_name ...])

`BROADCAST_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the Broadcast Join algorithm on specified tables. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ BROADCAST_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

Note:

- Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

- This hint can be used in combination with the HASH_JOIN_BUILD hint and HASH_JOIN_PROBE hint to control the Build side and Probe side of the Broadcast Join algorithm.

NO_DECORRELATE()

The NO_DECORRELATE() hint tells the optimizer not to try to perform decorrelation for the correlated subquery in the specified query block. This hint is applicable to the EXISTS, IN, ANY, ALL, SOME subqueries and scalar subqueries that contain correlated columns (that is, correlated subqueries).

When this hint is used in a query block, the optimizer will not try to perform decorrelation for the correlated columns between the subquery and its outer query block, but always use the Apply operator to execute the query.

By default, TiDB tries to perform decorrelation for correlated subqueries to achieve higher execution efficiency. However, in some scenarios, decorrelation might actually reduce the execution efficiency. In this case, you can use this hint to manually tell the optimizer not to perform decorrelation. For example:

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
```

```
-- Not using NO_DECORRELATE().
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

+--
    ↪ --------------------------------+---------+----------+--------------+--------
    ↪
```

From the preceding execution plan, you can see that the optimizer has automatically performed decorrelation. The decorrelated execution plan does not have the Apply operator. Instead, the plan has join operations between the subquery and the outer query block. The original filter condition (`t2.b = t1.b`) with the correlated column becomes a regular join condition.

```
-- Using NO_DECORRELATE().
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);

   ↪          | keep order:false, stats:pseudo
   ↪                                               |
+--
   ↪ ---------------------------------------+----------+----------+--------------
   ↪
```

From the preceding execution plan, you can see that the optimizer does not perform decorrelation. The execution plan still contains the Apply operator. The filter condition (`t2.b = t1.b`) with the correlated column is still the filter condition when accessing the `t2` table.

HASH_AGG()

The `HASH_AGG()` hint tells the optimizer to use the hash aggregation algorithm in all the aggregate functions in the specified query block. This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.
    ↪ id;
```

STREAM_AGG()

The `STREAM_AGG()` hint tells the optimizer to use the stream aggregation algorithm in all the aggregate functions in the specified query block. Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ STREAM_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1
    ↪ .id;
```

MPP_1PHASE_AGG()

`MPP_1PHASE_AGG()` tells the optimizer to use the one-phase aggregation algorithm for all aggregate functions in the specified query block. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ MPP_1PHASE_AGG() */ COUNT(*) FROM t1, t2 WHERE t1.a > 10 GROUP
    ↪ BY t1.id;
```

> **Note:**
>
> Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

MPP_2PHASE_AGG()

`MPP_2PHASE_AGG()` tells the optimizer to use the two-phase aggregation algorithm for all aggregate functions in the specified query block. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ MPP_2PHASE_AGG() */ COUNT(*) FROM t1, t2 WHERE t1.a > 10 GROUP
    ↪ BY t1.id;
```

> **Note:**
>
> Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

USE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 use index(idx1, idx2);` statement.

```
SELECT /*+ USE_INDEX(t1, idx1, idx2) */ * FROM t1;
```

> **Note:**
>
> If you specify only the table name but not index name in this hint, the execution does not consider any index but scan the entire table.

FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es).

The usage and effect of `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` are the same as the usage and effect of `USE_INDEX(t1_name, idx1_name [, idx2_name ...])`.

The following 4 queries have the same effect:

```
SELECT /*+ USE_INDEX(t, idx1) */ * FROM t;
SELECT /*+ FORCE_INDEX(t, idx1) */ * FROM t;
SELECT * FROM t use index(idx1);
SELECT * FROM t force index(idx1);
```

IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to ignore the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 ignore index(idx1, idx2);` statement.

```
select /*+ IGNORE_INDEX(t1, idx1, idx2) */ * from t t1;
```

ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])

The `ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and read the specified index in order.

> **Warning:**
>
> This hint might cause SQL statements to fail. It is recommended to test it first. If an error occurs during the test, remove the hint. If the test runs normally, you can continue using it.

This hint is usually applied in the following scenario:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
| id                        | estRows | task    | access object     | operator
   ↪ info              |
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
| Limit_10                  | 10.00   | root      |                    | offset:0,
   ↪ count:10         |
|  ─IndexReader_14          | 10.00   | root      |                    | index:
   ↪ Limit_13             |
|    ─Limit_13              | 10.00   | cop[tikv] |                    | offset:0,
   ↪  count:10         |
|      ─IndexFullScan_12    | 10.00   | cop[tikv] | table:t, index:a(a) | keep
   ↪  order:true, stats:pseudo |
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
```

The optimizer generates two types of plan for this query: `Limit + IndexScan(keep ↪ order: true)` and `TopN + IndexScan(keep order: false)`. When the `ORDER_INDEX` hint is used, the optimizer chooses the first plan that reads the index in order.

> **Note:**

- If the query itself does not need to read the index in order (that is, without a hint, the optimizer does not generate a plan that reads the index in order in any situation), when the `ORDER_INDEX` hint is used, the error `Can't find a proper physical plan for this query` occurs. In this case, you need to remove the corresponding `ORDER_INDEX` hint.
- The index on a partitioned table cannot be read in order, so do not use the `ORDER_INDEX` hint on the partitioned table and its related indexes.

NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])

The `NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and not to read the specified index in order. This hint is usually applied in the following scenario.

The following example shows that the effect of the query statement is equivalent to `SELECT * FROM t t1 use index(idx1, idx2);`:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ NO_ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
| id                        | estRows | task     | access object     | operator
   ↪ info               |
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
| TopN_7                    | 10.00   | root     |                   | test.t.a,
   ↪  offset:0, count:10 |
| ─IndexReader_14           | 10.00   | root     |                   | index:
   ↪ TopN_13                |
|   ─TopN_13                | 10.00   | cop[tikv] |                   | test.t.a
   ↪ , offset:0, count:10 |
|     ─IndexFullScan_12     | 10000.00 | cop[tikv] | table:t, index:a(a) |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
```

The same as the example of `ORDER_INDEX` hint, the optimizer generates two types of plans for this query: `Limit + IndexScan(keep order: true)` and `TopN + IndexScan(` ↪ `keep order: false)`. When the `NO_ORDER_INDEX` hint is used, the optimizer will choose the latter plan to read the index out of order.

AGG_TO_COP()

The `AGG_TO_COP()` hint tells the optimizer to push down the aggregate operation in the specified query block to the coprocessor. If the optimizer does not push down some aggregate function that is suitable for pushdown, then it is recommended to use this hint. For example:

```
select /*+ AGG_TO_COP() */ sum(t1.a) from t t1;
```

LIMIT_TO_COP()

The `LIMIT_TO_COP()` hint tells the optimizer to push down the `Limit` and `TopN` operators in the specified query block to the coprocessor. If the optimizer does not perform such an operation, it is recommended to use this hint. For example:

```
SELECT /*+ LIMIT_TO_COP() */ * FROM t WHERE a = 1 AND b > 10 ORDER BY c
    ↪ LIMIT 1;
```

READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])

The `READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])` hint tells the optimizer to read specific table(s) from specific storage engine(s). Currently, this hint supports two storage engine parameters - `TIKV` and `TIFLASH`. If a table has an alias, use the alias as the parameter of `READ_FROM_STORAGE()`; if the table does not has an alias, use the table's original name as the parameter. For example:

```
select /*+ READ_FROM_STORAGE(TIFLASH[t1], TIKV[t2]) */ t1.a from t t1, t
    ↪ t2 where t1.a = t2.a;
```

USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to access a specific table with the index merge method. Index merge has two types: intersection type and union type. For details, see Explain Statements Using Index Merge.

If you explicitly specify the list of indexes, TiDB selects indexes from the list to build index merge; if you do not specify the list of indexes, TiDB selects indexes from all available indexes to build index merge.

For the intersection-type index merge, the given list of indexes is a required parameter in the hint. For the union-type index merge, the given list of indexes is an optional parameter in the hint. See the following example.

```
SELECT /*+ USE_INDEX_MERGE(t1, idx_a, idx_b, idx_c) */ * FROM t1 WHERE t1.
    ↪ a > 10 OR t1.b > 10;
```

When multiple `USE_INDEX_MERGE` hints are made to the same table, the optimizer tries to select the index from the union of the index sets specified by these hints.

> **Note:**
>
> The parameters of `USE_INDEX_MERGE` refer to index names, rather than column names. The index name of the primary key is `primary`.

LEADING(t1_name [, tl_name ...])

The `LEADING(t1_name [, tl_name ...])` hint reminds the optimizer that, when generating the execution plan, to determine the order of multi-table joins according to the order of table names specified in the hint. For example:

```
SELECT /*+ LEADING(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id and t2.
    ↪ id = t3.id;
```

In the above query with multi-table joins, the order of joins is determined by the order of table names specified in the `LEADING()` hint. The optimizer will first join `t1` and `t2` and then join the result with `t3`. This hint is more general than `STRAIGHT_JOIN`.

The `LEADING` hint does not take effect in the following situations:

- Multiple `LEADING` hints are specified.
- The table name specified in the `LEADING` hint does not exist.
- A duplicated table name is specified in the `LEADING` hint.
- The optimizer cannot perform join operations according to the order as specified by the `LEADING` hint.
- The `straight_join()` hint already exists.
- The query contains an outer join together with the Cartesian product.

In the preceding situations, a warning is generated.

```
-- Multiple `LEADING` hints are specified.
SELECT /*+ LEADING(t1, t2) LEADING(t3) */ * FROM t1, t2, t3 WHERE t1.id =
    ↪ t2.id and t2.id = t3.id;

-- To learn why the `LEADING` hint fails to take effect, execute `show
    ↪ warnings`.
SHOW WARNINGS;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | We can only use one leading hint at most, when multiple
    ↪ leading hints are used, all leading hints will be invalid |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
```

Note:

If the query statement includes an outer join, in the hint you can specify only the tables whose join order can be swapped. If there is a table in the hint whose join order cannot be swapped, the hint will be invalid. For example, in `SELECT * FROM t1 LEFT JOIN (t2 JOIN t3 JOIN t4)ON t1.a = t2.a;`, if you want to control the join order of `t2`, `t3`, and `t4` tables, you cannot specify `t1` in the `LEADING` hint.

MERGE()

Using the `MERGE()` hint in queries with common table expressions (CTE) can disable the materialization of the subqueries and expand the subquery inlines into CTE. This hint is only applicable to non-recursive CTE. In some scenarios, using `MERGE()` brings higher execution efficiency than the default behavior of allocating a temporary space. For example, pushing down query conditions or in nesting CTE queries:

```
-- Uses the hint to push down the predicate of the outer query.
WITH CTE AS (SELECT /*+ MERGE() */ * FROM tc WHERE tc.a < 60) SELECT * FROM
    ↪  CTE WHERE CTE.a < 18;

-- Uses the hint in a nested CTE query to expand a CTE inline into the
    ↪ outer query.
WITH CTE1 AS (SELECT * FROM t1), CTE2 AS (WITH CTE3 AS (SELECT /*+ MERGE()
    ↪ */ * FROM t2), CTE4 AS (SELECT * FROM t3) SELECT * FROM CTE3, CTE4)
    ↪ SELECT * FROM CTE1, CTE2;
```

Note:

`MERGE()` is only applicable to simple CTE queries. It is not applicable in the following situations:

- Recursive CTE
- Subqueries with inlines that cannot be expanded, such as aggregate operators, window functions, and `DISTINCT`.

When the number of CTE references is too high, the query performance might be lower than the default materialization behavior.

11.3.4.2.3 Hints that take effect globally

The global hint works in views. When specified as a global hint, the hint defined in a query can take effect inside the view. To specify a global hint, first use the `QB_NAME` hint to define a query block name, and then add the target hints in the form of `ViewName@QueryBlockName`.

Step 1: Define the query block name of the view using the `QB_NAME` hint

Use the `QB_NAME` hint to define a new name for each query block of the view. The definition of the `QB_NAME` hint for views is the same as that for query blocks, but the syntax is extended from `QB_NAME(QB)` to `QB_NAME(QB, ViewName@QueryBlockName [. ViewName@QueryBlockName .ViewName@QueryBlockName ...])`.

Note:

There is a white space between `@QueryBlockName` and the immediately following `.ViewName@QueryBlockName`. Otherwise, the `.ViewName@QueryBlockName` will be treated as a part of the `QueryBlockName`. For example, `QB_NAME(v2_1, v2@SEL_1 .@SEL_1)` is valid, while `QB_NAME(v2_1, v2@SEL_1.@SEL_1)` cannot be parsed correctly.

- For a simple statement with a single view and no subqueries, the following example specifies the first query block name of view `v`:

```
SELECT /* Comment: The name of the current query block is the default
    ↪ @SEL_1 */ * FROM v;
```

For view `v`, the first view name in the list (`ViewName@QueryBlockName [. ViewName@QueryBlockName .ViewName@QueryBlockName ...]`) starting from the query statement is `v@SEL_1`. The first query block of the view `v` can be declared as `QB_NAME(v_1, v@SEL_1 .@SEL_1)`, or simply written as `QB_NAME(v_1, v)`, omitting `@SEL_1`:

```
CREATE VIEW v AS SELECT /* Comment: The name of the current query
    ↪ block is the default @SEL_1 */ * FROM t;

-- Specifies the global hint
SELECT /*+ QB_NAME(v_1, v) USE_INDEX(t@v_1, idx) */ * FROM v;
```

- For a complex statement with nested views and subqueries, the following example specifies the names for each of two query blocks of the view `v1` and `v2`:

```
SELECT /* Comment: The name of the current query block is the default
    ↪  @SEL_1 */ * FROM v2 JOIN (
    SELECT /* Comment: The name of the current query block is the
        ↪ default @SEL_2 */ * FROM v2) vv;
```

For the first view `v2`, the first view name in the list starting from the first query statement is `v2@SEL_1`. For the second view `v2`, the first view name is `v2@SEL_2`. The following example only considers the first view `v2`.

The first query block of view `v2` can be declared as `QB_NAME(v2_1, v2@SEL_1 .@SEL ↪ _1)`, and the second query block of the view `v2` can be declared as `QB_NAME(v2_2, ↪ v2@SEL_1 .@SEL_2)`:

```
CREATE VIEW v2 AS
    SELECT * FROM t JOIN /* Comment: For view v2, the name of the
        ↪ current query block is the default @SEL_1. So, the current
        ↪ query block view list is v2@SEL_1 .@SEL_1 */
    (
        SELECT COUNT(*) FROM t1 JOIN v1 /* Comment: For view v2, the
            ↪ name of the current query block is the default @SEL_2.
            ↪ So, the current query block view list is v2@SEL_1 .@SEL_
            ↪ 2 */
    ) tt;
```

For view `v1`, the first view name in the list starting from the preceding statement is `v2@SEL_1 .v1@SEL_2`. The first query block in view `v1` can be declared as `QB_NAME ↪ (v1_1, v2@SEL_1 .v1@SEL_2 .@SEL_1)`, and the second query block in view `v1` can be declared as `QB_NAME(v1_2, v2@SEL_1 .v1@SEL_2 .@SEL_2)`:

```
CREATE VIEW v1 AS SELECT * FROM t JOIN /* Comment: For view `v1`, the
    ↪ name of the current query block is the default @SEL_1. So, the
    ↪ current query block view list is v2@SEL_1 .@SEL_2 .v1@SEL_1 */
    (
        SELECT COUNT(*) FROM t1 JOIN t2 /* Comment: For view `v1`, the
            ↪ name of the current query block is the default @SEL_2.
            ↪ So, the current query block view list is v2@SEL_1 .@SEL_
            ↪ 2 .v1@SEL_2 */
```

```
) tt;
```

Note:

- To use global hints with views, you must define the corresponding `QB_NAME` hints in the view. Otherwise, the global hints will not take effect.
- When using a hint to specify multiple table names in a view, you need to ensure that the table names appearing in the same hint are in the same query block of the same view.
- When you define the `QB_NAME` hint in a view for the outermost query block:
  - For the first item of the view list in the `QB_NAME`, if the `@SEL_` is not explicitly declared, the default is consistent with the query block position where the `QB_NAME` is defined. That is, the query `SELECT /*+ QB_NAME(qb1, v2)*/ * FROM v2 JOIN (SELECT /*+ QB_NAME(qb2, v2)*/ * FROM v2)vv;` is equivalent to `SELECT /*+ QB_NAME(qb1, v2@SEL_1)*/ * FROM v2 JOIN (SELECT /*+ QB_NAME(qb2, v2@SEL_2)*/ * FROM v2)vv;`.
  - For items other than the first item of the view list in the `QB_NAME`, only `@SEL_1` can be omitted. That is, if `@SEL_1` is declared in the first query block of the current view, `@SEL_1` can be omitted. Otherwise, `@SEL_` cannot be omitted. For the preceding example:
    - The first query block of the view `v2` can be declared as `QB_NAME(v2_1, v2)`.
    - The second query block of the view `v2` can be declared as `QB_NAME(v2_2, v2.@SEL_2)`.
    - The first query block of the view `v1` can be declared as `QB_NAME(v1_1, v2.v1@SEL_2)`.
    - The second query block of the view `v1` can be declared as `QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2)`.

Step 2: Add the target hints

After defining the `QB_NAME` hint for query blocks of the view, you can add required hints that take effect in query blocks in the form of `ViewName@QueryBlockName` to make them effective inside the view. For example:

- Specify the `MERGE_JOIN()` hint for the first query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_1, v2) merge_join(t@v2_1) */ * FROM v2;
```

- Specify the `MERGE_JOIN()` and `STREAM_AGG()` hints for the second query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_2, v2.@SEL_2) merge_join(t1@v2_2) stream_agg(
    ↪ @v2_2) */ * FROM v2;
```

- Specify the `HASH_JOIN()` hint for the first query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_1, v2.v1@SEL_2) hash_join(t@v1_1) */ * FROM v2;
```

- Specify the `HASH_JOIN()` and `HASH_AGG()` hints for the second query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2) hash_join(t1@v1_2) hash
    ↪ _agg(@v1_2) */ * FROM v2;
```

11.3.4.2.4 Hints that take effect in the whole query

This category of hints can only follow behind the **first** `SELECT`, `UPDATE` or `DELETE` keyword, which is equivalent to modifying the value of the specified system variable when this query is executed. The priority of the hint is higher than that of existing system variables.

> **Note:**
>
> This category of hints also has an optional hidden variable `@QB_NAME`, but the hint takes effect in the whole query even if you specify the variable.

NO_INDEX_MERGE()

The `NO_INDEX_MERGE()` hint disables the index merge feature of the optimizer.

For example, the following query will not use index merge:

```
select /*+ NO_INDEX_MERGE() */ * from t where t.a > 0 or t.b > 0;
```

In addition to this hint, setting the `tidb_enable_index_merge` system variable also controls whether to enable this feature.

> **Note:**

- `NO_INDEX_MERGE` has a higher priority over `USE_INDEX_MERGE`. When both hints are used, `USE_INDEX_MERGE` does not take effect.
- For a subquery, `NO_INDEX_MERGE` only takes effect when it is placed at the outermost level of the subquery.

USE_TOJA(boolean_value)

The `boolean_value` parameter can be `TRUE` or `FALSE`. The `USE_TOJA(TRUE)` hint enables the optimizer to convert an `in` condition (containing a sub-query) to join and aggregation operations. Comparatively, the `USE_TOJA(FALSE)` hint disables this feature.

For example, the following query will convert `in (select t2.a from t2)subq` to corresponding join and aggregation operations:

```
select /*+ USE_TOJA(TRUE) */ t1.a, t1.b from t1 where t1.a in (select t2.a
    ↪ from t2) subq;
```

In addition to this hint, setting the `tidb_opt_insubq_to_join_and_agg` system variable also controls whether to enable this feature.

MAX_EXECUTION_TIME(N)

The `MAX_EXECUTION_TIME(N)` hint places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it. In the following hint, `MAX_EXECUTION_TIME(1000)` means that the timeout is 1000 milliseconds (that is, 1 second):

```
select /*+ MAX_EXECUTION_TIME(1000) */ * from t1 inner join t2 where t1.id
    ↪  = t2.id;
```

In addition to this hint, the `global.max_execution_time` system variable can also limit the execution time of a statement.

MEMORY_QUOTA(N)

The `MEMORY_QUOTA(N)` hint places a limit `N` (a threshold value in MB or GB) on how much memory a statement is permitted to use. When a statement's memory usage exceeds this limit, TiDB produces a log message based on the statement's over-limit behavior or just terminates it.

In the following hint, `MEMORY_QUOTA(1024 MB)` means that the memory usage is limited to 1024 MB:

```
select /*+ MEMORY_QUOTA(1024 MB) */ * from t;
```

In addition to this hint, the `tidb_mem_quota_query` system variable can also limit the memory usage of a statement.

READ_CONSISTENT_REPLICA()

The `READ_CONSISTENT_REPLICA()` hint enables the feature of reading consistent data from the TiKV follower node. For example:

```
select /*+ READ_CONSISTENT_REPLICA() */ * from t;
```

In addition to this hint, setting the `tidb_replica_read` environment variable to `'follower'` or `'leader'` also controls whether to enable this feature.

IGNORE_PLAN_CACHE()

The `IGNORE_PLAN_CACHE()` hint reminds the optimizer not to use the Plan Cache when handling the current `prepare` statement.

This hint is used to temporarily disable the Plan Cache for a certain type of queries when prepare-plan-cache is enabled.

In the following example, the Plan Cache is forcibly disabled when executing the `prepare` statement.

```
prepare stmt from 'select /*+ IGNORE_PLAN_CACHE() */ * from t where t.id = ?';
```

SET_VAR(VAR_NAME=VAR_VALUE)

You can temporarily modify the value of system variables during statement execution by using the `SET_VAR(VAR_NAME=VAR_VALUE)` hint. After the statement is executed, the value of the system variable in the current session is automatically restored to the original value. This hint can be used to modify some system variables related to the optimizer and executor. For a list of system variables that can be modified using this hint, refer to System Variables.

Warning:

- It is strongly recommended not to modify variables that are not explicitly supported, as this might cause unpredictable behavior.
- Do not write `SET_VAR` in subqueries. Otherwise it might not take effect. For more information, see `SET_VAR` does not take effect when written in subqueries.

The following is an example:

```
SELECT /*+ SET_VAR(MAX_EXECUTION_TIME=1234) */ @@MAX_EXECUTION_TIME;
SELECT @@MAX_EXECUTION_TIME;
```

After executing the preceding SQL statements, the first query returns the value `1234` set in the hint, instead of the default value of `MAX_EXECUTION_TIME`. The second query returns the default value of the variable.

```
+----------------------+
| @@MAX_EXECUTION_TIME |
+----------------------+
|                 1234 |
+----------------------+
1 row in set (0.00 sec)
+----------------------+
| @@MAX_EXECUTION_TIME |
+----------------------+
|                    0 |
+----------------------+
1 row in set (0.00 sec)
```

STRAIGHT_JOIN()

The `STRAIGHT_JOIN()` hint reminds the optimizer to join tables in the order of table names in the `FROM` clause when generating the join plan.

```
SELECT /*+ STRAIGHT_JOIN() */ * FROM t t1, t t2 WHERE t1.a = t2.a;
```

Note:

- `STRAIGHT_JOIN` has higher priority over `LEADING`. When both hints are used, `LEADING` does not take effect.
- It is recommended to use the `LEADING` hint, which is more general than the `STRAIGHT_JOIN` hint.

NTH_PLAN(N)

The `NTH_PLAN(N)` hint reminds the optimizer to select the `N`th physical plan found during the physical optimization. `N` must be a positive integer.

If the specified `N` is beyond the search range of the physical optimization, TiDB will return a warning and select the optimal physical plan based on the strategy that ignores this hint.

This hint does not take effect when the cascades planner is enabled.

In the following example, the optimizer is forced to select the third physical plan found during the physical optimization:

```
SELECT /*+ NTH_PLAN(3) */ count(*) from t where a > 5;
```

> **Note:**
>
> `NTH_PLAN(N)` is mainly used for testing, and its compatibility is not guaranteed in later versions. Use this hint **with caution**.

RESOURCE_GROUP(resource_group_name)

`RESOURCE_GROUP(resource_group_name)` is used for Resource Control to isolate resources. This hint temporarily executes the current statement using the specified resource group. If the specified resource group does not exist, this hint will be ignored.

Example:

```
SELECT /*+ RESOURCE_GROUP(rg1) */ * FROM t limit 10;
```

> **Note:**
>
> Starting from v8.2.0, TiDB introduces privilege control for this hint. When the system variable `tidb_resource_control_strict_mode` is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege to use this hint. If you do not have the required privilege, this hint is ignored, and TiDB returns a warning. You can view the details by executing `SHOW WARNINGS;` after the query.

11.3.4.2.5 Troubleshoot common issues that hints do not take effect

Hints do not take effect because your MySQL command-line client strips hints

MySQL command-line clients earlier than 5.7.7 strip optimizer hints by default. If you want to use the Hint syntax in these earlier versions, add the `--comments` option when starting the client. For example: `mysql -h 127.0.0.1 -P 4000 -uroot --comments`.

Hints do not take effect because the database name is not specified

If you do not specify the database name when creating a connection, hints might not take effect. For example:

When connecting to TiDB, you use the `mysql -h127.0.0.1 -P4000 -uroot` command without the `-D` option, and then execute the following SQL statements:

```
SELECT /*+ use_index(t, a) */ a FROM test.t;
SHOW WARNINGS;
```

Because TiDB cannot identify the database for table `t`, the `use_index(t, a)` hint does not take effect.

```
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                |
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
| Warning | 1815 | use_index(.t, a) is inapplicable, check whether the
    ↪ table(.t) exists |
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Hints do not take effect because the database name is not explicitly specified in cross-table queries

When executing cross-table queries, you need to explicitly specify database names. Otherwise, hints might not take effect. For example:

```
USE test1;
CREATE TABLE t1(a INT, KEY(a));
USE test2;
CREATE TABLE t2(a INT, KEY(a));
SELECT /*+ use_index(t1, a) */ * FROM test1.t1, t2;
SHOW WARNINGS;
```

In the preceding statements, because table `t1` is not in the current `test2` database, the `use_index(t1, a)` hint does not take effect.

```
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                |
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
| Warning | 1815 | use_index(test2.t1, a) is inapplicable, check whether
    ↪ the table(test2.t1) exists |
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
```

```
1 row in set (0.00 sec)
```

In this case, you need to specify the database name explicitly by using `use_index(test1.t1, a)` instead of `use_index(t1, a)`.

Hints do not take effect because they are placed in wrong locations

Hints cannot take effect if they are not placed directly after the specific keywords. For example:

```
SELECT * /*+ use_index(t, a) */ FROM t;
SHOW WARNINGS;
```

The warning is as follows:

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1064 | You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your TiDB version for the right syntax to use [
    ↪ parser:8066]Optimizer hint can only be followed by certain keywords
    ↪ like SELECT, INSERT, etc. |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

In this case, you need to place the hint directly after the `SELECT` keyword. For more details, see the Syntax section.

`INL_JOIN` hint does not take effect

`INL_JOIN` hint does not take effect when built-in functions are used on columns for joining tables

In some cases, if you use a built-in function on a column that joins tables, the optimizer might fail to choose the `IndexJoin` plan, resulting in the `INL_JOIN` hint not taking effect either.

For example, the following query uses the built-in function `substr` on the column `tname` that joins tables:

```
CREATE TABLE t1 (id varchar(10) primary key, tname varchar(10));
CREATE TABLE t2 (id varchar(10) primary key, tname varchar(10));
```

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id=t2.id and
    ↪ SUBSTR(t1.tname,1,2)=SUBSTR(t2.tname,1,2);
```

The execution plan is as follows:

```
+--
    ↪ ----------------------------+---------+----------+--------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info                                                |
+--
    ↪ ----------------------------+---------+----------+--------------+-----------
    ↪
| HashJoin_12                 | 12500.00 | root    |               | inner join,
    ↪ equal:[eq(test.t1.id, test.t2.id) eq(Column#5, Column#6)] |
|  ─Projection_17(Build)    | 10000.00 | root    |               | test.t2.id,
    ↪  test.t2.tname, substr(test.t2.tname, 1, 2)->Column#6 |
|    ─TableReader_19        | 10000.00 | root    |               | data:
    ↪ TableFullScan_18                                    |
|      ─TableFullScan_18    | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo                                 |
|  ─Projection_14(Probe)    | 10000.00 | root    |               | test.t1.id,
    ↪  test.t1.tname, substr(test.t1.tname, 1, 2)->Column#5 |
|    ─TableReader_16        | 10000.00 | root    |               | data:
    ↪ TableFullScan_15                                    |
|      ─TableFullScan_15    | 10000.00 | cop[tikv] | table:t1 | keep order:
    ↪ false, stats:pseudo                                 |
+--
    ↪ ----------------------------+---------+----------+--------------+-----------
    ↪
7 rows in set, 1 warning (0.01 sec)
```

```
SHOW WARNINGS;
```

```
+---------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                |
+---------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | Optimizer Hint /*+ INL_JOIN(t1, t2) */ or /*+ TIDB_INLJ(
    ↪ t1, t2) */ is inapplicable |
+---------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

As you can see from the preceding example, the `INL_JOIN` hint does not take effect. This is due to a limitation of the optimizer that prevents using the `Projection` or `Selection` operator as the probe side of `IndexJoin`.

Starting from TiDB v8.0.0, you can avoid this issue by setting `tidb_enable_inl_join_inner_multi_pattern` to `ON`.

```
SET @@tidb_enable_inl_join_inner_multi_pattern=ON;
Query OK, 0 rows affected (0.00 sec)

EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id=t2.id AND
    ↪ SUBSTR(t1.tname,1,2)=SUBSTR(t2.tname,1,2);
+--
    ↪ ---------------------------+-------------+----------+--------------+--------

    ↪ pseudo                                                          |
```

```
+--
    ↪ ---------------------------+-------------+----------+--------------+-------
    ↪
7 rows in set (0.00 sec)
```

`INL_JOIN`, `INL_HASH_JOIN`, and `INL_MERGE_JOIN` hints do not take effect due to collation incompatibility

When the collation of the join key is incompatible between two tables, the `IndexJoin` operator cannot be utilized to execute the query. In this case, the `INL_JOIN`, `INL_HASH_JOIN`, and `INL_MERGE_JOIN` hints do not take effect. For example:

```
CREATE TABLE t1 (k varchar(8), key(k)) COLLATE=utf8mb4_general_ci;
CREATE TABLE t2 (k varchar(8), key(k)) COLLATE=utf8mb4_bin;
EXPLAIN SELECT /*+ tidb_inlj(t1) */ * FROM t1, t2 WHERE t1.k=t2.k;
```

The execution plan is as follows:

```
+--
    ↪ ---------------------------+----------+----------+--------------------+------
    ↪
| id                          | estRows | task     | access object      |
    ↪ operator info                                |
+--
    ↪ ---------------------------+----------+----------+--------------------+------
    ↪
| HashJoin_19                 | 12487.50 | root     |                    | inner
    ↪ join, equal:[eq(test.t1.k, test.t2.k)] |
| ─IndexReader_24(Build)      | 9990.00 | root     |                     | index:
    ↪ IndexFullScan_23                      |

`INL_JOIN` hint does not take effect due to join order

The `INL_JOIN(t1, t2)` or `TIDB_INLJ(t1, t2)` hint semantically instructs `t1` and `t2` to act as inner tables in an `IndexJoin` operator to join with other tables, rather than directly joining them using an `IndexJoin` operator. For example:

```
EXPLAIN SELECT /*+ inl_join(t1, t3) */ * FROM t1, t2, t3 WHERE t1.id = t2.
    ↪ id AND t2.id = t3.id AND t1.id = t3.id;

```

In the preceding example, `t1` and `t3` are not directly joined together by an `IndexJoin`.

To perform a direct `IndexJoin` between `t1` and `t3`, you can first use `LEADING(t1, t3)` hint to specify the join order of `t1` and `t3`, and then use the `INL_JOIN` hint to specify the join algorithm. For example:

```
EXPLAIN SELECT /*+ leading(t1, t3), inl_join(t3) */ * FROM t1, t2, t3 WHERE
    ↪  t1.id = t2.id AND t2.id = t3.id AND t1.id = t3.id;
+--
    ↪ ------------------------------+---------+----------+--------------+--------
    ↪
| id                           | estRows | task    | access object | operator
    ↪  info
    ↪
    ↪ |
+--

Using hints causes the `Can't find a proper physical plan for this query` error

The `Can't find a proper physical plan for this query` error might occur in the following scenarios:

- A query itself does not require reading indexes in order. That is, for this query, the optimizer does not generate a plan to read indexes in order in any case without using hints. In this case, if the `ORDER_INDEX` hint is specified, this error occurs. To resolve this issue, remove the corresponding `ORDER_INDEX` hint.
- A query excludes all possible join methods by using the `NO_JOIN` related hints.

```
CREATE TABLE t1 (a INT);
CREATE TABLE t2 (a INT);
```

```
EXPLAIN SELECT /*+ NO_HASH_JOIN(t1), NO_MERGE_JOIN(t1) */ * FROM t1, t2
    ↪ WHERE t1.a=t2.a;
ERROR 1815 (HY000): Internal : Can't find a proper physical plan for this
    ↪ query
```

- The system variable `tidb_opt_enable_hash_join` is set to `OFF`, and all other join types are also excluded.

```
CREATE TABLE t1 (a INT);
CREATE TABLE t2 (a INT);
set tidb_opt_enable_hash_join=off;
EXPLAIN SELECT /*+ NO_MERGE_JOIN(t1) */ * FROM t1, t2 WHERE t1.a=t2.a;
ERROR 1815 (HY000): Internal : Can't find a proper physical plan for this
    ↪ query
```

`SET_VAR` does not take effect when written in subqueries

`SET_VAR` is used to modify the value of system variables for the current statement. Do not write it in subqueries. If you write it in a subquery, `SET_VAR` might not take effect due to the special handling of subqueries.

In the following example, `SET_VAR` is written in the subquery, so it does not take effect.

```
mysql> SELECT @@MAX_EXECUTION_TIME, a FROM (SELECT /*+ SET_VAR(MAX_
    ↪ EXECUTION_TIME=123) */ 1 as a) t;
+----------------------+---+
| @@MAX_EXECUTION_TIME | a |
+----------------------+---+
|                    0 | 1 |
+----------------------+---+
1 row in set (0.00 sec)
```

In the following example, `SET_VAR` is not written in a subquery, so it takes effect.

```
mysql> SELECT /*+ SET_VAR(MAX_EXECUTION_TIME=123) */ @@MAX_EXECUTION_TIME,
    ↪ a FROM (SELECT 1 as a) t;
+----------------------+---+
| @@MAX_EXECUTION_TIME | a |
+----------------------+---+
|                  123 | 1 |
+----------------------+---+
1 row in set (0.00 sec)
```

11.3.4.3 SQL Plan Management (SPM)

SQL Plan Management is a set of functions that execute SQL bindings to manually interfere with SQL execution plans. These functions include SQL binding, baseline capturing, and baseline evolution.

11.3.4.3.1 SQL binding

An SQL binding is the basis of SPM. The Optimizer Hints document introduces how to select a specific execution plan using hints. However, sometimes you need to interfere with execution selection without modifying SQL statements. With SQL bindings, you can select a specified execution plan without modifying SQL statements.

> **Note:**
>
> To use SQL bindings, you need to have the `SUPER` privilege. If TiDB prompts that you do not have sufficient privileges, see Privilege Management to add the required privileges.

Create a binding

You can create a binding for a SQL statement according to a SQL statement or a historical execution plan.

Create a binding according to a SQL statement

```
CREATE [GLOBAL | SESSION] BINDING [FOR BindableStmt] USING BindableStmt;
```

This statement binds SQL execution plans at the GLOBAL or SESSION level. Currently, supported bindable SQL statements (BindableStmt) in TiDB include `SELECT`, `DELETE`, `UPDATE`, and `INSERT` / `REPLACE` with `SELECT` subqueries. The following is an example:

```
CREATE GLOBAL BINDING USING SELECT /*+ use_index(orders, orders_book_id_
    ↪ idx) */ * FROM orders;
CREATE GLOBAL BINDING FOR SELECT * FROM orders USING SELECT /*+ use_index(
    ↪ orders, orders_book_id_idx) */ * FROM orders;
```

> **Note:**
>
> Bindings have higher priority over manually added hints. Therefore, when you execute a statement containing a hint while a corresponding binding is present, the hint controlling the behavior of the optimizer does not take effect. However, other types of hints are still effective.

Specifically, two types of these statements cannot be bound to execution plans due to syntax conflicts. A syntax error will be reported during binding creation. See the following examples:

```
-- Type one: Statements that get the Cartesian product by using the `JOIN`
    ↪  keyword and not specifying the associated columns with the `USING`
    ↪ keyword.
CREATE GLOBAL BINDING for
    SELECT * FROM orders o1 JOIN orders o2
USING
    SELECT * FROM orders o1 JOIN orders o2;

-- Type two: `DELETE` statements that contain the `USING` keyword.
CREATE GLOBAL BINDING for
    DELETE FROM users USING users JOIN orders ON users.id = orders.user_id
USING
    DELETE FROM users USING users JOIN orders ON users.id = orders.user_id;
```

You can bypass syntax conflicts by using equivalent statements. For example, you can rewrite the above statements in the following ways:

```
-- Rewrite of type one statements: Delete the `JOIN` keyword. Replace it
    ↪ with a comma.
CREATE GLOBAL BINDING for
    SELECT * FROM orders o1, orders o2
USING
    SELECT * FROM orders o1, orders o2;

-- Rewrite of type two statements: Remove the `USING` keyword from the `
    ↪ DELETE` statement.
CREATE GLOBAL BINDING for
    DELETE users FROM users JOIN orders ON users.id = orders.user_id
USING
    DELETE users FROM users JOIN orders ON users.id = orders.user_id;
```

> **Note:**
>
> When creating execution plan bindings for `INSERT` / `REPLACE` statements with `SELECT` subqueries, you need to specify the optimizer hints you want to bind in the `SELECT` subquery, not after the `INSERT` / `REPLACE` keyword. Otherwise, the optimizer hints do not take effect as intended.

Here are two examples:

```
-- The hint takes effect in the following statement.
CREATE GLOBAL BINDING for
    INSERT INTO orders SELECT * FROM pre_orders WHERE status = 'VALID' AND
        ↪ created <= (NOW() - INTERVAL 1 HOUR)
USING
    INSERT INTO orders SELECT /*+ use_index(@sel_1 pre_orders, idx_created)
        ↪  */ * FROM pre_orders WHERE status = 'VALID' AND created <= (NOW
        ↪ () - INTERVAL 1 HOUR);

-- The hint cannot take effect in the following statement.
CREATE GLOBAL BINDING for
    INSERT INTO orders SELECT * FROM pre_orders WHERE status = 'VALID' AND
        ↪ created <= (NOW() - INTERVAL 1 HOUR)
USING
    INSERT /*+ use_index(@sel_1 pre_orders, idx_created) */ INTO orders
        ↪ SELECT * FROM pre_orders WHERE status = 'VALID' AND created <= (
        ↪ NOW() - INTERVAL 1 HOUR);
```

If you do not specify the scope when creating an execution plan binding, the default scope is SESSION. The TiDB optimizer normalizes bound SQL statements and stores them in the system table. When processing SQL queries, if a normalized statement matches one of the bound SQL statements in the system table and the system variable `tidb_use_plan_baselines` is set to `on` (the default value is `on`), TiDB then uses the corresponding optimizer hint for this statement. If there are multiple matchable execution plans, the optimizer chooses the least costly one to bind.

`Normalization` is a process that converts a constant in an SQL statement to a variable parameter and explicitly specifies the database for tables referenced in the query, with standardized processing on the spaces and line breaks in the SQL statement. See the following example:

```
SELECT * FROM users WHERE balance > 100
-- After normalization, the above statement is as follows:
SELECT * FROM bookshop . users WHERE balance > ?
```

Note:

In the normalization process, `?` in the `IN` predicate is normalized as `...`.

For example:

```
SELECT * FROM books WHERE type IN ('Novel')
SELECT * FROM books WHERE type IN ('Novel','Life','Education')
-- After normalization, the above statements are as follows:
```

```
SELECT * FROM bookshop . books WHERE type IN ( ... )
SELECT * FROM bookshop . books WHERE type IN ( ... )
```

After normalization, `IN` predicates of different lengths are recognized as the same statement, so you only need to create one binding that applies to all these predicates.

For example:

```
CREATE TABLE t (a INT, KEY(a));
CREATE BINDING FOR SELECT * FROM t WHERE a IN (?) USING SELECT
    ↪  /*+ use_index(t, idx_a) */ * FROM t WHERE a in (?);

SELECT * FROM t WHERE a IN (1);
SELECT @@LAST_PLAN_FROM_BINDING;
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
+--------------------------+

SELECT * FROM t WHERE a IN (1, 2, 3);
SELECT @@LAST_PLAN_FROM_BINDING;
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
+--------------------------+
```

Bindings created in TiDB clusters earlier than v7.4.0 might contain `IN (?)`. After the upgrade to v7.4.0 or a later version, these bindings will be modified to `IN (...)`.

For example:

```
-- Create a binding on v7.3.0
mysql> CREATE GLOBAL BINDING FOR SELECT * FROM t WHERE a IN (1)
    ↪  USING SELECT /*+ use_index(t, idx_a) */ * FROM t WHERE
    ↪ a IN (1);
mysql> SHOW GLOBAL BINDINGS;

+--
    ↪ ----------------------------------------------+----------------------------
    ↪
```

When a SQL statement has bound execution plans in both GLOBAL and SESSION scopes, because the optimizer ignores the bound execution plan in the GLOBAL scope when it encounters the SESSION binding, the bound execution plan of this statement in the SESSION scope shields the execution plan in the GLOBAL scope.

For example:

```
-- Creates a GLOBAL binding and specifies using `sort merge join` in this
   ↪ binding.
CREATE GLOBAL BINDING for
    SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
    SELECT /*+ merge_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- The execution plan of this SQL statement uses the `sort merge join`
   ↪ specified in the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Creates another SESSION binding and specifies using `hash join` in this
   ↪  binding.
CREATE BINDING for
    SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
    SELECT /*+ hash_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- In the execution plan of this statement, `hash join` specified in the
   ↪ SESSION binding is used, instead of `sort merge join` specified in
   ↪ the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;
```

When the first `SELECT` statement is being executed, the optimizer adds the `sm_join(` ↪ `t1, t2)` hint to the statement through the binding in the GLOBAL scope. The top node of the execution plan in the `explain` result is MergeJoin. When the second `SELECT` statement is being executed, the optimizer uses the binding in the SESSION scope instead of the binding in the GLOBAL scope and adds the `hash_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is HashJoin.

Each standardized SQL statement can have only one binding created using `CREATE` ↪ `BINDING` at a time. When multiple bindings are created for the same standardized SQL statement, the last created binding is retained, and all previous bindings (created and evolved) are marked as deleted. But session bindings and global bindings can coexist and are not affected by this logic.

In addition, when you create a binding, TiDB requires that the session is in a database context, which means that a database is specified when the client is connected or `use ${` ↪ `database}` is executed.

The original SQL statement and the bound statement must have the same text after

normalization and hint removal, or the binding will fail. Take the following examples:

- This binding can be created successfully because the texts before and after parameterization and hint removal are the same: `SELECT * FROM test . t WHERE a > ?`

```
CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM t
    ↪ use index (idx) WHERE a > 2
```

- This binding will fail because the original SQL statement is processed as `SELECT * ↪ FROM test . t WHERE a > ?`, while the bound SQL statement is processed differently as `SELECT * FROM test . t WHERE b > ?`.

```
CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM t
    ↪ use index(idx) WHERE b > 2
```

> **Note:**
>
> For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, you need to create execution plan bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

Create a binding according to a historical execution plan

To make the execution plan of a SQL statement fixed to a historical execution plan, you can use Plan Digest to bind that historical execution plan to the SQL statement, which is more convenient than binding it according to a SQL statement. In addition, you can bind the execution plan for multiple SQL statements at once. For more details and examples, see `CREATE [GLOBAL|SESSION] BINDING`.

When using this feature, note the following:

- The feature generates hints according to historical execution plans and uses the generated hints for binding. Because historical execution plans are stored in Statement Summary Tables, before using this feature, you need to enable the `tidb_enable_stmt ↪ _summary` system variable first.
- For TiFlash queries, Join queries with three or more tables, and queries that contain subqueries, the auto-generated hints are not adequate, which might result in the plan not being fully bound. In such cases, a warning will occur when creating a binding.
- If a historical execution plan is for a SQL statement with hints, the hints will be added to the binding. For example, after executing `SELECT /*+ max_execution_ ↪ time(1000)*/ * FROM t`, the binding created with its Plan Digest will include `max_execution_time(1000)`.

The SQL statement of this binding method is as follows:

```
CREATE [GLOBAL | SESSION] BINDING FROM HISTORY USING PLAN DIGEST
    ↪ StringLiteralOrUserVariableList;
```

The preceding statement binds an execution plan to a SQL statement using Plan Digest. The default scope is SESSION. The applicable SQL statements, priorities, scopes, and effective conditions of the created bindings are the same as that of bindings created according to SQL statements.

To use this binding method, you need to first get the Plan Digest corresponding to the target historical execution plan in `statements_summary`, and then create a binding using the Plan Digest. The detailed steps are as follows:

1. Get the Plan Digest corresponding to the target execution plan in `statements_summary`.

   For example:

   ```
   CREATE TABLE t(id INT PRIMARY KEY , a INT, KEY idx_a(a));
   SELECT /*+ IGNORE_INDEX(t, idx_a) */ * FROM t WHERE a = 1;
   SELECT * FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE QUERY_SAMPLE
       ↪ _TEXT = 'SELECT /*+ IGNORE_INDEX(t, idx_a) */ * FROM t WHERE a =
       ↪ 1'\G
   ```

   The following is a part of the example query result of `statements_summary`:

   ```
   SUMMARY_BEGIN_TIME: 2022-12-01 19:00:00
   ...........
        DIGEST_TEXT: select * from `t` where `a` = ?
   ...........
        PLAN_DIGEST: 4
           ↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb
           ↪
              PLAN: id                task      estRows operator info
                 ↪                      actRows execution info
                 ↪
                 ↪ memory    disk
                    TableReader_7    root      10     data:Selection_6
                       ↪                    0      time:4.05ms, loops:1,
                       ↪ cop_task: {num: 1, max: 598.6µs, proc_keys: 0,
                       ↪ rpc_num: 2, rpc_time: 609.8µs, copr_cache_hit_
                       ↪ ratio: 0.00, distsql_concurrency: 15} 176 Bytes
                       ↪  N/A
                     └─Selection_6     cop[tikv]  10     eq(test.t.a, 1)
                       ↪                    0      tikv_task:{time:560.8
                       ↪ µs, loops:0}
                       ↪
                       ↪ N/A        N/A
   ```

```
                    └─TableFullScan_5 cop[tikv] 10000 table:t, keep
                      ↪ order:false, stats:pseudo 0 tikv_task:{time
                      ↪ :560.8µs, loops:0}
                      ↪
                      ↪ N/A        N/A
    BINARY_PLAN: 6
       ↪ QOYCuQDCg1UYWJsZVJlYWRlcl83Ev8BCgtTZWxlY3Rpb25fNhKOAQoPBSJQRnVsbFNjYW5f
       ↪ /
       ↪ QSkAAQHwW4jDQDgCQAJKCwoJCgR0ZXN0EgF0Uh5rZWVwIG9yZGVyOmZhbHNlLCBzdGF0czpw
       ↪ ////CQMEAXgJCBD///8
       ↪ BIQFzCDhVQw19BAAkBX0QUg9lcSgBfCAudC5hLCAxKWrmYQAYHOi0gc6hBB1hJAFAAVIQZGF
       ↪ ////////////8BGAE=
```

In this example, you can see that the execution plan corresponding to Plan Digest is `4e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb`.

2. Use Plan Digest to create a binding:

```
CREATE BINDING FROM HISTORY USING PLAN DIGEST '4
   ↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb';
```

To verify whether the created binding takes effect, you can view bindings:

```
SHOW BINDINGS\G
```

```
*************************** 1. row ***************************
Original_sql: select * from `test` . `t` where `a` = ?
    Bind_sql: SELECT /*+ use_index(@`sel_1` `test`.`t` ) ignore_index(`t` `
       ↪ idx_a`)*/ * FROM `test`.`t` WHERE `a` = 1
       ..........
  Sql_digest: 6909
     ↪ a1bbce5f64ade0a532d7058dd77b6ad5d5068aee22a531304280de48349f
 Plan_digest:
1 row in set (0.01 sec)

ERROR:
No query specified
```

```
SELECT * FROM t WHERE a = 1;
SELECT @@LAST_PLAN_FROM_BINDING;
```

```
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
```

```
+--------------------------+
1 row in set (0.00 sec)
```

Remove a binding

You can remove a binding according to a SQL statement or SQL Digest.

Remove a binding according to a SQL statement

```
DROP [GLOBAL | SESSION] BINDING FOR BindableStmt;
```

This statement removes a specified execution plan binding at the GLOBAL or SESSION level. The default scope is SESSION.

Generally, the binding in the SESSION scope is mainly used for test or in special situations. For a binding to take effect in all TiDB processes, you need to use the GLOBAL binding. A created SESSION binding shields the corresponding GLOBAL binding until the end of the SESSION, even if the SESSION binding is dropped before the session closes. In this case, no binding takes effect and the plan is selected by the optimizer.

The following example is based on the example in create binding in which the SESSION binding shields the GLOBAL binding:

```
-- Drops the binding created in the SESSION scope.
drop session binding for SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Views the SQL execution plan again.
explain SELECT * FROM t1,t2 WHERE t1.id = t2.id;
```

In the example above, the dropped binding in the SESSION scope shields the corresponding binding in the GLOBAL scope. The optimizer does not add the `sm_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is not fixed to MergeJoin by this hint. Instead, the top node is independently selected by the optimizer according to the cost estimation.

Remove a binding according to SQL Digest

In addition to removing a binding according to a SQL statement, you can also remove a binding according to SQL Digest. For more details and examples, see DROP [GLOBAL| ↪ SESSION] BINDING.

```
DROP [GLOBAL | SESSION] BINDING FOR SQL DIGEST
    ↪ StringLiteralOrUserVariableList;
```

This statement removes an execution plan binding corresponding to SQL Digest at the GLOBAL or SESSION level. The default scope is SESSION. You can get the SQL Digest by viewing bindings.

Note:

Executing `DROP GLOBAL BINDING` drops the binding in the current tidb-server instance cache and changes the status of the corresponding row in the system table to 'deleted'. This statement does not directly delete the records in the system table, because other tidb-server instances need to read the 'deleted' status to drop the corresponding binding in their cache. For the records in these system tables with the status of 'deleted', at every 100 `bind-info-lease` (the default value is `3s`, and `300s` in total) interval, the background thread triggers an operation of reclaiming and clearing on the bindings of `update_time` before 10 `bind-info-lease` (to ensure that all tidb-server instances have read the 'deleted' status and updated the cache).

Change binding status

Change binding status according to a SQL statement

```
SET BINDING [ENABLED | DISABLED] FOR BindableStmt;
```

You can execute this statement to change the status of a binding. The default status is ENABLED. The effective scope is GLOBAL by default and cannot be modified.

When executing this statement, you can only change the status of a binding from `Disabled` to `Enabled` or from `Enabled` to `Disabled`. If no binding is available for status changes, a warning message is returned, saying `There are no bindings can be set the status. Please check the SQL text`. Note that a binding in `Disabled` status is not used by any query.

Change binding status according to `sql_digest`

In addition to changing the binding status according to a SQL statement, you can also change the binding status according to `sql_digest`:

```
SET BINDING [ENABLED | DISABLED] FOR SQL DIGEST 'sql_digest';
```

The binding status that can be changed by `sql_digest` and the effect is the same as those changed according to a SQL statement. If no binding is available for status changes, a warning message `can't find any binding for 'sql_digest'` is returned.

View bindings

```
SHOW [GLOBAL | SESSION] BINDINGS [ShowLikeOrWhere]
```

This statement outputs the execution plan bindings at the GLOBAL or SESSION level according to the order of binding update time from the latest to earliest. The default scope is SESSION. Currently `SHOW BINDINGS` outputs 11 columns, as shown below:

Column Name	Note
original_sql	Original SQL statement after parameterization
bind_sql	Bound SQL statement with hints
default_db	Default database
status	Status including `enabled` (replacing the `using` status from v6.0), `disabled`, `deleted`, `invalid`, `rejected`, and `pending` ↪ `verify`
create_time	Creating time
update_time	Updating time
charset	Character set
collation	Ordering rule

Column Name	Note
source	The way in which a binding is created, including `manual` (created according to a SQL statement), `history` (created according to a historical execution plan), `capture` (captured automatically by TiDB), and `evolve` (evolved automatically by TiDB)
sql_digest	Digest of a normalized SQL statement
plan_digest	Digest of an execution plan

Troubleshoot a binding

You can use either of the following methods to troubleshoot a binding:

- Use the system variable `last_plan_from_binding` to show whether the execution plan used by the last executed statement is from the binding.

```
-- Create a global binding
CREATE GLOBAL BINDING for
    SELECT * FROM t
USING
    SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

SELECT * FROM t;
SELECT @@[SESSION.]last_plan_from_binding;
```

```
+--------------------------+
| @@last_plan_from_binding |
+--------------------------+
|                        1 |
+--------------------------+
1 row in set (0.00 sec)
```

- Use the `explain format = 'verbose'` statement to view the query plan of a SQL statement. If the SQL statement uses a binding, you can run `show warnings` to check which binding is used in the SQL statement.

```
-- Create a global binding

CREATE GLOBAL BINDING for
    SELECT * FROM t
USING
    SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

-- Use explain format = 'verbose' to view the execution plan of a SQL
    ↪  statement

explain format = 'verbose' SELECT * FROM t;

-- Run `show warnings` to view the binding used in the query.

show warnings;
```

```
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
| Level | Code | Message
    ↪                                                                  |
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
| Note | 1105 | Using the bindSQL: SELECT /*+ USE_INDEX(`t` `idx_a`)*/
    ↪  * FROM `test`.`t` |
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

Cache bindings

Each TiDB instance has a least recently used (LRU) cache for bindings. The cache capacity is controlled by the system variable `tidb_mem_quota_binding_cache`. You can view bindings that are cached in the TiDB instance.

To view the cache status of bindings, run the `SHOW binding_cache status` statement. In this statement, the effective scope is GLOBAL by default and cannot be modified. This statement returns the number of available bindings in the cache, the total number of available bindings in the system, memory usage of all cached bindings, and the total memory for the cache.

```
SHOW binding_cache status;
```

```
+------------------+------------------+-------------+-------------+
| bindings_in_cache | bindings_in_table | memory_usage | memory_quota |
+------------------+------------------+-------------+-------------+
|                1 |                1 | 159 Bytes   | 64 MB       |
+------------------+------------------+-------------+-------------+
1 row in set (0.00 sec)
```

11.3.4.3.2 Utilize the statement summary table to obtain queries that need to be bound

Statement summary records recent SQL execution information, such as latency, execution times, and corresponding query plans. You can query statement summary tables to get qualified `plan_digest`, and then create bindings according to these historical execution plans.

The following example queries `SELECT` statements that have been executed more than 10 times in the past two weeks, and have multiple execution plans without SQL binding. It sorts the queries by the execution times, and binds the top 100 queries to their fastest plans.

```
WITH stmts AS (                                          -- Gets all
    ↪ information
  SELECT * FROM INFORMATION_SCHEMA.CLUSTER_STATEMENTS_SUMMARY
  UNION ALL
  SELECT * FROM INFORMATION_SCHEMA.CLUSTER_STATEMENTS_SUMMARY_HISTORY
),
best_plans AS (
  SELECT plan_digest, `digest`, avg_latency,
  CONCAT('create global binding from history using plan digest "', plan_
     ↪ digest, '"') as binding_stmt
  FROM stmts t1
  WHERE avg_latency = (SELECT min(avg_latency) FROM stmts t2 -- The plan
     ↪ with the lowest query latency
                       WHERE t2.`digest` = t1.`digest`)
)
```

```
SELECT any_value(digest_text) as query,
      SUM(exec_count) as exec_count,
      plan_hint, binding_stmt
FROM stmts, best_plans
WHERE stmts.`digest` = best_plans.`digest`
  AND summary_begin_time > DATE_SUB(NOW(), interval 14 day) -- Executed in
     ↪ the past 2 weeks
  AND stmt_type = 'Select'                                  -- Only consider
     ↪ select statements
  AND schema_name NOT IN ('INFORMATION_SCHEMA', 'mysql') -- Not an internal
     ↪  query
  AND plan_in_binding = 0                                   -- No binding yet
GROUP BY stmts.`digest`
  HAVING COUNT(DISTINCT(stmts.plan_digest)) > 1         -- This query is
     ↪ unstable. It has more than 1 plan.
        AND SUM(exec_count) > 10                            -- High-frequency,
           ↪ and has been executed more than 10 times.
ORDER BY SUM(exec_count) DESC LIMIT 100;                    -- Top 100 high-
   ↪ frequency queries.
```

By applying certain filtering conditions to obtain queries that meet the criteria, you can then directly execute the statements in the corresponding `binding_stmt` column to create bindings.

```
+-----------------------------------------------+------------+-----------------------------
   ↪
| query                                         | exec_count | plan_hint
   ↪                                                                  | binding_stmt
   ↪
   ↪ |
+-----------------------------------------------+------------+-----------------------------
   ↪
| select * from `t` where `a` = ? and `b` = ? | 401 | use_index(@`sel_1` `
   ↪ test`.`t` `a`), no_order_index(@`sel_1` `test`.`t` `a`) | create
   ↪ global binding from history using plan digest "0
   ↪ d6e97fb1191bbd08dddefa7bd007ec0c422b1416b152662768f43e64a9958a6" |
| select * from `t` where `b` = ? and `c` = ? | 104 | use_index(@`sel_1` `
   ↪ test`.`t` `b`), no_order_index(@`sel_1` `test`.`t` `b`) | create
   ↪ global binding from history using plan digest "80
   ↪ c2aa0aa7e6d3205755823aa8c6165092c8521fb74c06a9204b8d35fc037dd9" |
+-----------------------------------------------+------------+-----------------------------
   ↪
```

11.3.4.4.3.3 Cross-database binding

Starting from v7.6.0, you can create cross-database bindings in TiDB by using the wildcard * to represent a database name in the binding creation syntax. Before creating cross-database bindings, you need to first enable the tidb_opt_enable_fuzzy_binding system variable.

You can use cross-database bindings to simplify the process of fixing execution plans in scenarios where data is categorized and stored across different databases, and each database maintains identical object definitions and executes similar application logic. The following are some common use cases:

- When you run SaaS or PaaS services on TiDB, where the data of each tenant is stored in separate databases for easier data maintenance and management
- When you performed database sharding in a single instance and retained the original database schema after migrating to TiDB, that is, the data in the original instance is categorized and stored by database

In these scenarios, cross-database binding can effectively mitigate SQL performance issues caused by uneven distribution and rapid changes in user data and workload. SaaS providers can use cross-database bindings to fix execution plans validated by applications with large data volumes, thereby avoiding potential performance issues due to the rapid growth of applications with small data volumes.

To create a cross-database binding, you only need to use * to represent the database name when creating a binding. For example:

```
CREATE GLOBAL BINDING USING SELECT /*+ use_index(t, idx_a) */ * FROM t; --
    ↪  Create a GLOBAL scope standard binding.
CREATE GLOBAL BINDING USING SELECT /*+ use_index(t, idx_a) */ * FROM *.t;
    ↪ -- Create a GLOBAL scope cross-database binding.
SHOW GLOBAL BINDINGS;
```

The output is as follows:

```
+--
    ↪ -------------------------+-------------------------------------------------+-
    ↪
| Original_sql            | Bind_sql                                          |
    ↪ Default_db | Status | Create_time        | Update_time          |
    ↪ Charset | Collation    | Source | Sql_digest
    ↪                                              | Plan_digest |
+--
    ↪ -------------------------+-------------------------------------------------+-
    ↪
| select * from `test` . `t` | SELECT /*+ use_index(`t` `idx_a`)*/ * FROM `
    ↪ test`.`t` | test | enabled | 2023-12-29 14:19:01.332 | 2023-12-29
    ↪ 14:19:01.332 | utf8 | utf8_general_ci | manual | 8
    ↪ b193b00413fdb910d39073e0d494c96ebf24d1e30b131ecdd553883d0e29b42 | |
```

```
| select * from `*` . `t` | SELECT /*+ use_index(`t` `idx_a`)*/ * FROM
    ↪ `*`.`t` |     | enabled | 2023-12-29 14:19:02.232 | 2023-12-29
    ↪ 14:19:02.232 | utf8 | utf8_general_ci | manual | 8
    ↪ b193b00413fdb910d39073e0d494c96ebf24d1e30b131ecdd553883d0e29b42 | |
+--
    ↪ -------------------------+-----------------------------------------------+-
    ↪
```

In the `SHOW GLOBAL BINDINGS` output, the `Default_db` field value of a cross-database binding is empty, and the database name in the `Original_sql` and `Bind_sql` fields is represented as `*`. This binding applies to `select * from t` queries in all databases, not just in a specific database.

For the same query, both cross-database and standard bindings can coexist. TiDB matches bindings in the following order: SESSION scope standard bindings > SESSION scope cross-database bindings > GLOBAL scope standard bindings > GLOBAL scope cross-database bindings.

Apart from the creation syntax, cross-database bindings share the same deletion and status change syntax as standard bindings. The following is a detailed usage example.

1. Create databases `db1` and `db2`, and create two tables in each database:

```
CREATE DATABASE db1;
CREATE TABLE db1.t1 (a INT, KEY(a));
CREATE TABLE db1.t2 (a INT, KEY(a));
CREATE DATABASE db2;
CREATE TABLE db2.t1 (a INT, KEY(a));
CREATE TABLE db2.t2 (a INT, KEY(a));
```

2. Enable the cross-database binding feature:

```
SET tidb_opt_enable_fuzzy_binding=1;
```

3. Create a cross-database binding:

```
CREATE GLOBAL BINDING USING SELECT /*+ use_index(t1, idx_a), use_index
    ↪ (t2, idx_a) */ * FROM *.t1, *.t2;
```

4. Execute queries and verify whether the binding is used:

```
SELECT * FROM db1.t1, db1.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
```

```
+-------------------------+

SELECT * FROM db2.t1, db2.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+-------------------------+
| @@LAST_PLAN_FROM_BINDING |
+-------------------------+
|                       1 |
+-------------------------+

SELECT * FROM db1.t1, db2.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+-------------------------+
| @@LAST_PLAN_FROM_BINDING |
+-------------------------+
|                       1 |
+-------------------------+

USE db1;
SELECT * FROM t1, db2.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+-------------------------+
| @@LAST_PLAN_FROM_BINDING |
+-------------------------+
|                       1 |
+-------------------------+
```

5. View the binding:

```
SHOW GLOBAL BINDINGS;
+--
   ↪ ----------------------------------------+----------------------------
   ↪
| Original_sql                              | Bind_sql
   ↪
   ↪ | Default_db | Status | Create_time        | Update_time
   ↪          | Charset | Collation      | Source | Sql_digest
   ↪                                                | Plan_digest |
+--
   ↪ ----------------------------------------+----------------------------
   ↪
| select * from ( `*` . `t1` ) join `*` . `t2` | SELECT /*+ use_index
   ↪ (`t1` `idx_a`) use_index(`t2` `idx_a`)*/ * FROM (`*` . `t1`)
   ↪ JOIN `*` . `t2` | | enabled | 2023-12-29 14:22:28.144 |
   ↪ 2023-12-29 14:22:28.144 | utf8 | utf8_general_ci | manual |
```

```
    ↪ ea8720583e80644b58877663eafb3579700e5f918a748be222c5b741a696daf4
    ↪ | |
+--
    ↪ ----------------------------------------+-----------------------------
    ↪
```

6. Delete the cross-database binding:

```
DROP GLOBAL BINDING FOR SQL DIGEST '
    ↪ ea8720583e80644b58877663eafb3579700e5f918a748be222c5b741a696daf4'
    ↪ ;
SHOW GLOBAL BINDINGS;
Empty set (0.00 sec)
```

11.3.4.3.4 Baseline capturing

Used for preventing regression of execution plans during an upgrade, this feature captures queries that meet capturing conditions and creates bindings for these queries.

A plan baseline refers to a collection of accepted plans that the optimizer can use for executing a SQL statement. Generally, TiDB adds a plan into the plan baseline only after confirming that the plan performs well. A plan in this context encompasses all the necessary plan-related details (such as SQL plan identifier, hint set, bind values, and optimizer environment) that the optimizer requires to reproduce an execution plan.

Enable capturing

To enable baseline capturing, set `tidb_capture_plan_baselines` to `on`. The default value is `off`.

> **Note:**
>
> Because the automatic binding creation function relies on Statement Summary, make sure to enable Statement Summary before using automatic binding.

After automatic binding creation is enabled, the historical SQL statements in the Statement Summary are traversed every `bind-info-lease` (the default value is `3s`), and a binding is automatically created for SQL statements that appear at least twice. For these SQL statements, TiDB automatically binds the execution plan recorded in Statement Summary.

However, TiDB does not automatically capture bindings for the following types of SQL statements:

- `EXPLAIN` and `EXPLAIN ANALYZE` statements.
- SQL statements executed internally in TiDB, such as `SELECT` queries used for automatically loading statistical information.
- Statements that contain `Enabled` or `Disabled` bindings.
- Statements that are filtered out by capturing conditions.

> **Note:**
>
> Currently, a binding generates a group of hints to fix an execution plan generated by a query statement. In this way, for the same query, the execution plan does not change. For most OLTP queries, including queries using the same index or Join algorithm (such as HashJoin and IndexJoin), TiDB guarantees plan consistency before and after the binding. However, due to the limitations of hints, TiDB cannot guarantee plan consistency for some complex queries, such as Join of more than two tables, MPP queries, and complex OLAP queries.

For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, TiDB automatically captures bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

> **Note:**
>
> Because TiDB has some embedded SQL statements to ensure the correctness of some features, baseline capturing by default automatically shields these SQL statements.

Filter out bindings

This feature allows you to configure a blocklist to filter out queries whose bindings you do not want to capture. A blocklist has three dimensions, table name, frequency, and user name.

Usage

Insert filtering conditions into the system table `mysql.capture_plan_baselines_blacklist`. Then the filtering conditions take effect in the entire cluster immediately.

```
-- Filter by table name
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('table', 'test.t');
```

```
-- Filter by database name and table name through wildcards
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('table', 'test.table_*');
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('table', 'db_*.table_*');

-- Filter by frequency
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('frequency', '2');

-- Filter by user name
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('user', 'user1');
```

Dimension name	Description	Remarks
table	Filter by table name. Each filtering rule is in the `db.table` format. The supported filtering syntax includes Plain table names and Wildcards.	Case insensitive. If a table name contains illegal characters, the log returns a warning message `[sql-bind] failed to load mysql .capture_plan_baselines_ blacklist`.
frequency	Filter by frequency. SQL statements executed more than once are captured by default. You can set a high frequency to capture statements that are frequently executed.	Setting frequency to a value smaller than 1 is considered illegal, and the log returns a warning message `[sql-bind] frequency threshold is less than 1, ignore it`. If multiple frequency filter rules are inserted, the value with the highest frequency prevails.
user	Filter by user name. Statements executed by blocklisted users are not captured.	If multiple users execute the same statement and their user names are all in the blocklist, this statement is not captured.

Note:

- Modifying a blocklist requires the super privilege.
- If a blocklist contains illegal filters, TiDB returns the warning message `[sql-bind] unknown capture filter type, ignore it` in the log.

Prevent regression of execution plans during an upgrade

Before upgrading a TiDB cluster, you can use baseline capturing to prevent regression of execution plans by performing the following steps:

1. Enable baseline capturing and keep it working.

> **Note:**
> Test data shows that long-term working of baseline capturing has a slight impact on the performance of the cluster load. Therefore, it is recommended to enable baseline capturing as long as possible so that important plans (appear twice or above) are captured.

2. Upgrade the TiDB cluster. After the upgrade, TiDB uses those captured bindings to ensure execution plan consistency.
3. After the upgrade, delete bindings as required.

    - Check the binding source by running the `SHOW GLOBAL BINDINGS` statement.

      In the output, check the `Source` field to see whether a binding is captured (`capture`) or manually created (`manual`).
    - Determine whether to retain the captured bindings:

```
-- View the plan with the binding enabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = true;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;

-- View the plan with the binding disabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = false;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;
```

        - If the execution plan is consistent, you can delete the binding safely.
        - If the execution plan is inconsistent, you need to identify the cause, for example, by checking statistics. In this case, you need to retain the binding to ensure plan consistency.

11.3.4.3.5 Baseline evolution

Baseline evolution is an important feature of SPM introduced in TiDB v4.0.

As data updates, the previously bound execution plan might no longer be optimal. The baseline evolution feature can automatically optimize the bound execution plan.

In addition, baseline evolution, to a certain extent, can also avoid the jitter brought to the execution plan caused by the change of statistical information.

Usage

Use the following statement to enable automatic binding evolution:

```
SET GLOBAL tidb_evolve_plan_baselines = ON;
```

The default value of `tidb_evolve_plan_baselines` is `off`.

Warning:

- Baseline evolution is an experimental feature. Unknown risks might exist. It is **NOT** recommended that you use it in the production environment.
- This variable is forcibly set to `off` until the baseline evolution feature becomes generally available (GA). If you try to enable this feature, an error is returned. If you have already used this feature in a production environment, disable it as soon as possible. If you find that the binding status is not as expected, get support from PingCAP or the community.

After the automatic binding evolution feature is enabled, if the optimal execution plan selected by the optimizer is not among the binding execution plans, the optimizer marks the plan as an execution plan that waits for verification. At every `bind-info-lease` (the default value is `3s`) interval, an execution plan to be verified is selected and compared with the binding execution plan that has the least cost in terms of the actual execution time. If the plan to be verified has shorter execution time (the current criterion for the comparison is that the execution time of the plan to be verified is no longer than 2/3 that of the binding execution plan), this plan is marked as a usable binding. The following example describes the process above.

Assume that table `t` is defined as follows:

```
CREATE TABLE t(a INT, b INT, KEY(a), KEY(b));
```

Perform the following query on table `t`:

```
SELECT * FROM t WHERE a < 100 AND b < 100;
```

In the table defined above, few rows meet the `a < 100` condition. But for some reason, the optimizer mistakenly selects the full table scan instead of the optimal execution plan that uses index `a`. You can first use the following statement to create a binding:

```
CREATE GLOBAL BINDING for SELECT * FROM t WHERE a < 100 AND b < 100 USING
    ↪ SELECT * FROM t use index(a) WHERE a < 100 AND b < 100;
```

When the query above is executed again, the optimizer selects index `a` (influenced by the binding created above) to reduce the query time.

Assuming that as insertions and deletions are performed on table `t`, an increasing number of rows meet the `a < 100` condition and a decreasing number of rows meet the `b < 100` condition. At this time, using index `a` under the binding might no longer be the optimal plan.

The binding evolution can address this kind of issues. When the optimizer recognizes data change in a table, it generates an execution plan for the query that uses index `b`. However, because the binding of the current plan exists, this query plan is not adopted and executed. Instead, this plan is stored in the backend evolution list. During the evolution process, if this plan is verified to have an obviously shorter execution time than that of the current execution plan that uses index `a`, index `b` is added into the available binding list. After this, when the query is executed again, the optimizer first generates the execution plan that uses index `b` and makes sure that this plan is in the binding list. Then the optimizer adopts and executes this plan to reduce the query time after data changes.

To reduce the impact that the automatic evolution has on clusters, use the following configurations:

- Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is `600s`. In the actual verification process, the maximum execution time is also limited to no more than twice the time of the verified execution plan.
- Set `tidb_evolve_plan_task_start_time` (`00:00 +0000` by default) and `tidb_` ↪ `evolve_plan_task_end_time` (`23:59 +0000` by default) to limit the time window.

Notes

Because the baseline evolution automatically creates a new binding, when the query environment changes, the automatically created binding might have multiple behavior choices. Pay attention to the following notes:

- Baseline evolution only evolves standardized SQL statements that have at least one global binding.
- Because creating a new binding deletes all previous bindings (for a standardized SQL statement), the automatically evolved binding will be deleted after manually creating a new binding.
- All hints related to the calculation process are retained during the evolution. These hints are as follows:

Hint	Description
`memory_quota`	The maximum memory that can be used for a query.
`use_toja`	Whether the optimizer transforms sub-queries to Join.
`use_cascades`	Whether to use the cascades optimizer.
`no_index_merge`	Whether the optimizer uses Index Merge as an option for reading tables.
`read_consistent_replica`	Whether to forcibly enable Follower Read when reading tables.
`max_execution_time`	The longest duration for a query.

- `read_from_storage` is a special hint in that it specifies whether to read data from TiKV or from TiFlash when reading tables. Because TiDB provides isolation reads, when the isolation condition changes, this hint has a great influence on the evolved execution plan. Therefore, when this hint exists in the initially created binding, TiDB ignores all its evolved bindings.

11.3.4.3.6 Upgrade checklist

During cluster upgrade, SQL Plan Management (SPM) might cause compatibility issues and make the upgrade fail. To ensure a successful upgrade, you need to include the following list for upgrade precheck:

- When you upgrade from a version earlier than v5.2.0 (that is, v4.0, v5.0, and v5.1) to the current version, make sure that `tidb_evolve_plan_baselines` is disabled before the upgrade. To disable this variable, perform the following steps.

```
-- Check whether `tidb_evolve_plan_baselines` is disabled in the
   ↪ earlier version.
```

```
SELECT @@global.tidb_evolve_plan_baselines;

-- If `tidb_evolve_plan_baselines` is still enabled, disable it.

SET GLOBAL tidb_evolve_plan_baselines = OFF;
```

- Before you upgrade from v4.0 to the current version, you need to check whether the syntax of all queries corresponding to the available SQL bindings is correct in the new version. If any syntax errors exist, delete the corresponding SQL binding. To do that, perform the following steps.

```
-- Check the query corresponding to the available SQL binding in the
   ↪ version to be upgraded.

SELECT bind_sql FROM mysql.bind_info WHERE status = 'using';

-- Verify the result from the above SQL query in the test environment
   ↪  of the new version.

bind_sql_0;
bind_sql_1;
...

-- In the case of a syntax error (ERROR 1064 (42000): You have an
   ↪ error in your SQL syntax), delete the corresponding binding.
-- For any other errors (for example, tables are not found), it means
   ↪  that the syntax is compatible. No other operation is needed.
```

11.3.4.4 The Blocklist of Optimization Rules and Expression Pushdown

This document introduces how to use the blocklist of optimization rules and the blocklist of expression pushdown to control the behavior of TiDB.

11.3.4.4.1 The blocklist of optimization rules

The blocklist of optimization rules is one way to tune optimization rules, mainly used to manually disable some optimization rules.

Important optimization rules

Optimization Rule	Rule Name	Description
Column pruning	column_prune	One operator will prune the column if it is not needed by the upper executor.
Decorrelate subquery	decorrelate	Tries to rewrite the correlated subquery to non-correlated join or aggregation.

Optimization Rule	Rule Name	Description
Aggregation elimination	aggregation_eliminate	Tries to remove unnecessary aggregation operators from the execution plan.
Projection elimination	projection_eliminate	Removes unnecessary projection operators from the execution plan.

Optimization Rule	Rule Name	Description
Max/Min elimination	max_min_eliminate	Rewrites some max/min functions in aggregation to the `order by + limit 1` form.
Predicate push-down	predicate_push_down	Tries to push predicates down to the operator that is closer to the data source.

Optimization Rule	Rule Name	Description
Outer join elimination	outer_join_eliminate	Tries to remove the unnecessary left join or right join from the execution plan.

Optimization Rule	Rule Name	Description
Partition pruning	partition_processor	Prunes partitions which are rejected by the predicates and rewrite partitioned table query to the `UnionAll` ↪ ↪ `+` ↪ ↪ `Partition` ↪ ↪ `Datasource` ↪ form.
Aggregation push-down	aggregation_push_down	Tries to push aggregations down to their children.

Optimization Rule	Rule Name	Description
TopN push-down	topn_push_down	Tries to push the TopN operator to the place closer to the data source.
Join reorder	join_reorder	Decides the order of multi-table joins.
Derive TopN or Limit from window functions	derive_topn_from_window	Derives the TopN or Limit operator from window functions.

Disable optimization rules

You can use the blocklist of optimization rules to disable some of them if some rules lead to a sub-optimal execution plan for special queries.

Usage

Note:

All the following operations need the `super privilege` privilege of the database. Each optimization rule has a name. For example, the name of column pruning is `column_prune`. The names of all optimization rules can be found in the second column of the table Important Optimization Rules.

- If you want to disable some rules, write its name to the `mysql.opt_rule_blacklist` table. For example:

```
INSERT INTO mysql.opt_rule_blacklist VALUES("join_reorder"), ("topn_
    ↪ push_down");
```

Executing the following SQL statement can make the above operation take effect immediately. The effective range includes all old connections of the corresponding TiDB server:

```
admin reload opt_rule_blacklist;
```

Note:

`admin reload opt_rule_blacklist` only takes effect on the TiDB server where the above statement has been run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

- If you want to re-enable a rule, delete the corresponding data in the table, and then run the `admin reload` statement:

```
DELETE FROM mysql.opt_rule_blacklist WHERE name IN ("join_reorder", "
    ↪ topn_push_down");
```

```
admin reload opt_rule_blacklist;
```

11.3.4.4.2 The blocklist of expression pushdown

The blocklist of expression pushdown is one way to tune the expression pushdown, mainly used to manually disable some expressions of some specific data types.

Expressions that are supported to be pushed down

For more information about the expressions that are supported to be pushed down, see Supported expressions for pushdown to TiKV.

Disable the pushdown of specific expressions

When you get wrong results due to the expression pushdown, you can use the blocklist to make a quick recovery for the application. More specifically, you can add some of the supported functions or operators to the `mysql.expr_pushdown_blacklist` table to disable the pushdown of specific expressions.

The schema of `mysql.expr_pushdown_blacklist` is shown as follows:

```
DESC mysql.expr_pushdown_blacklist;
```

```
+------------+-------------+------+------+-------------------+-------+
| Field      | Type        | Null | Key | Default           | Extra |
+------------+-------------+------+------+-------------------+-------+
| name       | char(100)   | NO   |     | NULL              |       |
| store_type | char(100)  | NO   |     | tikv,tiflash,tidb |     |
| reason     | varchar(200) | YES |     | NULL              |       |
+------------+-------------+------+------+-------------------+-------+
3 rows in set (0.00 sec)
```

Here is the description of each field above:

- `name`: The name of the function that is disabled to be pushed down.
- `store_type`: To specify the component that you want to prevent the function from being pushed down to for computing. Available components are `tidb`, `tikv`, and `tiflash`. The `store_type` is case-insensitive. If you need to specify multiple components, use a comma to separate each component.
    - When `store_type` is `tidb`, it indicates whether the function can be executed in other TiDB servers while the TiDB memory table is being read.
    - When `store_type` is `tikv`, it indicates whether the function can be executed in TiKV server's Coprocessor component.
    - When `store_type` is `tiflash`, it indicates whether the function can be executed in TiFlash Server's Coprocessor component.
- `reason`: To record the reason why this function is added to the blocklist.

Usage

This section describes how to use the blocklist of expression pushdown.

Add to the blocklist

To add one or more expressions (functions or operators) to the blocklist, perform the following steps:

1. Insert the corresponding function name or operator name, and the set of components you want to disable the pushdown, to the `mysql.expr_pushdown_blacklist` table.

2. Execute `admin reload expr_pushdown_blacklist`.

Remove from the blocklist

To remove one or more expressions from the blocklist, perform the following steps:

1. Delete the corresponding function name or operator name, and the set of components you want to disable the pushdown, from the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

> **Note:**
>
> `admin reload expr_pushdown_blacklist` only takes effect on the TiDB server where this statement is run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

11.3.4.4.3 Expression blocklist usage example

In the following example, the `<` and `>` operators are added to the blocklist, and then the `>` operator is removed from the blocklist.

To judge whether the blocklist takes effect, observe the results of `EXPLAIN` (See TiDB Query Execution Plan Overview).

1. The predicates `a < 2` and `a > 2` in the `WHERE` clause of the following SQL statement can be pushed down to TiKV.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
   ↪ ----------------------+----------+-----------+---------------+-----------
   ↪
| id                    | estRows | task    | access object | operator
   ↪ info                |
+--
   ↪ ----------------------+----------+-----------+---------------+-----------
   ↪
| TableReader_7         | 0.00    | root    |               | data:
   ↪ Selection_6                |
| └─Selection_6         | 0.00    | cop[tikv] |             | gt(ssb_1.t.
   ↪ a, 2), lt(ssb_1.t.a, 2) |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo |
```

```
+--
    ↪ ----------------------+----------+-----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

2. Insert the expression to the `mysql.expr_pushdown_blacklist` table and execute `admin reload expr_pushdown_blacklist`.

```
INSERT INTO mysql.expr_pushdown_blacklist VALUES('<','tikv',''), ('>',
    ↪ 'tikv','');
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

3. Observe the execution plan again and you will find that both the `<` and `>` operators are not pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 and a > 2;
```

```
+--
    ↪ ----------------------+----------+-----------+---------------+-----------
    ↪
| id                    | estRows | task      | access object | operator
    ↪ info                |
+--
    ↪ ----------------------+----------+-----------+---------------+-----------
    ↪
| Selection_7           | 10000.00 | root      |               | gt(ssb_1.t.a
    ↪ , 2), lt(ssb_1.t.a, 2) |
| └─TableReader_6       | 10000.00 | root      |               | data:
    ↪ TableFullScan_5           |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t       | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

4. Remove one expression (here is `>`) from the blocklist and execute `admin reload expr_pushdown_blacklist`.

```
DELETE FROM mysql.expr_pushdown_blacklist WHERE name = '>';
```

```
Query OK, 1 row affected (0.01 sec)
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

5. Observe the execution plan again and you will find that < is not pushed down while > is pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
| id                        | estRows | task      | access object | operator
   ↪  info            |
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
| Selection_8               | 0.00     | root      |               | lt(ssb_1.t
   ↪ .a, 2)           |
| └─TableReader_7           | 0.00     | root      |               | data:
   ↪ Selection_6           |
|   └─Selection_6           | 0.00     | cop[tikv] |               | gt(ssb_1.
   ↪ t.a, 2)           |
|     └─TableFullScan_5     | 10000.00 | cop[tikv] | table:t       | keep
   ↪ order:false, stats:pseudo |
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
4 rows in set (0.00 sec)
```

11.3.4.5 Optimizer Fix Controls

As the product evolves iteratively, the behavior of the TiDB optimizer changes, which in turn generates more reasonable execution plans. However, in some particular scenarios, the new behavior might lead to unexpected results. For example:

- The effect of some behaviors relies on a specific scenario. Changes that bring improvements to most scenarios might cause regressions to others.

- Sometimes, the relationship between changes in the behavior details and their consequences is very complicated. An improvement in a certain behavior might cause overall regression.

Therefore, TiDB provides the Optimizer Fix Controls feature that allows you to make fine-grained control of TiDB optimizer behaviors by setting values for a group of fixes. This document describes the Optimizer Fix Controls feature and how to use them, and lists all the fixes that TiDB currently supports for Optimizer Fix Controls.

11.3.4.5.1 Introduction to `tidb_opt_fix_control`

Starting from v6.5.3 and v7.1.0, TiDB provides the `tidb_opt_fix_control` system variable to control the behavior of the optimizer in a more fine-grained way.

Each fix is a control item used to adjust the behavior in the TiDB optimizer for one particular purpose. It is denoted by a number that corresponds to a GitHub Issue that contains the technical details of the behavior change. For example, for fix `44262`, you can review what it controls in Issue 44262.

The `tidb_opt_fix_control` system variable accepts multiple fixes as one value, separated by commas (`,`). The format is `"<#issue1>:<value1>,<#issue2>:<value2>,...,<#issueN>:<valueN>"`, where `<#issueN>` is the fix number. For example:

```
SET SESSION tidb_opt_fix_control = '44262:ON,44389:ON';
```

11.3.4.5.2 Optimizer Fix Controls reference

33031 New in v8.0.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to allow plan cache for partitioned tables. If it is set to `ON`, neither Prepared statement plan cache nor Non-prepared statement plan cache will be enabled for partitioned tables.

44262 New in v6.5.3 and v7.2.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to allow the use of Dynamic pruning mode to access the partitioned table when the GlobalStats are missing.

44389 New in v6.5.3 and v7.2.0

- Default value: `OFF`

- Possible values: `ON`, `OFF`
- For filters such as `c = 10 and (a = 'xx' or (a = 'kk' and b = 1))`, this variable controls whether to try to build more comprehensive scan ranges for `IndexRangeScan`.

44823 New in v7.3.0

- Default value: `200`
- Possible values: `[0, 2147483647]`
- To save memory, Plan Cache does not cache queries with parameters exceeding the specified number of this variable. `0` means no limit.

44830 New in v6.5.7 and v7.3.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether Plan Cache is allowed to cache execution plans with the `PointGet` operator generated during physical optimization.

44855 New in v6.5.4 and v7.3.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- In some scenarios, when the `Probe` side of an `IndexJoin` operator contains a `Selection` operator, TiDB severely overestimates the row count of `IndexScan`. This might cause suboptimal query plans to be selected instead of `IndexJoin`.
- To mitigate this issue, TiDB has introduced an improvement. However, due to potential query plan fallback risks, this improvement is disabled by default.
- This variable controls whether to enable the preceding improvement.

45132 New in v7.4.0

- Default value: `1000`
- Possible values: `[0, 2147483647]`
- This variable sets the threshold for the optimizer's heuristic strategy to select access paths. If the estimated rows for an access path (such as `Index_A`) is much smaller than that of other access paths (default `1000` times), the optimizer skips the cost comparison and directly selects `Index_A`.
- `0` means to disable this heuristic strategy.

45798 New in v7.5.0

- Default value: `ON`

- Possible values: `ON`, `OFF`
- This variable controls whether Plan Cache is allowed to cache execution plans that access generated columns.

46177 New in v6.5.6, v7.1.3 and v7.5.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether the optimizer explores enforced plans during query optimization after finding an unenforced plan.

47400 New in v8.4.0

- Default value: `ON`
- Possible values: `ON`, `OFF`
- Due to challenges in accurately estimating the number of qualified rows for each plan step in a query plan, the optimizer might estimate a smaller value for `estRows`. This variable controls whether to limit the minimum value of `estRows`.
- `ON`: limits the minimum value of `estRows` to 1, which is the new behavior introduced in v8.4.0 and is consistent with other databases, such as Oracle and DB2.
- `OFF`: disables the minimum row estimate limit, which maintains the behavior consistent with versions before v8.4.0. In this case, `estRows` might be zero.

52592 New in v8.4.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to disable the `Point Get` and `Batch Point Get` operators for query execution. The default value `OFF` means that `Point Get` and `Batch Point Get` can be used for query execution. If set to `ON`, the optimizer disables `Point Get` and `Batch Point Get`, forcing the selection of Coprocessor for query execution.
- `Point Get` and `Batch Point Get` do not support column projection (that is, they cannot return only a subset of the columns), so in some scenarios, their execution efficiency might be lower than that of the Coprocessor, and setting this variable to `ON` can improve query performance. The following are recommended scenarios for setting this variable to `ON`:
    - Wide tables with many columns, where only a few columns are queried.
    - Tables with large JSON values, where the JSON column is not queried, or only a small portion of the JSON column is queried.

52869 New in v8.1.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- As stated in the **Note** of Explain Statements Using Index Merge, if the optimizer can choose the single index scan method (other than full table scan) for a query plan, the optimizer will not automatically use index merge.
- You can remove this limitation by enabling this fix control. Removing this limitation enables the optimizer to choose index merge automatically in more queries, but might cause the optimizer to ignore the optimal execution plans. Therefore, it is recommended to conduct sufficient tests on actual use cases before removing this limitation to make sure that it will not cause performance regressions.

54337 New in v8.3.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- Currently, the TiDB optimizer has limitations in deriving index ranges for complex conjunctive conditions where each conjunct comprises a list of ranges. This can be addressed by applying general range intersection.
- You can remove this limitation by enabling this fix control, allowing the optimizer to handle complex range intersections. However, for conditions with a large number of conjuncts (more than 10), there is a slight risk of increased optimization time.

12 Tutorials

12.1 Multiple Availability Zones in One Region Deployment

As a distributed SQL database, TiDB combines the best features of the traditional relational database and the scalability of the NoSQL database, and is highly available across availability zones (AZs). This document introduces the deployment of multiple AZs in one region.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.1.1 Raft protocol

Raft is a distributed consensus algorithm. Using this algorithm, both PD and TiKV, among components of the TiDB cluster, achieve disaster recovery of data, which is implemented through the following mechanisms:

- The essential role of Raft members is to perform log replication and act as a state machine. Among Raft members, data replication is implemented by replicating logs. Raft members change their own states in different conditions to elect a leader to provide services.
- Raft is a voting system that follows the majority protocol. In a Raft group, if a member gets the majority of votes, its membership changes to leader. In other words, when the majority of nodes remain in the Raft group, a leader can be elected to provide services.

To take advantage of Raft's reliability, the following conditions must be met in a real deployment scenario:

- Use at least three servers in case one server fails.
- Use at least three racks in case one rack fails.
- Use at least three AZs in case one AZ fails.
- Deploy TiDB in at least three regions in case data safety issue occurs in one region.

The native Raft protocol does not have good support for an even number of replicas. Considering the impact of cross-region network latency, three AZs in the same region might be the most suitable solution to a highly available and disaster tolerant Raft deployment.

12.1.2 Three AZs in one region deployment

TiDB clusters can be deployed in three AZs in the same region. In this solution, data replication across the three AZs is implemented using the Raft protocol within the cluster. These three AZs can provide read and write services at the same time. Data consistency is not affected even if one AZ fails.

12.1.2.1 Simple architecture

TiDB, TiKV, and PD are distributed among three AZs, which is the most common deployment with the highest availability.

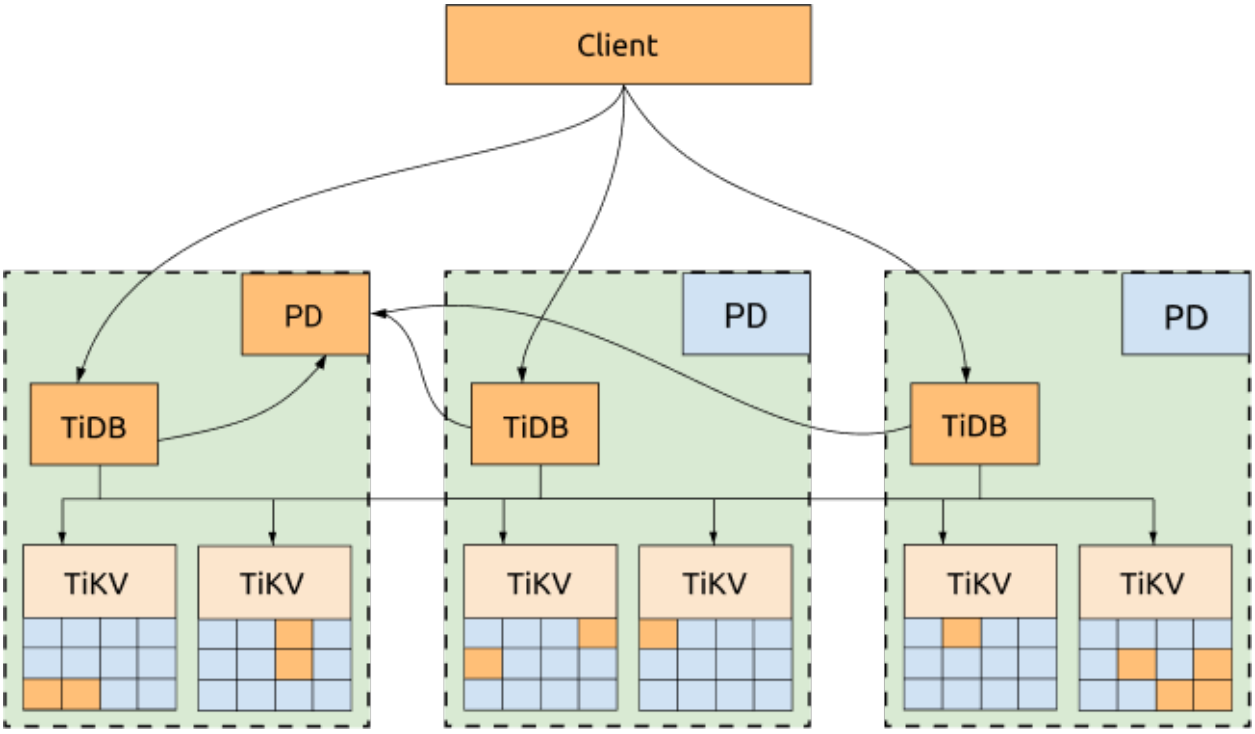

Figure 412: 3-AZ Deployment Architecture

Advantages:

- All replicas are distributed among three AZs, with high availability and disaster recovery capability.
- No data will be lost if one AZ is down (RPO = 0).
- Even if one AZ is down, the other two AZs will automatically start leader election and automatically resume services within a certain period (within 20 seconds in most cases). See the following diagram for more information:

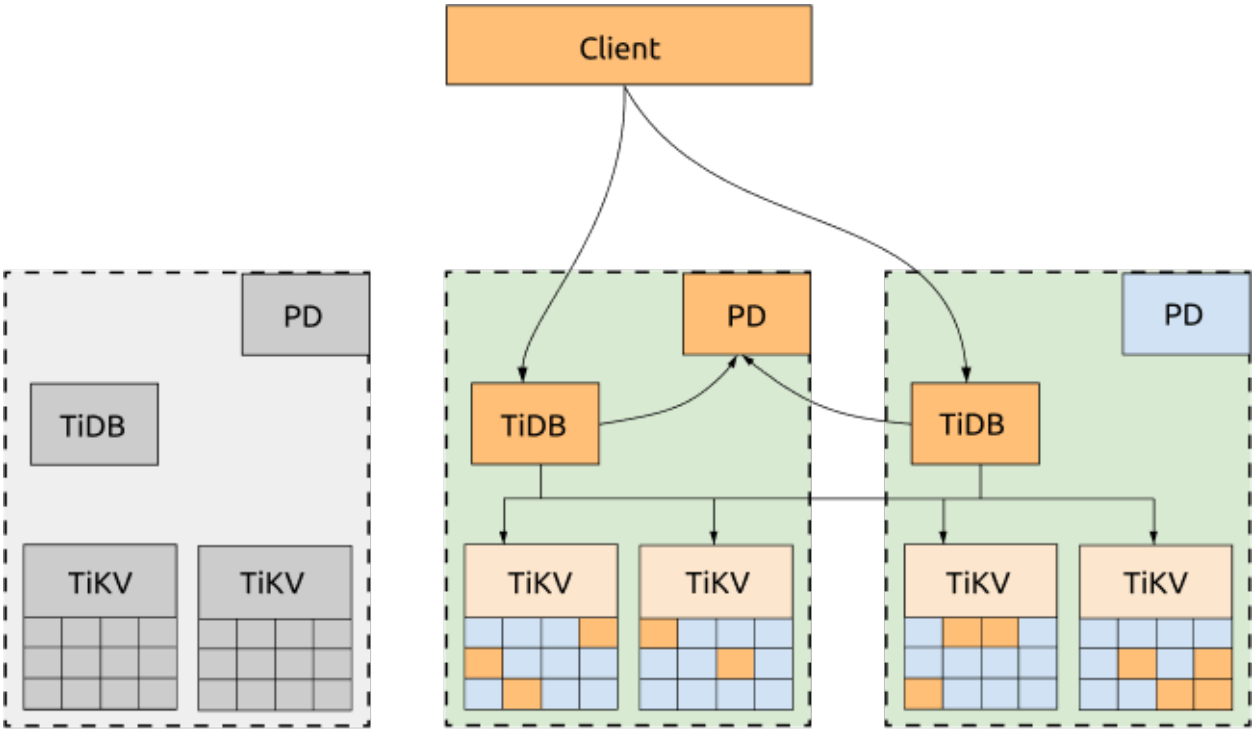

Figure 413: Disaster Recovery for 3-AZ Deployment

Disadvantages:

The performance can be affected by the network latency.

- For writes, all the data has to be replicated to at least two AZs. Because TiDB uses a two-phase commit for writes, the write latency is at least twice the latency of the network between two AZs.
- The read performance will also be affected by the network latency if the leader is not in the same AZ with the TiDB node that sends the read request.
- Each TiDB transaction needs to obtain TimeStamp Oracle (TSO) from the PD leader. So if the TiDB and PD leaders are not in the same AZ, the performance of the transactions will also be affected by the network latency because each transaction with the write request has to obtain TSO twice.

12.1.2.2 Optimized architecture

If not all of the three AZs need to provide services to the applications, you can dispatch all the requests to one AZ and configure the scheduling policy to migrate the TiKV Region leader and PD leader to the same AZ. In this way, neither obtaining TSO nor reading TiKV Regions will be impacted by the network latency across AZs. If this AZ is down, the PD leader and TiKV Region leader will be automatically elected in other surviving AZs, and you just need to switch the requests to the AZs that are still alive.

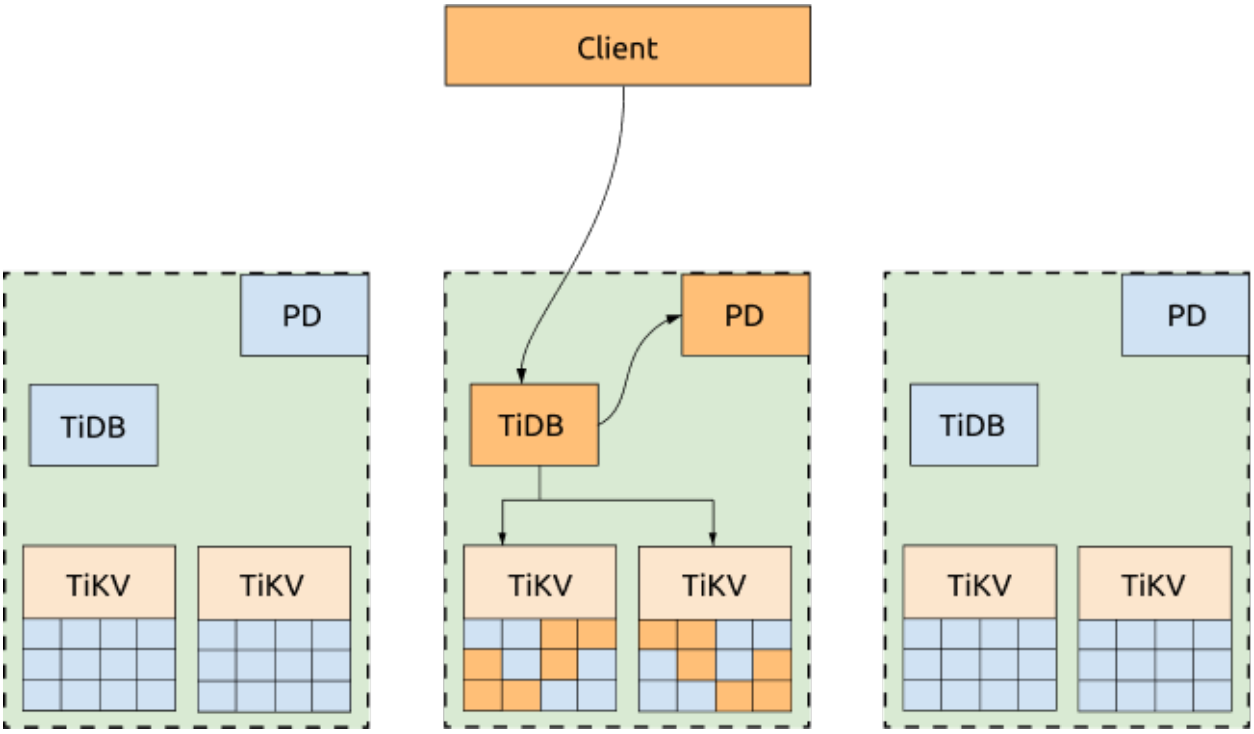

Figure 414: Read Performance Optimized 3-AZ Deployment

Advantages:

The cluster's read performance and the capability to get TSO are improved. A configuration template of scheduling policy is as follows:

```
-- Evicts all leaders of other AZs to the AZ that provides services to the
   ↪ application.
config set label-property reject-leader LabelName labelValue

-- Migrates PD leaders and sets priority.
member leader transfer pdName1
member leader_priority pdName1 5
member leader_priority pdName2 4
member leader_priority pdName3 3
```

Note:

Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

Disadvantages:

- Write scenarios are still affected by network latency across AZs. This is because Raft follows the majority protocol and all written data must be replicated to at least two AZs.
- The TiDB server that provides services is only in one AZ.
- All application traffic is processed by one AZ and the performance is limited by the network bandwidth pressure of that AZ.
- The capability to get TSO and the read performance are affected by whether the PD server and TiKV server are up in the AZ that processes application traffic. If these servers are down, the application is still affected by the cross-center network latency.

12.1.2.3 Deployment example

This section provides a topology example, and introduces TiKV labels and TiKV labels planning.

12.1.2.3.1 Topology example

The following example assumes that three AZs (AZ1, AZ2, and AZ3) are located in one region; each AZ has two sets of racks and each rack has three servers. The example ignores the hybrid deployment or the scenario where multiple instances are deployed on one machine. The deployment of a TiDB cluster (three replicas) on three AZs in one region is as follows:

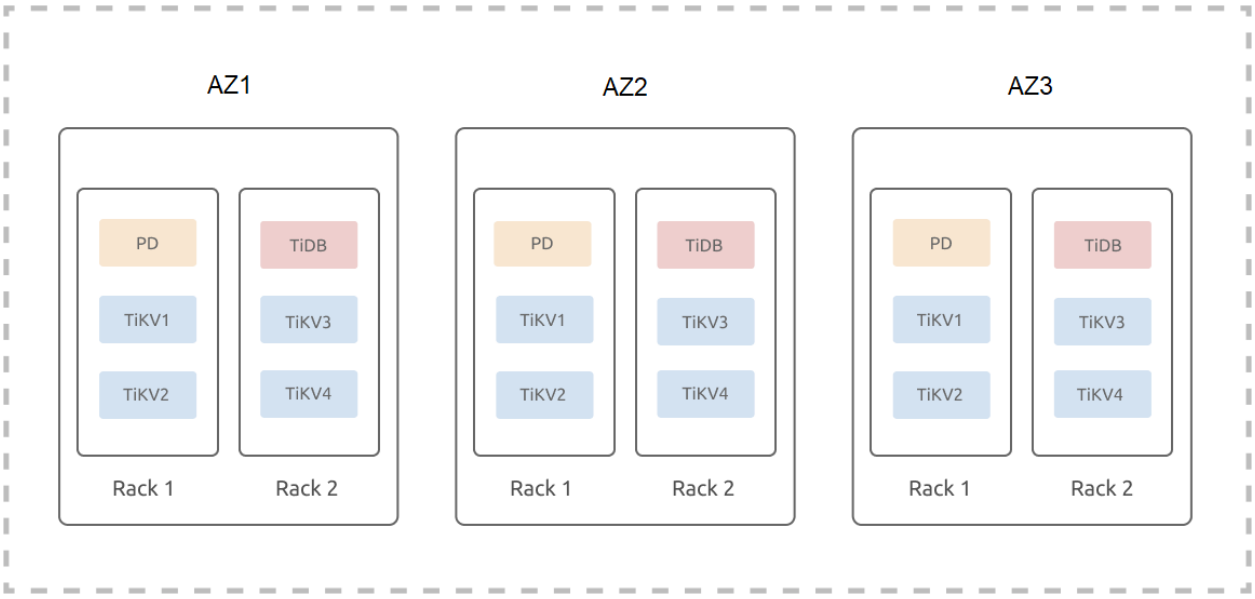

Figure 415: 3-AZ in One Region

12.1.2.3.2 TiKV labels

TiKV is a Multi-Raft system where data is divided into Regions and the size of each Region is 96 MB by default. Three replicas of each Region form a Raft group. For a TiDB cluster of three replicas, because the number of Region replicas is independent of the TiKV instance numbers, three replicas of a Region are only scheduled to three TiKV instances. This means that even if the cluster is scaled out to have N TiKV instances, it is still a cluster of three replicas.

Because a Raft group of three replicas tolerates only one replica failure, even if the cluster is scaled out to have N TiKV instances, this cluster still tolerates only one replica failure. Two failed TiKV instances might cause some Regions to lose replicas and the data in this cluster is no longer complete. SQL requests that access data from these Regions will fail. The probability of two simultaneous failures among N TiKV instances is much higher than the probability of two simultaneous failures among three TiKV instances. This means that the more TiKV instances the Multi-Raft system is scaled out to have, the less the availability of the system.

Because of the preceding limitation, `label` is used to describe the location information of TiKV. The label information is refreshed to the TiKV startup configuration file with deployment or rolling upgrade operations. The started TiKV reports its latest label information to PD. Based on the user-registered label name (the label metadata) and the TiKV topology, PD optimally schedules Region replicas and improves the system availability.

12.1.2.3.3 TiKV labels planning example

To improve the availability and disaster recovery of the system, you need to design and plan TiKV labels according to your existing physical resources and the disaster recovery capability. You also need to edit the cluster initialization configuration file according to the planned topology:

```
server_configs:
  pd:
    replication.location-labels: ["zone","az","rack","host"]

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r1", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r2", host: "32" }
  - host: 10.63.10.33
    config:
```

```
    server.labels: { zone: "z1", az: "az1", rack: "r2", host: "33" }

- host: 10.63.10.34
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r1", host: "34" }
- host: 10.63.10.35
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r1", host: "35" }
- host: 10.63.10.36
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r2", host: "36" }
- host: 10.63.10.37
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r2", host: "37" }

- host: 10.63.10.38
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r1", host: "38" }
- host: 10.63.10.39
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r1", host: "39" }
- host: 10.63.10.40
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r2", host: "40" }
- host: 10.63.10.41
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r2", host: "41" }
```

In the preceding example, `zone` is the logical availability zone layer that controls the isolation of replicas (three replicas in the example cluster).

Considering that the AZs might be scaled out in the future, the three-layer label structure (`az`, `rack`, and `host`) is not directly adopted. Assuming that `AZ2`, `AZ3`, and `AZ4` are to be scaled out, you only need to scale out the AZs in the corresponding availability zone and scale out the racks in the corresponding AZ.

If this three-layer label structure is directly adopted, after scaling out an AZ, you might need to apply new labels and the data in TiKV needs to be rebalanced.

12.1.2.4 High availability and disaster recovery analysis

The multiple AZs in one region deployment can guarantee that if one AZ fails, the cluster can automatically recover services without manual intervention. Data consistency is also guaranteed. Note that scheduling policies are used to optimize performance, but when a failure occurs, these policies prioritize availability over performance.

12.2 Three Availability Zones in Two Regions Deployment

This document introduces the architecture and configuration of the three availability zones (AZs) in two regions deployment.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.2.1 Overview

The architecture of three AZs in two regions is a highly available and disaster tolerant deployment solution that provides a production data AZ, a disaster recovery AZ in the same region, and a disaster recovery AZ in another region. In this mode, the three AZs in two regions are interconnected. If one AZ fails or suffers from a disaster, other AZs can still operate well and take over the key applications or all applications. Compared with the multi-AZ in one region deployment, this solution has the advantage of cross-region high availability and can survive region-level natural disasters.

The distributed database TiDB natively supports the three-AZ-in-two-region architecture by using the Raft algorithm, and guarantees the consistency and high availability of data within a database cluster. Because the network latency across AZs in the same region is relatively low, the application traffic can be dispatched to two AZs in the same region, and the traffic load can be shared by these two AZs by controlling the distribution of TiKV Region leaders and PD leaders.

12.2.2 Deployment architecture

This section takes the example of Seattle and San Francisco to explain the deployment mode of three AZs in two regions for the distributed database of TiDB.

In this example, two AZs (AZ1 and AZ2) are located in Seattle and another AZ (AZ3) is located in San Francisco. The network latency between AZ1 and AZ2 is lower than 3 milliseconds. The network latency between AZ3 and AZ1/AZ2 in Seattle is about 20 milliseconds (ISP dedicated network is used).

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to three AZs in two regions: AZ1 in Seattle, AZ2 in Seattle, and AZ3 in San Francisco.
- The cluster has five replicas, two in AZ1, two in AZ2, and one in AZ3. For the TiKV component, each rack has a label, which means that each rack has a replica.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

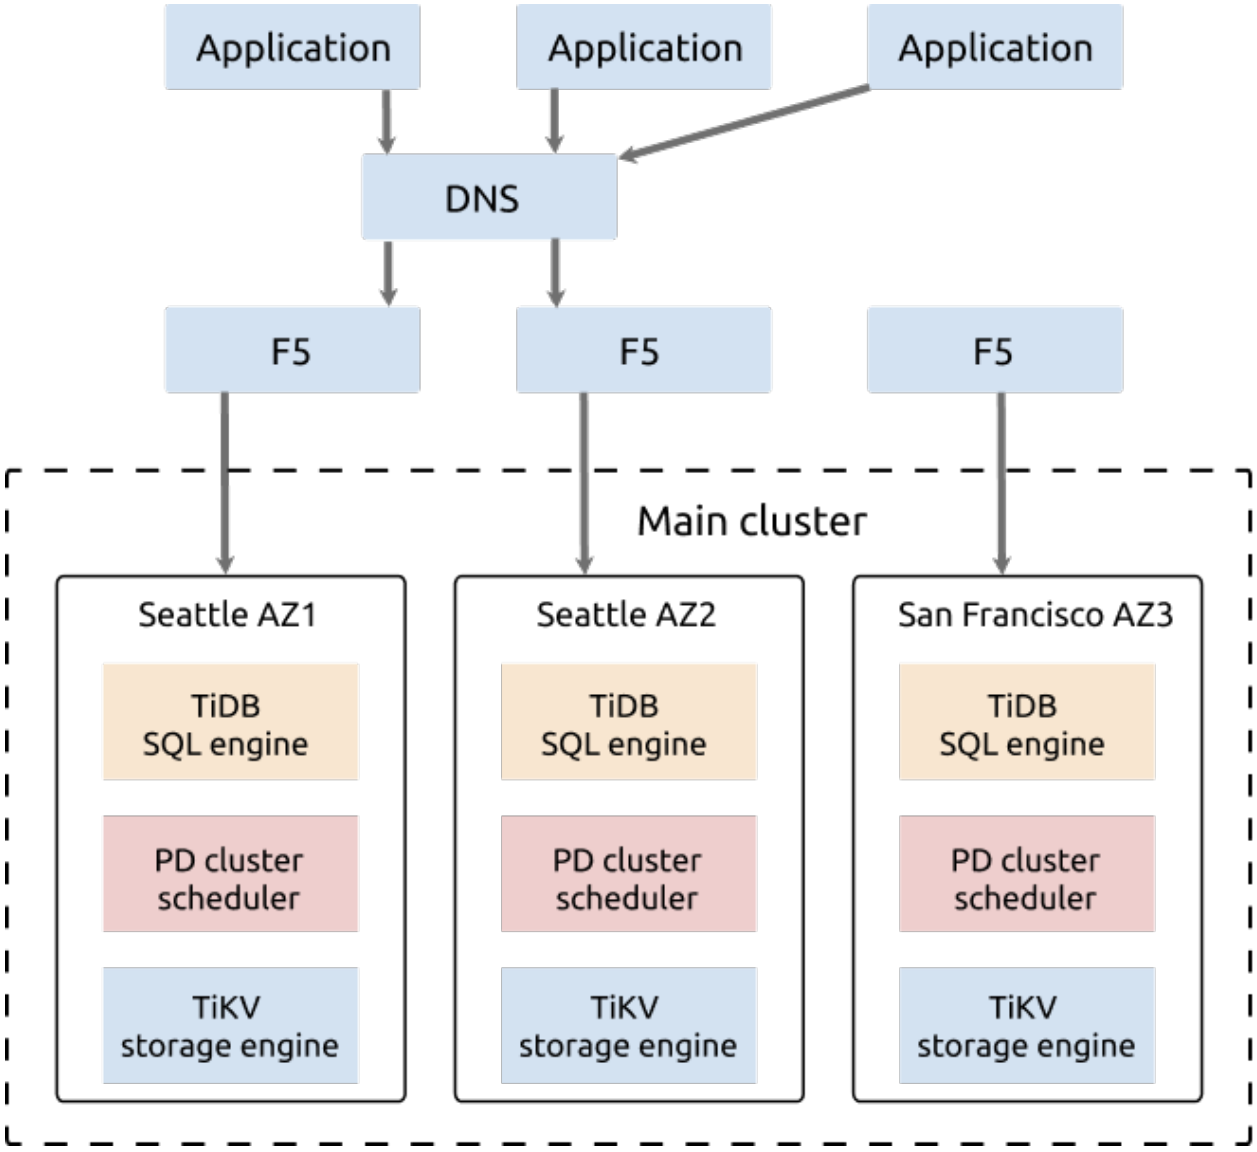

Figure 416: 3-AZ-in-2-region architecture

This architecture is highly available. The distribution of Region leaders is restricted to the two AZs (AZ1 and AZ2) that are in the same region (Seattle). Compared with the three-AZ solution in which the distribution of Region leaders is not restricted, this architecture has the following advantages and disadvantages:

- **Advantages**
  - Region leaders are in AZs of the same region with low latency, so the write is faster.
  - The two AZs can provide services at the same time, so the resource usage rate is higher.

- If one AZ fails, services are still available and data safety is ensured.

- **Disadvantages**

  - Because the data consistency is achieved by the Raft algorithm, when two AZs in the same region fail at the same time, only one surviving replica remains in the disaster recovery AZ in another region (San Francisco). This cannot meet the requirement of the Raft algorithm that most replicas survive. As a result, the cluster can be temporarily unavailable. Maintenance staff needs to recover the cluster from the one surviving replica and a small amount of hot data that has not been replicated will be lost. But this case is a rare occurrence.
  - Because the ISP dedicated network is used, the network infrastructure of this architecture has a high cost.
  - Five replicas are configured in three AZs in two regions, data redundancy increases, which brings a higher storage cost.

12.2.2.1 Deployment details

The configuration of the three AZs in two regions (Seattle and San Francisco) deployment plan is illustrated as follows:

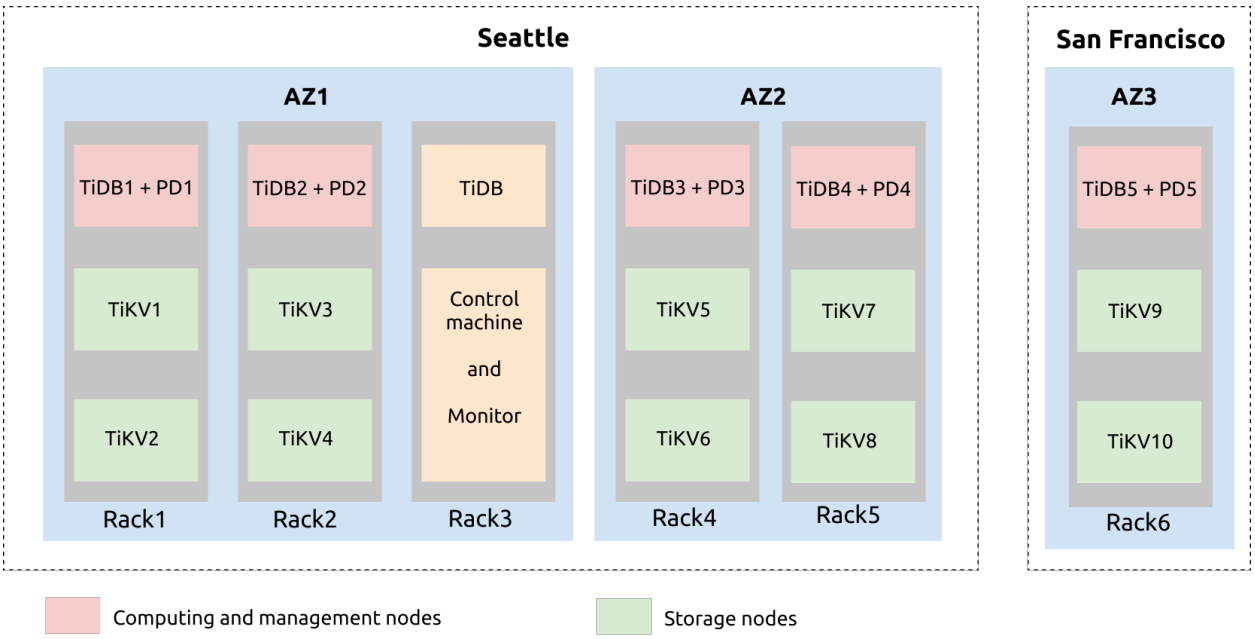

Figure 417: 3-AZ-2-region

From the preceding illustration, you can see that Seattle has two AZs: AZ1 and AZ2. AZ1 has three sets of racks: rac1, rac2, and rac3. AZ2 has two racks: rac4 and rac5. The AZ3 in San Francisco has the rac6 rack.

In the rac1 of AZ1, one server is deployed with TiDB and PD services, and the other two servers are deployed with TiKV services. Each TiKV server is deployed with two TiKV instances (tikv-server). This is similar to rac2, rac4, rac5, and rac6.

The TiDB server, the control machine, and the monitoring server are on rac3. The TiDB server is deployed for regular maintenance and backup. Prometheus, Grafana, and the restore tools are deployed on the control machine and monitoring machine.

12.2.3 Configuration

12.2.3.1 Example

See the following `tiup topology.yaml` yaml file for example:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
  tikv:
    server.grpc-compression-type: gzip
  pd:
    replication.location-labels: ["az","replication zone","rack","host"]

pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
  - host: 10.63.10.13
    name: "pd-13"
  - host: 10.63.10.14
    name: "pd-14"

tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
  - host: 10.63.10.12
  - host: 10.63.10.13
```

```
  - host: 10.63.10.14

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
          ↪ }
  - host: 10.63.10.31
    config:
      server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
          ↪ }
  - host: 10.63.10.32
    config:
      server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
          ↪ }
  - host: 10.63.10.33
    config:
      server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
          ↪ }
  - host: 10.63.10.34
    config:
      server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
          ↪ }
      raftstore.raft-min-election-timeout-ticks: 50
      raftstore.raft-max-election-timeout-ticks: 60

monitoring_servers:
  - host: 10.63.10.60

grafana_servers:
  - host: 10.63.10.60

alertmanager_servers:
  - host: 10.63.10.60
```

12.2.3.2 Labels design

In the deployment of three AZs in two regions, the label design requires taking availability and disaster recovery into account. It is recommended that you define the four levels (`az`, `replication zone`, `rack`, and `host`) based on the physical structure of the deployment.

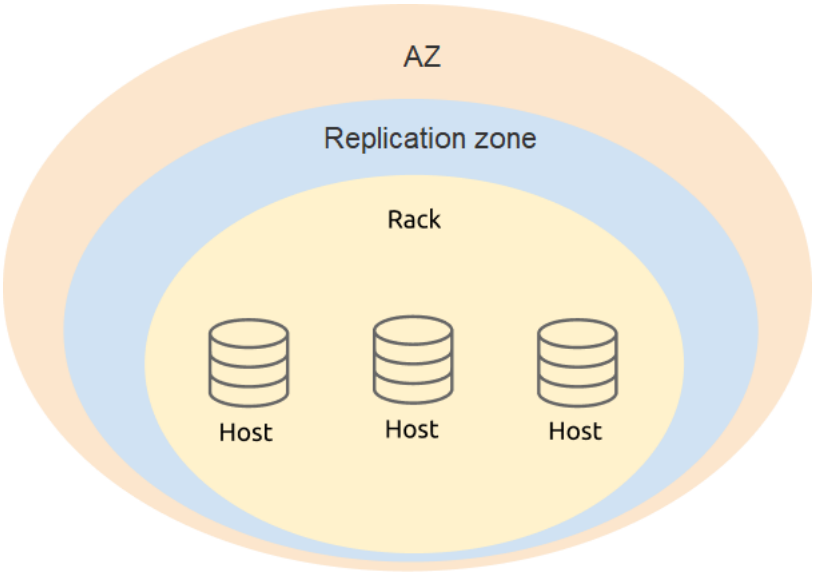

Figure 418: Label logical definition

In the PD configuration, add level information of TiKV labels:

```
server_configs:
  pd:
    replication.location-labels: ["az","replication zone","rack","host"]
```

The configuration of `tikv_servers` is based on the label information of the real physical deployment location of TiKV, which makes it easier for PD to perform global management and scheduling.

```
tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
          ↪ }
  - host: 10.63.10.31
    config:
      server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
          ↪ }
  - host: 10.63.10.32
    config:
      server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
          ↪ }
  - host: 10.63.10.33
    config:
      server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
          ↪ }
  - host: 10.63.10.34
```

```
config:
  server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
     ↪ }
```

12.2.3.3 Optimize parameter configuration

In the deployment of three AZs in two regions, to optimize performance, you need to not only configure regular parameters, but also adjust component parameters.

- Enable gRPC message compression in TiKV. Because data of the cluster is transmitted in the network, you can enable the gRPC message compression to lower the network traffic.

```
server.grpc-compression-type: gzip
```

- Optimize the network configuration of the TiKV node in another region (San Francisco). Modify the following TiKV parameters for AZ3 in San Francisco and try to prevent the replica in this TiKV node from participating in the Raft election.

```
raftstore.raft-min-election-timeout-ticks: 50
raftstore.raft-max-election-timeout-ticks: 60
```

> **Note:**
>
> Using `raftstore.raft-min-election-timeout-ticks` and `raftstore.` ↪ `raft-max-election-timeout-ticks` to configure larger election timeout ticks for a TiKV node can significantly decrease the likelihood of Regions on that node becoming Leaders. However, in a disaster scenario where some TiKV nodes are offline and the remaining active TiKV nodes lag behind in Raft logs, only Regions on this TiKV node with large election timeout ticks can become Leaders. Because Regions on this TiKV node must wait for at least the duration set by 'raftstore.raft-min-election-timeout-ticks' before initiating an election, it is recommended to avoid setting these values excessively large to prevent potential impact on the cluster availability in such scenarios.

- Configure scheduling. After the cluster is enabled, use the `tiup ctl:v{CLUSTER_` ↪ `VERSION} pd` tool to modify the scheduling policy. Modify the number of TiKV Raft replicas. Configure this number as planned. In this example, the number of replicas is five.

```
config set max-replicas 5
```

- Forbid scheduling the Raft leader to AZ3. Scheduling the Raft leader to another region (AZ3) causes unnecessary network overhead between AZ1/AZ2 in Seattle and AZ3 in San Francisco. The network bandwidth and latency also affect the performance of the TiDB cluster.

```
config set label-property reject-leader dc 3
```

Note:

Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

- Configure the priority of PD. To avoid the situation where the PD leader is in another region (AZ3), you can increase the priority of local PD (in Seattle) and decrease the priority of PD in another region (San Francisco). The larger the number, the higher the priority. In all available PD nodes, the node with the highest priority number becomes the leader.

```
member leader_priority PD-10 5
member leader_priority PD-11 5
member leader_priority PD-12 5
member leader_priority PD-13 5
member leader_priority PD-14 1
```

12.3 Two Availability Zones in One Region Deployment

This document introduces the deployment mode of two availability zones (AZs) in one region, including the architecture, configuration, how to enable this deployment mode, and how to use replicas in this mode.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.3.1 Introduction

TiDB usually adopts the multi-AZ deployment solution to ensure high availability and disaster recovery capability. The multi-AZ deployment solution includes multiple deployment modes, such as multiple AZs in one region and multiple AZs in two regions. This document introduces the deployment mode of two AZs in one region. Deployed in this mode, TiDB can

also meet the requirements of high availability and disaster recovery, with a lower cost. This deployment solution adopts Data Replication Auto Synchronous mode, or the DR Auto-Sync mode.

Under the mode of two AZs in one region, the two AZs are less than 50 kilometers apart. They are usually located in the same region or in two adjacent regions. The network latency between the two AZs is lower than 1.5 milliseconds and the bandwidth is higher than 10 Gbps.

12.3.2 Deployment architecture

This section takes the example of a region where two availability zones AZ1 and AZ2 are located respectively in the east and west. AZ1 is the primary AZ and AZ2 is the disaster recovery (DR) AZ.

The architecture of the cluster deployment is as follows:

- The cluster has six replicas: three Voter replicas in AZ1, and two Voter replicas along with one Learner replica in AZ2. For the TiKV component, each rack has a proper label.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

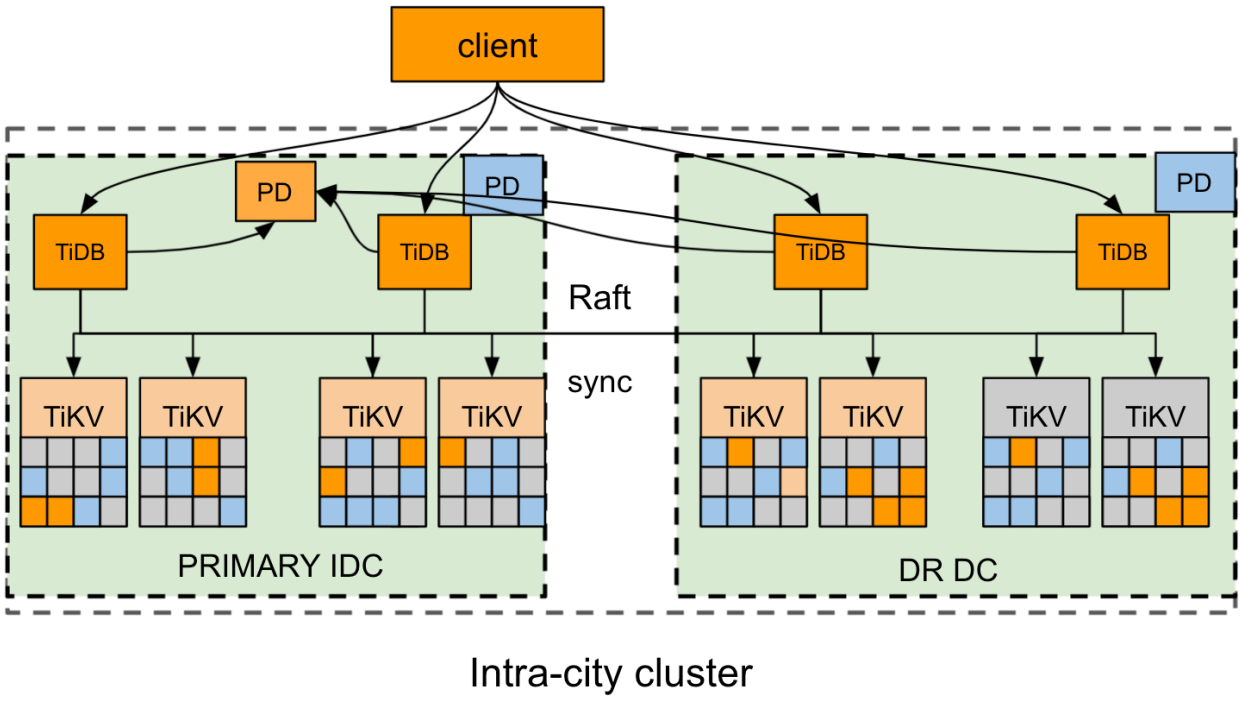

Figure 419: 2-AZ-in-1-region architecture

This deployment solution defines three statuses to control and identify the replication status of the cluster, which restricts the replication mode of TiKV. The replication mode of the cluster can automatically and adaptively switch between the three statuses. For details, see the Status switch section.

- **sync**: Synchronous replication mode. In this mode, at least one replica in the disaster recovery AZ synchronizes with the primary AZ. The Raft algorithm ensures that each log is replicated to the DR based on the label.
- **async**: Asynchronous replication mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. The Raft algorithm follows the majority protocol to replicate logs.
- **sync-recover**: Synchronous recovery mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. Raft gradually switches to the label replication mode and then reports the label information to PD.

12.3.3 Configuration

12.3.3.1 Example

The following `tiup topology.yaml` example file is a typical topology configuration for the two availability zones in one region deployment mode:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"
server_configs:
  pd:
    replication.location-labels: ["az","rack","host"]
pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
  - host: 10.63.10.12
tikv_servers:
  - host: 10.63.10.30
```

```
    config:
      server.labels: { az: "east", rack: "east-1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { az: "east", rack: "east-2", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { az: "east", rack: "east-3", host: "32" }
  - host: 10.63.10.33
    config:
      server.labels: { az: "west", rack: "west-1", host: "33" }
  - host: 10.63.10.34
    config:
      server.labels: { az: "west", rack: "west-2", host: "34" }
  - host: 10.63.10.35
    config:
      server.labels: { az: "west", rack: "west-3", host: "35" }
monitoring_servers:
  - host: 10.63.10.60
grafana_servers:
  - host: 10.63.10.60
alertmanager_servers:
  - host: 10.63.10.60
```

12.3.3.2 Placement Rules

To deploy a cluster based on the planned topology, you need to use Placement Rules to determine the locations of the cluster replicas. Taking the deployment of four replicas (two Voter replicas are at the primary AZ, one Voter replica, and one Learner replica are at the disaster recovery AZ) as an example, you can use the Placement Rules to configure the replicas as follows:

```
cat rule.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "az-east",
        "start_key": "",
        "end_key": "",
        "role": "voter",
```

```
    "count": 3,
    "label_constraints": [
      {
        "key": "az",
        "op": "in",
        "values": [
          "east"
        ]
      }
    ],
    "location_labels": [
      "az",
      "rack",
      "host"
    ]
  },
  {
    "group_id": "pd",
    "id": "az-west-1",
    "start_key": "",
    "end_key": "",
    "role": "follower",
    "count": 2,
    "label_constraints": [
      {
        "key": "az",
        "op": "in",
        "values": [
          "west"
        ]
      }
    ],
    "location_labels": [
      "az",
      "rack",
      "host"
    ]
  },
  {
    "group_id": "pd",
    "id": "az-west-2",
    "start_key": "",
    "end_key": "",
    "role": "learner",
    "count": 1,
```

```
      "label_constraints": [
        {
          "key": "az",
          "op": "in",
          "values": [
            "west"
          ]
        }
      ],
      "location_labels": [
        "az",
        "rack",
        "host"
      ]
    }
  ]
 }
]
```

To use the configurations in `rule.json`, run the following command to back up the existing configuration to the `default.json` file and overwrite the existing configuration with `rule.json`:

```
pd-ctl config placement-rules rule-bundle load --out="default.json"
pd-ctl config placement-rules rule-bundle save --in="rule.json"
```

If you need to roll back to the previous configuration, you can restore the backup file `default.json` or write the following JSON file manually and overwrite the current configuration with this JSON file:

```
cat default.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "default",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 5
      }
    ]
```

```
  }
]
```

12.3.3.3 Enable the DR Auto-Sync mode

The replication mode is controlled by PD. You can configure the replication mode in the PD configuration file using one of the following methods:

- Method 1: Configure the PD configuration file, and then deploy a cluster.

```
[replication-mode]
replication-mode = "dr-auto-sync"
[replication-mode.dr-auto-sync]
label-key = "az"
primary = "east"
dr = "west"
primary-replicas = 3
dr-replicas = 2
wait-store-timeout = "1m"
wait-recover-timeout = "0s"
pause-region-split = false
```

- Method 2: If you have deployed a cluster, use pd-ctl commands to modify the configurations of PD.

```
config set replication-mode dr-auto-sync
config set replication-mode dr-auto-sync label-key az
config set replication-mode dr-auto-sync primary east
config set replication-mode dr-auto-sync dr west
config set replication-mode dr-auto-sync primary-replicas 3
config set replication-mode dr-auto-sync dr-replicas 2
```

Descriptions of configuration items:

- `replication-mode` is the replication mode to be enabled. In the preceding example, it is set to `dr-auto-sync`. By default, the majority protocol is used.
- `label-key` is used to distinguish different AZs and needs to match Placement Rules. In this example, the primary AZ is “east” and the disaster recovery AZ is “west”.
- `primary-replicas` is the number of Voter replicas in the primary AZ.
- `dr-replicas` is the number of Voter replicas in the disaster recovery (DR) AZ.
- `wait-store-timeout` is the waiting time for switching to asynchronous replication mode when network isolation or failure occurs. If the time of network failure exceeds the waiting time, asynchronous replication mode is enabled. The default waiting time is 60 seconds.

- `wait-recover-timeout` is the waiting time for switching back to the `sync-recover` status after the network recovers. The default value is 0 seconds.
- `pause-region-split` controls whether to pause Region split operations in the `async_wait` and `async` statuses. Pausing Region split can prevent temporary partial data loss in the DR AZ when synchronizing data in the `sync-recover` status. The default value is `false`.

To check the current replication status of the cluster, use the following API:

```
curl http://pd_ip:pd_port/pd/api/v1/replication_mode/status
```

```
{
  "mode": "dr-auto-sync",
  "dr-auto-sync": {
    "label-key": "az",
    "state": "sync"
  }
}
```

12.3.3.3.1 Status switch

The replication mode of a cluster can automatically and adaptively switch between three statuses:

- When the cluster is normal, the synchronous replication mode is enabled to maximize the data integrity of the disaster recovery AZ.
- When the network connection between the two AZs fails or the disaster recovery AZ breaks down, after a pre-set protective interval, the cluster enables the asynchronous replication mode to ensure the availability of the application.
- When the network reconnects or the disaster recovery AZ recovers, the TiKV node joins the cluster again and gradually replicates the data. Finally, the cluster switches to the synchronous replication mode.

The details for the status switch are as follows:

1. **Initialization**: At the initialization stage, the cluster is in the synchronous replication mode. PD sends the status information to TiKV, and all TiKV nodes strictly follow the synchronous replication mode to work.
2. **Switch from sync to async**: PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node fails or is disconnected. If the number of failed nodes exceeds the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can no longer serve the data replication and it is necessary to switch the status. When the failure or

disconnect time exceeds the time set by `wait-store-timeout`, PD switches the status of the cluster to the async mode. Then PD sends the status of async to all TiKV nodes, and the replication mode for TiKV switches from two-availability-zone replication to the native Raft majority.

3. **Switch from async to sync**: PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node is reconnected. If the number of failed nodes is less than the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can be enabled again. PD first switches the status of the cluster to sync-recover and sends the status information to all TiKV nodes. All Regions of TiKV gradually switch to the two-availability-zone synchronous replication mode and then report the heartbeat information to PD. PD records the status of TiKV Regions and calculates the recovery progress. When all TiKV Regions finish the switching, PD switches the replication mode to sync.

12.3.3.4 Disaster recovery

This section introduces the disaster recovery solution of the two AZs in one region deployment.

When a disaster occurs to a cluster in the synchronous replication mode, you can perform data recovery with `RPO = 0`:

- If the primary AZ fails and most of the Voter replicas are lost, but complete data exists in the disaster recovery AZ, the lost data can be recovered from the disaster recovery AZ. At this time, manual intervention is required with professional tools. You can get support from PingCAP or the community for a recovery solution.
- If the disaster recovery AZ fails and a few Voter replicas are lost, the cluster automatically switches to the asynchronous replication mode.

When a disaster occurs to a cluster that is not in the synchronous replication mode and you cannot perform data recovery with `RPO = 0`:

- If most of the Voter replicas are lost, manual intervention is required with professional tools. You can get support from PingCAP or the community for a recovery solution.

12.4 Read Historical Data

12.4.1 Use Stale Read (Recommended)

12.4.1.1 Usage Scenarios of Stale Read

This document describes the usage scenarios of Stale Read. Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism,

you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes.

When you are using Stale Read, TiDB will randomly select a replica for data reading, which means that all replicas are available for data reading. If your application cannot tolerate reading non-real-time data, do not use Stale Read; otherwise, the data read from the replica might not be the latest data written into TiDB.

12.4.1.1.1 Scenario examples

- Scenario one: If a transaction only involves read operations and is tolerant of data staleness to some extent, you can use Stale Read to get historical data. Using Stale Read, TiDB makes the query requests sent to any replica at the expense of some real-time performance, and thus increases the throughput of query executions. Especially in some scenarios where small tables are queried, if strongly consistent reads are used, leader might be concentrated on a certain storage node, causing the query pressure to be concentrated on that node as well. Therefore, that node might become a bottleneck for the whole query. Stale Read, however, can improve the overall query throughput and significantly improve the query performance.
- Scenario two: In some scenarios of geo-distributed deployment, if strongly consistent follower reads are used, to make sure that the data read from the Followers is consistent with that stored in the Leader, TiDB requests `Readindex` from different data centers for verification, which increases the access latency for the whole query process. With Stale Read, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query. For more information, see Local Read under Three Data Centers Deployment.

12.4.1.1.2 Usages

TiDB provides the methods of performing Stale Read at the statement level, the session level and the global level as follows:

- Statement level
  - Specifying an exact point in time (**recommended**): If you need TiDB to read data that is globally consistent from a specific point in time without violating the isolation level, you can specify the corresponding timestamp of that point in time in the query statement. For detailed usage, see `AS OF TIMESTAMP` clause.
  - Specifying a time range: If you need TiDB to read the data as new as possible within a time range without violating the isolation level, you can specify the time range in the query statement. Within the specified time range, TiDB selects a suitable timestamp to read the corresponding data. “Suitable” means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed

replica and the read operations are not blocked. For detailed usage, refer to the introduction of the AS OF TIMESTAMP Clause and the TIDB_BOUNDED_STALENESS function.

- Session level
    - Specifying a time range: In a session, if you need TiDB to read the data as new as possible within a time range in subsequent queries without violating the isolation level, you can specify the time range by setting the `tidb_read_staleness` system variable. For detailed usage, refer to `tidb_read_staleness`.

Besides, TiDB provides a way to specify an exact point in time at the session or global level by setting the `tidb_external_ts` and `tidb_enable_external_ts_read` system variables. For detailed usage, refer to Perform Stale Read Using `tidb_external_ts`.

Reduce Stale Read latency

The Stale Read feature periodically advances the Resolved TS timestamp of the TiDB cluster, which ensures that TiDB reads data that meets transaction consistency. If the timestamp used by Stale Read (for example, `AS OF TIMESTAMP '2016-10-08 16:45:26'`) is greater than the Resolved TS, Stale Read will trigger TiDB to advance the Resolved TS first and wait for the advance to complete before reading the data, leading to an increase in latency.

To reduce the Stale Read latency, you can modify the following TiKV configuration item to make TiDB advance the Resolved TS timestamp more frequently:

```
[resolved-ts]
advance-ts-interval = "20s" # The default value is "20s". You can set it to
    ↪ a smaller value such as "1s" to advance the Resolved TS timestamp
    ↪ more frequently.
```

Note:

Decreasing the preceding TiKV configuration item will lead to an increase in TiKV CPU usage and traffic between nodes.

For more information about the internals of Resolved TS and diagnostic techniques, see Understanding Stale Read and safe-ts in TiKV.

12.4.1.1.3 Restrictions

When a Stale Read query for a table is pushed down to TiFlash, the query will return an error if this table has newer DDL operations executed after the read timestamp specified

by the query. This is because TiFlash only supports reading data from the tables with the latest schemas.

Take the following table as an example:

```
create table t1(id int);
alter table t1 set tiflash replica 1;
```

Execute the following DDL operation after one minute:

```
alter table t1 add column c1 int not null;
```

Then, use Stale Read to query the data from one minute ago:

```
set @@session.tidb_enforce_mpp=1;
select * from t1 as of timestamp NOW() - INTERVAL 1 minute;
```

TiFlash will report an error as follows:

```
ERROR 1105 (HY000): other error for mpp stream: From MPP<query:<query_ts
    ↪ :1673950975508472943, local_query_id:18, server_id:111947, start_ts
    ↪ :438816196526080000>,task_id:1>: Code: 0, e.displayText() = DB::
    ↪ TiFlashException: Table 323 schema version 104 newer than query
    ↪ schema version 100, e.what() = DB::TiFlashException,
```

To avoid this error, you can change the read timestamp specified by Stale Read to the time after the DDL operation.

12.4.1.2 Read Historical Data Using the `AS OF TIMESTAMP` Clause

This document describes how to perform the Stale Read feature using the `AS OF TIMESTAMP` clause to read historical data in TiDB, including specific usage examples and strategies for saving historical data.

TiDB supports reading historical data through a standard SQL interface, which is the `AS OF TIMESTAMP` SQL clause, without the need for special clients or drivers. After data is updated or deleted, you can read the historical data before the update or deletion using this SQL interface.

> **Note:**
>
> When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

12.4.1.2.1 Syntax

You can use the `AS OF TIMESTAMP` clause in the following three ways:

- `SELECT ... FROM ... AS OF TIMESTAMP`
- `START TRANSACTION READ ONLY AS OF TIMESTAMP`
- `SET TRANSACTION READ ONLY AS OF TIMESTAMP`

If you want to specify an exact point of time, you can set a datetime value or use a time function in the `AS OF TIMESTAMP` clause. The format of datetime is like "2016-10-08 16:45:26.999", with millisecond as the minimum time unit, but for most of the time, the time unit of second is enough for specifying a datetime, such as "2016-10-08 16:45:26". You can also get the current time to the millisecond using the `NOW(3)` function. If you want to read the data of several seconds ago, it is **recommended** to use an expression such as `NOW()- INTERVAL 10 SECOND`.

If you want to specify a time range, you can use the `TIDB_BOUNDED_STALENESS()` function in the clause. When this function is used, TiDB selects a suitable timestamp within the specified time range. "Suitable" means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. You need to use `TIDB_BOUNDED_STALENESS(t1, t2)` to call this function. `t1` and `t2` are the two ends of the time range, which can be specified using either datetime values or time functions.

Here are some examples of the `AS OF TIMESTAMP` clause:

- `AS OF TIMESTAMP '2016-10-08 16:45:26'`: Tells TiDB to read the latest data stored at 16:45:26 on October 8, 2016.
- `AS OF TIMESTAMP NOW()- INTERVAL 10 SECOND`: Tells TiDB to read the latest data stored 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 16:45:29')`: Tells TiDB to read the data as new as possible within the time range of 16:45:26 to 16:45:29 on October 8, 2016.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW()- INTERVAL 20 SECOND, NOW())`: Tells TiDB to read the data as new as possible within the time range of 20 seconds ago to the present.

> **Note:**
>
> In addition to specifying a timestamp, the most common use of the `AS OF TIMESTAMP` clause is to read data that is several seconds old. If this approach is used, it is recommended to read historical data older than 5 seconds.

> You need to deploy the NTP service for your TiDB and PD nodes when you use Stale Read. This avoids the situation where the specified timestamp used by TiDB goes ahead of the latest TSO allocating progress (such as a timestamp several seconds ahead), or is later than the GC safe point timestamp. When the specified timestamp goes beyond the service scope, TiDB returns an error.
>
> To reduce the latency and improve the timeliness of the Stale Read data, you can modify the TiKV `advance-ts-interval` configuration item. See Reduce Stale Read latency for details.

12.4.1.2.2 Usage examples

This section describes different ways to use the `AS OF TIMESTAMP` clause with several examples. It first introduces how to prepare the data for recovery, and then shows how to use `AS OF TIMESTAMP` in `SELECT`, `START TRANSACTION READ ONLY AS OF TIMESTAMP`, and `SET TRANSACTION READ ONLY AS OF TIMESTAMP` respectively.

Prepare data sample

To prepare data for recovery, create a table first and insert several rows of data:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

View the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

View the current time:

```
select now();
```

```
+---------------------+
| now()               |
+---------------------+
| 2021-05-26 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

Confirm that the data of the row is updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Read historical data using the `SELECT` statement

You can use the `SELECT ... FROM ... AS OF TIMESTAMP` statement to read data from a time point in the past.

```
select * from t as of timestamp '2021-05-26 16:45:26';
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Note:

When reading multiple tables using one `SELECT` statement, you need to make sure that the format of TIMESTAMP EXPRESSIONs is consistent. For example, `select * from t as of timestamp NOW()- INTERVAL 2 SECOND, c as of timestamp NOW()- INTERVAL 2 SECOND;`. In addition, you must specify the `AS OF` information for the relevant table in the `SELECT` statement; otherwise, the `SELECT` statement reads the latest data by default.

Read historical data using the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement to start a read-only transaction based on a time point in the past. The transaction reads historical data of the given time.

```
start transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
```

```
|   3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> If you start a transaction with the statement `START TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

Read historical data using the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement to set the next transaction as a read-only transaction based on a specified time point in the past. The transaction reads historical data of the given time.

```
set transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
begin;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Note:

If you start a transaction with the statement `SET TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

12.4.1.3 Read Historical Data Using the `tidb_read_staleness` System Variable

To support reading the historical data, in v5.4, TiDB introduces a new system variable `tidb_read_staleness`. This document describes how to read historical data through this system variable, including detailed operating procedures.

12.4.1.3.1 Feature description

The `tidb_read_staleness` system variable is used to set the time range of historical data that TiDB can read in the current session. The data type of this variable is int type, and the scope of it is `SESSION`. After setting the value, TiDB selects a timestamp as new as possible from the range allowed by this variable, and all subsequent read operations are performed against this timestamp. For example, if the value of this variable is set to `-5`, on the condition that TiKV has the corresponding historical version's data, TiDB selects a timestamp as new as possible within a 5-second time range.

After enabling `tidb_read_staleness`, you still can perform the following operations:

- Insert, modify, delete data or perform DML operations in the current session. These statements are not affected by `tidb_read_staleness`.
- Start an interactive transaction in the current session. Queries within this transaction still read the latest data.

After reading the historical data, you can read the latest data in the following two ways:

- Start a new session.

- Set the value of the `tidb_read_staleness` variable to `""` using the `SET` statement.

> **Note:**
>
> To reduce the latency and improve the timeliness of the Stale Read data, you can modify the TiKV `advance-ts-interval` configuration item. See Reduce Stale Read latency for details.

12.4.1.3.2 Usage examples

This section describes how to use `tidb_read_staleness` with examples.

1. Create a table, and insert a few rows of data into the table:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. Check out the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

4. Confirm that the data has been updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

5. Set the `tidb_read_staleness` system variable.

   The scope of this variable is `SESSION`. After setting its value, TiDB reads the latest version data before the time set by the value.

   The following setting indicates that TiDB selects a timestamp as new as possible within the time range from 5 seconds ago to now and uses it as the timestamp for reading historical data:

```
set @@tidb_read_staleness="-5";
```

```
Query OK, 0 rows affected (0.00 sec)
```

Note:

- Use `@@` instead of `@` before `tidb_read_staleness`. `@@` means system variables, and `@` means user variables.
- You need to set the historical time range (the value of `tidb_read_staleness`) according to the total time that you spent in step 3 and step 4. Otherwise, the latest data will be displayed in the query results, not the historical data. Therefore, you need to adjust this time range according to the time you spent on operations. For example, in this example, since the set time range is 5 seconds, you need to complete step 3 and step 4 within 5 seconds.

The data read here is the data before the update, that is, the historical data:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
```

```
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. After un-setting this variable as follows, TiDB can read the latest data:

```
set @@tidb_read_staleness="";
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)

12.4.1.4 Read Historical Data Using the `tidb_external_ts` Variable

To support reading the historical data, TiDB v6.4.0 introduces a system variable `tidb_external_ts`. This document describes how to read historical data through this system variable, including detailed usage examples.

12.4.1.4.1 Scenarios

Read historical data from a specified point in time is very useful for data replication tools such as TiCDC. After the data replication tool completes the data replication before a certain point in time, you can set the `tidb_external_ts` system variable of the downstream TiDB to read the data before that point in time. This prevents the data inconsistency caused by data replication.

12.4.1.4.2 Feature description

The system variable `tidb_external_ts` specifies the timestamp of the historical data to be read when `tidb_enable_external_ts_read` is enabled.

The system variable `tidb_enable_external_ts_read` controls whether to read historical data in the current session or globally. The default value is `OFF`, which means the feature of reading historical data is disabled, and the `tidb_external_ts` value is ignored. When `tidb_enable_external_ts_read` is set to `ON` globally, all queries read historical data before

the time specified by `tidb_external_ts`. If `tidb_enable_external_ts_read` is set to `ON` only for a certain session, only queries in that session read historical data.

When the `tidb_enable_external_ts_read` is enabled, TiDB becomes read-only. All write queries will fail with an error like `ERROR 1836 (HY000): Running in read-only mode`.

12.4.1.4.3 Usage examples

This section describes how to use the `tidb_external_ts` variable to read historical data with examples.

1. Create a table and insert some rows into the table:

```
CREATE TABLE t (c INT);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
INSERT INTO t VALUES (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
SELECT * FROM t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. Set `tidb_external_ts` to `@@tidb_current_ts`:

```
START TRANSACTION;
SET GLOBAL tidb_external_ts=@@tidb_current_ts;
COMMIT;
```

4. Insert a new row and confirm that it is inserted:

```
INSERT INTO t VALUES (4);
```

```
Query OK, 1 row affected (0.001 sec)
```

```
SELECT * FROM t;
```

```
+------+
| id   |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
+------+
4 rows in set (0.00 sec)
```

5. Set `tidb_enable_external_ts_read` to `ON` and then view data in the table:

```
SET tidb_enable_external_ts_read=ON;
SELECT * FROM t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Because `tidb_external_ts` is set to the timestamp before the new row is inserted, the newly inserted row is not returned after the `tidb_enable_external_ts_read` is enabled.

12.4.2 Read Historical Data Using the System Variable `tidb_snapshot`

This document describes how to read data from the history versions using the system variable `tidb_snapshot`, including specific usage examples and strategies for saving historical data.

> **Note:**
>
> You can also use the Stale Read feature to read historical data, which is more recommended.

12.4.2.1 Feature description

TiDB implements a feature to read history data using the standard SQL interface directly without special clients or drivers.

> **Note:**
>
> - Even when data is updated or removed, its history versions can be read using the SQL interface.
> - When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

12.4.2.2 How TiDB reads data from history versions

The `tidb_snapshot` system variable is introduced to support reading history data. About the `tidb_snapshot` variable:

- The variable is valid in the `SESSION` scope.
- Its value can be modified using the `SET` statement.
- The data type for the variable is text.
- The variable accepts TSO (Timestamp Oracle) and datetime. TSO is a globally unique time service, which is obtained from PD. The acceptable datetime format is "2016-10-08 16:45:26.999". Generally, the datetime can be set using second precision, for example "2016-10-08 16:45:26".
- When the variable is set, TiDB creates a Snapshot using its value as the timestamp, just for the data structure and there is no any overhead. After that, all the `SELECT` operations will read data from this Snapshot.

> **Note:**
>
> Because the timestamp in TiDB transactions is allocated by Placement Driver (PD), the version of the stored data is also marked based on the timestamp allocated by PD. When a Snapshot is created, the version number is based on the value of the `tidb_snapshot` variable. If there is a large difference between the local time of the TiDB server and the PD server, use the time of the PD server.

After reading data from history versions, you can read data from the latest version by ending the current Session or using the `SET` statement to set the value of the `tidb_snapshot` variable to "" (empty string).

12.4.2.3 How TiDB manages the data versions

TiDB implements Multi-Version Concurrency Control (MVCC) to manage data versions. The history versions of data are kept because each update/removal creates a new version of the data object instead of updating/removing the data object in-place. But not all the versions are kept. If the versions are older than a specific time, they will be removed completely to reduce the storage occupancy and the performance overhead caused by too many history versions.

In TiDB, Garbage Collection (GC) runs periodically to remove the obsolete data versions. For GC details, see TiDB Garbage Collection (GC)

Pay special attention to the following:

- `tidb_gc_life_time`: This system variable is used to configure the retention time of earlier modifications (default: `10m0s`).
- The output of `SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point'`. This is the current `safePoint` where you can read historical data up to. It is updated every time the garbage collection process is run.

12.4.2.4 Example

1. At the initial stage, create a table and insert several rows of data:

```
mysql> create table t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into t values (1), (2), (3);
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. View the timestamp of the table:

```
mysql> select now();
+---------------------+
| now()               |
```

```
+---------------------+
| 2016-10-08 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

4. Update the data in one row:

```
mysql> update t set c=22 where c=2;
Query OK, 1 row affected (0.00 sec)
```

5. Make sure the data is updated:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. Set the `tidb_snapshot` variable whose scope is Session. The variable is set so that the latest version before the value can be read.

> **Note:**
> In this example, the value is set to be the time before the update operation.

```
mysql> set @@tidb_snapshot="2016-10-08 16:45:26";
Query OK, 0 rows affected (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

Result: The read from the following statement is the data before the update operation, which is the history data.

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

7. Set the `tidb_snapshot` variable to be "" (empty string) and you can read the data from the latest version:

```
mysql> set @@tidb_snapshot="";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

12.4.2.5 How to restore historical data

Before you restore data from an older version, make sure that Garbage Collection (GC) does not clear the history data while you are working on it. This can be done by setting the `tidb_gc_life_time` variable as the following example shows. Do not forget to set the variable back to the previous value after the restore.

```
SET GLOBAL tidb_gc_life_time="60m";
```

Note:

Increasing the GC life time from the default 10 minutes to half an hour or more will result in additional versions of rows being retained, which might require more disk space. This might also affect the performance of certain operations such as scans when TiDB needs to skip these additional versions of the same rows during data reads.

To restore data from an older version, you can use one of the following methods:

- For simple cases, use `SELECT` after setting the `tidb_snapshot` variable and copy-paste the output, or use `SELECT ... INTO OUTFILE` and then use `LOAD DATA` to import the data later on.
- Use Dumpling to export a historical snapshot. Dumpling performs well in exporting larger sets of data.

12.5 Best Practices

12.5.1 TiDB Best Practices

This document summarizes the best practices of using TiDB, including the use of SQL and optimization tips for Online Analytical Processing (OLAP) and Online Transactional Processing (OLTP) scenarios, especially the optimization options specific for TiDB.

Before you read this document, it is recommended that you read three blog posts that introduce the technical principles of TiDB:

- TiDB Internal (I) - Data Storage
- TiDB Internal (II) - Computing
- TiDB Internal (III) - Scheduling

12.5.1.1 Preface

Database is a generic infrastructure system. It is important to consider various user scenarios during the development process and to modify the data parameters or the way to use according to actual situations in specific business scenarios.

TiDB is a distributed database compatible with the MySQL protocol and syntax. But with the internal implementation and supporting of distributed storage and transactions, the way of using TiDB is different from MySQL.

12.5.1.2 Basic concepts

The best practices are closely related to its implementation principles. It is recommended that you learn some of the basic mechanisms, including the Raft consensus algorithm, distributed transactions, data sharding, load balancing, the mapping solution from SQL to Key-Value (KV), the implementation method of secondary indexing, and distributed execution engines.

This section is an introduction to these concepts. For detailed information, refer to PingCAP blog posts.

12.5.1.2.1 Raft

Raft is a consensus algorithm that ensures data replication with strong consistency. At the bottom layer, TiDB uses Raft to replicate data. TiDB writes data to the majority of the replicas before returning the result of success. In this way, even though a few replicas might get lost, the system still has the latest data. For example, if there are three replicas, the system does not return the result of success until data has been written to two replicas. Whenever a replica is lost, at least one of the remaining two replicas have the latest data.

To store three replicas, compared with the replication of Source-Replica, Raft is more efficient. The write latency of Raft depends on the two fastest replicas, instead of the slowest one. Therefore, the implementation of geo-distributed and multiple active data centers becomes possible by using the Raft replication. In the typical scenario of three data centers distributing in two sites, to guarantee the data consistency, TiDB just needs to successfully write data into the local data center and the closer one, instead of writing to all three data centers. However, this does not mean that cross-data center deployment can be implemented in any scenario. When the amount of data to be written is large, the bandwidth and latency between data centers become the key factors. If the write speed exceeds the bandwidth or the latency is too high, the Raft replication mechanism still cannot work well.

12.5.1.2.2 Distributed transactions

TiDB provides complete distributed transactions and the model has some optimizations on the basis of Google Percolator. This document introduces the following features:

- Optimistic transaction model

  TiDB's optimistic transaction model does not detect conflicts until the commit phase. If there are conflicts, the transaction needs retry. But this model is inefficient if the conflict is severe, because operations before retry are invalid and need to repeat.

  Assume that the database is used as a counter. High access concurrency might lead to severe conflicts, resulting in multiple retries or even timeouts. Therefore, in the scenario of severe conflicts, it is recommended to use the pessimistic transaction mode or to solve problems at the system architecture level, such as placing counter in Redis. Nonetheless, the optimistic transaction model is efficient if the access conflict is not very severe.

- Pessimistic transaction mode

  In TiDB, the pessimistic transaction mode has almost the same behavior as in MySQL. The transaction applies a lock during the execution phase, which avoids retries in conflict situations and ensures a higher success rate. By applying the pessimistic locking, you can also lock data in advance using `SELECT FOR UPDATE`.

  However, if the application scenario has fewer conflicts, the optimistic transaction model has better performance.

- Transaction size limit

  As distributed transactions need to conduct two-phase commit and the bottom layer performs Raft replication, if a transaction is very large, the commit process would be quite slow, and the following Raft replication process is thus stuck. To avoid this problem, the transaction size is limited:

  - A transaction is limited to 5,000 SQL statements (by default)
  - Each Key-Value entry is no more than 6 MB (by default)
  - The total size of Key-Value entries is no more than 10 GB.

  You can find similar limits in Google Cloud Spanner.

12.5.1.2.3 Data sharding

TiKV automatically shards bottom-layered data according to the range of keys. Each Region is a range of keys, which is a left-closed and right-open interval, `[StartKey, EndKey ↪ )`. When the amount of Key-Value pairs in a Region exceeds a certain value, the Region automatically splits into two.

12.5.1.2.4 Load balancing

Placement Driver (PD) balances the load of the cluster according to the status of the entire TiKV cluster. The unit of scheduling is Region and the logic is the strategy configured by PD.

12.5.1.2.5 SQL on KV

TiDB automatically maps the SQL structure into Key-Value structure. For details, see TiDB Internal (II) - Computing.

Simply put, TiDB performs the following operations:

- A row of data is mapped to a Key-Value pair. The key is prefixed with `TableID` and suffixed with the row ID.
- An index is mapped as a Key-Value pair. The key is prefixed with `TableID+IndexID` and suffixed with the index value.

The data or indexes in the same table have the same prefix. These Key-Values are at adjacent positions in the key space of TiKV. Therefore, when the amount of data to be written is large and all is written to one table, the write hotspot is created. The situation gets worse when some index values of the continuous written data is also continuous (for example, fields that increase with time, like `update time`), which creates a few write hotspots and becomes the bottleneck of the entire system.

Similarly, if all data is read from a focused small range (for example, the continuous tens or hundreds of thousands of rows of data), an access hotspot of data is likely to occur.

12.5.1.2.6 Secondary index

TiDB supports the complete secondary indexes, which are also global indexes. Many queries can be optimized by index. Thus, it is important for applications to make good use of secondary indexes.

Lots of MySQL experience is also applicable to TiDB. It is noted that TiDB has its unique features. The following are a few notes when using secondary indexes in TiDB.

- The more secondary indexes, the better?

  Secondary indexes can speed up queries, but adding an index has side effects. The previous section introduces the storage model of indexes. For each additional index, there will be one more Key-Value when inserting a row. Therefore, the more indexes, the slower the writing speed and the more space it takes up.

  In addition, too many indexes affects the runtime of the optimizer, and inappropriate indexes mislead the optimizer. Thus, more secondary indexes does not mean better performance.

- Which columns should create indexes?

  As is mentioned above, index is important but the number of indexes should be proper. You must create appropriate indexes according to the application characteristics. In principle, you need to create an index on the columns involved in the query to improve the performance. The following are situations that need to create indexes:

  - For columns with a high degree of differentiation, filtered rows are remarkably reduced through indexes.
  - If there are multiple query criteria, you can choose composite indexes. Note to put the columns with the equivalent condition before composite indexes.

  For example, if a commonly used query is `select * from t where c1 = 10 and c2 = 100 and c3 > 10`, you can create a composite index `Index cidx (c1, c2, c3)`. In this way, you can use the query condition to create an index prefix and then scan.

- The difference between querying through indexes and directly scanning the table

  TiDB has implemented global indexes, so indexes and data of the table are not necessarily on the same data sharding. When querying through indexes, it should firstly scan indexes to get the corresponding row ID and then use the row ID to get the data. Thus, this method involves two network requests and has a certain performance overhead.

  If the query involves lots of rows, scanning index proceeds concurrently. When the first batch of results is returned, getting the data of the table can then proceed. Therefore, this is a parallel + pipeline model. Though the two accesses create overhead, the latency is not high.

  The following two conditions do not have the problem of two accesses:

  - Columns of the index have already met the query requirement. Assume that the `c` column on the `t` table has an index and the query is `select c from t where c > 10;`. At this time, all needed data can be obtained if you access the index. This situation is called `Covering Index`. But if you focus more on the query performance, you can put into index a portion of columns that do not need to be filtered but need to be returned in the query result, creating composite index. Take `select c1, c2 from t where c1 > 10;` as an example. You can optimize this query by creating composite index `Index c12 (c1, c2)`.
  - The primary key of the table is integer. In this case, TiDB uses the value of the primary key as row ID. Thus, if the query condition is on the primary key, you can directly construct the range of the row ID, scan the table data, and get the result.

- Query concurrency

  As data is distributed across many Regions, queries run in TiDB concurrently. But the concurrency by default is not high in case it consumes lots of system resources. Besides, the OLTP query usually does not involve a large amount of data and the low concurrency is enough. But for the OLAP query, the concurrency is high and TiDB modifies the query concurrency through the following system variables:

  - `tidb_distsql_scan_concurrency`:

    The concurrency of scanning data, including scanning the table and index data.
  - `tidb_index_lookup_size`:

    If it needs to access the index to get row IDs before accessing the table data, it uses a batch of row IDs as a single request to access the table data. This parameter sets the size of a batch. The larger batch increases latency, while the smaller one might lead to more queries. The proper size of this parameter is related to the amount of data that the query involves. Generally, no modification is required.
  - `tidb_index_lookup_concurrency`:

If it needs to access the index to get row IDs before accessing the table data, the concurrency of getting data through row IDs every time is modified through this parameter.

- Ensure the order of results through indexes

  You can use indexes to filter or sort data. Firstly, get row IDs according to the index order. Then, return the row content according to the return order of row IDs. In this way, the returned results are ordered according to the index column. It has been mentioned earlier that the model of scanning index and getting row is parallel + pipeline. If the row is returned according to the index order, a high concurrency between two queries does not reduce latency. Thus, the concurrency is low by default, but it can be modified through the `tidb_index_serial_scan_concurrency` variable.

- Reverse index scan

  TiDB supports scanning an ascending index in reverse order, at a speed slower than normal scan by 20%. If the data is changed frequently and thus too many versions exist, the performance overhead might be higher. It is recommended to avoid reverse index scans as much as possible.

12.5.1.3 Scenarios and practices

In the last section, we discussed some basic implementation mechanisms of TiDB and their influence on usage. This section introduces specific usage scenarios and operation practices, from deployment to application usage.

12.5.1.3.1 Deployment

Before deployment, read Software and Hardware Requirements.

It is recommended to deploy the TiDB cluster using TiUP. This tool can deploy, stop, destroy, and upgrade the whole cluster, which is quite convenient. It is not recommended to manually deploy the TiDB cluster, which might be troublesome to maintain and upgrade later.

12.5.1.3.2 Data import

To improve the write performance during the import process, you can tune TiKV's parameters as stated in Tune TiKV Memory Parameter Performance.

12.5.1.3.3 Write

As mentioned before, TiDB limits the size of a single transaction in the Key-Value layer. As for the SQL layer, a row of data is mapped to a Key-Value entry. For each additional index, one more Key-Value entry is added.

> **Note:**
>
> When you set the size limit for transactions, you need to consider the overhead of TiDB encoding and the extra transaction key. It is recommended that **the number of rows of each transaction is less than 200 and the data size of a single row is less than 100 KB**; otherwise, the performance is bad.

It is recommended to split statements into batches or add a limit to the statements, whether they are `INSERT`, `UPDATE` or `DELETE` statements.

When deleting a large amount of data, it is recommended to use `Delete from t where xx limit 5000;`. It deletes through the loop and use `Affected Rows == 0` as a condition to end the loop.

If the amount of data that needs to be deleted at a time is large, this loop method gets slower and slower because each deletion traverses backward. After deleting the previous data, lots of deleted flags remain for a short period (then all is cleared by Garbage Collection) and affect the following `DELETE` statement. If possible, it is recommended to refine the `WHERE` condition. Assume that you need to delete all data on `2017-05-26`, you can use the following statements:

```
for i from 0 to 23:
    while affected_rows > 0:
        delete from t where insert_time >= i:00:00 and insert_time < (i+1)
            ↪ :00:00 limit 5000;
        affected_rows = select affected_rows()
```

This pseudocode means to split huge chunks of data into small ones and then delete, so that the earlier `Delete` statements do not affect the later ones.

12.5.1.3.4 Query

For query requirements and specific statements, refer to System Variables.

You can control the concurrency of SQL execution through the `SET` statement and the selection of the `Join` operator through hints.

In addition, you can also use MySQL's standard index selection, the hint syntax, or control the optimizer to select indexes through `Use Index/Ignore Index hint`.

If the application scenario has both OLTP and OLAP workloads, you can send the OLTP request and OLAP request to different TiDB servers, diminishing the impact of OLAP on OLTP. It is recommended to use machines with high-performance hardware (for example, more processor cores and larger memory) for the TiDB server that processes OLAP workloads.

To completely isolate OLTP and OLAP workloads, it is recommended to run OLAP applications on TiFlash. TiFlash is a columnar storage engine with great performance on OLAP workloads. TiFlash can achieve physical isolation on the storage layer and guarantees consistent reads.

12.5.1.3.5 Monitoring and log

The monitoring metrics is the best method to learn the status of the system. It is recommended that you deploy the monitoring system along with your TiDB cluster.

TiDB uses Grafana + Prometheus to monitor the system status. The monitoring system is automatically deployed and configured if you deploy TiDB using TiUP.

There are lots of items in the monitoring system, the majority of which are for TiDB developers. You do not have to understand these items without an in-depth knowledge of the source code. Some items that are related to applications or to the state of system key components are selected and put in a separate `overview` panel for users.

In addition to monitoring, you can also view the system logs. The three components of TiDB, tidb-server, tikv-server, and pd-server, each has a `--log-file` parameter. If this parameter has been configured when the cluster is started, logs are stored in the file configured by the parameter and log files are automatically archived on a daily basis. If the `--log-file` parameter has not been configured, the log is output to `stderr`.

Starting from TiDB 4.0, TiDB provides TiDB Dashboard UI to improve usability. You can access TiDB Dashboard by visiting http://$%7BPD_IP%7D:$%7BPD_PORT%7D/dashboard in your browser. TiDB Dashboard provides features such as viewing cluster status, performance analysis, traffic visualization, cluster diagnostics, and log searching.

12.5.1.3.6 Documentation

The best way to learn about a system or solve the problem is to read its documentation and understand its implementation principles.

TiDB has a large number of official documents both in Chinese and English. If you have met an issue, you can start from FAQ and TiDB Cluster Troubleshooting Guide. You can also search the issue list or create an issue in TiDB repository on GitHub.

TiDB also has many useful migration tools. See Migration Tool Overview for details.

For more articles on the technical details of TiDB, see the PingCAP official blog site.

12.5.1.4 Best scenarios for TiDB

TiDB is suitable for the following scenarios:

- The data volume is too large for a standalone database
- You do not want to do sharding
- The access mode has no obvious hotspot

- Transactions, strong consistency, and disaster recovery are required
- You hope to have real-time Hybrid Transaction/Analytical Processing (HTAP) analytics and reduce storage links

12.5.2 Best Practices for Developing Java Applications with TiDB

This document introduces the best practice for developing Java applications to better use TiDB. Based on some common Java application components that interact with the backend TiDB database, this document also provides the solutions to commonly encountered issues during development.

12.5.2.1 Database-related components in Java applications

Common components that interact with the TiDB database in Java applications include:

- Network protocol: A client interacts with a TiDB server via the standard MySQL protocol.
- JDBC API and JDBC drivers: Java applications usually use the standard JDBC (Java Database Connectivity) API to access a database. To connect to TiDB, you can use a JDBC driver that implements the MySQL protocol via the JDBC API. Such common JDBC drivers for MySQL include MySQL Connector/J and MariaDB Connector/J.
- Database connection pool: To reduce the overhead of creating a connection each time it is requested, applications usually use a connection pool to cache and reuse connections. JDBC DataSource defines a connection pool API. You can choose from different open-source connection pool implementations as needed.
- Data access framework: Applications usually use a data access framework such as MyBatis and Hibernate to further simplify and manage the database access operations.
- Application implementation: The application logic controls when to send what commands to the database. Some applications use Spring Transaction aspects to manage transactions' start and commit logics.

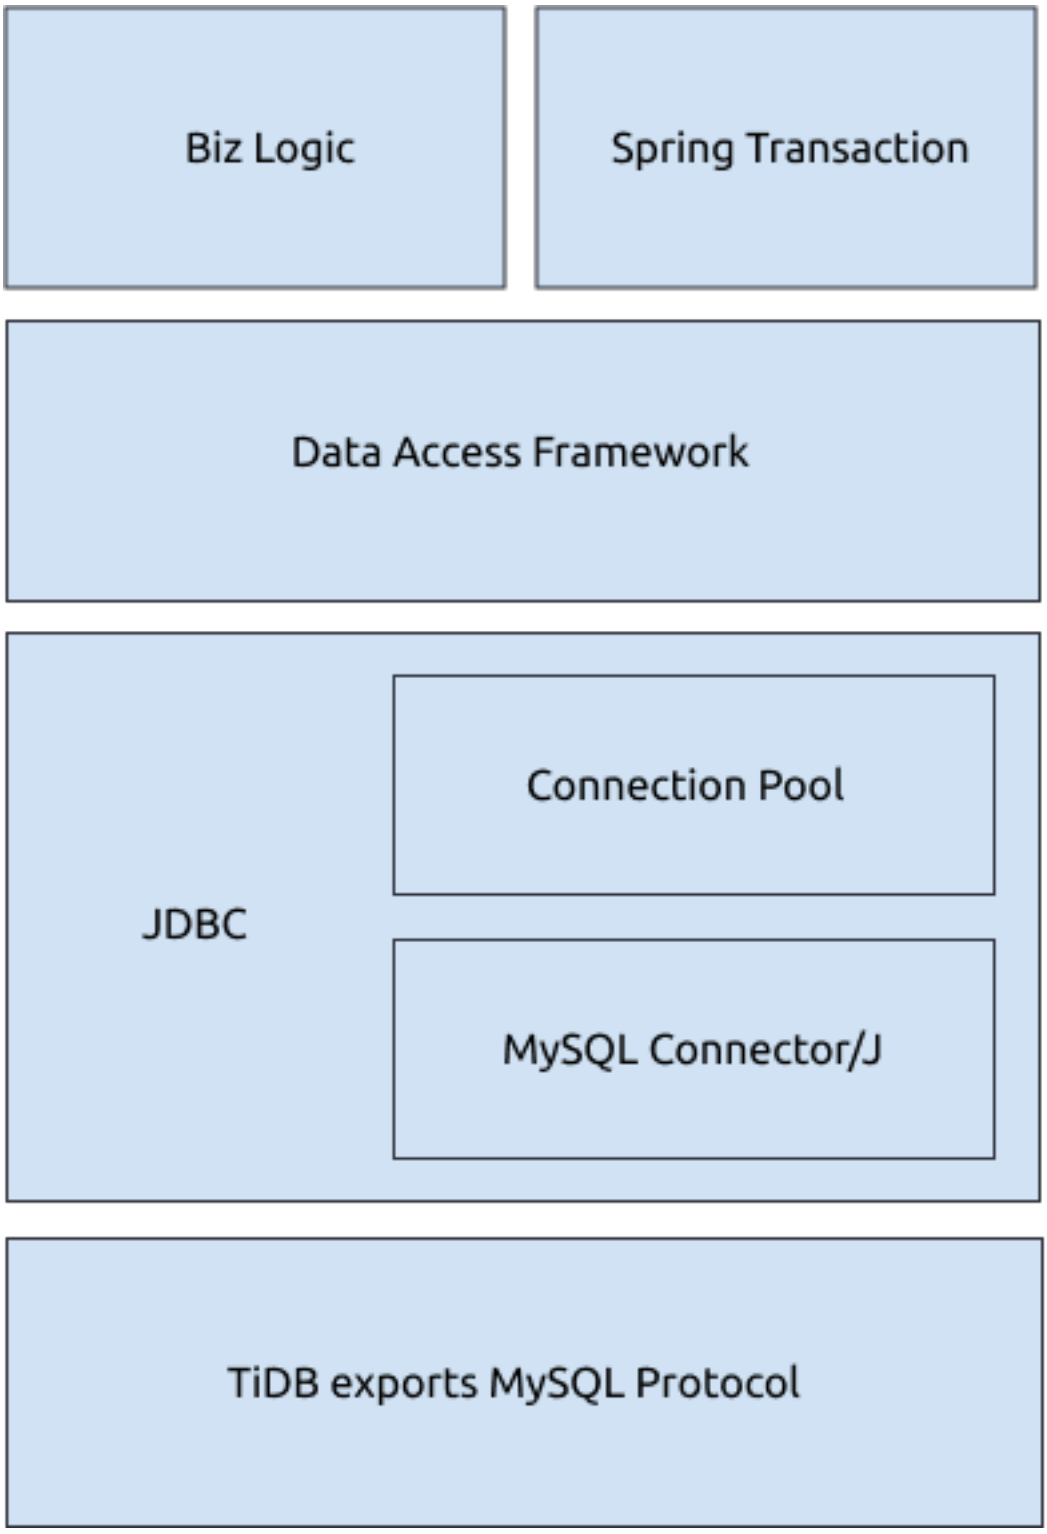

Figure 420: Java application components

From the above diagram, you can see that a Java application might do the following things:

- Implement the MySQL protocol via the JDBC API to interact with TiDB.
- Get a persistent connection from the connection pool.
- Use a data access framework such as MyBatis to generate and execute SQL statements.
- Use Spring Transaction to automatically start or stop a transaction.

The rest of this document describes the issues and their solutions when you develop a Java application using the above components.

12.5.2.2 JDBC

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

12.5.2.2.1 JDBC API

For JDBC API usage, see JDBC official tutorial. This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use Prepared Statements instead of regular execution from a text file and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see MySQL JDBC parameters.

Use Batch API

For batch inserts, you can use the `addBatch/executeBatch` API. The `addBatch()` method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

Note:

In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.

If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see Batch-related parameters.

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and save them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time, and waits until the client's memory is ready and it requests for the next batch.

The following two processing methods are usually used in JDBC:

- The first method: Set `FetchSize` to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

  When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise, the error `No statements may be issued when any streaming result sets are open and in use on a given connection. Ensure that you have called .close()on any active streaming result sets before attempting more queries.` is returned.

  To avoid such an error in queries before the client finishes reading or closes `resultset`, you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- The second method: Use Cursor Fetch by first setting `FetchSize` as a positive integer and then configuring `useCursorFetch = true` in the JDBC URL.

TiDB supports both methods, but it is recommended that you use the first method that sets `FetchSize` to `Integer.MIN_VALUE`, because it is a simpler implementation and has better execution efficiency.

For the second method, TiDB first loads all data to the TiDB node, and then returns data to the client according to the `FetchSize`. Therefore, it usually consumes more memory

than the first method. If `tidb_enable_tmp_storage_on_oom` is set to `ON`, TiDB might temporarily write the result to the hard disk.

If the `tidb_enable_lazy_cursor_fetch` system variable is set to `ON`, TiDB tries to read part of the data only when the client fetches it, which uses less memory. For more details and limitations, read the complete descriptions for the `tidb_enable_lazy_cursor_fetch` system variable.

12.5.2.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces MySQL Connector/J's parameter configurations (If you use MariaDB, see MariaDB's parameter configurations). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to `Prepare`.

`useServerPrepStmts`

`useServerPrepStmts` is set to `false` by default, that is, even if you use the Prepare API, the "prepare" operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

`cachePrepStmts`

Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the "prepare" operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

`prepStmtCacheSqlLimit`

After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` configuration (the default value is `256`). This configuration controls the maximum length of the Prepared Statements cached on the client.

The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

You need to check whether this setting is too small if you:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

`prepStmtCacheSize`

`prepStmtCacheSize` controls the number of cached Prepared Statements (the default value is `25`). If your application requires "preparing" many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements` ↪ `=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare("insert into t (a) values(?)");
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
insert into t(a) values(10);
insert into t(a) values(11);
insert into t(a) values(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
insert into t(a) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple "values" keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
insert into t (a) values (10) on duplicate key update a = 10;
insert into t (a) values (11) on duplicate key update a = 11;
insert into t (a) values (12) on duplicate key update a = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
insert into t (a) values (10) on duplicate key update a = values(a);
insert into t (a) values (11) on duplicate key update a = values(a);
insert into t (a) values (12) on duplicate key update a = values(a);
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
insert into t (a) values (10), (11), (12) on duplicate key update a =
    ↪ values(a);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
update t set a = 10 where id = 1; update t set a = 11 where id = 2; update
    ↪ t set a = 12 where id = 3;
```

In addition, because of a client bug, if you want to configure `rewriteBatchedStatements` `↪ =true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Integrate parameters

Through monitoring, you might notice that although the application only performs `INSERT` operations to the TiDB cluster, there are a lot of redundant `SELECT` statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless

for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` includes a group of configurations. To get the detailed configurations in MySQL Connector/J 8.0 and those in MySQL Connector/J 5.1, see mysql-connector-j 8.0 and mysql-connector-j 5.1 respectively.

After it is configured, you can check the monitoring to see a decreased number of `SELECT` statements.

> **Note:**
>
> Enabling `useConfigs=maxPerformance` requires MySQL Connector/J version 8.0.33 or later. For more details, see MySQL JDBC Bug.

Timeout-related parameters

TiDB provides two MySQL-compatible parameters that controls the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. The default value of both parameters is `0`, which by default allows the connection to be infinitely idle and infinitely busy (an infinite duration for one SQL statement to execute).

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables=wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

Typical JDBC connection string parameters

Combining the preceding parameter values, the JDBC connection string configuration is as follows:

```
jdbc:mysql://<IP_ADDRESS>:<PORT_NUMBER>/<DATABASE_NAME>?characterEncoding=
    ↪ UTF-8&useSSL=false&useServerPrepStmts=true&cachePrepStmts=true&
    ↪ prepStmtCacheSqlLimit=10000&prepStmtCacheSize=1000&useConfigs=
    ↪ maxPerformance&rewriteBatchedStatements=true
```

> **Note:**

> If you are connecting over a public network, you need to set `useSSL=true` and enable TLS between TiDB clients and servers.

12.5.2.3 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least), because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

TiDB supports the following Java connection pools:

- HikariCP
- tomcat-jdbc
- druid
- c3p0
- dbcp

In practice, some connection pools might persistently use specific active sessions. Although the total number of connections appears evenly distributed across TiDB compute nodes, uneven distribution of active connections can lead to actual load imbalance. In distributed scenarios, it is recommended to use HikariCP, which manages connection lifecycles effectively and helps prevent active connections from being fixed on certain nodes, achieving balanced load distribution.

12.5.2.3.1 Typical connection pool configuration

The following is an example configuration for HikariCP:

```
hikari:
  maximumPoolSize: 20
  poolName: hikariCP
  connectionTimeout: 30000
  maxLifetime: 1200000
  keepaliveTime: 120000
```

The parameter explanations are as follows. For more details, refer to the official HikariCP documentation.

- `maximumPoolSize`: the maximum number of connections in the pool. The default value is `10`. In containerized environments, it is recommended to set this to 4–10 times the number of CPU cores available to the Java application. Setting this value too high can lead to resource wastage, while setting it too low can slow down connection acquisition. See About Pool Sizing for more details.

- `minimumIdle`: HikariCP recommends not setting this parameter. The default value is equal to the value of `maximumPoolSize`, which disables connection pool scaling. This ensures that connections are readily available during traffic spikes and avoids delays caused by connection creation.
- `connectionTimeout`: the maximum time (in milliseconds) that an application waits to acquire a connection from the pool. The default value is `30000` milliseconds (30 seconds). If no available connection is obtained within this time, a `SQLException` exception occurs.
- `maxLifetime`: the maximum lifetime (in milliseconds) of a connection in the pool. The default value is `1800000` milliseconds (30 minutes). Connections in use are not affected. After the connection is closed, it will be removed according to this setting. Setting this value too low can cause frequent reconnections. If you are using `graceful-wait-before-shutdown`, ensure this value is less than the wait time.
- `keepaliveTime`: the interval (in milliseconds) between keepalive operations on connections in the pool. This setting helps prevent disconnections caused by database or network idle timeouts. The default value is `120000` milliseconds (2 minutes). The pool prefers using the JDBC4 `isValid()` method to keep idle connections alive.

12.5.2.3.2 Probe configuration

The connection pool maintains persistent connections from clients to TiDB as follows:

- Before v5.4, TiDB does not proactively close client connections by default (unless an error is reported).
- Starting from v5.4, TiDB automatically closes client connections after `28800` seconds (this is, `8` hours) of inactivity by default. You can control this timeout setting using the TiDB and MySQL compatible `wait_timeout` variable. For more information, see JDBC Query Timeout.

Moreover, there might be network proxies such as LVS or HAProxy between clients and TiDB. These proxies typically proactively clean up connections after a specific idle period (determined by the proxy's idle configuration). In addition to monitoring the proxy's idle configuration, connection pools also need to maintain or probe connections for keep-alive.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
    ↪ . The driver has not received any packets from the server. com.mysql.
    ↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
    ↪ failure
```

If `n` in `n milliseconds ago` is `0` or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as `3600000` in the above example), it is likely that this connection was idle for a long time and then closed by the intermediate proxy. The usual

solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

12.5.2.4 Data access framework

Applications often use some kind of data access framework to simplify database access.

12.5.2.4.1 MyBatis

MyBatis is a popular Java data access framework. It is mainly used to manage SQL queries and complete the mapping between result sets and Java objects. MyBatis is highly compatible with TiDB. MyBatis rarely has problems based on its historical issues.

Here this document mainly focuses on the following configurations.

Mapper parameters

MyBatis Mapper supports two parameters:

- `select 1 from t where id = #{param1}` will be converted to `select 1 from t where id =?` as a Prepared Statement and be "prepared", and the actual parameter will be used for reuse. You can get the best performance when using this parameter with the previously mentioned Prepare connection parameters.
- `select 1 from t where id = ${param2}` will be replaced with `select 1 from t where id = 1` as a text file and be executed. If this statement is replaced with different parameters and is executed, MyBatis will send different requests for "preparing" the statements to TiDB. This might cause TiDB to cache a large number of Prepared Statements, and executing SQL operations this way has injection security risks.

Dynamic SQL Batch

Dynamic SQL - foreach

To support the automatic rewriting of multiple `INSERT` statements into the form of `insert ... values(...), (...), ...`, in addition to configuring `rewriteBatchedStatements=true` in JDBC as mentioned before, MyBatis can also use dynamic SQL to semi-automatically generate batch inserts. Take the following mapper as an example:

```
<insert id="insertTestBatch" parameterType="java.util.List" fetchSize="1">
  insert into test
   (id, v1, v2)
  values
  <foreach item="item" index="index" collection="list" separator=",">
  (
   #{item.id}, #{item.v1}, #{item.v2}
  )
  </foreach>
  on duplicate key update v2 = v1 + values(v1)
</insert>
```

This mapper generates an `insert on duplicate key update` statement. The number of `(?,?,?)` following "values" is determined by the number of passed lists. Its final effect is similar to using `rewriteBatchStatements=true`, which also effectively reduces communication overhead between the client and TiDB.

As mentioned before, you also need to note that the Prepared Statements will not be cached after their maximum length exceeds the value of `prepStmtCacheSqlLimit`.

Streaming result

A previous section introduces how to stream read execution results in JDBC. In addition to the corresponding configurations of JDBC, if you want to read a super large result set in MyBatis, you also need to note that:

- You can set `fetchSize` for a single SQL statement in the mapper configuration (see the previous code block). Its effect is equivalent to calling `setFetchSize` in JDBC.
- You can use the query interface with `ResultHandler` to avoid getting the entire result set at once.
- You can use the `Cursor` class for stream reading.

If you configure mappings using XML, you can stream read results by configuring `fetchSize="-2147483648"(Integer.MIN_VALUE)` in the mapping's `<select>` section.

```
<select id="getAll" resultMap="postResultMap" fetchSize="-2147483648">
  select * from post;
</select>
```

If you configure mappings using code, you can add the `@Options(fetchSize = Integer .MIN_VALUE)` annotation and keep the type of results as `Cursor` so that the SQL results can be read in streaming.

```
@Select("select * from post")
@Options(fetchSize = Integer.MIN_VALUE)
Cursor<Post> queryAllPost();
```

12.5.2.4.2 `ExecutorType`

You can choose `ExecutorType` during `openSession`. MyBatis supports three types of executors:

- Simple: The Prepared Statements are called to JDBC for each execution (if the JDBC configuration item `cachePrepStmts` is enabled, repeated Prepared Statements will be reused)
- Reuse: The Prepared Statements are cached in `executor`, so that you can reduce duplicate calls for Prepared Statements without using the JDBC `cachePrepStmts`
- Batch: Each update operation (`INSERT`/`DELETE`/`UPDATE`) will first be added to the batch, and will be executed until the transaction commits or a `SELECT` query is performed. If `rewriteBatchStatements` is enabled in the JDBC layer, it will try to rewrite the statements. If not, the statements will be sent one by one.

Usually, the default value of `ExecutorType` is `Simple`. You need to change `ExecutorType` when calling `openSession`. If it is the batch execution, you might find that in a transaction the `UPDATE` or `INSERT` statements are executed pretty fast, but it is slower when reading data or committing the transaction. This is actually normal, so you need to note this when troubleshooting slow SQL queries.

12.5.2.5 Spring Transaction

In the real world, applications might use Spring Transaction and AOP aspects to start and stop transactions.

By adding the `@Transactional` annotation to the method definition, AOP starts the transaction before the method is called, and commits the transaction before the method returns the result. If your application has a similar need, you can find `@Transactional` in code to determine when the transaction is started and closed.

Pay attention to a special case of embedding. If it occurs, Spring will behave differently based on the Propagation configuration.

12.5.2.6 Misc

This section introduces some useful tools for Java to help you troubleshoot issues.

12.5.2.6.1 Troubleshooting tools

Using the powerful troubleshooting tools of JVM is recommended when an issue occurs in your Java application and you do not know the application logic. Here are a few common tools:

jstack

jstack is similar to pprof/goroutine in Go, which can easily troubleshoot the process stuck issue.

By executing `jstack pid`, you can output the IDs and stack information of all threads in the target process. By default, only the Java stack is output. If you want to output the C++ stack in the JVM at the same time, add the `-m` option.

By using jstack multiple times, you can easily locate the stuck issue (for example, a slow query from application's view due to using Batch ExecutorType in Mybatis) or the application deadlock issue (for example, the application does not send any SQL statement because it is preempting a lock before sending it).

In addition, `top -p $ PID -H` or Java swiss knife are common methods to view the thread ID. Also, to locate the issue of "a thread occupies a lot of CPU resources and I don't know what it is executing", do the following steps:

- Use `printf "%x\n" pid` to convert the thread ID to hexadecimal.
- Go to the jstack output to find the stack information of the corresponding thread.

jmap & mat

Unlike pprof/heap in Go, jmap dumps the memory snapshot of the entire process (in Go, it is the sampling of the distributor), and then the snapshot can be analyzed by another tool mat.

Through mat, you can see the associated information and attributes of all objects in the process, and you can also observe the running status of the thread. For example, you can use mat to find out how many MySQL connection objects exist in the current application, and what is the address and status information of each connection object.

Note that mat only handles reachable objects by default. If you want to troubleshoot young GC issues, you can adjust mat configuration to view unreachable objects. In addition, for investigating the memory allocation of young GC issues (or a large number of short-lived objects), using Java Flight Recorder is more convenient.

trace

Online applications usually do not support modifying the code, but it is often desired that dynamic instrumentation is performed in Java to locate issues. Therefore, using btrace or arthas trace is a good option. They can dynamically insert trace code without restarting the application process.

Flame graph

Obtaining flame graphs in Java applications is tedious. For details, see Java Flame Graphs Introduction: Fire For Everyone!.

12.5.2.7 Conclusion

Based on commonly used Java components that interact with databases, this document describes the common problems and solutions for developing Java applications with TiDB. TiDB is highly compatible with the MySQL protocol, so most of the best practices for MySQL-based Java applications also apply to TiDB.

12.5.2.8 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

12.5.3 Best Practices for Using HAProxy in TiDB

This document describes best practices for configuration and usage of HAProxy in TiDB. HAProxy provides load balancing for TCP-based applications. From TiDB clients, you can manipulate data just by connecting to the floating virtual IP address provided by HAProxy, which helps to achieve load balance in the TiDB server layer.

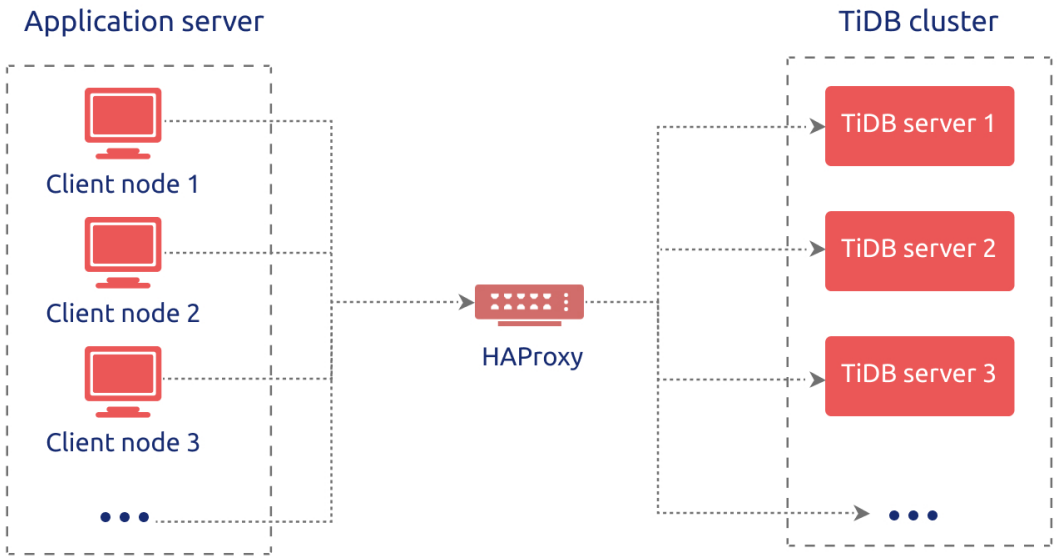

Figure 421: HAProxy Best Practices in TiDB

Note:

The minimum version of HAProxy that works with all versions of TiDB is v1.5. Between v1.5 and v2.1, you need to set the `post-41` option in `mysql-check`. It is recommended to use HAProxy v2.2 or newer.

12.5.3.1 HAProxy overview

HAProxy is free, open-source software written in C language that provides a high availability load balancer and proxy server for TCP and HTTP-based applications. Because of its

fast and efficient use of CPU and memory, HAProxy is now widely used by many well-known websites such as GitHub, Bitbucket, Stack Overflow, Reddit, Tumblr, Twitter, Tuenti, and AWS (Amazon Web Services).

HAProxy is written in the year 2000 by Willy Tarreau, the core contributor to the Linux kernel, who is still responsible for the maintenance of the project and provides free software updates in the open-source community. In this guide, HAProxy 2.6 is used. It is recommended to use the latest stable version. See the released version of HAProxy for details.

12.5.3.2 Basic features

- High Availability: HAProxy provides high availability with support for a graceful shutdown and a seamless switchover;
- Load Balancing: Two major proxy modes are supported: TCP, also known as layer 4, and HTTP, also known as layer 7. No less than 9 load balancing algorithms are supported, such as roundrobin, leastconn and random;
- Health Check: HAProxy periodically checks the status of HTTP or TCP mode of the server;
- Sticky Session: HAProxy can stick a client to a specific server for the duration when the application does not support sticky sessions;
- SSL: HTTPS communication and resolution are supported;
- Monitoring and Statistics: Through the web page, you can monitor the service state and traffic flow in real time.

12.5.3.3 Before you begin

Before you deploy HAProxy, make sure that you meet the hardware and software requirements.

12.5.3.3.1 Hardware requirements

According to the HAProxy documentation, the minimum hardware configuration for HAProxy is shown in the following table. Under the Sysbench `oltp_read_write` workload, the maximum QPS for this configuration is about 50K. You can increase the server configuration according to your load balancing environment.

Hardware resource	Minimum specification
CPU	2 cores, 3.5 GHz
Memory	4 GB
Storage	50 GB (SATA)
Network Interface Card	10G Network Card

12.5.3.3.2 Software requirements

You can use the following operating systems and make sure the required dependencies are installed. If you use yum to install HAProxy, the dependencies are installed along with it and you do not need to separately install them again.

Operating systems

Linux distribution	Version
Red Hat Enterprise Linux	7 or 8
CentOS	7 or 8
Oracle Enterprise Linux	7 or 8
Ubuntu LTS	18.04 or later versions

Note:

- For more information about other supported operating systems, see HAProxy documentation.

Dependencies

- epel-release
- gcc
- systemd-devel

To install the dependencies above, run the following command:

```
yum -y install epel-release gcc systemd-devel
```

12.5.3.4 Deploy HAProxy

You can easily use HAProxy to configure and set up a load-balanced database environment. This section shows general deployment operations. You can customize the configuration file based on your actual scenario.

12.5.3.4.1 Install HAProxy

1. Download the package of the HAProxy 2.6.2 source code:

   ```
   wget https://www.haproxy.org/download/2.6/src/haproxy-2.6.2.tar.gz
   ```

2. Extract the package:

```
tar zxf haproxy-2.6.2.tar.gz
```

3. Compile the application from the source code:

```
cd haproxy-2.6.2
make clean
make -j 8 TARGET=linux-glibc USE_THREAD=1
make PREFIX=${/app/haproxy} SBINDIR=${/app/haproxy/bin} install #
    ↪ Replace `${/app/haproxy}` and `${/app/haproxy/bin}` with your
    ↪ custom directories.
```

4. Reconfigure the profile:

```
echo 'export PATH=/app/haproxy/bin:$PATH' >> /etc/profile
. /etc/profile
```

5. Check whether the installation is successful:

```
which haproxy
```

HAProxy commands

Execute the following command to print a list of keywords and their basic usage:

```
haproxy --help
```

Option	Description
`-v`	Reports the version and build date.
`-vv`	Displays the version, build options, libraries versions and usable pollers.
`-d`	Enables debug mode.

Option	Description
`-db`	Disables background mode and multi-process mode.
`-dM [<` `↪ byte` `↪ >]`	Forces memory poisoning, which means that each and every memory region allocated with malloc() or pool_alloc2() will be filled with `<byte>` before being passed to the caller.
`-V`	Enables verbose mode (disables quiet mode).
`-D`	Starts as a daemon.
`-C <dir>`	Changes to directory `<dir>` before loading configuration files.

Option	Description
`-W`	Master-worker mode.
`-q`	Sets “quiet” mode: This disables some messages during the configuration parsing and during startup.
`-c`	Only performs a check of the configuration files and exits before trying to bind.
`-n <` ↪ `limit` ↪ `>`	Limits the per-process connection limit to `<limit>`.
`-m <` ↪ `limit` ↪ `>`	Limits the total allocatable memory to `<limit>` megabytes across all processes.

Option	Description
`-N <limit>`	Sets the default per-proxy maxconn to `<limit>` instead of the builtin default value (usually 2000).
`-L <name>`	Changes the local peer name to `<name>`, which defaults to the local hostname.
`-p <file>`	Writes all processes' PIDs into `<file>` during startup.
`-de`	Disables the use of epoll(7). epoll(7) is available only on Linux 2.6 and some custom Linux 2.4 systems.
`-dp`	Disables the use of poll(2). select(2) might be used instead.

Option	Description
`-dS`	Disables the use of splice(2), which is broken on older kernels.
`-dR`	Disables SO_REUSEPORT usage.
`-dr`	Ignores server address resolution failures.
`-dV`	Disables SSL verify on the server side.

Option	Description
`-sf <pidlist>`	Sends the “finish” signal to the PIDs in pidlist after startup. The processes which receive this signal wait for all sessions to finish before exiting. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGUSR1 are sent.

Option	Description
`-st <pidlist>`	Sends the "terminate" signal to the PIDs in pidlist after startup. The processes which receive this signal terminate immediately, closing all active sessions. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGTERM are sent.

Option	Description
`-x <unix_socket>`	Connects to the specified socket and retrieves all the listening sockets from the old process. Then, these sockets are used instead of binding new ones.
`-S <bind>[,<bind_options>...]`	In master-worker mode, creates a master CLI. This CLI enables access to the CLI of every worker. Useful for debugging, it's a convenient way of accessing a leaving process.

For more details on HAProxy command line options, refer to Management Guide of HAProxy and General Commands Manual of HAProxy.

12.5.3.4.2 Configure HAProxy

A configuration template is generated when you use yum to install HAProxy. You can also customize the following configuration items according to your scenario.

```
global                                  # Global configuration.
   log         127.0.0.1 local2         # Global syslog servers (up to two).
   chroot      /var/lib/haproxy         # Changes the current directory and
      ↪ sets superuser privileges for the startup process to improve
      ↪ security.
   pidfile     /var/run/haproxy.pid     # Writes the PIDs of HAProxy processes
      ↪  into this file.
   maxconn     4096                     # The maximum number of concurrent
      ↪ connections for a single HAProxy process. It is equivalent to the
      ↪ command-line argument "-n".
   nbthread    48                       # The maximum number of threads. (The
      ↪ upper limit is equal to the number of CPUs)
   user        haproxy                  # Same with the UID parameter.
   group       haproxy                  # Same with the GID parameter. A

      ↪ connect to an upstream server. If the number of connection attempts
      ↪  exceeds the value, the backend server is considered unavailable.
   timeout connect 2s                   # The maximum time to wait for a
      ↪ connection attempt to a backend server to succeed. It should be set
      ↪  to a shorter time if the server is located on the same LAN as
      ↪ HAProxy.
   timeout client 30000s                # The maximum inactivity time on the
      ↪ client side.
   timeout server 30000s                # The maximum inactivity time on the
      ↪ server side.

listen admin_stats                      # The name of the Stats page reporting
   ↪  information from frontend and backend. You can customize the name
   ↪ according to your needs.
   bind 0.0.0.0:8080                    # The listening port.
   mode http                            # The monitoring mode.
   option httplog                       # Enables HTTP logging.
   maxconn 10                           # The maximum number of concurrent
      ↪ connections.
```

```
  stats refresh 30s                   # Automatically refreshes the Stats
     ↪ page every 30 seconds.
  stats uri /haproxy                  # The URL of the Stats page.
  stats realm HAProxy                 # The authentication realm of the
     ↪ Stats page.
  stats auth admin:pingcap123         # User name and password in the Stats
     ↪ page. You can have multiple user names.
  stats hide-version                  # Hides the version information of
     ↪ HAProxy on the Stats page.
  stats admin if TRUE                 # Manually enables or disables the
     ↪ backend server (supported in HAProxy 1.4.9 or later versions).

listen tidb-cluster                   # Database load balancing.
  bind 0.0.0.0:3390                   # The Floating IP address and
     ↪ listening port.
  mode tcp                            # HAProxy uses layer 4, the transport
     ↪ layer.
  balance leastconn                   # The server with the smallest number
     ↪ of connections receives the connection. "leastconn" is recommended
     ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
     ↪  than protocols using short sessions, such as HTTP. The algorithm
     ↪ is dynamic, which means that server weights might be adjusted on
     ↪ the fly for slow starts for instance.
  server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
     ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
     ↪ detected as successful twice, the server is considered available;
     ↪ if it is detected as failed three times, the server is considered
     ↪ unavailable.
  server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

To check the source IP address using `SHOW PROCESSLIST`, you need to configure the PROXY protocol to connect to TiDB.

```
  server tidb-1 10.9.18.229:4000 send-proxy check inter 2000 rise 2 fall 3
  server tidb-2 10.9.39.208:4000 send-proxy check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 send-proxy check inter 2000 rise 2 fall 3
```

Note:

Before using the PROXY protocol, you need to configure `proxy-protocol.networks` in the configuration file of the TiDB server.

12.5.3.4.3 Start HAProxy

To start HAProxy, run `haproxy`. `/etc/haproxy/haproxy.cfg` is read by default (recommended).

```
haproxy -f /etc/haproxy/haproxy.cfg
```

12.5.3.4.4 Stop HAProxy

To stop HAProxy, use the `kill -9` command.

1. Run the following command:

```
ps -ef | grep haproxy
```

2. Terminate the process of HAProxy:

```
kill -9 ${haproxy.pid}
```

12.5.4 Highly Concurrent Write Best Practices

This document describes best practices for handling highly-concurrent write-heavy workloads in TiDB, which can help to facilitate your application development.

12.5.4.1 Target audience

This document assumes that you have a basic understanding of TiDB. It is recommended that you first read the following three blog articles that explain TiDB fundamentals, and TiDB Best Practices:

- Data Storage
- Computing
- Scheduling

12.5.4.2 Highly-concurrent write-intensive scenario

The highly concurrent write scenario often occurs when you perform batch tasks in applications, such as clearing and settlement. This scenario has the following features:

- A huge volume of data
- The need to import historical data into database in a short time
- The need to read a huge volume of data from database in a short time

These features pose these challenges to TiDB:

- The write or read capacity must be linearly scalable.
- Database performance is stable and does not decrease as a huge volume of data is written concurrently.

For a distributed database, it is important to make full use of the capacity of all nodes and to prevent a single node from becoming the bottleneck.

12.5.4.3 Data distribution principles in TiDB

To address the above challenges, it is necessary to start with the data segmentation and scheduling principle of TiDB. Refer to Scheduling for more details.

TiDB splits data into Regions, each representing a range of data with a size limit of 96M by default. Each Region has multiple replicas, and each group of replicas is called a Raft Group. In a Raft Group, the Region Leader executes the read and write tasks (TiDB supports Follower-Read) within the data range. The Region Leader is automatically scheduled by the Placement Driver (PD) component to different physical nodes evenly to distribute the read and write pressure.

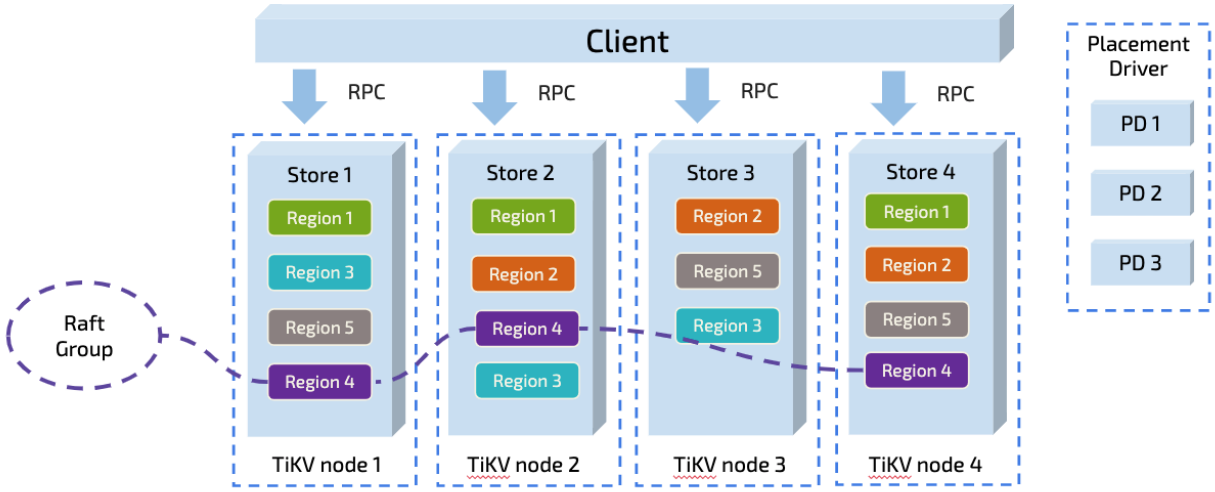

Figure 422: TiDB Data Overview

In theory, if an application has no write hotspot, TiDB, by the virtue of its architecture, can not only linearly scale its read and write capacities, but also make full use of the distributed resources. From this point of view, TiDB is especially suitable for the high-concurrent and write-intensive scenario.

However, the actual situation often differs from the theoretical assumption.

> **Note:**
>
> No write hotspot in an application means the write scenario does not have any `AUTO_INCREMENT` primary key or monotonically increasing index.

12.5.4.4 Hotspot case

The following case explains how a hotspot is generated. Take the table below as an example:

```
CREATE TABLE IF NOT EXISTS TEST_HOTSPOT(
     id        BIGINT PRIMARY KEY,
     age       INT,
     user_name VARCHAR(32),
     email     VARCHAR(128)
)
```

This table is simple in structure. In addition to `id` as the primary key, no secondary index exists. Execute the following statement to write data into this table. `id` is discretely generated as a random number.

```
SET SESSION cte_max_recursion_depth = 1000000;
INSERT INTO TEST_HOTSPOT
SELECT
  n,                                    -- ID
  RAND()*80,                            -- Number between 0 and 80
  CONCAT('user-',n),
  CONCAT(
    CHAR(65 + (RAND() * 25) USING ascii), -- Number between 65 and 65+25,
       ↪ converted to a character, A-Z
    '-user-',
    n,
    '@example.com'
  )
FROM
  (WITH RECURSIVE nr(n) AS
    (SELECT 1                           -- Start CTE at 1
      UNION ALL SELECT n + 1            -- increase n with 1 every loop
      FROM nr WHERE n < 1000000         -- stop loop at 1_000_000
    ) SELECT n FROM nr
  ) a;
```

The load comes from executing the above statement intensively in a short time.

In theory, the above operation seems to comply with the TiDB best practices, and no hotspot is caused in the application. The distributed capacity of TiDB can be fully used with adequate machines. To verify whether it is truly in line with the best practices, a test is conducted in the experimental environment, which is described as follows:

For the cluster topology, 2 TiDB nodes, 3 PD nodes and 6 TiKV nodes are deployed. Ignore the QPS performance, because this test is to clarify the principle rather than for benchmark.

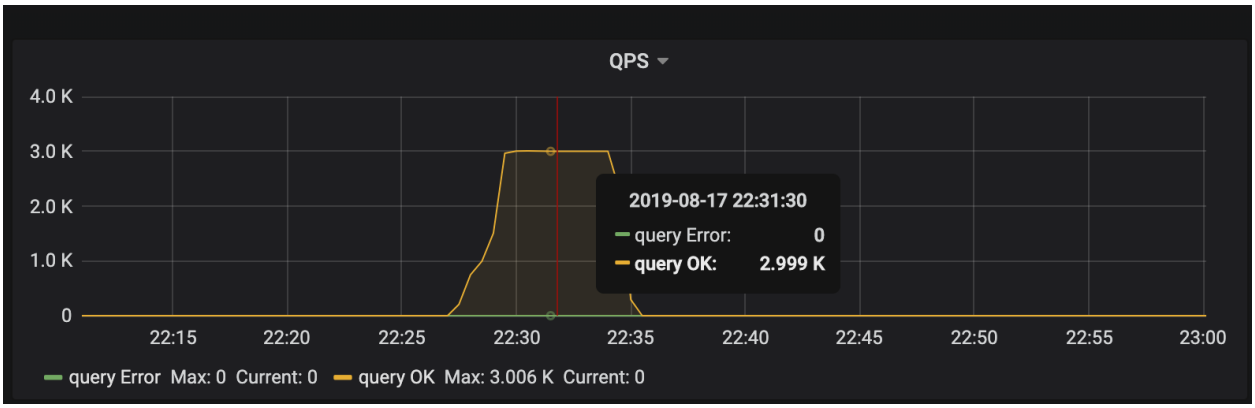

Figure 423: QPS1

The client starts "intensive" write requests in a short time, which is 3K QPS received by TiDB. In theory, the load pressure should be evenly distributed to 6 TiKV nodes. However, from the CPU usage of each TiKV node, the load distribution is uneven. The `tikv-3` node is the write hotspot.

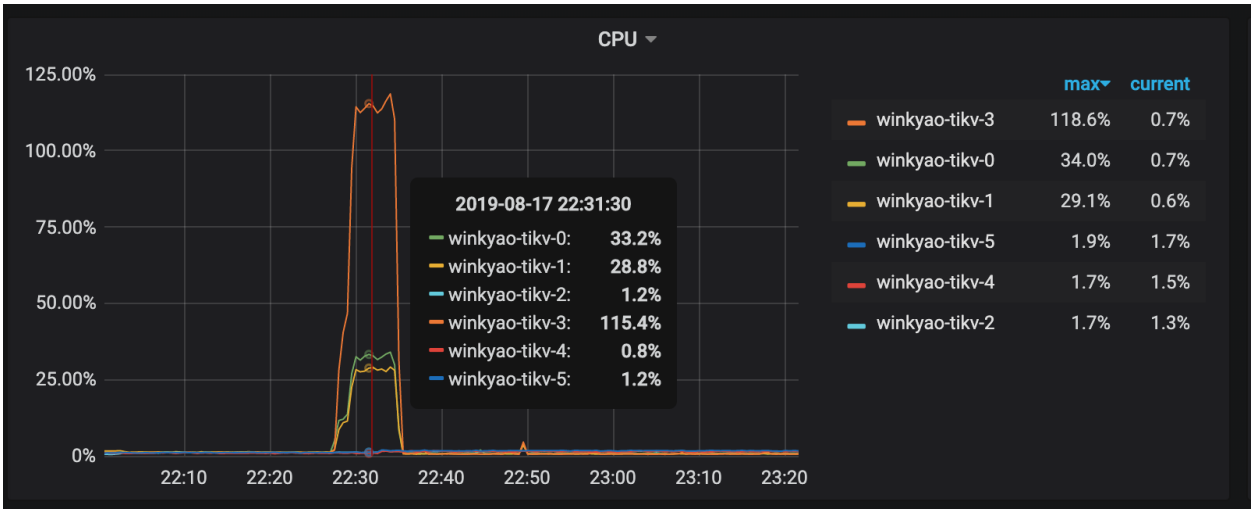

Figure 424: QPS2

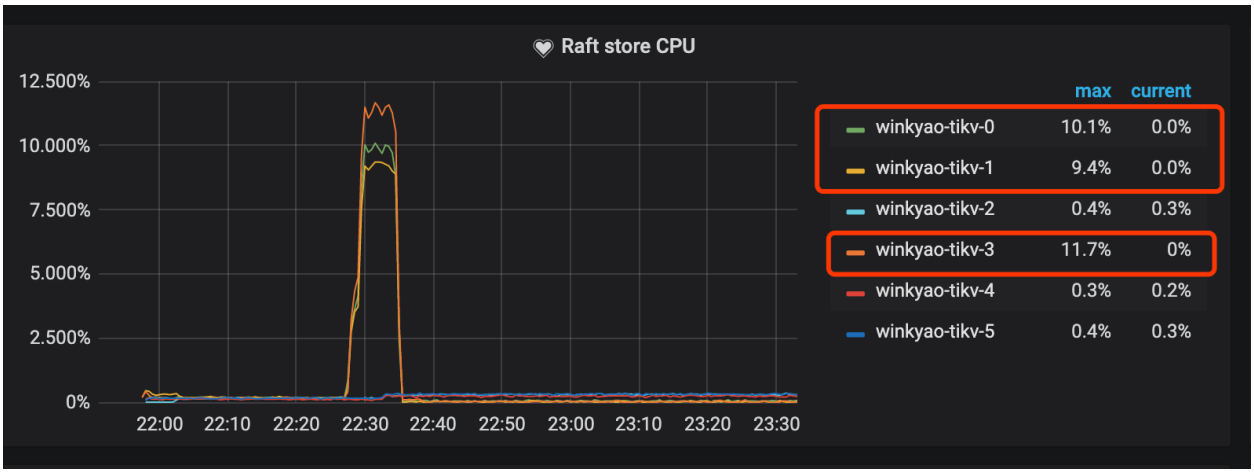

Figure 425: QPS3

Raft store CPU is the CPU usage rate for the `raftstore` thread, usually representing the write load. In this scenario, `tikv-3` is the Leader of this Raft Group; `tikv-0` and `tikv-1` are the followers. The loads of other nodes are almost empty.

The monitoring metrics of PD also confirms that hotspot has been caused.

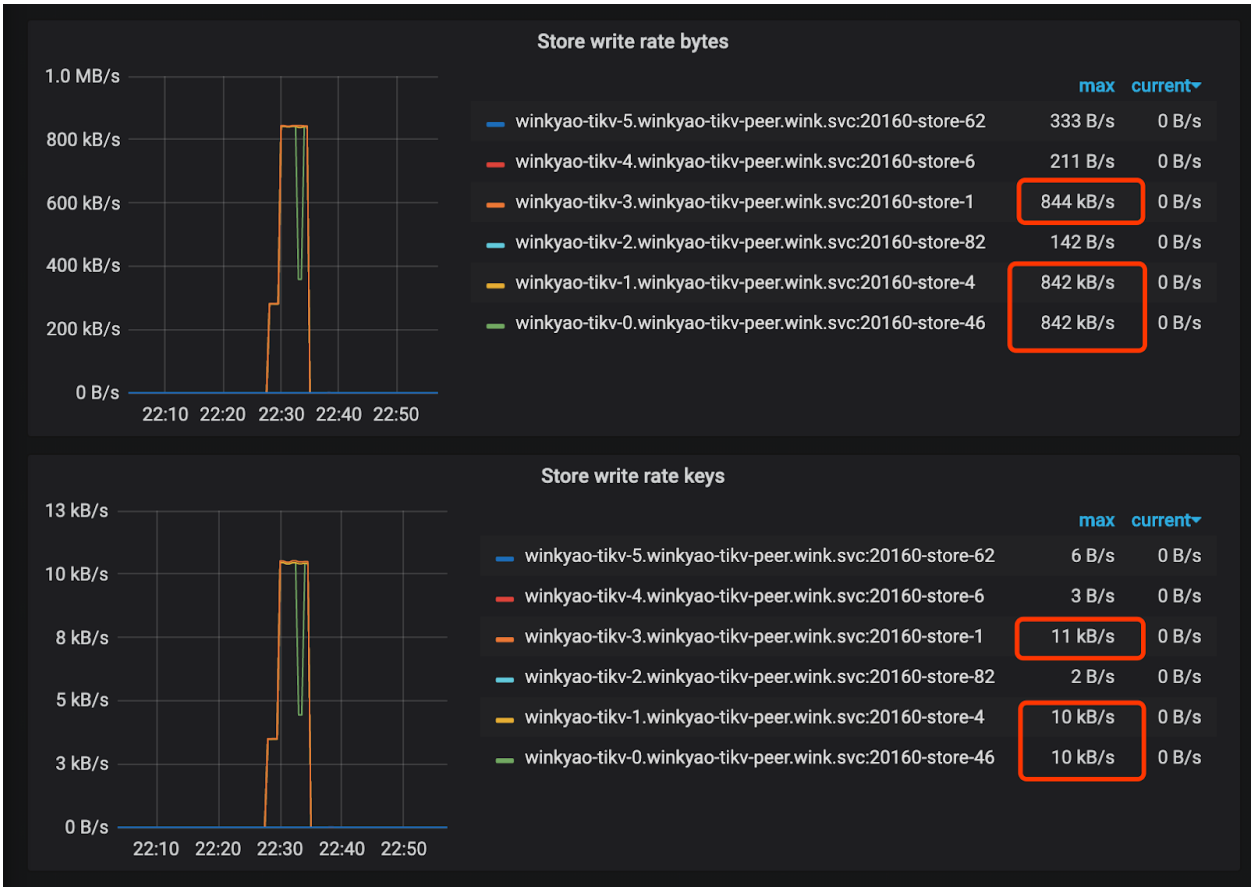

Figure 426: QPS4

12.5.4.5 Hotspot causes

In the above test, the operation does not reach the ideal performance expected in the best practices. This is because only one Region is split by default to store the data of each newly created table in TiDB, with the following data range:

```
[CommonPrefix + TableID, CommonPrefix + TableID + 1)
```

In a short period of time, a huge volume of data is continuously written to the same Region.

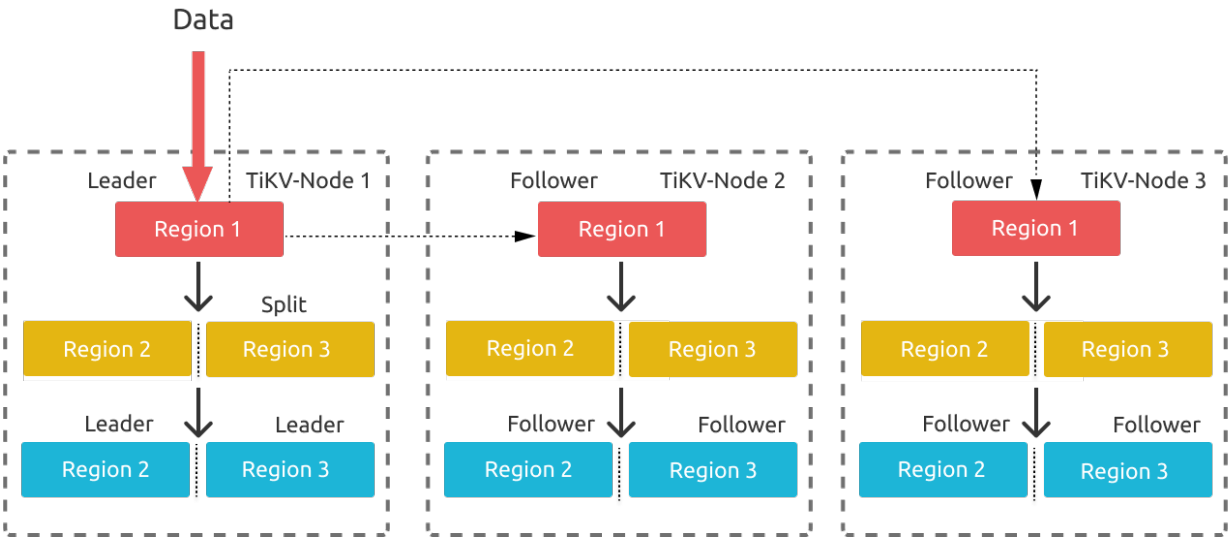

Figure 427: TiKV Region Split

The above diagram illustrates the Region splitting process. As data is continuously written into TiKV, TiKV splits a Region into multiple Regions. Because the leader election is started on the original store where the Region Leader to be split is located, the leaders of the two newly split Regions might be still on the same store. This splitting process might also happen on the newly split Region 2 and Region 3. In this way, write pressure is concentrated on TiKV-Node 1.

During the continuous write process, after finding that hotspot is caused on Node 1, PD evenly distributes the concentrated Leaders to other nodes. If the number of TiKV nodes is more than the number of Region replicas, TiKV will try to migrate these Regions to idle nodes. These two operations during the write process are also reflected in the PD's monitoring metrics:

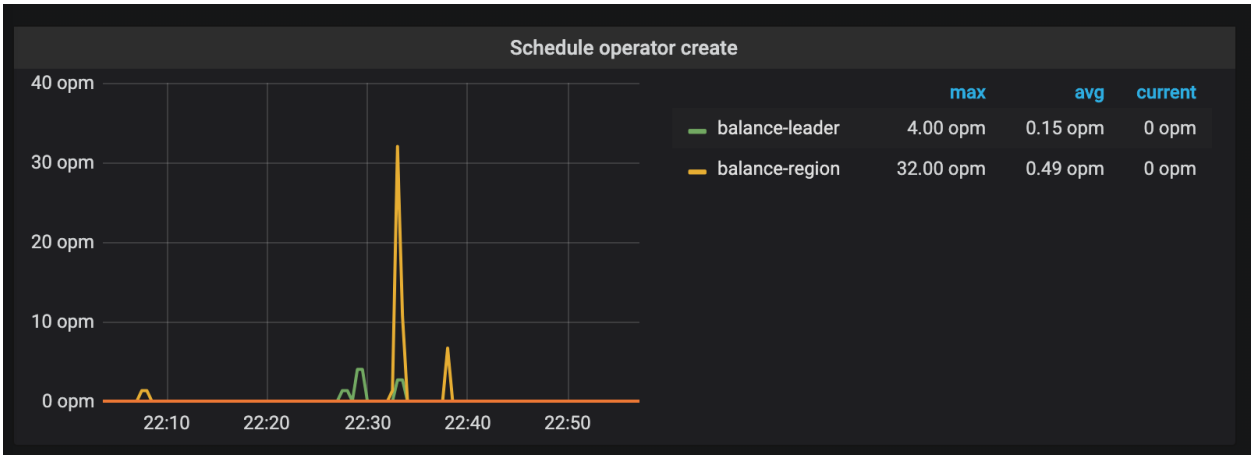

Figure 428: QPS5

After a period of continuous writes, PD automatically schedules the entire TiKV cluster to a state where pressure is evenly distributed. By that time, the capacity of the whole cluster can be fully used.

In most cases, the above process of causing a hotspot is normal, which is the Region warm-up phase of database. However, you need to avoid this phase in highly-concurrent write-intensive scenarios.

12.5.4.6 Hotspot solution

To achieve the ideal performance expected in theory, you can skip the warm-up phase by directly splitting a Region into the desired number of Regions and scheduling these Regions in advance to other nodes in the cluster.

In v3.0.x, v2.1.13 and later versions, TiDB supports a new feature called Split Region. This new feature provides the following new syntaxes:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (upper_
    ↪ value) REGIONS region_num
```

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_list)]
```

However, TiDB does not automatically perform this pre-split operation. The reason is related to the data distribution in TiDB.

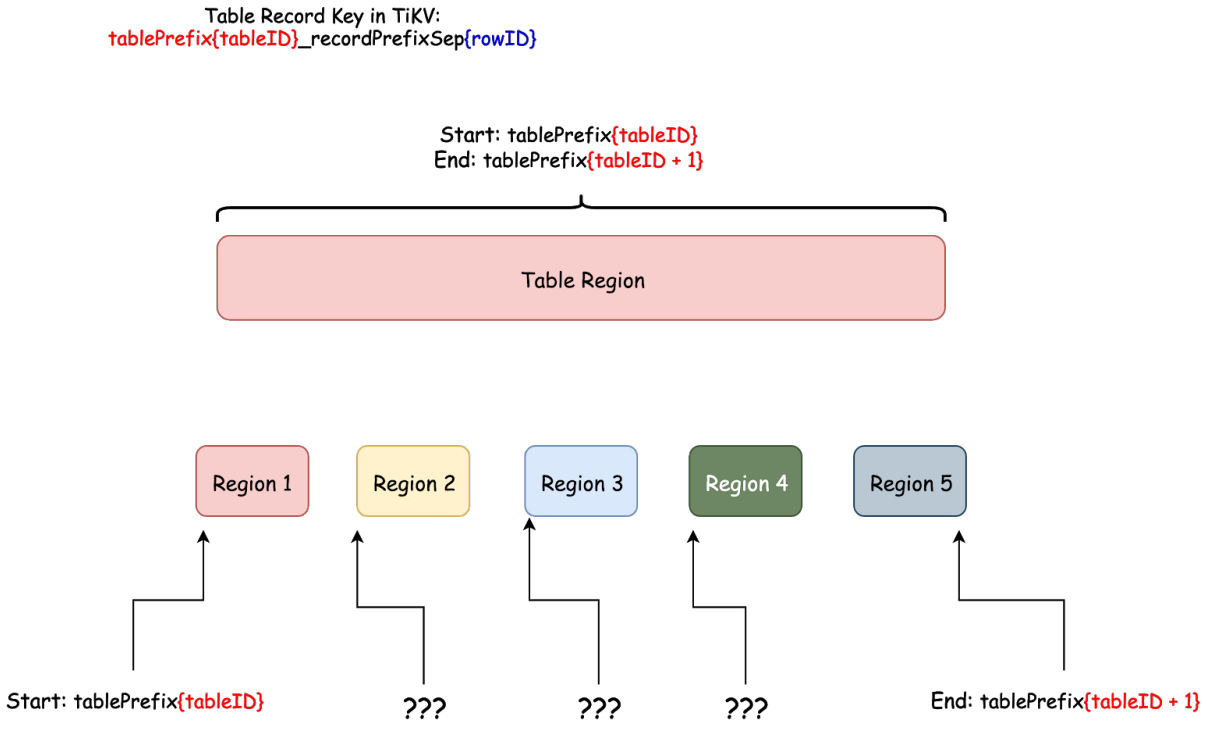

Figure 429: Table Region Range

From the diagram above, according to the encoding rule of a row's key, the `rowID` is the only variable part. In TiDB, `rowID` is an `Int64` integer. However, you might not need to evenly split the `Int64` integer range to the desired number of ranges and then to distribute these ranges to different nodes, because Region split must also be based on the actual situation.

If the write of `rowID` is completely discrete, the above method will not cause hotspots. If the row ID or index has a fixed range or prefix (for example, discretely insert data into the range of `[2000w, 5000w)`), no hotspot will be caused either. However, if you split a Region using the above method, data might still be written to the same Region at the beginning.

TiDB is a database for general usage and does not make assumptions about the data distribution. So it uses only one Region at the beginning to store the data of a table and automatically splits the Region according to the data distribution after real data is inserted.

Given this situation and the need to avoid the hotspot problem, TiDB offers the `Split Region` syntax to optimize performance for the highly-concurrent write-heavy scenario. Based on the above case, now scatter Regions using the `Split Region` syntax and observe the load distribution.

Because the data to be written in the test is entirely discrete within the positive range, you can use the following statement to pre-split the table into 128 Regions within the range of `minInt64` and `maxInt64`:

```
SPLIT TABLE TEST_HOTSPOT BETWEEN (0) AND (9223372036854775807) REGIONS 128;
```

After the pre-split operation, execute the `SHOW TABLE test_hotspot REGIONS;` statement to check the status of Region scattering. If the values of the `SCATTERING` column are all `0`, the scheduling is successful.

You can also check the Region leader distribution using the following SQL statement. You need to replace `table_name` with the actual table name.

```
SELECT
    p.STORE_ID,
    COUNT(s.REGION_ID) PEER_COUNT
FROM
    INFORMATION_SCHEMA.TIKV_REGION_STATUS s
    JOIN INFORMATION_SCHEMA.TIKV_REGION_PEERS p ON s.REGION_ID = p.REGION_ID
WHERE
    TABLE_NAME = 'table_name'
    AND p.is_leader = 1
GROUP BY
    p.STORE_ID
ORDER BY
    PEER_COUNT DESC;
```

Then operate the write load again:

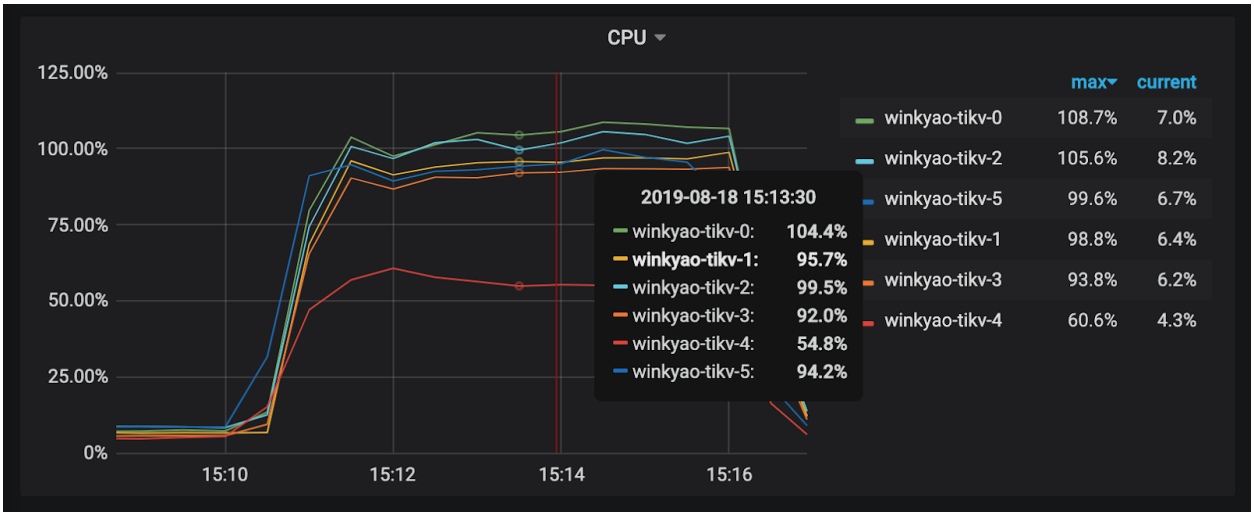

Figure 430: QPS6

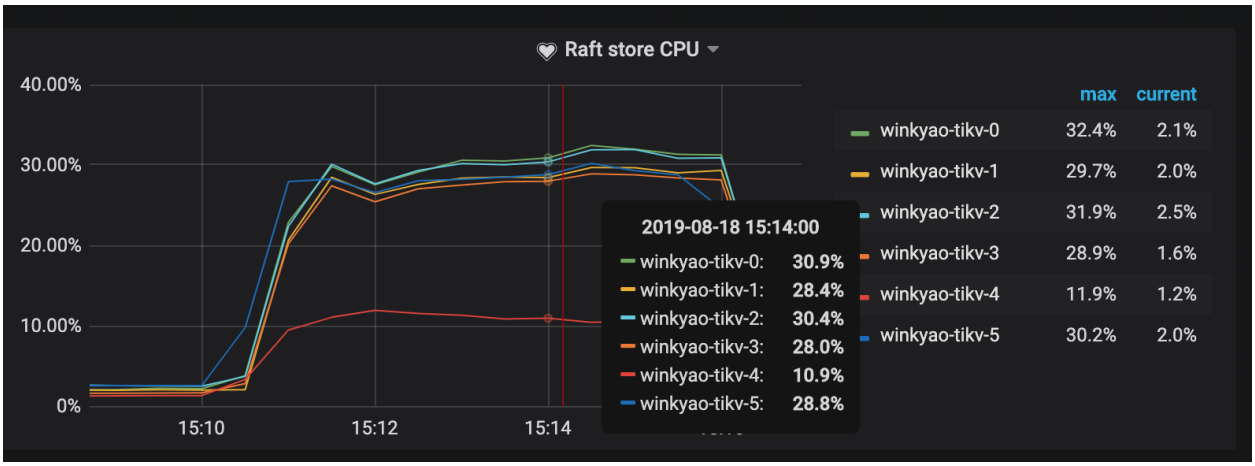

Figure 431: QPS7

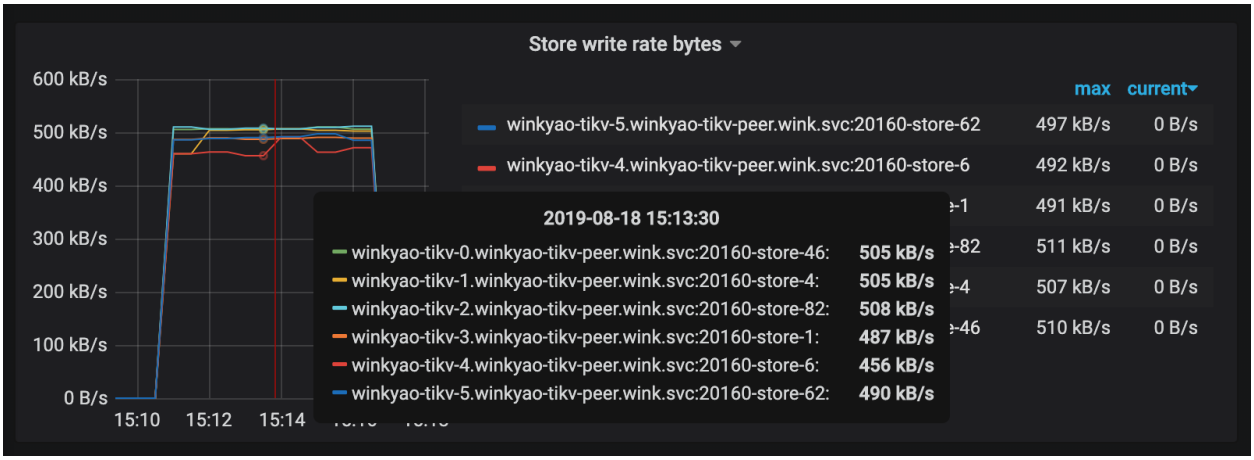

Figure 432: QPS8

You can see that the apparent hotspot problem has been resolved now.

In this case, the table is simple. In other cases, you might also need to consider the hotspot problem of index. For more details on how to pre-split the index Region, refer to Split Region.

12.5.4.7 Complex hotspot problems

Problem one:

If a table does not have a primary key, or the primary key is not the `Int` type and you do not want to generate a randomly distributed primary key ID, TiDB provides an implicit `_tidb_rowid` column as the row ID. Generally, when you do not use the `SHARD_ROW_ID_BITS` parameter, the values of the `_tidb_rowid` column are also monotonically increasing, which might causes hotspots too. Refer to `SHARD_ROW_ID_BITS` for more details.

To avoid the hotspot problem in this situation, you can use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` when creating a table. For more details about `PRE_SPLIT_REGIONS`, refer to Pre-split Regions.

`SHARD_ROW_ID_BITS` is used to randomly scatter the row ID generated in the `_tidb_rowid` column. `PRE_SPLIT_REGIONS` is used to pre-split the Region after a table is created.

> **Note:**
>
> The value of `PRE_SPLIT_REGIONS` must be smaller than or equal to that of `SHARD_ROW_ID_BITS`.

Example:

```
create table t (a int, b int) SHARD_ROW_ID_BITS = 4 PRE_SPLIT_REGIONS=3;
```

- `SHARD_ROW_ID_BITS = 4` means that the values of `tidb_rowid` will be randomly distributed into 16 (16=2^4) ranges.
- `PRE_SPLIT_REGIONS=3` means that the table will be pre-split into 8 (2^3) Regions after it is created.

When data starts to be written into table `t`, the data is written into the pre-split 8 Regions, which avoids the hotspot problem that might be caused if only one Region exists after table creation.

> **Note:**
>
> The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`.
>
> This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to `global`, then TiDB will not return the results to the client until all the Regions are split and scattered. Otherwise, TiDB writes data before the scattering is completed, which will have a significant impact on write performance.

Problem two:

If a table's primary key is an integer type, and if the table uses `AUTO_INCREMENT` to ensure the uniqueness of the primary key (not necessarily continuous or incremental), you cannot use `SHARD_ROW_ID_BITS` to scatter the hotspot on this table because TiDB directly uses the row values of the primary key as `_tidb_rowid`.

To address the problem in this scenario, you can replace `AUTO_INCREMENT` with `AUTO_RANDOM` (a column attribute) when inserting data. Then TiDB automatically assigns values to the integer primary key column, which eliminates the continuity of the row ID and scatters the hotspot.

12.5.4.8 Parameter configuration

In v2.1, the latch mechanism is introduced in TiDB to identify transaction conflicts in advance in scenarios where write conflicts frequently appear. The aim is to reduce the retry of transaction commits in TiDB and TiKV caused by write conflicts. Generally, batch tasks use the data already stored in TiDB, so the write conflicts of transaction do not exist. In this situation, you can disable the latch in TiDB to reduce memory allocation for small objects:

```
[txn-local-latches]
enabled = false
```

12.5.5 Best Practices for Monitoring TiDB Using Grafana

When you deploy a TiDB cluster using TiUP and have added Grafana and Prometheus in the topology configuration, a set of Grafana + Prometheus monitoring platform is deployed simultaneously to collect and display metrics for various components and machines in the TiDB cluster. This document describes best practices for monitoring TiDB using Grafana. It aims to help you use metrics to analyze the status of the TiDB cluster and diagnose problems.

12.5.5.1 Monitoring architecture

Prometheus is a time series database with a multi-dimensional data model and a flexible query language. Grafana is an open source monitoring system for analyzing and visualizing metrics.

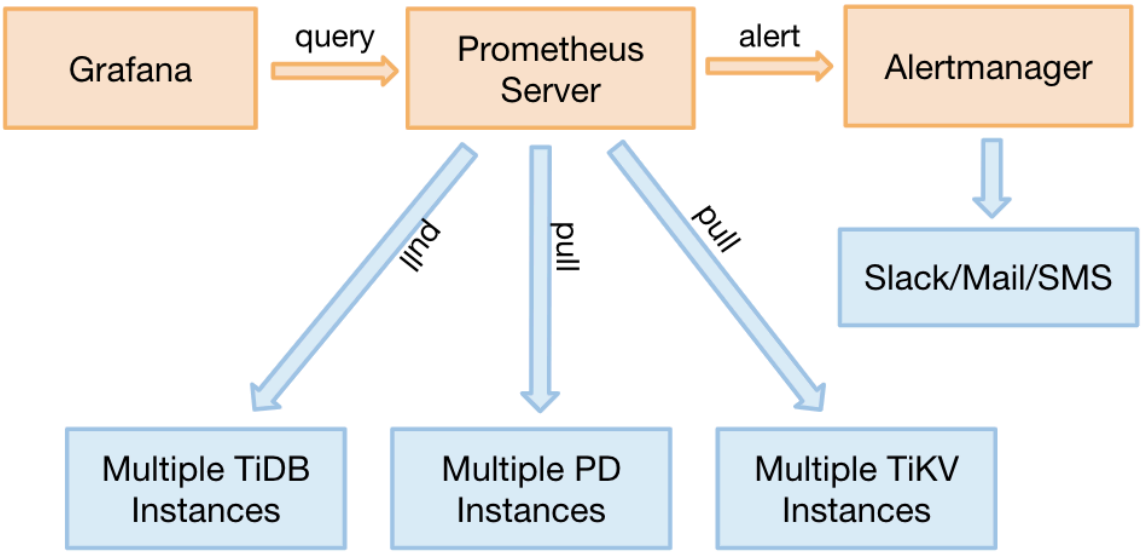

Figure 433: The monitoring architecture in the TiDB cluster

For TiDB 2.1.3 or later versions, TiDB monitoring supports the pull method. It is a good adjustment with the following benefits:

- There is no need to restart the entire TiDB cluster if you need to migrate Prometheus. Before adjustment, migrating Prometheus requires restarting the entire cluster because the target address needs to be updated.

- You can deploy 2 separate sets of Grafana + Prometheus monitoring platforms (not highly available) to prevent a single point of monitoring.
- The Pushgateway which might become a single point of failure is removed.

12.5.5.2 Source and display of monitoring data

The three core components of TiDB (TiDB server, TiKV server and PD server) obtain metrics through the HTTP interface. These metrics are collected from the program code, and the default ports are as follows:

Component	Port
TiDB server	10080
TiKV server	20180
PD server	2379

Execute the following command to check the QPS of a SQL statement through the HTTP interface. Take the TiDB server as an example:

```
curl http://__tidb_ip__:10080/metrics |grep tidb_executor_statement_total
```

```
### Check the real-time QPS of different types of SQL statements. The
    ↪ numbers below are the cumulative values of counter type (scientific
    ↪ notation).
tidb_executor_statement_total{type="Delete"} 520197
tidb_executor_statement_total{type="Explain"} 1
tidb_executor_statement_total{type="Insert"} 7.20799402e+08
tidb_executor_statement_total{type="Select"} 2.64983586e+08
tidb_executor_statement_total{type="Set"} 2.399075e+06
tidb_executor_statement_total{type="Show"} 500531
tidb_executor_statement_total{type="Use"} 466016
```

The data above is stored in Prometheus and displayed on Grafana. Right-click the panel and then click the **Edit** button (or directly press the E key) shown in the following figure:

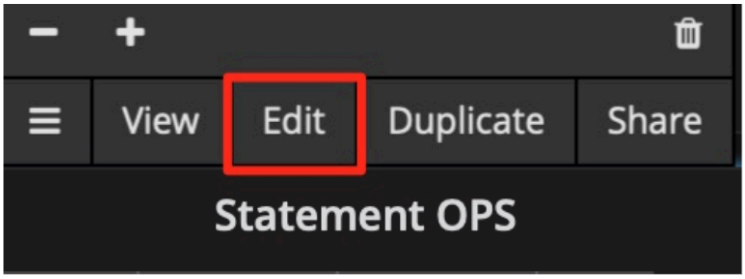

Figure 434: The Edit entry for the Metrics tab

After clicking the **Edit** button, you can see the query expression with the `tidb_executor_statement_total` metric name on the Metrics tab. The meanings of some items on the panel are as follows:

- `rate[1m]`: The growth rate in one minute. It can only be used for the data of counter type.
- `sum`: The sum of values.
- `by type`: The summed data is grouped by type in the original metric value.
- `Legend format`: The format of the metric name.
- `Resolution`: The step width defaults to 15 seconds. Resolution means whether to generate one data point for multiple pixels.

The query expression on the **Metrics** tab is as follows:

Figure 435: The query expression on the Metrics tab

Prometheus supports many query expressions and functions. For more details, refer to Prometheus official website.

12.5.5.3 Grafana tips

This section introduces seven tips for efficiently using Grafana to monitor and analyze the metrics of TiDB.

12.5.5.3.1 Tip 1: Check all dimensions and edit the query expression

In the example shown in the source and display of monitoring data section, the data is grouped by type. If you want to know whether you can group by other dimensions and quickly check which dimensions are available, you can use the following method: **Only keep**

the metric name on the query expression, no calculation, and leave the `Legend format` field blank. In this way, the original metrics are displayed. For example, the following figure shows that there are three dimensions (`instance`, `job` and `type`):

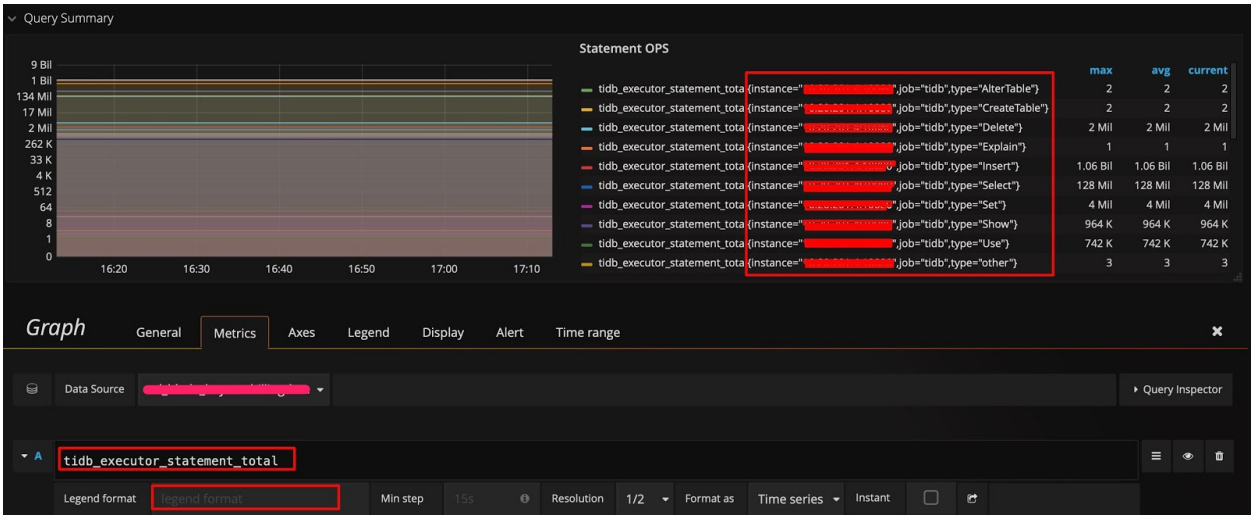

Figure 436: Edit query expression and check all dimensions

Then you can modify the query expression by adding the `instance` dimension after `type`, and adding `{{instance}}` to the `Legend format` field. In this way, you can check the QPS of different types of SQL statements that are executed on each TiDB server:

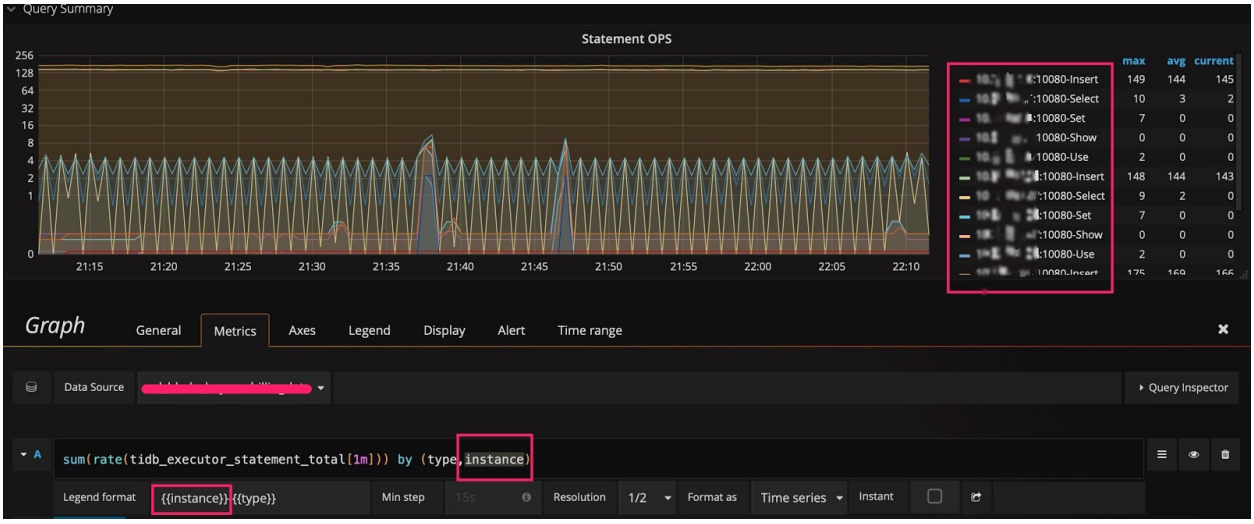

Figure 437: Add an instance dimension to the query expression

12.5.5.3.2 Tip 2: Switch the scale of the Y-axis

Take Query Duration as an example, the Y-axis defaults to be on a binary logarithmic scale (log2n), which narrows the gap in display. To amplify changes, you can switch it to a linear scale. Comparing the following two figures, you can easily notice the difference in display, and locate the time when an SQL statement runs slowly.

Of course, a linear scale is not suitable for all situations. For example, if you observe the performance trend for the duration of a month, there might be noises with a linear scale, making it hard to observe.

The Y-axis uses a binary logarithmic scale by default:

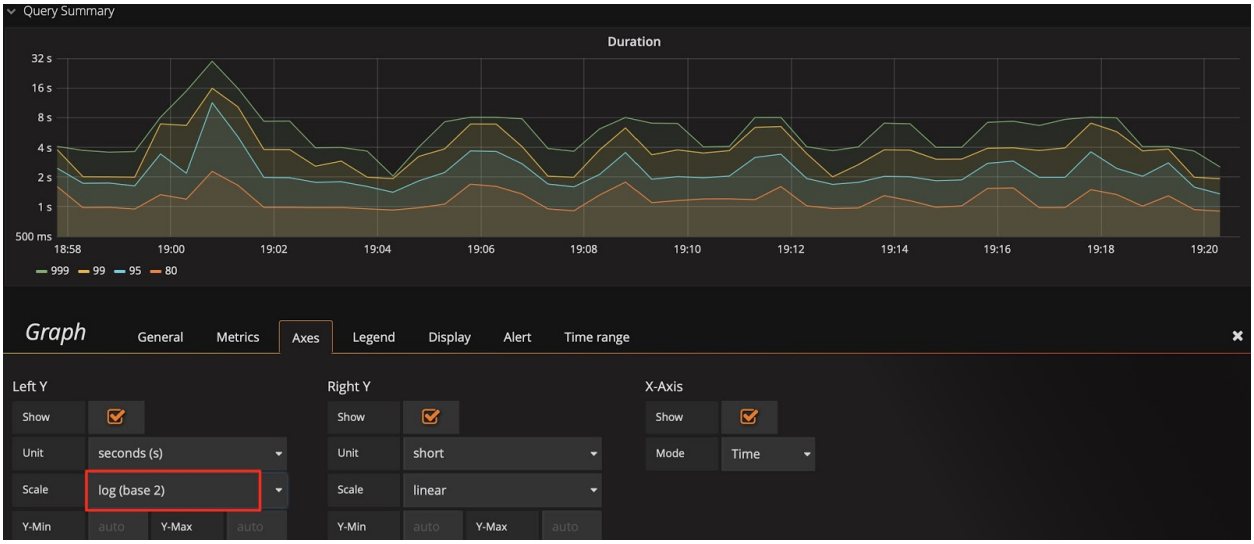

Figure 438: The Y-axis uses a binary logarithmic scale

Switch the Y-axis to a linear scale:

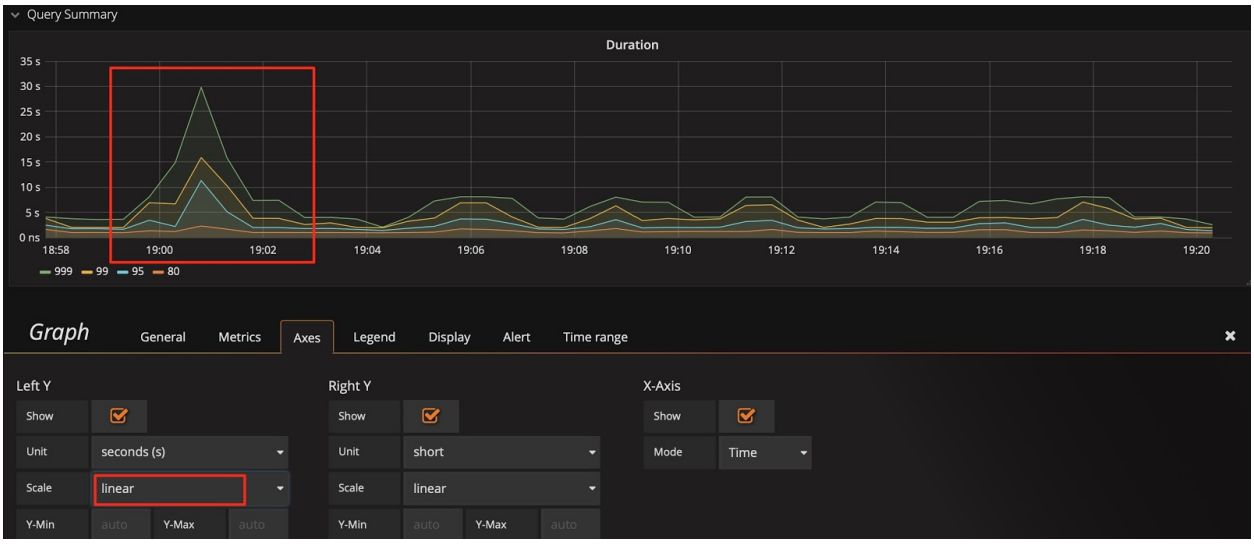

Figure 439: Switch to a linear scale

Tip:

Combining tip 2 with tip 1, you can find a `sql_type` dimension to help you immediately analyze whether the `SELECT` statement or the `UPDATE` statement is slow; you can even locate the instance with slow SQL statements.

12.5.5.3.3 Tip 3: Modify the baseline of the Y-axis to amplify changes

You might still cannot see the trend after switching to the linear scale. For example, in the following figure, you want to observe the real-time change of `Store size` after scaling the cluster, but due to the large baseline, small changes are not visible. In this situation, you can modify the baseline of the Y-axis from `0` to `auto` to zoom in the upper part. Check the two figures below, you can see data migration begins.

The baseline defaults to `0`:

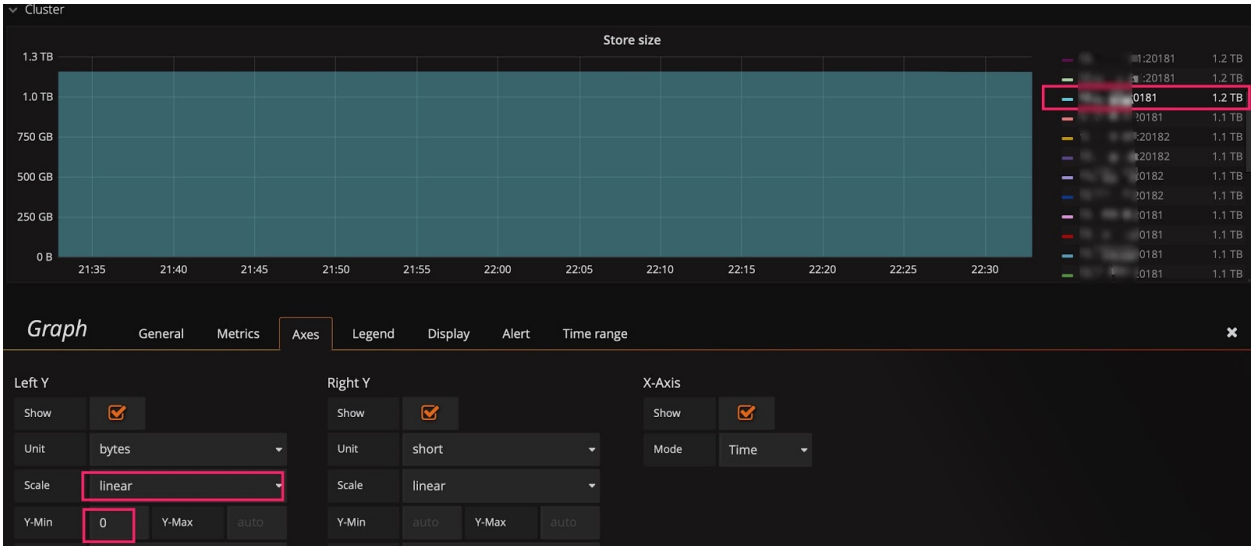

Figure 440: Baseline defaults to 0

Change the baseline to `auto`:

Figure 441: Change the baseline to auto

12.5.5.3.4 Tip 4: Use Shared crosshair or Tooltip

In the **Settings** panel, there is a **Graph Tooltip** panel option which defaults to **Default**.

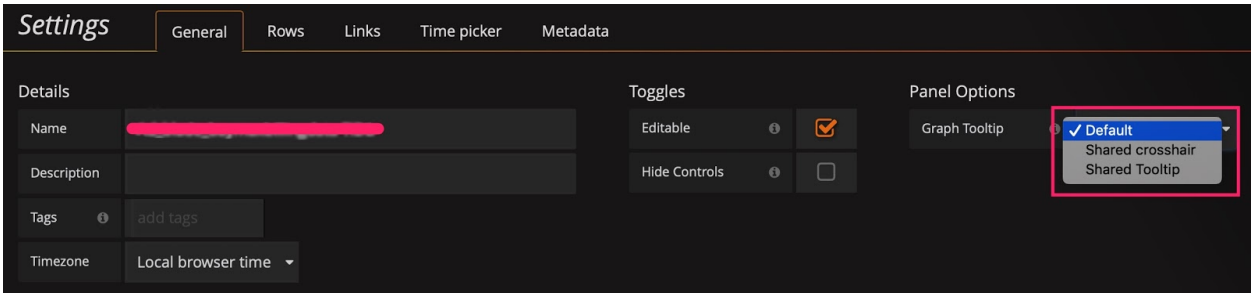

Figure 442: Graphic presentation tools

You can use **Shared crosshair** and **Shared Tooltip** respectively to test the effect as shown in the following figures. Then, the scales are displayed in linkage, which is convenient to confirm the correlation of two metrics when diagnosing problems.

Set the graphic presentation tool to **Shared crosshair**:

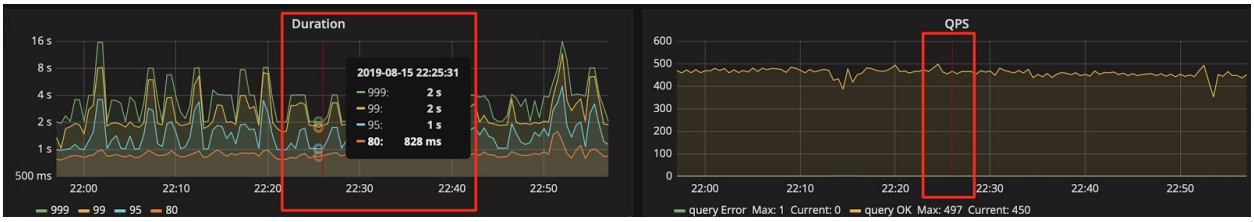

Figure 443: Set the graphical presentation tool to Shared crosshair

Set the graphical presentation tool to **Shared Tooltip**:

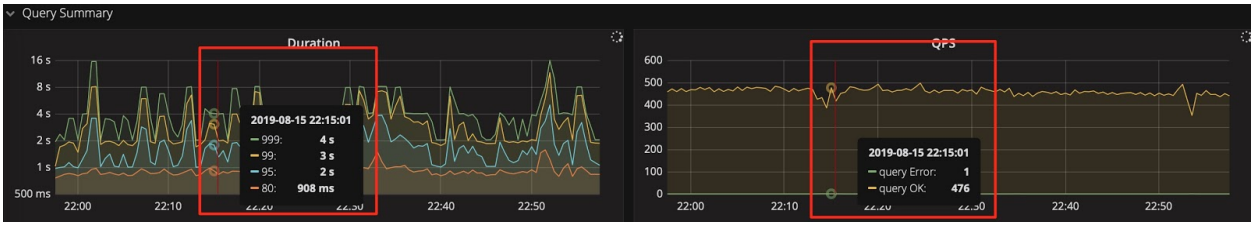

Figure 444: Set the graphic presentation tool to Shared Tooltip

12.5.5.3.5 Tip 5: Enter `IP address:port number` to check the metrics in history

PD's dashboard only shows the metrics of the current leader. If you want to check the status of a PD leader in history and it no longer exists in the drop-down list of the `instance` field, you can manually enter `IP address:2379` to check the data of the leader.

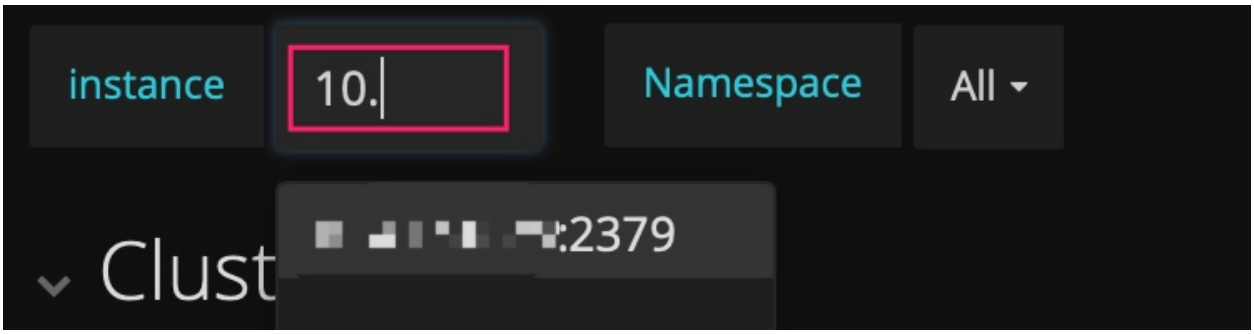

Figure 445: Check the metrics in history

12.5.5.3.6 Tip 6: Use the `Avg` function

Generally, only `Max` and `Current` functions are available in the legend by default. When the metrics fluctuate greatly, you can add other summary functions such as the `Avg` function to the legend to check the overall trend for the duration of time.

Add summary functions such as the `Avg` function:

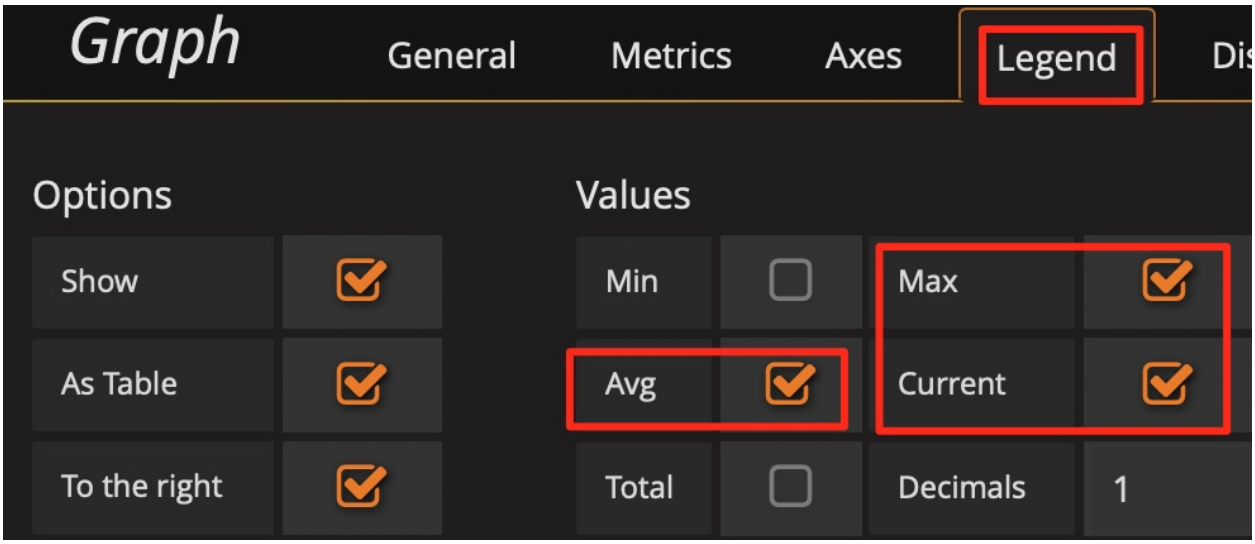

Figure 446: Add summary functions such as Avg

Then check the overall trend:

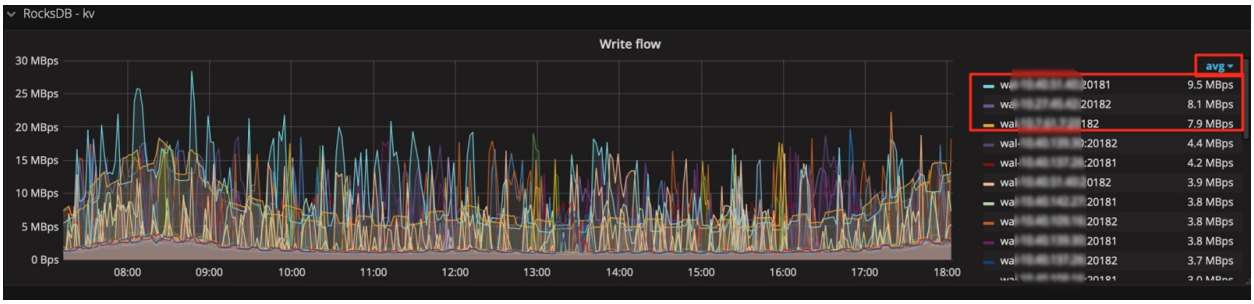

Figure 447: Add Avg function to check the overall trend

12.5.5.3.7 Tip 7: Use the API of Prometheus to obtain the result of query expressions

Grafana obtains data through the API of Prometheus and you can use this API to obtain information as well. In addition, it also has the following usages:

- Automatically obtains information such as the cluster size and status.
- Makes minor changes to the expression to provide information for the report, such as counting the total amount of QPS per day, the peak value of QPS per day, and the response time per day.
- Performs regular health inspection on the important metrics.

The API of Prometheus is shown as follows:

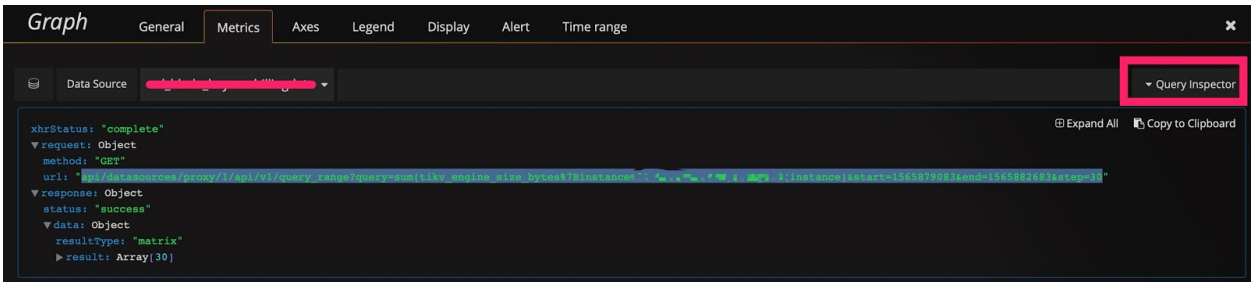

Figure 448: The API of Prometheus

```
curl -u user:pass 'http://__grafana_ip__:3000/api/datasources/proxy/1/api/v1
    ↪ /query_range?query=sum(tikv_engine_size_bytes%7
    ↪ Binstancexxxxxxxxx20180%22%7D)%20by%20(instance)&start=1565879269&end
    ↪ =1565882869&step=30' |python -m json.tool
```

```

12.5.5.4 Summary

The Grafana + Prometheus monitoring platform is a very powerful tool. Making good use of it can improve efficiency, saving you a lot of time on analyzing the status of the TiDB cluster. More importantly, it can help you diagnose problems. This tool is very useful in the operation and maintenance of TiDB clusters, especially when there is a large amount of data.

12.5.6 PD Scheduling Best Practices

This document details the principles and strategies of PD scheduling through common scenarios to facilitate your application. This document assumes that you have a basic understanding of TiDB, TiKV and PD with the following core concepts:

- leader/follower/learner
- operator
- operator step
- pending/down
- region/peer/Raft group
- region split
- scheduler
- store

> **Note:**
>
> This document initially targets TiDB 3.0. Although some features are not supported in earlier versions (2.x), the underlying mechanisms are similar and this document can still be used as a reference.

12.5.6.1 PD scheduling policies

This section introduces the principles and processes involved in the scheduling system.

12.5.6.1.1 Scheduling process

The scheduling process generally has three steps:

1. Collect information

   Each TiKV node periodically reports two types of heartbeats to PD:

   - `StoreHeartbeat`: Contains the overall information of stores, including disk capacity, available storage, and read/write traffic
   - `RegionHeartbeat`: Contains the overall information of regions, including the range of each region, peer distribution, peer status, data volume, and read/write traffic

   PD collects and restores this information for scheduling decisions.

2. Generate operators

   Different schedulers generate the operators based on their own logic and requirements, with the following considerations:

- Do not add peers to a store in abnormal states (disconnected, down, busy, low space)
- Do not balance regions in abnormal states
- Do not transfer a leader to a pending peer
- Do not remove a leader directly
- Do not break the physical isolation of various region peers
- Do not violate constraints such as label property

3. Execute operators

   To execute the operators, the general procedure is:

   1. The generated operator first joins a queue managed by `OperatorController`.
   2. `OperatorController` takes the operator out of the queue and executes it with a certain amount of concurrency based on the configuration. This step is to assign each operator step to the corresponding region leader.
   3. The operator is marked as "finish" or "timeout" and removed from the queue.

12.5.6.1.2 Load balancing

Region primarily relies on `balance-leader` and `balance-region` schedulers to achieve load balance. Both schedulers target distributing regions evenly across all stores in the cluster but with separate focuses: `balance-leader` deals with region leader to balance incoming client requests, whereas `balance-region` concerns itself with each region peer to redistribute the pressure of storage and avoid exceptions like out of storage space.

`balance-leader` and `balance-region` share a similar scheduling process:

1. Rate stores according to their resource availability.
2. `balance-leader` or `balance-region` constantly transfer leaders or peers from stores with high scores to those with low scores.

However, their rating methods are different. `balance-leader` uses the sum of all region sizes corresponding to leaders in a store, whereas the way of `balance-region` is relatively complicated. Depending on the specific storage capacity of each node, the rating method of `balance-region` might:

- based on the amount of data when there is sufficient storage (to balance data distribution among nodes).
- based on the available storage when there is insufficient storage (to balance the storage availability on different nodes).
- based on the weighted sum of the two factors above when neither of the situations applies.

Because different nodes might differ in performance, you can also set the weight of load balancing for different stores. `leader-weight` and `region-weight` are used to control the leader weight and region weight respectively ("1" by default for both). For example, when the `leader-weight` of a store is set to "2", the number of leaders on the node is about twice as many as that of other nodes after the scheduling stabilizes. Similarly, when the `leader-weight` of a store is set to "0.5", the number of leaders on the node is about half as many as that of other nodes.

12.5.6.1.3 Hot regions scheduling

For hot regions scheduling, use `hot-region-scheduler`. Since TiDB v3.0, the process is performed as follows:

1. Count hot regions by determining read/write traffic that exceeds a certain threshold for a certain period based on the information reported by stores.
2. Redistribute these regions in a similar way to load balancing.

For hot write regions, `hot-region-scheduler` attempts to redistribute both region peers and leaders; for hot read regions, `hot-region-scheduler` only redistributes region leaders.

12.5.6.1.4 Cluster topology awareness

Cluster topology awareness enables PD to distribute replicas of a region as much as possible. This is how TiKV ensures high availability and disaster recovery capability. PD continuously scans all regions in the background. When PD finds that the distribution of regions is not optimal, it generates an operator to replace peers and redistribute regions.

The component to check region distribution is `replicaChecker`, which is similar to a scheduler except that it cannot be disabled. `replicaChecker` schedules based on the configuration of `location-labels`. For example, `[zone,rack,host]` defines a three-tier topology for a cluster. PD attempts to schedule region peers to different zones first, or to different racks when zones are insufficient (for example, 2 zones for 3 replicas), or to different hosts when racks are insufficient.

12.5.6.1.5 Scale-down and failure recovery

Scale-down refers to the process when you take a store offline and mark it as "offline" using a command. PD replicates the regions on the offline node to other nodes by scheduling. Failure recovery applies when stores failed and cannot be recovered. In this case, regions with peers distributed on the corresponding store might lose replicas, which requires PD to replenish on other nodes.

The processes of scale-down and failure recovery are basically the same. `replicaChecker` ↪ finds a region peer in abnormal states, and then generates an operator to replace the abnormal peer with a new one on a healthy store.

12.5.6.1.6 Region merge

Region merge refers to the process of merging adjacent small regions. It serves to avoid unnecessary resource consumption by a large number of small or even empty regions after data deletion. Region merge is performed by `mergeChecker`, which processes in a similar way to `replicaChecker`: PD continuously scans all regions in the background, and generates an operator when contiguous small regions are found.

Specifically, when a newly split Region exists for more than the value of `split-merge-interval` (`1h` by default), if the following conditions occur at the same time, this Region triggers the Region merge scheduling:

- The size of this Region is smaller than the value of the `max-merge-region-size`. Starting from v8.4.0, the default value is changed from 20 MiB to 54 MiB. The new default value is automatically applied only to newly created clusters. Existing clusters are not affected.
- The number of keys in this Region is smaller than the value of `max-merge-region-keys`. Starting from v8.4.0, the default value is changed from 200000 to 540000. The new default value is automatically applied only to newly created clusters. Existing clusters are not affected.

12.5.6.2 Query scheduling status

You can check the status of scheduling system through metrics, pd-ctl and logs. This section briefly introduces the methods of metrics and pd-ctl. Refer to PD Monitoring Metrics and PD Control for details.

12.5.6.2.1 Operator status

The **Grafana PD/Operator** page shows the metrics about operators, among which:

- Schedule operator create: Operator creating information
- Operator finish duration: Execution time consumed by each operator
- Operator step duration: Execution time consumed by the operator step

You can query operators using pd-ctl with the following commands:

- `operator show`: Queries all operators generated in the current scheduling task
- `operator show [admin | leader | region]`: Queries operators by type

12.5.6.2.2 Balance status

The **Grafana PD/Statistics - Balance** page shows the metrics about load balancing, among which:

- Store leader/region score: Score of each store
- Store leader/region count: The number of leaders/regions in each store
- Store available: Available storage on each store

You can use store commands of pd-ctl to query balance status of each store.

12.5.6.2.3 Hot Region status

The **Grafana PD/Statistics - hotspot** page shows the metrics about hot regions, among which:

- Hot write region's leader/peer distribution: the leader/peer distribution in hot write regions
- Hot read region's leader distribution: the leader distribution in hot read regions

You can also query the status of hot regions using pd-ctl with the following commands:

- `hot read`: Queries hot read regions
- `hot write`: Queries hot write regions
- `hot store`: Queries the distribution of hot regions by store
- `region topread [limit]`: Queries the region with top read traffic
- `region topwrite [limit]`: Queries the region with top write traffic

12.5.6.2.4 Region health

The **Grafana PD/Cluster/Region health** panel shows the metrics about regions in abnormal states.

You can query the list of regions in abnormal states using pd-ctl with region check commands:

- `region check miss-peer`: Queries regions without enough peers
- `region check extra-peer`: Queries regions with extra peers
- `region check down-peer`: Queries regions with down peers
- `region check pending-peer`: Queries regions with pending peers

12.5.6.3 Control scheduling strategy

You can use pd-ctl to adjust the scheduling strategy from the following three aspects. Refer to PD Control for more details.

12.5.6.3.1 Add/delete scheduler manually

PD supports dynamically adding and removing schedulers directly through pd-ctl. For example:

- `scheduler show`: Shows currently running schedulers in the system
- `scheduler remove balance-leader-scheduler`: Removes (disable) balance-leader-scheduler
- `scheduler add evict-leader-scheduler 1`: Adds a scheduler to remove all leaders in Store 1

12.5.6.3.2 Add/delete Operators manually

PD also supports adding or removing operators directly through pd-ctl. For example:

- `operator add add-peer 2 5`: Adds peers to Region 2 in Store 5
- `operator add transfer-leader 2 5`: Migrates the leader of Region 2 to Store 5
- `operator add split-region 2`: Splits Region 2 into two regions evenly in size
- `operator remove 2`: Removes currently pending operator in Region 2

12.5.6.3.3 Adjust scheduling parameter

You can check the scheduling configuration using the `config show` command in pd-ctl, and adjust the values using `config set {key} {value}`. Common adjustments include:

- `leader-schedule-limit`: Controls the concurrency of transferring leader scheduling
- `region-schedule-limit`: Controls the concurrency of adding/deleting peer scheduling
- `enable-replace-offline-replica`: Determines whether to enable the scheduling to take nodes offline
- `enable-location-replacement`: Determines whether to enable the scheduling that handles the isolation level of regions
- `max-snapshot-count`: Controls the maximum concurrency of sending/receiving snapshots for each store

12.5.6.4 PD scheduling in common scenarios

This section illustrates the best practices of PD scheduling strategies through several typical scenarios.

12.5.6.4.1 Leaders/regions are not evenly distributed

The rating mechanism of PD determines that leader count and region count of different stores cannot fully reflect the load balancing status. Therefore, it is necessary to confirm whether there is load imbalancing from the actual load of TiKV or storage usage.

Once you have confirmed that leaders/region are not evenly distributed, you need to check the rating of different stores.

If the scores of different stores are close, it means PD mistakenly believes that leaders/regions are evenly distributed. Possible reasons are:

- There are hot regions that cause load imbalancing. In this case, you need to analyze further based on hot regions scheduling.
- There are a large number of empty regions or small regions, which leads to a great difference in the number of leaders in different stores and high pressure on Raft store. This is the time for a region merge scheduling.
- Hardware and software environment varies among stores. To control the distribution of leader/region, you can refer to Load balancing and adjust the values of `leader-weight` and `region-weight`.
- Other unknown reasons. Still you can adjust the values of `leader-weight` and `region-weight` to control the distribution of leader/region.

If there is a big difference in the rating of different stores, you need to examine the operator-related metrics, with special focus on the generation and execution of operators. There are two main situations:

- When operators are generated normally but the scheduling process is slow, it is possible that:
    - The scheduling speed is limited by default for load balancing purpose. You can adjust `leader-schedule-limit` or `region-schedule-limit` to larger values without significantly impacting regular services. In addition, you can also properly ease the restrictions specified by `max-pending-peer-count` and `max-snapshot-count`.
    - Other scheduling tasks are running concurrently, which slows down the balancing. In this case, if the balancing takes precedence over other scheduling tasks, you can stop other tasks or limit their speeds. For example, if you take some nodes offline when balancing is in progress, both operations consume the quota of `region-schedule-limit`. In this case, you can limit the speed of scheduler to remove nodes, or simply set `enable-replace-offline-replica = false` to temporarily disable it.
    - The scheduling process is too slow. You can check the **Operator step duration** metric to confirm the cause. Generally, steps that do not involve sending and receiving snapshots (such as `TransferLeader`, `RemovePeer`, `PromoteLearner`) should be completed in milliseconds, while steps that involve snapshots (such as `AddLearner` and `AddPeer`) are expected to be completed in tens of seconds. If the duration is obviously too long, it could be caused by high pressure on TiKV or bottleneck in network, which needs specific analysis.
- PD fails to generate the corresponding balancing scheduler. Possible reasons include:
    - The scheduler is not activated. For example, the corresponding scheduler is deleted, or its limit it set to "0".

- Other constraints. For example, `evict-leader-scheduler` in the system prevents leaders from being migrating to the corresponding store. Or label property is set, which makes some stores reject leaders.
- Restrictions from the cluster topology. For example, in a cluster of 3 replicas across 3 data centers, 3 replicas of each region are distributed in different data centers due to replica isolation. If the number of stores is different among these data centers, the scheduling can only reach a balanced state within each data center, but not balanced globally.

12.5.6.4.2 Taking nodes offline is slow

This scenario requires examining the generation and execution of operators through related metrics.

If operators are successfully generated but the scheduling process is slow, possible reasons are:

- The scheduling speed is limited by default. You can adjust `leader-schedule-limit` or `replica-schedule-limit` to larger values. Similarly, you can consider loosening the limits on `max-pending-peer-count` and `max-snapshot-count`.
- Other scheduling tasks are running concurrently and racing for resources in the system. You can refer to the solution in Leaders/regions are not evenly distributed.
- When you take a single node offline, a number of region leaders to be processed (around 1/3 under the configuration of 3 replicas) are distributed on the node to remove. Therefore, the speed is limited by the speed at which snapshots are generated by this single node. You can speed it up by manually adding an `evict-leader-scheduler` to migrate leaders.

If the corresponding operator fails to generate, possible reasons are:

- The operator is stopped, or `replica-schedule-limit` is set to "0".
- There is no proper node for region migration. For example, if the available capacity size of the replacing node (of the same label) is less than 20%, PD will stop scheduling to avoid running out of storage on that node. In such case, you need to add more nodes or delete some data to free the space.

12.5.6.4.3 Bringing nodes online is slow

Currently, bringing nodes online is scheduled through the balance region mechanism. You can refer to Leaders/regions are not evenly distributed for troubleshooting.

12.5.6.4.4 Hot regions are not evenly distributed

Hot regions scheduling issues generally fall into the following categories:

- Hot regions can be observed via PD metrics, but the scheduling speed cannot keep up to redistribute hot regions in time.

  Solution: adjust `hot-region-schedule-limit` to a larger value, and reduce the limit quota of other schedulers to speed up hot regions scheduling. Or you can adjust `hot-region-cache-hits-threshold` to a smaller value to make PD more sensitive to traffic changes.

- Hotspot formed on a single region. For example, a small table is intensively scanned by a massive amount of requests. This can also be detected from PD metrics. Because you cannot actually distribute a single hotspot, you need to manually add a `split-region` operator to split such a region.

- The load of some nodes is significantly higher than that of other nodes from TiKV-related metrics, which becomes the bottleneck of the whole system. Currently, PD counts hotspots through traffic analysis only, so it is possible that PD fails to identify hotspots in certain scenarios. For example, when there are intensive point lookup requests for some regions, it might not be obvious to detect in traffic, but still the high QPS might lead to bottlenecks in key modules.

  Solutions: Firstly, locate the table where hot regions are formed based on the specific business. Then add a `scatter-range-scheduler` scheduler to make all regions of this table evenly distributed. TiDB also provides an interface in its HTTP API to simplify this operation. Refer to TiDB HTTP API for more details.

12.5.6.4.5 Region merge is slow

Similar to slow scheduling, the speed of region merge is most likely limited by the configurations of `merge-schedule-limit` and `region-schedule-limit`, or the region merge scheduler is competing with other schedulers. Specifically, the solutions are:

- If it is known from metrics that there are a large number of empty regions in the system, you can adjust `max-merge-region-size` and `max-merge-region-keys` to smaller values to speed up the merge. This is because the merge process involves replica migration, so the smaller the region to be merged, the faster the merge is. If the merge operators are already generated rapidly, to further speed up the process, you can set `patrol-region-interval` to `10ms` (the default value of this configuration item is `10ms` in v5.3.0 and later versions of TiDB). This makes region scanning faster at the cost of more CPU consumption.

- A lot of tables have been created and then emptied (including truncated tables). These empty Regions cannot be merged if the split table attribute is enabled. You can disable this attribute by adjusting the following parameters:

  - TiKV: Set `split-region-on-table` to `false`. You cannot modify the parameter dynamically.
  - PD: Use PD Control to set the parameters required by your cluster situation.

- Suppose that your cluster has no TiDB instance, and the value of `key-type` is set to `raw` or `txn`. In this case, PD can merge Regions across tables, regardless of the value of `enable-cross-table-merge setting`. You can modify the `key-type` parameter dynamically.

```
config set key-type txn
```

- Suppose that your cluster has a TiDB instance, and the value of `key-type` is set to `table`. In this case, PD can merge Regions across tables only if the value of `enable-cross-table-merge` is set to `true`. You can modify the `key-type` parameter dynamically.

```
config set enable-cross-table-merge true
```

If the modification does not take effect, refer to FAQ - Why the modified `toml` configuration for TiKV/PD does not take effect?.

> **Note:**
> After enabling Placement Rules, properly switch the value of `key-type` to avoid the failure of decoding.

For v3.0.4 and v2.1.16 or earlier, the `approximate_keys` of regions are inaccurate in specific circumstances (most of which occur after dropping tables), which makes the number of keys break the constraints of `max-merge-region-keys`. To avoid this problem, you can adjust `max-merge-region-keys` to a larger value.

12.5.6.4.6 Troubleshoot TiKV node

If a TiKV node fails, PD defaults to setting the corresponding node to the **down** state after 30 minutes (customizable by configuration item `max-store-down-time`), and rebalancing replicas for regions involved.

Practically, if a node failure is considered unrecoverable, you can immediately take it offline. This makes PD replenish replicas soon in another node and reduces the risk of data loss. In contrast, if a node is considered recoverable, but the recovery cannot be done in 30 minutes, you can temporarily adjust `max-store-down-time` to a larger value to avoid unnecessary replenishment of the replicas and resources waste after the timeout.

In TiDB v5.2.0, TiKV introduces the mechanism of slow TiKV node detection. By sampling the requests in TiKV, this mechanism works out a score ranging from 1 to 100. A TiKV node with a score higher than or equal to 80 is marked as slow. You can add `evict-slow-store-scheduler` to detect and schedule slow nodes. If only one TiKV is detected as slow, and the slow score reaches the limit (80 by default), the Leader in this node will be evicted (similar to the effect of `evict-leader-scheduler`).

Note:

Leader eviction is accomplished by PD sending scheduling requests to TiKV slow nodes and then TiKV executing the received scheduling requests sequentially. Due to factors such as **slow I/O**, slow nodes might experience request accumulation, causing some Leaders to wait until the delayed requests are processed before handling **Leader eviction** requests. This results in an overall extended time for **Leader eviction**. Therefore, when you enable `evict-slow-store-scheduler`, it is recommended to enable `store-io-pool-size` as well to mitigate this situation.

12.5.7 Best Practices for TiKV Performance Tuning with Massive Regions

In TiDB, data is split into Regions, each storing data for a specific key range. These Regions are distributed among multiple TiKV instances. As data is written into a cluster, millions of Regions might be created. Too many Regions on a single TiKV instance can bring a heavy burden to the cluster and affect its performance.

This document introduces the workflow of Raftstore (a core module of TiKV), explains why a massive amount of Regions affect the performance, and offers methods for tuning TiKV performance.

12.5.7.1 Raftstore workflow

A TiKV instance has multiple Regions on it. The Raftstore module drives the Raft state machine to process Region messages. These messages include processing read or write requests on Regions, persisting or replicating Raft logs, and processing Raft heartbeats. However, an increasing number of Regions can affect performance of the whole cluster. To understand this, it is necessary to learn the workflow of Raftstore shown as follows:

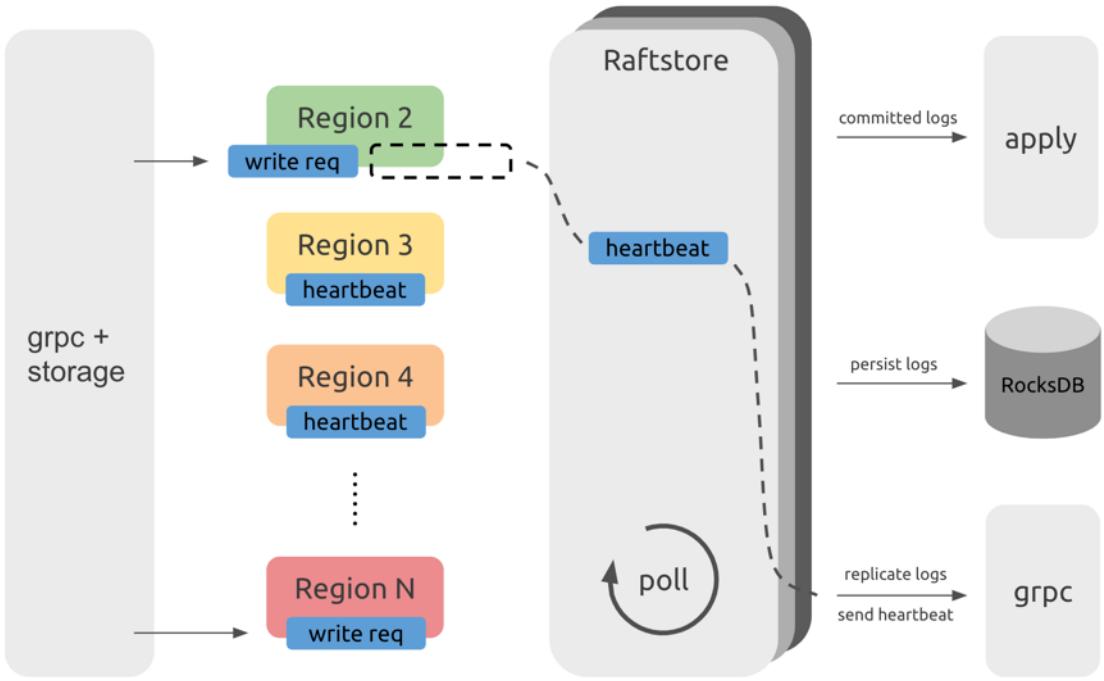

Figure 449: Raftstore Workflow

> **Note:**
>
> This diagram only illustrates the workflow of Raftstore and does not represent the actual code structure.

From the above diagram, you can see that requests from the TiDB servers, after passing through the gRPC and storage modules, become read and write messages of KV (key-value), and are sent to the corresponding Regions. These messages are not immediately processed but are temporarily stored. Raftstore polls to check whether each Region has messages to process. If a Region has messages to process, Raftstore drives the Raft state machine of this Region to process these messages and perform subsequent operations according to the state changes of these messages. For example, when write requests come in, the Raft state machine stores logs into disk and sends logs to other Region replicas; when the heartbeat interval is reached, the Raft state machine sends heartbeat information to other Region replicas.

12.5.7.2 Performance problem

From the Raftstore workflow diagram, messages in each Region are processed one by one. When a large number of Regions exist, it takes Raftstore some time to process the heartbeats of these Regions, which can cause some delay. As a result, some read and write requests are not processed in time. If read and write pressure is high, the CPU usage of the

Raftstore thread might easily become the bottleneck, which further increases the delay and affects the performance.

Generally, if the CPU usage of the loaded Raftstore reaches 85% or higher, Raftstore goes into a busy state and becomes the bottleneck. At the same time, `propose wait duration` can be as high as hundreds of milliseconds.

Note:

- For the CPU usage of Raftstore as mentioned above, Raftstore is single-threaded. If Raftstore is multi-threaded, you can increase the CPU usage threshold (85%) proportionally.
- Because I/O operations exist in the Raftstore thread, CPU usage cannot reach 100%.

12.5.7.2.1 Performance monitoring

You can check the following monitoring metrics in Grafana's **TiKV Dashboard**:

- `Raft store CPU` in the **Thread-CPU** panel

  Reference value: lower than `raftstore.store-pool-size * 85%`.

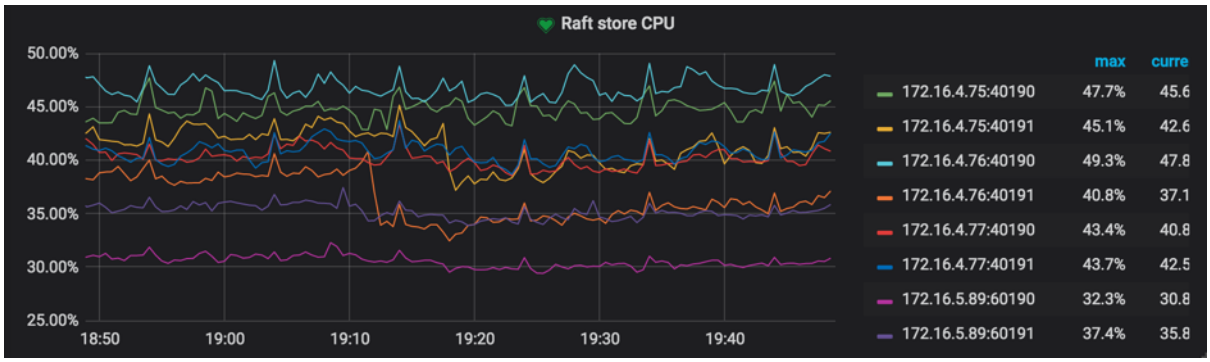

Figure 450: Check Raftstore CPU

- `Propose wait duration` in the **Raft Propose** panel

  `Propose wait duration` is the delay between the time a request is sent to Raftstore and the time Raftstore actually starts processing the request. Long delay means that Raftstore is busy, or that processing the append log is time-consuming, making Raftstore unable to process the request in time.

  Reference value: lower than 50~100 ms according to the cluster size

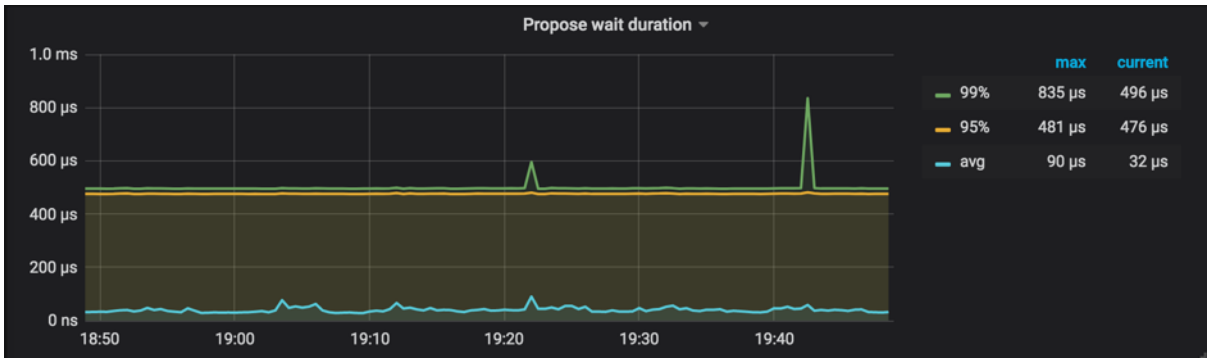

Figure 451: Check Propose wait duration

- `Commit log duration` in the **Raft IO** panel

  `Commit log duration` is the time Raftstore takes to commit Raft logs to the majority of members in the respective Region. The possible reasons for a high value of this metric with significant fluctuations include the following:

  - The workload on Raftstore is heavy.
  - The append log operation is slow.
  - Raft logs cannot be committed timely due to network congestion.

Reference value: lower than 200-500 ms.

```
![Check Commit log duration](./media/best-practices/commit-log-duration.png)
```

12.5.7.3 Performance tuning methods

After finding out the cause of a performance problem, try to solve it from the following two aspects:

- Reduce the number of Regions on a single TiKV instance
- Reduce the number of messages for a single Region

12.5.7.3.1 Method 1: Increase Raftstore concurrency

Raftstore has been upgraded to a multi-threaded module since TiDB v3.0, which greatly reduces the possibility that a Raftstore thread becomes the bottleneck.

By default, `raftstore.store-pool-size` is configured to `2` in TiKV. If a bottleneck occurs in Raftstore, you can properly increase the value of this configuration item according to the actual situation. But to avoid introducing unnecessary thread switching overhead, it is recommended that you do not set this value too high.

12.5.7.3.2 Method 2: Enable Hibernate Region

In the actual situation, read and write requests are not evenly distributed on every Region. Instead, they are concentrated on a few Regions. Then you can minimize the number of messages between the Raft leader and the followers for the temporarily idle Regions, which is the feature of Hibernate Region. In this feature, Raftstore doesn't send tick messages to the Raft state machines of idle Regions if not necessary. Then these Raft state machines will not be triggered to generate heartbeat messages, which can greatly reduce the workload of Raftstore.

Hibernate Region is enabled by default in TiKV master. You can configure this feature according to your needs. For details, refer to Configure Hibernate Region.

12.5.7.3.3 Method 3: Enable `Region Merge`

> **Note:**
>
> `Region Merge` is enabled by default since TiDB v3.0.

You can also reduce the number of Regions by enabling `Region Merge`. Contrary to `Region Split`, `Region Merge` is the process of merging adjacent small Regions through scheduling. After dropping data or executing the `Drop Table` or `Truncate Table` statement, you can merge small Regions or even empty Regions to reduce resource consumption.

Enable `Region Merge` by configuring the following parameters:

```
config set max-merge-region-size 54
config set max-merge-region-keys 540000
config set merge-schedule-limit 8
```

Refer to Region Merge and the following three configuration parameters in the PD configuration file for more details:

- `max-merge-region-size`
- `max-merge-region-keys`
- `merge-schedule-limit`

The default configuration of the `Region Merge` parameters is rather conservative. You can speed up the `Region Merge` process by referring to the method provided in PD Scheduling Best Practices.

12.5.7.3.4 Method 4: Increase the number of TiKV instances

If I/O resources and CPU resources are sufficient, you can deploy multiple TiKV instances on a single machine to reduce the number of Regions on a single TiKV instance; or you can increase the number of machines in the TiKV cluster.

12.5.7.3.5 Method 5: Adjust `raft-base-tick-interval`

In addition to reducing the number of Regions, you can also reduce pressure on Raftstore by reducing the number of messages for each Region within a unit of time. For example, you can properly increase the value of the `raft-base-tick-interval` configuration item:

```
[raftstore]
raft-base-tick-interval = "2s"
```

In the above configuration, `raft-base-tick-interval` is the time interval at which Raftstore drives the Raft state machine of each Region, which means at this time interval, Raftstore sends a tick message to the Raft state machine. Increasing this interval can effectively reduce the number of messages from Raftstore.

Note that this interval between tick messages also determines the intervals between `election timeout` and `heartbeat`. See the following example:

```
raft-election-timeout = raft-base-tick-interval * raft-election-timeout-
    ↪ ticks
raft-heartbeat-interval = raft-base-tick-interval * raft-heartbeat-ticks
```

If Region followers have not received the heartbeat from the leader within the `raft ↪ -election-timeout` interval, these followers determine that the leader has failed and start a new election. `raft-heartbeat-interval` is the interval at which a leader sends a heartbeat to followers. Therefore, increasing the value of `raft-base-tick-interval` can reduce the number of network messages sent from Raft state machines but also makes it longer for Raft state machines to detect the leader failure.

12.5.7.3.6 Method 6: Adjust Region size

The default size of a Region is 256 MiB, and you can reduce the number of Regions by setting Regions to a larger size. For more information, see Tune Region Performance.

> **Note:**
>
> Starting from v8.4.0, the default Region size is increased from 96 MiB to 256 MiB. If you have not modified the Region size manually, when you upgrade a TiKV cluster to v8.4.0 or later, the TiKV cluster's default Region size will automatically be updated to 256 MiB.

> **Note:**

> Customized Region size is an experimental feature before TiDB v6.5.0. If you need to resize the Region size, it is recommended that you upgrade to v6.5.0 or a later version.

12.5.7.3.7 Method 7: Increase the maximum number of connections for Raft communication

By default, the maximum number of connections used for Raft communication between TiKV nodes is 1. Increasing this number can help alleviate blockage issues caused by heavy communication workloads of a large number of Regions. For detailed instructions, see `grpc-raft-conn-num`.

> **Note:**
>
> To reduce unnecessary thread switching overhead and mitigate potential negative impacts from batch processing, it is recommended to set the number within the range of `[1, 4]`.

12.5.7.4 Other problems and solutions

This section describes some other problems and solutions.

12.5.7.4.1 Switching PD Leader is slow

PD needs to persist Region Meta information on etcd to ensure that PD can quickly resume to provide Region routing services after switching the PD Leader node. As the number of Regions increases, the performance problem of etcd appears, making it slower for PD to get Region Meta information from etcd when PD is switching the Leader. With millions of Regions, it might take more than ten seconds or even tens of seconds to get the meta information from etcd.

To address this problem, `use-region-storage` is enabled by default in PD since TiDB v3.0. With this feature enabled, PD stores Region Meta information on local LevelDB and synchronizes the information among PD nodes through other mechanisms.

12.5.7.4.2 PD routing information is not updated in time

In TiKV, pd-worker regularly reports Region Meta information to PD. When TiKV is restarted or switches the Region leader, PD needs to recalculate Region's `approximate-size / keys` through statistics. Therefore, with a large number of Regions, the single-threaded pd-worker might become the bottleneck, causing tasks to be piled up and not

processed in time. In this situation, PD cannot obtain certain Region Meta information in time so that the routing information is not updated in time. This problem does not affect the actual reads and writes, but might cause inaccurate PD scheduling and require several round trips when TiDB updates Region cache.

You can check **Worker pending tasks** under **Task** in the **TiKV Grafana** panel to determine whether pd-worker has tasks piled up. Generally, `pending tasks` should be kept at a relatively low value.

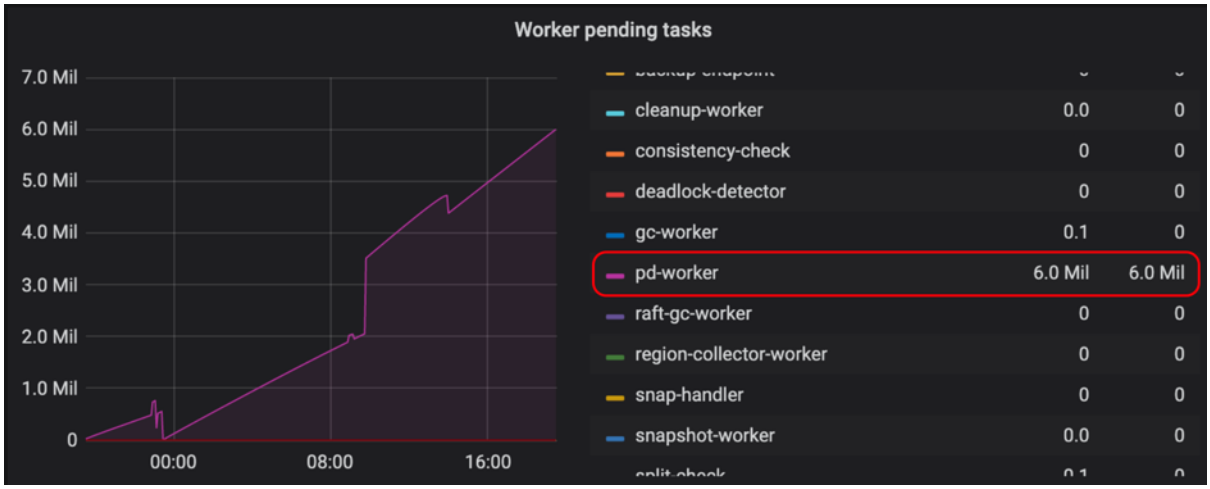

Figure 452: Check pd-worker

pd-worker has been optimized for better performance since v3.0.5. If you encounter a similar problem, it is recommended to upgrade to the latest version.

12.5.7.4.3 Prometheus is slow to query metrics

In a large-scale cluster, as the number of TiKV instances increases, Prometheus has greater pressure to query metrics, making it slower for Grafana to display these metrics. To ease this problem, metrics pre-calculation is configured since v3.0.

12.5.8 Best Practices for Three-Node Hybrid Deployment

For a TiDB cluster, if you have no requirements on high performance but need to control the cost, you can deploy the TiDB, TiKV, and PD components on three machines in a hybrid way.

This document offers an example of three-node hybrid deployment and a TPC-C test against the deployed cluster. Based on this example, this document offers best practices for the deployment scenario and its parameter adjustment.

12.5.8.1 Prerequisites for deployment and the test method

In this example, three physical machines are used for deployment, each with 16 CPU cores and 32 GB of memory. On each machine (node), one TiDB instance, one TiKV instance, and one PD instance are deployed in a hybrid way.

Because PD and TiKV both store information on the disk, the read and write latency of disk directly affects the latency of the PD and TiKV services. To avoid the situation that PD and TiKV compete for disk resources and affect each other, it is recommended to use different disks for PD and TiKV.

In this example, the TPC-C 5000 Warehouse data is used in TiUP bench and the test lasts 12 hours with the `terminals` parameter set to `128` (concurrency). Close attention is paid to metrics related to performance stability of the cluster.

The image below shows the QPS monitor of the cluster within 12 hours with the default parameter configuration. From the image, you can see an obvious performance jitter.

Figure 453: QPS with default config

After the parameter adjustment, the performance is improved.

Figure 454: QPS with modified config

12.5.8.2 Parameter adjustment

Performance jitter occurs in the image above, because the default thread pool configuration and the resource allocation to background tasks are for machines with sufficient resources. In the hybrid deployment scenario, the resources are shared among multiple components, so you need to limit the resource consumption via configuration parameters.

The final cluster configuration for this test is as follows:

```
tikv:
    readpool.unified.max-thread-count: 6
    server.grpc-concurrency: 2
    storage.scheduler-worker-pool-size: 2
    gc.max-write-bytes-per-sec: 300K
    rocksdb.max-background-jobs: 3
    rocksdb.max-sub-compactions: 1
    rocksdb.rate-bytes-per-sec: "200M"

  tidb:
    performance.max-procs: 8
```

The following sections introduce the meanings and the adjustment methods of these parameters.

12.5.8.2.1 Configuration of TiKV thread pool size

This section offers best practices for adjusting parameters that relate to the resource allocation of thread pools for foreground applications. Reducing these thread pool sizes will compromise performance, but in the hybrid deployment scenario with limited resources, the cluster itself is hard to achieve high performance. In this scenario, the overall stability of the cluster is preferred over performance.

If you conduct an actual load test, you can first use the default configuration and observe the actual resource usage of each thread pool. Then you can adjust the corresponding configuration items and reduce the sizes of the thread pools that have lower usage.

`readpool.unified.max-thread-count`

The default value of this parameter is 80% of the number of machine threads. In a hybrid deployment scenario, you need to manually calculate and specify this value. You can first set it to 80% of the expected number of CPU threads used by TiKV.

`server.grpc-concurrency`

This parameter defaults to `4`. Because in the existing deployment plan, the CPU resources are limited and the actual requests are few. You can observe the monitoring panel, lower the value of this parameter, and keep the usage rate below 80%.

In this test, the value of this parameter is set to `2`. Observe the **gRPC poll CPU** panel and you can see that the usage rate is just around 80%.

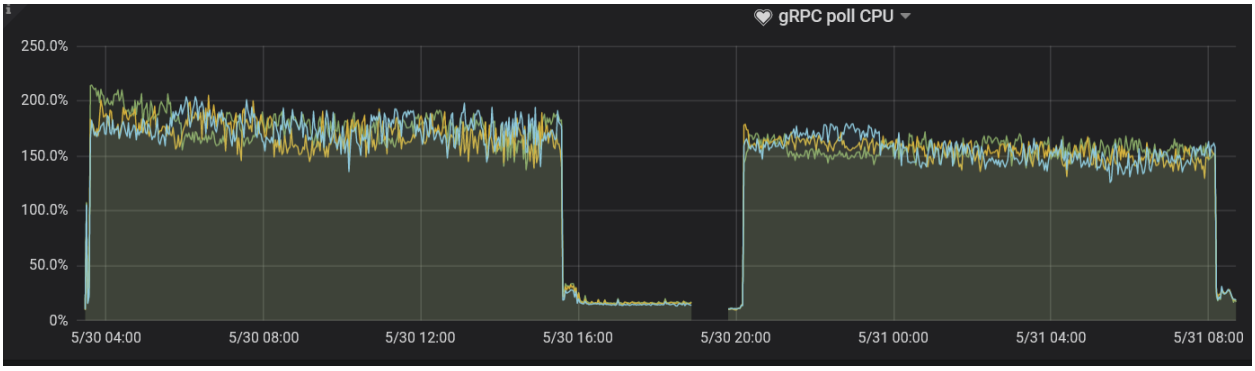

Figure 455: gRPC Pool CPU

`storage.scheduler-worker-pool-size`

When TiKV detects that the CPU core number of the machine is greater than or equal to `16`, this parameter value defaults to `8`. When the CPU core number is smaller than `16`, the parameter value defaults to `4`. This parameter is used when TiKV converts complex transaction requests to simple key-value reads or writes, but the scheduler thread pool does not performs any writes.

Ideally, the usage rate of the scheduler thread pool is kept between 50% and 75%. Similar to the gRPC thread pool, the `storage.scheduler-worker-pool-size` parameter defaults to a larger value during the hybrid deployment, which makes resource usage insufficient. In this test, the value of this parameter is set to `2`, which is in line with the best practices, a conclusion drawn by observing the corresponding metrics in the **Scheduler worker CPU** panel.

Figure 456: Scheduler Worker CPU

12.5.8.2.2 Resource configuration for TiKV background tasks

In addition to foreground tasks, TiKV regularly sorts data and cleans outdated data in background tasks. The default configuration allocates sufficient resources to these tasks for

the scenario of high-traffic writes.

However, in the hybrid deployment scenario, this default configuration is not in line with the best practices. You need to limit the resource usage of background tasks by adjusting the following parameters.

`rocksdb.max-background-jobs` and `rocksdb.max-sub-compactions`

The RocksDB thread pool is used to perform compaction and flush jobs. The default value of `rocksdb.max-background-jobs` is `8`, which obviously exceeds the resource that is in need. Therefore, the value should be adjusted to limit the resource usage.

`rocksdb.max-sub-compactions` indicates the number of concurrent sub-tasks allowed for a single compaction job, which defaults to `3`. You can lower this value when the write traffic is not high.

In the test, the `rocksdb.max-background-jobs` value is set to `3` and the `rocksdb.max-sub-compactions` value is set to `1`. No write stall occurs during the 12-hour test with the TPC-C load. When optimizing the two parameter values according to the actual load, you can lower the values gradually based on monitoring metrics:

- If write stall occurs, increase the value of `rocksdb.max-background-jobs`.
- If the write stall persists, set the value of `rocksdb.max-sub-compactions` to `2` or `3`.

`rocksdb.rate-bytes-per-sec`

This parameter is used to limit the disk traffic for the background compaction jobs. The default configuration has no limit for this parameter. To avoid the situation that compaction jobs occupy the resources of foreground services, you can adjust this parameter value according to the sequential read and write speed of the disk, which reserves enough disk bandwidth for foreground services.

The method of optimizing the RocksDB thread pool is similar to that of optimizing the compaction thread pool. You can determine whether the value you have adjusted is suitable according to whether write stall occurs.

`gc.max_write_bytes_per_sec`

Because TiDB uses the multi-version concurrency control (MVCC) model, TiKV periodically cleans old version data in the background. When the available resources are limited, this operation causes periodical performance jitter. You can use the `gc.max_write_bytes_per_sec` parameter to limit the resource usage of such an operation.

Figure 457: GC Impact

In addition to setting this parameter value in the configuration file, you can also dynamically adjust this value in tikv-ctl.

```
tiup ctl:v<CLUSTER_VERSION> tikv --host=${ip:port} modify-tikv-config -n gc.
    ↪ max_write_bytes_per_sec -v ${limit}
```

Note:

In application scenarios with frequent updates, limiting GC traffic might cause the MVCC versions to pile up and affect read performance. Currently, to achieve a balance between performance jitter and performance decrease, you might need to try multiple times to adjust the value of this parameter.

12.5.8.2.3 TiDB parameter adjustment

Generally, you can adjust the TiDB parameters of execution operators using system variables such as `tidb_hash_join_concurrency` and `tidb_index_lookup_join_concurrency`.

In this test, these parameters are not adjusted. In the load test of your actual application, if the execution operators consume an excessive amount of CPU resources, you can limit the resource usage of specific operators according to your application scenario. For more details, see TiDB system variables.

`performance.max-procs`

This parameter is used to control how many CPU cores an entire Go process can use. By default, the value is equal to the number of CPU cores of the current machine or cgroups.

When Go is running, a proportion of threads is used for background tasks such as GC. If you do not limit the value of the `performance.max-procs` parameter, these background tasks will consume too much CPU.

12.5.9 Local Read under Three Data Centers Deployment

In the model of three data centers, a Region has three replicas which are isolated in each data center. However, due to the requirement of strongly consistent read, TiDB must access the Leader replica of the corresponding data for every query. If the query is generated in a data center different from that of the Leader replica, TiDB needs to read data from another data center, thus causing the access latency to increase.

This document describes how to use the Stale Read feature to avoid cross-center access and reduce the access latency at the expense of real-time data availability.

12.5.9.1 Deploy a TiDB cluster of three data centers

For the three-data-center deployment method, refer to Multiple Data Centers in One City Deployment.

Note that if both the TiKV and TiDB nodes have the configuration item `labels` configured, the TiKV and TiDB nodes in the same data center must have the same value for the `zone` label. For example, if a TiKV node and a TiDB node are both in the data center `dc-1`, then the two nodes need to be configured with the following label:

```
[labels]
zone=dc-1
```

12.5.9.2 Perform local read using Stale Read

Stale Read is a mechanism that TiDB provides for the users to read historical data. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes. When using Stale Read in some scenarios of geo-distributed deployment, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query process.

When TiDB receives a Stale Read query, if the `zone` label of that TiDB node is configured, and `tidb_replica_read` is set to `closest-replicas`, then TiDB sends the request to the TiKV node with the same `zone` label where the corresponding data replica resides.

For how to perform Stale Read, see Perform Stale Read using the `AS OF TIMESTAMP` clause.

12.5.10 UUID Best Practices

12.5.10.1 Overview of UUIDs

When used as a primary key, instead of an `AUTO_INCREMENT` integer value, a universally unique identifier (UUID) delivers the following benefits:

- UUIDs can be generated on multiple systems without risking conflicts. In some cases, this means that the number of network trips to TiDB can be reduced, leading to improved performance.
- UUIDs are supported by most programming languages and database systems.
- When used as a part of a URL, a UUID is not vulnerable to enumeration attacks. In comparison, with an `AUTO_INCREMENT` number, it is possible to guess the invoice IDs or user IDs.

12.5.10.2 Best practices

12.5.10.2.1 Store as binary

The textual UUID format looks like this: `ab06f63e-8fe7-11ec-a514-5405db7aad56`, which is a string of 36 characters. By using `UUID_TO_BIN()`, the textual format can be converted into a binary format of 16 bytes. This allows you to store the text in a `BINARY(16)` column. When retrieving the UUID, you can use the `BIN_TO_UUID()` function to get back to the textual format.

12.5.10.2.2 UUID format binary order and a clustered PK

The `UUID_TO_BIN()` function can be used with one argument, the UUID or with two arguments where the second argument is a `swap_flag`.

It is recommended to not set the `swap_flag` with TiDB to avoid hotspots.

You can also explicitly set the `CLUSTERED` option for UUID based primary keys to avoid hotspots.

To demonstrate the effect of the `swap_flag`, here are two tables with an identical structure. The difference is that the data inserted into `uuid_demo_1` uses `UUID_TO_BIN(?, 0)` and `uuid_demo_2` uses `UUID_TO_BIN(?, 1)`.

In the screenshot of the Key Visualizer below, you can see that writes are concentrated in a single region of the `uuid_demo_2` table that has the order of the fields swapped in the binary format.

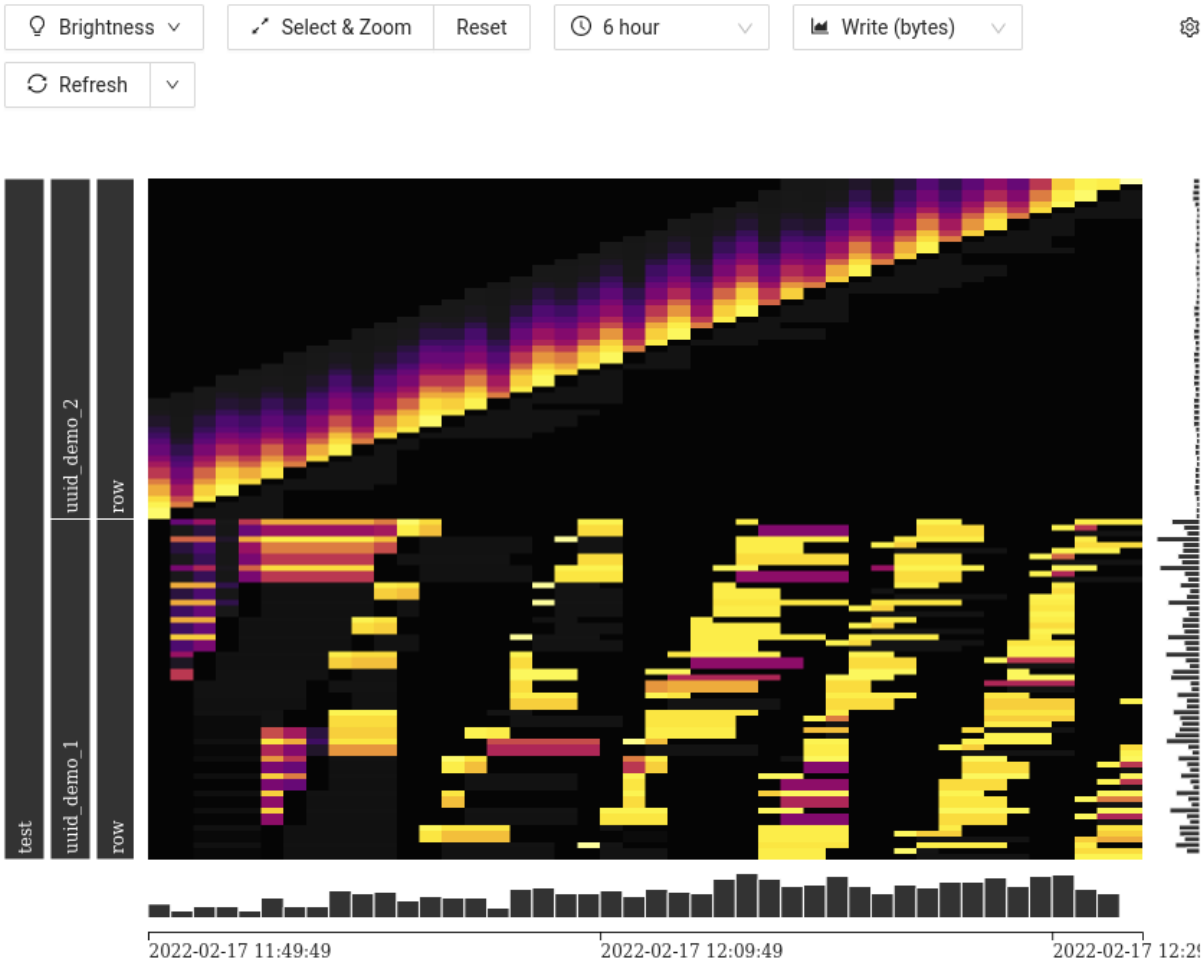

Figure 458: Key Visualizer

```
CREATE TABLE `uuid_demo_1` (
  `uuid` varbinary(16) NOT NULL,
  `c1` varchar(255) NOT NULL,
  PRIMARY KEY (`uuid`) CLUSTERED
)
```

```
CREATE TABLE `uuid_demo_2` (
  `uuid` varbinary(16) NOT NULL,
  `c1` varchar(255) NOT NULL,
  PRIMARY KEY (`uuid`) CLUSTERED
)
```

12.5.10.3 MySQL compatibility

UUIDs can be used in MySQL as well. The `BIN_TO_UUID()` and `UUID_TO_BIN()` functions were introduced in MySQL 8.0. The `UUID()` function is available in earlier MySQL versions as well.

12.5.11 Best Practices for Read-Only Storage Nodes

This document introduces how to configure read-only storage nodes and how to direct backup, analysis, testing, and other traffic to these nodes. In this way, loads with high tolerance for delay can be physically isolated from important online services.

12.5.11.1 Procedures

12.5.11.1.1 1. Specify some TiKV nodes as read-only

To specify some TiKV nodes as read-only, you can mark these nodes with a special label (use `$` as the prefix of the label key). Unless you explicitly specify these nodes to store some data using Placement Rules, PD does not schedule any data to these nodes.

You can configure a read-only node by running the `tiup cluster edit-config` command:

```
tikv_servers:
  - host: ...
    ...
    labels:
      $mode: readonly
```

12.5.11.1.2 2. Use Placement Rules to store data on read-only nodes as learners

1. Run the `pd-ctl config placement-rules` command to export the default Placement Rules:

   ```
   pd-ctl config placement-rules rule-bundle load --out="rules.json"
   ```

   If you have not configured Placement Rules before, the output is as follows:

   ```
   [
     {
       "group_id": "pd",
       "group_index": 0,
       "group_override": false,
       "rules": [
         {
           "group_id": "pd",
   ```

```
      "id": "default",
      "start_key": "",
      "end_key": "",
      "role": "voter",
      "count": 3
    }
  ]
 }
]
```

2. Store all data on the read-only nodes as a learner. The following example is based on the default configuration:

```
[
 {
  "group_id": "pd",
  "group_index": 0,
  "group_override": false,
  "rules": [
   {
    "group_id": "pd",
    "id": "default",
    "start_key": "",
    "end_key": "",
    "role": "voter",
    "count": 3
   },
   {
    "group_id": "pd",
    "id": "readonly",
    "start_key": "",
    "end_key": "",
    "role": "learner",
    "count": 1,
    "label_constraints": [
     {
      "key": "$mode",
      "op": "in",
      "values": [
       "readonly"
      ]
     }
    ],
    "version": 1
   }
```

```
    ]
  }
]
```

3. Use the `pd-ctl config placement-rules` command to write the preceding configurations to PD:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

Note:

- If you perform the preceding operations on a cluster with a large dataset, the entire cluster might need some time to completely replicate data to read-only nodes. During this period, the read-only nodes might not be able to provide services.
- Because of the special implementation of backup, the learner number of each label cannot exceed 1. Otherwise, it will generate duplicate data during backup.

12.5.11.1.3 3. Use Follower Read to read data from read-only nodes

3.1 Use Follower Read in TiDB

To read data from read-only nodes when using TiDB, you can set the system variable `tidb_replica_read` to `learner`:

```
set tidb_replica_read=learner;
```

3.2 Use Follower Read in TiSpark

To read data from read-only nodes when using TiSpark, you can set the configuration item `spark.tispark.replica_read` to `learner` in the Spark configuration file:

```
spark.tispark.replica_read learner
```

3.3 Use Follower Read when backing up cluster data

To read data from read-only nodes when backing up cluster data, you can specify the `--replica-read-label` option in the br command line. Note that when running the following command in shell, you need to use single quotes to wrap the label to prevent `$` from being parsed.

```
tiup br backup full ... --replica-read-label '$mode:readonly'
```

12.6 Placement Rules

> **Note:**
>
> This document introduces how to manually specify placement rules in Placement Driver (PD). It is now recommended to use Placement Rules in SQL. This offers a more convenient way to configure the placement of tables and partitions.

Placement Rules, introduced in v5.0, is a replica rule system that guides PD to generate corresponding schedules for different types of data. By combining different scheduling rules, you can finely control the attributes of any continuous data range, such as the number of replicas, the storage location, the host type, whether to participate in Raft election, and whether to act as the Raft leader.

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to Disable Placement Rules.

12.6.1 Rule system

The configuration of the whole rule system consists of multiple rules. Each rule can specify attributes such as the number of replicas, the Raft role, the placement location, and the key range in which this rule takes effect. When PD is performing schedule, it first finds the rule corresponding to the Region in the rule system according to the key range of the Region, and then generates the corresponding schedule to make the distribution of the Region replica comply with the rule.

The key ranges of multiple rules can have overlapping parts, which means that a Region can match multiple rules. In this case, PD decides whether the rules overwrite each other or take effect at the same time according to the attributes of rules. If multiple rules take effect at the same time, PD will generate schedules in sequence according to the stacking order of the rules for rule matching.

In addition, to meet the requirement that rules from different sources are isolated from each other, these rules can be organized in a more flexible way. Therefore, the concept of "Group" is introduced. Generally, users can place rules in different groups according to different sources.

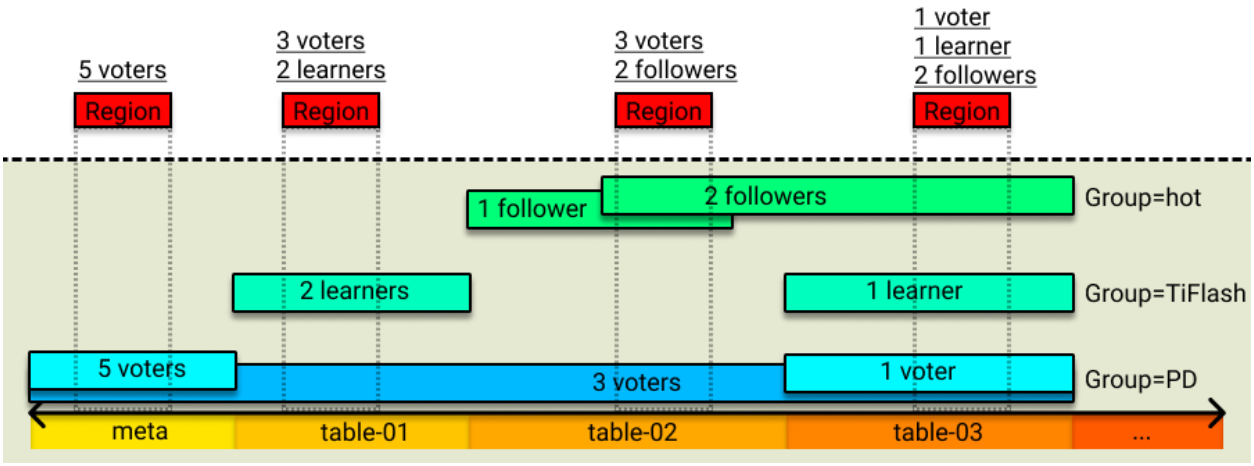

Figure 459: Placement rules overview

12.6.1.1 Rule fields

The following table shows the meaning of each field in a rule:

Field name	Type and restriction	Description
`GroupID`	`string`	The group ID that marks the source of the rule.
`ID`	`string`	The unique ID of a rule in a group.
`Index`	`int`	The stacking sequence of rules in a group.
`Override`	`true/false`	Whether to overwrite rules with smaller index (in a g
`StartKey`	`string`, in hexadecimal form	Applies to the starting key of a range.
`EndKey`	`string`, in hexadecimal form	Applies to the ending key of a range.
`Role`	`string`	Replica roles, including voter/leader/follower/learner.
`Count`	`int`, positive integer	The number of replicas.
`LabelConstraint`	`[]Constraint`	Filters nodes based on the label.
`LocationLabels`	`[]string`	Used for physical isolation.
`IsolationLevel`	`string`	Used to set the minimum physical isolation level

`LabelConstraint` is similar to the function in Kubernetes that filters labels based on these four primitives: `in`, `notIn`, `exists`, and `notExists`. The meanings of these four primitives are as follows:

- `in`: the label value of the given key is included in the given list.
- `notIn`: the label value of the given key is not included in the given list.
- `exists`: includes the given label key.
- `notExists`: does not include the given label key.

The meaning and function of `LocationLabels` are the same with those earlier than v4.0. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology:

the cluster has multiple zones (Availability Zones), each zone has multiple racks, and each rack has multiple hosts. When performing schedule, PD first tries to place the Region's peers in different zones. If this try fails (such as there are three replicas but only two zones in total), PD guarantees to place these replicas in different racks. If the number of racks is not enough to guarantee isolation, then PD tries the host-level isolation.

The meaning and function of `IsolationLevel` is elaborated in Cluster topology configuration. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology with `LocationLabels` and set `IsolationLevel` to `zone`, then PD ensures that all peers of each Region are placed in different zones during the scheduling. If the minimum isolation level restriction on `IsolationLevel` cannot be met (for example, 3 replicas are configured but there are only 2 data zones in total), PD will not try to make up to meet this restriction. The default value of `IsolationLevel` is an empty string, which means that it is disabled.

12.6.1.2 Fields of the rule group

The following table shows the description of each field in a rule group:

Field name	Type and restriction	Description
`ID`	`string`	The group ID that marks the source of the rule.
`Index`	`int`	The stacking sequence of different groups.
`Override`	`true/false`	Whether to override groups with smaller indexes.

12.6.2 Configure rules

The operations in this section are based on pd-ctl, and the commands involved in the operations also support calls via HTTP API.

12.6.2.1 Enable Placement Rules

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to Disable Placement Rules. To enable this feature after it has been disabled, you can modify the PD configuration file as follows before initializing the cluster:

```
[replication]
enable-placement-rules = true
```

In this way, PD enables this feature after the cluster is successfully bootstrapped and generates corresponding rules according to the `max-replicas`, `location-labels`, and `isolation-level` configurations:

```
{
  "group_id": "pd",
  "id": "default",
  "start_key": "",
```

```
  "end_key": "",
  "role": "voter",
  "count": 3,
  "location_labels": ["zone", "rack", "host"],
  "isolation_level": ""
}
```

For a bootstrapped cluster, you can also enable Placement Rules dynamically through pd-ctl:

```
pd-ctl config placement-rules enable
```

PD also generates default rules based on the `max-replicas`, `location-labels`, and `isolation-level` configurations.

Note:

- When Placement Rules are enabled and multiple rules exist, the previously configured `max-replicas`, `location-labels`, and `isolation-level` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.
- When Placement Rules are enabled and only one default rule exists, TiDB will automatically update this default rule when `max-replicas`, `location-labels`, or `isolation-level` configurations are changed.

12.6.2.2 Disable Placement Rules

You can use pd-ctl to disable the Placement Rules feature and switch to the previous scheduling strategy.

```
pd-ctl config placement-rules disable
```

Note:

After disabling Placement Rules, PD uses the original `max-replicas`, `location-labels`, and `isolation-level` configurations. The modification of rules (when Placement Rules is enabled) will not update these three configurations in real time. In addition, all the rules that have been configured remain in PD and will be used the next time you enable Placement Rules.

12.6.2.3 Set rules using pd-ctl

> **Note:**
>
> The change of rules affects the PD scheduling in real time. Improper rule setting might result in fewer replicas and affect the high availability of the system.

pd-ctl supports using the following methods to view rules in the system, and the output is a JSON-format rule or a rule list.

- To view the list of all rules:

```
pd-ctl config placement-rules show
```

- To view the list of all rules in a PD Group:

```
pd-ctl config placement-rules show --group=pd
```

- To view the rule of a specific ID in a Group:

```
pd-ctl config placement-rules show --group=pd --id=default
```

- To view the rule list that matches a Region:

```
pd-ctl config placement-rules show --region=2
```

  In the above example, `2` is the Region ID.

Adding rules and editing rules are similar. You need to write the corresponding rules into a file and then use the `save` command to save the rules to PD:

```
cat > rules.json <<EOF
[
    {
        "group_id": "pd",
        "id": "rule1",
        "role": "voter",
        "count": 3,
        "location_labels": ["zone", "rack", "host"]
    },
    {
        "group_id": "pd",
```

```
        "id": "rule2",
        "role": "voter",
        "count": 2,
        "location_labels": ["zone", "rack", "host"]
    }
]
EOF

» ./pd-ctl -u 127.0.0.1:2379 config placement-rules save --in=rules.json
Success!
```

The above operation writes `rule1` and `rule2` to PD. If a rule with the same `GroupID` + `ID` already exists in the system, this rule is overwritten.

To delete a rule, you only need to set the `count` of the rule to `0`, and the rule with the same `GroupID` + `ID` will be deleted. The following command deletes the `pd / rule2` rule:

```
cat > rules.json <<EOF
[
    {
        "group_id": "pd",
        "id": "rule2"
    }
]
EOF

» ./pd-ctl -u 127.0.0.1:2379 config placement-rules save --in=rules.json
Success!
```

12.6.2.4 Use pd-ctl to configure rule groups

- To view the list of all rule groups:

```
pd-ctl config placement-rules rule-group show
```

- To view the rule group of a specific ID:

```
pd-ctl config placement-rules rule-group show pd
```

- To set the `index` and `override` attributes of the rule group:

```
pd-ctl config placement-rules rule-group set pd 100 true
```

- To delete the configuration of a rule group (use the default group configuration if there is any rule in the group):

```
pd-ctl config placement-rules rule-group delete pd
```

12.6.2.5 Use pd-ctl to batch update groups and rules in groups

To view and modify the rule groups and all rules in the groups at the same time, execute the `rule-bundle` subcommand.

In this subcommand, `get {group_id}` is used to query a group, and the output result shows the rule group and rules of the group in a nested form:

```
pd-ctl config placement-rules rule-bundle get pd
```

The output of the above command:

```
{
  "group_id": "pd",
  "group_index": 0,
  "group_override": false,
  "rules": [
    {
      "group_id": "pd",
      "id": "default",
      "start_key": "",
      "end_key": "",
      "role": "voter",
      "count": 3
    }
  ]
}
```

To write the output to a file, add the `--out` argument to the `rule-bundle get` subcommand, which is convenient for subsequent modification and saving.

```
pd-ctl config placement-rules rule-bundle get pd --out="group.json"
```

After the modification is finished, you can use the `rule-bundle set` subcommand to save the configuration in the file to the PD server. Unlike the `save` command described in Set rules using pd-ctl, this command replaces all the rules of this group on the server side.

```
pd-ctl config placement-rules rule-bundle set pd --in="group.json"
```

12.6.2.6 Use pd-ctl to view and modify all configurations

You can also view and modify all configuration using pd-ctl. To do that, save all configuration to a file, edit the configuration file, and then save the file to the PD server to overwrite the previous configuration. This operation also uses the `rule-bundle` subcommand.

For example, to save all configuration to the `rules.json` file, execute the following command:

```
pd-ctl config placement-rules rule-bundle load --out="rules.json"
```

After editing the file, execute the following command to save the configuration to the PD server:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

12.6.2.7 Use tidb-ctl to query the table-related key range

If you need special configuration for metadata or a specific table, you can execute the `keyrange` command in tidb-ctl to query related keys. Remember to add `--encode` at the end of the command.

```
tidb-ctl keyrange --database test --table ttt --encode
```

```
global ranges:
  meta: (6d00000000000000f8, 6e00000000000000f8)
  table: (7400000000000000f8, 7500000000000000f8)
table ttt ranges: (NOTE: key range might be changed after DDL)
  table: (748000000000000ff2d000000000000000f8, 7480000000000000
    ↪ ff2e00000000000000f8)
  table indexes: (748000000000000ff2d5f690000000000fa, 7480000000000000
    ↪ ff2d5f720000000000fa)
    index c2: (748000000000000ff2d5f698000000000ff0000010000000000fa,
      ↪ 748000000000000ff2d5f698000000000ff0000020000000000fa)
    index c3: (748000000000000ff2d5f698000000000ff0000020000000000fa,
      ↪ 748000000000000ff2d5f698000000000ff0000030000000000fa)
    index c4: (748000000000000ff2d5f698000000000ff0000030000000000fa,
      ↪ 748000000000000ff2d5f698000000000ff0000040000000000fa)
  table rows: (748000000000000ff2d5f720000000000fa, 7480000000000000
    ↪ ff2e00000000000000f8)
```

> **Note:**
>
> DDL and other operations can cause table ID changes, so you need to update the corresponding rules at the same time.

12.6.3 Typical usage scenarios

This section introduces the typical usage scenarios of Placement Rules.

12.6.3.1 Scenario 1: Use three replicas for normal tables and five replicas for the metadata to improve cluster disaster tolerance

You only need to add a rule that limits the key range to the range of metadata, and set the value of `count` to `5`. Here is an example of this rule:

```
{
  "group_id": "pd",
  "id": "meta",
  "index": 1,
  "override": true,
  "start_key": "6d00000000000000f8",
  "end_key": "6e00000000000000f8",
  "role": "voter",
  "count": 5,
  "location_labels": ["zone", "rack", "host"]
}
```

12.6.3.2 Scenario 2: Place five replicas in three data centers in the proportion of 2:2:1, and the Leader should not be in the third data center

Create three rules. Set the number of replicas to `2`, `2`, and `1` respectively. Limit the replicas to the corresponding data centers through `label_constraints` in each rule. In addition, change `role` to `follower` for the data center that does not need a Leader.

```
[
   {
       "group_id": "pd",
       "id": "zone1",
       "start_key": "",
       "end_key": "",
       "role": "voter",
       "count": 2,
       "label_constraints": [
          {"key": "zone", "op": "in", "values": ["zone1"]}
       ],
       "location_labels": ["rack", "host"]
   },
   {
       "group_id": "pd",
       "id": "zone2",
       "start_key": "",
       "end_key": "",
       "role": "voter",
       "count": 2,
       "label_constraints": [
          {"key": "zone", "op": "in", "values": ["zone2"]}
       ],
       "location_labels": ["rack", "host"]
```

```
    },
    {
        "group_id": "pd",
        "id": "zone3",
        "start_key": "",
        "end_key": "",
        "role": "follower",
        "count": 1,
        "label_constraints": [
            {"key": "zone", "op": "in", "values": ["zone3"]}
        ],
        "location_labels": ["rack", "host"]
    }
]
```

12.6.3.3 Scenario 3: Add two TiFlash replicas for a table

Add a separate rule for the row key of the table and limit `count` to `2`. Use `label_constraints` to ensure that the replicas are generated on the node of `engine = tiflash`. Note that a separate `group_id` is used here to ensure that this rule does not overlap or conflict with rules from other sources in the system.

```
{
  "group_id": "tiflash",
  "id": "learner-replica-table-ttt",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "learner",
  "count": 2,
  "label_constraints": [
    {"key": "engine", "op": "in", "values": ["tiflash"]}
  ],
  "location_labels": ["host"]
}
```

12.6.3.4 Scenario 4: Add two follower replicas for a table in the Beijing node with high-performance disks

The following example shows a more complicated `label_constraints` configuration. In this rule, the replicas must be placed in the `bj1` or `bj2` machine room, and the disk type must be `nvme`.

```
{
  "group_id": "follower-read",
  "id": "follower-read-table-ttt",
```

```
  "start_key": "7480000000000000ff2d00000000000000f8",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "follower",
  "count": 2,
  "label_constraints": [
    {"key": "zone", "op": "in", "values": ["bj1", "bj2"]},
    {"key": "disk", "op": "in", "values": ["nvme"]}
  ],
  "location_labels": ["host"]
}
```

12.6.3.5 Scenario 5: Migrate a table to the nodes with SSD disks

Different from scenario 3, this scenario is not to add new replica(s) on the basis of the existing configuration, but to forcibly override the other configuration of a data range. So you need to specify an `index` value large enough and set `override` to `true` in the rule group configuration to override the existing rule.

The rule:

```
{
  "group_id": "ssd-override",
  "id": "ssd-table-45",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "voter",
  "count": 3,
  "label_constraints": [
    {"key": "disk", "op": "in", "values": ["ssd"]}
  ],
  "location_labels": ["rack", "host"]
}
```

The rule group:

```
{
  "id": "ssd-override",
  "index": 1024,
  "override": true,
}
```

12.7 Load Base Split

Load Base Split is a new feature introduced in TiDB 4.0. It aims to solve the hotspot issue caused by unbalanced access between Regions, such as full table scans for small tables.

12.7.1 Scenarios

In TiDB, it is easy to generate hotspots when the load is concentrated on certain nodes. PD tries to schedule the hot Regions so that they are distributed as evenly as possible across all nodes for better performance.

However, the minimum unit for PD scheduling is Region. If the number of hotspots in a cluster is smaller than the number of nodes, or if a few hotspots have far more load than other Regions, PD can only move the hotspot from one node to another, but not make the entire cluster share the load.

This scenario is especially common with workloads that are mostly read requests, such as full table scans and index lookups for small tables, or frequent access to some fields.

Previously, the solution to this problem was to manually execute a command to split one or more hotspot Regions, but this approach has two problems:

- Evenly splitting a Region is not always the best choice, because requests might be concentrated on a few keys. In such cases, hotspots might still be on one of the Regions after evenly splitting, and it might take multiple even splits to realize the goal.
- Human intervention is not timely or simple.

12.7.2 Implementation principles

Load Base Split automatically splits the Region based on statistics. It identifies the Regions whose read load or CPU usage consistently exceeds the threshold for 10 seconds, and splits these Regions at a proper position. When choosing the split position, Load Base Split tries to balance the access load of both Regions after the split and avoid access across Regions.

The Region split by Load Base Split will not be merged quickly. On the one hand, PD's `MergeChecker` skips the hot Regions; on the other hand, PD also determines whether to merge two Regions according to `QPS` in the heartbeat information, to avoid the merging of two Regions with high `QPS`.

12.7.3 Usage

The Load Base Split feature is currently controlled by the following parameters:

- `split.qps-threshold`: The QPS threshold at which a Region is identified as a hotspot. The default value is `3000` per second when `region-split-size` is less than 4 GB; otherwise the default value is `7000`.
- `split.byte-threshold`: (Introduced in v5.0) The traffic threshold at which a Region is identified as a hotspot. The unit is byte. The default value is 30 MiB per second when `region-split-size` is less than 4 GB; otherwise the default value is 100 MiB per second.

- `split.region-cpu-overload-threshold-ratio`: (Introduced in v6.2.0) The CPU usage threshold (the percentage of CPU time of the read thread pool) at which a Region is identified as a hotspot. The default value is `0.25` when `region-split-size` is less than 4 GB; otherwise the default value is `0.75`.

If a Region meets one of the following conditions for 10 consecutive seconds, TiKV tries to split the Region:

- the sum of its read requests exceeds `split.qps-threshold`.
- its traffic exceeds `split.byte-threshold`.
- its CPU usage in the Unified Read Pool exceeds `split.region-cpu-overload-threshold-ratio`.

Load Base Split is enabled by default, but the parameter is set to a rather high value. If you want to disable this feature, set `split.qps-threshold` and `split.byte-threshold` high enough and set `split.region-cpu-overload-threshold-ratio` to `0` at the same time.

To modify the parameter, take either of the following two methods:

- Use a SQL statement:

```
# Set the QPS threshold to 1500
SET config tikv split.qps-threshold=1500;
# Set the byte threshold to 15 MiB (15 * 1024 * 1024)
SET config tikv split.byte-threshold=15728640;
# Set the CPU usage threshold to 50%
SET config tikv split.region-cpu-overload-threshold-ratio=0.5;
```

- Use TiKV:

```
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.qps-threshold":"1500"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.byte-threshold":"15728640"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.region-cpu-overload-threshold-ratio":"0.5"}'
```

Accordingly, you can view the configuration by either of the following two methods:

- Use a SQL statement:

```
show config where type='tikv' and name like '%split.qps-threshold%';
```

- Use TiKV:

```
curl "http://ip:status_port/config"
```

Note:

Starting from v4.0.0-rc.2, you can modify and view the configuration using SQL statements.

12.8 Store Limit

Store Limit is a feature of PD, introduced in TiDB 3.0. It is designed to control the scheduling speed in a finer manner for better performance in different scenarios.

12.8.1 Implementation principles

PD performs scheduling at the unit of operator. An operator might contain several scheduling operations. For example:

```
"replace-down-replica {mv peer: store [2] to [3]} (kind:region,replica,
    ↪ region:10(4,5), createAt:2020-05-18 06:40:25.775636418 +0000 UTC m
    ↪ =+2168762.679540369, startAt:2020-05-18 06:40:25.775684648 +0000 UTC
    ↪ m=+2168762.679588599, currentStep:0, steps:[add learner peer 20 on
    ↪ store 3, promote learner peer 20 on store 3 to voter, remove peer on
    ↪ store 2])"
```

In this above example, the `replace-down-replica` operator contains the following specific operations:

1. Add a learner peer with the ID `20` to `store 3`.
2. Promote the learner peer with the ID `20` on `store 3` to a voter.
3. Delete the peer on `store 2`.

Store Limit achieves the store-level speed limit by maintaining a mapping from store IDs to token buckets in memory. The different operations here correspond to different token buckets. Currently, Store Limit only supports limiting the speed of two operations: adding learners/peers and deleting peers. That is, each store has two types of token buckets.

Every time an operator is generated, it checks whether enough tokens exist in the token buckets for its operations. If yes, the operator is added to the scheduling queue, and the corresponding token is taken from the token bucket. Otherwise, the operator is abandoned. Because the token bucket replenishes tokens at a fixed rate, the speed limit is thus achieved.

Store Limit is different from other limit-related parameters in PD (such as `region-schedule-limit` and `leader-schedule-limit`) in that it mainly limits the consuming speed of operators, while other parameters limits the generating speed of operators. Before introducing the Store Limit feature, the speed limit of scheduling is mostly at the global scope. Therefore, even if the global speed is limited, it is still possible that the scheduling operations are concentrated on some stores, affecting the performance of the cluster. By limiting the speed at a finer level, Store Limit can better control the scheduling behavior.

12.8.2 Usage

The parameters of Store Limit can be configured using `pd-ctl`.

12.8.2.1 View setting of the current store

To view the limit setting of the current store, run the following commands:

```
store limit                     // Shows the speed limit of adding and deleting peers in all stores.
store limit add-peer            // Shows the speed limit of adding peers in all stores.
store limit remove-peer         // Shows the speed limit of deleting peers in all stores.
```

12.8.2.2 Set limit for all stores

To set the speed limit for all stores, run the following commands:

```
store limit all 5               // All stores can at most add and delete 5 peers per minute.
store limit all 5 add-peer      // All stores can at most add 5 peers per minute.
store limit all 5 remove-peer   // All stores can at most delete 5 peers per minute.
```

12.8.2.3 Set limit for a single store

To set the speed limit for a single store, run the following commands:

```
store limit 1 5                 // store 1 can at most add and delete 5 peers per minute.
store limit 1 5 add-peer        // store 1 can at most add 5 peers per minute.
store limit 1 5 remove-peer     // store 1 can at most delete 5 peers per minute.
```

12.8.2.4 Principles of store limit v2

> **Warning:**
>
> Store limit v2 is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

When `store-limit-version` is set to `v2`, store limit v2 takes effect. In v2 mode, the limit of operators are dynamically adjusted based on the capability of TiKV snapshots. When TiKV has fewer pending tasks, PD increases its scheduling tasks. Otherwise, PD reduces the scheduling tasks for the node. Therefore, you do not need to manually set `store limit` to speed up the scheduling process.

In v2 mode, the execution speed of TiKV becomes the main bottleneck during migration. You can check whether the current scheduling speed has reached the upper limit through the **TiKV Details** > **Snapshot** > **Snapshot Speed** panel. To increase or decrease the scheduling speed of a node, you can adjust the TiKV snapshot limit (`snap-io-max-bytes-per-sec`).

12.9 Execution Principles and Best Practices of DDL Statements

This document provides an overview of the execution principles and best practices related to DDL statements in TiDB. The principles include the DDL Owner module and the online DDL change process.

12.9.1 DDL execution principles

TiDB uses an online and asynchronous approach to execute DDL statements. This means that DML statements in other sessions are not blocked while DDL statements are being executed. In other words, you can change the definitions of database objects using online and asynchronous DDL statements while your applications are running.

12.9.1.1 Types of DDL statements

Based on whether DDL statements block the user application during execution, DDL statements can be divided into the following types:

- **Offline DDL statements**: When the database receives a DDL statement from the user, it first locks the database object to be modified and then changes the metadata. During the DDL execution, the database blocks the user application from modifying data.

- **Online DDL statements**: When a DDL statement is executed in the database, a specific method is used to ensure that the statement does not block the user application. This allows the user to submit modifications during the DDL execution. The method also ensures the correctness and consistency of the corresponding database object during the execution process.

Based on whether to operate the data included in the target DDL object, DDL statements can be divided into the following types:

- **Logical DDL statements**: Logical DDL statements usually only modify the metadata of the database object, without processing the data stored in the object, for example, changing the table name or changing the column name.

  In TiDB, logical DDL statements are also referred to as "general DDL". These statements typically have a short execution time, often taking only a few tens of milliseconds or seconds to complete. As a result, they do not consume much system resource and do not affect the workload on the application.

- **Physical DDL statements**: Physical DDL statements not only modify the metadata of the object to be changed, but also modify the user data stored in the object. For example, when TiDB creates an index for a table, it not only changes the definition of the table, but also performs a full table scan to build the newly added index.

  In TiDB, physical DDL statements are also referred to as "reorg DDL", which stands for reorganization. Currently, physical DDL statements only include `ADD INDEX` and lossy column type changes (such as changing from an `INT` type to a `CHAR` type). These statements take a long time to execute, and the execution time is affected by the amount of data in the table, the machine configuration, and the application workload.

  Executing physical DDL statements can have an impact on the workload of the application for two reasons. On the one hand, it consumes CPU and I/O resources from TiKV to read data and write new data. On the other hand, **the TiDB node serving as DDL Owners** or **those TiDB nodes scheduled by the TiDB Distributed eXecution Framework (DXF) to execute `ADD INDEX` tasks** consume CPU resources from TiDB to perform the corresponding computations.

> **Note:**
>
> The execution of a physical DDL task typically causes the greatest impact on the user application. Therefore, to minimize this impact, the key point is to optimize the design of physical DDL statements during execution. This helps to reduce the impact on the user application.

12.9.1.2 TiDB DDL module

The TiDB DDL module introduces the role of the DDL Owner (or Owner), which serves as a proxy for executing all DDL statements within the TiDB cluster. In the current implementation, only one TiDB node in the entire cluster can be elected as the Owner at any given time. Once a TiDB node is elected as Owner, the worker started in that TiDB node can handle the DDL tasks in the cluster.

TiDB uses the election mechanism of etcd to elect a node to host the Owner from multiple TiDB nodes. By default, each TiDB node can potentially be elected as the Owner (you can configure `run-ddl` to manage node participation in the election). The elected Owner node has a term, and it actively maintains the term by renewing it. When the Owner node is down, another node can be elected as the new Owner through etcd and continue executing DDL tasks in the cluster.

A simple illustration of the DDL Owner is as follows:

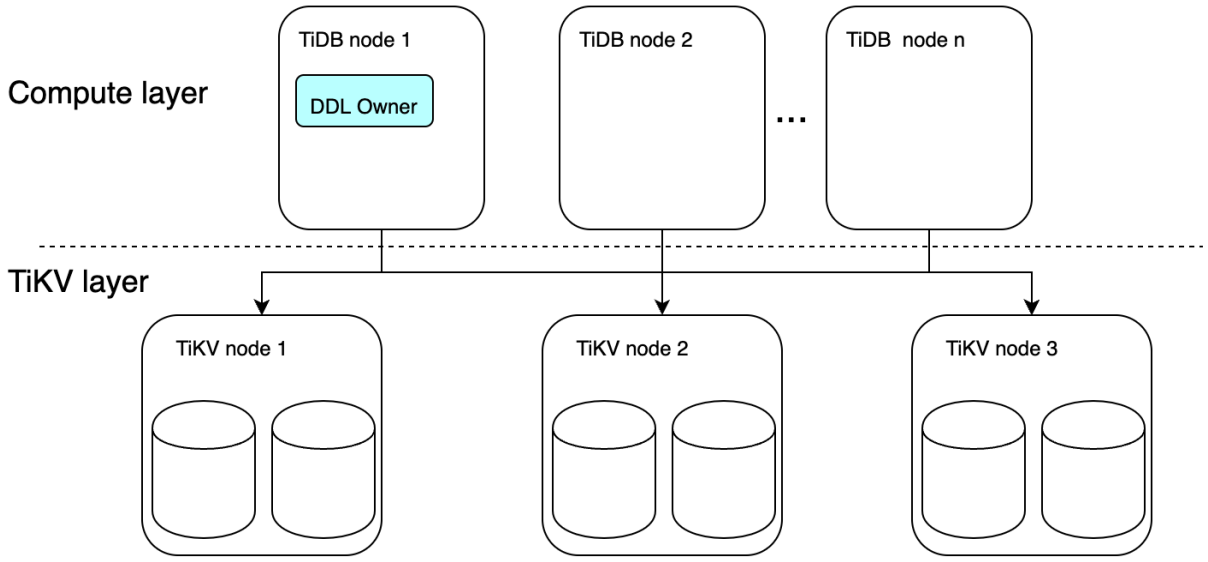

Figure 460: DDL Owner

You can use the `ADMIN SHOW DDL` statement to view the current DDL owner:

```
ADMIN SHOW DDL;
```

```
+--
    ↪ ----------+--------------------------------------+--------------+------------
    ↪
| SCHEMA_VER | OWNER_ID                             | OWNER_ADDRESS | RUNNING_JOBS
    ↪  | SELF_ID                          | QUERY |
+--
    ↪ ----------+--------------------------------------+--------------+------------
    ↪
```

```
|        26 | 2d1982af-fa63-43ad-a3d5-73710683cc63 | 0.0.0.0:4000 |      | 2
    ↪ d1982af-fa63-43ad-a3d5-73710683cc63 | |
+--

    ↪
1 row in set (0.00 sec)
```

12.9.1.3 How the online DDL asynchronous change works in TiDB

From the beginning of its design, the TiDB DDL module has opted for an online asynchronous change mode, which lets you modify your applications without experiencing any downtime.

DDL changes involve transitioning from one state to another, typically from a "before change" state to an "after change" state. With online DDL changes, this transition occurs by introducing multiple small version states that are mutually compatible. During the execution of a DDL statement, TiDB nodes in the same cluster are allowed to have different small version changes, as long as the difference between the small versions of the change objects is not more than two versions. This is possible because adjacent small versions can be mutually compatible.

In this way, evolving through multiple small versions ensures that metadata can be correctly synchronized across multiple TiDB nodes. This helps maintain the correctness and consistency of user transactions that involve changing data during the process.

Taking `ADD INDEX` as an example, the entire process of state change is as follows:

```
absent -> delete only -> write only -> write reorg -> public
```

For users, the newly created index is unavailable before the `public` state.

Before TiDB v6.2.0, because the Owner can only execute one DDL task of the same type (either logical or physical) at a time, which is relatively strict, and affects the user experience.

If there is no dependency between DDL tasks, parallel execution does not affect data correctness and consistency. For example, user A adds an index to the `T1` table, while user B deletes a column from the `T2` table. These two DDL statements can be executed in parallel.

To improve the user experience of DDL execution, starting from v6.2.0, TiDB enables the Owner to determine the relevance of DDL tasks. The logic is as follows:

- DDL statements to be performed on the same table are mutually blocked.
- `DROP DATABASE` and DDL statements that affect all objects in the database are mutually blocked.
- Adding indexes and column type changes on different tables can be executed concurrently.

- Starting from v8.2.0, logical DDL statements for different tables can be executed in parallel.
- In other cases, DDL can be executed based on the level of availability for concurrent DDL execution.

Specifically, TiDB 6.2.0 has enhanced the DDL execution framework in the following aspects:

- The DDL Owner can execute DDL tasks in parallel based on the preceding logic.
- The first-in-first-out issue in the DDL Job queue has been addressed. The DDL Owner no longer selects the first job in the queue, but instead selects the job that can be executed at the current time.
- The number of workers that handle physical DDL statements has been increased, enabling multiple physical DDL statements to be executed in parallel.

  Because all DDL tasks in TiDB are implemented using an online change approach, TiDB can determine the relevance of new DDL jobs through the Owner, and schedule DDL tasks based on this information. This approach enables the distributed database to achieve the same level of DDL concurrency as traditional databases.

The concurrent DDL framework enhances the execution capability of DDL statements in TiDB, making it more compatible with the usage patterns of commercial databases.

Before v6.2.0, the process of handling asynchronous schema changes in the TiDB SQL layer is as follows:

1. MySQL Client sends a DDL request to a TiDB server.
2. After receiving the request, a TiDB server parses and optimizes the request at the MySQL Protocol layer, and then sends it to the TiDB SQL layer for execution.

   Once the SQL layer of TiDB receives the DDL request, it starts the `start job` module to encapsulate the request into a specific DDL job (that is, a DDL task), and then stores this job in the corresponding DDL job queue in the KV layer based on the statement type. The corresponding worker is notified of the job that requires processing.
3. When receiving the notification to process the job, the worker determines whether it has the role of the DDL Owner. If it does, it directly processes the job. Otherwise, it exits without any processing.

   If a TiDB server is not the Owner role, then another node must be the Owner. The worker of the node in the Owner role periodically checks whether there is an available job that can be executed. If such a job is identified, the worker will process the job.

4. After the worker processes the Job, it removes the job from the job queue in the KV layer and places it in the `job history queue`. The `start job` module that encapsulated the job periodically checks the ID of the job in the `job history queue` to see whether it has been processed. If so, the entire DDL operation corresponding to the job ends.

5. TiDB server returns the DDL processing result to the MySQL Client.

Before TiDB v6.2.0, the DDL execution framework had the following limitations:

- The TiKV cluster only has two queues: `general job queue` and `add index job queue`, which handle logical DDL and physical DDL, respectively.
- The DDL Owner always processes DDL jobs in a first-in-first-out way.
- The DDL Owner can only execute one DDL task of the same type (either logical or physical) at a time, which is relatively strict, and affects the user experience.

These limitations might lead to some "unintended" DDL blocking behavior. For more details, see SQL FAQ - DDL Execution.

12.9.2 Best practices

12.9.2.1 Balance the physical DDL execution speed and the impact on application load through system variables

When executing physical DDL statements (including adding indexes or column type changes), you can adjust the values of the following system variables to balance the speed of DDL execution and the impact on application load:

- `tidb_ddl_reorg_worker_cnt`: This variable sets the number of reorg workers for a DDL operation, which controls the concurrency of backfilling.

- `tidb_ddl_reorg_batch_size`: This variable sets the batch size for a DDL operation in the `re-organize` phase, which controls the amount of data to be backfilled.

  Recommended values:

  - If there is no other load, you can increase the values of `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` to speed up the `ADD INDEX` operation. For example, you can set the values of the two variables to `20` and `2048`, respectively.
  - If there is other load, you can decrease the values of `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` to minimize the impact on other application. For example, you can set the values of the these variables to `4` and `256`, respectively.

Tip:

- The preceding two variables can be dynamically adjusted during the execution of a DDL task, and take effect in the next transaction batch.
- Choose the appropriate time to execute the DDL operation based on the type of the operation and the application load pressure. For example, it is recommended to run the `ADD INDEX` operation when the application load is low.
- Because the duration of adding an index is relatively long, TiDB will execute the task in the background after the command is sent. If the TiDB server is down, the execution will not be affected.

12.9.2.2 Quickly create many tables by concurrently sending DDL requests

A table creation operation takes about 50 milliseconds. The actual time taken to create a table might be longer because of the framework limitations.

To create tables faster, it is recommended to send multiple DDL requests concurrently to achieve the fastest table creation speed. If you send DDL requests serially and do not send them to the Owner node, the table creation speed will be very slow.

12.9.2.3 Make multiple changes in a single `ALTER` statement

Starting from v6.2.0, TiDB supports modifying multiple schema objects (such as columns and indexes) of a table in a single `ALTER` statement while ensuring the atomicity of the entire statement. Therefore, it is recommended to make multiple changes in a single `ALTER` statement.

12.9.2.4 Check the read and write performance

When TiDB is adding an index, the phase of backfilling data will cause read and write pressure on the cluster. After the `ADD INDEX` command is sent and the `write reorg` phase starts, it is recommended to check the read and write performance metrics of TiDB and TiKV on the Grafana dashboard and the application response time, to determine whether the `ADD INDEX` operation affects the cluster.

12.9.3 DDL-related commands

- `ADMIN SHOW DDL`: Used to view the status of TiDB DDL operations, including the current schema version number, the DDL ID and address of the DDL Owner, the DDL task and SQL being executed, and the DDL ID of the current TiDB instance. For details, see `ADMIN SHOW DDL`.

- `ADMIN SHOW DDL JOBS`: Used to view the detailed status of DDL tasks running in the cluster environment. For details, see `ADMIN SHOW DDL JOBS`.
- `ADMIN SHOW DDL JOB QUERIES job_id [, job_id]`: Used to view the original SQL statement of the DDL task corresponding to the `job_id`. For details, see `ADMIN SHOW DDL JOB QUERIES`.
- `ADMIN CANCEL DDL JOBS job_id, [, job_id]`: Used to cancel DDL tasks that have been submitted but not completed. After the cancellation is completed, the SQL statement that executes the DDL task returns the `ERROR 8214 (HY000): Cancelled DDL job` error.

  If a completed DDL task is canceled, you can see the `DDL Job:90 not found` error in the `RESULT` column, which means that the task has been removed from the DDL waiting queue.
- `ADMIN PAUSE DDL JOBS job_id [, job_id]`: Used to pause the DDL jobs that are being executed. After the command is executed, the SQL statement that executes the DDL job is displayed as being executed, while the background job has been paused. For details, refer to `ADMIN PAUSE DDL JOBS`.

  You can only pause DDL tasks that are in progress or still in the queue. Otherwise, the `Job 3 can't be paused now` error is shown in the `RESULT` column.
- `ADMIN RESUME DDL JOBS job_id [, job_id]`: Used to resume the DDL tasks that have been paused. After the command is executed, the SQL statement that executes the DDL task is displayed as being executed, and the background task is resumed. For details, refer to `ADMIN RESUME DDL JOBS`.

  You can only resume a paused DDL task. Otherwise, the `Job 3 can't be resumed` error is shown in the `RESULT` column.

12.9.4 Common questions

For common questions about DDL execution, see SQL FAQ - DDL execution.

12.10 Use PD Microservices

12.10.1 PD Microservices

Starting from v8.0.0, PD supports the microservice mode, which splits the timestamp allocation and cluster scheduling functions of PD into the following two independently deployed microservices. In this way, these two functions are decoupled from the routing function of PD, which allows PD to focus on the routing service for metadata.

- `tso` microservice: provides monotonically increasing timestamp allocation for the entire cluster.

- `scheduling` microservice: provides scheduling functions for the entire cluster, including but not limited to load balancing, hot spot handling, replica repair, and replica placement.

Each microservice is deployed as an independent process. If you configure more than one replica for a microservice, the microservice automatically implements a primary-secondary fault-tolerant mode to ensure high availability and reliability of the service.

> **Warning:**
>
> Currently, the PD microservices feature is experimental. It is not recommended that you use it in production environments. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

12.10.1.1 Usage scenarios

PD microservices are typically used to address performance bottlenecks in PD and improve PD service quality. With this feature, you can avoid the following issues:

- Long-tail latency or jitter in TSO allocations due to excessive pressure in PD clusters
- Service unavailability of the entire cluster due to failures in the scheduling module
- Bottleneck issues solely caused by PD

In addition, when the scheduling module is changed, you can update the `scheduling` microservice independently without restarting PD, thus avoiding any impact on the overall service of the cluster.

> **Note:**
>
> If the performance bottleneck of a cluster is not caused by PD, there is no need to enable microservices, because using microservices increases the number of components and raises operational costs.

12.10.1.2 Restrictions

- Currently, the `tso` microservice does not support dynamic start and stop. After enabling or disabling the `tso` microservice, you need to restart the PD cluster for the changes to take effect.

- Only the TiDB component supports a direct connection to the `tso` microservice through service discovery, while other components need to forward requests to the `tso` microservice through PD to obtain timestamps.
- Microservices are not compatible with the Data Replication Auto Synchronous (DR Auto-Sync) feature.
- Microservices are not compatible with the TiDB system variable `tidb_enable_tso_follower_proxy`.
- Because hibernate Regions might exist in a cluster, during a primary and secondary switchover of the `scheduling` microservice, the scheduling function of the cluster might be unavailable for a certain period (up to `peer-stale-state-check-interval`, which is five minutes by default) to avoid redundant scheduling.

12.10.1.3 Usage

PD microservices can be deployed using TiDB Operator or TiUP.

For TiDB clusters deployed using TiDB Operator, you can deploy and configure PD microservices according to the following documents:

- Deploy PD microservices
- Configure PD microservices
- Modify PD microservices
- Scale PD microservice components

For TiDB clusters deployed using TiUP, you can deploy and configure PD microservices according to the following documents:

- Deploy PD microservices
- Scale PD microservice nodes
- Configure the `tso` microservice
  - Configure via the configuration file
  - Configure via command line flags
- Configure the `scheduling` microservice
  - Configure via the configuration file
  - Configure via command line flags

To deploy and configure PD microservices in a TiDB local cluster using TiUP Playground, see the following document:

- Deploy PD microservices

12.10.1.4 Notes

When deploying and using PD microservices, pay attention to the following:

- After you enable microservices and restart PD for a cluster, PD stops allocating TSO for the cluster. Therefore, you need to deploy the `tso` microservice in the cluster when you enable microservices.
- If the `scheduling` microservice is deployed in a cluster, the scheduling function of the cluster is provided by the `scheduling` microservice. If the `scheduling` microservice is not deployed, the scheduling function of the cluster is still provided by PD.
- The `scheduling` microservice supports dynamic switching, which is enabled by default (`enable-scheduling-fallback` defaults to `true`). If the process of the `scheduling` microservice is terminated, PD continues to provide scheduling services for the cluster by default.

  If the binary versions of the `scheduling` microservice and PD are different, to prevent changes in the scheduling logic, you can disable the dynamic switching function of the `scheduling` microservice by executing `pd-ctl config set enable-scheduling-fallback false`. After this function is disabled, PD will not take over the scheduling service when the process of the `scheduling` microservice is terminated. This means that the scheduling service of the cluster will be unavailable until the `scheduling` microservice is restarted.

12.10.1.5 Tool compatibility

Microservices do not affect the normal use of data import, export, and other replication tools.

12.10.1.6 FAQs

- How can I determine if PD becomes a performance bottleneck?

When your cluster is in a normal state, you can check monitoring metrics in the Grafana PD panel. If the `TiDB - PD server TSO handle time` metric shows a notable increase in latency or the `Heartbeat - TiKV side heartbeat statistics` metric shows a significant number of pending items, it indicates that PD becomes a performance bottleneck.

12.10.2 Scale PD Microservices Nodes Using TiUP

This document describes how to scale PD microservice nodes (including TSO and Scheduling nodes) in a cluster and how to switch the PD working mode using TiUP.

To view the current cluster name list, run `tiup cluster list`.

For example, the original topology of the cluster is as follows:

Host IP	Service
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV
10.0.1.6	TSO
10.0.1.7	Scheduling

12.10.2.1 Add TSO/Scheduling nodes

> **Note:**
>
> To add TSO/Scheduling nodes to a TiDB cluster that have not enabled PD microservices yet, follow the instructions in Switch from regular mode to microservices mode instead.

This section exemplifies how to add a TSO node (at IP address `10.0.1.8`) and a Scheduling node (at IP address `10.0.1.9`) to a TiDB cluster with PD microservices enabled.

12.10.2.1.1 1. Configure the scale-out topology

> **Note:**
>
> - By default, the port and directory information is not required. However, in the case of multiple instances on a single machine, you need to allocate different ports and directories for these instances. If the ports or directories have conflicts, you will receive a notification during deployment or scaling.
> - Starting from TiUP v1.0.0, the scale-out configuration inherits the `global` configuration of the original cluster.

Add the scale-out topology configuration in the `scale-out.yml` file:

```
vi scale-out.yml
```

The following is the configuration example for the TSO node:

```
tso_servers:
  - host: 10.0.1.8
    port: 3379
```

The following is the configuration example for the Scheduling node:

```
scheduling_servers:
  - host: 10.0.1.9
    port: 3379
```

To view the configuration of the current cluster, run `tiup cluster edit-config <cluster-name>`. Because the parameter configuration of `global` and `server_configs` is inherited by `scale-out.yml`, it also takes effect in `scale-out.yml`.

12.10.2.1.2 2. Run the scale-out command

Before you run the `scale-out` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

1. Check for potential risks:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --user root
    [-p] [-i /home/root/.ssh/gcp_rsa]
```

2. Enable automatic repair:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --apply --
    user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

3. Run the `scale-out` command:

```
tiup cluster scale-out <cluster-name> scale-out.yml [-p] [-i /home/root
    /.ssh/gcp_rsa]
```

In the preceding commands:

- `scale-out.yml` is the scale-out configuration file.
- `--user root` indicates logging in to the target machine as the `root` user to complete the cluster scale out. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]` are optional. If you have configured login to the target machine without a password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

If you see `Scaled cluster <cluster-name> out successfully`, the scale-out operation succeeds.

12.10.2.1.3 3. Check the cluster status

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser to monitor the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV
10.0.1.6	TSO
10.0.1.7	Scheduling
10.0.1.8	TSO
10.0.1.9	Scheduling

12.10.2.2 Remove TSO/Scheduling nodes

> **Note:**
>
> For a cluster with PD microservices enabled, if you need to switch it to non-microservice mode, follow the instructions in Switch from microservices mode to regular mode instead.

This section exemplifies how to remove a TSO node (at IP address `10.0.1.8`) and a Scheduling node (at IP address `10.0.1.9`) from a TiDB cluster with multiple TSO or Scheduling nodes.

12.10.2.2.1 1. View the node ID information

```
tiup cluster display <cluster-name>
```

```
Starting /root/.tiup/components/cluster/v1.16/cluster display <cluster-name>

TiDB Cluster: <cluster-name>

TiDB Version: v8.4.0
```

```
ID      Role        Host    Ports                          Status Data Dir
   ↪      Deploy Dir

   ↪ scheduling-3379  deploy/scheduling-3379

10.0.1.9:3379 scheduling 10.0.1.9  3379                        Up      data/
   ↪ scheduling-3379  deploy/scheduling-3379
```

12.10.2.2.2 2. Run scale-in commands

```
tiup cluster scale-in <cluster-name> --node 10.0.1.8:3379
tiup cluster scale-in <cluster-name> --node 10.0.1.9:3379
```

The `--node` parameter is the ID of the node to be taken offline.

If you see `Scaled cluster <cluster-name> in successfully`, the scale-in operation succeeds.

12.10.2.2.3 3. Check the cluster status

Run the following command to check if the nodes are successfully removed:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser to monitor the status of the entire cluster.

After the scale-in, the current topology is as follows:

Host IP	Service
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV
10.0.1.6	TSO
10.0.1.7	Scheduling

12.10.2.3 Switch the PD working mode

You can switch PD services between the following two working modes:

- Regular mode: provides routing service, timestamp allocation, and cluster scheduling functions solely by PD nodes.
- Microservice mode: enables you to deploy the PD timestamp allocation function to TSO nodes (providing `tso` microservices) and the cluster scheduling function to Scheduling nodes (providing `scheduling` microservices) separately. In this way, these two functions are decoupled from the routing function of PD, which allows PD nodes to focus on the routing service for metadata.

> **Note:**
>
> During the mode switching, PD services will be unavailable for a few minutes.

12.10.2.3.1 Switch from regular mode to microservices mode

For a cluster that has not enabled PD microservices, you can switch it to PD microservice mode and add a TSO node (at IP address `10.0.1.8`) and a Scheduling node (at IP address `10.0.1.9`) to it as follows:

1. Add the scale-out topology configuration in the `scale-out.yml` file:

```
vi scale-out.yml
```

   The following is a configuration example:

```
tso_servers:
  - host: 10.0.1.8
    port: 3379
scheduling_servers:
  - host: 10.0.1.9
    port: 3379
```

2. Modify the cluster configuration and switch the cluster to PD microservice mode:

```
tiup cluster edit-config <cluster-name>
```

   Add `pd_mode: ms` to `global`:

```
global:
  user: tidb
   ssh_port: 22
   listen_host: 0.0.0.0
   deploy_dir: /tidb-deploy
   data_dir: /tidb-data
   os: linux
   arch: amd64
   systemd_mode: system
   pd_mode: ms
```

3. Perform a rolling update of the PD node configuration:

```
tiup cluster reload <cluster-name> -R pd
```

> **Note:**
>
> The PD timestamp allocation service will be unavailable after you run the preceding `reload` command and will be available again once the `scale-out` command in the next step completes execution.

4. Run the `scale-out` command to add PD microservice nodes:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

12.10.2.3.2 Switch from microservices mode to regular mode

For a cluster with PD microservices enabled (assume that it has a TSO node at IP address `10.0.1.8` and a Scheduling node at IP address `10.0.1.9`), you can switch it to non-microservice mode as follows:

1. Modify the cluster configuration and switch the cluster to non-microservice mode:

```
tiup cluster edit-config <cluster-name>
```

Remove `pd_mode: ms` from `global`:

```
global:
  user: tidb
   ssh_port: 22
   listen_host: 0.0.0.0
   deploy_dir: /tidb-deploy
   data_dir: /tidb-data
   os: linux
   arch: amd64
   systemd_mode: system
```

2. Run the `scale-in` command to remove all PD microservice nodes:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.8:3379,10.0.1.9:3379
```

> **Note:**
> The PD timestamp allocation service will be unavailable after you run the preceding `scale-in` command and will be available again once the `reload` command in the next step completes execution.

3. Perform a rolling update of the PD node configuration:

```
tiup cluster reload <cluster-name> -R pd
```

12.10.3 TSO Configuration File

The TSO node is used for providing the `tso` microservice for PD. This document is applicable only in PD microservice mode.

Tip:

If you need to adjust the value of a configuration item, refer to Modify the configuration.

12.10.3.0.1 `name`

- The name of the TSO node
- Default value: `"TSO"`
- To start multiple TSO nodes, use a unique name for each node.

12.10.3.0.2 `data-dir`

- The directory in which the TSO node stores data
- Default value: `"default.${name}"`

12.10.3.0.3 `listen-addr`

- The client URL that the current TSO node listens to
- Default value: `"http://127.0.0.1:3379"`
- When deploying a cluster, you must specify the IP address of the current host as `listen-addr` (for example, `"http://192.168.100.113:3379"`). If the node runs on Docker, specify the Docker IP address as `"http://0.0.0.0:3379"`.

12.10.3.0.4 `advertise-listen-addr`

- The URL for the client to access the TSO node
- Default value: `"${listen-addr}"`
- In some situations such as in Docker or NAT network environments, if a client cannot access the TSO node through the default client URLs listened to by the TSO node, you must manually set `advertise-listen-addr` for client access.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 3379:3379`. In this case, you can set `advertise-listen-addr="http://192.168.100.113:3379"`. Then, the client can find this service through `http://192.168.100.113:3379`.

12.10.3.0.5 `backend-endpoints`

- The list of backend endpoints of other TSO nodes that the current TSO node listens to
- Default value: `"http://127.0.0.1:2379"`

12.10.3.0.6 `lease`

- The timeout of the TSO Primary Key lease. After the timeout, the system re-elects a Primary.
- Default value: `3`
- Unit: seconds

12.10.3.0.7 `tso-update-physical-interval`

- The interval at which the TSO physical time is updated.
- Within the default update interval of the TSO physical time (`50ms`), the TSO server provides at most 262144 TSOs. To get more TSOs, you can reduce the value of this configuration item. The minimum value is `1ms`.
- Shortening this interval might increase the CPU usage of the TSO server. According to tests, compared with the update interval of `50ms`, the CPU usage of the TSO server increases by about 10% when the interval is `1ms`.
- Default value: `50ms`
- Minimum value: `1ms`

12.10.3.1 security

Configuration items related to security

12.10.3.1.1 `cacert-path`

- The path of the CA file
- Default value: ""

12.10.3.1.2 `cert-path`

- The path of the Privacy Enhanced Mail (PEM) file that contains the X.509 certificate
- Default value: ""

12.10.3.1.3 `key-path`

- The path of the PEM file that contains the X.509 key
- Default value: ""

12.10.3.1.4 `redact-info-log`

- Controls whether to enable log redaction in TSO node logs.
- When you set the configuration value to `true`, user data is redacted in TSO node logs.
- Default value: `false`

12.10.3.2 log

Configuration items related to logs.

12.10.3.2.1 `level`

- Specifies the level of the output log.
- Optional value: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`
- Default value: `"info"`

12.10.3.2.2 `format`

- The log format
- Optional value: `"text"`, `"json"`
- Default value: `"text"`

12.10.3.2.3 `disable-timestamp`

- Controls whether to disable the automatically generated timestamp in logs.
- Default value: `false`

12.10.3.3 log.file

Configuration items related to the log file

12.10.3.3.1 `max-size`

- The maximum size of a single log file. When this value is exceeded, the system automatically splits the log into several files.
- Default value: `300`
- Unit: MiB
- Minimum value: `1`

12.10.3.3.2 `max-days`

- The maximum number of days in which a log is kept.
- If the configuration item is unset or set to the default value `0`, TSO does not clean up log files.
- Default value: `0`

12.10.3.3.3 `max-backups`

- The maximum number of log files to be kept.
- If the configuration item is unset or set to the default value `0`, TSO keeps all log files.
- Default value: `0`

12.10.3.4 metric

Configuration items related to monitoring

12.10.3.4.1 `interval`

- The interval at which monitoring metric data is pushed to Prometheus
- Default value: `15s`

12.10.4 TSO Configuration Flags

The TSO node is used for providing the `tso` microservice for PD. You can configure it using command-line flags or environment variables.

12.10.4.1 `--advertise-listen-addr`

- The URL for the client to access the TSO node.
- Default: `${listen-addr}`
- In some situations such as in Docker or NAT network environments, if a client cannot access the TSO node through the default client URLs listened to by `tso`, you must manually set `--advertise-listen-addr` for client access.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 3379:3379`. In this case, you can set `--advertise-listen-addr="http://192.168.100.113:3379"` ↪ . Then, the client can find this service through `http://192.168.100.113:3379`.

12.10.4.2 `--backend-endpoints`

- The list of backend endpoints of other TSO nodes that the current TSO node listens to.
- Default: `http://127.0.0.1:2379`

12.10.4.3 `--cacert`

- The file path of CA, used to enable TLS.
- Default: `""`

12.10.4.4 `--cert`

- The path of the PEM file including the X.509 certificate, used to enable TLS.
- Default: `""`

12.10.4.5 `--config`

- The configuration file.
- Default: `""`
- If you specify a configuration file, the TSO node first reads configurations from that file. If the same configurations are also specified via command line flags, the TSO node uses the command line flag configurations to overwrite those in the configuration file.

12.10.4.6 `--data-dir`

- The path to the data directory on the TSO node.
- Default: `"default.${name}"`

12.10.4.7 `--key`

- The path of the PEM file including the X.509 key, used to enable TLS.
- Default: `""`

12.10.4.8 `--listen-addr`

- The client URL that the current TSO node listens to.
- Default: `"http://127.0.0.1:3379"`
- When deploying a cluster, you must specify the IP address of the current host as `--listen-addr` (for example, `"http://192.168.100.113:3379"`). If the node runs on Docker, specify the Docker IP address as `"http://0.0.0.0:3379"`.

12.10.4.9 `--log-file`

- The log file.
- Default: `""`
- If this flag is not set, logs are output to "stderr". If this flag is set, logs are output to the corresponding file.

12.10.4.10 `--name` New in v8.3.0

- The name of the current TSO node.
- Default: `"tso-${hostname}"`
- If you need to start multiple TSO nodes, it is recommended to configure different names for different nodes for easier identification.

12.10.4.11 `-L`

- The log level.
- Default: `"info"`
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`

12.10.4.12 `-V, --version`

- Output the version information and exit.

12.10.5 Scheduling Configuration File

The Scheduling node is used for providing the `scheduling` microservice for PD. This document is applicable only in PD microservice mode.

> **Tip:**
>
> If you need to adjust the value of a configuration item, refer to Modify the configuration.

12.10.5.0.1 `name`

- The name of the Scheduling node
- Default value: `"Scheduling"`
- To start multiple Scheduling nodes, use a unique name for each node.

12.10.5.0.2 `data-dir`

- The directory in which the Scheduling node stores data
- Default value: `"default.${name}"`

12.10.5.0.3 `listen-addr`

- The client URL that the current Scheduling node listens to
- Default value: `"http://127.0.0.1:3379"`
- When deploying a cluster, you must specify the IP address of the current host as `listen-addr` (for example, `"http://192.168.100.113:3379"`). If the node runs on Docker, specify the Docker IP address as `"http://0.0.0.0:3379"`.

12.10.5.0.4 `advertise-listen-addr`

- The URL for the client to access the Scheduling node
- Default value: `"${listen-addr}"`
- In some situations such as in Docker or NAT network environments, if a client cannot access the Scheduling node through the default client URLs listened to by the Scheduling node, you must manually set `advertise-listen-addr` for client access.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 3379:3379`. In this case, you can set `advertise-listen-addr="http://192.168.100.113:2379"`. Then, the client can find this service through `http://192.168.100.113:2379`.

12.10.5.0.5 `backend-endpoints`

- The list of backend endpoints of other Scheduling nodes that the current Scheduling node listens to
- Default value: `"http://127.0.0.1:2379"`

12.10.5.0.6 `lease`

- The timeout of the Scheduling Primary Key lease. After the timeout, the system re-elects a Primary.
- Default value: `3`
- Unit: seconds

12.10.5.1 security

Configuration items related to security

12.10.5.1.1 `cacert-path`

- The path of the CA file
- Default value: “”

12.10.5.1.2 `cert-path`

- The path of the Privacy Enhanced Mail (PEM) file that contains the X.509 certificate
- Default value: “”

12.10.5.1.3 `key-path`

- The path of the PEM file that contains the X.509 key
- Default value: “”

12.10.5.1.4 `redact-info-log`

- Controls whether to enable log redaction in Scheduling node logs.
- When you set the configuration value to `true`, user data is redacted in Scheduling node logs.
- Default value: `false`

12.10.5.2 log

Configuration items related to logs.

12.10.5.2.1 `level`

- Specifies the level of the output log.
- Optional value: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`
- Default value: `"info"`

12.10.5.2.2 `format`

- The log format
- Optional value: `"text"`, `"json"`
- Default value: `"text"`

12.10.5.2.3 `disable-timestamp`

- Controls whether to disable the automatically generated timestamp in logs.
- Default value: `false`

12.10.5.3 log.file

Configuration items related to the log file

12.10.5.3.1 `max-size`

- The maximum size of a single log file. When this value is exceeded, the system automatically splits the log into several files.
- Default value: `300`
- Unit: MiB
- Minimum value: `1`

12.10.5.3.2 `max-days`

- The maximum number of days in which a log is kept.
- If the configuration item is unset or set to the default value `0`, Scheduling does not clean up log files.
- Default value: `0`

12.10.5.3.3 `max-backups`

- The maximum number of log files to be kept.
- If the configuration item is unset or set to the default value `0`, Scheduling keeps all log files.
- Default value: `0`

12.10.5.4 metric

Configuration items related to monitoring

12.10.5.4.1 `interval`

- The interval at which monitoring metric data is pushed to Prometheus
- Default value: `15s`

12.10.6 Scheduling Configuration Flags

The Scheduling node is used for providing the `scheduling` microservice for PD. You can configure it using command-line flags or environment variables.

12.10.6.1 `--advertise-listen-addr`

- The URL for the client to access the Scheduling node.
- Default: `${listen-addr}`
- In some situations such as in Docker or NAT network environments, if a client cannot access the Scheduling node through the default client URLs listened to by `scheduling`, you must manually set `--advertise-listen-addr` for client access.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 3379:3379`. In this case, you can set `--advertise-listen-addr="http://192.168.100.113:3379"` ↪ . Then, the client can find this service through `http://192.168.100.113:3379`.

12.10.6.2 `--backend-endpoints`

- The list of backend endpoints of other Scheduling nodes that the current Scheduling node listens to.
- Default: `http://127.0.0.1:2379`

12.10.6.3 `--cacert`

- The file path of CA, used to enable TLS.
- Default: `""`

12.10.6.4 `--cert`

- The path of the PEM file including the X.509 certificate, used to enable TLS.
- Default: `""`

12.10.6.5 `--config`

- The configuration file.
- Default: `""`
- If you specify a configuration file, the Scheduling node first reads configurations from that file. If the same configurations are also specified via command line flags, the Scheduling node uses the command line flag configurations to overwrite those in the configuration file.

12.10.6.6 `--data-dir`

- The path to the data directory on the Scheduling node.
- Default: `"default.${name}"`

12.10.6.7 `--key`

- The path of the PEM file including the X.509 key, used to enable TLS.
- Default: `""`

12.10.6.8 `--listen-addr`

- The client URL that the current Scheduling node listens to.
- Default: `"http://127.0.0.1:3379"`
- When deploying a cluster, you must specify the IP address of the current host as `--listen-addr` (for example, `"http://192.168.100.113:3379"`). If the node runs on Docker, specify the Docker IP address as `"http://0.0.0.0:3379"`.

12.10.6.9 `--log-file`

- The log file.
- Default: `""`
- If this flag is not set, logs are output to "stderr". If this flag is set, logs are output to the corresponding file.

12.10.6.10 `--name` New in v8.3.0

- The name of the current Scheduling node.
- Default: `"scheduling-${hostname}"`
- If you need to start multiple Scheduling nodes, it is recommended to configure different names for different nodes for easier identification.

12.10.6.11 `-L`

- The log level.
- Default: `"info"`
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`

12.10.6.12 `-V, --version`

- Output the version information and exit.

13 TiDB Tools

13.1 TiDB Tools Overview

TiDB provides a rich set of tools to help you deploy and maintain TiDB, manage data (such as data migration, backup & restore, and data comparison), and run Spark SQL on TiKV. You can select the applicable tools according to your needs.

13.1.1 Deployment and operation Tools

TiDB provides TiUP and TiDB Operator to meet your deployment and operation needs in different system environments.

13.1.1.1 Deploy and operate TiDB on physical or virtual machines - TiUP

TiUP is a TiDB package manager on physical or virtual machines. TiUP can manage multiple TiDB components such as TiDB, PD, and TiKV. To start any component in the TiDB ecosystem, you just need to execute a single line of TiUP command.

TiUP provides TiUP cluster, a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

The following are the basics of TiUP:

- Terminology and Concepts
- Deploy a TiDB Cluster Using TiUP
- Manage TiUP Components with TiUP Commands
- Applicable TiDB versions: v4.0 and later versions

13.1.1.2 Deploy and operate TiDB on Kubernetes - TiDB Operator

TiDB Operator is an automatic operation system for managing TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

The following are the basics of TiDB Operator:

- TiDB Operator Architecture
- Get Started with TiDB Operator on Kubernetes
- Applicable TiDB versions: v2.1 and later versions

13.1.2 Data management tools

TiDB provides multiple data management tools, such as import and export, backup and restore, incremental data replication, and data validation.

13.1.2.1 Data migration - TiDB Data Migration (DM)

TiDB Data Migration (DM) is a tool that supports full data migration and incremental data replication from MySQL/MariaDB to TiDB.

The following are the basics of DM:

- Source: MySQL/MariaDB
- Target: TiDB clusters
- Supported TiDB versions: all versions
- Kubernetes support: use TiDB Operator to deploy TiDB DM on Kubernetes.

If the data volume is less than 1 TB, it is recommended to migrate data from MySQL/-MariaDB to TiDB directly using DM. The migration process includes full data migration and incremental data replication.

If the data volume is greater than 1 TB , take the following steps:

1. Use Dumpling to export the full data from MySQL/MariaDB.
2. Use TiDB Lightning to import the data exported in Step 1 to the TiDB cluster.
3. Use TiDB DM to replicate the incremental data from MySQL/MariaDB to TiDB.

Note:

The Syncer tool is no longer maintained. For scenarios related to Syncer, it is recommended that you use DM to perform incremental replication.

13.1.2.2 Full data export - Dumpling

Dumpling supports logical full data export from MySQL or TiDB.

The following are the basics of Dumpling:

- Source: MySQL/TiDB clusters
- Output: SQL/CSV files
- Supported TiDB versions: all versions
- Kubernetes support: No

Note:

PingCAP previously maintained a fork of the mydumper project with enhancements specific to TiDB. Starting from v7.5.0, Mydumper is deprecated and most of its features have been replaced by Dumpling. It is strongly recommended that you use Dumpling instead of mydumper.

13.1.2.3 Full data import - TiDB Lightning

TiDB Lightning supports full data import of a large dataset into a TiDB cluster.

TiDB Lightning supports the following modes:

- `Physical Import Mode`: TiDB Lightning parses data into ordered key-value pairs and directly imports them into TiKV. This mode is usually for importing a large amount of data (at the TB level) to a new cluster. During the import, the cluster cannot provide services.
- `Logical Import Mode`: This mode uses TiDB/MySQL as the backend, which is slower than the `Physical Import Mode` but can be performed online. It also supports importing data to MySQL.

The following are the basics of TiDB Lightning:

- Data source:

  - The output files of Dumpling
  - Other compatible CSV files
  - Parquet files exported from Amazon Aurora, Apache Hive, or Snowflake
- Supported TiDB versions: v2.1 and later versions
- Kubernetes support: Yes. See Quickly restore data into a TiDB cluster on Kubernetes using TiDB Lightning for details.

> **Note:**
>
> The Loader tool is no longer maintained. For scenarios related to Loader, it is recommended that you use `Logical Import Mode` instead.

13.1.2.4 Backup and restore - Backup & Restore (BR)

Backup & Restore (BR) is a command-line tool for distributed backup and restore of the TiDB cluster data. BR can effectively back up and restore TiDB clusters of huge data volume.

The following are the basics of BR:

- Input and output data source
  - Snapshot backup and restore: SST + `backupmeta` file
  - Log backup and PITR: Log backup files
- Supported TiDB versions: v4.0 and later versions
- Kubernetes support: Yes. See Back up Data to S3-Compatible Storage Using BR and Restore Data from S3-Compatible Storage Using BR for details.

13.1.2.5 Incremental data replication - TiCDC

TiCDC is a tool used for replicating incremental data of TiDB by pulling change logs from TiKV. It can restore data to a state consistent with any TSO in upstream. TiCDC also provides the TiCDC Open Protocol to support other systems to subscribe to data changes.

The following are the basics of TiCDC:

- Source: TiDB clusters
- Target: TiDB clusters, MySQL, Kafka, and Confluent
- Supported TiDB versions: v4.0.6 and later versions

13.1.2.6 sync-diff-inspector

sync-diff-inspector is a tool that compares data stored in the MySQL or TiDB databases. In addition, you can also use sync-diff-inspector to repair data in the scenario where a small amount of data is inconsistent.

The following are the basics of sync-diff-inspector:

- Source: MySQL/TiDB clusters
- Target: MySQL/TiDB clusters
- Supported TiDB versions: all versions

13.1.3 OLAP Query tool - TiSpark

TiSpark is a product developed by PingCAP to address the complexiy of OLAP queries. It combines strengths of Spark, and the features of distributed TiKV clusters and TiDB to provide a one-stop Hybrid Transactional and Analytical Processing (HTAP) solution.

13.2 TiDB Tools Use Cases

This document introduces the common use cases of TiDB tools and how to choose the right tool for your scenario.

13.2.1 Deploy and operate TiDB on physical or virtual machines

If you need to deploy and operate TiDB on physical or virtual machines, you can install TiUP, and then use TiUP to manage TiDB components such as TiDB, PD, and TiKV.

13.2.2 Deploy and operate TiDB on Kubernetes

If you need to deploy and operate TiDB on Kubernetes, you can deploy a Kubernetes cluster, and then deploy TiDB Operator. After that, you can use TiDB Operator to deploy and operate a TiDB cluster.

13.2.3 Import data from CSV to TiDB

If you need to import the compatible CSV files exported by other tools to TiDB, use TiDB Lightning.

13.2.4 Import full data from MySQL/Aurora

If you need to import full data from MySQL/Aurora, use Dumpling first to export data as SQL dump files, and then use TiDB Lightning to import data into the TiDB cluster.

13.2.5 Migrate data from MySQL/Aurora

If you need to migrate both full data and incremental data from MySQL/Aurora, use TiDB Data Migration (DM) to perform the Migrate Data from Amazon Aurora to TiDB.

If the full data volume is large (at the TB level), you can first use Dumpling and TiDB Lightning to perform the full data migration, and then use DM to perform the incremental data migration.

13.2.6 Back up and restore TiDB cluster

If you need to back up a TiDB cluster or restore backed up data to the cluster, use BR (Backup & Restore).

In addition, BR can also be used to perform incremental backup and incremental restore of TiDB cluster data.

13.2.7 Migrate data to TiDB

If you need to migrate data from a TiDB cluster to another TiDB cluster, use Dumpling to export full data from TiDB as SQL dump files, and then use TiDB Lightning to import data to another TiDB cluster.

If you also need to migrate incremental data, you can use TiCDC.

13.2.8 TiDB incremental data subscription

If you need to subscribe to TiDB's incremental changes, you can use TiCDC.

13.3 Download TiDB Tools

This document describes how to download the TiDB Toolkit.

TiDB Toolkit contains frequently used TiDB tools, such as data export tool Dumpling, data import tool TiDB Lightning, and backup and restore tool BR.

Tip:

- If your deployment environment has internet access, you can deploy a TiDB tool using a single TiUP command, so there is no need to download the TiDB Toolkit separately.
- If you need to deploy and maintain TiDB on Kubernetes, instead of downloading the TiDB Toolkit, follow the steps in TiDB Operator offline installation.

13.3.1 Environment requirements

- Operating system: Linux
- Architecture: amd64 or arm64

13.3.2 Download link

You can download TiDB Toolkit from the following link:

```
https://download.pingcap.org/tidb-community-toolkit-{version}-linux-{arch}.
    ↪ tar.gz
```

`{version}` in the link indicates the version number of TiDB and `{arch}` indicates the architecture of the system, which can be `amd64` or `arm64`. For example, the download link for `v8.4.0` in the `amd64` architecture is `https://download.pingcap.org/tidb-community ↪ -toolkit-v8.4.0-linux-amd64.tar.gz`.

> **Note:**
>
> If you need to download the PD Control tool `pd-ctl`, download the TiDB installation package separately from `https://download.pingcap.org/tidb ↪ -community-server-{version}-linux-{arch}.tar.gz`.

13.3.3 TiDB Toolkit description

Depending on which tools you want to use, you can install the corresponding offline packages as follows:

Tool	Offline package name
TiUP	tiup-linux-{arch}.tar.gz tiup-{tiup-version}-linux-{arch}.tar.gz dm-{tiup-version}-linux-{arch}.tar.gz server-{version}-linux-{arch}.tar.gz
Dumpling	dumpling-{version}-linux-{arch}.tar.gz
TiDB Lightning	tidb-lightning-ctl tidb-lightning-{version}-linux-{arch}.tar.gz

Tool	Offline package name
TiDB Data Migration (DM)	dm-worker-{version}-linux-{arch}.tar.gz dm-master-{version}-linux-{arch}.tar.gz dmctl-{version}-linux-{arch}.tar.gz
TiCDC	cdc-{version}-linux-{arch}.tar.gz
Backup & Restore (BR)	br-{version}-linux-{arch}.tar.gz
sync-diff-inspector	sync_diff_inspector
PD Recover	pd-recover-{version}-linux-{arch}.tar

Note:

`{version}` depends on the version of the tool you are installing. `{arch}` depends on the architecture of the system, which can be `amd64` or `arm64`.

13.4 TiUP

13.4.1 TiUP Documentation Map

13.4.1.1 User guide

- TiUP Overview: Gives an overall introduction to TiUP, for example, how to install and use TiUP, and the related terminologies.
- TiUP Terminology and Concepts: Explains the terms that you might bump into when using TiUP, and help you understand the key concepts of TiUP
- TiUP Component Management: Introduces all TiUP commands in detail, and how to use TiUP to download, update and delete components
- TiUP FAQ: Introduces common issues when you use TiUP, including FAQs of the third-party components of TiUP
- TiUP Troubleshooting Guide: Introduces the troubleshooting methods and solutions if you encounter issues when using TiUP
- TiUP Reference Guide: Introduces detailed references, including commands, components, and mirrors.

13.4.1.2 TiUP resources

- TiUP Release Notes
- TiUP Issues: Lists TiUP GitHub issues

13.4.2 TiUP Overview

Starting with TiDB 4.0, TiUP, as the package manager, makes it far easier to manage different cluster components in the TiDB ecosystem. Now you can run any component with only a single line of TiUP commands.

13.4.2.1 Install TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

This command installs TiUP in the `$HOME/.tiup` folder. The installed components and the data generated by their operation are also placed in this folder. This command also automatically adds `$HOME/.tiup/bin` to the `PATH` environment variable in the Shell `.profile` file, so you can use TiUP directly.

After installation, you can check the version of TiUP:

```
tiup --version
```

```
1.14.0 tiup
Go Version: go1.21.4
Git Ref: v1.14.0
GitHash: c3e9fc518aea0da66a37f82ee5a516171de9c372
```

Note:

For TiUP versions starting from v1.11.3, the telemetry is disabled by default in newly deployed TiUP, and usage information is not collected and shared with PingCAP. For details about what is shared and how to disable the sharing, see Telemetry.

13.4.2.2 TiUP ecosystem introduction

TiUP is not only a package manager in the TiDB ecosystem. Its ultimate mission is to enable everyone to use TiDB ecosystem tools **easier than ever before** by building its own ecosystem. This requires introducing additional packages to enrich the TiUP ecosystem.

This series of TiUP documents introduce what these packages do and how you can use them.

In the TiUP ecosystem, you can get help information by adding `--help` to any command, such as the following command to get help information for TiUP itself:

```
tiup --help
```

```
TiUP is a command-line component management tool that can help to download
    ↪ and install
TiDB platform components to the local system. You can run a specific version
    ↪  of a component via
"tiup <component>[:version]". If no version number is specified, the latest
    ↪ version installed
```

```
locally will be used. If the specified component does not have any version
    ↪ installed locally,
the latest stable version will be downloaded from the repository.

Usage:
  tiup [flags] <command> [args...]
  tiup [flags] <component> [args...]
  tiup [command]

Examples:
  $ tiup playground                # Quick start
  $ tiup playground nightly        # Start a playground with the latest
      ↪ nightly version
  $ tiup install <component>[:version] # Install a component of specific
      ↪ version
  $ tiup update --all              # Update all installed components to the
      ↪ latest version
  $ tiup update --nightly          # Update all installed components to the
      ↪ nightly version
  $ tiup update --self             # Update the "tiup" to the latest version
  $ tiup list                      # Fetch the latest supported components
      ↪ list
  $ tiup status                    # Display all running/terminated
      ↪ instances
  $ tiup clean <name>              # Clean the data of running/terminated
      ↪ instance (Kill process if it's running)
  $ tiup clean --all               # Clean the data of all running/
      ↪ terminated instances

Available Commands:
  install    Install a specific version of a component
  list       List the available TiDB components or versions
  uninstall  Uninstall components or versions of a component
  update     Update tiup components to the latest version
  status     List the status of instantiated components
  clean      Clean the data of instantiated components
  mirror     Manage a repository mirror for TiUP components
  telemetry  Controls things about telemetry
  env        Show the list of system environment variable that related to
      ↪ TiUP
  history    Display the historical execution record of TiUP, displays 100
      ↪ lines by default
  link       Link component binary to $TIUP_HOME/bin/
  unlink     Unlink component binary to $TIUP_HOME/bin/
  help       Help about any command
```

```
  completion Generate the autocompletion script for the specified shell

Flags:
     --binary <component>[:version] Print binary path of a specific version
        ↪  of a component <component>[:version]
                                    and the latest version installed will be
                                       ↪ selected if no version specified
     --binpath string               Specify the binary path of component
        ↪ instance
  -h, --help                        help for tiup
  -T, --tag string                  [Deprecated] Specify a tag for component
     ↪ instance
  -v, --version                     Print the version of tiup

Use "tiup [command] --help" for more information about a command.
```

The output is long but you can focus on only two parts:

- Available commands
  - install: used to install a specific version of a component
  - list: used to view the list of available TiDB components or available versions of a component
  - uninstall: used to uninstall components or versions of a component
  - update: used to update the component version
  - status: used to view the running history of components
  - clean: used to clear the running log of components
  - mirror: used to clone a private mirror from the official mirror
  - telemetry: used to control the telemetry feature
  - env: used to show the list of system environment variables that related to TiUP
  - history: used to display the historical execution record of TiUP (100 lines by default)
  - link: used to link component binary to $TIUP_HOME/bin/
  - unlink: used to unlink component binary to $TIUP_HOME/bin/
  - help: used to print out help information
  - completion: used to generate the command line autocompletion script for the specified shell (including bash, zsh, fish, and powershell)
- Available components
  - playground: used to start a TiDB cluster locally
  - client: client used to connect to TiUP Playground
  - cluster: used to deploy a TiDB cluster for production environments
  - bench: used to stress test the database

Note:

- The number of available components will continue to grow. To check the latest supported components, execute the `tiup list` command.
- The list of available versions of components will also continue to grow. To check the latest supported component versions, execute the `tiup list <component>` command.

TiUP commands are implemented in TiUP's internal code and used for package management operations, while TiUP components are independent component packages installed by TiUP commands.

For example, if you run the `tiup list` command, TiUP directly runs its own internal code; if you run the `tiup playground` command, TiUP first checks whether there is a local package named "playground", and if not, TiUP downloads the package from the mirror, and then run it.

13.4.3 TiUP Terminology and Concepts

This document explains important terms and concepts of TiUP.

13.4.3.1 TiUP components

The TiUP program contains only a few commands for downloading, updating, and uninstalling components. TiUP expands its functions with various components. A **component** is a program or script that can be run. When running a component through `tiup <component>`, TiUP adds a set of environment variables, creates the data directory for the program, and then runs the program.

By running the `tiup <component>` command, you can run a component supported by TiUP. The running logic is:

- If you specify a version of a component through `tiup <component>[:version]`:
    - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
    - If the component has one or more versions installed locally, but there is no version specified by you, TiUP downloads the specified version from the mirror server.
    - If the specified version of the component is installed locally, TiUP sets the environment variable to run the installed version.
- If you run a component through `tiup <component>` and specify no version:

- If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
- If one or more versions have been installed locally, TiUP sets the environment variable to run the latest installed version.

13.4.3.2 TiUP mirrors

All components of TiUP are downloaded from the TiUP mirrors. TiUP mirrors contain the TAR package of each component and the corresponding meta information (version, entry startup file, checksum). TiUP uses PingCAP's official mirrors by default. You can customize the mirror source through the `TIUP_MIRRORS` environment variable.

TiUP mirrors can be a local file directory or an online HTTP server:

- `TIUP_MIRRORS=/path/to/local tiup list`
- `TIUP_MIRRORS=https://private-mirrors.example.com tiup list`

13.4.4 Manage TiUP Components with TiUP Commands

You can use the following TiUP commands to manage components in the TiUP ecosystem:

- list: Queries the component list. By using this TiUP command, you can see all the optional components to install and all the optional versions of each component.
- install: Installs the specific version of a component.
- update: Updates a component to the latest version.
- uninstall: Uninstalls a component.
- status: Checks the status of a running component.
- clean: Cleans up the instance on which a component is deployed.
- help: Prints the help information. If you append another TiUP command to this command, the usage of the appended command is printed.
- link: Links the binary of the component to the executable directory (`$TIUP_HOME/bin/`).
- unlink: Deletes the soft link generated by the `tiup link` command.

This document introduces the common component management operations and the corresponding TiUP commands.

13.4.4.1 Query the component list

You can use the `tiup list` command to query the component list. This usage of this command is as follows:

- `tiup list`: checks which components can be installed.

- `tiup list ${component}`: checks which versions of a specific component can be installed.

You can also use the following flags in the above commands:

- `--installed`: checks which components or which version of a specific component has been installed locally. `---all`: views all components, including the hidden ones `---verbose`: views all columns (including installed versions and supported platforms)

Example 1: View all currently installed components.

```
tiup list --installed
```

Example 2: Get a list of the TiKV component of all installable versions from the server.

```
tiup list tikv
```

13.4.4.2 Install components

You can use the `tiup install` command to query the component list. This usage of this command is as follows:

- `tiup install <component>`: installs the latest stable version of a specified component.
- `tiup install <component>:[version]`: installs the specified version of a specified component.

Example 1: Use TiUP to install the latest stable version of TiDB.

```
tiup install tidb
```

Example 2: Use TiUP to install the nightly version of TiDB.

```
tiup install tidb:nightly
```

Example 3: Use TiUP to install TiKV v8.4.0.

```
tiup install tikv:v8.4.0
```

13.4.4.3 Upgrade components

After a new version of a component is published, you can use the `tiup update` command to upgrade this component. The usage of this command is basically the same as that of `tiup install`, except for the following flags:

- `--all`: Upgrades all components.
- `--nightly`: Upgrades to the nightly version.
- `--self`: Upgrades TiUP itself to the latest version.
- `--force`: Forcibly upgrades to the latest version.

Example 1: Upgrade all components to the latest versions.

```
tiup update --all
```

Example 2: Upgrade all components to the nightly version.

```
tiup update --all --nightly
```

Example 3: Upgrade TiUP to the latest version.

```
tiup update --self
```

13.4.4.4 Operate components

After the installation is complete, you can use the `tiup <component>` command to start the corresponding component:

```
tiup [flags] <component>[:version] [args...]

Flags:
  -T, --tag string                Specifies the tag for the component
      ↪ instance.
```

To use this command, you need to specify the component name and the optional version. If no version is specified, the latest stable version (installed) of this component is used.

Before the component is started, TiUP creates a directory for it, and then puts this component into the directory for operation. The component generates all the data in this directory, and the name of this directory is the tag name specified when the component operates. If no tag is specified, a tag name is randomly generated. This working directory will be *automatically deleted* when the instance is terminated.

If you want to start the same component multiple times and reuse the previous working directory, you can use `--tag` to specify the same name when the component is started. After the tag is specified, the working directory will *not be automatically deleted* when the instance is terminated, which makes it convenient to reuse the working directory.

Example 1: Operate TiDB v8.4.0.

```
tiup tidb:v8.4.0
```

Example 2: Specify the tag with which TiKV operates.

```
tiup --tag=experiment tikv
```

13.4.4.4.1 Query the operating status of a component

You can use the `tiup status` command to check the operating status of a component:

```
tiup status
```

By executing this command, you will get a list of instances, one instance per line. The list contains the following columns:

- `Name`: The tag name of the instance.
- `Component`: The component name of the instance.
- `PID`: The process ID of the operating instance.
- `Status`: The instance status. `RUNNING` means that the instance is operating. `TERM` means that the instance is terminated.
- `Created Time`: The starting time of the instance.
- `Directory`: The working directory of the instance, which can be specified using `--tag`.
- `Binary`: The executable program of the instance, which can be specified using `--binpath`.
- `Args`: The arguments of the operating instance.

13.4.4.4.2 Clean component instance

You can use the `tiup clean` command to clean up component instances and delete the working directory. If the instance is still operating before the cleaning, the related process is killed first. The command usage is as follows:

```
tiup clean [tag] [flags]
```

The following flag is supported:

- `--all`: Cleans up all instance information.

In the above command, `tag` is the instance tag to be cleaned. If `--all` is used, no tag is passed.

Example 1: Clean up the component instance with the `experiment` tag name.

```
tiup clean experiment
```

Example 2: Clean up all component instances.

```
tiup clean --all
```

13.4.4.4.3 Uninstall components

The components installed using TiUP take up local disk space. If you do not want to keep too many components of old versions, you can check which versions of a component are currently installed, and then uninstall this component.

You can use the `tiup uninstall` command to uninstall all versions or specific versions of a component. This command also supports uninstalling all components. The command usage is as follows:

```
tiup uninstall [component][:version] [flags]
```

The following flags are supported in this command:

- `--all`: Uninstalls all components or versions.
- `--self`: Uninstalls TiUP itself.

`component` is the component to be uninstalled. `version` is the version to be uninstalled. Both `component` and `version` can be ignored in the `tiup uninstall` command. If you ignore either one of these two, you need to add the `--all` flag.

- If the version is ignored, adding `--all` means to uninstall all versions of this component.
- If the version and the component are both ignored, adding `--all` means to uninstall all components of all versions.

Example 1: Uninstall TiDB v8.4.0.

```
tiup uninstall tidb:v8.4.0
```

Example 2: Uninstall TiKV of all versions.

```
tiup uninstall tikv --all
```

Example 3: Uninstall all installed components.

```
tiup uninstall --all
```

13.4.4.4.4 Link components

TiUP v1.13.0 adds the experimental `link` and `unlink` commands to link the binary of a component to the executable directory (`$TIUP_HOME/bin/`) and remove the link. This feature enables you to call a component without going through TiUP each time, while preserving the ability to switch between different versions. However, this method lacks the process of automatic update checking and setting certain environment variables and some components (such as ctl) cannot be used. Therefore, it is recommended to use it only when necessary.

Example 1: install and link the latest version of the cluster component

```
tiup install cluster
tiup link cluster
```

Example 2: switch the cluster component to version v1.13.0

```
tiup link cluster:v1.13.0
```

The following is the output of the `tiup link cluster` command:

```
package cluster provides these executables: tiup-cluster
```

This indicates that the binary name of the cluster component is `tiup-cluster`. After the link command is completed, you can use the cluster component by directly typing `tiup -cluster` into the command line.

Example 3: cancel the link of the cluster component

```
tiup unlink cluster
```

Example 4: manage the version of TiUP

Before v1.13.0, TiUP is installed in `~/.tiup/bin/` and different versions cannot coexist. Starting from v1.13.0, you can install and link TiUP like any other components.

```
tiup update --self # update tiup itself to a version that supports link
tiup link tiup:v1.13.0
```

13.4.5 TiUP FAQs

This document collects the frequently asked questions (FAQs) about TiUP.

13.4.5.1 Can TiUP not use the official mirror source?

TiUP supports specifying the mirror source through the `TIUP_MIRRORS` environment variable. The address of the mirror source can be a local directory or an HTTP server address. If your environment cannot access the network, you can create your own offline mirror source to use TiUP.

After using an unofficial mirror, if you want the official mirror back and use it, take one of the following measures:

- Set the `TIUP_MIRRORS` variable to the official mirror address: `https://tiup-mirrors.pingcap.com`.
- Make sure that the `TIUP_MIRRORS` variable is not set, and then execute the `tiup mirror set https://tiup-mirrors.pingcap.com` command.

13.4.5.2 How do I put my own component into the TiUP mirrors?

TiUP does not support third-party components for the time being, but the TiUP Team has developed the TiUP component development specifications and is developing the tiup-publish component. After everything is ready, a contributor can publish their own components to TiUP's official mirrors by using the `tiup publish <comp> <version>` command.

13.4.5.3 What is the difference between the TiUP playground and TiUP cluster components?

The TiUP playground component is mainly used to build a stand-alone development environment on Linux or macOS operating systems. It helps you get started quickly and run a specified version of the TiUP cluster easily. The TiUP cluster component is mainly used to deploy and maintain a production environment cluster, which is usually a large-scale cluster. TiDB clusters deployed by TiUP Playground might lack some features and operational capabilities, and it is not recommended for complete functional and stability testing.

13.4.5.4 How do I write the topology file for the TiUP cluster component?

Refer to these templates to write the topology file. The templates include:

- Multi-DC deployment topology
- Minimal deployment topology
- Complete topology file

You can edit your topology file based on the templates and your needs.

13.4.5.5 Can multiple instances be deployed on the same host?

You can use the TiUP cluster component to deploy multiple instances on the same host, but with different ports and directories configured; otherwise, directory and port conflicts might occur.

13.4.5.6 Are port and directory conflicts detected within the same cluster?

Port and directory conflicts in the same cluster are detected during deployment and scaling. If there is any directory or port conflict, the deployment or scaling process is interrupted.

13.4.5.7 Are port and directory conflicts detected among different clusters?

If multiple different clusters are deployed by the same TiUP control machine, the port and directory conflicts among these clusters are detected during deployment and scaling. If the clusters are deployed by different TiUP control machines, conflict detection is not supported currently.

13.4.5.8 During cluster deployment, TiUP received an `ssh: handshake failed: read tcp 10.10.10.34:38980 -> 10.10.10.34:3600: read: connection reset by peer` error

The error might occur because the default number of concurrent threads of TiUP exceeds the default maximum number of SSH connections. To solve the issue, you can increase the default number of SSH connections, and then restart the sshd service:

```
vi /etc/ssh/sshd_config
```

```
MaxSessions 1000
MaxStartups 1000
```

13.4.6 TiUP Troubleshooting Guide

This document introduces some common issues when you use TiUP and the troubleshooting methods. If this document does not include the issues you bump into, file a new issue in the Github TiUP repository.

13.4.6.1 Troubleshoot TiUP commands

13.4.6.1.1 Can't see the latest component list using `tiup list`

TiUP does not update the latest component list from the mirror server every time. You can forcibly refresh the component list by running `tiup list`.

13.4.6.1.2 Can't see the latest version information of a component using `tiup list <component>`

Same as the previous issue, the component version information is only obtained from the mirror server when there is no local cache. You can refresh the component list by running `tiup list <component>`.

13.4.6.1.3 Component downloading process is interrupted

Unstable network might result in an interrupted component downloading process. You can try to download the component again. If you cannot download it after trying multiple times, it might be caused by the CDN server and you can report the issue here.

13.4.6.1.4 A checksum error occurs during component downloading process

Because the CDN server has a short cache time, the new checksum file might not match the component package. Try to download again after 5 minutes. If the new checksum file still does not match the component package, report the issue here.

13.4.6.2 Troubleshoot TiUP cluster component

13.4.6.2.1 `unable to authenticate, attempted methods [none publickey]` is prompted during deployment

During deployment, component packages are uploaded to the remote host and the initialization is performed. This process requires connecting to the remote host. This error is caused by the failure to find the SSH private key to connect to the remote host.

To solve this issue, confirm whether you have specified the private key by running `tiup cluster deploy -i identity_file`:

- If the `-i` flag is not specified, it might be that TiUP does not automatically find the private key path. It is recommended to explicitly specify the private key path using `-i`.
- If the `-i` flag is specified, it might be that TiUP cannot log in to the remote host using the specified private key. You can verify it by manually executing the `ssh -i identity_file user@remote` command.
- If a password is used to log in to the remote host, make sure that you have specified the `-p` flag and entered the correct login password.

13.4.6.2.2 The process of upgrading the cluster using the TiUP cluster component is interrupted

To avoid misuse cases, the TiUP cluster component does not support the upgrade of specified nodes, so after the upgrade fails, you need to perform the upgrade operations again, including idempotent operations during the upgrade process.

The upgrade process can be divided into the following steps:

1. Back up the old version of components on all nodes
2. Distribute new components to remote
3. Perform a rolling restart to all components

If the upgrade is interrupted during a rolling restart, instead of repeating the `tiup cluster upgrade` operation, you can use `tiup cluster restart -N <node1> -N <node2>` to restart the nodes that have not completed the restart.

If the number of un-restarted nodes of the same component is relatively large, you can also restart a certain type of component by running `tiup cluster restart -R <component>`.

13.4.6.2.3 During the upgrade, you find that `node_exporter-9100.service/blackbox_expor` does not exist

If you previously migrated your cluster from TiDB Ansible and the exporter was not deployed in TiDB Ansible, this situation might happen. To solve it, you can manually copy the missing files from other nodes to the new node for the time being. The TiUP team will complete the missing components during the migration process.

13.4.7 Command Reference

13.4.7.1 TiUP Reference

TiUP serves as the package manager of the TiDB ecosystem. It manages components in the TiDB ecosystem, such as TiDB, PD, and TiKV.

13.4.7.1.1 Syntax

```
tiup [flags] <command> [args...]   # Executes a command
#### or
tiup [flags] <component> [args...] # Runs a component
```

You can use the `--help` command to get the information of a specific command. The summary of each command shows its parameters and their usage. Mandatory parameters are shown in angle brackets, and optional parameters are shown in square brackets.

`<command>` represents the command name. For the list of supported commands, see the Command list below. `<component>` represents the component name. For the list of supported components, see the Component list below.

13.4.7.1.2 Options

–binary

- If you enable this option, the specified binary file path is printed.
    - Executing `tiup --binary <component>` will have the path of the latest stable installed `<component>` component printed. If `<component>` is not installed, an error is returned.
    - Executing `tiup --binary <component>:<version>` will have the path of the installed `<component>` component's `<version>` printed. If this `<version>` is not printed, an error is returned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be used in commands of the `tiup [flags] <component > [args...]` format.

–binpath

> **Note:**
>
> This option can only be used in commands of the `tiup [flags] <component > [args...]` format.

- Specifies the path of the component to be executed. When a component is executed, if you do not want to use the binary file in the TiUP mirror, you can add this option to specify using the binary file in a custom path.
- Data type: `STRING`

-T, –tag

- Specifies a tag for the component to be started. Some components need to use disk storage during the execution, and TiUP allocates a temporary storage directory for this execution. If you want TiUP to allocate a fixed directory, you can use `-T/--tag` to specify the name of the directory, so that the same batch of files can be read and written in multiple executions with the same tag.
- Data type: `STRING`

-v, –version

Prints the TiUP version.

–help

Prints the help information.

13.4.7.1.3 Command list

TiUP has multiple commands, and these commands have multiple sub-commands. For the specific commands and their detailed descriptions, click the corresponding links in the list below:

- install: Installs a component.
- list: Shows the component list.
- uninstall: Uninstalls a component.
- update: Updates the installed component.
- status: Shows the running status of a component.
- clean: Cleans the data directory of a component.
- mirror: Manages the mirror.
- telemetry: Enables or disables the telemetry.
- completion: Completes the TiUP command.
- env: Shows the TiUP-related environment variables.
- help: Shows the help information of a command or component.

13.4.7.1.4 Component list

- cluster: Manages the TiDB cluster in a production environment.
- dm: Manages the TiDB Data Migration (DM) cluster in a production environment.

13.4.7.2 TiUP Commands

13.4.7.2.1 tiup clean

The `tiup clean` command is used to clear the data generated during component operation.

Syntax

```
tiup clean [name] [flags]
```

The value of `[name]` is the `Name` field output by the `status` command. If `[name]` is omitted, you must add the `--all` option in the `tiup clean` command.

Option

–all

- Clears all operation records
- Data type: Boolean
- Default: false

Output

```
Clean instance of `%s`, directory: %s
```

<< Back to the previous page - TiUP Reference command list

13.4.7.2.2 tiup completion

To reduce user costs, TiUP provides the `tiup completion` command to generate a configuration file for automatic command-line completion. Currently, TiUP supports completing `bash` and `zsh` commands.

If you want to complete `bash` commands, you need to install `bash-completion` first. See the following instructions:

- On macOS: If your bash version is earlier than 4.1, run `brew install bash-completion`; otherwise, run `brew install bash-completion@2`.
- On Linux: Use a package manager to install `bash-completion`. For example, run `yum install bash-completion` or `apt install bash-completion`.

Syntax

```
tiup completion <shell>
```

`<shell>` is used to set the type of shell you use. Currently, `bash` and `zsh` are supported.

Usage

bash

Write the `tiup completion bash` command into a file and source the file in `.bash_profile`. See the following example:

```
tiup completion bash > ~/.tiup.completion.bash

printf "
##### tiup shell completion
source '$HOME/.tiup.completion.bash'
" >> $HOME/.bash_profile

source $HOME/.bash_profile
```

zsh

```
tiup completion zsh > "${fpath[1]}/_tiup"
```

<< Back to the previous page - TiUP Reference command list

13.4.7.2.3 tiup env

TiUP provides users with flexible and customized interfaces, some of which are implemented using environment variables. The `tiup env` command is used to query the user-defined environment variables that TiUP supports and their values.

Syntax

```
tiup env [name1...N]
```

`[name1...N]` is used to view the specified environment variables. If it is not specified, all supported environment variables are viewed by default.

Option

None

Output

- If `[name1...N]` is not specified, a list of "{key}"="{value}" is output.
- If `[name1...N]` is specified, the "{value}" list is output in order.

In the above output, if `value` is empty, it means that the value of the environment variable is not set. In this case, TiUP uses the default value.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.4 tiup help

The TiUP command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option.

Syntax

```
tiup help [command]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of TiUP is viewed.

Option

None

Output

The help information of `[command]` or TiUP.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.5 tiup install

The `tiup install` command is used for component installation. It downloads the component package of a specified version from the mirror repository and decompresses it in the local TiUP data directory for later use. In addition, when TiUP needs to run a component that does not exist in the mirror repository, it tries to download the component first and then runs it automatically. If the component does not exist in the repository, an error is reported.

Syntax

```
tiup install <component1>[:version] [component2...N] [flags]
```

`<component1>` and `<component2>` represent component names, and `[version]` represents an optional version number. If `version` is not added, the latest stable version of the specified component is installed. `[component2...N]` means that you can specify multiple components or multiple versions of the same component at the same time.

Option

None

Output

- Normally outputs the download information of the component.
- If the component does not exist, the `The component "%s" not found` error is reported.
- If the version does not exist, the `version %s not supported by component %s` error is reported.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.6 tiup list

The command `tiup list` is used to get the list of available components of a mirror.

Syntax

```
tiup list [component] [flags]
```

`[component]` is an optional parameter used to specify a certain component. If `[component]` is set, TiUP lists all versions of the specified component; if not, TiUP lists all components.

Options

–all

- Displays all components. By default, TiUP does not show hidden components.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–installed

- Only displays components and versions that have been installed.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–verbose

- Displays installed component versions in the components list.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `[component]` is not set:
  - If `--verbose` is specified: TiUP outputs a component information list consisting of `Name` (component name), `Installed` (installed versions), `Owner` (component owner), and `Description` (component description).

- If `--verbose` is not specified: TiUP outputs a component information list consisting of `Name` (component name), `Owner` (component owner), and `Description` (component description).

- If `[component]` is set:
  - If the specified component exists: TiUP outputs a version information list of the specified component, consisting of `Version` (version number), `Installed` (installation status), `Release` (release date), and `Platforms` (supported platforms).
  - If the specified component does not exist: TiUP reports the error `failed to fetch component: unknown component`.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.7 tiup mirror

tiup mirror

In TiUP, mirror is an important concept. TiUP currently supports two forms of mirroring:

- Local mirror: the TiUP client and the mirror are on the same machine, and the client accesses the mirror through the file system.
- Remote mirror: the TiUP client and the mirror are not on the same machine, and the client accesses the mirror through network.

The `tiup mirror` command is used to manage mirrors and provides ways to create mirrors, distribute components, and manage keys.

Syntax

```
tiup mirror <command> [flags]
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the command list below.

Option

None

Command list

- genkey: generates the private key file
- sign: signs a specific file using a private key file
- init: initiates an empty mirror
- set: sets the current mirror
- grant: grants a new component owner for the current mirror
- publish: publishes new components to the current mirror

- modify: modifies the attributes of the components in the current mirror
- rotate: updates the root certificate in the current mirror
- clone: clones a new mirror from an existing one
- merge: merges mirrors

<< Back to the previous page - TiUP Reference command list

tiup mirror clone

The command `tiup mirror clone` is used to clone an existing mirror or clone some of its components to create a new mirror. The new mirror has the same components as the old one, but uses a different signature key.

Syntax

```
tiup mirror clone <target-dir> [global version] [flags]
```

- `<target-dir>` is used to set the local path to the cloned mirror. If the path does not exist, TiUP automatically creates one.
- If `[global version]` is specified, TiUP tries to clone all components of the specified version. If some components do not have the specified version, then TiUP clones its latest version.

Options

-f, –full

- Whether to clone the whole mirror. If this option is set, other options becomes ignored and TiUP completely clones all components of all versions from the targeted mirror.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-a, –arch

- Only clones components that can run on the specified platform.
- Data type: `STRING`
- Default: “amd64,arm64”

-o, –os

- Only clones components that can run on the specified operating system.
- Data type: `STRING`
- Default: “linux,darwin”

–prefix

- Whether to only match the prefix of versions. By default, TiUP downloads a component version when it is strictly matched. If this option is set, TiUP also downloads component versions of which prefixes are matched.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–{component}

- Specifies the version list of the component to be cloned. Fill component names in `{component}`. You can run `tiup list --all` to view available component names.
- Data type: Strings
- Default: Null

<< Back to the previous page - TiUP Mirror command list

tiup mirror genkey

TiUP mirror, according its definition, has three roles of users:

- Mirror administrators: They have the permission to modify `root.json`, `index.json`, `snapshot.json`, and `timestamp.json`.
- Component owners: They have the permission to modify the corresponding component.
- Normal users: They can download and use the components.

Because TiUP requires the signature of the corresponding owner/administrator to modify a file, owners/administrators must have his or her own private key. The command `tiup mirror genkey` is used to generate a private key.

> **Warning:**
>
> **DO NOT** transmit private keys over the Internet.

Syntax

```
tiup mirror genkey [flags]
```

Options

-n, –name

- Specifies the name of the key, which also determines the name of the final generated file. The path of the generated private key file is `${TIUP_HOME}/keys/{name}.json`. `TIUP_HOME` refers to the home directory of TiUP, which is `$HOME/.tiup` by default. `name` refers to the private key name that `-n/--name` specifies.
- Data type: `STRING`
- Default: "private"

-p, –public

- Shows the corresponding public key of the private key specified in the option `-n/--name`.
- TiUP does not create a new private key when `-p/--public` is specified. If the private key specified in `-n/--name` does not exist, TiUP returns an error.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–save

- Saves the information of the public key as a file in the current directory. The file name is `{hash-prefix}-public.json`. `hash-prefix` is the first 16 bits of the key ID.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `-p/--public` is not specified:
  - If the private key specified in `-n/--name` exists: TiUP outputs `Key already exists, skipped`.
  - If the private key specified in `-n/--name` does not exist: TiUP outputs `private key have been write to ${TIUP_HOME}/keys/{name}.json`.
- If `-p/--public` is specified:
  - If the private key specified in `-n/--name` does not exist: TiUP reports the error `Error: open ${TIUP_HOME}/keys/{name}.json: no such file or directory`.
  - If the private key specified in `-n/--name` exists: TiUP outputs the content of the corresponding public key.

<< Back to the previous page - TiUP Mirror command list

tiup mirror grant

The `tiup mirror grant` command is used to introduce a component owner to the current mirror.

Component owners can use their keys to publish new components or to modify components they previously published. Before adding a new component owner, the component owner to be added needs to send his or her own public key to the mirror administrator.

> **Note:**
>
> This command is only supported when the current mirror is a local mirror.

Syntax

```
tiup mirror grant <id> [flags]
```

`<id>` stands for the component owner's ID, which must be unique in the whole mirror. It is recommended to use an ID that matches the regular expression `^[a-z\d](?:[a-z\d]|-(?=[a-z\d])){0,38}$`.

Options

-k, –key

- Specifies the key of the introduced component owner. This key can either be public or private. If it is a private key, TiUP converts it to the corresponding public key before storing it in the mirror.
- A key can be used by only one component owner.
- Data type: `STRING`
- Default: "${TIUP_HOME}/keys/private.json"

-n, –name

- Specifies the name of the component owner. The name is displayed on the `Owner` field of the component list. If `-n/--name` is not specified, `<id>` is used as the component owner's name.
- Data type: `STRING`
- Default: `<id>`

Outputs

- If the command is executed successfully, there is no output.

- If the component owner's ID is duplicated, TiUP reports the error `Error: owner %s exists`.
- If the key is used by another component owner, TiUP reports the error `Error: key %s exists`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror init

The command `tiup mirror init` is used to initialize an empty mirror. The initialized mirror does not contain any components or component owners. The command only generates the following files for the initialized mirror:

```
+ <mirror-dir>                                # Mirror's root directory
|-- root.json                                 # Mirror's root certificate
|-- 1.index.json                              # Component/user index
|-- snapshot.json                             # Mirror's latest snapshot
|-- timestamp.json                            # Mirror's latest timestamp
|--+ keys                                     # Mirror's private key (can be
   ↪ moved to other locations)
   |-- {hash1..hashN}-root.json               # Private key of the root
      ↪ certificate
   |-- {hash}-index.json                      # Private key of the indexes
   |-- {hash}-snapshot.json                   # Private key of the snapshots
   |-- {hash}-timestamp.json                  # Private key of the timestamps
```

For the specific usage and content format of the above files, refer to TiUP Mirror Reference Guide.

Syntax

```
tiup mirror init <path> [flags]
```

`<path>` is used to specify a local directory where TiUP generates and stores mirror files. The local directory can be a relative path. If the specified directory already exists, it must be empty; if it does not exist, TiUP creates it automatically.

Options

-k, –key-dir

- Specifies the directory where TiUP generates private key files. If the specified directory does not exist, TiUP automatically creates it.
- Data type: `STRING`
- If this option is not specified in the command, TiUP generates private key files in `{path}/keys` by default.

Outputs

- If the command is executed successfully, there is no output.
- If the specified `<path>` is not empty, TiUP reports the error `Error: the target path '%s' is not an empty directory`.
- If the specified `<path>` is not a directory, TiUP reports the error `Error: fdopendir: not a directory`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror merge

The `tiup mirror merge` command is used to merge one or more mirrors to the current mirror.

To execute this command, the following conditions must be met:

- The owner IDs of all components of the target mirror exist in the current mirror.
- The `${TIUP_HOME}/keys` directory of the user who executes this command contains all the private keys corresponding to the above owner IDs in the current mirror (you can use the command `tiup mirror set` to switch the current mirror to the mirror that is currently authorized to modify).

Syntax

```
tiup mirror merge <mirror-dir-1> [mirror-dir-N] [flags]
```

- `<mirror-dir-1>`: the first mirror to be merged into the current mirror
- `[mirror-dir-N]`: the Nth mirror to be merged into the current mirror

Option

None

Outputs

- If the command is executed successfully, there is no output.
- If the current mirror does not have a component owner of the target mirror, or if `${TIUP_HOME}/keys` does not have the owner's private key, TiUP reports the `Error: missing owner keys for owner %s on component %s` error.

<< Back to the previous page - TiUP Mirror command list

tiup mirror modify

The `tiup mirror modify` command is used to modify published components. Only valid component owners can modify the components that they have published on their own. For the method to publish a component, refer to the `publish` command.

Syntax

```
tiup mirror modify <component>[:version] [flags]
```

Each parameter is explained as follows:

- `<component>`: the component name
- `[version]`: the component version to modify. If it is not specified, the entire component is modified.

Options

-k, –key

- Specifies the component owner's private key used for signing the component information (`{component}.json`).
- Data type: `STRING`
- If this option is not specified in the command, `"${TIUP_HOME}/keys/private.json"` is used by default to sign the component information.

–yank

Marks a specified component or version as unavailable.

- After the component is marked as unavailable, you can neither see it in the result list of `tiup list` nor install the new version of the component.
- After a component version is marked as unavailable, you can neither see it in the result list of `tiup list <component>` nor install this version.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–hide

- Specifies whether to hide the component. If a component is hidden, you cannot see it in the result list of `tiup list`. To see the hidden component, you can use `tiup list --all`.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be applied to the component, not to the component version.

–standalone

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be applied to the component, not to the component version.

Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
    - If the mirror is a remote mirror, TiUP reports the error `Error: The server refused, make sure you have access to this component`.
    - If the mirror is a local mirror, TiUP reports the error `Error: the signature is not correct`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror publish

The command `tiup mirror publish` is used to publish a new component or a new version of an existing component. Only component owner that has the access to the target component can publish it. To add a new component owner, see the usage of the grant command.

Syntax

```
tiup mirror publish <comp-name> <version> <tarball> <entry> [flags]
```

The meaning of each parameter is as follows:

- `<comp-name>`: The name of the components, such as `tidb`. It is recommended to use a string that matches the regular expression `^[a-z\d](?:[a-z\d]|-(?=[a-z\d])){0,38}$`.
- `<version>`: The version of the component to be published. The version number needs to follow the requirements of Semantic Versioning.
- `<tarball>`: The local directory of the `.tar.gz` package. You need to put dependencies and the executable file of the component in this package. TiUP uploads this package to the mirror.
- `<entry>`: The location of the component's executable file in `<tarball>`.

Options

-k, –key

- Specifies the component owner's private key. The client uses the private key to sign `{component}.json` files.
- Data type: `STRING`
- Default: "${TIUP_HOME}/keys/private.json"

–arch

- Specifies the platform on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the platform from the following options:
  - `amd64`: Indicates that the files run on AMD64 machines.
  - `arm64`: Indicates that the files run on ARM64 machines.
  - `any`: Indicates that the files, such as scripts, run on both AMD64 and ARM64 machines.
- Data type: `STRING`
- Default: "${GOARCH}"

> **Note:**
>
> If `--arch` is set to `any`, then `--os` must be set to `any` as well.

–os

- Specifies the operating system on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the operating system from the following options:
    - `linux`: Indicates that the files run on the Linux operating system.
    - `darwin`: Indicates that the files run on the Darwin operating system.
    - `any`: Indicates that the files, such as scripts, run on both the Linux and Darwin operating systems.
- Data type: `STRING`
- Default: "${GOOS}"

> **Note:**
>
> If `--os` is set to `any`, then `--arch` must be set to `any` as well.

–desc

- Specifies the description of the component.
- Data type: `String`
- Default: NULL

–hide

- Specifies whether the component is hidden. If it is a hidden component, it can be seen in the result list of `tiup list -all`, but not in that of `tiup list`.
- Data type: `STRING`
- Default: NULL

–standalone

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
    - If the mirror is a remote mirror, TiUP reports the error `Error: The server refused, make sure you have access to this component`.
    - If the mirror is a local mirror, TiUP reports the error `Error: the signature is not correct`.

<< Back to the previous page - TiUP Mirror command list

tiup mirror rotate

`root.json` is an important file in a TiUP mirror. It stores the public keys needed for the entire system and is the basis of the chain of trust in TiUP. It mainly contains the following parts:

- Signatures of mirror administrators. For the official mirror, there are five signatures. For an initialized mirror, there are three signatures by default.
- The public keys used to verify the following files:
    - root.json
    - index.json
    - snapshot.json
    - timestamp.json
- Expiration date of `root.json`. For the official mirror, the expiration date is one year later than the creation date of `root.json`.

For detailed description of TiUP mirror, see TiUP Mirror Reference.

You need to update `root.json` in the following cases:

- Replace the key of the mirror.
- Update the expiration date of certificate files.

After the content of `root.json` is updated, the file must be re-signed by all administrators; otherwise, the client rejects the file. The update process is as follows:

1. The user (client) updates the content of `root.json`.
2. All administrators sign the new `root.json` file.
3. tiup-server updates `snapshot.json` to record the version of the new `root.json` file.
4. tiup-server signs the new `snapshot.json` file.
5. tiup-server updates `timestamp.json` to record the hash value of the new `snapshot.json` file.
6. tiup-server signs the new `timestamp.json` file.

TiUP uses the command `tiup mirror rotate` to automate the above process.

Note:

- For TiUP versions earlier than v1.5.0, running this command does not returns a correct new `root.json` file. See #983.
- Before using this command, make sure that all TiUP clients are upgraded to v1.5.0 or a later version.

Syntax

```
tiup mirror rotate [flags]
```

After executing this command, TiUP starts an editor for the user to modify the file content to the target value, such as changing the value of the `expires` field to a later date. Then, TiUP changes the `version` field from `N` to `N+1` and saves the file. After the file is saved, TiUP starts a temporary HTTP server and waits for all mirror administrators to sign the file.

For how mirror administrators sign files, refer to the `sign` command.

Options

–addr

- Specifies the listening address of the temporary server. You need to make sure that the address is accessible to other mirror administrators so that they can use the `sign` command to sign the file.
- Data type: `STRING`
- If this option is not specified in the command, TiUP listens on `0.0.0.0:8080` by default.

Outputs

The current signature status of each mirror administrator.

<< Back to the previous page - TiUP Mirror command list

tiup mirror set

The `tiup mirror set` command is used to switch the current mirror and supports two forms of mirrors: local file system and remote network address.

The address of the official mirror is `https://tiup-mirrors.pingcap.com`.

Syntax

```
tiup mirror set <mirror-addr> [flags]
```

`<mirror-addr>` is the mirror address, which has two forms:

- Network address: starts with `http` or `https`. For example, `http://172.16.5.5:8080`, `https://tiup-mirrors.pingcap.com`.
- Local file path: the absolute path of the mirror directory. For example, `/path/to/local-tiup-mirror`.

Option

-r, –root

This option specifies the root certificate.

As the most critical part of mirror security, the root certificate of each mirror is different from one another. When you use the network mirror, it might suffer from man-in-the-middle attacks. To avoid such attacks, it is recommended to manually download the root certificate of the root network mirror to the local:

```
wget <mirror-addr>/root.json -O /path/to/local/root.json
```

Perform a manual check to ensure that the root certificate is correct, and then switch the mirror by manually specifying the root certificate:

```
tiup mirror set <mirror-addr> -r /path/to/local/root.json
```

In the steps above, if the mirror is attacked before the `wget` command, you can find that the root certificate is incorrect. If the mirror is attacked after the `wget` command, TiUP will find that the mirror does not match the root certificate.

- Data type: `String`
- Default: `{mirror-dir}/root.json`

Output

None

<< Back to the previous page - TiUP Mirror command list

tiup mirror sign

The `tiup mirror sign` command is used to sign the metadata files (*.json) defined in TiUP mirror. These metadata files might be stored on the local file system or remotely stored using the HTTP protocol to provide a signature entry.

Syntax

```
tiup mirror sign <manifest-file> [flags]
```

`<manifest-file>` is the address of the file to be signed, which has two forms:

- Network address, which starts with HTTP or HTTPS, such as `http://172.16.5.5:8080/rotate/root.json`
- Local file path, which is a relative path or an absolute path

If it is a network address, this address must provide the following features:

- Supports the access via `http get` that returns the complete content of the signed file (including the `signatures` field).
- Supports the access via `http post`. The client adds the signature to the `signatures` field of the content that is returned by `http get` and posts to this network address.

Options

-k, –key

- Specifies the location of the private key used for signing the `{component}.json` file.
- Data type: `STRING`
- - If this option is not specified in the command, `"${TIUP_HOME}/keys/private.json"` is used by default.

–timeout

- Specifies the access timeout time for signing through the network. The unit is in seconds.
- Data type: `INT`
- Default: 10

> **Note:**
>
> This option is valid only when `<manifest-file>` is a network address.

Output

- If the command is executed successfully, there is no output.
- If the file has been signed by the specified key, TiUP reports the error `Error: this manifest file has already been signed by specified key`.
- If the file is not a valid manifest, TiUP reports the error `Error: unmarshal manifest : %s`.

<< Back to the previous page - TiUP Mirror command list

13.4.7.2.8 tiup status

The `tiup status` command is used to view the operation information of the components after you run the components using the `tiup [flags] <component> [args...]` command.

> **Note:**
>
> You can only check the information of the following components:
>
> - Components that are still in operation
> - Components that run through the tag specified by `tiup -T/--tag`

Syntax

```
tiup status [flags]
```

Option

None

Output

A table consisting of the following fields:

- `Name`: The tag name specified by `-T/--tag`. If not specified, it is a random string.
- `Component`: The operating components.
- `PID`: The corresponding process ID of the operating components.
- `Status`: The status of the operating components.
- `Created Time`: The starting time of the components.
- `Directory`: The data directory of the components.
- `Binary`: The binary file path of the components.
- `Args`: The starting arguments of the operating components.

Component status

A component can run in one of the following statuses:

- Up: The component is running normally.
- Down or Unreachable: The component is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the component has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- Pending Offline: The data on the component is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- Unknown: The running status of the component is unknown.

> **Note:**
>
> `Pending Offline` in TiUP, `Offline` returned by PD API, and `Leaving` in TiDB Dashboard indicate the same status.

Component status derives from the PD scheduling information. For more details, see Information collection.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.9 tiup telemetry

Starting from v1.11.3, the telemetry is disabled by default in newly deployed TiUP, and usage information is not collected and shared with PingCAP. In versions earlier than v1.11.3, the telemetry is enabled by default in TiUP, and usage information is collected and shared with PingCAP to improve the product.

When TiUP telemetry is enabled, usage information is shared with PingCAP when TiUP commands are executed, including (but not limited to):

- Randomly generated telemetry identifiers.
- The execution status of the TiUP command, such as whether the command execution is successful and the duration of command execution.
- Situations using TiUP for deployment, such as target machine hardware information, component version number, and modified deployment configuration name.

The information below is not shared:

- The accurate name of the cluster
- The cluster topology
- The cluster configuration file

TiUP uses the `tiup telemetry` command to control telemetry.

Syntax

```
tiup telemetry <command>
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the commands section below.

Commands

status

The `tiup telemetry status` command is used to view the current telemetry settings and output the following information:

- `status`: specifies enabling or disabling the telemetry `(enable|disable)`.
- `uuid`: specifies the randomly generated telemetry identifiers.

reset

The `tiup telemetry reset` command is used to reset the current telemetry identifier and replaces it with a new random identifier.

enable

The `tiup telemetry enable` command is used to enable the telemetry.

disable

The `tiup telemetry disable` command is used to disable the telemetry.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.10 tiup uninstall

The `tiup uninstall` command is used to uninstall the installed components.

Syntax

```
tiup uninstall <component1>:<version> [component2...N] [flags]
```

- `<component1>`: the name of the component to uninstall.
- `<version>`: the version to uninstall. If this field is omitted, all installed versions of the component are uninstalled. For security reasons, the `--all` option must be added when `<version>` is omitted, indicating that all versions of a component need to be uninstalled.
- `[component2...N]`: multiple components or versions to uninstall.

Options

–all

- Uninstalls all installed versions of the specified component(s). You must use this option when `<version>` is omitted.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–self

- Uninstalls TiUP itself. When this option is used, all data downloaded from the mirror is deleted, but the data generated by TiUP and its components is retained. The data is stored in the directory specified by the `TIUP_HOME` environment variable. If `TIUP_HOME` is not set, the default value is `~/.tiup/`.

- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the command exits without any error, `Uninstalled component "%s" successfully ↪ !` is output.
- If neither `<version>` nor `--all` is specified, the `Use "tiup uninstall tidbx --all ↪ " if you want to remove all versions.` error is reported.

<< Back to the previous page - TiUP Reference command list

13.4.7.2.11 tiup update

The `tiup update` command is used to update the installed components or TiUP itself.

Syntax

```
tiup update [component1][:version] [component2..N] [flags]
```

- `[component1]`: the name of the component to update.
- `[version]`: the version to update. If this field is omitted, it means updating to the latest stable version of the component.
- `[component2...N]`: specifies updating multiple components or versions. If no component is specified, which means `[component1][:version] [component2..N]` is empty, you need to use the `--all` or the `--self` option together.

The update operation does not delete the old version. You can still specify using the old version during execution.

Options

–all

- If no component is specified, this option must be specified.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–force

- If the specified version of the component is already installed, the update operation is skipped by default. Specifying this option will have the installed version forcibly updated.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–nightly

- Updates the specified components to the nightly version. The `tiup update` command with this option is equivalent to the `tiup update <component>:nightly` command.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–self

- Updates TiUP itself.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the update is successful, `Updated successfully!` is output.
- If target version does not exist, the `Error: version %s not supported by component %s` error is reported.

<< Back to the previous page - TiUP Reference command list

13.4.7.3 TiUP Cluster Commands

13.4.7.3.1 TiUP Cluster

TiUP Cluster is a cluster management component of TiUP written in Golang. You can use the TiUP Cluster component to perform daily operations and maintenance, including deploying, starting, shutting down, destroying, elastic scaling, upgrading TiDB clusters, and managing TiDB cluster parameters.

Syntax

```
tiup cluster [command] [flags]
```

`[command]` is the name of the command. For the supported commands, refer to the command list below.

Options

–ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: `STRING`
- Supported values:
  - `builtin`: uses the easyssh client built in tiup-cluster as the SSH client.
  - `system`: uses the default SSH client of the current operating system.
  - `none`: The SSH client is not used. The deployment is only for the current machine.
- If this option is not specified in the command, `builtin` is used as the default value.

–ssh-timeout

- Specifies the SSH connection timeout in seconds.
- Data type: `UINT`
- If this option is not specified in the command, the default timeout is `5` seconds.

–wait-timeout

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying systemctl to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each step is `120` seconds.

-y, –yes

- Skips the secondary confirmation of all risky operations. Using this option is not recommended, unless you are using a script to call TiUP.

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-v, –version

- Prints the current version of TiUP Cluster.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- import: imports a cluster deployed by Ansible
- template: outputs the topology template
- check: checks a cluster before and after the deployment
- deploy: deploys a cluster based on a specified topology
- list: queries the list of deployed clusters
- display: displays the status of a specified cluster
- start: starts a specified cluster
- stop: stops a specified cluster
- restart: restarts a specified cluster
- scale-in: scales in a specified cluster
- scale-out: scales out a specified cluster
- upgrade: upgrades a specified cluster
- prune: cleans up the instances in the Tombstone status for a specified cluster
- edit-config: modifies the configuration of a specified cluster
- reload: reloads the configuration of a specified cluster
- patch: replaces a service in a deployed cluster
- rename: renames a cluster
- clean: deletes data from the specified cluster
- destroy: destroys a specified cluster
- audit: queries the operation audit log of a specified cluster
- replay: retries the specified command
- enable: enables the auto-enabling of the cluster service after a machine is restarted
- disable: disables the auto-enabling of the cluster service after a machine is restarted
- meta backup: backs up the TiUP meta file required for the operation and maintenance of a specified cluster

- meta restore: restores the TiUP meta file of a specified cluster
- help: prints the help information

<< Back to the previous page - TiUP Reference component list

13.4.7.3.2 tiup cluster audit

The `tiup cluster audit` command is used to view commands executed on all clusters in the history and the execution log of each command.

Syntax

```
tiup cluster audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, it means checking the execution log of the specified `audit-id`.

Option

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `[audit-id]` is specified, the corresponding execution log is output.
- If `[audit-id]` is not specified, a table with the following fields is output:
  - ID: the `audit-id` corresponding to the record
  - Time: the execution time of the command corresponding to the record
  - Command: the command corresponding to the record

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.3 tiup cluster audit cleanup

The `tiup cluster audit cleanup` command is used to clean up the logs generated in executing the `tiup cluster`command.

Syntax

```
tiup cluster audit cleanup [flags]
```

Options

–retain-days

- Specifies the days for which logs are retained.
- Data type: `INT`
- Default value: `60`, in the unit of day.
- By default, logs generated within the last 60 days are retained, which means logs generated before 60 days are removed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

```
clean audit log successfully
```

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.4 tiup cluster check

For a formal production environment, before the environment goes live, you need to perform a series of checks to ensure the clusters are in their best performance. To simplify the manual check steps, TiUP Cluster provides the `check` command to check whether the hardware and software environments of the target machines of a specified cluster meet the requirements to work normally.

List of check items

Operating system version

Check the operating system distribution and version of the deployed machines. For a list of supported versions, see OS and platform requirements.

CPU EPOLLEXCLUSIVE

Check whether the CPU of the target machine supports EPOLLEXCLUSIVE.

numactl

Check whether `numactl` is installed on the target machine. If tied cores are configured on the target machine, you must install `numactl`.

System time

Check whether the system time of the target machine is synchronized. Compare the system time of the target machine with that of the central control machine, and report an error if the deviation exceeds a certain threshold (500 ms).

System time zone

Check whether the system time zone of the target machines is synchronized. Compare the time zone configuration of these machines and report an error if the time zone is inconsistent.

Time synchronization service

Check whether the time synchronization service is configured on the target machine. Namely, check whether ntpd is running.

Swap partitioning

Check whether swap partitioning is enabled on the target machine. It is recommended to disable swap partitioning.

Kernel parameters

Check the values of the following kernel parameters:

- `net.ipv4.tcp_tw_recycle`: 0
- `net.ipv4.tcp_syncookies`: 0
- `net.core.somaxconn`: 32768
- `vm.swappiness`: 0
- `vm.overcommit_memory`: 0 or 1
- `fs.file-max`: 1000000

Transparent Huge Pages (THP)

Check whether THP is enabled on the target machine. It is recommended to disable THP.

System limits

Check the limit values in the `/etc/security/limits.conf` file:

```
<deploy-user> soft nofile 1000000
<deploy-user> hard nofile 1000000
<deploy-user> soft stack 10240
```

`<deploy-user>` is the user who deploys and runs the TiDB cluster, and the last column is the minimum value required for the system.

SELinux

Check whether SELinux is enabled. It is required to disable SELinux.

Firewall

Check whether the FirewallD service is enabled. It is recommended to either disable the FirewallD service or add permission rules for each service in the TiDB cluster.

irqbalance

Check whether the irqbalance service is enabled. It is recommended to enable the irqbalance service.

Disk mount options

Check the mount options for ext4 partitions. Make sure the mount options include the nodelalloc option and the noatime option.

Port usage

Check if the ports defined in the topology (including the auto-completion default ports) are already used by the processes on the target machine.

> **Note:**
>
> The port usage check assumes that a cluster is not started yet. If a cluster is already deployed and started, the port usage check on the cluster fails because the ports must be in use in this case.

CPU core number

Check the CPU information of the target machine. For a production cluster, it is recommended that the number of the CPU logical core is greater than or equal to 16.

> **Note:**
>
> CPU core number is not checked by default. To enable the check, you need to add the `-enable-cpu` option to the command.

Memory size

Check the memory size of the target machine. For a production cluster, it is recommended that the total memory capacity is greater than or equal to 32GB.

> **Note:**
>
> Memory size is not checked by default. To enable the check, you need to add the `-enable-mem` option to the command.

Fio disk performance test

Use flexible I/O tester (fio) to test the performance of the disk where `data_dir` is located, including the following three test items:

- fio_randread_write_latency
- fio_randread_write
- fio_randread

> **Note:**
>
> The fio disk performance test is not performed by default. To perform the test, you need to add the `-enable-disk` option to the command.

Syntax

```
tiup cluster check <topology.yml | cluster-name> [flags]
```

- If a cluster is not deployed yet, you need to pass the topology.yml file that is used to deploy the cluster. According to the content in this file, tiup-cluster connects to the corresponding machine to perform the check.
- If a cluster is already deployed, you can use the `<cluster-name>` as the check object.
- If you want to check the scale-out YAML file for an existing cluster, you can use both `<scale-out.yml>` and `<cluster-name>` as the check objects.

> **Note:**
>
> If `<cluster-name>` is used for the check, you need to add the `--cluster` option in the command.

Options

–apply

- Attempts to automatically repair the failed check items. Currently, tiup-cluster only attempts to repair the following check items:
  - SELinux
  - firewall
  - irqbalance
  - kernel parameters
  - System limits
  - THP (Transparent Huge Pages)
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Note:

`tiup cluster check` also supports repairing the `scale-out.yml` file for an existing cluster with the following command format:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --
    ↪ apply --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

–cluster

- Indicates that the check is for a cluster that has been deployed.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.
- Command format:

```
tiup cluster check <topology.yml | cluster-name> --cluster [flags]
```

Note:

- If the `tiup cluster check <cluster-name>` command is used, you must add the `--cluster` option: `tiup cluster check <cluster-name > --cluster`.

- `tiup cluster check` also supports checking the `scale-out.yml` file for an existing cluster with the following command format:

```
shell  tiup cluster check <cluster-name> scale-out.yml --
↪ cluster --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

-N, –node

- Specifies the nodes to be checked. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are checked by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

-R, –role

- Specifies the roles to be checked. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are checked by default.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

–enable-cpu

- Enables the check of CPU core number.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–enable-disk

- Enables the fio disk performance test.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–enable-mem

- Enables the memory size check.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–u, –user

- Specifies the user name to connect to the target machine. The specified user needs to have the password-free sudo root privileges on the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the user who executes the command is used as the default value.

Note:

This option is valid only if the `-cluster` option is false. Otherwise, the value of this option is fixed to the username specified in the topology file for the cluster deployment.

-i, –identity_file

- Specifies the key file to connect to the target machine.
- Data type: `STRING`
- The option is enabled by default with `~/.ssh/id_rsa` (the default value) passed in.

Note:

This option is valid only if the `--cluster` option is false. Otherwise, the value of this option is fixed to `${TIUP_HOME}/storage/cluster/clusters/<cluster-name>/ssh/id_rsa`.

-p, –password

- Logs in with a password when connecting to the target machine.
  - If the `--cluster` option is added for a cluster, the password is the password of the user specified in the topology file when the cluster was deployed.
  - If the `--cluster` option is not added for a cluster, the password is the password of the user specified in the `-u/--user` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

A table containing the following fields:

- `Node`: the target node
- `Check`: the check item
- `Result`: the check result (Pass, Warn, or Fail)
- `Message`: the result description

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.5 tiup cluster clean

In the test environment, sometimes you might need to reset the cluster back to the state as it has been just deployed, which means deleting all data. You can do that easily using the `tiup cluster clean` command. After running it, the cluster is stopped and then cluster data is deleted. After restarting the cluster manually, you will get a clean cluster.

> **Warning:**
>
> This command will first stop the cluster even if you choose only to clean up logs. Therefore, do not use it in a production environment.

Syntax

```
tiup cluster clean <cluster-name> [flags]
```

`<cluster-name>` is the cluster to clean.

Options

–all

- Cleans data and the log at the same time. It is equivalent to specifying `--data` and `--log` at the same time.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.
- If it is not specified, you must specify at lease one of the following options:
  - –data: Cleans data
  - –log: Cleans the log

–data

- Cleans data. If neither of it nor `--all` is specified, data will not be cleaned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–log

- Cleans the log. If neither of it nor `--all` is specified, the log will not be cleaned.

- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–ignore-node

- Specifies the node that does not need cleaning. To specify multiple nodes, you can use this option multiple times. For example, `--ignore-node <node-A> --ignore-node <node-B>`.
- Data type: `StringArray`
- Default: empty

–ignore-role

- Specifies the role that does not need cleaning. To specify multiple roles, you can use this option multiple times. For example, `--ignore-role <role-A> --ignore-role <role-B>`.
- Data type: `StringArray`
- Default: empty

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.6 tiup cluster deploy

The `tiup cluster deploy` command is used to deploy a new cluster.

Syntax

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

- `<cluster-name>`: the name of the new cluster, which cannot be the same as the existing cluster names.

- `<version>`: the version number of the TiDB cluster to deploy, such as `v8.4.0`.
- `<topology.yaml>`: the prepared topology file.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option with `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–ignore-config-check

- This option is used to skip the configuration check. After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration.
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.
- Default: false

–no-labels

- This option is used to skip the label check.

- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD cannot learn the cluster topology, so PD might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See Schedule Replicas by Topology Labels for label configuration.
- For the test environment, this risk might matter and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–skip-create-user

- During the cluster deployment, tiup-cluster checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The deployment log.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.7 tiup cluster destroy

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup cluster destroy` command performs the following operations:

- Stops the cluster.

- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by tiup-cluster, also delete the parent directory.

Syntax

```
tiup cluster destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to destroy.

Options

–force

- In some cases, some nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to ignore these errors.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–retain-node-data

- Specifies the nodes that need to retain data. If you need to specify more than one node, use this option multiple times: `--retain-node-data <node-A> --retain-node-data ↪ <node-B>`.
- Data type: `StringArray`
- Default: empty

–retain-role-data

- Specifies the role that needs to retain data. If you need to specify more than one role, use this option multiple times: `--retain-role-data <role-A> --retain-role ↪ -data <role-B>`.
- Data type: `StringArray`
- Default: empty

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.8 tiup cluster disable

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup cluster disable` command. This command executes `systemctl disable <service >` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup cluster disable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be disabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.9 tiup cluster display

If you want to see the operation status of each component in the cluster, it is obviously inefficient to log in to each machine one by one. Therefore, tiup-cluster provides the `tiup cluster display` command to efficiently complete this task.

Syntax

```
tiup cluster display <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

–dashboard

- By default, all node information of the entire cluster is displayed. With the `--dashboard` option, only dashboard information is displayed.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-N, –node

- Specifies the node to display. If this option is not specified, all nodes are displayed. The value of this option is a comma-separated list of node IDs. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are checked by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

-R, –role

- Specifies the role to display. If it is not specified, all roles are displayed. The value of this option is a comma-separated list of node roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are displayed by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are displayed.

–process

- Displays the CPU and memory usage information of the node when this option is enabled. This option is disabled by default.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–uptime

- Displays the `uptime` information of the node when this option is enabled. This option is disabled by default.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

–status-timeout

- Specifies the timeout period for obtaining the node status information.
- Data type: `INT`
- Default value: `10`, in the unit of second.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- The cluster name
- The cluster version
- SSH Client Type
- Dashboard address
- The table with the following fields:
    - ID: the node ID, composed of `IP:PORT`
    - Role: the service role deployed on this node (such as TiDB, TiKV)
    - Host: the IP of the machine corresponding to the node
    - Ports: the port number occupied by the service
    - OS/Arch: the operating system and the machine architecture of this node
    - Status: the current status of the node service
    - Data Dir: the data directory of the service. `-` means no data directory.
    - Deploy Dir: the deployment directory of the service

Node service status

A node service can run in one of the following statuses:

- Up: The node service is running normally.
- Down or Unreachable: The node service is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the node service has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- Pending Offline: The data on the node service is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- Unknown: The running status of the node service is unknown.

> **Note:**
>
> `Pending Offline` in TiUP, `Offline` returned by PD API, and `Leaving` in TiDB Dashboard indicate the same status.

Node service status derives from the PD scheduling information. For more details, see Information collection.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.10 tiup cluster edit-config

If you need to modify the cluster configuration after the cluster is deployed, you can use the `tiup cluster edit-config` command that starts an editor for you to modify the topology file of a cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

> **Note:**
>
> - When you modify the configuration, you cannot add or delete machines. For how to add machines, see Scale out a cluster. For how to delete machines, see Scale in a cluster.
> - After you execute the `tiup cluster edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup cluster reload` command to reload the configuration.

Syntax

```
tiup cluster edit-config <cluster-name> [flags]
```

`<cluster-name>` is the cluster to operate on.

Option

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

- If the command is successfully executed, there is no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error will be reported, reminding you to edit the file again. For the fields that cannot be modified, see the topology file.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.11 tiup cluster enable

The `tiup cluster enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

> **Note:**
>
> When all clusters are shut down and restarted, the order of service startup is determined by the node's operating system startup order. When the restart order is incorrect, in some cases, the restarted cluster still cannot provide services. For example, if TiKV is started first but PD is not started, systemd gives up if TiKV is restarted multiple times while PD is not found).

Syntax

```
tiup cluster enable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be enabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

Note:

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

Note:

If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.12 tiup cluster help

tiup-cluster provides a wealth of help information for users in the command line interface. You can obtain it via the `help` command or the `--help` option. `tiup cluster help <command>` is basically equivalent to `tiup cluster <command> --help`.

Syntax

```
tiup cluster help [command] [flags]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of tiup-cluster is viewed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The help information of the `[command]` or tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.13 tiup cluster import

Before TiDB v4.0, TiDB clusters were mainly deployed using TiDB Ansible. For TiDB v4.0 and later releases, TiUP Cluster provides the `import` command to transfer the clusters to the tiup-cluster component for management.

Note:

- After importing the TiDB Ansible configuration to TiUP for management, **DO NOT** use TiDB Ansible for cluster operations anymore. Otherwise, conflicts might be caused due to inconsistent meta information.
- If the clusters deployed using TiDB Ansible are in any of the following situations, do not use the `import` command.
  - Clusters with TLS encryption enabled
  - Pure KV clusters (clusters without TiDB instances)
  - Clusters with Kafka enabled
  - Clusters with Spark enabled
  - Clusters with TiDB Lightning/TiKV Importer enabled
  - Clusters still using the old `push` mode to collect monitoring metrics (if you keep the default mode `pull` unchanged, using the `import` command is supported)
  - Clusters in which the non-default ports (the ports configured in the `group_vars` directory are compatible) are separately configured in the `inventory.ini` configuration file using `node_exporter_port` / `blackbox_exporter_port`

- If some nodes in the cluster deployed using TiDB Ansible are deployed without monitoring components, you should first use TiDB Ansible to add the corresponding node information in the `monitored_servers` section of the `inventory.ini` file, and then use the `deploy.yaml` playbook to fully deploy monitoring components. Otherwise, when you perform maintenance operations after the cluster is imported into TiUP, errors might occur due to the lack of monitoring components.

Syntax

```
tiup cluster import [flags]
```

Options

-d, –dir

- Specifies the directory where TiDB Ansible is located.
- Data type: `STRING`
- The option is enabled by default with the current directory (the default value) passed in.

–ansible-config

- Specifies the path of the Ansible configuration file.
- Data type: `STRING`
- The option is enabled by default with `. /ansible.cfg` (the default value) passed in.

–inventory

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- The option is enabled by default with `inventory.ini` (the default value) passed in.

–no-backup

- Controls whether to disable the backup of files in the directory where TiDB Ansible is located.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. After a successful import, everything in the directory specified by the `-dir` option is backed up to the `${TIUP ↪ _HOME}/.tiup/storage/cluster/clusters/{cluster-name}/ansible-backup` directory. If there are multiple inventory files (when multiple clusters are deployed) in this directory, it is recommended to enable this option. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–rename

- Renames the imported cluster.
- Data type: `STRING`
- Default: NULL. If this option is not specified in the command, the cluster_name specified in inventory is used as the cluster name.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the import process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.14 tiup cluster list

tiup-cluster supports deploying multiple clusters using the same control machine. The `tiup cluster list` command outputs all clusters deployed by the currently logged-in user using this control machine.

> **Note:**
>
> The deployed cluster data is stored in the `~/.tiup/storage/cluster/` ↪ `clusters/` directory by default, so on the same control machine, the currently logged-in user cannot view the clusters deployed by other users.

Syntax

```
tiup cluster list [flags]
```

Options

-h, –help

- Prints help information.
- Data type: `BOOLEAN`

- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

Outputs the table with the following fields:

- Name: the cluster name
- User: the deployment user
- Version: the cluster version
- Path: the path of the cluster deployment data on the control machine
- PrivateKey: the path of the private key that is used to connect the cluster

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.15 tiup cluster meta backup

The TiUP meta file is used for cluster operation and maintenance (OM). If this file is lost, you cannot use TiUP to manage the cluster. To avoid this situation, you can use the `tiup cluster meta backup` command to back up the TiUP meta file regularly.

Syntax

```
tiup cluster meta backup <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup dm list` command.

Options

–file (string, defaults to the current directory)

Specifies the target directory to store the TiUP meta backup file.

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.16 tiup cluster meta restore

To restore the TiUP meta file, you can use the `tiup cluster meta restore` command to restore from the backup file.

Syntax

```
tiup cluster meta restore <cluster-name> <backup-file> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on.
- `<backup-file>` is the path to the TiUP meta backup file.

> **Note:**
>
> The restore operation overwrites the current meta file. It is recommended to restore the meta file only when it is lost.

Options

-h, –help

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.17 tiup cluster patch

If you need to dynamically replace the binaries of a service while the cluster is running (namely, keep the cluster available during the replacement process), you can use the `tiup cluster patch` command. After the command is executed, TiUP does the following things:

- Uploads the binary package for replacement to the target machine.
- If the target service is a storage service such as TiKV or TiFlash, TiUP first takes the related nodes offline via the API.
- Stops the target service.

- Unpacks the binary package and replace the service.
- Starts the target service.

Syntax

```
tiup cluster patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated.
- `<package-path>`: The path to the binary package used for replacement.

Preparation

Before running the `tiup cluster patch` command, you need to pack the binary package required. Take the following steps:

1. Determine the following variables:

    - `${component}`: the name of the component to be replaced (such as `tidb`, `tikv`, or `pd`).
    - `${version}`: the version of the component (such as `v8.4.0` or `v7.5.4`).
    - `${os}`: the operating system (`linux`).
    - `${arch}`: the platform on which the component runs (`amd64`, `arm64`).

2. Download the current component package using the command:

    ```
    wget https://tiup-mirrors.pingcap.com/${component}-${version}-${os}-${
        ↪ arch}.tar.gz -O /tmp/${component}-${version}-${os}-${arch}.tar.gz
    ```

3. Create a temporary directory to pack files and change to it:

    ```
    mkdir -p /tmp/package && cd /tmp/package
    ```

4. Extract the original binary package:

    ```
    tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz
    ```

5. Check out the file structure in the temporary directory:

    ```
    find .
    ```

6. Copy the binary files or configuration files to their corresponding locations in the temporary directory.

7. Pack all files in the temporary directory:

    ```
    tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *
    ```

After you have completed the preceding steps, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the `<package-path>` in the `tiup cluster patch` command.

Options

–overwrite

- After you patch a certain component (such as TiDB or TiKV), when the tiup cluster scales out the component, TiUP uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specified the option `--overwrite` in the command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–transfer-timeout

- When restarting the PD or TiKV service, TiKV/PD first transfers the leader of the node to be restarted to another node. Because the transfer process takes some time, you can use the option `--transfer-timeout` to set the maximum waiting time (in seconds). After the timeout, TiUP directly restarts the service.
- Data type: `UINT`
- If this option is not specified, TiUP directly restarts the service after waiting for `600` seconds.

> **Note:**
>
> If TiUP directly restarts the service after the timeout, the service performance might jitter.

-N, –node

- Specifies nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node ID from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any nodes to replace by default.

> **Note:**
>
> If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the role deployed on a node from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any roles to replace by default.

> **Note:**
>
> If the option `-N, --node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

–offline

- Declares that the current cluster is not running. When the option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.18 tiup cluster prune

When scaling in the cluster, for some components, TiUP does not immediately stop their services or delete their data. You need to wait for the data scheduling to complete and then manually execute the `tiup cluster prune` command to clean up.

Syntax

```
tiup cluster prune <cluster-name> [flags]
```

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of the cleanup process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.19 tiup cluster reload

After modifying the cluster configuration, the cluster needs to be reloaded using the `tiup cluster reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running, and follows the upgrade process to restart the services in order according to the upgrade process. The cluster is still available during the restart process.

Syntax

```
tiup cluster reload <cluster-name> [flags]
```

`<cluster-name>`: the cluster name to operate on.

Options

–force

- Ignores errors in the reloading process and forces reload.
- Data type: `BOOLEAN`
- Default: false

–transfer-timeout

- When restarting PD or TiKV, the leader of the restarted node is migrated to other nodes first, and the migration process takes some time. You can set the maximum wait time (in seconds) by setting `-transfer-timeout`. After the timeout, the service can be restarted directly without waiting.
- Data type: `UINT`
- Default: 600

Note:

In the case of skipping the waiting and restarting directly, the service performance might jitter.

–ignore-config-check

- After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration. If you want to skip this check, you can use this option.
- Data type: `BOOLEAN`
- Default: false

-N, –node

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

Note:

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

-R, –role

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. The role is the second column of the cluster status table.

- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

> **Note:**
>
> 1. If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
> 2. If the `--skip-restart` option is specified, the `-R, --role` option is invalid.

–skip-restart

The `tiup cluster reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

–pre-restart-script

> **Warning:**
>
> This option is experimental and is not recommended for production deployments.

- Runs a script before the reload.
- Data type: `STRINGS`
- This option specifies the path of a script to be run on the node that is to be reloaded. It does not take effect when `--skip-restart` is set to `true`.

–post-restart-script

> **Warning:**
>
> This option is experimental and is not recommended for production deployments.

- Runs a script after the reload.
- Data type: `STRINGS`
- This option specifies the path of a script to be run after the reload of a node. It does not take effect when `--skip-restart` is set to `true`.

Output

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.20 tiup cluster rename

The cluster name is specified when the cluster is deployed. If you want to change the cluster name after the cluster is deployed, you can use the command `tiup cluster rename`.

> **Note:**
>
> If the `dashboard_dir` field of `grafana_servers` is configured for the TiUP cluster, after you execute the command `tiup cluster rename` to rename the cluster, the following additional steps are required:
>
> - For the `*.json` files in the local dashboards directory, update the `datasource` field of each file to the new cluster name, because the value of `datasource` must be the name of the cluster.
> - Execute the command `tiup cluster reload -R grafana`.

Syntax

```
tiup cluster rename <old-cluster-name> <new-cluster-name> [flags]
```

- `<old-cluster-name>`: The old cluster name.
- `<new-cluster-name>`: The new cluster name.

Options

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The execution log of the tiup-cluster.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.21 tiup cluster replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup cluster replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup cluster replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-id`s using the `tiup cluster audit` command.

Option

-h, –help

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.22 tiup cluster restart

The command `tiup cluster restart` is used to restart all or some of the services of the specified cluster.

> **Note:**
>
> During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup cluster restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

> **Note:**
>
> If the option `-R, --role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specified the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

Note:

If the option `-N, --node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.23 tiup cluster scale-in

The `tiup cluster scale-in` command is used to scale in the cluster, which takes the services of the specified nodes offline, removes the specified nodes from the cluster, and deletes the remaining files from those nodes.

Particular handling of components' offline process

Because the TiKV and TiFlash components are taken offline asynchronously (which requires TiUP to remove the node through API first) and the stopping process takes a long time (which requires TiUP to continuously check whether the node is successfully taken offline), the TiKV and TiFlash components are handled particularly as follows:

- For TiKV and TiFlash components:

    1. TiUP Cluster takes the node offline through API and directly exits without waiting for the process to be completed.
    2. To check the status of the nodes being scaled in, you need to execute the `tiup cluster display` command and wait for the status to become `Tombstone`.
    3. To clean up the nodes in the `Tombstone` status, you need to execute the `tiup cluster prune` command. The `tiup cluster prune` command performs the following operations:
        - Stops the services of the nodes that have been taken offline.
        - Cleans up the data files of the nodes that have been taken offline.

- Updates the cluster topology and removes the nodes that have been taken offline.

For other components:

- When taking the PD components offline, TiUP Cluster quickly deletes the specified nodes from the cluster through API, stops the service of the specified PD nodes, and then deletes the related data files from the nodes.
- When taking other components down, TiUP Cluster directly stops the node services and deletes the related data files from the specified nodes.

Syntax

```
tiup cluster scale-in <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to scale in. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

-N, –node

- Specifies the nodes to take down. Multiple nodes are separated by commas.
- Data type: `STRING`
- There is no default value. This option is mandatory and the value must be not null.

–force

- Controls whether to forcibly remove the specified nodes from the cluster. Sometimes, the host of the node to take offline might be down, which makes it impossible to connect to the node via SSH for operations, so you can forcibly remove the node from the cluster using the `--force` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

> **Warning:**
>
> When you use this option to forcibly remove TiKV or TiFlash nodes that are in service or are pending offline, these nodes will be deleted immediately without waiting for data to be migrated. This imposes a very high risk of data loss. If data loss occurs in the region where the metadata is located, the entire cluster will be unavailable and unrecoverable.

–transfer-timeout

- When a PD or TiKV node is to be removed, the Region leader on the node will be transferred to another node first. Because the transferring process takes some time, you can set the maximum waiting time (in seconds) by configuring `--transfer-timeout`. After the timeout, the `tiup cluster scale-in` command skips waiting and starts the scaling-in directly.
- Data type: `UINT`
- The option is enabled by default with `600` seconds (the default value) passed in.

> **Note:**
>
> If a PD or TiKV node is taken offline directly without waiting for the leader transfer to be completed, the service performance might jitter.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the scaling-in process.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.24 tiup cluster scale-out

The `tiup cluster scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The tiup-cluster component first establishes an SSH connection to the new node, creates the necessary directories on the target node, then performs the deployment and starts the service.

When PD is scaled out, new PD nodes are added to the cluster by the join operation, and the configuration of the services associated with PD is updated; other services are directly started and added to the cluster.

Syntax

```
tiup cluster scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

`<topology.yaml>`: the prepared topology file. This topology file should only contain the new nodes that are to be added to the current cluster.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: false

–no-labels

- This option is used to skip the label check.
- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD does not know the cluster topology, so it might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point of failure. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See Schedule Replicas by Topology Labels for label configuration.
- For the test environment, this risk might not matter, and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- Default: false

–skip-create-user

- During the cluster deployment, tiup-cluster checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`

- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of scaling out.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.25 tiup cluster start

The `tiup cluster start` command is used to start all services or some services of the specified cluster.

Syntax

```
tiup cluster start <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

–init

Starts the cluster in a safe way. It is recommended to use this option when the cluster is started for the first time. This method generates the password of the TiDB root user at startup and returns the password in the command line interface.

Note:

- After safe start of a TiDB cluster, you cannot log in to the database using the root user without a password. Therefore, you need to record the password returned by the command line for future logins.
- The password is generated only once. If you do not record or forget the password, refer to Forget the `root` password to change the password.

-N, –node

- Specifies the nodes to be started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-R, –role

- Specifies the roles of nodes to be started. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of starting the service.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.26 tiup cluster stop

The `tiup cluster stop` command is used to stop all services or some services of the specified cluster.

> **Note:**
>
> If the core services of a cluster are stopped, the cluster cannot provide services anymore.

Syntax

```
tiup cluster stop <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

-N, –node

- Specifies the nodes to be stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the command stops all the nodes by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-R, –role

- Specifies the roles of nodes to be stopped. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`

- If this option is not specified in the command, the command stops all the roles by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of stopping the service.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.27 tiup cluster template

Before deploying the cluster, you need to prepare a topology file of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup cluster template` command.

Syntax

```
tiup cluster template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 PD instances
- 3 TiKV instances
- 3 TiDB instances
- 2 TiFlash instances
- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

–full

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

–local

- Outputs a simple topology template for the local cluster, which can be used directly, and the `global` parameter can be adjusted as needed.
- This template creates a PD service, a TiDB service, a TiKV service, a Prometheus service, and a Grafana service.

–multi-dc

- Outputs the topology template of multiple data centers. To enable this option, add it to the command.
- If this option is not specified, the topology template of a single data center is output by default.

-h, –help

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

<< Back to the previous page - TiUP Cluster command list

13.4.7.3.28 tiup cluster upgrade

The `tiup cluster upgrade` command is used to upgrade the specified cluster to a specific version.

Syntax

```
tiup cluster upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>`: the cluster name to operate on. If you forget the cluster name, you can check it with the cluster list command.
- `<version>`: the target version to upgrade to, such as `v8.4.0`. Currently, it is only allowed to upgrade to a version higher than the current cluster, that is, no downgrade is allowed. It is also not allowed to upgrade to the nightly version.

Options

–force

- To upgrade the cluster, you need to ensure that the cluster is currently started. In some cases, you might want to upgrade when the cluster is not started. At this time, you can use `--force` to ignore the error during the upgrade, forcibly replace the binary file and start the cluster.
- Data type: `BOOLEAN`
- Default: false

> **Note:**
>
> Forcing an upgrade of the cluster that is providing services might result in service unavailability. Unstarted clusters are started automatically after a successful upgrade.

–transfer-timeout

- When upgrading PD or TiKV, the leader of the upgraded node is migrated to other nodes first. The migration process takes some time, and you can set the maximum wait time (in seconds) by the `-transfer-timeout` option. After the timeout, the wait is skipped and the service is upgraded directly.
- Data type: `uint`
- Default: 600

> **Note:**
>
> If the wait is skipped and the service is upgraded directly, the service performance might jitter.

–ignore-config-check

- After the binary is updated, a configuration check is performed on the TiDB, TiKV and PD components using `<binary> --config-check <config-file>`. `<binary>` is the path to the newly deployed binary and `<config-file>` is the configuration file generated based on the user configuration. To skip this check, you can use the `--ignore-config-check` option.
- Data type: `BOOLEAN`

- Default: false

–ignore-version-check

- Before upgrading, TiUP checks whether the target version is greater than or equal to the current version. To skip this check, you can use the `--ignore-version-check` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–offline

- Declares that the current cluster is not running. When this option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of the cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

–pd-version

- Specifies the version of PD. If this option is set, the version of PD will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of PD remains consistent with the cluster version.

–tikv-version

- Specifies the version of TiKV. If this option is set, the version of TiKV will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of TiKV remains consistent with the cluster version.

–tikv-cdc-version

- Specifies the version of TiKV CDC. If this option is set, the version of TiKV CDC will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of TiKV CDC remains consistent with the cluster version.

–tiflash-version

- Specifies the version of TiFlash. If this option is set, the version of TiFlash will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of TiFlash remains consistent with the cluster version.

–cdc-version

- Specifies the version of TiCDC. If this option is set, the version of TiCDC will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of TiCDC remains consistent with the cluster version.

–tiproxy-version

- Specifies the version of TiProxy. If this option is set, the version of TiProxy will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of TiProxy remains consistent with the cluster version.

–tidb-dashboard-version

- Specifies the version of TiDB Dashboard. If this option is set, the version of TiDB Dashboard will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of TiDB Dashboard remains consistent with the cluster version.

–alertmanager-version

- Specifies the version of alert manager. If this option is set, the version of alert manager will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of alert manager remains consistent with the cluster version.

–blackbox-exporter-version

- Specifies the version of Blackbox Exporter. If this option is set, the version of Blackbox Exporter will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of Blackbox Exporter remains consistent with the cluster version.

–node-exporter-version

- Specifies the version of Node Exporter. If this option is set, the version of Node Exporter will no longer be consistent with the cluster version.
- Data type: `STRINGS`
- If this option is not set, the version of Node Exporter remains consistent with the cluster version.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

—pre-upgrade-script

> **Warning:**
>
> This option is experimental and is not recommended for production deployments.

- Runs a script before the upgrade.
- Data type: `STRINGS`
- This option specifies the path of a script to be run on the node that is to be upgraded.

—post-upgrade-script

> **Warning:**
>
> This option is experimental and is not recommended for production deployments.

- Runs a script after the upgrade.
- Data type: `STRINGS`
- This option specifies the path of a script to be run after the upgrade of a node. This script will be executed on the upgraded node itself.

Output

The log of the upgrading progress.

<< Back to the previous page - TiUP Cluster command list

13.4.7.4 TiUP DM Commands

13.4.7.4.1 TiUP DM

Similar to TiUP Cluster which is used to manage TiDB clusters, TiUP DM is used to manage DM clusters. You can use the TiUP DM component to perform daily operations and maintenance tasks of DM clusters, including deploying, starting, stopping, destroying, elastic scaling, upgrading DM clusters, and managing the configuration parameters of DM clusters.

Syntax

```
tiup dm [command] [flags]
```

`[command]` is used to pass the name of the command. See the Command list for supported commands.

Options

–ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: `STRING`
- Support values:
  - `builtin`: Uses the built-in easyssh client of tiup-cluster as the SSH client.
  - `system`: Uses the default SSH client of the current operating system.
  - `none`: No SSH client is used. The deployment is only for the current machine.
- If this option is not specified in the command, `builtin` is used as the default value.

–ssh-timeout

- Specifies the SSH connection timeout in seconds.

- Data type: `UINT`
- If this option is not specified in the command, the default timeout is `5` seconds.

–wait-timeout

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying systemctl to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each steps is `120` seconds.

-y, –yes

- Skips the secondary confirmation of all risky operations. It is not recommended to use this option unless you use a script to call TiUP.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-v, –version

- Prints the current version of TiUP DM.
- Data type:`BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, –help

- Prints help information about the specified command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- import: Imports a DM v1.0 cluster deployed by DM-Ansible.
- template: Outputs the topology template.
- deploy: Deploys a cluster based on a specified topology.
- list: Queries the list of deployed clusters.

- display: Displays the status of a specified cluster.
- start: Starts a specified cluster.
- stop: Stops a specified cluster.
- restart: Restarts a specified cluster.
- scale-in: Scales in a specified cluster.
- scale-out: Scales out a specified cluster.
- upgrade: Upgrades a specified cluster.
- prune: Cleans up instances in the Tombstone status for a specified cluster.
- edit-config: Modifies the configuration of a specified cluster.
- reload: Reloads the configuration of a specified cluster.
- patch: Replaces a specified service in a deployed cluster.
- destroy: Destroys a specified cluster.
- audit: Queries the operation audit log of a specified cluster.
- replay: Replays the specified commands
- enable: Enables the auto-enabling of the cluster service after a machine is restarted.
- disable: Disables the auto-enabling of the cluster service after a machine is restarted.
- help: Prints help information.

<< Back to the previous page - TiUP Reference component list

13.4.7.4.2 tiup dm audit

The `tiup dm audit` command is used to view historical commands executed on all clusters and the execution log of each command.

Syntax

```
tiup dm audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, the execution log of the specified `audit-id` is checked.

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

- If `[audit-id]` is specified, the corresponding execution log is output.
- If `[audit-id]` is not specified, a table with the following fields is output:

- ID: the `audit-id` corresponding to this record
- Time: the execution time of the command corresponding to the record
- Command: the command corresponding to the record

<< Back to the previous page - TiUP DM command list

13.4.7.4.3 tiup dm deploy

The `tiup dm deploy` command is used to deploy a new cluster.

Syntax

```
tiup dm deploy <cluster-name> <version> <topology.yaml> [flags]
```

- `<cluster-name>`: the name of the new cluster, which cannot be the same as the existing cluster names.
- `<version>`: the version number of the DM cluster to be deployed, such as `v2.0.0`.
- `<topology.yaml>`: the prepared topology file.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- Default: `~/.ssh/id_rsa`

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.

- Data type: `BOOLEAN`
- Default: false

Output

The deployment log.

<< Back to the previous page - TiUP DM command list

13.4.7.4.4 tiup dm destroy

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup dm destroy` command performs the following operations:

- Stops the cluster.
- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by `tiup-dm`, also delete the parent directory.

Syntax

```
tiup dm destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to be destroyed.

Option

-h, –help

- Prints the help information.
- Data type: `Boolean`
- Default: false

Output

The execution log of the tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.5 tiup dm disable

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup dm disable` command. This command executes `systemctl disable <service>` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup dm disable <cluster-name> [flags]
```

`<cluster-name>` is the cluster whose service auto-enabling is to be disabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-h, –help

Prints the help information.

Output

The execution log of the tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.6 tiup dm display

If you want to check the operational status of each component in a DM cluster, it is inefficient to log in to each machine one by one. Therefore, tiup-dm provides the `tiup dm display` command to do this job efficiently.

Syntax

```
tiup dm display <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated. If you forget the cluster name, you can check it using the `tiup dm list` command.

Options

-N, –node

- Specifies the IDs of the nodes to query, splitting by commas for multiple nodes. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: `STRING`
- This option is enabled by default with `[]` (which means all nodes) passed in.

> **Note:**
>
> If `-R, --role` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

-R, –role

- Specifies the roles to query, splitting by commas for multiple roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: `STRING`
- This option is enabled by default with `[]` (which means all roles) passed in.

> **Note:**
>
> If `-N, --node` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

- Cluster name
- Cluster version
- SSH client type
- A table containing the following fields:
  - `ID`: the node ID, consisting of IP:PORT.
  - `Role`: the service role deployed on the node (for example, TiDB or TiKV).
  - `Host`: the IP address of the machine corresponding to the node.
  - `Ports`: the port number used by the service.
  - `OS/Arch`: the operating system and machine architecture of the node.
  - `Status`: the current status of the services on the node.
  - `Data Dir`: the data directory of the service. `-` means that there is no data directory.
  - `Deploy Dir`: the deployment directory of the service.

<< Back to the previous page - TiUP DM command list

13.4.7.4.7 tiup dm edit-config

If you need to modify the cluster service configuration after the cluster is deployed, you can use the `tiup dm edit-config` command that starts an editor for you to modify the topology file. of the specified cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

Note:

- When you modify the configuration, you cannot add or delete machines. For how to add machines, see Scale out a cluster. For how to delete machines, see Scale in a cluster.
- After you execute the `tiup dm edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup dm reload` command to reload the configuration.

Syntax

```
tiup dm edit-config <cluster-name> [flags]
```

`<cluster-name>`: the cluster to operate on.

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

- Normally, no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error is reported, reminding you to edit the file again. For the fields that cannot be modified, see the topology file.

<< Back to the previous page - TiUP DM command list

13.4.7.4.8 tiup dm enable

The `tiup dm enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

Syntax

```
tiup dm enable <cluster-name> [flags]
```

`<cluster-name>` is the cluster whose service auto-enabling is to be enabled.

Options

-N, –node

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-R, –role

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

-h, –help

Prints the help information.

Output

the execution log of tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.9 tiup dm help

tiup-dm command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option. Basically, `tiup dm help <command >` is equivalent to `tiup dm <command> --help`.

Syntax

```
tiup dm help [command] [flags]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of `tiup-dm` is viewed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The help information of `[command]` or `tiup-dm`.

<< Back to the previous page - TiUP DM command list

13.4.7.4.10 tiup dm import Only for upgrading DM v1.0

This command is used only for upgrading DM clusters from v1.0 to v2.0 or later versions.

In DM v1.0, the cluster is basically deployed using TiDB Ansible. TiUP DM provides the `import` command to import v1.0 clusters and redeploy the clusters in DM v2.0.

Note:

- The command does not support importing DM Portal components from DM v1.0 clusters.
- Before importing the cluster, stop running the original cluster first.
- For data migration tasks that need to be upgraded to v2.0, do not execute `stop-task` on these tasks.
- The command only supports importing to DM v2.0.0-rc.2 and later versions.
- The `import` command is used to import a DM v1.0 cluster to a new DM v2.0 cluster. If you need to import data migration tasks to an existing v2.0 cluster, refer to Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+
- The deployment directories of some components might be different from those in the original cluster. You can check it with the `display` command.
- Before importing the cluster, run `tiup update --self && tiup update dm` to upgrade TiUP DM components to the latest version.
- After the cluster is imported, there is only one DM-master node in the cluster. You can refer to the `scale out` command to scale out the DM-master node.

Syntax

```
tiup dm import [flags]
```

Options

-v, –cluster-version

- Specifies the version number for redeploying. You must use a version later than v2.0.0-rc.2 (including v2.0.0-rc.2).
- Data type: `STRING`
- This option is **required** to execute the command.

-d, –dir

- Specifies the directory of TiDB Ansible.
- Data type: `STRING`
- If this option is not specified in the command, the current directory is the default directory.

–inventory

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- If this option is not specified in the command, the default file name is `"inventory.ini"`.

–rename

- Renames the imported cluster.
- Data type: `STRING`
- If this option is not specified in the command, the default cluster name is the `cluster_name` specified in the inventory file.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the importing process.

<< Back to the previous page - TiUP DM command list

13.4.7.4.11 tiup dm list

`tiup-dm` supports deploying multiple clusters using the same control machine. You can use the `tiup dm list` command to check which clusters are deployed using the control machine by the currently logged-in user.

> **Note:**
>
> By default, the data of the deployed clusters is stored in the `~/.tiup/storage/dm/clusters/` directory. The currently logged-in user cannot view the clusters deployed by other users on the same control machine.

Syntax

```
tiup dm list [flags]
```

Options

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

A table consisting of the following fields:

- `Name`: the cluster name.
- `User`: the user who deployed the cluster.
- `Version`: the cluster version.
- `Path`: the path of the cluster deployment data on the control machine.
- `PrivateKey`: the path of the private key to the cluster.

<< Back to the previous page - TiUP DM command list

13.4.7.4.12 Apply Hotfix to DM Clusters Online

If you need to dynamically replace the binaries of a service while the cluster is running (that is, to keep the cluster available during the replacement), you can use the `tiup dm patch` command. The command does the following:

- Uploads the binary package for replacement to the target machine.

- Takes the related nodes offline using the API.
- Stops the target service.
- Unpacks the binary package and replaces the service.
- Starts the target service.

Syntax

```
tiup dm patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated
- `<package-path>`: The path to the binary package used for replacement

Preparation

You need to pack the binary package required for this command in advance according to the following steps:

- Determine the name `${component}` of the component to be replaced (dm-master, dm-worker …), the `${version}` of the component (v2.0.0, v2.0.1 …), and the operating system `${os}` and platform `${arch}` on which the component runs.
- Download the current component package using the command `wget https://tiup-mirrors.pingcap.com/${component}-${version}-${os}-${arch}.tar.gz -O /tmp/${component}-${version}-${os}-${arch}.tar.gz`.
- Run `mkdir -p /tmp/package && cd /tmp/package` to create a temporary directory to pack files.
- Run `tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz` to unpack the original binary package.
- Run `find .` to view the file structure in the temporary package directory.
- Copy the binary files or configuration files to the corresponding locations in the temporary directory.
- Run `tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *` to pack the files in the temporary directory.
- Finally, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the value of `<package-path>` in the `tiup dm patch` command.

Options

–overwrite

- After you patch a certain component (such as dm-worker), when the tiup-dm scales out the component, tiup-dm uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specify the option `--overwrite` in the command.
- Data type: `BOOLEAN`

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-N, –node

- Specifies the nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all nodes to replace by default.

> **Note:**
>
> If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all roles to replace by default.

> **Note:**
>
> If the option `-N, --node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

–offline

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Example

The following example shows how to apply `v5.3.0-hotfix` to the `v5.3.0` cluster deployed using TiUP. The operations might vary if you deploy the cluster using other methods.

> **Note:**
>
> Hotfix is used only for emergency fixes. Its daily maintenance is complicated. It is recommend that you upgrade the DM cluster to an official version as soon as it is released.

Preparations

Before applying a hotfix, prepare the hotfix package `dm-linux-amd64.tar.gz` and confirm the current DM software version:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0

Git Commit Hash: 20626babf21fc381d4364646c40dd84598533d66
Git Branch: heads/refs/tags/v5.3.0
UTC Build Time: 2021-11-29 08:29:49
Go Version: go version go1.16.4 linux/amd64
```

Prepare the patch package and apply it to the DM cluster

1. Prepare the DM software package that matches the current version:

```
mkdir -p /tmp/package
tar -zxvf /root/.tiup/storage/dm/packages/dm-master-v5.3.0-linux-amd64.
    ↪ tar.gz -C /tmp/package/
tar -zxvf /root/.tiup/storage/dm/packages/dm-worker-v5.3.0-linux-amd64.
    ↪ tar.gz -C /tmp/package/
```

2. Replace the binary file with the hotfix package:

```
# Decompress the hotfix package and use it to replace the binary file.
cd /root; tar -zxvf dm-linux-amd64.tar.gz
cp /root/dm-linux-amd64/bin/dm-master /tmp/package/dm-master/dm-master
cp /root/dm-linux-amd64/bin/dm-worker /tmp/package/dm-worker/dm-worker
# Re-package the modified files.
# Note that the packaging method might be different for other
    ↪ deployment methods.
cd /tmp/package/ && tar -czvf dm-master-hotfix-linux-amd64.tar.gz dm-
    ↪ master/
cd /tmp/package/ && tar -czvf dm-worker-hotfix-linux-amd64.tar.gz dm-
    ↪ worker/
```

3. Apply the hotfix:

   Query the cluster status. The following uses the cluster named `dm-test` as an example:

```
tiup dm display dm-test
```

   Output:

```
Cluster type:     dm
Cluster name:     dm-test
Cluster version:  v5.3.0
Deploy user:      tidb
SSH type:         builtin
ID                Role               Host         Ports     OS/Arch
    ↪ Status    Data Dir                          Deploy Dir
--                ----               ----         -----     -------
    ↪ ------    --------                          ----------
172.16.100.21:9093 alertmanager     172.16.100.21 9093/9094 linux/x86_
    ↪ 64 Up      /home/tidb/dm/data/alertmanager-9093 /home/tidb/dm/
    ↪ deploy/alertmanager-9093
172.16.100.21:8261 dm-master        172.16.100.21 8261/8291 linux/x86_
    ↪ 64 Healthy|L /home/tidb/dm/data/dm-master-8261 /home/tidb/dm/
    ↪ deploy/dm-master-8261
172.16.100.21:8262 dm-worker        172.16.100.21 8262     linux/x86_64
    ↪  Free     /home/tidb/dm/data/dm-worker-8262 /home/tidb/dm/deploy/
    ↪ dm-worker-8262
172.16.100.21:3000 grafana          172.16.100.21 3000     linux/x86_64
    ↪  Up       -                                 /home/tidb/dm/deploy/
    ↪ grafana-3000
172.16.100.21:9090 prometheus       172.16.100.21 9090     linux/x86_64
    ↪  Up       /home/tidb/dm/data/prometheus-9090 /home/tidb/dm/deploy
    ↪ /prometheus-9090
Total nodes: 5
```

Apply the hotfix to the specified node or specified role. If both `-R` and `-N` are specified, the intersection will be taken.

```
# Apply hotfix to a specified node.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -N
    ↪ 172.16.100.21:8261
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -N
    ↪ 172.16.100.21:8262
# Apply hotfix to a specified role.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -R dm-master
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -R dm-worker
```

4. Query the hotfix application result:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0-20211230
Git Commit Hash: ca7070c45013c24d34bd9c1e936071253451d707
Git Branch: heads/refs/tags/v5.3.0-20211230
UTC Build Time: 2022-01-05 14:19:02
Go Version: go version go1.16.4 linux/amd64
```

The cluster information changes accordingly:

```
tiup dm display dm-test
```

Output:

```
Starting component `dm`: /root/.tiup/components/dm/v1.8.1/tiup-dm
    ↪ display dm-test
Cluster type:     dm
Cluster name:     dm-test
Cluster version:  v5.3.0
Deploy user:      tidb

<< Back to the previous page - TiUP DM command list

13.4.7.4.13 tiup dm prune

When you scale in the cluster(/tiup/tiup-component-dm-scale-in.md), a small amount of metadata in etcd is not cleaned up, which usually causes no problem. If you need to clean up the metadata, you can manually execute the `tiup dm prune` command.

Syntax

```
tiup dm prune <cluster-name> [flags]
```

Option

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of the cleanup process.

<< Back to the previous page - TiUP DM command list

13.4.7.4.14 tiup dm reload

After modifying the cluster configuration, the cluster needs to be reloaded using the `tiup dm reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running and restarts the service in order according to the upgrade process. The cluster remains available during the restart process.

Syntax

```
tiup dm reload <cluster-name> [flags]
```

<cluster-name>: the name of the cluster to operate on.

Options

-N, –node

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

Note:

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

-R, –role

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

Note:

- If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-R, --role` option is invalid.

–skip-restart

The `tiup dm reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The execution log of the tiup-dm.

<< Back to the previous page - TiUP DM command list

13.4.7.4.15 tiup dm replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup dm replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup dm replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-id`s using the `tiup dm audit` command.

Option

-h, –help

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

<< Back to the previous page - TiUP DM command list

13.4.7.4.16 tiup dm restart

The command `tiup dm restart` is used to restart all or some of the services of the specified cluster.

> **Note:**
>
> During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup dm restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

> **Note:**
>
> If the option `-R, --role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, –role

- Specifies the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

Note:

If the option `-N, --node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-h, –help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

<< Back to the previous page - TiUP DM command list

13.4.7.4.17 tiup dm scale-in

The `tiup dm scale-in` command is used to scale in the cluster. Scaling in the cluster means taking the service offline, which eventually removes the specified node from the cluster and deletes the remaining related files.

Syntax

```
tiup dm scale-in <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be scaled in. If you need to scale in multiple nodes, split them by commas.
- Data type: `STRINGS`
- Default: no. This option is mandatory and the value must be not null.

–force

- In some cases, some scale-in nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to remove these nodes from the cluster.

- Data type: `BOOLEAN`
- Default: false. If this option is not specified in the command, the specified nodes are not forcibly removed.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of scaling in.

<< Back to the previous page - TiUP DM command list

13.4.7.4.18 tiup dm scale-out

The `tiup dm scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The `tiup-dm` components first establish an SSH connection to the new node, create the necessary directories on the target node, then perform the deployment and start the service.

Syntax

```
tiup dm scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

`<topology.yaml>`: the prepared topology file. This topology file should only contain the new nodes that are to be added to the current cluster.

Options

-u, –user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

-i, –identity_file

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, –password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: false

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of scaling out.

<< Back to the previous page - TiUP DM command list

13.4.7.4.19 tiup dm start

The `tiup dm start` command is used to start all or part of the services of the specified cluster.

Syntax

```
tiup dm start <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be started. If not specified, all nodes are started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-R, –role

- Specifies the roles to be started. If not specified, all roles are started. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of starting the service.

<< Back to the previous page - TiUP DM command list

13.4.7.4.20 tiup dm stop

The `tiup dm stop` command is used to stop all or part of the services of the specified cluster.

> **Note:**
>
> The cluster cannot provide services after the core service is stopped.

Syntax

```
tiup dm stop <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the cluster list command.

Options

-N, –node

- Specifies the nodes to be stopped. If not specified, all nodes are stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

> **Note:**
>
> If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-R, –role

- Specifies the roles to be stopped. If not specified, all roles are stopped. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

> **Note:**
>
> If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: false

Output

The log of stopping the service.

<< Back to the previous page - TiUP DM command list

13.4.7.4.21 tiup dm template

Before deploying the cluster, you need to prepare a topology file of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup dm template` command.

Syntax

```
tiup dm template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 DM-master instances
- 3 DM-worker instances
- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

–full

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

-h, –help

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

<< Back to the previous page - TiUP DM command list

13.4.7.4.22 tiup dm upgrade

The `tiup dm upgrade` command is used to upgrade a specified cluster to a specific version.

Syntax

```
tiup dm upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup dm list` command.
- `<version>` is the target version to be upgraded to, such as `v8.4.0`. Currently, only upgrading to a later version is allowed, and upgrading to an earlier version is not allowed, which means the downgrade is not allowed. Upgrading to a nightly version is not allowed either.

Options

–offline

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

-h, –help

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Log of the service upgrade process.

<< Back to the previous page - TiUP DM command list

13.4.8 Topology Configuration File for TiDB Deployment Using TiUP

To deploy or scale TiDB using TiUP, you need to provide a topology file (sample) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

When you deploy a TiDB cluster using TiUP, TiUP also deploys monitoring servers, such as Prometheus, Grafana, and Alertmanager. In the meantime, if you scale out this cluster, TiUP also adds the new nodes into monitoring scope. To customize the configurations of the preceding monitoring servers, you can follow the instructions in Customize Configurations of Monitoring Servers.

13.4.8.1 File structure

A topology configuration file for TiDB deployment using TiUP might contain the following sections:

- global: The cluster's global configuration. Some of the configuration items use the default values and you can configure them separately in each instance.
- monitored: Configuration for monitoring services, namely, the blackbox_exporter and the `node_exporter`. On each machine, a `node_exporter` and a `blackbox_exporter` are deployed.
- server_configs: Components' global configuration. You can configure each component separately. If an instance has a configuration item with the same name, the instance's configuration item will take effect.
- component_versions: Component version. You can configure it when a component does not use the cluster version. This section is introduced in tiup-cluster v1.14.0.
- pd_servers: The configuration of the PD instance. This configuration specifies the machines to which the PD component is deployed.
- tidb_servers: The configuration of the TiDB instance. This configuration specifies the machines to which the TiDB component is deployed.
- tikv_servers: The configuration of the TiKV instance. This configuration specifies the machines to which the TiKV component is deployed.
- tiflash_servers: The configuration of the TiFlash instance. This configuration specifies the machines to which the TiFlash component is deployed.
- tiproxy_servers: The configuration of the TiProxy instance. This configuration specifies the machines to which the TiProxy component is deployed.
- kvcdc_servers: The configuration of the TiKV-CDC instance. This configuration specifies the machines to which the TiKV-CDC component is deployed.
- cdc_servers: The configuration of the TiCDC instance. This configuration specifies the machines to which the TiCDC component is deployed.
- tispark_masters: The configuration of the TiSpark master instance. This configuration specifies the machines to which the TiSpark master component is deployed. Only one node of TiSpark master can be deployed.
- tispark_workers: The configuration of the TiSpark worker instance. This configuration specifies the machines to which the TiSpark worker component is deployed.
- tso_servers: The configuration of the TSO instance. This configuration specifies the machines to which the `tso` microservice is deployed (requires configuring `pd_mode: "ms"` in `global` to enable PD microservices).
- scheduling_servers: The configuration of the Scheduling instance. This configuration specifies the machines to which the `scheduling` microservice is deployed (requires

configuring `pd_mode: "ms"` in `global` to enable PD microservices).

- monitoring_servers: Specifies the machines to which Prometheus and NGMonitoring are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- grafana_servers: The configuration of the Grafana instance. This configuration specifies the machines to which Grafana is deployed.
- alertmanager_servers: The configuration of the Alertmanager instance. This configuration specifies the machines to which Alertmanager is deployed.

13.4.8.1.1 `global`

The `global` section corresponds to the cluster's global configuration and has the following fields:

- `user`: The user used to start the deployed cluster. The default value is `"tidb"`. If the user specified in the `<user>` field does not exist on the target machine, this user is automatically created.
- `group`: The user group to which a user belongs. It is specified when the user is created. The value defaults to that of the `<user>` field. If the specified group does not exist, it is automatically created.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. The default value is `22`.
- `enable_tls`: Specifies whether to enable TLS for the cluster. After TLS is enabled, the generated TLS certificate must be used for connections between components or between the client and the component. The default value is `false`.
- `listen_host`: Specifies the default listening IP address. If it is empty, each instance automatically sets it to `::` or `0.0.0.0` based on whether its `host` field contains `:`. This field is introduced in tiup-cluster v1.14.0.
- `deploy_dir`: The deployment directory of each component. The default value is `"deployed"`. Its application rules are as follows:
  - If the absolute path of `deploy_dir` is configured at the instance level, the actual deployment directory is `deploy_dir` configured for the instance.
  - For each instance, if you do not configure `deploy_dir`, its default value is the relative path `<component-name>-<component-port>`.
  - If `global.deploy_dir` is an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.
  - If `global.deploy_dir` is a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.

- `data_dir`: The data directory. Default value: `"data"`. Its application rules are as follows:

    - If the absolute path of `data_dir` is configured at the instance level, the actual deployment directory is `data_dir` configured for the instance.
    - For each instance, if you do not configure `data_dir`, its default value is `<global.data_dir>`.
    - If `data_dir` is a relative path, the component data is placed in `<deploy_dir>/<data_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.

- `log_dir`: The log directory. Default value: `"log"`. Its application rules are as follows:

    - If the absolute path `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
    - For each instance, if you not configure `log_dir`, its default value is `<global.log_dir>`.
    - If `log_dir` is a relative path, the component log is placed in `<deploy_dir>/<log_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.

- `os`: The operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is "linux".

- `arch`: The CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are "amd64" and "arm64". The default value is "amd64".

- `pd_mode`: The PD working mode. The field controls whether to enable PD microservices. The supported value is "ms". Specifying this field means enabling PD microservices.

- `resource_control`: Runtime resource control. All configurations in this field are written into the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:

    - `memory_limit`: Limits the maximum runtime memory. For example, "2G" means that the maximum memory of 2 GB can be used.
    - `cpu_quota`: Limits the maximum CPU usage at runtime. For example, "200%".
    - `io_read_bandwidth_max`: Limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M"`.
    - `io_write_bandwidth_max`: Limits maximum I/O bandwidth for disk writes. For example, `/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M`.

- `limit_core`: Controls the size of core dump.

A `global` configuration example is as follows:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the above configuration, the `tidb` user is used to start the cluster. At the same time, each component is restricted to a maximum of 2 GB of memory when it is running.

13.4.8.1.2 `monitored`

`monitored` is used to configure the monitoring service on the target machine: `node_exporter` and `blackbox_exporter`. The following fields are included:

- `node_exporter_port`: The service port of `node_exporter`. The default value is `9100`.
- `blackbox_exporter_port`: The service port of `blackbox_exporter`. The default value is `9115`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

A `monitored` configuration example is as follows:

```
monitored:
  node_exporter_port: 9100
  blackbox_exporter_port: 9115
```

The above configuration specifies that `node_exporter` uses the `9100` port and `blackbox_exporter` uses the `9115` port.

13.4.8.1.3 `server_configs`

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configuration of this section can be overwritten by the configurations with the same names in an instance. `server_configs` mainly includes the following fields:

- `tidb`: TiDB service-related configuration. For the complete configuration, see TiDB configuration file.
- `tikv`: TiKV service-related configuration. For the complete configuration, see TiKV configuration file.
- `pd`: PD service-related configuration. For the complete configuration, see PD configuration file.
- `tiflash`: TiFlash service-related configuration. For the complete configuration, see TiFlash configuration file.
- `tiflash_learner`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- `tiproxy`: TiProxy service-related configuration. For the complete configuration, see TiProxy configuration file.
- `cdc`: TiCDC service-related configuration. For the complete configuration, see Deploy TiCDC.
- `tso`: `tso` microservice-related configuration. For the complete configuration, see TSO configuration file.
- `scheduling`: `scheduling` microservice-related configuration. For the complete configuration, see Scheduling configuration file.

A `server_configs` configuration example is as follows:

```
server_configs:
  tidb:
    lease: "45s"
    split-table: true
    token-limit: 1000
    instance.tidb_enable_ddl: true
  tikv:
    log-level: "info"
    readpool.unified.min-thread-count: 1
```

The above configuration specifies the global configuration of TiDB and TiKV.

13.4.8.1.4 component_versions

> **Note:**
>
> For components that share a version number, such as TiDB, TiKV, PD, and TiCDC, there are no complete tests to ensure that they work properly in a mixed-version deployment scenario. Ensure that you use this section only in test environments, or with the help of technical support.

`component_versions` is used to specify the version number of a certain component.

- When `component_versions` is not configured, each component either uses the same version number as the TiDB cluster (such as PD and TiKV), or uses the latest version (such as Alertmanager).
- When `component_versions` is configured, the corresponding component will use the specified version, and this version will be used in subsequent cluster scaling and upgrade operations.

Make sure you only configure it when you need to use a specific version of a component.

`component_versions` contains the following fields:

- `tikv`: The version of the TiKV component
- `tiflash`: The version of the TiFlash component
- `pd`: The version of the PD component
- `tidb_dashboard`: The version of the standalone TiDB Dashboard component
- `cdc`: The version of the CDC component
- `kvcdc`: The version of the TiKV-CDC component
- `tiproxy`: The version of the TiProxy component
- `prometheus`: The version of the Prometheus component
- `grafana`: The version of the Grafana component
- `alertmanager`: The version of the Alertmanager component
- `tso`: The version of the TSO component
- `scheduling`: The version of the Scheduling component

The following is an example configuration for `component_versions`:

```
component_versions:
  kvcdc: "v1.1.1"
```

The preceding configuration specifies the version number of TiKV-CDC to be `v1.1.1`.

13.4.8.1.5 `pd_servers`

`pd_servers` specifies the machines to which PD services are deployed. It also specifies the service configuration on each machine. `pd_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the PD services are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `name`: Specifies the name of the PD instance. Different instances must have unique names; otherwise, instances cannot be deployed.
- `client_port`: Specifies the port that PD uses to connect to the client. The default value is 2379.
- `peer_port`: Specifies the port for communication between PDs. The default value is 2380.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `pd` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pd` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.

- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `name`
- `client_port`
- `peer_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `pd_servers` configuration example is as follows:

```
pd_servers:
  - host: 10.0.1.11
    config:
      schedule.max-merge-region-size: 20
      schedule.max-merge-region-keys: 200000
  - host: 10.0.1.12
```

The above configuration specifies that PD will be deployed on `10.0.1.11` and `10.0.1.12`, and makes specific configurations for the PD of `10.0.1.11`.

13.4.8.1.6 `tidb_servers`

`tidb_servers` specifies the machines to which TiDB services are deployed. It also specifies the service configuration on each machine. `tidb_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiDB services are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.

- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of TiDB services, which is used to provide connection to the MySQL client. The default value is `4000`.
- `status_port`: The listening port of the TiDB status service, which is used to view the status of the TiDB services from the external via HTTP requests. The default value is `10080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tidb` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tidb` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`

- log_dir
- arch
- os

A tidb_servers configuration example is as follows:

```
tidb_servers:
  - host: 10.0.1.14
    config:
      log.level: warn
      log.slow-query-file: tidb-slow-overwrited.log
  - host: 10.0.1.15
```

13.4.8.1.7 tikv_servers

tikv_servers specifies the machines to which TiKV services are deployed. It also specifies the service configuration on each machine. tikv_servers is an array, and each element of the array contains the following fields:

- host: Specifies the machine to which the TiKV services are deployed. The field value is an IP address and is mandatory.
- listen_host: When the machine has multiple IP addresses, listen_host specifies the listening IP address of the service. The default value is 0.0.0.0.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- port: The listening port of the TiKV services. The default value is 20160.
- status_port: The listening port of the TiKV status service. The default value is 20180.
- deploy_dir: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the deploy_dir directory configured in global.
- data_dir: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the data_dir directory configured in global.
- log_dir: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the log_dir directory configured in global.
- numa_node: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".

- `config`: The configuration rule of this field is the same as the `tikv` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tikv` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `tikv_servers` configuration example is as follows:

```
tikv_servers:
  - host: 10.0.1.14
    config:
      server.labels: { zone: "zone1", host: "host1" }
  - host: 10.0.1.15
    config:
      server.labels: { zone: "zone1", host: "host2" }
```

13.4.8.1.8 `tiflash_servers`

`tiflash_servers` specifies the machines to which TiFlash services are deployed. It also specifies the service configuration on each machine. This section is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiFlash services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `tcp_port`: The port of the TiFlash TCP service for internal testing purposes. The default value is `9000`. Starting from TiUP v1.12.5, this configuration item does not take effect on clusters that are v7.1.0 or later.
- `flash_service_port`: The port via which TiFlash provides services. TiDB reads data from TiFlash via this port. The default value is `3930`.
- `metrics_port`: TiFlash's status port, which is used to output metric data. The default value is `8234`.
- `flash_proxy_port`: The port of the built-in TiKV. The default value is `20170`.
- `flash_proxy_status_port`: The status port of the built-in TiKV. The default value is `20292`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`. TiFlash supports multiple `data_dir` directories separated by commas.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `tmp_path`: The storage path of TiFlash temporary files. The default value is [`path` or the first directory of `storage.latest.dir`] + "/tmp".
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tiflash` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tiflash` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `learner_config`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.

- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

After the deployment, for the fields above, you can only add directories to `data_dir`; for the fields below, you cannot modified these fields:

- `host`
- `tcp_port`
- `flash_service_port`
- `flash_proxy_port`
- `flash_proxy_status_port`
- `metrics_port`
- `deploy_dir`
- `log_dir`
- `tmp_path`
- `arch`
- `os`

A `tiflash_servers` configuration example is as follows:

```
tiflash_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

13.4.8.1.9 `tiproxy_servers`

`tiproxy_servers` specifies the machines to which the TiProxy services are deployed and the service configuration on each machine. `tiproxy_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the IP address of the machine to which the TiProxy services are deployed. This field is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.

- `port`: The listening port of the TiProxy SQL services. The default value is `6000`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated based on the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated based on the `data_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is of string type. The value is the ID of the NUMA node, such as `"0,1"`.
- `config`: The configuration rule of this field is the same as the `tiproxy` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tiproxy` content in `server_configs`. If these two fields overlap, the content of this field takes effect. Subsequently, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

Among the above fields, you cannot modify the following configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `arch`
- `os`

A `tiproxy_servers` configuration example is as follows:

```
tiproxy_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

13.4.8.1.10 `kvcdc_servers`

`kvcdc_servers` specifies the machines to which the TiKV-CDC services are deployed. It also specifies the service configuration on each machine. `kvcdc_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiKV-CDC services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the TiKV-CDC services. The default value is `8600`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data-dir`: Specifies the directory that TiKV-CDC uses to store temporary files primarily for sorting (optional). The free disk space for this directory is recommended to be greater than or equal to 500 GiB.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `gc-ttl`: The TTL (Time to Live, in seconds) of the service-level GC safepoint in PD set by TiKV-CDC (optional). It is the duration that replication tasks can be suspended, defaulting to `86400`, which is 24 hours. Note that suspending replication tasks affects the progress of TiKV garbage collection safepoint. The longer the `gc-ttl`, the longer changefeeds can be suspended, but at the same time, more obsolete data will be kept and occupy more space. Vice versa.
- `tz`: The time zone that the TiKV-CDC services use. TiKV-CDC uses this time zone when internally converting time data types such as timestamp and when replicating data to the downstream. The default value is the local time zone where the process runs.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The address of the configuration file that TiKV-CDC uses (optional).
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `kvcdc_servers` configuration example is as follows:

```
kvcdc_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

13.4.8.1.11 `cdc_servers`

`cdc_servers` specifies the machines to which the TiCDC services are deployed. It also specifies the service configuration on each machine. `cdc_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiCDC services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the TiCDC services. The default value is `8300`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

- `gc-ttl`: The Time To Live (TTL) duration of the service level GC safepoint set by TiCDC in PD, in seconds. The default value is `86400`, which is 24 hours.
- `tz`: The time zone that the TiCDC services use. TiCDC uses this time zone when internally converting time data types such as timestamp and when replicating data to the downstream. The default value is the local time zone where the process runs.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The field content is merged with the `cdc` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.
- `ticdc_cluster_id`: Specifies the TiCDC cluster ID corresponding to the service. If this field is not specified, the service joins the default TiCDC cluster. This field only takes effect in TiDB v6.3.0 or later versions.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`
- `ticdc_cluster_id`

A `cdc_servers` configuration example is as follows:

```
cdc_servers:
  - host: 10.0.1.20
    gc-ttl: 86400
    data_dir: "/cdc-data"
  - host: 10.0.1.21
    gc-ttl: 86400
    data_dir: "/cdc-data"
```

13.4.8.1.12 `tispark_masters`

`tispark_masters` specifies the machines to which the master node of TiSpark is deployed. It also specifies the service configuration on each machine. `tispark_masters` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiSpark master is deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path of the JRE environment to be used. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `spark_config`: Configures to configure the TiSpark services. Then, a configuration file is generated and sent to the machine specified in `host`.
- `spark_env`: Configures the environment variables when Spark starts.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- host
- listen_host
- port
- web_port
- deploy_dir
- arch
- os

A tispark_masters configuration example is as follows:

```
tispark_masters:
  - host: 10.0.1.21
    spark_config:
      spark.driver.memory: "2g"
      spark.eventLog.enabled: "False"
      spark.tispark.grpc.framesize: 2147483647
      spark.tispark.grpc.timeout_in_sec: 100
      spark.tispark.meta.reload_period_in_sec: 60
      spark.tispark.request.command.priority: "Low"
      spark.tispark.table.scan_concurrency: 256
    spark_env:
      SPARK_EXECUTOR_CORES: 5
      SPARK_EXECUTOR_MEMORY: "10g"
      SPARK_WORKER_CORES: 5
      SPARK_WORKER_MEMORY: "10g"
  - host: 10.0.1.22
```

13.4.8.1.13 tispark_workers

tispark_workers specifies the machines to which the worker nodes of TiSpark are deployed. It also specifies the service configuration on each machine. tispark_workers is an array. Each array element contains the following fields:

- host: Specifies the machine to which the TiSpark workers are deployed. The field value is an IP address and is mandatory.
- listen_host: When the machine has multiple IP addresses, listen_host specifies the listening IP address of the service. The default value is 0.0.0.0.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- port: Spark's listening port, used for communication before the node. The default value is 7077.

- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path in which the JRE environment to be used is located. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`
- `deploy_dir`
- `arch`
- `os`

A `tispark_workers` configuration example is as follows:

```
tispark_workers:
  - host: 10.0.1.22
  - host: 10.0.1.23
```

13.4.8.1.14 `tso_servers`

`tso_servers` specifies the machines to which the `tso` microservices are deployed. It also specifies the service configuration on each machine. `tso_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the IP address of the machine to which the `tso` microservices are deployed. The field value is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Specifies the listening port of the `tso` microservices. The default value is `3379`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.

- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `config`: The configuration rule of this field is the same as the `tso` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tso` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Subsequently, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

Among the preceding fields, you cannot modify these fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `arch`
- `os`

A `tso_servers` configuration example is as follows:

```
tso_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

13.4.8.1.15 `scheduling_servers`

`scheduling_servers` specifies the machines to which `scheduling` microservices are deployed. It also specifies the service configuration on each machine. `scheduling_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the IP address of the machine to which the `scheduling` microservices are deployed. The field is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Specifies the listening port of the `scheduling` microservices. The default value is 3379.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.

- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `config`: The configuration rule of this field is the same as the `scheduling` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `scheduling` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Subsequently, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

Among the preceding fields, you cannot modify these fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `arch`
- `os`

A `scheduling_servers` configuration example is as follows:

```
scheduling_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

13.4.8.1.16 `monitoring_servers`

`monitoring_servers` specifies the machines to which the Prometheus services are deployed. It also specifies the service configuration on each machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the monitoring services are deployed. The field value is an IP address and is mandatory.
- `ng_port`: Specifies the port that NgMonitoring listens to. Introduced in TiUP v1.7.0, this field supports Continuous Profiling and Top SQL. The default value is `12020`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Prometheus services. The default value is `9090`.

- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `storage_retention`: The retention time of the Prometheus monitoring data. The default value is `"30d"`.
- `rule_dir`: Specifies a local directory that should contain complete `*.rules.yml` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the rules for Prometheus.
- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
    - `remote_write`: See the Prometheus document `<remote_write>`.
    - `remote_read`: See the Prometheus document `<remote_read>`.
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

- `additional_args`: Introduced in TiUP v1.15.0, this field configures additional parameters for running Prometheus. This field is an array, and each element of the array is a Prometheus running parameter. For example, to enable the Prometheus hot reload feature, you can set this field to `--web.enable-lifecycle`.

- `additional_scrape_conf`: Customized Prometheus scrape configuration. When you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `additional_scrape_conf` field to the corresponding parameters of the Prometheus configuration file. For more information, see Customize Prometheus scrape configuration.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:
  - host: 10.0.1.11
    rule_dir: /local/rule/dir
    additional_args:
    - --web.enable-lifecycle
    remote_config:
      remote_write:
      - queue_config:
          batch_send_deadline: 5m
          capacity: 100000
          max_samples_per_send: 10000
          max_shards: 300
        url: http://127.0.0.1:8003/write
      remote_read:
      - url: http://127.0.0.1:8003/read
      external_alertmanagers:
      - host: 10.1.1.1
        web_port: 9093
      - host: 10.1.1.2
        web_port: 9094
```

13.4.8.1.17 `grafana_servers`

`grafana_servers` specifies the machines to which the Grafana services are deployed. It also specifies the service configuration on each machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Grafana services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Grafana services. The default value is `3000`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `username`: The user name on the Grafana login interface.
- `password`: The password corresponding to Grafana.
- `dashboard_dir`: Specifies a local directory that should contain complete `dashboard (*.json)` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the dashboards for Grafana.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.
- `config`: This field is used to add custom configurations to Grafana. When you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `config` field to the Grafana configuration file `grafana.ini`. For more information, see Customize other Grafana configurations.

> **Note:**
>
> If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. For the `*.json` files in the local dashboards directory, update the value of the `datasource` field to the new cluster name (because `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:
  - host: 10.0.1.11
    dashboard_dir: /local/dashboard/dir
```

13.4.8.1.18 `alertmanager_servers`

`alertmanager_servers` specifies the machines to which the Alertmanager services are deployed. It also specifies the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Alertmanager services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `web_port`: Specifies the port used that Alertmanager uses to provide web services. The default value is `9093`.
- `cluster_port`: Specifies the communication port between one Alertmanger and other Alertmanager. The default value is `9094`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.

- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config_file`: Specifies a local file that is transferred to the target machine during the initialization phase of the cluster configuration as the configuration of Alertmanager.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.
- `listen_host`: Specifies the listening address so that Alertmanager can be accessed through a proxy. It is recommended to configure it as `0.0.0.0`. For more information, see Customize Alertmanager configurations.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
  - host: 10.0.1.11
    config_file: /local/config/file
  - host: 10.0.1.12
    config_file: /local/config/file
```

13.4.9 Topology Configuration File for DM Cluster Deployment Using TiUP

To deploy or scale a TiDB Data Migration (DM) cluster, you need to provide a topology file (sample) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

13.4.9.1 File structure

A topology configuration file for DM cluster deployment using TiUP might contain the following sections:

- global: the cluster's global configuration. Some of the configuration items use the default values of the cluster, and you can configure them separately in each instance.
- server_configs: the components' global configuration. You can configure each component separately. If an instance has a configuration item with the same key, the instance's configuration item will take effect.
- master_servers: the configuration of the DM-master instance. The configuration specifies the machines to which the master service of the DM component is deployed.
- worker_servers: the configuration of the DM-worker instance. The configuration specifies the machines to which the worker service of the DM component is deployed.
- monitoring_servers: specifies the machines to which the Prometheus instances are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- grafana_servers: the configuration of the Grafana instances. The configuration specifies the machines to which the Grafana instances are deployed.
- alertmanager_servers: the configuration of the Alertemanager instances. The configuration specifies the machines to which the Alertmanager instances are deployed.

13.4.9.1.1 `global`

The `global` section corresponds to the cluster's global configuration and has the following fields:

- `user`: the user to start the deployed cluster. The default value is "tidb". If the user specified in the `<user>` field does not exist on the target machine, TiUP will automatically try to create the user.
- `group`: the user group to which a user belongs when the user is automatically created. The default value is the same as the `<user>` field. If the specified group does not exist, it will be created automatically.
- `ssh_port`: the SSH port to connect to the target machine for operations. The default value is "22".

- `deploy_dir`: the deployment directory for each component. The default value is "deploy". The construction rules are as follows:
    - If the absolute path `deploy_dir` is configured at the instance level, the actual deployment directory is the `deploy_dir` configured for the instance.
    - For each instance, if you do not configure `deploy_dir`, the default value is the relative path `<component-name>-<component-port>`.
    - If `global.deploy_dir` is set to an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.
    - If `global.deploy_dir` is set to a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.
- `data_dir`: the data directory. The default value is "data". The construction rules are as follows.
    - If the absolute path `data_dir` is configured at the instance level, the actual data directory is the `data_dir` configured for the instance.
    - For each instance, if `data_dir` is not configured, the default value is `<global.data_dir>`.
    - If `data_dir` is set to a relative path, the component data is stored in `<deploy_dir>/<data_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- `log_dir`: the data directory. The default value is "log". The construction rules are as follows.
    - If the absolute path of `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
    - For each instance, if `log_dir` is not configured by the user, the default value is `<global.log_dir>`.
    - If `log_dir` is a relative path, the component logs will be stored in `<deploy_dir>/<log_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- `os`: the operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is "linux".
- `arch`: the CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are "amd64" and "arm64". The default value is "amd64".
- `resource_control`: runtime resource control. All configurations in this field are written to the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
    - `memory_limit`: limits the maximum memory at runtime. For example, "2G" means that the maximum memory of 2 GB can be used.
    - `cpu_quota`: limits the maximum CPU usage at runtime. For example, "200%".

- `io_read_bandwidth_max`: limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M"`.
- `io_write_bandwidth_max`: limits the maximum I/O bandwidth for disk writes. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M"` ↪ .
- `limit_core`: controls the size of core dump.

A `global` configuration example:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the example, the configuration specifies that the `tidb` user is used to start the cluster, and that each component is limited to a maximum of 2 GB of memory when it is running.

13.4.9.1.2 `server_configs`

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configurations in the `server_configs` section can be overwritten by the configurations with the same keys in an instance. `server_configs` mainly contains the following fields:

- `master`: the configuration related to the DM-master service. For all the supported configuration items, see DM-master Configuration File.
- `worker`: the configuration related to the DM-worker service, For all the supported configuration items, see DM-worker Configuration File.

A `server_configs` configuration example is as follows:

```
server_configs:
  master:
    log-level: info
    rpc-timeout: "30s"
    rpc-rate-limit: 10.0
    rpc-rate-burst: 40
  worker:
    log-level: info
```

13.4.9.2 `master_servers`

`master_servers` specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. `master_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `name`: specifies the name of the DM-master instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- `port`: specifies the port on which DM-master provides services. The default value is "8261".
- `peer_port`: specifies the port for communication between DM-masters. The default value is "8291".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: the configuration rules of this field are the same as that of `master` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `master` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.
- `v1_source_path`: when upgrading from v1.0.x, you can specify the directory where the configuration file of the V1 source is located in this field.

In the `master_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`

- name
- port
- peer_port
- deploy_dir
- data_dir
- log_dir
- arch
- os
- v1_source_path

A master_servers configuration example is as follows:

```
master_servers:
  - host: 10.0.1.11
    name: master1
    ssh_port: 22
    port: 8261
    peer_port: 8291
    deploy_dir: "/dm-deploy/dm-master-8261"
    data_dir: "/dm-data/dm-master-8261"
    log_dir: "/dm-deploy/dm-master-8261/log"
    numa_node: "0,1"
    # The following configs are used to overwrite the `server_configs.master
       ↪ ` values.
    config:
      log-level: info
      rpc-timeout: "30s"
      rpc-rate-limit: 10.0
      rpc-rate-burst: 40
  - host: 10.0.1.18
    name: master2
  - host: 10.0.1.19
    name: master3
```

13.4.9.3 worker_servers

worker_servers specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. worker_servers is an array. Each array element contains the following fields:

- host: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- ssh_port: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the ssh_port in the global section is used.

- `name`: specifies the name of the DM-worker instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- `port`: specifies the port on which DM-worker provides services. The default value is "8262".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: the configuration rules of this field are the same as that of `worker` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `worker` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `worker_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `name`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `worker_servers` configuration example is as follows:

```
worker_servers:
  - host: 10.0.1.12
    ssh_port: 22
    port: 8262
    deploy_dir: "/dm-deploy/dm-worker-8262"
    log_dir: "/dm-deploy/dm-worker-8262/log"
    numa_node: "0,1"
    # config is used to overwrite the `server_configs.worker` values
    config:
      log-level: info
  - host: 10.0.1.19
```

13.4.9.3.1 `monitoring_servers`

`monitoring_servers` specifies the machines to which the Prometheus service is deployed. You can also specify the service configuration on the machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Prometheus provides services. The default value is "9090".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1"
- `storage_retention`: specifies the retention time of the Prometheus monitoring data. The default value is "15d".
- `rule_dir`: specifies a local directory where the complete `*.rules.yml` files are located. The files in the specified directory will be sent to the target machine as the Prometheus rules during the initialization phase of the cluster configuration.

- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
    - `remote_write`: See the Prometheus document `<remote_write>`.
    - `remote_read`: See the Prometheus document `<remote_read>`.
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `monitoring_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:
  - host: 10.0.1.11
    rule_dir: /local/rule/dir
    remote_config:
      remote_write:
      - queue_config:
          batch_send_deadline: 5m
          capacity: 100000
          max_samples_per_send: 10000
          max_shards: 300
        url: http://127.0.0.1:8003/write
      remote_read:
```

```
  - url: http://127.0.0.1:8003/read\
  external_alertmanagers:
  - host: 10.1.1.1
  web_port: 9093
  - host: 10.1.1.2
  web_port: 9094
```

13.4.9.3.2 grafana_servers

`grafana_servers` specifies the machines to which the Grafana service is deployed. You can also specify the service configuration on the machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Grafana provides services. The default value is "3000".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy ↪ _dir` configuration in the `global` section.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `username`: specifies the username of the Grafana login screen.
- `password`: specifies the corresponding password of Grafana.
- `dashboard_dir`: specifies a local directory where the complete `dashboard(*.json)` files are located. The files in the specified directory will be sent to the target machine as Grafana dashboards during the initialization phase of the cluster configuration.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

> **Note:**
>
> If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. In the local `dashboards` directory, update the value of the `datasource` field to the new cluster name (the `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

In `grafana_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:
  - host: 10.0.1.11
    dashboard_dir: /local/dashboard/dir
```

13.4.9.3.3 `alertmanager_servers`

`alertmanager_servers` specifies the machines to which the Alertmanager service is deployed. You can also specify the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `web_port`: specify the port on which Alertmanager provides web services. The default value is "9093".
- `cluster_port`: Specify the communication port between one Alertmanger and other Alertmanager. The default value is "9094".
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.

- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is a string type. The field value is the ID of the NUMA node, such as "0,1"
- `config_file`: specifies a local file. The specified file will be sent to the target machine as the configuration for Alertmanager during the initialization phase of the cluster configuration.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of systemd is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In `alertmanager_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

An `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
  - host: 10.0.1.11
    config_file: /local/config/file
  - host: 10.0.1.12
    config_file: /local/config/file
```

13.4.10 TiUP Mirror Reference Guide

TiUP mirrors are TiUP's component warehouse, which stores components and their metadata. TiUP mirrors take the following two forms:

- Directory on the local disk: serves the local TiUP client, which is called a local mirror in this document.

- HTTP mirror started based on the remote disk directory: serves the remote TiUP client, which is called a remote mirror in this document.

13.4.10.1 Create and update mirror

You can create a TiUP mirror using one of the following two methods:

- Execute `tiup mirror init` to create a mirror from scratch.
- Execute `tiup mirror clone` to clone from an existing mirror.

After the mirror is created, you can add components to or delete components from the mirror using the `tiup mirror` commands. TiUP updates a mirror by adding files and assigning a new version number to it, rather than deleting any files from the mirror.

13.4.10.2 Mirror structure

A typical mirror structure is as follows:

```
+ <mirror-dir>                                  # Mirror's root directory
|-- root.json                                   # Mirror's root certificate
|-- {2..N}.root.json                            # Mirror's root certificate
|-- {1..N}.index.json                           # Component/user index
|-- {1..N}.{component}.json                     # Component metadata
|-- {component}-{version}-{os}-{arch}.tar.gz # Component binary package
|-- snapshot.json                               # Mirror's latest snapshot
|-- timestamp.json                              # Mirror's latest timestamp
|--+ commits                                    # Mirror's update log (deletable)
   |--+ commit-{ts1..tsN}
      |-- {N}.root.json
      |-- {N}.{component}.json
      |-- {N}.index.json
      |-- {component}-{version}-{os}-{arch}.tar.gz
      |-- snapshot.json
      |-- timestamp.json
|--+ keys                                       # Mirror's private key (can be
   ↪ moved to other locations)
   |-- {hash1..hashN}-root.json                 # Private key of the root
      ↪ certificate
   |-- {hash}-index.json                        # Private key of the indexes
   |-- {hash}-snapshot.json                     # Private key of the snapshots
   |-- {hash}-timestamp.json                    # Private key of the timestamps
```

Note:

- The `commits` directory stores the logs generated in the process of mirror update and is used to roll back the mirror. You can delete the old log directories regularly when the disk space is insufficient.
- The private key stored in the `keys` directory is sensitive. It is recommended to keep it separately.

13.4.10.2.1 Root directory

In a TiUP mirror, the root certificate is used to store the public key of other metadata files. Each time any metadata file (`*.json`) is obtained, TiUP client needs to find the corresponding public key in the installed `root.json` based on the metadata file type (root, index, snapshot, timestamp). Then TiUP client uses the public key to verify whether the signature is valid.

The root certificate's format is as follows:

```
{
    "signatures": [                                     # Each metadata file
        ↪  has some signatures which are signed by several private keys
        ↪ corresponding to the file.
        {
            "keyid": "{id-of-root-key-1}",              # The ID of the
                ↪ first private key that participates in the signature. This
                ↪ ID is obtained by hashing the content of the public key
                ↪ that corresponds to the private key.
            "sig": "{signature-by-root-key-1}"          # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",              # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"          # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {                                         # The signed part.
        "_type": "root",                                # The type of this
            ↪ file. root.json's type is root.
        "expires": "{expiration-date-of-this-file}",    # The expiration
            ↪ time of the file. If the file expires, the client rejects the
            ↪ file.
        "roles": {                                      # Records the keys
            ↪ used to sign each metadata file.
```

```
        "{role:index,root,snapshot,timestamp}": {     # Each involved
            ↪ metadata file includes index, root, snapshot, and timestamp
            ↪ .
            "keys": {                                 # Only the key's
                ↪ signature recorded in `keys` is valid.
                "{id-of-the-key-1}": {                # The ID of the
                    ↪ first key used to sign {role}.

                }
            },
            "threshold": {N},                         # Indicates that the
                ↪  metadata file needs at least N key signatures.
            "url": "/{role}.json"                     # The address from
                ↪ which the file can be obtained. For index files, prefix
                ↪  it with the version number (for example, /{N}.index.
                ↪ json).
        }
    },
    "spec_version": "0.1.0",                          # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": {N}                                    # The version number
        ↪  of this file. You need to create a new {N+1}.root.json every
        ↪ time you update the file, and set its version to N + 1.
  }
}
```

13.4.10.2.2 Index

The index file records all the components in the mirror and the owner information of the components.

The index file's format is as follows:

```
{
    "signatures": [                                         # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                 # The ID of the
                ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",            # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "index",                                   # The file type.
        "components": {                                     # The component list
            ↪ .
            "{component1}": {                               # The name of the
                ↪ first component.
                "hidden": {bool},                           # Whether it is a
                    ↪ hidden component.
                "owner": "{owner-id}",                      # The component
                    ↪ owner's ID.
                "standalone": {bool},                       # Whether it is a
                    ↪ standalone component.
                "url": "/{component}.json",                 # The address from
                    ↪ which the component can be obtained. You need to prefix
                    ↪  it with the version number (for example, /{N}.{
                    ↪ component}.json).
                "yanked": {bool}                            # Indicates whether

            },
            ...
            "{componentN}": {                               # The name of the
                ↪ Nth component.
                ...
            },
```

```
},
"default_components": ["{component1}".."{componentN}"], # The default
    ↪  component that a mirror must contain. Currently, this field
    ↪ defaults to empty (disabled).
"expires": "{expiration-date-of-this-file}",     # The expiration
    ↪ time of the file. If the file expires, the client rejects the
    ↪ file.
"owners": {
    "{owner1}": {                                # The ID of the
        ↪ first owner.
        "keys": {                                # Only the key's
            ↪ signature recorded in `keys` is valid.
            "{id-of-the-key-1}": {               # The first key of
                ↪ the owner.
                "keytype": "rsa",                # The key's type.
                    ↪ Currently, the key type is fixed as rsa.
                "keyval": {                      # The key's payload.
                    "public": "{public-key-content}" # The public key's
                        ↪  content.
                },
                "scheme": "rsassa-pss-sha256"    # Currently, the
                    ↪ scheme is fixed as rsassa-pss-sha256.
            },
            ...
            "{id-of-the-key-N}": {               # The Nth key of the
                ↪  owner.
                ...
            }
        },
        "name": "{owner-name}",                  # The name of the
            ↪ owner.
        "threshold": {N}                          # Indicates that
            ↪ the components owned by the owner must have at least N
            ↪ valid signatures.
    },
    ...
    "{ownerN}": {                                # The ID of the Nth
        ↪ owner.
        ...
    }
}
"spec_version": "0.1.0",                         # The specified
    ↪ version followed by this file. If the file structure is
    ↪ changed in the future, the version number needs to be upgraded
    ↪ . The current version number is 0.1.0.
```

```
        "version": {N}                                      # The version number
           ↪  of this file. You need to create a new {N+1}.index.json every
           ↪  time you update the file, and set its version to N + 1.
    }
}
```

13.4.10.2.3 Component

The component's metadata file records information of the component-specific platform and the version.

The component metadata file's format is as follows:

```
{
    "signatures": [                                         # The file's
       ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                 # The ID of the
               ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",            # The signed part of
               ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
               ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
               ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "component",                               # The file type.
        "description": "{description-of-the-component}", # The description of
           ↪  the component.
        "expires": "{expiration-date-of-this-file}",        # The expiration
           ↪ time of the file. If the file expires, the client rejects the
           ↪ file.
        "id": "{component-id}",                             # The globally
           ↪ unique ID of the component.
        "nightly": "{nightly-cursor}",                      # The nightly cursor
           ↪ , and the value is the latest nightly version number (for
           ↪ example, v5.0.0-nightly-20201209).
        "platforms": {                                      # The component's
           ↪ supported platforms (such as darwin/amd64, linux/arm64).
           "{platform-pair-1}": {
```

```
            "{version-1}": {                          # The semantic
                ↪ version number (for example, v1.0.0).
                "dependencies": null,                 # Specifies the
                    ↪ dependency relationship between components. The
                    ↪ field is not used yet and is fixed as null.
                "entry": "{entry}",                   # The relative path
                    ↪ of the entry binary file in the tar package.
                "hashs": {                            # The checksum of
                    ↪ the tar package. sha256 and sha512 are used.
                    "sha256": "{sum-of-sha256}",
                    "sha512": "{sum-of-sha512}",
                },
                "length": {length-of-tar},            # The length of the
                    ↪ tar package.
                "released": "{release-time}",         # The release date
                    ↪ of the version.
                "url": "{url-of-tar}",                # The download
                    ↪ address of the tar package.
                "yanked": {bool}                      # Indicates whether
                    ↪ this version is disabled.
            }
        },
        ...
        "{platform-pair-N}": {
            ...
        }
    },
    "spec_version": "0.1.0",                          # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": {N}                                    # The version number
        ↪  of this file. You need to create a new {N+1}.{component}.json
        ↪  every time you update the file, and set its version to N + 1.
}
```

13.4.10.2.4 Snapshot

The snapshot file records the version number of each metadata file:

The snapshot file's structure is as follows:

```
{
    "signatures": [                                   # The file's
        ↪ signature.
        {
```

```
        "keyid": "{id-of-index-key-1}",                 # The ID of the
            ↪ first private key that participates in the signature.
        "sig": "{signature-by-index-key-1}",            # The signed part of
            ↪  this file by this private key.
    },
    ...
    {
        "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
            ↪ private key that participates in the signature.
        "sig": "{signature-by-root-key-N}"              # The signed part of
            ↪  this file by this private key.
    }
],
"signed": {
    "_type": "snapshot",                                # The file type.
    "expires": "{expiration-date-of-this-file}",        # The expiration
        ↪ time of the file. If the file expires, the client rejects the
        ↪ file.
    "meta": {                                           # Other metadata
        ↪ files' information.
        "/root.json": {
            "length": {length-of-json-file},            # The length of root
                ↪ .json
            "version": {version-of-json-file}           # The version of
                ↪ root.json
        },
        "/index.json": {
            "length": {length-of-json-file},
            "version": {version-of-json-file}
        },
        "/{component-1}.json": {
            "length": {length-of-json-file},
            "version": {version-of-json-file}
        },
        ...
        "/{component-N}.json": {
            ...
        }
    },
    "spec_version": "0.1.0",                            # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": 0                                        # The version number
        ↪  of this file, which is fixed as 0.
```

```
    }
```

13.4.10.2.5 Timestamp

The timestamp file records the checksum of the current snapshot.

The timestamp file's format is as follows:

```
{
    "signatures": [                                         # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                 # The ID of the
                ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",            # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "timestamp",                               # The file type.
        "expires": "{expiration-date-of-this-file}",        # The expiration
            ↪ time of the file. If the file expires, the client rejects the
            ↪ file.
        "meta": {                                           # The information of
            ↪  snapshot.json.
            "/snapshot.json": {
                "hashes": {
                    "sha256": "{sum-of-sha256}"             # snapshot.json's
                        ↪ sha256.
                },
                "length": {length-of-json-file}             # The length of
                    ↪ snapshot.json.
            }
        },
        "spec_version": "0.1.0",                            # The specified
            ↪ version followed by this file. If the file structure is
            ↪ changed in the future, the version number needs to be upgraded
            ↪ . The current version number is 0.1.0.
```

```
    "version": {N}                                          # The version number
       ↪ of this file. You need to overwrite timestamp.json every time
       ↪ you update the file, and set its version to N + 1.
```

13.4.10.3 Client workflow

The client uses the following logic to ensure that the files downloaded from the mirror are safe:

- A `root.json` file is included with the binary when the client is installed.
- The running client performs the following tasks based on the existing `root.json`:
    1. Obtain the version from `root.json` and mark it as `N`.
    2. Request `{N+1}.root.json` from the mirror. If the request is successful, use the public key recorded in `root.json` to verify whether the file is valid.
    3. Request `timestamp.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
    4. Check whether the checksum of `snapshot.json` recorded in `timestamp.json` matches the checksum of the local `snapshot.json`. If the two do not match, request the latest `snapshot.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
    5. Obtain the version number `N` of the `index.json` file from `snapshot.json` and request `{N}.index.json` from the mirror. Then use the public key recorded in `root.json` to verify whether the file is valid.
    6. For components such as `tidb.json` and `tikv.json`, the client obtains the version numbers `N` of the components from `snapshot.json` and requests `{N}.{component ↪ }.json` from the mirror. Then the client uses the public key recorded in `index.json` to verify whether the file is valid.
    7. For component's tar files, the client obtains the URLs and checksums of the files from `{component}.json` and request the URLs for the tar packages. Then the client verifies whether the checksum is correct.

13.4.11 TiUP Components

13.4.11.1 Quickly Deploy a Local TiDB Cluster

The TiDB cluster is a distributed system that consists of multiple components. A typical TiDB cluster consists of at least three PD nodes, three TiKV nodes, and two TiDB nodes. If you want to have a quick experience on TiDB, you might find it time-consuming and complicated to manually deploy so many components. This document introduces the playground component of TiUP and how to use it to quickly build a local TiDB test environment.

13.4.11.1.1 TiUP playground overview

The basic usage of the playground component is shown as follows:

```
tiup playground ${version} [flags]
```

If you directly execute the `tiup playground` command, TiUP uses the locally installed TiDB, TiKV, and PD components or installs the stable version of these components to start a TiDB cluster that consists of one TiKV instance, one TiDB instance, one PD instance, and one TiFlash instance.

This command actually performs the following operations:

- Because this command does not specify the version of the playground component, TiUP first checks the latest version of the installed playground component. Assume that the latest version is v1.12.3, then this command works the same as `tiup playground:v1.12.3`.
- If you have not used TiUP playground to install the TiDB, TiKV, and PD components, the playground component installs the latest stable version of these components, and then start these instances.
- Because this command does not specify the version of the TiDB, PD, and TiKV component, TiUP playground uses the latest version of each component by default. Assume that the latest version is v8.4.0, then this command works the same as `tiup playground:v1.12.3 v8.4.0`.
- Because this command does not specify the number of each component, TiUP playground, by default, starts a smallest cluster that consists of one TiDB instance, one TiKV instance, one PD instance, and one TiFlash instance.
- After starting each TiDB component, TiUP playground reminds you that the cluster is successfully started and provides you some useful information, such as how to connect to the TiDB cluster through the MySQL client and how to access the TiDB Dashboard.

You can use the following command to view the command-line flags of the playground component:

```
tiup playground --help
```

13.4.11.1.2 Examples

Check available TiDB versions

```
tiup list tidb
```

Start a TiDB cluster of a specific version

```
tiup playground ${version}
```

Replace `${version}` with the target version number.

Start a TiDB cluster of the nightly version

```
tiup playground nightly
```

In the command above, `nightly` indicates the latest development version of TiDB.

Override PD's default configuration

First, you need to copy the PD configuration template. Assume you place the copied file to `~/config/pd.toml` and make some changes according to your need, then you can execute the following command to override PD's default configuration:

```
tiup playground --pd.config ~/config/pd.toml
```

Replace the default binary files

By default, when playground is started, each component is started using the binary files from the official mirror. If you want to put a temporarily compiled local binary file into the cluster for testing, you can use the `--{comp}.binpath` flag for replacement. For example, execute the following command to replace the binary file of TiDB:

```
tiup playground --db.binpath /xx/tidb-server
```

Start multiple component instances

By default, only one instance is started for each TiDB, TiKV, and PD component. To start multiple instances for each component, add the following flag:

```
tiup playground --db 3 --pd 3 --kv 3
```

Specify a tag when starting the TiDB cluster to store the data

After you stop a TiDB cluster started using TiUP playground, all cluster data is cleaned up as well. To start a TiDB cluster using TiUP playground and ensure that the cluster data is not cleaned up automatically, you can specify a tag when starting the cluster. After specifying the tag, you can find the cluster data in the `~/.tiup/data` directory. Run the following command to specify a tag:

```
tiup playground --tag ${tag_name}
```

For a cluster started in this way, the data files are retained after the cluster is stopped. You can use this tag to start the cluster next time so that you can use the data kept since the cluster was stopped.

13.4.11.1.3 Quickly connect to the TiDB cluster started by playground

TiUP provides the `client` component, which is used to automatically find and connect to a local TiDB cluster started by playground. The usage is as follows:

```
tiup client
```

This command provides a list of TiDB clusters that are started by playground on the current machine on the console. Select the TiDB cluster to be connected. After clicking Enter, a built-in MySQL client is opened to connect to TiDB.

13.4.11.1.4 View information of the started cluster

```
tiup playground display
```

The command above returns the following results:

```
Pid   Role    Uptime
---   ----    ------
84518 pd      35m22.929404512s
84519 tikv    35m22.927757153s
86189 tidb    exited
86526 tidb    34m28.293148663s
```

13.4.11.1.5 Scale out a cluster

The command-line parameter for scaling out a cluster is similar to that for starting a cluster. You can scale out two TiDB instances by executing the following command:

```
tiup playground scale-out --db 2
```

13.4.11.1.6 Scale in a cluster

You can specify a `pid` in the `tiup playground scale-in` command to scale in the corresponding instance. To view the `pid`, execute `tiup playground display`.

```
tiup playground scale-in --pid 86526
```

13.4.11.1.7 Deploy PD microservices

Starting from v8.2.0, PD microservice mode (experimental) can be deployed using TiUP. You can deploy the `tso` microservice and `scheduling` microservice for your cluster using TiUP Playground as follows:

```
tiup playground v8.4.0 --pd.mode ms --pd 3 --tso 2 --scheduling 2
```

- `--pd.mode`: setting it to `ms` means enabling the microservice mode for PD.
- `--pd <num>`: specifies the number of APIs for PD microservices. It must be at least `1`.
- `--tso <num>`: specifies the number of instances to be deployed for the `tso` microservice.
- `--scheduling <num>`: specifies the number of instances to be deployed for the `scheduling` microservice.

13.4.11.2 Deploy and Maintain an Online TiDB Cluster Using TiUP

This document focuses on how to use the TiUP cluster component. For the complete steps of online deployment, refer to Deploy a TiDB Cluster Using TiUP.

Similar to the TiUP playground component used for a local test deployment, the TiUP cluster component quickly deploys TiDB for production environment. Compared with playground, the cluster component provides more powerful production cluster management features, including upgrading, scaling, and even operation and auditing.

For the help information of the cluster component, run the following command:

```
tiup cluster
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.12.3/
    ↪ cluster
Deploy a TiDB cluster for production

Usage:
  tiup cluster [command]

Available Commands:
  check       Precheck a cluster
  deploy      Deploy a cluster for production
  start       Start a TiDB cluster
  stop        Stop a TiDB cluster
  restart     Restart a TiDB cluster
  scale-in    Scale in a TiDB cluster
  scale-out   Scale out a TiDB cluster
  destroy     Destroy a specified cluster
  clean       (Experimental) Clean up a specified cluster
  upgrade     Upgrade a specified TiDB cluster
  display     Display information of a TiDB cluster
  list        List all clusters
  audit       Show audit log of cluster operation
  import      Import an existing TiDB cluster from TiDB-Ansible
  edit-config Edit TiDB cluster config
  reload      Reload a TiDB cluster's config and restart if needed
  patch       Replace the remote package with a specified package and restart
     ↪  the service
  help        Help about any command

Flags:
  -c, --concurrency int  Maximum number of concurrent tasks allowed (
     ↪ defaults to `5`)
      --format string    (EXPERIMENTAL) The format of output, available
         ↪ values are [default, json] (default "default")
```

```
  -h, --help              help for tiup
      --ssh string        (Experimental) The executor type. Optional values
         ↪ are 'builtin', 'system', and 'none'.
      --ssh-timeout uint Timeout in seconds to connect a host via SSH.
         ↪ Operations that don't need an SSH connection are ignored. (
         ↪ default 5)
  -v, --version         TiUP version
      --wait-timeout uint Timeout in seconds to wait for an operation to
         ↪ complete. Inapplicable operations are ignored. (defaults to
         ↪ `120`)
  -y, --yes               Skip all confirmations and assumes 'yes'
```

13.4.11.2.1 Deploy the cluster

To deploy the cluster, run the `tiup cluster deploy` command. The usage of the command is as follows:

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

This command requires you to provide the cluster name, the TiDB cluster version (such as `v8.4.0`), and a topology file of the cluster.

To write a topology file, refer to the example. The following file is an example of the simplest topology:

> **Note:**
>
> The topology file used by the TiUP cluster component for deployment and scaling is written using yaml syntax, so make sure that the indentation is correct.

```
---

pd_servers:
  - host: 172.16.5.134
    name: pd-134
  - host: 172.16.5.139
    name: pd-139
  - host: 172.16.5.140
    name: pd-140

tidb_servers:
  - host: 172.16.5.134
```

```
  - host: 172.16.5.139
  - host: 172.16.5.140

tikv_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

tiflash_servers:
  - host: 172.16.5.141
  - host: 172.16.5.142
  - host: 172.16.5.143

tiproxy_servers:
  - host: 172.16.5.144

grafana_servers:
  - host: 172.16.5.134

monitoring_servers:
  - host: 172.16.5.134
```

By default, TiUP is deployed as the binary files running on the amd64 architecture. If the target machine is the arm64 architecture, you can configure it in the topology file:

```
global:
  arch: "arm64"        # Configures all machines to use the binary files of
     ↪ the arm64 architecture by default

tidb_servers:
  - host: 172.16.5.134
    arch: "amd64"      # Configures this machine to use the binary files of
       ↪ the amd64 architecture
  - host: 172.16.5.139
    arch: "arm64"      # Configures this machine to use the binary files of
       ↪ the arm64 architecture
  - host: 172.16.5.140 # Machines that are not configured with the arch
     ↪ field use the default value in the global field, which is arm64 in
     ↪ this case.

...
```

Save the file as `/tmp/topology.yaml`. If you want to use TiDB v8.4.0 and your cluster name is `prod-cluster`, run the following command:

```
tiup cluster deploy -p prod-cluster v8.4.0 /tmp/topology.yaml
```

During the execution, TiUP asks you to confirm your topology again and requires the root password of the target machine (the `-p` flag means inputting password):

```
Please confirm your topology:
TiDB Cluster: prod-cluster
TiDB Version: v8.4.0
Type       Host         Ports                          OS/Arch      Directories

    2. Please confirm there is no port/directory conflicts in same host.
Do you want to continue? [y/N]:
```

After you enter the password, TiUP cluster downloads the required components and deploy them on the corresponding machines. When you see the following message, the deployment is successful:

```
Deployed cluster `prod-cluster` successfully
```

13.4.11.2.2 View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup cluster list
```

```
Starting /root/.tiup/components/cluster/v1.12.3/cluster list
Name         User Version   Path
   ↪ PrivateKey
----         ---- -------   ----
   ↪ ----------
prod-cluster tidb v8.4.0  /root/.tiup/storage/cluster/clusters/prod-cluster
   ↪  /root/.tiup/storage/cluster/clusters/prod-cluster/ssh/id_rsa
```

13.4.11.2.3 Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup cluster start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup cluster ↪ list`.

TiUP uses `systemd` to start a daemon process. If the process terminates unexpectedly, it will be pulled up after 15 seconds.

13.4.11.2.4 Check the cluster status

TiUP provides the `tiup cluster display` command to view the status of each component in the cluster. With this command, you don't have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.12.3/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v8.4.0
ID               Role       Host         Ports                          OS/
   ↪ Arch     Status Data Dir           Deploy Dir
--               ----       ----         -----
   ↪ -------     ------ --------           ----------
```

```

```

The `Status` column uses `Up` or `Down` to indicate whether the service is running normally.

For the PD component, `|L` or `|UI` might be appended to `Up` or `Down`. `|L` indicates that the PD node is a Leader, and `|UI` indicates that TiDB Dashboard is running on the PD node.

13.4.11.2.5 Scale in a cluster

> **Note:**
>
> This section describes only the syntax of the scale-in command. For detailed steps of online scaling, refer to Scale a TiDB Cluster Using TiUP.

Scaling in a cluster means making some node(s) offline. This operation removes the specific node(s) from the cluster and deletes the remaining files.

Because the offline process of the TiKV and TiFlash components is asynchronous (which requires removing the node through API), and the process takes a long time (which requires continuous observation on whether the node is successfully taken offline), special treatment is given to the TiKV and TiFlash components.

- For TiKV and TiFlash:
    - TiUP cluster takes the node offline through API and directly exits without waiting for the process to be completed.
    - Afterwards, when a command related to the cluster operation is executed, TiUP cluster examines whether there is a TiKV or TiFlash node that has been taken offline. If not, TiUP cluster continues with the specified operation; If there is, TiUP cluster takes the following steps:
        1. Stop the service of the node that has been taken offline.
        2. Clean up the data files related to the node.
        3. Remove the node from the cluster topology.
- For other components:
    - When taking the PD component down, TiUP cluster quickly deletes the specified node from the cluster through API, stops the service of the specified PD node, and deletes the related data files.
    - When taking other components down, TiUP cluster directly stops the node service and deletes the related data files.

The basic usage of the scale-in command:

```
tiup cluster scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two flags: the cluster name and the node ID. The node ID can be obtained by using the `tiup cluster display` command in the previous section.

For example, to make the TiKV node on `172.16.5.140` offline, run the following command:

```
tiup cluster scale-in prod-cluster -N 172.16.5.140:20160
```

By running `tiup cluster display`, you can see that the TiKV node is marked `Offline`:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.12.3/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v8.4.0
ID                  Role       Host         Ports                            OS/

```

After PD schedules the data on the node to other TiKV nodes, this node will be deleted automatically.

13.4.11.2.6 Scale out a cluster

> **Note:**
>
> This section describes only the syntax of the scale-out command. For detailed steps of online scaling, refer to Scale a TiDB Cluster Using TiUP.

The scale-out operation has an inner logic similar to that of deployment: the TiUP cluster component firstly ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

When you scale out PD, the node is added to the cluster by `join`, and the configurations of services associated with PD are updated. When you scale out other services, the service is started directly and added to the cluster.

All services conduct correctness validation when they are scaled out. The validation results show whether the scaling-out is successful.

To add a TiKV node and a PD node in the `tidb-test` cluster, take the following steps:

1. Create a `scale.yaml` file, and add IPs of the new TiKV and PD nodes:

> **Note:**
>
> You need to create a topology file, which includes only the description of the new nodes, not the existing nodes.

```
---

pd_servers:
  - host: 172.16.5.140

tikv_servers:
  - host: 172.16.5.140
```

2. Perform the scale-out operation. TiUP cluster adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup cluster scale-out tidb-test scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup cluster display tidb-test`.

13.4.11.2.7 Rolling upgrade

> **Note:**
>
> This section describes only the syntax of the upgrade command. For detailed steps of online upgrade, refer to Upgrade TiDB Using TiUP.

The rolling upgrade feature leverages the distributed capabilities of TiDB. The upgrade process is made as transparent as possible to the application, and does not affect the business.

Before the upgrade, TiUP cluster checks whether the configuration file of each component is rational. If so, the components are upgraded node by node; if not, TiUP reports an error and exits. The operations vary with different nodes.

Operations for different nodes

- Upgrade the PD node
  - First, upgrade non-Leader nodes.
  - After all the non-Leader nodes are upgraded, upgrade the Leader node.
    - The upgrade tool sends a command to PD that migrates Leader to an already upgraded node.
    - After the Leader role is switched to another node, upgrade the previous Leader node.
  - During the upgrade, if any unhealthy node is detected, the tool stops this upgrade operation and exits. You need to manually analyze the cause, fix the issue and run the upgrade again.
- Upgrade the TiKV node
  - First, add a scheduling operation in PD that migrates the Region Leader of this TiKV node. This ensures that the upgrade process does not affect the business.
  - After the Leader is migrated, upgrade this TiKV node.
  - After the upgraded TiKV is started normally, remove the scheduling of the Leader.
- Upgrade other services
  - Stop the service normally and update the node.

Upgrade command

The flags for the upgrade command is as follows:

```
Usage:
  cluster upgrade <cluster-name> <version> [flags]

Flags:
      --force                Force upgrade won't transfer leader
  -h, --help                 help for upgrade
      --transfer-timeout int Timeout in seconds when transferring PD and
          ↪ TiKV store leaders (default 600)

Global Flags:
      --ssh string       (Experimental) The executor type. Optional values
          ↪ are 'builtin', 'system', and 'none'.
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes              Skip all confirmations and assumes 'yes'
```

For example, the following command upgrades the cluster to v8.4.0:

```
tiup cluster upgrade tidb-test v8.4.0
```

13.4.11.2.8 Update configuration

If you want to dynamically update the component configurations, the TiUP cluster component saves a current configuration for each cluster. To edit this configuration, execute the `tiup cluster edit-config <cluster-name>` command. For example:

```
tiup cluster edit-config prod-cluster
```

TiUP cluster opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano`.

After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup cluster reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

> **Note:**
>
> For monitoring components, customize the configuration by executing the `tiup cluster edit-config` command to add a custom configuration path on the corresponding instance. For example:

```
---

grafana_servers:
  - host: 172.16.5.134
    dashboard_dir: /path/to/local/dashboards/dir

monitoring_servers:
  - host: 172.16.5.134
    rule_dir: /path/to/local/rules/dir

alertmanager_servers:
  - host: 172.16.5.134
    config_file: /path/to/local/alertmanager.yml
```

The content and format requirements for files under the specified path are as follows:

- The folder specified in the `dashboard_dir` field of `grafana_servers` must contain full `*.json` files.
- The folder specified in the `rule_dir` field of `monitoring_servers` must contain full `*.rules.yml` files.
- For the format of files specified in the `config_file` field of `alertmanager_servers`, refer to the Alertmanager configuration template.

When you execute `tiup reload`, TiUP first deletes all old configuration files in the target machine and then uploads the corresponding configuration from the control machine to the corresponding configuration directory of the target machine. Therefore, if you want to modify a particular configuration file, make sure that all configuration files (including the unmodified ones) are in the same directory. For example, to modify Grafana's `tidb.json` file, you need to first copy all the `*.json` files from Grafana's `dashboards` directory to your local directory. Otherwise, other JSON files will be missing from the target machine.

Note:

If you have configured the `dashboard_dir` field of `grafana_servers`, after executing the `tiup cluster rename` command to rename the cluster, you need to complete the following operations:

1. In the local `dashboards` directory, change the cluster name to the new cluster name.
2. In the local `dashboards` directory, change `datasource` to the new cluster name, because `datasource` is named after the cluster name.
3. Execute the `tiup cluster reload -R grafana` command.

13.4.11.2.9 Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  cluster patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --offline             Patch a stopped cluster
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the roles
      --transfer-timeout uint Timeout in seconds when transferring PD and
          ↪ TiKV store leaders, also for TiCDC drain one capture (default
          ↪ 600)

Global Flags:
  -c, --concurrency int  max number of parallel tasks allowed (default 5)
      --format string    (EXPERIMENTAL) The format of output, available
          ↪ values are [default, json] (default "default")
      --ssh string       (EXPERIMENTAL) The executor type: 'builtin', '
          ↪ system', 'none'.
      --ssh-timeout uint Timeout in seconds to connect host via SSH, ignored
          ↪  for operations that don't need an SSH connection. (default 5)
      --wait-timeout uint Timeout in seconds to wait for an operation to
          ↪ complete, ignored for operations that don't fit. (default 120)
  -y, --yes              Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

13.4.11.2.10 Import TiDB Ansible cluster

> **Note:**
>
> Currently, TiUP cluster's support for TiSpark is still **experimental**. It is not supported to import a TiDB cluster with TiSpark enabled.

Before TiUP is released, TiDB Ansible is often used to deploy TiDB clusters. To enable TiUP to take over the cluster deployed by TiDB Ansible, use the `import` command.

The usage of the `import` command is as follows:

```
tiup cluster import --help
```

```
Import an exist TiDB cluster from TiDB-Ansible

Usage:
  cluster import [flags]

Flags:
  -d, --dir string      The path to TiDB-Ansible directory
  -h, --help            help for import
      --inventory string The name of inventory file (default "inventory.ini
         ↪ ")
      --no-backup       Don't backup ansible dir, useful when there're
         ↪ multiple inventory files
  -r, --rename NAME     Rename the imported cluster to NAME

Global Flags:
      --ssh string      (Experimental) The executor type. Optional values are
         ↪  'builtin', 'system', and 'none'.
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

You can use either of the following commands to import a TiDB Ansible cluster:

```
cd tidb-ansible
tiup cluster import
```

```
tiup cluster import --dir=/path/to/tidb-ansible
```

13.4.11.2.11 View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
  tiup cluster audit [audit-id] [flags]

Flags:
  -h, --help help for audit
```

If the `[audit-id]` flag is not specified, the command shows a list of commands that have been executed. For example:

```
tiup cluster audit
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.12.3/
    ↪ cluster audit
ID     Time                       Command
--     ----                       -------
4BLhr0 2024-11-11T23:55:09+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .12.3/cluster deploy test v8.4.0 /tmp/topology.yaml
4BKWjF 2024-11-11T23:36:57+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .12.3/cluster deploy test v8.4.0 /tmp/topology.yaml
4BKVwH 2024-11-11T23:02:08+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .12.3/cluster deploy test v8.4.0 /tmp/topology.yaml
4BKKH1 2024-11-11T16:39:04+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .12.3/cluster destroy test
4BKKDx 2024-11-11T16:36:57+08:00 /home/tidb/.tiup/components/cluster/v1
    ↪ .12.3/cluster deploy test v8.4.0 /tmp/topology.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` of a command as the flag as follows:

```
tiup cluster audit 4BLhr0
```

13.4.11.2.12 Run commands on a host in the TiDB cluster

To run command on a host in the TiDB cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
  cluster exec <cluster-name> [flags]

Flags:
      --command string the command run on cluster host (default "ls")
  -h, --help           help for exec
```

```
  -N, --node strings  Only exec on host with specified nodes
  -R, --role strings  Only exec on host with specified roles
      --sudo          use root permissions (default false)

Global Flags:
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes            Skip all confirmations and assumes 'yes'
```

For example, to execute `ls /tmp` on all TiDB nodes, run the following command:

```
tiup cluster exec test-cluster --command='ls /tmp'
```

13.4.11.2.13 Cluster controllers

Before TiUP is released, you can control the cluster using `tidb-ctl`, `tikv-ctl`, `pd-ctl`, and other tools. To make the tools easier to download and use, TiUP integrates them into an all-in-one component, `ctl`.

```
Usage:
  tiup ctl:v<CLUSTER_VERSION> {tidb/pd/tikv/etcd} [flags]

Flags:
  -h, --help help for tiup
```

This command has a corresponding relationship with those of the previous tools:

```
tidb-ctl [args] = tiup ctl tidb [args]
pd-ctl [args] = tiup ctl pd [args]
tikv-ctl [args] = tiup ctl tikv [args]
etcdctl [args] = tiup ctl etcd [args]
```

For example, if you previously view the store by running `pd-ctl -u http://127.0.0.1:2379 store`, now you can run the following command in TiUP:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://127.0.0.1:2379 store
```

13.4.11.2.14 Environment checks for target machines

You can use the `check` command to perform a series of checks on the environment of the target machine and output the check results. By executing the `check` command, you can find common unreasonable configurations or unsupported situations. The command flag list is as follows:

```
Usage:
  tiup cluster check <topology.yml | cluster-name> [flags]
Flags:
```

```
      --apply                Try to fix failed checks
      --cluster              Check existing cluster, the input is a cluster
         ↪ name.
      --enable-cpu           Enable CPU thread count check
      --enable-disk          Enable disk IO (fio) check
      --enable-mem           Enable memory size check
  -h, --help                 help for check
  -i, --identity_file string The path of the SSH identity file. If specified
     ↪ , public key authentication will be used.
  -p, --password             Use password of target hosts. If specified,
     ↪ password authentication will be used.
      --user string          The user name to login via SSH. The user must
         ↪ has root (or sudo) privilege.
```

By default, this command is used to check the environment before deployment. By specifying the `--cluster` flag to switch the mode, you can also check the target machines of an existing cluster, for example:

```
#### check deployed servers before deployment
tiup cluster check topology.yml --user tidb -p
#### check deployed servers of an existing cluster
tiup cluster check <cluster-name> --cluster
```

The CPU thread count check, memory size check, and disk performance check are disabled by default. For the production environment, it is recommended that you enable the three checks and make sure they pass to obtain the best performance.

- CPU: If the number of threads is greater than or equal to 16, the check is passed.
- Memory: If the total size of physical memory is greater than or equal to 32 GB, the check is passed.
- Disk: Execute `fio` test on the partitions of `data_dir` and record the results.

When running the checks, if the `--apply` flag is specified, the program automatically repairs the failed items. Automatic repair is limited to some items that can be adjusted by modifying the configuration or system parameters. Other unrepaired items need to be handled manually according to the actual situation.

Environment checks are not necessary for deploying a cluster. For the production environment, it is recommended to perform environment checks and pass all check items before deployment. If not all the check items are passed, the cluster might be deployed and run normally, but the best performance might not be obtained.

13.4.11.2.15 Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you

might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--ssh=system` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup cluster deploy <cluster-name> <version> <topo> --ssh=system`. Fill in the name of your cluster for `<cluster-name>`, the TiDB version to be deployed (such as `v8.4.0`) for `<version>`, and the topology file for `<topo>`.
- Start a cluster: `tiup cluster start <cluster-name> --ssh=system`
- Upgrade a cluster: `tiup cluster upgrade ... --ssh=system`

You can add `--ssh=system` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
#### or
export TIUP_NATIVE_SSH=1
#### or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--ssh` at the same time, `--ssh` has higher priority.

> **Note:**
>
> During the process of cluster deployment, if you need to use a password for connection (`-p`) or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

13.4.11.2.16 Migrate control machine and back up TiUP data

The TiUP data is stored in the `.tiup` directory in the user's home directory. To migrate the control machine, you can take the following steps to copy the `.tiup` directory to the corresponding target machine:

1. Execute `tar czvf tiup.tar.gz .tiup` in the home directory of the original machine.
2. Copy `tiup.tar.gz` to the home directory of the target machine.
3. Execute `tar xzvf tiup.tar.gz` in the home directory of the target machine.
4. Add the `.tiup` directory to the `PATH` environment variable.

   If you use `bash` and you are a `tidb` user, you can add `export PATH=/home/tidb ↪ /.tiup/bin:$PATH` in `~/.bashrc` and execute `source ~/.bashrc`. Then make corresponding adjustments according to the shell and the user you use.

> **Note:**
>
> It is recommended that you back up the `.tiup` directory regularly to avoid the loss of TiUP data caused by abnormal conditions, such as disk damage of the control machine.

13.4.11.2.17 Back up and restore meta files for cluster deployment and O&M

If the meta files used for operation and maintenance (O&M) are lost, managing the cluster using TiUP will fail. It is recommended that you back up the meta files regularly by running the following command:

```
tiup cluster meta backup ${cluster_name}
```

If the meta files are lost, you can restore them by running the following command:

```
tiup cluster meta restore ${cluster_name} ${backup_file}
```

> **Note:**
>
> The restore operation overwrites the current meta files. Therefore, it is recommended to restore the meta files only when they are lost.

13.4.11.3 Create a Private Mirror

When creating a private cloud, usually, you need to use an isolated network environment, where the official mirror of TiUP is not accessible. Therefore, you can create a private mirror, which is mainly implemented by the `mirror` command. You can also use the `mirror` command for offline deployment. A private mirror also allows you to use components that you build and package by yourself.

13.4.11.3.1 TiUP `mirror` overview

Execute the following command to get the help information of the `mirror` command:

```
tiup mirror --help
```

```
The `mirror` command is used to manage a component repository for TiUP, you
    ↪  can use
it to create a private repository, or to add new component to an existing
    ↪ repository.
The repository can be used either online or offline.
It also provides some useful utilities to help manage keys, users, and
    ↪ versions
of components or the repository itself.

Usage:
  tiup mirror <command> [flags]

Available Commands:
  init        Initialize an empty repository
  sign        Add signatures to a manifest file
  genkey      Generate a new key pair
  clone       Clone a local mirror from a remote mirror and download all
      ↪ selected components
  merge       Merge two or more offline mirrors
  publish     Publish a component
  show        Show the mirror address
  set         Set mirror address
  modify      Modify published component
  renew       Renew the manifest of a published component.
  grant       grant a new owner
  rotate      Rotate root.json

Global Flags:
      --help              Help for this command

Use "tiup mirror [command] --help" for more information about a command.
```

13.4.11.3.2 Clone a mirror

You can run the `tiup mirror clone` command to build a local mirror:

```
tiup mirror clone <target-dir> [global-version] [flags]
```

- `target-dir`: used to specify the directory in which cloned data is stored.

- `global-version`: used to quickly set a global version for all components.

The `tiup mirror clone` command provides many optional flags (might provide more in the future). These flags can be divided into the following categories according to their intended usages:

- Determines whether to use prefix matching to match the version when cloning

  If the `--prefix` flag is specified, the version number is matched by prefix for the clone. For example, if you specify `--prefix` as "v5.0.0", then "v5.0.0-rc", and "v5.0.0" are matched.

- Determines whether to use the full clone

  If you specify the `--full` flag, you can clone the official mirror fully.

> **Note:**
> If `--full`, `global-version` flags, and the component versions are not specified, only some meta information is cloned.

- Determines whether to clone packages from the specific platform

  If you want to clone packages only for a specific platform, use `-os` and `-arch` to specify the platform. For example:

  - Execute the `tiup mirror clone <target-dir> [global-version] --os=linux` command to clone for linux.
  - Execute the `tiup mirror clone <target-dir> [global-version] --arch=amd64` command to clone for amd64.
  - Execute the `tiup mirror clone <target-dir> [global-version] --os=linux --arch=amd64` command to clone for linux/amd64.

- Determines whether to clone a specific version of a package

  If you want to clone only one version (not all versions) of a component, use `--<component>=<version>` to specify this version. For example:

  - Execute the `tiup mirror clone <target-dir> --tidb v8.4.0` command to clone the v8.4.0 version of the TiDB component.
  - Run the `tiup mirror clone <target-dir> --tidb v8.4.0 --tikv all` command to clone the v8.4.0 version of the TiDB component and all versions of the TiKV component.
  - Run the `tiup mirror clone <target-dir> v8.4.0` command to clone the v8.4.0 version of all components in a cluster.

After cloning, signing keys are set up automatically.

Manage the private repository

You can share the repository cloned using `tiup mirror clone` among hosts either by sharing files via SCP, NFS, or by making the repository available over the HTTP or HTTPS protocol. Use `tiup mirror set <location>` to specify the location of the repository.

```
tiup mirror set /shared_data/tiup
```

```
tiup mirror set https://tiup-mirror.example.com/
```

> **Note:**
>
> If you run `tiup mirror set...` on the machine where you run `tiup mirror clone`, the next time you run `tiup mirror clone...`, the machine clones from the local mirror, not the remote one. Therefore, you need to reset the mirror by running `tiup mirror set --reset` before updating the private mirror.

Another way of using a mirror is to use the `TIUP_MIRRORS` environment variable. Here is an example for running `tiup list` with a private repository.

```
export TIUP_MIRRORS=/shared_data/tiup
tiup list
```

`TIUP_MIRRORS` setting can permanently change the mirror configuration, for example, `tiup mirror set`. For details, see tiup issue #651.

Update the private repository

If you run the `tiup mirror clone` command again with the same `target-dir`, the machine will create new manifests and download the latest versions of components available.

> **Note:**
>
> Before recreating the manifest, ensure that all components and versions (including earlier ones downloaded previously) are included.

13.4.11.3.3 Custom repository

You can create a custom repository to work with TiDB components like TiDB, TiKV, or PD that you build by yourself. It is also possible to create your own tiup components.

To create your own components, run the `tiup package` command and perform as instructed in Component packaging.

Create a custom repository

To create an empty repository in `/data/mirror`:

```
tiup mirror init /data/mirror
```

As part of creating the repository, keys will be written to `/data/mirror/keys`.

To create a new private key in `~/.tiup/keys/private.json`:

```
tiup mirror genkey
```

Grant `jdoe` with private key `~/.tiup/keys/private.json` ownership of `/data/mirror`:

```
tiup mirror set /data/mirror
tiup mirror grant jdoe
```

Work with custom components

1. Create a custom component called hello.

```
$ cat > hello.c << END
> #include <stdio.h>
int main() {
  printf("hello\n");
  return (0);
}
END
$ gcc hello.c -o hello
$ tiup package hello --entry hello --name hello --release v0.0.1
```

`package/hello-v0.0.1-linux-amd64.tar.gz` is created.

2. Create a repository and a private key, and grant ownership to the repository.

```
$ tiup mirror init /tmp/m
$ tiup mirror genkey
$ tiup mirror set /tmp/m
$ tiup mirror grant $USER
```

```
tiup mirror publish hello v0.0.1 package/hello-v0.0.1-linux-amd64.tar.
    ↪ gz hello
```

3. Run the component. If it is not installed yet, it will be downloaded first.

```
$ tiup hello
```

```
The component `hello` version is not installed; downloading from
    ↪ repository.
Starting component `hello`: /home/dvaneeden/.tiup/components/hello/v0
    ↪ .0.1/hello
hello
```

With `tiup mirror merge`, you can merge a repository with custom components into another one. This assumes that all components in `/data/my_custom_components` are signed by the current `$USER`.

```
$ tiup mirror set /data/my_mirror
$ tiup mirror grant $USER
$ tiup mirror merge /data/my_custom_components
```

13.4.11.4 Stress Test TiDB Using TiUP Bench Component

When you test the performance of a database, it is often required to stress test the database. To facilitate this, TiUP has integrated the bench component, which provides multiple workloads for stress testing. You can access these workloads by the following commands:

```
tiup bench tpcc # Benchmark a database using TPC-C
tiup bench tpch # Benchmark a database using TPC-H
tiup bench ch   # Benchmark a database using CH-benCHmark
tiup bench ycsb # Benchmark a database using YCSB
tiup bench rawsql # Benchmark a database using arbitrary SQL files
```

`tpcc`, `tpch`, `ch`, and `rawsql` share the following common command flags. However, `ycsb` is mainly configured by a `.properties` file, which is described in its usage guide.

```
  -t, --acThreads int      OLAP client concurrency, only for CH-benCHmark (
    ↪ default to 1)
      --conn-params string Session variables, such as setting `--conn-params
        ↪  tidb_isolation_read_engines='tiflash'` for TiDB queries and
        ↪ setting `--conn-params sslmode=disable` for PostgreSQL
        ↪ connections
      --count int          Total execution count (0 means infinite count)
  -D, --db string          Database name (default to "test")
  -d, --driver string      Database driver: mysql, postgres (default to "
    ↪ mysql")
      --dropdata           Clean up historical data before preparing
  -H, --host strings       Database host (default to [127.0.0.1])
      --ignore-error       Ignore errors when running workload
      --interval duration  Output interval time (default to 10s)
      --isolation int      Isolation Level (0: Default; 1: ReadUncommitted;
```

```
                          2: ReadCommitted; 3: WriteCommitted; 4:
                             ↪ RepeatableRead;
                          5: Snapshot; 6: Serializable; 7: Linerizable)
    --max-procs int       runtime.GOMAXPROCS of golang, the limits of how
       ↪ many cores can be used
    --output string       Output style. Valid values can be { plain | table
       ↪  | json } (default to "plain")
-p, --password string     Database password
-P, --port ints           Database port (default to [4000])
    --pprof string        Address of pprof endpoint
    --silence             Don't print errors when running workload
-S, --statusPort int      Database status port (default to 10080)
-T, --threads int         Thread concurrency (default to 1)
    --time duration       Total execution time (default to 2562047h47m16
       ↪ .854775807s)
-U, --user string         Database user (default to "root")
```

- You can pass comma-separated values to `--host` and `--port` to enable client-side load balancing. For example, when you specify `--host 172.16.4.1,172.16.4.2 ↪ --port 4000,4001`, the program will connect to 172.16.4.1:4000, 172.16.4.1:4001, 172.16.4.2:4000, and 172.16.4.2:4001, chosen in round-robin fashion.
- `--conn-params` must follow the format of query string. Different databases might have different parameters. For example:
  - `--conn-params tidb_isolation_read_engines='tiflash'` forces TiDB to read from TiFlash.
  - `--conn-params sslmode=disable` disables SSL when you connect to PostgreSQL.
- When running CH-benCHmark, you can use `--ap-host`, `--ap-port`, and `--ap-conn- ↪ params` to specify a standalone TiDB server for OLAP queries.

The following sections describe how to run TPC-C, TPC-H, YCSB tests using TiUP.

13.4.11.4.1 Run TPC-C test using TiUP

The TiUP bench component supports the following commands and flags to run the TPC-C test:

```
Available Commands:
  check      Check data consistency for the workload
  cleanup    Cleanup data for the workload
  prepare    Prepare data for the workload
  run        Run workload
```

```
Flags:
      --check-all          Run all consistency checks
  -h, --help               Help for TPC-C
      --partition-type int Partition type: 1 - HASH, 2 - RANGE, 3 - LIST (
          ↪ HASH-like), 4 - LIST (RANGE-like) (default to 1)
      --parts int          Number of partitions (default to 1)
      --warehouses int     Number of warehouses (default to 10)
```

Test procedures

The following provides simplified steps for running a TPC-C test. For detailed steps, see How to Run TPC-C Test on TiDB.

1. Create 4 warehouses using 4 partitions via hash:

```
tiup bench tpcc --warehouses 4 --parts 4 prepare
```

2. Run the TPC-C test:

```
tiup bench tpcc --warehouses 4 --time 10m run
```

3. Check the consistency:

```
tiup bench tpcc --warehouses 4 check
```

4. Clean up data:

```
tiup bench tpcc --warehouses 4 cleanup
```

Preparing data via SQL might be slow when you want to run a benchmark with a large data set. In that case, you can generate data in the CSV format by the following commands and then import it to TiDB via TiDB Lightning.

- Generate the CSV file:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
    ↪ csv
```

- Generate the CSV file for the specified table:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
    ↪ csv --tables history,orders
```

13.4.11.4.2 Run TPC-H test using TiUP

The TiUP bench component supports the following commands and parameters to run the TPC-H test:

```
Available Commands:
  cleanup    Cleanup data for the workload
  prepare    Prepare data for the workload
  run        Run workload

Flags:
      --check          Check output data, only when the scale factor equals 1
  -h, --help           help for tpch
      --queries string All queries (default "q1,q2,q3,q4,q5,q6,q7,q8,q9,q10,
          ↪ q11,q12,q13,q14,q15,q16,q17,q18,q19,q20,q21,q22")
      --sf int         scale factor
```

Test procedures

1. Prepare data:

   ```
   tiup bench tpch --sf=1 prepare
   ```

2. Collect statistics:

   For the OLAP scenarios, to ensure that the TiDB optimizer can generate the optimal execution plan, execute the following SQL statements to collect statistics in advance. **Be sure to set `tidb_analyze_column_options` to `ALL`, otherwise collecting statistics can result in a significant drop in query performance.**

   ```
   set global tidb_analyze_column_options='ALL';
   ```

3. Run the TPC-H test by executing one of the following commands:

   - If you check the result, run this command:

     ```
     tiup bench tpch --count=22 --sf=1 --check=true run
     ```

   - If you do not check the result, run this command:

     ```
     tiup bench tpch --count=22 --sf=1 run
     ```

4. Clean up data:

   ```
   tiup bench tpch cleanup
   ```

13.4.11.4.3 Run YCSB test using TiUP

You can stress test both TiDB and TiKV via YCSB.

Stress test TiDB

1. Prepare data:

```
tiup bench ycsb load tidb -p tidb.instances="127.0.0.1:4000" -p
    ↪ recordcount=10000
```

2. Run the YCSB workload:

```
# The read-write percent is 95% by default
tiup bench ycsb run tidb -p tidb.instances="127.0.0.1:4000" -p
    ↪ operationcount=10000
```

Stress test TiKV

1. Prepare data:

```
tiup bench ycsb load tikv -p tikv.pd="127.0.0.1:2379" -p recordcount
    ↪ =10000
```

2. Run the YCSB workload:

```
# The read-write percent is 95% by default
tiup bench ycsb run tikv -p tikv.pd="127.0.0.1:2379" -p operationcount
    ↪ =10000
```

13.4.11.4.4 Run RawSQL test using TiUP

You can write an arbitrary query in a SQL file, and then use it for the test by executing `tiup bench rawsql` as follows:

1. Prepare data and the query:

```
-- Prepare data
CREATE TABLE t (a int);
INSERT INTO t VALUES (1), (2), (3);

-- Save your query in a SQL file. For example, you can save the
    ↪ following query in `demo.sql`.
SELECT a, sleep(rand()) FROM t WHERE a < 4*rand();
```

2. Run the RawSQL test:

```
tiup bench rawsql run --count 60 --query-files demo.sql
```

13.5 TiDB Operator

TiDB Operator is an automatic operation system for TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB Operator documentation (also named as TiDB on Kubernetes documentation) is independent of the TiDB documentation. To access the documentation, click the following link:

- TiDB on Kubernetes documentation

13.6 TiDB Data Migration

13.6.1 TiDB Data Migration Overview

TiDB Data Migration (DM) is an integrated data migration task management platform, which supports the full data migration and the incremental data replication from MySQL-compatible databases (such as MySQL, MariaDB, and Aurora MySQL) into TiDB. It can help to reduce the operation cost of data migration and simplify the troubleshooting process.

13.6.1.1 Basic features

- **Compatibility with MySQL.** DM is compatible with the MySQL protocol and most of the features and syntax of MySQL 5.7 and MySQL 8.0.
- **Replicating DML and DDL events.** It supports parsing and replicating DML and DDL events in MySQL binlog.
- **Migrating and merging MySQL shards.** DM supports migrating and merging multiple MySQL database instances upstream to one TiDB database downstream. It supports customizing replication rules for different migration scenarios. It can automatically detect and handle DDL changes of upstream MySQL shards, which greatly reduces the operational cost.
- **Various types of filters.** You can predefine event types, regular expressions, and SQL expressions to filter out MySQL binlog events during the data migration process.
- **Centralized management.** DM supports thousands of nodes in a cluster. It can run and manage a large number of data migration tasks concurrently.
- **Optimization of the third-party Online Schema Change process.** In the MySQL ecosystem, tools such as gh-ost and pt-osc are widely used. DM optimizes its change process to avoid unnecessary migration of intermediate data. For details, see online-ddl.
- **High availability.** DM supports data migration tasks to be scheduled freely on different nodes. The running tasks are not affected when a small number of nodes crash.

13.6.1.2 Quick installation

Run the following command to install DM:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
tiup install dm dmctl
```

13.6.1.3 Usage restrictions

Before using the DM tool, note the following restrictions:

- Database version requirements
    - MySQL version 5.6 ~ 8.0
    - MariaDB version >= 10.1.2 (experimental features)

> **Note:**
>
> If there is a primary-secondary migration structure between the upstream MySQL/MariaDB servers, then choose the following version.
>
> - MySQL version > 5.7.1
> - MariaDB version >= 10.1.3

- DDL syntax compatibility
    - Currently, TiDB is not compatible with all the DDL statements that MySQL supports. Because DM uses the TiDB parser to process DDL statements, it only supports the DDL syntax supported by the TiDB parser. For details, see MySQL Compatibility.
    - DM reports an error when it encounters an incompatible DDL statement. To solve this error, you need to manually handle it using dmctl, either skipping this DDL statement or replacing it with specified DDL statements. For details, see Skip or replace abnormal SQL statements.
    - DM does not replicate view-related DDL statements and DML statements to the downstream TiDB cluster. It is recommended that you create the view in the downstream TiDB cluster manually.
- GBK character set compatibility
    - DM does not support migrating `charset=GBK` tables to TiDB clusters earlier than v5.4.0.
- Binlog compatibility

- DM does not support the MySQL 8.0 new feature binlog Transaction_payload_event. Using binlog Transaction_payload_event might result in data inconsistency between upstream and downstream.

- Vector data type replication

  - DM does not support migrating or replicating MySQL 9.0 vector data types to TiDB.

13.6.1.4 Contributing

You are welcome to participate in the DM open sourcing project. Your contribution would be highly appreciated. For more details, see CONTRIBUTING.md.

13.6.1.5 Community support

You can learn about DM through the online documentation. If you have any questions, contact us on GitHub.

13.6.1.6 License

DM complies with the Apache 2.0 license. For more details, see LICENSE.

13.6.1.7 DM versions

Before v5.4, the DM documentation is independent of the TiDB documentation. To access these earlier versions of the DM documentation, click one of the following links:

- DM v5.3 documentation
- DM v2.0 documentation
- DM v1.0 documentation

Note:

- Since October 2021, DM's GitHub repository has been moved to pingcap/tiflow. If you see any issues with DM, submit your issue to the `pingcap/tiflow` repository for feedback.
- In earlier versions (v1.0 and v2.0), DM uses version numbers that are independent of TiDB. Since v5.3, DM uses the same version number as TiDB. The next version of DM v2.0 is DM v5.3. There are no compatibility changes from DM v2.0 to v5.3, and the upgrade process is the same as a normal upgrade, only an increase in version number.

13.6.2 Data Migration Architecture

This document introduces the architecture of Data Migration (DM).

DM consists of three components: DM-master, DM-worker, and dmctl.

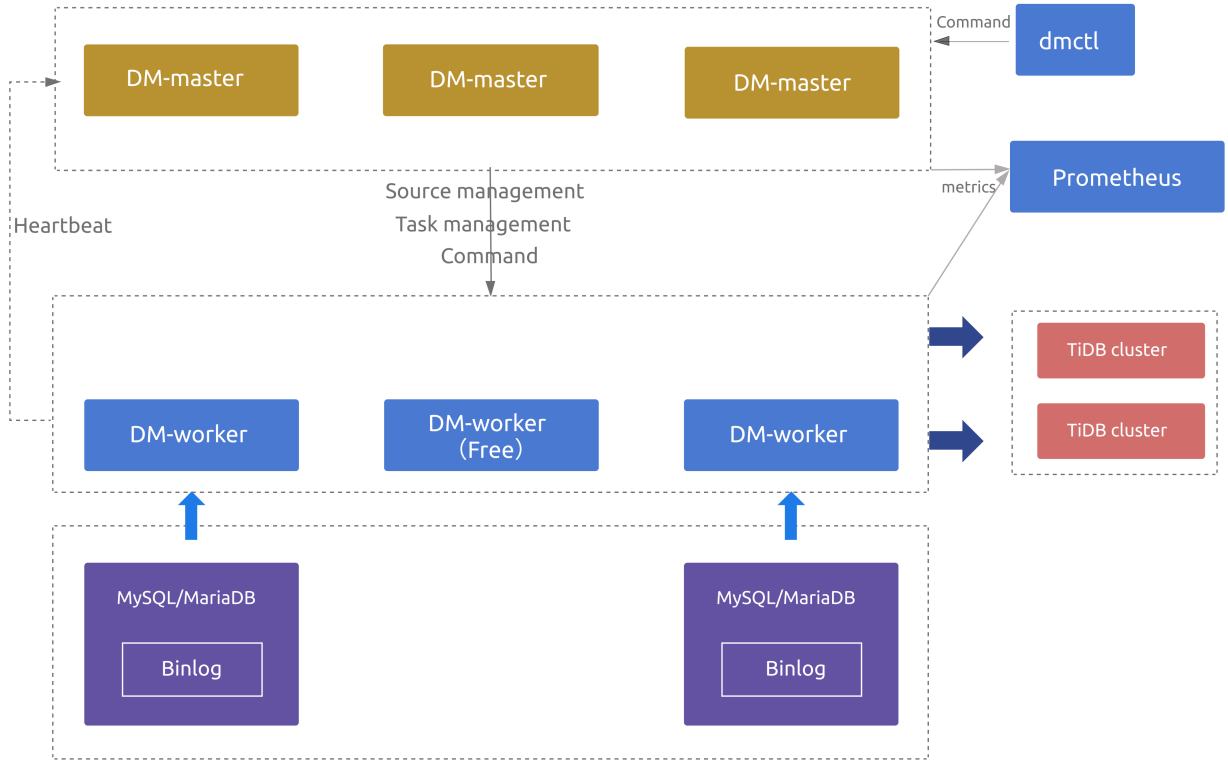

Figure 461: Data Migration architecture

13.6.2.1 Architecture components

13.6.2.1.1 DM-master

DM-master manages and schedules the operations of data migration tasks.

- Storing the topology information of the DM cluster
- Monitoring the running state of DM-worker processes
- Monitoring the running state of data migration tasks
- Providing a unified portal for the management of data migration tasks
- Coordinating the DDL migration of sharded tables in each instance under the sharding scenario

13.6.2.1.2 DM-worker

DM-worker executes specific data migration tasks.

- Persisting the binlog data to the local storage
- Storing the configuration information of the data migration subtasks
- Orchestrating the operation of the data migration subtasks
- Monitoring the running state of the data migration subtasks

For more details of DM-worker, see DM-worker Introduction.

13.6.2.1.3 dmctl

dmctl is a command line tool used to control the DM cluster.

- Creating, updating, or dropping data migration tasks
- Checking the state of data migration tasks
- Handling errors of data migration tasks
- Verifying the configuration correctness of data migration tasks

13.6.2.2 Architecture features

13.6.2.2.1 High availability

When you deploy multiple DM-master nodes, all DM-master nodes use the embedded etcd to form a cluster. The DM-master cluster is used to store metadata such as cluster node information and task configuration. The leader node elected through etcd is used to provide services such as cluster management and data migration task management. Therefore, if the number of available DM-master nodes exceeds half of the deployed nodes, the DM cluster can normally provide services.

When the number of deployed DM-worker nodes exceeds the number of upstream MySQL/MariaDB nodes, the extra DM-worker nodes are idle by default. If a DM-worker node goes offline or is isolated from the DM-master leader, DM-master automatically schedules data migration tasks of the original DM-worker node to other idle DM-worker nodes. (If a DM-worker node is isolated, it automatically stops the data migration tasks on it); if there are no available idle DM-worker nodes, the data migration tasks of the original DM-worker are temporarily hung until one DM-worker node becomes idle, and then the tasks are automatically resumed.

> **Note:**
>
> When the data migration task is in the process of full export or import, the migration task does not support high availability. Here are the main reasons:

- For the full export, MySQL does not support exporting from a specific snapshot point yet. This means that after the data migration task is rescheduled or restarted, the export cannot resume from the previous interruption point.
- For the full import, DM-worker does not support reading exported full data across the nodes yet. This means that after the data migration task is scheduled to a new DM-worker node, you cannot read the exported full data on the original DM-worker node before the scheduling happens.

13.6.3 Quick Start Guide for TiDB Data Migration

This document describes how to migrate data from MySQL to TiDB using TiDB Data Migration (DM). This guide is a quick demo of DM features and is not recommended for any production environment.

13.6.3.1 Step 1: Deploy a DM cluster

1. Install TiUP, and install `dmctl` using TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
tiup install dm dmctl
```

2. Generate the minimal deployment topology file of a DM cluster:

```
tiup dm template
```

3. Copy the configuration information in the output, and save it as the `topology.yaml` file with the modified IP address. Deploy the DM cluster with the `topology.yaml` file using TiUP:

```
tiup dm deploy dm-test 6.0.0 topology.yaml -p
```

13.6.3.2 Step 2: Prepare the data source

You can use one or multiple MySQL instances as an upstream data source.

1. Create a configuration file for each data source as follows:

```
source-id: "mysql-01"
from:
  host: "127.0.0.1"
```

```
  user: "root"
  password: "fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg="
  port: 3306
```

2. Add the source to the DM cluster by running the following command. `mysql-01.yaml` is the configuration file created in the previous step.

```
tiup dmctl --master-addr=127.0.0.1:8261 operate-source create mysql-01.
    ↪ yaml # use one of master_servers as the argument of --master-
    ↪ addr
```

If you do not have a MySQL instance for testing, you can create a MySQL instance in Docker by taking the following steps:

1. Create a MySQL configuration file:

```
mkdir -p /tmp/mysqltest && cd /tmp/mysqltest

cat > my.cnf <<EOF
[mysqld]
bind-address   = 0.0.0.0
character-set-server=utf8
collation-server=utf8_bin
default-storage-engine=INNODB
transaction-isolation=READ-COMMITTED
server-id      = 100
binlog_format  = row
log_bin        = /var/lib/mysql/mysql-bin.log
show_compatibility_56 = ON
EOF
```

2. Start the MySQL instance using Docker:

```
docker run --name mysql-01 -v /tmp/mysqltest:/etc/mysql/conf.d -e MYSQL
    ↪ _ROOT_PASSWORD=my-secret-pw -d -p 3306:3306 mysql:5.7
```

3. After the MySQL instance is started, access the instance:

> **Note:**
>
> This command is only suitable for trying out data migration, and cannot be used in production environments or stress tests.

```
mysql -uroot -p -h 127.0.0.1 -P 3306
```

13.6.3.3 Step 3: Prepare a downstream database

You can choose an existing TiDB cluster as a target for data migration.

If you do not have a TiDB cluster for testing, you can quickly build a demonstration environment by running the following command:

```
tiup playground
```

13.6.3.4 Step 4: Prepare test data

Create a test table and data in one or multiple data sources. If you use an existing MySQL database, and the database contains available data, you can skip this step.

```
drop database if exists `testdm`;
create database `testdm`;
use `testdm`;
create table t1 (id bigint, uid int, name varchar(80), info varchar(100),
    ↪ primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=utf8mb4
    ↪ COLLATE=utf8mb4_bin;
create table t2 (id bigint, uid int, name varchar(80), info varchar(100),
    ↪ primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=utf8mb4
    ↪ COLLATE=utf8mb4_bin;
insert into t1 (id, uid, name) values (1, 10001, 'Gabriel García Márquez'),
    ↪  (2, 10002, 'Cien años de soledad');
insert into t2 (id, uid, name) values (3, 20001, 'José Arcadio Buendía'),
    ↪ (4, 20002, 'Úrsula Iguarán'), (5, 20003, 'José Arcadio');
```

13.6.3.5 Step 5: Create a data migration task

1. Create a task configuration file `testdm-task.yaml`:

```
name: testdm
task-mode: all

target-database:
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: "" # If the password is not empty, it is recommended to use
      ↪  a password encrypted with dmctl.

# Configure the information of one or multiple data sources
mysql-instances:
  - source-id: "mysql-01"
    block-allow-list: "ba-rule1"
```

```
block-allow-list:
  ba-rule1:
    do-dbs: ["testdm"]
```

2. Create the task using dmctl:

```
tiup dmctl --master-addr 127.0.0.1:8261 start-task testdm-task.yaml
```

You have successfully created a task that migrates data from a `mysql-01` database to TiDB.

13.6.3.6 Step 6: Check the status of the task

After the task is created, you can use the `dmctl query-status` command to check the status of the task:

```
tiup dmctl --master-addr 127.0.0.1:8261 query-status testdm
```

13.6.4 TiDB Data Migration (DM) Best Practices

TiDB Data Migration (DM) is a data migration tool developed by PingCAP. It supports full and incremental data migration from MySQL-compatible databases such as MySQL, Percona MySQL, MariaDB, Amazon RDS for MySQL, and Amazon Aurora into TiDB.

You can use DM in the following scenarios:

- Perform full and incremental data migration from a single MySQL-compatible database instance to TiDB
- Migrate and merge MySQL shards of small datasets (less than 1 TiB) to TiDB
- In the data hub scenario, such as the middle platform of business data, and real-time aggregation of business data, use DM as the middleware for data migration

This document introduces how to use DM in an elegant and efficient way, and how to avoid common mistakes when using DM.

13.6.4.1 Performance limitations

Performance item	Limitation
Max work nodes	1000
Max task number	600
Max QPS	30k QPS/worker
Max Binlog throughput	20 MB/s/worker
Table number limit per task	Unlimited

- DM supports managing 1000 work nodes simultaneously, and the maximum number of tasks is 600. To ensure the high availability of work nodes, you should reserve some work nodes as standby nodes. The recommended number of standby nodes is 20% to 50% of the number of the work nodes that have running migration tasks.
- A single work node can theoretically support replication QPS of up to 30K QPS/-worker. It varies for different schemas and workloads. The ability to handle upstream binlogs is up to 20 MB/s/worker.
- If you want to use DM as a data replication middleware for long-term use, you need to carefully design the deployment architecture of DM components. For more information, see Deploy DM-master and DM-worker

13.6.4.2 Before data migration

Before data migration, the design of the overall solution is critical. The following sections describe best practices and scenarios from the business perspective and the implementation perspective.

13.6.4.2.1 Best practices for the business side

To distribute the workload evenly on multiple nodes, the design for the distributed database is different from traditional databases. The solution needs to ensure both low migration cost and logic correctness after migration. The following sections describe best practices before data migration.

Business impact of AUTO_INCREMENT in schema design

`AUTO_INCREMENT` in TiDB is compatible with `AUTO_INCREMENT` in MySQL. However, as a distributed database, TiDB usually has multiple computing nodes (entries for the client end). When the application data is written, the workload is evenly distributed. This leads to the result that when there is an `AUTO_INCREMENT` column in the table, the auto-increment IDs of the column might be inconsecutive. For more details, see AUTO_INCREMENT.

If your business has a strong dependence on auto-increment IDs, consider using the MySQL-compatible `AUTO_INCREMENT` mode or the `SEQUENCE` function.

Usage of clustered indexes

When you create a table, you can declare that the primary key is either a clustered index or a non-clustered index. The following sections describe the pros and cons of each choice.

- Clustered indexes

  Clustered indexes use the primary key as the handle ID (row ID) for data storage. Querying using the primary key can avoid table lookup, which effectively improves the query performance. However, if the table is write-intensive and the primary key uses `AUTO_INCREMENT`, it is very likely to cause write hotspot problems, resulting in a mediocre performance of the cluster and the performance bottleneck of a single storage node.

- Non-clustered indexes + `shard row id bit`

  Using non-clustered indexes and `shard row id bit`, you can avoid the write hotspot problem when using `AUTO_INCREMENT`. However, table lookup in this scenario can affect the query performance when querying using the primary key.

- Clustered indexes + external distributed ID generators

  If you want to use clustered indexes and keep the IDs consecutive, consider using external distributed ID generators, such as the Snowflake algorithm and Leaf. The application program generates sequence IDs, which can guarantee that the IDs are consecutive to a certain extent. It also retains the benefits of using clustered indexes. But you need to customize the applications.

- Clustered indexes + `AUTO_RANDOM`

  This solution can retain the benefits of using clustered indexes and avoid the write hotspot problem. It requires less effort for customization. You can modify the schema attribute when you switch to use TiDB as the write database. In subsequent queries, if you have to use the ID column to sort data, you can use the `AUTO_RANDOM` ID column and left shift 5 bits to ensure the order of the query data. For example:

```
CREATE TABLE t (a bigint PRIMARY KEY AUTO_RANDOM, b varchar(255));
Select a, a<<5 ,b from t order by a <<5 desc
```

The following table summarizes the pros and cons of each solution.

Scenario	Recommended solution	Pros	Cons
TiDB will act as the primary and write-intensive database. The business logic strongly relies on the continuity of the primary key IDs.	Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Use `SEQUENCE` as the primary key column.	It can avoid data write hotspots and ensure the continuity and monotonic increment of business data.	The throughput capacity of data write is decreased to ensure data write continuity. The performance of primary key queries is decreased.
TiDB will act as the primary and write-intensive database. The business logic strongly relies on the increment of the primary key IDs.	Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Use an application ID generator to generate the primary key IDs.	It can avoid data write hotspots,	

guarantee the performance of data write, and guarantee the increment of business data, but cannot guarantee continuity. |

You need to customize the application.

External ID generators strongly rely on the clock accuracy and might introduce failures.

| |

TiDB will act as the primary and write-intensive database.

The business logic does not rely on the continuity of the primary key IDs.

| Create tables with clustered indexes and set `AUTO_RANDOM` for the primary key column. |

It can avoid data write hotspots and has excellent query performance of primary keys.

You can smoothly switch from `AUTO_INCREMENT` to `AUTO_RANDOM`.

|

The primary key IDs are random.

The write throughput ability is limited.

It is recommended to sort the business data by using the insert time column.

If you have to use the primary key ID to sort data, you can left shift 5 bits to query, which can guarantee the increment of the data.

| | TiDB will act as a read-only database. | Create tables with non-clustered indexes and set `SHARD_ROW_ID_BIT`. Keep the primary key column consistent with the data source. |

It can avoid data write hotspots.

It requires less customization cost.

The query performance of primary keys is impacted. |

13.6.4.2.2 Key points for MySQL shards

Splitting and merging

It is recommended that you use DM to migrate and merge MySQL shards of small datasets to TiDB.

Besides data merging, another typical scenario is data archiving. Data is constantly being written. As time goes by, large amounts of data gradually change from hot data to warm or even cold data. Fortunately, in TiDB, you can set different placement rules for data. The minimum granularity of the rules is a partition.

Therefore, it is recommended that for write-intensive scenarios, you need to evaluate from the beginning whether you need to archive data and store hot and cold data on different media separately. If you need to archive data, you can set the partitioning rules before migration (TiDB does not support Table Rebuild operations yet). It saves you from the need to recreate tables and import data in future.

The pessimistic mode and the optimistic mode

DM uses the pessimistic mode by default. In scenarios of migrating and merging MySQL shards, changes in upstream shard schemas can block DML writing to downstream databases. You need to wait until all the schemas are changed and have the same structure, and then continue the migration from the breakpoint.

- If the upstream schema changes take a long time, it might cause the upstream Binlog to be cleaned up. You can enable the relay log to avoid this problem. For more information, see Use the relay log.
- If you do not want to block data write due to upstream schema changes, consider using the optimistic mode. In this case, DM will not block the data migration even when it spots changes in the upstream shard schemas, but will continue to migrate the data. However, if DM spots incompatible formats in upstream and downstream, the migration task will stop. You need to resolve this issue manually.

The following table summarizes the pros and cons of optimistic mode and pessimistic modes.

Scenario	Pros	Cons
Scenario	Pros	Cons
Pessimistic mode (Default)	It can ensure that the data migrated to the downstream will not go wrong.	If there are a large number of shards, the migration task will be blocked for a long time, or even stop if the upstream binlogs have been cleaned up. You can enable the relay log to avoid this problem. For more infor-

Scenario	Pros	Cons
Optimistic mode	Upstream schema changes will not cause data migration latency.	In this mode, ensure that schema changes are compatible (check whether the incremental column has a default value). It is possible that the inconsistent data can be overlooked. For more information, see Merge and Migrate Data

Scenario	Pros	Cons

13.6.4.2.3 Other restrictions and impact

Data types in upstream and downstream

TiDB supports most MySQL data types. However, some special types are not supported yet (such as `SPATIAL`). For the compatibility of data types, see Data Types.

Character sets and collations

Since TiDB v6.0.0, the new framework for collations is used by default. In earlier versions, if you want TiDB to support utf8_general_ci, utf8mb4_general_ci, utf8_unicode_ci, utf8mb4_unicode_ci, gbk_chinese_ci and gbk_bin, you need to explicitly declare it when creating the cluster by setting the value of `new_collations_enabled_on_first_bootstrap` to `true`. For more information, see New framework for collations.

The default character set in TiDB is utf8mb4. It is recommended that you use utf8mb4 for the upstream and downstream databases and applications. If the upstream database has explicitly specified a character set or collation, you need to check whether TiDB supports it.

Since TiDB v6.0.0, GBK is supported. For more information, see the following documents:

- Character Set and Collation
- GBK compatibility

13.6.4.2.4 Best practices for deployment

Deploy DM-master and DM-worker

DM consists of DM-master and DM-worker nodes.

- DM-master manages the metadata of migration tasks and schedules DM-worker nodes. It is the core of the whole DM platform. Therefore, you can deploy DM-master as clusters to ensure high availability of the DM platform.
- DM-worker executes upstream and downstream migration tasks. A DM-worker node is stateless. You can deploy at most 1000 DM-worker nodes. When using DM, it is recommended that you reserve some idle DM-workers to ensure high availability.

Plan the migration tasks

When migrating and merging MySQL shards, you can split a migration task according to the types of shards in the upstream. For example, if `usertable_1~50` and `Logtable_1~50` are two types of shards, you can create two migration tasks. It can simplify the migration task template and effectively control the impact of interruption in data migration.

For migration of large datasets, you can refer to the following suggestions to split the migration task:

- If you need to migrate multiple databases in the upstream, you can split the migration task according to the number of databases.
- Split the task according to the write pressure in the upstream, that is, split the tables with frequent DML operations in the upstream to a separate migration task. Use another migration task to migrate the tables without frequent DML operations. This method can speed up the migration progress, especially when there are a large number of logs written to a table in the upstream. But if this table that contains a large number of logs does not affect the whole business, this method still works well.

Note that splitting the migration task can only guarantee the final consistency of data. Real-time consistency may deviate significantly due to various reasons.

The following table describes the recommended deployment plans for DM-master and DM-worker in different scenarios.

Scenario	DM-master deployment	DM-worker deployment

|

Small dataset (less than 1 TiB)

One-time data migration

| Deploy 1 DM-master node | Deploy 1~N DM-worker nodes according to the number of upstream data sources. Generally, 1 DM-worker node is recommended. | |

Large dataset (more than 1 TiB) and migrating and merging MySQL shards

One-time data migration

| It is recommended to deploy 3 DM-master nodes to ensure the availability of the DM cluster during long-time data migration. | Deploy DM-worker nodes according to the number of data sources or migration tasks. Besides working DM-worker nodes, it is recommended to deploy 1~3 idle DM-worker nodes. | | Long-term data replication | It is necessary to deploy 3 DM-master nodes. If you deploy DM-master nodes on the cloud, try to deploy them in different availability zones (AZ). | Deploy DM-worker nodes according to the number of data sources or migration tasks. It is necessary to deploy 1.5~2 times the number of DM-worker nodes that are actually needed. |

Choose and configure the upstream data source

DM backs up the full data of the entire database when performing full data migration, and uses the parallel logical backup method. During backing up MySQL, it adds a global read lock `FLUSH TABLES WITH READ LOCK`. DML and DDL operations of the upstream database will be blocked for a short time. Therefore, it is strongly recommended to use a backup database in upstream to perform the full data backup, and enable the GTID function of the data source (`enable-gtid: true`). In this way, you can avoid the impact from the upstream, and switch to the master node in the upstream to reduce the latency during the

incremental migration. For the instructions of switching the upstream MySQL data source, see Switch DM-worker Connection between Upstream MySQL Instances.

Note the following:

- You can only perform full data backup on the master node of the upstream database.

  In this scenario, you can set the `consistency` parameter to `none` in the configuration file, `mydumpers.global.extra-args: "--consistency none"`, to avoid adding a global read lock to the master node. But this might affect the data consistency of the full backup, which may lead to inconsistent data between the upstream and downstream.

- Use backup snapshots to perform full data migration (only applicable to the migration of MySQL RDS and Aurora RDS on AWS)

  If the database to be migrated is AWS MySQL RDS or Aurora RDS, you can use RDS snapshots to directly migrate the backup data in Amazon S3 to TiDB to ensure data consistency. For more information, see Migrate Data from Amazon Aurora to TiDB.

13.6.4.2.5 Details of configurations

Capitalization

TiDB schema names are case-insensitive by default, that is, `lower_case_table_names :2`. But most upstream MySQL databases use Linux systems that are case-sensitive by default. In this case, you need to set `case-sensitive` to `true` in the DM task configuration file to ensure that the schema can be correctly migrated from the upstream.

In a special case, for example, if there is a database in the upstream that has both uppercase tables such as `Table` and lowercase tables such as `table`, then an error occurs when creating the schema:

```
ERROR 1050 (42S01): Table '{tablename}' already exists
```

Filter rules

You can configure the filter rules as soon as you start configuring the data source. For more information, see Data Migration Task Configuration Guide. The benefits of configuring the filter rules are:

- Reduce the number of Binlog events that the downstream needs to process, thereby improving migration efficiency.
- Reduce unnecessary relay log storage, thereby saving disk space.

Note:

> When you migrate and merge MySQL shards, if you have configured filter rules in the data source, you must make sure that the rules match between the data source and the migration task. If they do not match, it may cause the issue that the migration task cannot receive incremental data for a long time.

Use the relay log

In the MySQL master/standby mechanism, the standby node saves a copy of relay logs to ensure the reliability and efficiency of asynchronous replication. DM also supports saving a copy of relay logs on DM-worker. You can configure information such as the storage location and expiration time. This feature applies to the following scenarios:

- During full and incremental data migration, if the amount of full data is large, the entire process takes more time than the time for the upstream binlogs to be archived. It causes the incremental replication task to fail to start normally. If you enable the relay log, DM-worker will start receiving relay logs when the full migration is started. This avoids the failure of the incremental task.
- When you use DM to perform long-time data replication, sometimes the migration task is blocked for a long time due to various reasons. If you enable the relay log, you can effectively deal with the problem of upstream binlogs being recycled due to the blocking of the migration task.

There are some restrictions on using the relay log. DM supports high availability. When a DM-worker fails, it will try to promote an idle DM-worker instance to a working instance. If the upstream binlogs do not contain the necessary migration logs, it may cause interruption. You need to intervene manually to copy the relay log to the new DM-worker node as soon as possible, and modify the corresponding relay meta file. For details, see Troubleshooting.

Use PT-osc/GH-ost in upstream

In daily MySQL operation and maintenance, usually you use tools such as PT-osc/GH-ost to change the schema online to minimize impact on the business. However, the whole process will be logged to MySQL Binlog. Migrating such data to TiDB downstream will result in a lot of unnecessary write operations, which is neither efficient nor economical.

To resolve this issue, DM supports third-party data tools such as PT-osc and GH-ost when you configure the migration task. When you use such tools, DM does not migrate redundant data and ensure data consistency. For details, see Migrate from Databases that Use GH-ost/PT-osc.

13.6.4.3 Best practices during migration

This section introduces how to troubleshoot problems you might encounter during migration.

13.6.4.3.1 Inconsistent schemas in upstream and downstream

Common errors include:

- `messages: Column count doesn't match value count: 3 (columns)vs 2 (values)`
- `Schema/Column doesn't match`

Usually such issues are caused by changed or added indexes in the downstream TiDB, or there are more columns in the downstream. When such errors occur, check whether the upstream and downstream schemas are inconsistent.

To resolve such issues, update the schema information cached in DM to be consistent with the downstream TiDB schema. For details, see Manage Table Schemas of Tables to be Migrated.

If the downstream has more columns, see Migrate Data to a Downstream TiDB Table with More Columns.

13.6.4.3.2 Interrupted migration task due to failed DDL

DM supports skipping or replacing DDL statements that cause a migration task to interrupt. For details, see Handle Failed DDL Statements.

13.6.4.4 Data validation after data migration

It is recommended that you validate the consistency of data after data migration. TiDB provides sync-diff-inspector to help you complete the data validation.

Now sync-diff-inspector can automatically manage the table list to be checked for data consistency through DM tasks. Compared with the previous manual configuration, it is more efficient. For details, see Data Check in the DM Replication Scenario.

Since DM v6.2.0, DM supports continuous data validation for incremental replication. For details, see Continuous Data Validation in DM.

13.6.4.5 Long-term data replication

If you use DM to perform a long-term data replication task, it is necessary to back up the metadata. On the one hand, it ensures the ability to rebuild the migration cluster. On the other hand, it can implement the version control of the migration task. For details, see Export and Import Data Sources and Task Configuration of Clusters.

13.6.5 Deploy a DM cluster

13.6.5.1 Software and Hardware Requirements for TiDB Data Migration

TiDB Data Migration (DM) supports mainstream Linux operating systems. See the following table for specific version requirements:

Linux OS	Version
Red Hat Enterprise Linux	7.3 or later
CentOS	7.3 or later
Oracle Enterprise Linux	7.3 or later
Ubuntu LTS	16.04 or later

DM can be deployed and run on Intel architecture servers and mainstream virtualization environments.

13.6.5.1.1 Recommended server requirements

DM can be deployed and run on a 64-bit generic hardware server platform (Intel x86-64 architecture). For servers used in the development, testing, and production environments, this section illustrates recommended hardware configurations (these do not include the resources used by the operating system).

Development and test environments

Component	CPU	Memory	Local Storage	Network	Number of Instances (Minimum Requirement)
DM-master	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	1
DM-worker	8 core+	16 GB+	SAS, 200 GB+ (Greater than the size of the migrated data)	Gigabit network card	The number of upstream MySQL instances

Note:

- In the test environment, DM-master and DM-worker used for functional verification can be deployed on the same server.
- To prevent interference with the accuracy of the performance test results, it is **not recommended** to use low-performance storage and network hardware configurations.
- If you need to verify the function only, you can deploy a DM-master on a single machine. The number of DM-worker deployed must be greater than or equal to the number of upstream MySQL instances. To ensure high availability, it is recommended to deploy more DM-workers.
- DM-worker stores full data in the `dump` and `load` phases. Therefore, the disk space for DM-worker needs to be greater than the total amount of data to be migrated. If the relay log is enabled for the migration task, DM-worker needs additional disk space to store upstream binlog data.

Production environment

Component	CPU	Memory	Hard Disk Type	Network	Number of Instances (Minimum Requirement)
DM-master	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	3

Component	CPU	Memory	Hard Disk Type	Network	Number of Instances (Minimum Requirement)
DM-worker	16 core+	32 GB+	SSD, 200 GB+ (Greater than the size of the migrated data)	10 Gigabit network card	Greater than the number of upstream MySQL instances
Monitor	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	1

Note:

- In the production environment, it is not recommended to deploy and run DM-master and DM-worker on the same server, because when DM-worker writes data to disks, it might interfere with the use of disks by DM-master's high availability component.
- If a performance issue occurs, you are recommended to modify the task configuration file according to the Optimize Configuration of DM document. If the performance is not effectively optimized by tuning the configuration file, you can try to upgrade the hardware of your server.

13.6.5.1.2 Downstream storage space requirements

The target TiKV cluster must have enough disk space to store the imported data. In

addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has `x 2` because:

- Indexes might take extra space.
- RocksDB has a space amplification effect.

You can estimate the data volume by using the following SQL statements to summarize the `DATA_LENGTH` field:

```
-- Calculate the size of all schemas
SELECT
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(DATA_LENGTH)) AS 'Data Size',
  FORMAT_BYTES(SUM(INDEX_LENGTH)) 'Index Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_SCHEMA;

-- Calculate the 5 largest tables
SELECT
  TABLE_NAME,
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(data_length)) AS 'Data Size',
  FORMAT_BYTES(SUM(index_length)) AS 'Index Size',
  FORMAT_BYTES(SUM(data_length+index_length)) AS 'Total Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_NAME,
  TABLE_SCHEMA
ORDER BY
  SUM(DATA_LENGTH+INDEX_LENGTH) DESC
LIMIT
  5;
```

13.6.5.2 Deploy a DM Cluster Using TiUP

TiUP is a cluster operation and maintenance tool introduced in TiDB 4.0. TiUP provides TiUP DM, a cluster management component written in Golang. By using TiUP DM, you can easily perform daily TiDB Data Migration (DM) operations, including deploying, starting, stopping, destroying, scaling, and upgrading a DM cluster, and manage DM cluster parameters.

TiUP supports deploying DM v2.0 or later DM versions. This document introduces how to deploy DM clusters of different topologies.

> **Note:**
>
> If your target machine's operating system supports SELinux, make sure that SELinux is **disabled**.

13.6.5.2.1 Prerequisites

- When DM performs a full data replication task, the DM-worker is bound with only one upstream database. The DM-worker first exports the full amount of data locally, and then imports the data into the downstream database. Therefore, the worker's host space must be large enough to store all upstream tables to be exported. The storage path is specified later when you create the task.
- You need to meet the hardware and software requirements when deploying a DM cluster.
- Starting from v8.0.0, if you need to encrypt database passwords, you must store a key file used for encrypting and decrypting database passwords in the DM-master in advance, and configure `secret-key-path` for DM-master before using the `dmctl encrypt` command.

13.6.5.2.2 Step 1: Install TiUP on the control machine

Log in to the control machine using a regular user account (take the `tidb` user as an example). All the following TiUP installation and cluster management operations can be performed by the `tidb` user.

1. Install TiUP by executing the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/install.sh | sh
```

   After the installing, `~/.bashrc` has been modified to add TiUP to PATH, so you need to open a new terminal or redeclare the global environment variables `source ~/.bashrc` to use it.

2. Install the TiUP DM component:

```
tiup install dm dmctl
```

13.6.5.2.3 Step 2: Edit the initialization configuration file

According to the intended cluster topology, you need to manually create and edit the cluster initialization configuration file.

You need to create a YAML configuration file (named `topology.yaml` for example) according to the configuration file template. For other scenarios, edit the configuration accordingly.

You can use the command `tiup dm template > topology.yaml` to generate a configuration file template quickly.

The configuration of deploying three DM-masters, three DM-workers, and one monitoring component instance is as follows:

```
#### The global variables apply to all other components in the configuration
   ↪ . If one specific value is missing in the component instance, the
   ↪ corresponding global variable serves as the default value.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/dm-deploy"
  data_dir: "/dm-data"

server_configs:
  master:
    log-level: info
    # rpc-timeout: "30s"
    # rpc-rate-limit: 10.0
    # rpc-rate-burst: 40
  worker:
    log-level: info

master_servers:
  - host: 10.0.1.11
    name: master1
    ssh_port: 22
    port: 8261
    # peer_port: 8291
    # deploy_dir: "/dm-deploy/dm-master-8261"
    # data_dir: "/dm-data/dm-master-8261"
    # log_dir: "/dm-deploy/dm-master-8261/log"
    # numa_node: "0,1"
    # The following configs are used to overwrite the `server_configs.master
       ↪ ` values.
    config:
      log-level: info
      # rpc-timeout: "30s"
```

```
    # rpc-rate-limit: 10.0
    # rpc-rate-burst: 40
  - host: 10.0.1.18
    name: master2
    ssh_port: 22
    port: 8261
  - host: 10.0.1.19
    name: master3
    ssh_port: 22
    port: 8261
#### If you do not need to ensure high availability of the DM cluster,
   ↪ deploy only one DM-master node, and the number of deployed DM-worker
   ↪ nodes must be no less than the number of upstream MySQL/MariaDB
   ↪ instances to be migrated.
#### To ensure high availability of the DM cluster, it is recommended to
   ↪ deploy three DM-master nodes, and the number of deployed DM-worker
   ↪ nodes must exceed the number of upstream MySQL/MariaDB instances to
   ↪ be migrated (for example, the number of DM-worker nodes is two more
   ↪ than the number of upstream instances).
worker_servers:
  - host: 10.0.1.12
    ssh_port: 22
    port: 8262
    # deploy_dir: "/dm-deploy/dm-worker-8262"
    # log_dir: "/dm-deploy/dm-worker-8262/log"
    # numa_node: "0,1"
    # The following configs are used to overwrite the `server_configs.worker
       ↪ ` values.
    config:
      log-level: info
  - host: 10.0.1.19
    ssh_port: 22
    port: 8262

monitoring_servers:
  - host: 10.0.1.13
    ssh_port: 22
    port: 9090
    # deploy_dir: "/tidb-deploy/prometheus-8249"
    # data_dir: "/tidb-data/prometheus-8249"
    # log_dir: "/tidb-deploy/prometheus-8249/log"

grafana_servers:
  - host: 10.0.1.14
    port: 3000
```

```
    # deploy_dir: /tidb-deploy/grafana-3000

alertmanager_servers:
  - host: 10.0.1.15
    ssh_port: 22
    web_port: 9093
    # cluster_port: 9094
    # deploy_dir: "/tidb-deploy/alertmanager-9093"
    # data_dir: "/tidb-data/alertmanager-9093"
    # log_dir: "/tidb-deploy/alertmanager-9093/log"
```

Note:

- It is not recommended to run too many DM-workers on one host. Each DM-worker should be allocated at least 2 core CPU and 4 GiB memory.
- Make sure that the ports among the following components are interconnected:
  - The `peer_port` (`8291` by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `port` of all DM-worker nodes (`8262` by default).
  - Each DM-worker node can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-worker nodes (`8262` by default).

For more `master_servers.host.config` parameter description, refer to master parameter. For more `worker_servers.host.config` parameter description, refer to worker parameter.

13.6.5.2.4 Step 3: Execute the deployment command

Note:

You can use secret keys or interactive passwords for security authentication when you deploy TiDB using TiUP:

- If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;
- If you use passwords, add the `-p` flag to enter the password interaction window;
- If password-free login to the target machine has been configured, no authentication is required.

```
tiup dm deploy ${name} ${version} ./topology.yaml -u ${ssh_user} [-p] [-i /
    ↪ home/root/.ssh/gcp_rsa]
```

The parameters used in this step are as follows.

Parameter	Description
`${name}`	The name of the DM cluster, eg: dm-test

Parameter	Description
`$ ↪ { ↪ version ↪ } ↪`	The version of the DM cluster. You can see other supported versions by running `tiup ↪ ↪ list ↪ ↪ dm ↪ - ↪ master ↪ .`
`./ ↪ topology ↪ . ↪ yaml ↪`	The path of the topology configuration file.

Parameter	Description
`-u` or `--user`	Log in to the target machine as the root user or other user account with ssh and sudo privileges to complete the cluster deployment.

Parameter	Description
`-p` or `--password`	The password of target hosts. If specified, password authentication is used.

Parameter	Description
`-i` or `--identity_file`	The path of the SSH identity file. If specified, public key authentication is used (default "/root/.ssh/id_r

At the end of the output log, you will see `Deployed cluster `dm-test` successfully`. This indicates that the deployment is successful.

13.6.5.2.5 Step 4: Check the clusters managed by TiUP

```
tiup dm list
```

TiUP supports managing multiple DM clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

```
Name  User  Version Path                                       PrivateKey
----  ----  ------- ----                                       ----------
dm-test tidb ${version} /root/.tiup/storage/dm/clusters/dm-test /root/.tiup
    ↪ /storage/dm/clusters/dm-test/ssh/id_rsa
```

13.6.5.2.6 Step 5: Check the status of the deployed DM cluster

To check the status of the `dm-test` cluster, execute the following command:

```
tiup dm display dm-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down`/`inactive`), and directory information.

13.6.5.2.7 Step 6: Start the DM cluster

```
tiup dm start dm-test
```

If the output log includes `Started cluster` `` `dm-test` `` `successfully`, the start is successful.

13.6.5.2.8 Step 7: Verify the running status of the DM cluster

Check the DM cluster status using TiUP:

```
tiup dm display dm-test
```

If the `Status` is `Up` in the output, the cluster status is normal.

13.6.5.2.9 Step 8: Managing migration tasks using dmctl

dmctl is a command-line tool used to control DM clusters. You are recommended to use dmctl via TiUP.

dmctl supports both the command mode and the interactive mode. For details, see Maintain DM Clusters Using dmctl.

13.6.5.2.10 Step 9: Encrypt the database password

After deployment, you can configure DM tasks to encrypt the database password. For more information, see Encrypt the database password.

13.6.5.3 Deploy a DM Cluster Offline Using TiUP

This document describes how to deploy a DM cluster offline using TiUP.

13.6.5.3.1 Step 1: Prepare the TiUP offline component package

- Install the TiUP package manager online.

    1. Install the TiUP tool:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.
    ↪ com/install.sh | sh
```

2. Redeclare the global environment variables:

```
source .bash_profile
```

3. Confirm whether TiUP is installed:

```
which tiup
```

- Pull the mirror using TiUP

1. Pull the needed components on a machine that has access to the Internet:

```
# You can modify ${version} to the needed version.
tiup mirror clone tidb-dm-${version}-linux-amd64 --os=linux --arch=
    ↪ amd64 \
    --dm-master=${version} --dm-worker=${version} --dmctl=${version
        ↪ } \
    --alertmanager=v0.17.0 --grafana=v4.0.3 --prometheus=v4.0.3 \
    --dm=v$(tiup --version|grep 'tiup'|awk -F ' ' '{print $1}')
```

The command above creates a directory named `tidb-dm-${version}-linux-
↪ amd64` in the current directory, which contains the component package managed by TiUP.

2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

```
tar czvf tidb-dm-${version}-linux-amd64.tar.gz tidb-dm-${version}-
    ↪ linux-amd64
```

`tidb-dm-${version}-linux-amd64.tar.gz` is an independent offline environment package.

13.6.5.3.2 Step 2: Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following command:

```
#### You can modify ${version} to the needed version.
tar xzvf tidb-dm-${version}-linux-amd64.tar.gz
sh tidb-dm-${version}-linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically executes the `tiup mirror set tidb-dm-${version}-linux-amd64` command to set the current mirror address to `tidb-dm-${version}-linux-amd64`.

To switch the mirror to another directory, manually execute the `tiup mirror set <mirror-dir>` command. If you want to switch back to the official mirror, execute `tiup mirror set https://tiup-mirrors.pingcap.com`.

13.6.5.3.3 Step 3: Edit the initialization configuration file

You need to edit the cluster initialization configuration file according to different cluster topologies.

For the full configuration template, refer to the TiUP configuration parameter template. Create a configuration file `topology.yaml`. In other combined scenarios, edit the configuration file as needed according to the templates.

The configuration of deploying three DM-masters, three DM-workers, and one monitoring component instance is as follows:

```
---
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/home/tidb/dm/deploy"
  data_dir: "/home/tidb/dm/data"
  # arch: "amd64"

master_servers:
  - host: 172.19.0.101
  - host: 172.19.0.102
  - host: 172.19.0.103

worker_servers:
  - host: 172.19.0.101
  - host: 172.19.0.102
  - host: 172.19.0.103

monitoring_servers:
  - host: 172.19.0.101

grafana_servers:
  - host: 172.19.0.101

alertmanager_servers:
  - host: 172.19.0.101
```

Note:

- If you do not need to ensure high availability of the DM cluster, deploy only one DM-master node, and the number of deployed DM-worker nodes must be no less than the number of upstream MySQL/MariaDB instances to be migrated.
- To ensure high availability of the DM cluster, it is recommended to deploy three DM-master nodes, and the number of deployed DM-worker nodes must be greater than the number of upstream MySQL/MariaDB instances to be migrated (for example, the number of DM-worker nodes is two more than the number of upstream instances).
- For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
- For parameters that should be effective on a specific node, configure these parameters in `config` of this node.
- Use `.` to indicate the subcategory of the configuration, such as `log.slow-threshold`. For more formats, see TiUP configuration template.
- For more parameter description, see master `config.toml.example` and worker `config.toml.example`.
- Make sure that the ports among the following components are interconnected:
  - The `peer_port` (`8291` by default) among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `port` of all DM-worker nodes (`8262` by default).
  - Each DM-worker node can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-master nodes (`8261` by default).
  - The TiUP nodes can connect to the `port` of all DM-worker nodes (`8262` by default).

13.6.5.3.4 Step 4: Execute the deployment command

Note:

> You can use secret keys or interactive passwords for security authentication when you deploy DM using TiUP:
>
> - If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;
> - If you use passwords, add the `-p` flag to enter the password interaction window;
> - If password-free login to the target machine has been configured, no authentication is required.

```
tiup dm deploy dm-test ${version} ./topology.yaml --user root [-p] [-i /home
    ↪ /root/.ssh/gcp_rsa]
```

In the above command:

- The name of the deployed DM cluster is `dm-test`.
- The version of the DM cluster is `${version}`. You can view the latest versions supported by TiUP by running `tiup list dm-master`.
- The initialization configuration file is `topology.yaml`.
- `--user root`: Log in to the target machine through the `root` key to complete the cluster deployment, or you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]`: optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the `root` user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.
- TiUP DM uses the embedded SSH client. If you want to use the SSH client native to the control machine system, edit the configuration according to using the system's native SSH client to connect to the cluster.

At the end of the output log, you will see `Deployed cluster `dm-test` successfully`. This indicates that the deployment is successful.

13.6.5.3.5 Step 5: Check the clusters managed by TiUP

```
tiup dm list
```

TiUP supports managing multiple DM clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

```
Name User Version Path                                        PrivateKey
---- ---- ------- ----                                        ----------
dm-test tidb ${version} /root/.tiup/storage/dm/clusters/dm-test /root/.tiup
    ↪ /storage/dm/clusters/dm-test/ssh/id_rsa
```

13.6.5.3.6 Step 6: Check the status of the deployed DM cluster

To check the status of the `dm-test` cluster, execute the following command:

```
tiup dm display dm-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down`/`inactive`), and directory information of the `dm-test` cluster.

13.6.5.3.7 Step 7: Start the cluster

```
tiup dm start dm-test
```

If the output log includes `Started cluster` `` `dm-test` `` `successfully`, the start is successful.

13.6.5.3.8 Step 8: Verify the running status of the cluster

Check the DM cluster status using TiUP:

```
tiup dm display dm-test
```

If the `Status` is `Up` in the output, the cluster status is normal.

13.6.5.4 Deploy Data Migration Using DM Binary

This document introduces how to quickly deploy the Data Migration (DM) cluster using DM binary.

> **Note:**
>
> In the production environment, it is recommended to use TiUP to deploy a DM cluster.

13.6.5.4.1 Download DM binary

The DM binary is included in the TiDB Toolkit. To download the TiDB Toolkit, see Download TiDB Tools.

13.6.5.4.2 Sample scenario

Suppose that you deploy a DM cluster based on this sample scenario:

Two DM-worker nodes and three DM-master nodes are deployed on five servers.

Here is the address of each node:

Instance	Server address	Port
DM-master1	192.168.0.4	8261
DM-master2	192.168.0.5	8261
DM-master3	192.168.0.6	8261
DM-worker1	192.168.0.7	8262
DM-worker2	192.168.0.8	8262

Based on this scenario, the following sections describe how to deploy the DM cluster.

Note:

- If you deploy multiple DM-master or DM-worker instances in a single server, the port and working directory of each instance must be unique.
- If you do not need to ensure high availability of the DM cluster, deploy only one DM-master node, and the number of deployed DM-worker nodes must be no less than the number of upstream MySQL/MariaDB instances to be migrated.
- To ensure high availability of the DM cluster, it is recommended to deploy three DM-master nodes, and the number of deployed DM-worker nodes must be greater than the number of upstream MySQL/MariaDB instances to be migrated (for example, the number of DM-worker nodes is two more than the number of upstream instances).
- Make sure that the ports among the following components are interconnected:
  - The `8291` ports among the DM-master nodes are interconnected.
  - Each DM-master node can connect to the `8262` ports of all DM-worker nodes.
  - Each DM-worker node can connect to the `8261` port of all DM-master nodes.

Deploy DM-master

You can configure DM-master by using command-line parameters or the configuration file.

DM-master command-line parameters

The following is the description of DM-master command-line parameters:

```
./dm-master --help
```

```
Usage of dm-master:
  -L string
        log level: debug, info, warn, error, fatal (default "info")
  -V    prints version and exit
  -advertise-addr string
        advertise address for client traffic (default "${master-addr}")
  -advertise-peer-urls string
        advertise URLs for peer traffic (default "${peer-urls}")
  -config string
        path to config file
  -data-dir string
        path to the data directory (default "default.${name}")
  -initial-cluster string
        initial cluster configuration for bootstrapping, e.g. dm-master=http
            ↪ ://127.0.0.1:8291
  -join string
        join to an existing cluster (usage: cluster's "${master-addr}" list,
            ↪ e.g. "127.0.0.1:8261,127.0.0.1:18261"
  -log-file string
        log file path
  -master-addr string
        master API server and status addr
  -name string
        human-readable name for this DM-master member
  -peer-urls string
        URLs for peer traffic (default "http://127.0.0.1:8291")
  -print-sample-config
        print sample config file of dm-worker
```

Note:

In some situations, you cannot use the above method to configure DM-master because some configurations are not exposed to the command line. In such cases, use the configuration file instead.

DM-master configuration file

The following is the configuration file of DM-master. It is recommended that you configure DM-master by using this method.

1. Write the following configuration to `conf/dm-master1.toml`:

   "'toml # Master Configuration. name = "master1"

   # Log configurations. log-level = "info" log-file = "dm-master.log"

   # The listening address of DM-master. master-addr = "192.168.0.4:8261"

   # The peer URLs of DM-master. peer-urls = "192.168.0.4:8291"

   # The value of `initial-cluster` is the combination of the `advertise-peer-urls` value of all DM-master nodes in the initial cluster. initial-cluster = "master1=http://192.168.0.4:8291,master2=http://192.168.0.5:8291,master3=http://192.168.0.6:8291"
   "'

2. Execute the following command in the terminal to run DM-master:

   ```
   bash  ./dm-master -config conf/dm-master1.toml
   ```

> **Note:**
> The console does not output logs after this command is executed. If you want to view the runtime log, you can execute `tail -f dm-master.log`.

3. For DM-master2 and DM-master3, change `name` in the configuration file to `master2` and `master3` respectively, and change `peer-urls` to `192.168.0.5:8291` and `192.168.0.6:8291` respectively. Then repeat Step 2.

Deploy DM-worker

You can configure DM-worker by using command-line parameters or the configuration file.

DM-worker command-line parameters

The following is the description of the DM-worker command-line parameters:

```
./dm-worker --help
```

```
Usage of worker:
  -L string
        log level: debug, info, warn, error, fatal (default "info")
  -V    prints version and exit
  -advertise-addr string
        advertise address for client traffic (default "${worker-addr}")
  -config string
        path to config file
```

```
-join string
     join to an existing cluster (usage: dm-master cluster's "${master-
        ↪ addr}")
-keepalive-ttl int
     dm-worker's TTL for keepalive with etcd (in seconds) (default 10)
-log-file string
     log file path
-name string
     human-readable name for DM-worker member
-print-sample-config
     print sample config file of dm-worker
-worker-addr string
     listen address for client traffic
```

Note:

In some situations, you cannot use the above method to configure DM-worker because some configurations are not exposed to the command line. In such cases, use the configuration file instead.

DM-worker configuration file

The following is the DM-worker configuration file. It is recommended that you configure DM-worker by using this method.

1. Write the following configuration to `conf/dm-worker1.toml`:

   “‘toml # Worker Configuration. name = “worker1”

   # Log configuration. log-level = “info” log-file = “dm-worker.log”

   # DM-worker address. worker-addr = “:8262”

   # The master-addr configuration of the DM-master nodes in the cluster. join = “192.168.0.4:8261,192.168.0.5:8261,192.168.0.6:8261” “‘

2. Execute the following command in the terminal to run DM-worker:

   `bash ./dm-worker -config conf/dm-worker1.toml`

3. For DM-worker2, change `name` in the configuration file to `worker2`. Then repeat Step 2.

Now, a DM cluster is successfully deployed.

13.6.5.5 Use Kubernetes

13.6.6 Tutorials

13.6.6.1 Create a Data Source for TiDB Data Migration

> **Note:**
>
> Before creating a data source, you need to Deploy a DM Cluster Using TiUP.

The document describes how to create a data source for the data migration task of TiDB Data Migration (DM).

A data source contains the information for accessing the upstream migration task. Because a data migration task requires referring its corresponding data source to obtain the configuration information of access, you need to create the data source of a task before creating a data migration task. For specific data source management commands, refer to Manage Data Source Configurations.

13.6.6.1.1 Step 1: Configure the data source

1. (optional) Encrypt the data source password

   In DM configuration files, it is recommended to use the password encrypted with dmctl. You can follow the example below to obtain the encrypted password of the data source, which can be used to write the configuration file later.

   Starting from v8.0.0, you must configure `secret-key-path` for DM-master before using the `tiup dmctl encrypt` command.

```
tiup dmctl encrypt 'abc!@#123'
```

```
MKxn0Qo3m3XOyjCnhEMtsUCm83EhGQDZ/T4=
```

2. Write the configuration file of the data source

   For each data source, you need an individual configuration file to create it. You can follow the example below to create a data source whose ID is "mysql-01". First create the configuration file `./source-mysql-01.yaml`:

```
source-id: "mysql-01" # The ID of the data source, you can refer this
    ↪ source-id in the task configuration and dmctl command to
    ↪ associate the corresponding data source.
```

```
from:
  host: "127.0.0.1"
  port: 3306
  user: "root"
  password: "MKxn0Qo3m3XOyjCnhEMtsUCm83EhGQDZ/T4=" # The user password
     ↪ of the upstream data source. It is recommended to use the
     ↪ password encrypted with dmctl.
  security:                                    # The TLS configuration of
     ↪  the upstream data source. If not necessary, it can be deleted.
    ssl-ca: "/path/to/ca.pem"
    ssl-cert: "/path/to/cert.pem"
    ssl-key: "/path/to/key.pem"
```

13.6.6.1.2 Step 2: Create a data source

You can use the following command to create a data source:

```
tiup dmctl --master-addr <master-addr> operate-source create ./source-mysql
   ↪ -01.yaml
```

For other configuration parameters, refer to Upstream Database Configuration File.

The returned results are as follows:

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

13.6.6.1.3 Step 3: Query the data source you created

After creating a data source, you can use the following command to query the data source:

- If you know the `source-id` of the data source, you can use the `dmctl config source` ↪ `<source-id>` command to directly check the configuration of the data source:

```
tiup dmctl --master-addr <master-addr> config source mysql-01
```

```
{
  "result": true,
  "msg": "",
  "cfg": "enable-gtid: false
    flavor: mysql
    source-id: mysql-01
    from:
      host: 127.0.0.1
      port: 3306
      user: root
      password: '******'
}
```

- If you do not know the `source-id`, you can use the `dmctl operate-source show` command to check the source database list, from which you can find the corresponding data source.

```
tiup dmctl --master-addr <master-addr> operate-source show
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "source is added but there is no free worker to bound
                ↪ ",
            "source": "mysql-02",
            "worker": ""
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

13.6.6.2 Manage Data Source Configurations in TiDB Data Migration

This document introduces how to manage data source configurations, including encrypting the MySQL password, operating the data source, and changing the bindings between upstream MySQL instances and DM-workers using dmctl.

13.6.6.2.1 Encrypt the database password

In DM configuration files, it is recommended to use the password encrypted with dmctl. For one original password, the encrypted password is different after each encryption.

> **Note:**
>
> Starting from v8.0.0, you must configure `secret-key-path` for DM-master before using the `dmctl encrypt` command.

```
./dmctl encrypt 'abc!@#123'
```

```
MKxn0Qo3m3XOyjCnhEMtsUCm83EhGQDZ/T4=
```

13.6.6.2.2 Operate data source

You can use the `operate-source` command to load, list or remove the data source configurations to the DM cluster.

```
help operate-source
```

```
`create`/`stop`/`show` upstream MySQL/MariaDB source.

Usage:
  dmctl operate-source <operate-type> [config-file ...] [--print-sample-
      ↪ config] [flags]

Flags:
  -h, --help                help for operate-source
  -p, --print-sample-config print sample config file of source

Global Flags:
  -s, --source strings MySQL Source ID
```

Flags description

- `create`: Creates one or more upstream database sources. When creating multiple data sources fails, DM rolls back to the state where the command was not executed.
- `stop`: Stops one or more upstream database sources. When stopping multiple data sources fails, some data sources might be stopped.
- `show`: Shows the added data source and the corresponding DM-worker.

- `config-file`: Specifies the file path of `source.yaml` and can pass multiple file paths.
- `--print-sample-config`: Prints the sample configuration file. This parameter ignores other parameters.

Usage example

Use the following `operate-source` command to create a source configuration file:

```
operate-source create ./source.yaml
```

For the configuration of `source.yaml`, refer to Upstream Database Configuration File Introduction.

The following is an example of the returned result:

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

Check data source configurations

> **Note:**
>
> The `config` command is only supported in DM v6.0 and later versions. For earlier versions, you must use the `get-config` command.

If you know the `source-id`, you can run `dmctl --master-addr <master-addr> config source <source-id>` to get the data source configuration.

```
config source mysql-replica-01
```

```
{
  "result": true,
    "msg": "",
    "cfg": "enable-gtid: false
```

```
    flavor: mysql
    source-id: mysql-replica-01
    from:
      host: 127.0.0.1
      port: 8407
      user: root
      password: '******'
}
```

If you don't know the `source-id`, you can run `dmctl --master-addr <master-addr> operate-source show` to list all data sources first.

```
operate-source show
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "source is added but there is no free worker to bound",
            "source": "mysql-replica-02",
            "worker": ""
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "dm-worker-1"
        }
    ]
}
```

13.6.6.2.3 Change the bindings between upstream MySQL instances and DM-workers

You can use the `transfer-source` command to change the bindings between upstream MySQL instances and DM-workers.

```
help transfer-source
```

```
Transfers an upstream MySQL/MariaDB source to a free worker.
Usage:
  dmctl transfer-source <source-id> <worker-id> [flags]
Flags:
```

```
  -h, --help  help for transfer-source
Global Flags:
  -s, --source strings MySQL Source ID.
```

Before transferring, DM checks whether the worker to be unbound still has running tasks. If the worker has any running tasks, you need to pause the tasks first, change the binding, and then resume the tasks.

Usage example

If you do not know the bindings of DM-workers, you can run `dmctl --master-addr <master-addr> list-member --worker` to list the current bindings of all workers.

```
list-member --worker
```

```
{
    "result": true,
    "msg": "",
    "members": [
        {
            "worker": {
                "msg": "",
                "workers": [
                    {
                        "name": "dm-worker-1",
                        "addr": "127.0.0.1:8262",
                        "stage": "bound",
                        "source": "mysql-replica-01"
                    },
                    {
                        "name": "dm-worker-2",
                        "addr": "127.0.0.1:8263",
                        "stage": "free",
                        "source": ""
                    }
                ]
            }
        }
    ]
}
```

In the above example, `mysql-replica-01` is bound to `dm-worker-1`. The below command transfers the binding worker of `mysql-replica-01` to `dm-worker-2`.

```
transfer-source mysql-replica-01 dm-worker-2
```

```
{
    "result": true,
    "msg": ""
}
```

Check whether the command takes effect by running `dmctl --master-addr <master-addr> list-member --worker`.

```
list-member --worker
```

```
{
    "result": true,
    "msg": "",
    "members": [
        {
            "worker": {
                "msg": "",
                "workers": [
                    {
                        "name": "dm-worker-1",
                        "addr": "127.0.0.1:8262",
                        "stage": "free",
                        "source": ""
                    },
                    {
                        "name": "dm-worker-2",
                        "addr": "127.0.0.1:8263",
                        "stage": "bound",
                        "source": "mysql-replica-01"
                    }
                ]
            }
        }
    ]
}
```

13.6.6.3 Data Migration Task Configuration Guide

This document introduces how to configure a data migration task in Data Migration (DM).

13.6.6.3.1 Configure data sources to be migrated

Before configuring the data sources to be migrated for the task, you need to first make sure that DM has loaded the configuration files of the corresponding data sources. The

following are some operation references:

- To view the data source, you can refer to Check the data source configuration.
- To create a data source, you can refer to Create data source.
- To generate a data source configuration file, you can refer to Source configuration file introduction.

The following example of `mysql-instances` shows how to configure data sources that need to be migrated for the data migration task:

```
---

##### ********* Basic configuration *********
name: test          # The name of the task. Should be globally unique.

##### ******** Data source configuration **********
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-01`.
  - source-id: "mysql-replica-02" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-02`.
```

13.6.6.3.2 Configure the downstream TiDB cluster

The following example of `target-database` shows how to configure the target TiDB cluster to be migrated to for the data migration task:

```
---

##### ********* Basic configuration *********
name: test          # The name of the task. Should be globally unique.

##### ******** Data source configuration **********
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-01`.
  - source-id: "mysql-replica-02" # Migrate data from the data source whose
    ↪ `source-id` is `mysql-replica-02`.

##### ******** Downstream TiDB database configuration **********
target-database:    # Configuration of target TiDB database.
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: ""      # If the password is not null, it is recommended to use
    ↪  a password encrypted with dmctl.
```

13.6.6.3.3 Configure tables to be migrated

> **Note:**
>
> If you do not need to filter specific tables or migrate specific tables, skip this configuration.

To configure the block and allow list of data source tables for the data migration task, perform the following steps:

1. Configure a global filter rule set of the block and allow list in the task configuration file.

```
block-allow-list:
  bw-rule-1:                          # The name of the block and allow
    ↪ list rule.
    do-dbs: ["test.*", "user"]     # The allow list of upstream schemas
      ↪ to be migrated. Wildcard characters (*?) are supported. You
      ↪ only need to configure either `do-dbs` or `ignore-dbs`. If
      ↪ both fields are configured, only `do-dbs` takes effect.
    # ignore-dbs: ["mysql", "account"] # The block list of upstream
      ↪ schemas to be migrated. Wildcard characters (*?) are
      ↪ supported.
    do-tables:                        # The allow list of upstream tables
      ↪ to be migrated. You only need to configure either `do-tables`
      ↪  or `ignore-tables`. If both fields are configured, only `do-
      ↪ tables` takes effect.
    - db-name: "test.*"
      tbl-name: "t.*"
    - db-name: "user"
      tbl-name: "information"
  bw-rule-2:                        # The name of the block allow list
    ↪ rule.
    ignore-tables:                  # The block list of data source tables
      ↪  needs to be migrated.
    - db-name: "user"
      tbl-name: "log"
```

   For detailed configuration rules, see Block and allow table lists.

2. Reference the block and allow list rules in the data source configuration to filter tables to be migrated.

```
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source
      ↪ whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-1" # The name of the block and allow
       ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
  - source-id: "mysql-replica-02" # Migrate data from the data source
      ↪ whose `source-id` is `mysql-replica-02`.
    block-allow-list: "bw-rule-2" # The name of the block and allow
       ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
```

13.6.6.3.4 Configure binlog events to be migrated

> **Note:**
>
> If you do not need to filter specific binlog events of certain schemas or tables, skip this configuration.

To configure the filters of binlog events for the data migration task, perform the following steps:

1. Configure a global filter rule set of binlog events in the task configuration file.

```
filters:                                    # The filter rule set of data
   ↪  source binlog events. You can set multiple rules at the same
   ↪ time.
  filter-rule-1:                            # The name of the filtering
     ↪ rule.
    schema-pattern: "test_*"                # The pattern of the data
       ↪ source schema name. Wildcard characters (*?) are supported.
    table-pattern: "t_*"                    # The pattern of the data
       ↪ source table name. Wildcard characters (*?) are supported.
    events: ["truncate table", "drop table"] # The event types to be
       ↪ filtered out in schemas or tables that match the `schema-
       ↪ pattern` or the `table-pattern`.
    action: Ignore                          # Whether to migrate (Do) or
       ↪ ignore (Ignore) the binlog that matches the filtering rule.
  filter-rule-2:
    schema-pattern: "test"
    events: ["all dml"]
```

```
    action: Do
```

For detailed configuration rules, see Binlog event filter.

2. Reference the binlog event filtering rules in the data source configuration to filter specified binlog events of specified tables or schemas in the data source.

```
mysql-instances:
  - source-id: "mysql-replica-01" # Migrate data from the data source
      ↪ whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-1" # The name of the block and allow
       ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-1"] # The name of the rule that filters
       ↪  specific binlog events of the data source. You can configure
       ↪  multiple rules here.
  - source-id: "mysql-replica-02" # Migrate data from the data source
      ↪ whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-2" # The name of the block and allow
       ↪ list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-2"] # The name of the rule that filters
       ↪  specific binlog events of the data source. You can configure
       ↪  multiple rules here.
```

13.6.6.3.5 Configure the mapping of data source tables to downstream TiDB tables

> **Note:**
>
> - If you do not need to migrate a certain table of the data source to the table with a different name in the downstream TiDB instance, skip this configuration.
> - If it is a shard merge task, you **must** set mapping rules in the task configuration file.

To configure the routing mapping rules for migrating data source tables to specified downstream TiDB tables, perform the following steps:

1. Configure a global routing mapping rule set in the task configuration file.

```
routes:                         # The routing mapping rule set between
  ↪ the data source tables and downstream TiDB tables. You can set
  ↪ multiple rules at the same time.
  route-rule-1:                 # The name of the routing mapping rule.
    schema-pattern: "test_*"    # The pattern of the upstream schema name
      ↪ . Wildcard characters (*?) are supported.
    table-pattern: "t_*"        # The pattern of the upstream table name.
      ↪  Wildcard characters (*?) are supported.
    target-schema: "test"       # The name of the downstream TiDB schema.
    target-table: "t"           # The name of the downstream TiDB table.
  route-rule-2:
    schema-pattern: "test_*"
    target-schema: "test"
```

For detailed configuration rules, see Table Routing.

2. Reference the routing mapping rules in the data source configuration to filter tables to be migrated.

```
mysql-instances:
  - source-id: "mysql-replica-01"               # Migrate data from the
    ↪ data source whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-1"               # The name of the block
      ↪ and allow list rule. If the DM version is earlier than v2
      ↪ .0.0-beta.2, use `black-white-list` instead.
    filter-rules: ["filter-rule-1"]             # The name of the rule
      ↪ that filters specific binlog events of the data source. You
      ↪ can configure multiple rules here.
    route-rules: ["route-rule-1", "route-rule-2"] # The name of the
      ↪ routing mapping rule. You can configure multiple rules here.
  - source-id: "mysql-replica-02"               # Migrate data from the
    ↪ data source whose `source-id` is `mysql-replica-02`.
    block-allow-list: "bw-rule-2"               # The name of the block
      ↪ and allow list rule. If the DM version is earlier than v2
      ↪ .0.0-beta.2, use `black-white-list` instead.
    filter-rules: ["filter-rule-2"]             # The name of the rule
      ↪ that filters specific binlog events of the data source. You
      ↪ can configure multiple rules here.
```

13.6.6.3.6 Configure a shard merge task

Note:

- If you need to migrate sharding DDL statements in a shard merge scenario, you **must** explicitly configure the `shard-mode` field. Otherwise, **DO NOT** configure `shard-mode` at all.
- Migrating sharding DDL statements is likely to cause many issues. Make sure you understand the principles and restrictions of DM migrating DDL statements before using this feature, and you **must** use this feature with caution.

The following example shows how to configure the task as a shard merge task:

```
---

##### ********* Basic information *********
name: test                  # The name of the task. Should be globally
   ↪ unique.
shard-mode: "pessimistic"   # The shard merge mode. Optional modes are ""/"
   ↪ pessimistic"/"optimistic". The "" mode is used by default which means
   ↪  sharding DDL merge is disabled. If the task is a shard merge task,
   ↪ set it to the "pessimistic" mode. After getting a deep understanding
   ↪ of the principles and restrictions of the "optimistic" mode, you can
   ↪ set it to the "optimistic" mode.
```

13.6.6.3.7 Other configurations

The following is an overall task configuration example of this document. The complete task configuration template can be found in DM task configuration file full introduction.

```
---

##### ********* Basic configuration *********
name: test                  # The name of the task. Should be globally
   ↪ unique.
shard-mode: "pessimistic"   # The shard merge mode. Optional modes are ""/"
   ↪ pessimistic"/"optimistic". The "" mode is used by default which means
   ↪  sharding DDL merge is disabled. If the task is a shard merge task,
   ↪ set it to the "pessimistic" mode. After getting a deep understanding
   ↪ of the principles and restrictions of the "optimistic" mode, you can
   ↪ set it to the "optimistic" mode.
task-mode: all              # The task mode. Can be set to `full`(only
   ↪ migrates full data)/`incremental`(replicates binlog synchronously)/`
   ↪ all` (replicates both full and incremental binlogs).
timezone: "UTC"           # The timezone used in SQL Session. By default,
   ↪ DM uses the global timezone setting in the target cluster, which
```

```
    ↪ ensures the correctness automatically. A customized timezone does not
    ↪  affect data migration but is unnecessary.

##### ******** Data source configuration **********
mysql-instances:
  - source-id: "mysql-replica-01"            # Migrate data from the data
      ↪ source whose `source-id` is `mysql-replica-01`.
    block-allow-list: "bw-rule-1"            # The name of the block and
       ↪ allow list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-1"]          # The name of the rule that
       ↪ filters specific binlog events of the data source. You can
       ↪ configure multiple rules here.
    route-rules: ["route-rule-1", "route-rule-2"] # The name of the routing
       ↪ mapping rule. You can configure multiple rules here.
  - source-id: "mysql-replica-02"            # Migrate data from the data
      ↪ source whose `source-id` is `mysql-replica-02`.
    block-allow-list: "bw-rule-2"            # The name of the block and
       ↪ allow list rule. If the DM version is earlier than v2.0.0-beta.2,
       ↪ use `black-white-list` instead.
    filter-rules: ["filter-rule-2"]          # The name of the rule that
       ↪ filters specific binlog events of the data source. You can
       ↪ configure multiple rules here.
    route-rules: ["route-rule-2"]            # The name of the routing
       ↪ mapping rule. You can configure multiple rules here.

##### ******** Downstream TiDB instance configuration **********
target-database:    # Configuration of the downstream database instance.
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: ""      # If the password is not null, it is recommended to use
     ↪  a password encrypted with dmctl.

##### ******** Feature configuration set **********
#### The filter rule set of tables to be migrated from the upstream database
    ↪  instance. You can set multiple rules at the same time.
block-allow-list:                  # Use black-white-list if the DM version
    ↪ is earlier than v2.0.0-beta.2.
  bw-rule-1:                       # The name of the block and allow list
     ↪ rule.
    do-dbs: ["test.*", "user"]     # The allow list of upstream schemas to
       ↪ be migrated. Wildcard characters (*?) are supported. You only need
       ↪  to configure either `do-dbs` or `ignore-dbs`. If both fields are
       ↪ configured, only `do-dbs` takes effect.
```

```
    # ignore-dbs: ["mysql", "account"] # The block list of upstream schemas
      ↪ to be migrated. Wildcard characters (*?) are supported.
    do-tables:                      # The allow list of upstream tables to be
      ↪  migrated. You only need to configure either `do-tables` or `
      ↪ ignore-tables`. If both fields are configured, only `do-tables`
      ↪ takes effect.
    - db-name: "test.*"
      tbl-name: "t.*"
    - db-name: "user"
      tbl-name: "information"
  bw-rule-2:                      # The name of the block allow list rule.
    ignore-tables:                # The block list of data source tables
      ↪ needs to be migrated.
    - db-name: "user"
      tbl-name: "log"

#### The filter rule set of data source binlog events.
filters:                                  # You can set multiple rules at
   ↪ the same time.
  filter-rule-1:                          # The name of the filtering rule.
    schema-pattern: "test_*"              # The pattern of the data source
      ↪ schema name. Wildcard characters (*?) are supported.
    table-pattern: "t_*"                  # The pattern of the data source
      ↪ table name. Wildcard characters (*?) are supported.
    events: ["truncate table", "drop table"] # The event types to be
      ↪ filtered out in schemas or tables that match the `schema-pattern`
      ↪ or the `table-pattern`.
    action: Ignore                        # Whether to migrate (Do) or
      ↪ ignore (Ignore) the binlog that matches the filtering rule.
  filter-rule-2:
    schema-pattern: "test"
    events: ["all dml"]
    action: Do

#### The routing mapping rule set between the data source and target TiDB
   ↪ instance tables.
routes:                       # You can set multiple rules at the same time.
  route-rule-1:               # The name of the routing mapping rule.
    schema-pattern: "test_*"  # The pattern of the data source schema name.
      ↪ Wildcard characters (*?) are supported.
    table-pattern: "t_*"      # The pattern of the data source table name.
      ↪ Wildcard characters (*?) are supported.
    target-schema: "test"     # The name of the downstream TiDB schema.
    target-table: "t"         # The name of the downstream TiDB table.
  route-rule-2:
```

```
    schema-pattern: "test_*"
    target-schema: "test"
```

13.6.6.4 TiDB Data Migration Shard Merge

TiDB Data Migration (DM) supports merging the DML and DDL data in the upstream MySQL/MariaDB sharded tables and migrating the merged data to the downstream TiDB tables.

If you need to migrate and merge MySQL shards of small datasets to TiDB, refer to this tutorial.

13.6.6.4.1 Restrictions

Currently, the shard merge feature is supported only in limited scenarios. For details, refer to Sharding DDL usage Restrictions in the pessimistic mode and Sharding DDL usage Restrictions in the optimistic mode.

13.6.6.4.2 Configure parameters

In the task configuration file, set `shard-mode` to `pessimistic`:

```
shard-mode: "pessimistic"
#### The shard merge mode. Optional modes are ""/"pessimistic"/"optimistic".
    ↪  The "" mode is used by default
#### which means sharding DDL merge is disabled. If the task is a shard
    ↪ merge task, set it to the "pessimistic"
#### mode. After getting a deep understanding of the principles and
    ↪ restrictions of the "optimistic" mode, you
#### can set it to the "optimistic" mode.
```

13.6.6.4.3 Handle sharding DDL locks manually

In some abnormal scenarios, you need to handle sharding DDL Locks manually.

13.6.6.5 TiDB Data Migration Table Routing

When you migrate data using TiDB Data Migration (DM), you can configure the table routing to migrate a certain table of the upstream MySQL or MariaDB instance to the specified table in the downstream.

Note:

- Configuring multiple different routing rules for a single table is not supported.
- The match rule of schema needs to be configured separately, which is used to migrate `CREATE/DROP SCHEMA xx`, as shown in `rule-2` of the Configure table routing section.

13.6.6.5.1 Configure table routing

```
routes:
  rule-1:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    target-schema: "test"
    target-table: "t"
    # extract-table, extract-schema, and extract-source are optional and
    # are required only when you need to extract information about sharded
    # tables, sharded schemas, and source datatabase information.
    extract-table:
      table-regexp: "t_(.*)"
      target-column: "c_table"
    extract-schema:
      schema-regexp: "test_(.*)"
      target-column: "c_schema"
    extract-source:
      source-regexp: "(.*)"
      target-column: "c_source"
  rule-2:
    schema-pattern: "test_*"
    target-schema: "test"
```

Regular expressions and wildcards are supported to match database and table names. In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following:

- Wildcards including `*`, `?`, and `[]` are supported. There can only be one `*` symbol in a wildcard match, and it must be at the end. For example, in `table-pattern: "t_*"`, `"t_*"` indicates all tables starting with `t_`. See wildcard matching for details.
- `table-regexp`, `schema-regexp`, and `source-regexp` only support regular expressions and cannot start with the `~` symbol.
- `schema-pattern` and `table-pattern` support both wildcards and regular expressions. Regular expressions must begin with the `~` symbol.

13.6.6.5.2 Parameter descriptions

- DM migrates the upstream MySQL or MariaDB instance tables that match the schema-pattern/table-pattern rule provided by Table selector to the downstream `target-schema/target-table`.
- For sharded tables that match the `schema-pattern/table-pattern` rules, DM extracts the table name by using the `extract-table.table-regexp` regular expression, the schema name by using the `extract-schema.schema-regexp` regular expression, and source information by using the `extract-source.source-regexp` regular expression. Then DM writes the extracted information to the corresponding `target-column` in the merged table in the downstream.

13.6.6.5.3 Usage examples

This section shows the usage examples in four different scenarios.

If you need to migrate and merge MySQL shards of small datasets to TiDB, refer to this tutorial.

Merge sharded schemas and tables

Assuming in the scenario of sharded schemas and tables, you want to migrate the `test_{1,2,3...}.t_{1,2,3...}` tables in two upstream MySQL instances to the `test.t` table in the downstream TiDB instance.

To migrate the upstream instances to the downstream `test.t`, you must create the following routing rules:

- `rule-1` is used to migrate DML or DDL statements of the table that matches `schema-pattern: "test_*"` and `table-pattern: "t_*"` to the downstream `test.t`.
- `rule-2` is used to migrate DDL statements of the schema that matches `schema-pattern: "test_*"`, such as `CREATE/DROP SCHEMA xx`.

> **Note:**
>
> - If the downstream `schema: test` already exists and is not to be deleted, you can omit `rule-2`.
> - If the downstream `schema: test` does not exist and only `rule-1` is configured, then it reports the `schema test doesn't exist` error during migration.

```
rule-1:
  schema-pattern: "test_*"
```

```
  table-pattern: "t_*"
  target-schema: "test"
  target-table: "t"
rule-2:
  schema-pattern: "test_*"
  target-schema: "test"
```

Extract table, schema, and source information and write into the merged table

Assuming in the scenario of sharded schemas and tables, you want to migrate the `test_{1,2,3...}.t_{1,2,3...}` tables in two upstream MySQL instances to the `test.t` table in the downstream TiDB instance. At the same time, you want to extract the source information of the sharded tables and write it to the downstream merged table.

To migrate the upstream instances to the downstream `test.t`, you must create routing rules similar to the previous section Merge sharded schemas and tables. In addition, you need to add the `extract-table`, `extract-schema`, and `extract-source` configurations:

- `extract-table`: For a sharded table matching `schema-pattern` and `table-pattern`, DM extracts the sharded table name by using `table-regexp` and writes the name suffix without the `t_` part to `target-column` of the merged table, that is, the `c_table` column.
- `extract-schema`: For a sharded schema matching `schema-pattern` and `table-pattern`, DM extracts the sharded schema name by using `schema-regexp` and writes the name suffix without the `test_` part to `target-column` of the merged table, that is, the `c_schema` column.
- `extract-source`: For a sharded table matching `schema-pattern` and `table-pattern`, DM writes the source instance information to the `target-column` of the merged table, that is, the `c_source` column.

```
rule-1:
  schema-pattern: "test_*"
  table-pattern: "t_*"
  target-schema: "test"
  target-table: "t"
  extract-table:
    table-regexp: "t_(.*)"
    target-column: "c_table"
  extract-schema:
    schema-regexp: "test_(.*)"
    target-column: "c_schema"
  extract-source:
    source-regexp: "(.*)"
    target-column: "c_source"
rule-2:
```

```
    schema-pattern: "test_*"
    target-schema: "test"
```

To extract the source information of upstream sharded tables to the merged table in the downstream, you **must manually create a merged table in the downstream before starting the migration**. The merged table must contain the three `target-columns` (`c_table`, `c_schema`, and `c_source`) used for specifying the source information. In addition, these columns **must be the last columns and be string types**.

```
CREATE TABLE `test`.`t` (
    a int(11) PRIMARY KEY,
    c_table varchar(10) DEFAULT NULL,
    c_schema varchar(10) DEFAULT NULL,
    c_source varchar(10) DEFAULT NULL
);
```

Assume that the upstream has the following two data sources:

Data source `mysql-01`:

```
mysql> select * from test_11.t_1;
+---+
| a |
+---+
| 1 |
+---+
mysql> select * from test_11.t_2;
+---+
| a |
+---+
| 2 |
+---+
mysql> select * from test_12.t_1;
+---+
| a |
+---+
| 3 |
+---+
```

Data source `mysql-02`:

```
mysql> select * from test_13.t_3;
+---+
| a |
+---+
| 4 |
+---+
```

After migration using DM, data in the merged table will be as follows:

```
mysql> select * from test.t;
+---+---------+----------+----------+
| a | c_table | c_schema | c_source |
+---+---------+----------+----------+
| 1 | 1       | 11       | mysql-01 |
| 2 | 2       | 11       | mysql-01 |
| 3 | 1       | 12       | mysql-01 |
| 4 | 3       | 13       | mysql-02 |
+---+---------+----------+----------+
```

Incorrect examples of creating merged tables

> **Note:**
>
> If any of the following errors occur, source information of sharded tables and schemas might fail to be written to the merged table.

- `c-table` is not in the last three columns:

```
CREATE TABLE `test`.`t` (
    c_table varchar(10) DEFAULT NULL,
    a int(11) PRIMARY KEY,
    c_schema varchar(10) DEFAULT NULL,
    c_source varchar(10) DEFAULT NULL
);
```

- `c-source` is absent:

```
CREATE TABLE `test`.`t` (
    a int(11) PRIMARY KEY,
    c_table varchar(10) DEFAULT NULL,
    c_schema varchar(10) DEFAULT NULL,
);
```

- `c_schema` is not a string type:

```
CREATE TABLE `test`.`t` (
    a int(11) PRIMARY KEY,
    c_table varchar(10) DEFAULT NULL,
    c_schema int(11) DEFAULT NULL,
    c_source varchar(10) DEFAULT NULL,
);
```

Merge sharded schemas

Assuming in the scenario of sharded schemas, you want to migrate the `test_{1,2,3...}` ↪ `.t_{1,2,3...}` tables in the two upstream MySQL instances to the `test.t_{1,2,3...}` tables in the downstream TiDB instance.

To migrate the upstream schemas to the downstream `test.t_[1,2,3]`, you only need to create one routing rule.

```
  rule-1:
    schema-pattern: "test_*"
    target-schema: "test"
```

Incorrect table routing

Assuming that the following two routing rules are configured and `test_1_bak.t_1_bak` matches both `rule-1` and `rule-2`, an error is reported because the table routing configuration violates the number limitation.

```
  rule-1:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    target-schema: "test"
    target-table: "t"
  rule-2:
    schema-pattern: "test_1_bak"
    table-pattern: "t_1_bak"
    target-schema: "test"
    target-table: "t_bak"
```

13.6.6.6 TiDB Data Migration Block and Allow Lists

When you migrate data using TiDB Data Migration (DM), you can configure the block and allow lists to filter or only migrate all operations of some databases or some tables.

13.6.6.6.1 Configure the block and allow lists

In the task configuration file, add the following configuration:

```
block-allow-list:          # Use black-white-list if the DM version is
   ↪ earlier than or equal to v2.0.0-beta.2.
  rule-1:
    do-dbs: ["test*"]      # Starting with characters other than "~"
       ↪ indicates that it is a wildcard;
                           # v1.0.5 or later versions support the regular
                              ↪ expression rules.
    do-tables:
    - db-name: "test[123]" # Matches test1, test2, and test3.
      tbl-name: "t[1-5]"   # Matches t1, t2, t3, t4, and t5.
    - db-name: "test"
      tbl-name: "t"
  rule-2:
    do-dbs: ["~^test.*"]   # Starting with "~" indicates that it is a
       ↪ regular expression.
    ignore-dbs: ["mysql"]
    do-tables:
    - db-name: "~^test.*"
      tbl-name: "~^t.*"
    - db-name: "test"
      tbl-name: "t*"
    ignore-tables:
    - db-name: "test"
      tbl-name: "log"
```

In simple scenarios, it is recommended that you use the wildcard for matching schemas and tables. However, note the following version differences:

- Wildcards including `*`, `?`, and `[]` are supported. There can only be one `*` symbol in a wildcard match, and it must be at the end. For example, in `tbl-name: "t*"`, `"t*"` indicates all tables starting with `t`. See wildcard matching for details.
- A regular expression must begin with the `~` character.

13.6.6.6.2 Parameter descriptions

- `do-dbs`: allow lists of the schemas to be migrated, similar to `replicate-do-db` in MySQL.
- `ignore-dbs`: block lists of the schemas to be migrated, similar to `replicate-ignore-db` in MySQL.
- `do-tables`: allow lists of the tables to be migrated, similar to `replicate-do-table` in MySQL. Both `db-name` and `tbl-name` must be specified.
- `ignore-tables`: block lists of the tables to be migrated, similar to `replicate-ignore-table` in MySQL. Both `db-name` and `tbl-name` must be specified.

If a value of the above parameters starts with the `~` character, the subsequent characters of this value are treated as a regular expression. You can use this parameter to match schema or table names.

13.6.6.6.3 Filtering process

- The filtering rules corresponding to `do-dbs` and `ignore-dbs` are similar to the Evaluation of Database-Level Replication and Binary Logging Options in MySQL.
- The filtering rules corresponding to `do-tables` and `ignore-tables` are similar to the Evaluation of Table-Level Replication Options in MySQL.

> **Note:**
>
> In DM and in MySQL, the block and allow lists filtering rules are different in the following ways:
>
> - In MySQL, `replicate-wild-do-table` and `replicate-wild-ignore-table` support wildcard characters. In DM, some parameter values directly supports regular expressions that start with the `~` character.
> - DM currently only supports binlogs in the `ROW` format, and does not support those in the `STATEMENT` or `MIXED` format. Therefore, the filtering rules in DM correspond to those in the `ROW` format in MySQL.
> - MySQL determines a DDL statement only by the database name explicitly specified in the `USE` section of the statement. DM determines a statement first based on the database name section in the DDL statement. If the DDL statement does not contain such a section, DM determines the statement by the `USE` section. Suppose that the SQL statement to be determined is `USE test_db_2; CREATE TABLE test_db_1.test_table (c1 INT PRIMARY KEY)`; that `replicate-do-db=test_db_1` is configured in MySQL and `do-dbs: ["test_db_1"]` is configured in DM. Then this rule only applies to DM and not to MySQL.

The filtering process of a `test.t` table is as follows:

1. Filter at the **schema** level:
    - If `do-dbs` is not empty, check whether a matched schema exists in `do-dbs`.
        - If yes, continue to filter at the **table** level.
        - If not, filter `test.t`.
    - If `do-dbs` is empty and `ignore-dbs` is not empty, check whether a matched schema exits in `ignore-dbs`.

- If yes, filter `test.t`.
- If not, continue to filter at the **table** level.

- If both `do-dbs` and `ignore-dbs` are empty, continue to filter at the **table** level.

2. Filter at the **table** level:

    1. If `do-tables` is not empty, check whether a matched table exists in `do-tables`.
        - If yes, migrate `test.t`.
        - If not, filter `test.t`.
    2. If `ignore-tables` is not empty, check whether a matched table exists in `ignore-tables`.
        - If yes, filter `test.t`.
        - If not, migrate `test.t`.
    3. If both `do-tables` and `ignore-tables` are empty, migrate `test.t`.

> **Note:**
>
> To check whether the schema `test` should be filtered, you only need to filter at the schema level.

13.6.6.6.4 Usage examples

Assume that the upstream MySQL instances include the following tables:

```
`logs`.`messages_2016`
`logs`.`messages_2017`
`logs`.`messages_2018`
`forum`.`users`
`forum`.`messages`
`forum_backup_2016`.`messages`
`forum_backup_2017`.`messages`
`forum_backup_2018`.`messages`
```

The configuration is as follows:

```
block-allow-list: # Use black-white-list if the DM version is earlier than or equal to v2.0.0-beta.2.
  bw-rule:
    do-dbs: ["forum_backup_2018", "forum"]
    ignore-dbs: ["~^forum_backup_"]
    do-tables:
    - db-name: "logs"
```

```
    tbl-name: "~_2018$"
  - db-name: "~^forum.*"
    tbl-name: "messages"
  ignore-tables:
  - db-name: "~.*"
    tbl-name: "^messages.*"
```

After applying the `bw-rule` rule:

Table	Whether to filter	Why filter
`logs` ↪ `.messages` ↪ `_` ↪ `2016` ↪	Yes	The schema `logs` fails to match any `do-dbs`.
`logs` ↪ `.messages` ↪ `_` ↪ `2017` ↪	Yes	The schema `logs` fails to match any `do-dbs`.
`logs` ↪ `.messages` ↪ `_` ↪ `2018` ↪	Yes	The schema `logs` fails to match any `do-dbs`.
`forum` ↪ `_` ↪ `backup` ↪ `_` ↪ `2016` ↪ `.messages` ↪	Yes	The schema `forum_backup_` ↪ `2016` fails to match any `do-dbs`.
`forum` ↪ `_` ↪ `backup` ↪ `_` ↪ `2017` ↪ `.messages` ↪	Yes	The schema `forum_backup_` ↪ `2017` fails to match any `do-dbs`.

Table	Whether to filter	Why filter
`forum` ↪ `.users` ↪	Yes	1. The schema `forum` matches `do-dbs` and continues to filter at the table level. 2. The schema and table fail to match any of `do-tables` and `ignore-tables` and `do-tables` is not empty.
`forum` ↪ `.messages` ↪	No	1. The schema `forum` matches `do-dbs` and continues to filter at the table level. 2. The table `messages` is in the `db-name: "~^` ↪ `forum.*",` ↪ `tbl-name:` ↪ `"messages"` of `do-tables`.
`forum` ↪ `_` ↪ `backup` ↪ `_` ↪ `2018` ↪ `.messages` ↪	No	1. The schema `forum_backup_` ↪ `2018` matches `do-dbs` and continues to filter at the table level. 2. The schema and table match the `db-name: "~^` ↪ `forum.*",` ↪ `tbl-name:` ↪ `"messages"` of `do-tables`.

13.6.6.7 TiDB Data Migration Binlog Event Filter

TiDB Data Migration (DM) provides the binlog event filter feature to filter out, block and report errors, or only receive specified types of binlog events for some schemas or tables. For example, you can filter out all `TRUNCATE TABLE` or `INSERT` events. The binlog event filter feature is more fine-grained than the block and allow lists feature.

13.6.6.7.1 Configure the binlog event filter

In the task configuration file, add the following configuration:

```
filters:
  rule-1:
    schema-pattern: "test_*"
     table-pattern: "t_*"
     events: ["truncate table", "drop table"]
    sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
     action: Ignore
```

Starting from DM v2.0.2, you can configure the binlog event filter in the source configuration file. For details, see Upstream Database Configuration File.

When you use the wildcard for matching schemas and tables, note the following:

- `schema-pattern` and `table-pattern` only support wildcards, including `*`, `?`, and `[]`. There can only be one `*` symbol in a wildcard match, and it must be at the end. For example, in `table-pattern: "t_*"`, `"t_*"` indicates all tables starting with `t_`. See wildcard matching for details.
- `sql-pattern` only supports regular expressions.

13.6.6.7.2 Parameter descriptions

- schema-pattern/table-pattern: the binlog events or DDL SQL statements of upstream MySQL or MariaDB instance tables that match `schema-pattern/table-pattern` are filtered by the rules below.
- `events`: the binlog event array. You can only select one or more `Events` from the following table:

Events	Type	Description
`all`		Includes all the events below
`all dml`		Includes all DML events below
`all ddl`		Includes all DDL events below

Events	Type	Description
`incompatible ddl changes`		Includes all incompatible DDL events, where "incompatible DDL" means DDL operations that might cause data loss
`none`		Includes none of the events below
`none ddl`		Includes none of the DDL events below
`none dml`		Includes none of the DML events below
`insert`	DML	The `INSERT` DML event
`update`	DML	The `UPDATE` DML event
`delete`	DML	The `DELETE` DML event
`create database`	DDL	The `CREATE DATABASE` DDL event
`drop database`	incompatible DDL	The `DROP DATABASE` DDL event
`create table`	DDL	The `CREATE TABLE` DDL event
`create index`	DDL	The `CREATE INDEX` DDL event
`drop table`	incompatible DDL	The `DROP TABLE` DDL event
`truncate table`	incompatible DDL	The `TRUNCATE TABLE` DDL event
`rename table`	incompatible DDL	The `RENAME TABLE` DDL event
`drop index`	incompatible DDL	The `DROP INDEX` DDL event
`alter table`	DDL	The `ALTER TABLE` DDL event
`value range decrease`	incompatible DDL	A DDL statement that decreases the value range of a column field, such as the `ALTER TABLE MODIFY COLUMN` statement that changes `VARCHAR(20)` to `VARCHAR(10)`
`precision decrease`	incompatible DDL	A DDL statement that decreases the precision of a column field, such as the `ALTER TABLE MODIFY COLUMN` statement that changes `Decimal(10, 2)` to `Decimal(10, 1)`

Events	Type	Description
`modify column`	incompatible DDL	A DDL statement that changes the type of a column field, such as the `ALTER TABLE MODIFY COLUMN` statement that changes `INT` to `VARCHAR`
`rename column`	incompatible DDL	A DDL statement that changes the name of a column, such as the `ALTER TABLE RENAME COLUMN` statement
`rename index`	incompatible DDL	A DDL statement that changes the index name, such as the `ALTER TABLE RENAME INDEX` statement
`drop column`	incompatible DDL	A DDL statement that drops a column from a table, such as the `ALTER TABLE DROP COLUMN` statement
`drop index`	incompatible DDL	A DDL statement that drops an index in a table, such as the `ALTER TABLE DROP INDEX` statement
`truncate` ↪ `table` ↪ `partition`	incompatible DDL	A DDL statement that removes all data from a specified partition, such as the `ALTER TABLE TRUNCATE` ↪ `PARTITION` statement
`drop primary` ↪ `key`	incompatible DDL	A DDL statement that drops the primary key, such as the `ALTER TABLE DROP PRIMARY` ↪ `KEY` statement
`drop unique` ↪ `key`	incompatible DDL	A DDL statement that drops a unique key, such as the `ALTER` ↪ `TABLE DROP UNIQUE KEY` statement

Events	Type	Description
`modify default value`	incompatible DDL	A DDL statement that modifies a column's default value, such as the `ALTER TABLE CHANGE DEFAULT` statement
`modify constraint`	incompatible DDL	A DDL statement that modifies the constraint, such as the `ALTER TABLE ADD CONSTRAINT` statement
`modify columns order`	incompatible DDL	A DDL statement that modifies the order of the columns, such as the `ALTER TABLE CHANGE AFTER` statement
`modify charset`	incompatible DDL	A DDL statement that modifies the charset of a column, such as the `ALTER TABLE MODIFY CHARSET` statement
`modify collation`	incompatible DDL	A DDL statement that modifies a column collation, such as the `ALTER TABLE MODIFY COLLATE` statement
`remove auto increment`	incompatible DDL	A DDL statement that removes an auto-incremental key
`modify storage engine`	incompatible DDL	A DDL statement that modifies the table storage engine, such as the `ALTER TABLE ENGINE = MyISAM` statement
`reorganize table partition`	incompatible DDL	A DDL statement that reorganizes partitions in a table, such as the `ALTER TABLE REORGANIZE PARTITION` statement

Events	Type	Description
`rebuild table` ↪ `partition`	incompatible DDL	A DDL statement that rebuilds the table partition, such as the `ALTER TABLE` ↪ `REBUILD PARTITION` statement
`exchange` ↪ `table` ↪ `partition`	incompatible DDL	A DDL statement that exchanges a partition between two tables, such as the `ALTER TABLE EXCHANGE` ↪ `PARTITION` statement
`coalesce` ↪ `table` ↪ `partition`	incompatible DDL	A DDL statement that decreases the number of partitions in a table, such as the `ALTER COALESCE PARTITION` statement

- `sql-pattern`: it is used to filter specified DDL SQL statements. The matching rule supports using a regular expression. For example, `"^DROP\\s+PROCEDURE"`.
- `action`: the string (`Do`/`Ignore`/`Error`). Based on the rules, it judges as follows:
    - `Do`: the allow list. The binlog is filtered in either of the following two conditions:
        - The type of the event is not in the `event` list of the rule.
        - The SQL statement of the event cannot be matched by `sql-pattern` of the rule.
    - `Ignore`: the block list. The binlog is filtered in either of the following two conditions:
        - The type of the event is in the `event` list of the rule.
        - The SQL statement of the event can be matched by `sql-pattern` of the rule.
    - `Error`: the error list. The binlog reports an error in either of the following two conditions:
        - The type of the event is in the `event` list of the rule.
        - The SQL statement of the event can be matched by `sql-pattern` of the rule.
    - When multiple rules match the same table, the rules are applied sequentially. The block list has a higher priority than the error list, and the error list has a higher priority than the allow list. For example:
        - If both the `Ignore` and `Error` rules are applied to the same table, the `Ignore` rule takes effect.
        - If both the `Error` and `Do` rules are applied to the same table, the `Error` rule takes effect.

13.6.6.7.3 Usage examples

This section shows the usage examples in the scenario of sharding (sharded schemas and tables).

Filter all sharding deletion operations

To filter out all deletion operations, configure the following two filtering rules:

- `filter-table-rule` filters out the `TRUNCATE TABLE`, `DROP TABLE` and `DELETE STATEMENT` operations of all tables that match the `test_*.t_*` pattern.
- `filter-schema-rule` filters out the `DROP DATABASE` operation of all schemas that match the `test_*` pattern.

```
filters:
  filter-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table", "delete"]
    action: Ignore
  filter-schema-rule:
    schema-pattern: "test_*"
    events: ["drop database"]
    action: Ignore
```

Only migrate sharding DML statements

To only migrate sharding DML statements, configure the following two filtering rules:

- `do-table-rule` only migrates the `CREATE TABLE`, `INSERT`, `UPDATE` and `DELETE` statements of all tables that match the `test_*.t_*` pattern.
- `do-schema-rule` only migrates the `CREATE DATABASE` statement of all schemas that match the `test_*` pattern.

> **Note:**
>
> The reason why the `CREATE DATABASE/TABLE` statement is migrated is that you can migrate DML statements only after the schema and table are created.

```
filters:
  do-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
```

```
    events: ["create table", "all dml"]
    action: Do
  do-schema-rule:
    schema-pattern: "test_*"
    events: ["create database"]
    action: Do
```

Filter out the SQL statements that TiDB does not support

To filter out the `PROCEDURE` statements that TiDB does not support, configure the following `filter-procedure-rule`:

```
filters:
  filter-procedure-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
    action: Ignore
```

`filter-procedure-rule` filters out the `^CREATE\\s+PROCEDURE` and `^DROP\\s+PROCEDURE` statements of all tables that match the `test_*.t_*` pattern.

Filter out the SQL statements that the TiDB parser does not support

For the SQL statements that the TiDB parser does not support, DM cannot parse them and get the `schema/table` information. So you must use the global filtering rule: `schema-pattern: "*"`.

> **Note:**
>
> To avoid filtering out data that need to be migrated, you must configure the global filtering rule as strictly as possible.

To filter out the `PARTITION` statements that the TiDB parser (of some version) does not support, configure the following filtering rule:

```
filters:
  filter-partition-rule:
    schema-pattern: "*"
    sql-pattern: ["ALTER\\s+TABLE[\\s\\S]*ADD\\s+PARTITION", "ALTER\\s+TABLE
      [\\s\\S]*DROP\\s+PARTITION"]
    action: Ignore
```

Report errors on some DDL statements

If you need to block and report errors on DDL statements generated by some upstream operations before DM replicates them to TiDB, you can use the following settings:

```
filters:
  filter-procedure-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "truncate table partition"]
    action: Error
```

13.6.6.8 Filter DMLs Using SQL Expressions

13.6.6.8.1 Overview

In the process of incremental data migration, you can filter certain types of binlog events using the Filter Binlog Events feature. For example, for archiving or auditing purposes, you can filter out `DELETE` events when migrating data to the downstream. However, Binlog Event Filter cannot judge with a greater granularity on whether to filter out a specific row of `DELETE` events.

To solve the above issue, DM supports filtering data during incremental migration using `binlog value filter` since v2.0.5. The binlog in the `ROW` format supported by DM has the values of all columns in binlog events. You can configure SQL expressions according to these values. If the SQL expressions evaluate a row change as `TRUE`, DM will not migrate the row change downstream.

For detailed operation and implementation, see Filter DML Events Using SQL Expressions.

13.6.6.9 TiDB Data Migration Support for Online DDL Tools

In the MySQL ecosystem, tools such as gh-ost and pt-osc are widely used. TiDB Data Migration (DM) provides supports for these tools to avoid migrating unnecessary intermediate data.

This document introduces the support for common online DDL tools, usage, and precautions in DM.

For the working principles and implementation methods of DM for online DDL tools, refer to online-ddl.

13.6.6.9.1 Restrictions

- DM only supports gh-ost and pt-osc.

- When `online-ddl` is enabled, the checkpoint corresponding to incremental replication should not be in the process of online DDL execution. For example, if an upstream online DDL operation starts at `position-A` and ends at `position-B` of the binlog, the starting point of incremental replication should be earlier than `position-A` or later than `position-B`; otherwise, an error occurs. For details, refer to FAQ.

13.6.6.9.2 Configure parameters
