In v2.0.5 and later versions, you need to use the `online-ddl` configuration item in the `task` configuration file.

- If the upstream MySQL/MariaDB (at the same time) uses the gh-ost or pt-osc tool, set `online-ddl` to `true` in the task configuration file:

```
online-ddl: true
```

> **Note:**
>
> Since v2.0.5, `online-ddl-scheme` has been deprecated, so you need to use `online-ddl` instead of `online-ddl-scheme`. That means that setting `online-ddl: true` overwrites `online-ddl-scheme`, and setting `online-ddl-scheme: "pt"` or `online-ddl-scheme: "gh-ost"` is converted to `online-ddl: true`.

Before v2.0.5 (not including v2.0.5), you need to use the `online-ddl-scheme` configuration item in the `task` configuration file.

- If the upstream MySQL/MariaDB uses the gh-ost tool, set it in the task configuration file:

```
online-ddl-scheme: "gh-ost"
```

- If the upstream MySQL/MariaDB uses the pt tool, set it in the task configuration file:

```
online-ddl-scheme: "pt"
```

13.6.6.10 Customize a Secret Key for DM Encryption and Decryption

Before v8.0.0, DM uses a fixed AES-256 secret key to encrypt and decrypt passwords in the data source and migration task configurations. However, using a fixed secret key might pose security risks, especially in environments where security is crucial. To enhance security, starting from v8.0.0, DM removes the fixed secret key and enables you to customize a secret key.

13.6.6.10.1 Usage

1. Create a custom key file, which must contain a 64-character hexadecimal AES-256 secret key. One way to generate this key is by calculating SHA256 checksum of random data, such as `head -n 256 /dev/urandom | sha256sum`.
2. In the DM-master command-line flags or configuration file, specify `secret-key-path` as the path of your custom key file.

13.6.6.10.2 Upgrade from a version earlier than v8.0.0

Because DM no longer uses the fixed secret key starting from v8.0.0, pay attention to the following when upgrading DM from versions earlier than v8.0.0:

- If plaintext passwords are used in both data source configurations and migration task configurations, no additional steps are required for the upgrade.
- If encrypted passwords are used in data source configurations and migration task configurations or if you want to use encrypted passwords in the future, you need to do the following:

    1. Add the `secret-key-path` parameter to the DM-master configuration file and specify it as the path of your custom key file. The file must contain a 64-character hexadecimal AES-256 key. If the fixed AES-256 secret key was used for encryption before upgrading, you can copy this secret key to your key file. Make sure all DM-master nodes use the same secret key configuration.
    2. Perform a rolling upgrade of DM-master first, followed by a rolling upgrade of DM-worker. For more information, see Rolling upgrade.

13.6.6.10.3 Update the secret key for encryption and decryption

To update the secret key used for encryption and decryption, take the following steps:

1. Update `secret-key-path` in the DM-master configuration file.

> **Note:**
>
> - Make sure all DM-master nodes are updated to the same secret key configuration.

- During the secret key update, do not create new data source configuration files or migration task configuration files.

2. Perform a rolling restart of DM-master.
3. Use the passwords encrypted with `tiup dmctl encrypt` (dmctl version >= v8.0.0) when you create new data source configuration files and migration task configuration files.

13.6.6.11 Manage a Data Migration Task

13.6.6.11.1 Migration Task Precheck

Before using DM to migrate data from upstream to downstream, a precheck helps detect errors in the upstream database configurations and ensures that the migration goes smoothly. This document introduces the DM precheck feature, including its usage scenario, check items, and arguments.

Usage scenario

To run a data migration task smoothly, DM triggers a precheck automatically at the start of the task and returns the check results. DM starts the migration only after the precheck is passed.

To trigger a precheck manually, run the `check-task` command.

For example:

```
tiup dmctl check-task ./task.yaml
```

Descriptions of check items

After a precheck is triggered for a task, DM checks the corresponding items according to your migration mode configuration.

This section lists all the precheck items.

Note:

In this document, check items that must be passed are labeled "(Mandatory)".

- If a mandatory check item does not pass, DM returns an error after the check and does not proceed with the migration task. In this case, modify the configurations according to the error message and retry the task after meeting the precheck requirements.
- If a non-mandatory check item does not pass, DM returns a warning after the check. DM automatically starts a migration task if the check result contains only warnings but no errors.

Common check items

Regardless of the migration mode you choose, the precheck always includes the following common check items:

- Database version
  - MySQL version > 5.5
  - MariaDB version >= 10.1.2

Warning:

- Migrating data from MySQL 8.0 to TiDB using DM is an experimental feature (introduced since DM v2.0). It is NOT recommended that you use it in a production environment.
- Migrating data from MariaDB to TiDB using DM is an experimental feature. It is NOT recommended that you use it in a production environment.

- Compatibility of the upstream MySQL table schema
  - Check whether the upstream tables have foreign keys, which are not supported by TiDB. A warning is returned if a foreign key is found in the precheck.
  - Check whether the upstream tables use character sets that are incompatible with TiDB. For more information, see TiDB Supported Character Sets.
  - Check whether the upstream tables have primary key constraints or unique key constraints (introduced from v1.0.7).

Warning:

- When the upstream uses incompatible character sets, you can still continue the replication by creating tables with the utf8mb4 character set in the downstream. However, this practice is not recommended. You are advised to replace the incompatible character set used by the upstream with another character set that is supported in downstream.
- When the upstream tables have no primary key constraints or unique key constraints, the same row of data might be replicated multiple times to the downstream, which might also affect the performance of replication. In a production environment, it is recommended that you specify primary key constraints or unique key constraints for the upstream table.

Check items for full data migration

For the full data migration mode (`task-mode: full`), in addition to the common check items, the precheck also includes the following check items:

- (Mandatory) dump permission of the upstream database
  - SELECT permission on INFORMATION_SCHEMA and dump tables
  - RELOAD permission if `consistency=flush`
  - LOCK TABLES permission on the dump tables if `consistency=flush/lock`
- (Mandatory) Consistency of upstream MySQL multi-instance sharding tables
  - In the pessimistic mode, check whether the table schemas of all sharded tables are consistent in the following items:
    - Number of columns
    - Column name
    - Column order
    - Column type
    - Primary key
    - Unique index
  - In the optimistic mode, check whether the schemas of all sharded tables meet the optimistic compatibility.
  - If a migration task was started successfully by the `start-task` command, the precheck of this task skips the consistency check.
- Auto-increment primary key in sharded tables
  - If sharded tables have auto-increment primary keys, the precheck returns a warning. If there are conflicts in auto-increment primary keys, see Handle conflicts of auto-increment primary key for solutions.

Check items for physical import

If you set `import-mode: "physical"` in the task configuration, the following check items are added to ensure that Physical Import runs normally. After following the prompts, if you find it difficult to meet the requirements of these check items, you can try to use the logical import mode to import data.

- Empty Regions in the downstream database
    - If the number of empty Regions is greater than `max(1000, 3 * the number of tables)` (the larger of "1000" and "3 times the number of tables"), the precheck returns a warning. You can adjust related PD parameters to speed up the merging of empty Regions and wait for the number of empty Regions to decrease. See PD Scheduling Best Practices - Slow Region Merge.
- Region distribution in the downstream database
    - Checks the number of Regions on different TiKV nodes. Assuming that the TiKV node with the lowest Region count has `a` Regions and the TiKV node with the highest Region count has `b` Regions, if `a / b` is less than 0.75, the precheck returns a warning. You can adjust related PD parameters to speed up the scheduling of Regions and wait for the number of Regions to change. See PD Scheduling Best Practices - Leader/Region distribution is not balanced.
- The versions of TiDB, PD, and TiKV in the downstream database
    - Physical import must call the interfaces of TiDB, PD, and TiKV. If the versions are not compatible, the precheck returns an error.
- The free space of the downstream database
    - Estimates the total sizes of all tables in the allow list in the upstream database (`source_size`). If the free space of the downstream database is less than `source_size`, the precheck returns an error. If the free space of the downstream database is less than the number of TiKV replicas * `source_size` * 2, the precheck returns a warning.
- Whether the downstream database is running tasks that are incompatible with physical import
    - Currently, physical import is incompatible with TiCDC and PITR tasks. If these tasks are running in the downstream database, the precheck returns an error.

Check items for incremental data migration

For the incremental data migration mode (`task-mode: incremental`), in addition to the common check items, the precheck also includes the following check items:

- (Mandatory) Upstream database REPLICATION permission
    - REPLICATION CLIENT permission
    - REPLICATION SLAVE permission
- Database primary-secondary configuration
    - To avoid primary-secondary replication failures, it is recommended that you specify the database ID `server_id` for the upstream database (GTID is recommended for non-AWS Aurora environments).
- (Mandatory) MySQL binlog configuration
    - Check whether binlog is enabled (required by DM).
    - Check whether `binlog_format=ROW` is configured (DM only supports the migration of binlog in the ROW format).
    - Check whether `binlog_row_image=FULL` is configured (DM only supports `binlog_row_image=FULL`).
    - If `binlog_do_db` or `binlog_ignore_db` is configured, check whether the database tables to be migrated meet the conditions of `binlog_do_db` and `binlog_ignore_db`.
- (Mandatory) Check if the upstream database is in an Online-DDL process (in which the `ghost` table is created but the `rename` phase is not executed yet). If the upstream is in the online-DDL process, the precheck returns an error. In this case, wait until the DDL to complete and retry.

Check items for full and incremental data migration

For the full and incremental data migration mode (`task-mode: all`), in addition to the common check items, the precheck also includes the full data migration check items and the incremental data migration check items.

Ignorable check items

Prechecks can find potential risks in your environments. It is not recommended to ignore check items. If your data migration task has special needs, you can use the `ignore-checking-items` configuration item to skip some check items.

Check item	Description
`dump_privilege`	Checks the dump privilege of the user in the upstream MySQL instance.

Check item	Description
`replication_privilege`	Checks the replication privilege of the user in the upstream MySQL instance.
`version`	Checks the version of the upstream database.
`server_id`	Checks whether server_id is configured in the upstream database.
`binlog_enable`	Checks whether binlog is enabled in the upstream database.
`table_schema`	Checks the compatibility of the table schemas in the upstream MySQL tables.
`schema_of_shard_tables`	Checks the consistency of the table schemas in the upstream MySQL multi-instance shards.

Check item	Description
auto_increment_ID	Checks whether the auto-increment primary key conflicts in the upstream MySQL multi-instance shards.
online_ddl	Checks whether the upstream is in the process of online-DDL.
empty_region	Checks the number of empty Regions in the downstream database for physical import.
region_distribution	Checks the distribution of Regions in the downstream database for physical import.
downstream_version	Checks the versions of TiDB, PD, and TiKV in the downstream database.
free_space	Checks the free space of the downstream database.

Check item	Description
`downstream_mutex_features`	Checks whether the downstream database is running tasks that are incompatible with physical import.

Note:

More ignorable check items are supported in versions earlier than v6.0. Since v6.0, DM does not allow ignoring some check items related to data safety. For example, if you configure the `binlog_row_image` parameter incorrectly, data might be lost during the replication.

Configure precheck arguments

The migration task precheck supports processing in parallel. Even if the number of rows in sharded tables reaches a million level, the precheck can be completed in minutes.

To specify the number of threads for the precheck, you can configure the `threads` argument of the `mydumpers` field in the migration task configuration file.

```
mydumpers:                          # Configuration arguments of the dump processing unit
  global:                           # Configuration name
    threads: 4                      # The number of threads that access the upstream when the dump processing unit performs the precheck and exports data from the upstream database (4 by default)
    chunk-filesize: 64              # The size of the files generated by the dump processing unit (64 MB by default)
    extra-args: "--consistency none" # Other arguments of the dump processing unit. You do not need to manually configure table-list in `extra-args`, because it is automatically generated by DM.
```

Note:

> The value of `threads` determines the number of physical connections between the upstream database and DM. An excessively large `threads` value might increase the load of the upstream. Therefore, you need to set `threads` to a proper value.

13.6.6.11.2 Create a Data Migration Task

You can use the `start-task` command to create a data migration task. When the data migration task is started, DM prechecks privileges and configurations.

```
help start-task
```

```
Starts a task as defined in the configuration file

Usage:
  dmctl start-task [-s source ...] [--remove-meta] <config-file> [flags]

Flags:
  -h, --help             help for start-task
      --remove-meta      whether to remove task's meta data
      --start-time string specify the start time of binlog replication, e.g.
        ↪ '2021-10-21 00:01:00' or 2021-10-21T00:01:00

Global Flags:
      --config string     Path to config file.
      --master-addr string Master API server address, this parameter is
        ↪ required when interacting with the dm-master
      --rpc-timeout string RPC timeout, default is 10m. (default "10m")
  -s, --source strings    MySQL Source ID.
      --ssl-ca string     Path of file that contains list of trusted SSL CAs
        ↪ for connection.
      --ssl-cert string   Path of file that contains X509 certificate in PEM
        ↪ format for connection.
      --ssl-key string    Path of file that contains X509 key in PEM format
        ↪ for connection.
  -V, --version           Prints version and exit.
```

Usage example

```
start-task [ -s "mysql-replica-01"] ./task.yaml
```

Flags description

- `-s`: (Optional) Specifies the MySQL source to execute `task.yaml`. If it is set, the command only starts the subtasks of the specified task on the MySQL source.
- `config-file`: (Required) Specifies the file path of `task.yaml`.
- `remove-meta`: (Optional) Specifies whether to remove the task's previous metadata when starting the task.
- `start-time`: (Optional) Specifies the start time of binlog replication.
    - Format: `'2021-10-21 00:01:00'` or `2021-10-21T00:01:00`.
    - For incremental tasks, you can specify a rough starting point for the task using this flag. This flag takes precedence over the binlog position in the task configuration file and the binlog position in the downstream checkpoint.
    - When the task already has a checkpoint, if you start the task using this flag, DM automatically enables safe mode until the replication passes the checkpoint. This is to avoid the data duplication error caused by resetting the task to an earlier position.
        - When you reset the task to an earlier position, if the table schema at that time point is different from the downstream at the current time point, the task might report an error.
        - When you reset the task to a later position, note that the skipped binlog might have dirty data left in the downstream.
    - When you specify an earlier start time, DM starts migration from the earliest binlog position available.
    - When you specify a later start time, DM reports an error: `start-time {input-time} is too late, no binlog location matches it`.

Returned results

```
start-task task.yaml
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

13.6.6.11.3 Query Task Status in TiDB Data Migration

This document introduces how to use the `query-status` command to query the task status, and the subtask status of DM.

Query result

It is recommended that you use `query-status` by the following steps:

1. Use `query-status` to check whether each on-going task is in the normal state.
2. If any error occurs in a task, use the `query-status <taskName>` command to see detailed error information. `<taskName>` in this command indicates the name of the task that encounters the error.

A successful query result is as follows:

```
» query-status
```

```
{
    "result": true,
    "msg": "",
    "tasks": [
        {
            "taskName": "test",
            "taskStatus": "Running",
            "sources": [
                "mysql-replica-01",
                "mysql-replica-02"
            ]
        },
        {
            "taskName": "test2",
            "taskStatus": "Paused",
            "sources": [
                "mysql-replica-01",
                "mysql-replica-02"
            ]
        }
    ]
}
```

Some fields in the query result are described as follows:

- `result`: Whether the query is successful.
- `msg`: The error message returned when the query fails.
- `tasks`: The list of migration tasks. Each task contains the following fields:
    - `taskName`: The name of the task.

- `taskStatus`: The status of the task. For detailed descriptions of `taskStatus`, refer to Task status.
- `sources`: The list of upstream MySQL databases.

Task status

The status of a DM migration task depends on the status of each subtask assigned to DM-worker. For detailed descriptions of subtask status, see Subtask status. The table below shows how the subtask status is related to task status.

Subtask status in a task	Task status
One subtask is in the `paused` ↪ state and error information is returned.	`Error` ↪ ↪ `-` ↪ ↪ `Some` ↪ ↪ `error` ↪ ↪ `occurred` ↪ ↪ `in` ↪ ↪ `subtask` ↪

Subtask status in a task	Task status
One subtask in the Sync phase is in the `Running` ↪ state but its Relay processing unit is not running (in the `Error` ↪ /`Paused` ↪ /`Stopped` ↪ state).	`Error` ↪ ↪ `-` ↪ ↪ `Relay` ↪ ↪ `status` ↪ ↪ `is` ↪ ↪ `Error` ↪ `/` ↪ `Paused` ↪ `/` ↪ `Stopped` ↪ ↪

Subtask status in a task	Task status
One subtask is in the `Paused` state and no error information is returned.	`Paused`
All subtasks are in the `New` state.	`New`
All subtasks are in the `Finished` state.	`Finished`

Subtask status in a task	Task status
All subtasks are in the `Stopped` state.	`Stopped`
Other situations	`Running`

Detailed query result

```
» query-status test
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "test-`test`.`t_target`",
                    "sync": {
                        "masterBinlog": "(bin.000001, 3234)",
```

```
                "masterBinlogGtid": "c0149e17-dff1-11e8-b6a8-0242
                    ↪ ac110004:1-14",
                "syncerBinlog": "(bin.000001, 2525)",
                "syncerBinlogGtid": "",
                "blockingDDLs": [
                    "USE `test`; ALTER TABLE `test`.`t_target` DROP
                        ↪ COLUMN `age`;"
                ],
                "unresolvedGroups": [
                    {
                        "target": "`test`.`t_target`",
                        "DDLs": [
                            "USE `test`; ALTER TABLE `test`.`t_target`
                                ↪ DROP COLUMN `age`;"
                        ],
                        "firstPos": "(bin|000001.000001, 3130)",
                        "synced": [
                            "`test`.`t2`"
                            "`test`.`t3`"
                            "`test`.`t1`"
                        ],
                        "unsynced": [
                        ]
                    }
                ],
                "synced": false,
                "totalRows": "12",
                "totalRps": "1",
                "recentRps": "1"
            }
        }
    ]
},
{
    "result": true,

                }
            }
        ]
    },
]
}
```

Some fields in the returned result are described as follows:

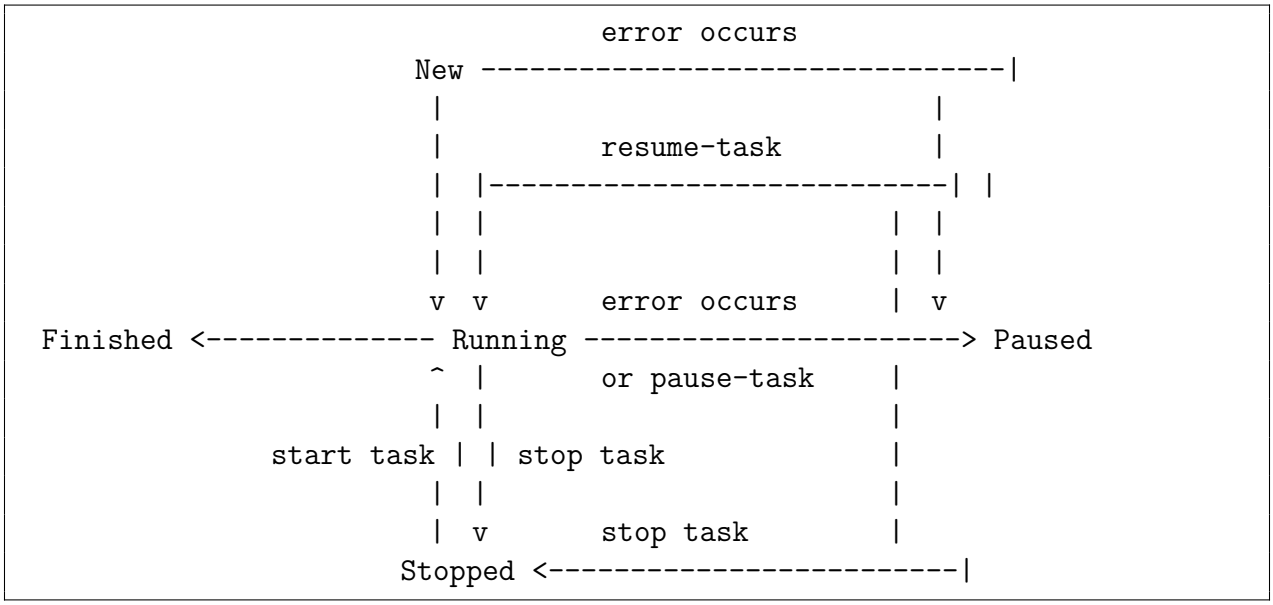
- `result`: Whether the query is successful.

- `msg`: The error message returned when the query fails.
- `sources`: The list of upstream MySQL instances. Each source contains the following fields:
    - `result`
    - `msg`
    - `sourceStatus`: The information of the upstream MySQL databases.
    - `subTaskStatus`: The information of all subtasks of upstream MySQL databases. Each subtask might contain the following fields:
        - `name`: The name of the subtask.
        - `stage`: The status of the subtask. For the status description and status switch relationship of "stage" of "subTaskStatus" of "sources", see the subtask status.
        - `unit`: The processing unit of DM, including "Check", "Dump", "Load", and "Sync".
        - `result`: Displays the error information if a subtask fails.
        - `unresolvedDDLLockID`: The sharding DDL lock ID, used for manually handling the sharding DDL lock in the abnormal condition. For operation details of "unresolvedDDLLockID" of "subTaskStatus" of "sources", see Handle Sharding DDL Locks Manually.
        - `sync`: The replication information of the `Sync` processing unit. This information is about the same component with the current processing unit.
            - `masterBinlog`: The binlog position in the upstream database.
            - `masterBinlogGtid`: The GTID information in the upstream database.
            - `syncerBinlog`: The position of the binlog that has been replicated in the `Sync` processing unit.
            - `syncerBinlogGtid`: The binlog position replicated using GTID.
            - `blockingDDLs`: The DDL list that is blocked currently. It is not empty only when all the upstream tables of this DM-worker are in the "synced" status. In this case, it indicates the sharding DDL statements to be executed or that are skipped.
            - `unresolvedGroups`: The sharding group that is not resolved. Each group contains the following fields:
                - `target`: The downstream database table to be replicated.
                - `DDLs`: A list of DDL statements.
                - `firstPos`: The starting position of the sharding DDL statement.
                - `synced`: The upstream sharded table whose executed sharding DDL statement has been read by the `Sync` unit.
                - `unsynced`: The upstream table that has not executed this sharding DDL statement. If any upstream tables have not finished replication, `blockingDDLs` is empty.
            - `synced`: Whether the incremental replication catches up with the upstream and has the same binlog position as that in the upstream. The save point is not refreshed in real time in the `Sync` background, so `false` of `synced` does not always mean a replication delay exits.

    - `totalRows`: The total number of rows that are replicated in this subtask.
    - `totalRps`: The number of rows that are replicated in this subtask per second.
    - `recentRps`: The number of rows that are replicated in this subtask in the last second.
  - `load`: The replication information of the `Load` processing unit.
    - `finishedBytes`: The number of bytes that have been loaded.
    - `totalBytes`: The total number of bytes that need to be loaded.
    - `progress`: The progress of the loading process.
    - `bps`: The speed of the full loading.
  - `dump`: The replication information of the `Dump` processing unit.
    - `totalTables`: The number of tables to be dumped.
    - `completedTables`: The number of tables that have been dumped.
    - `finishedBytes`: The number of bytes that have been dumped.
    - `finishedRows`: The number of rows that have been dumped.
    - `estimateTotalRows`: The estimated number of rows to be dumped.
    - `progress`: The progress of the dumping process.
    - `bps`: The dumping speed in bytes/second.

Subtask status

Status description



- `New`:
  - The initial status.
  - If the subtask does not encounter an error, it is switched to `Running`; otherwise it is switched to `Paused`.
- `Running`: The normal running status.
- `Paused`:
  - The paused status.
  - If the subtask encounters an error, it is switched to `Paused`.
  - If you run `pause-task` when the subtask is in the `Running` status, the task is switched to `Paused`.
  - When the subtask is in this status, you can run the `resume-task` command to resume the task.
- `Stopped`:
  - The stopped status.
  - If you run `stop-task` when the subtask is in the `Running` or `Paused` status, the task is switched to `Stopped`.

- When the subtask is in this status, you cannot use `resume-task` to resume the task.

- `Finished`:

  - The finished subtask status.
  - Only when the full replication subtask is finished normally, the task is switched to this status.

Status switch diagram

13.6.6.11.4 Pause a Data Migration Task

You can use the `pause-task` command to pause a data migration task.

`pause-task` differs from `stop-task` in that:

- `pause-task` only pauses a migration task. You can query the status information (retained in the memory) of the task using `query-status`. `stop-task` terminates a migration task and removes all information related to this task from the memory. This means you cannot use `query-status` to query the status information. `dm_meta` like "checkpoint" and data that have been migrated to the downstream are not removed.
- If `pause-task` is executed to pause the migration task, you cannot start a new task with the same name, neither can you get the relay log of the paused task removed, since this task does exist. If `stop-task` is executed to stop a task, you can start a new task with the same name, and you can get the relay log of the stopped task removed, since this task no longer exists.
- `pause-task` is usually used to pause a task for troubleshooting, while `stop-task` is to permanently remove a migration task, or to co-work with `start-task` to update the configuration information.

```
help pause-task
```

```
pause a specified running task

Usage:
 dmctl pause-task [-s source ...] <task-name | task-file> [flags]

Flags:
 -h, --help help for pause-task

Global Flags:
 -s, --source strings MySQL Source ID
```

Usage example

```
pause-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where you want to pause the subtasks of the migration task. If it is set, this command pauses only the subtasks on the specified MySQL source.
- `task-name| task-file`: (Required) Specifies the task name or task file path.

Returned results

```
pause-task test
```

```
{
    "op": "Pause",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

13.6.6.11.5 Resume a Data Migration Task

You can use the `resume-task` command to resume a data migration task in the `Paused` state. This is generally used in scenarios where you want to manually resume a data migration task after handling the error that get the task paused.

```
help resume-task
```

```
resume a specified paused task

Usage:
 dmctl resume-task [-s source ...] <task-name | task-file> [flags]

Flags:
 -h, --help help for resume-task

Global Flags:
 -s, --source strings MySQL Source ID
```

Usage example

```
resume-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where you want to resume the subtask of the migration task. If it is set, the command resumes only the subtasks on the specified MySQL source.
- `task-name | task-file`: (Required) Specifies the task name or task file path.

Returned results

```
resume-task test
```

```
{
    "op": "Resume",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

13.6.6.11.6 Stop a Data Migration Task

You can use the `stop-task` command to stop a data migration task. For differences between `stop-task` and `pause-task`, refer to Pause a Data Migration Task.

```
help stop-task
```

```
stop a specified task

Usage:
 dmctl stop-task [-s source ...] <task-name | task-file> [flags]

Flags:
 -h, --help  help for stop-task

Global Flags:
 -s, --source strings MySQL Source ID
```

Usage example

```
stop-task [-s "mysql-replica-01"] task-name
```

Flags description

- `-s`: (Optional) Specifies the MySQL source where the subtasks of the migration task (that you want to stop) run. If it is set, only subtasks on the specified MySQL source are stopped.
- `task-name | task-file`: (Required) Specifies the task name or task file path.

Returned results

```
stop-task test
```

```
{
    "op": "Stop",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

Note:

After you stop a migration task with the `stop-task` command, running `query-status` will no longer display the task. However, the checkpoint and other related information for this task is still retained in the `dm_meta` database.

- To start over the migration task, add the `--remove-meta` option when running the `start-task` command.
- To completely remove the migration task, manually delete the four tables that use the task name as a prefix from the `dm_meta` database.

13.6.7 Advanced Tutorials

13.6.7.1 Merge and Migrate Data from Sharded Tables

13.6.7.1.1 Merge and Migrate Data from Sharded Tables

This document introduces the sharding support feature provided by Data Migration (DM). This feature allows you to merge and migrate the data of tables with the same or different table schemas in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB. It supports not only migrating the upstream DML statements, but also coordinating to migrate the table schema change using DDL statements in multiple upstream sharded tables.

Overview

DM supports merging and migrating the data of multiple upstream sharded tables into one table in TiDB. During the migration, the DDL of each sharded table, and the DML before and after the DDL need to be coordinated. For the usage scenarios, DM supports two different modes: pessimistic mode and optimistic mode.

Note:

- To merge and migrate data from sharded tables, you must set `shard-mode` in the task configuration file.
- DM uses the pessimistic mode by default for the merge of the sharding support feature. (If there is no special description in the document, use the pessimistic mode by default.)

- It is not recommended to use this mode if you do not understand the principles and restrictions of the optimistic mode. Otherwise, it may cause serious consequences such as migration interruption and even data inconsistency.

The pessimistic mode

When an upstream sharded table executes a DDL statement, the migration of this sharded table will be suspended. After all other sharded tables execute the same DDL, the DDL will be executed in the downstream and the data migration task will restart. The advantage of this mode is that it can ensure that the data migrated to the downstream will not go wrong. For details, refer to shard merge in pessimistic mode. ####### The optimistic mode

DM will automatically modify the DDL executed on a sharded table into a statement compatible with other sharded tables, and then migrate to the downstream. This will not block the DML migration of any sharded tables. The advantage of this mode is that it will not block data migration when processing DDL. However, improper use will cause migration interruption or even data inconsistency. For details, refer to shard merge in optimistic mode.

Contrast

Pessimistic mode	Optimistic mode
Sharded tables that executes DDL suspend DML migration	Sharded tables that executes DDL continue DML migration
The DDL execution order and statements of each sharded table must be the same	Each sharded table only needs to keep the table schema compatible with each other

Pessimistic mode	Optimistic mode
The DDL is migrated to the downstream after the entire shard group is consistent	The DDL of each sharded table immediately affects the downstream
Wrong DDL operations can be intercepted after the detection	Wrong DDL operations will be migrated to the downstream, which may cause inconsistency between the upstream and downstream data before the detection

13.6.7.1.2 Merge and Migrate Data from Sharded Tables in the Pessimistic Mode

This document introduces the sharding support feature provided by Data Migration (DM) in the pessimistic mode (the default mode). This feature allows you to merge and migrate the data of tables with the same table schema in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB.

Restrictions

DM has the following sharding DDL usage restrictions in the pessimistic mode:

- For a logical **sharding group** (composed of all sharded tables that need to be merged and migrated into one same downstream table), it is limited to use one task containing exactly the sources of sharded tables to perform the migration.
- In a logical **sharding group**, the same DDL statements must be executed in the same order in all upstream sharded tables (the schema name and the table name can be different), and the next DDL statement cannot be executed unless the current DDL operation is completely finished.

    - For example, if you add `column A` to `table_1` before you add `column B`, then you cannot add `column B` to `table_2` before you add `column A`. Executing the DDL statements in a different order is not supported.

- In a sharding group, the corresponding DDL statements should be executed in all upstream sharded tables.
    - For example, if DDL statements are not executed on one or more upstream sharded tables corresponding to `DM-worker-2`, then other DM-workers that have executed the DDL statements pause their migration task and wait for `DM-worker -2` to receive the upstream DDL statements.
- The sharding group migration task does not support `DROP DATABASE`/`DROP TABLE`.
    - The sync unit in DM-worker automatically ignores the `DROP DATABASE`/`DROP TABLE` statement of upstream sharded tables.
- The sharding group migration task does not support `TRUNCATE TABLE`.
    - The sync unit in DM-worker automatically ignores the `TRUNCATE TABLE` statement of upstream sharded tables.
- The sharding group migration task supports `RENAME TABLE`, but with the following limitations (online DDL is supported in another solution):
    - A table can only be renamed to a new name that is not used by any other table.
    - A single `RENAME TABLE` statement can only involve a single `RENAME` operation.
- The sharding group migration task requires each DDL statement to involve operations on only one table.
- The table schema of each sharded table must be the same at the starting point of the incremental replication task, so as to make sure the DML statements of different sharded tables can be migrated into the downstream with a definite table schema, and the subsequent sharding DDL statements can be correctly matched and migrated.
- If you need to change the table routing rule, you have to wait for the migration of all sharding DDL statements to complete.
    - During the migration of sharding DDL statements, an error is reported if you use `dmctl` to change `router-rules`.
- If you need to `CREATE` a new table to a sharding group where DDL statements are being executed, you have to make sure that the table schema is the same as the newly modified table schema.
    - For example, both the original `table_1` and `table_2` have two columns (a, b) initially, and have three columns (a, b, c) after the sharding DDL operation, so after the migration the newly created table should also have three columns (a, b, c).
- Because the DM-worker that has received the DDL statements will pause the task to wait for other DM-workers to receive their DDL statements, the delay of data migration will be increased.

Background

Currently, DM uses the binlog in the `ROW` format to perform the migration task. The binlog does not contain the table schema information. When you use the `ROW` binlog to migrate data, if you have not migrated multiple upstream tables into the same downstream table, then there only exist DDL operations of one upstream table that can update the table schema of the downstream table. The `ROW` binlog can be considered to have the nature of self-description. During the migration process, the DML statements can be constructed accordingly with the column values and the downstream table schema.

However, in the process of merging and migrating sharded tables, if DDL statements are executed on the upstream tables to modify the table schema, then you need to perform extra operations to migrate the DDL statements so as to avoid the inconsistency between the DML statements produced by the column values and the actual downstream table schema.

Here is a simple example:

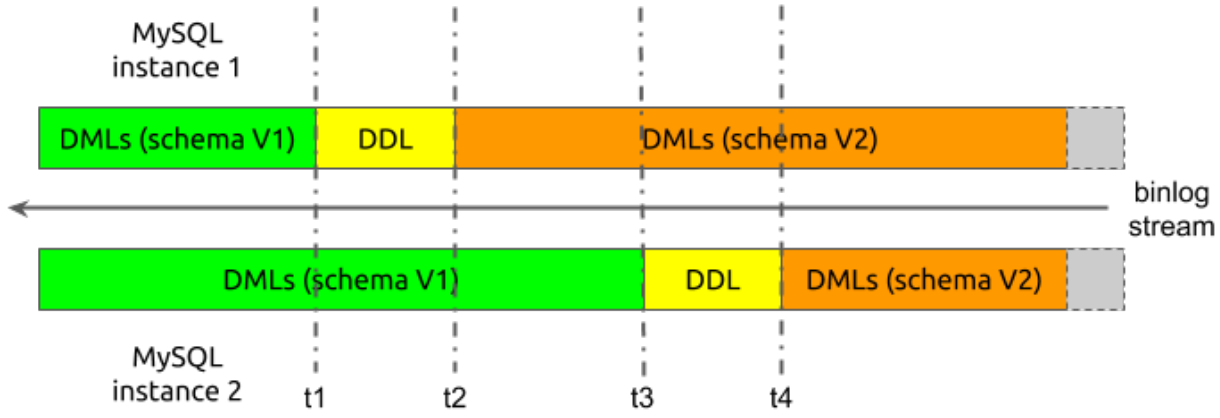


Figure 462: shard-ddl-example-1

In the above example, the merging process is simplified, where only two MySQL instances exist in the upstream and each instance has only one table. When the migration begins, the table schema version of two sharded tables is marked as `schema V1`, and the table schema version after executing DDL statements is marked as `schema V2`.

Now assume that in the migration process, the binlog data received from the two upstream sharded tables has the following time sequence:

1. When the migration begins, the sync unit in DM-worker receives the DML events of `schema V1` from the two sharded tables.
2. At `t1`, the sharding DDL events from instance 1 are received.
3. From `t2` on, the sync unit receives the DML events of `schema V2` from instance 1; but from instance 2, it still receives the DML events of `schema V1`.

4. At `t3`, the sharding DDL events from instance 2 are received.
5. From `t4` on, the sync unit receives the DML events of `schema V2` from instance 2 as well.

Assume that the DDL statements of sharded tables are not processed during the migration process. After DDL statements of instance 1 are migrated to the downstream, the downstream table schema is changed to `schema V2`. But for instance 2, the sync unit in DM-worker is still receiving DML events of `schema V1` from `t2` to `t3`. Therefore, when the DML statements of `schema V1` are migrated to the downstream, the inconsistency between the DML statements and the table schema can cause errors and the data cannot be migrated successfully.

Principles

This section shows how DM migrates DDL statements in the process of merging sharded tables based on the above example in the pessimistic mode.

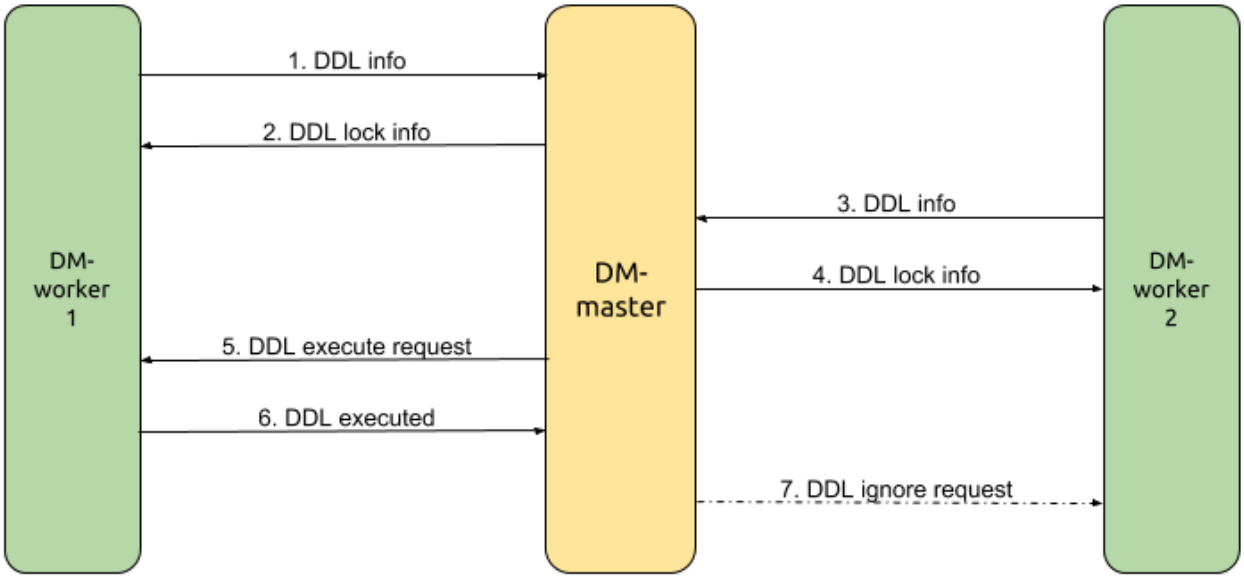

Figure 463: shard-ddl-flow

In this example, `DM-worker-1` migrates the data from MySQL instance 1 and `DM-worker-2` migrates the data from MySQL instance 2. `DM-master` coordinates the DDL migration among multiple DM-workers. Starting from `DM-worker-1` receiving the DDL statements, the DDL migration process is simplified as follows:

1. `DM-worker-1` receives the DDL statement from MySQL instance 1 at `t1`, pauses the data migration of the corresponding DDL and DML statements, and sends the DDL information to `DM-master`.

2. `DM-master` decides that the migration of this DDL statement needs to be coordinated based on the received DDL information, creates a lock for this DDL statement, sends the DDL lock information back to `DM-worker-1` and marks `DM-worker-1` as the owner of this lock at the same time.
3. `DM-worker-2` continues migrating the DML statement until it receives the DDL statement from MySQL instance 2 at `t3`, pauses the data migration of this DDL statement, and sends the DDL information to `DM-master`.
4. `DM-master` decides that the lock of this DDL statement already exists based on the received DDL information, and sends the lock information directly to `DM-worker-2`.
5. Based on the configuration information when the task is started, the sharded table information in the upstream MySQL instances, and the deployment topology information, `DM-master` decides that it has received this DDL statement of all upstream sharded tables to be merged, and requests the owner of the DDL lock (`DM-worker-1`) to migrate this DDL statement to the downstream.
6. `DM-worker-1` verifies the DDL statement execution request based on the DDL lock information received at Step #2, migrates this DDL statement to the downstream, and sends the results to `DM-master`. If this operation is successful, `DM-worker-1` continues migrating the subsequent (starting from the binlog at `t2`) DML statements.
7. `DM-master` receives the response from the lock owner that the DDL is successfully executed, and requests all other DM-workers (`DM-worker-2`) that are waiting for the DDL lock to ignore this DDL statement and then continue to migrate the subsequent (starting from the binlog at `t4`) DML statements.

The characteristics of DM handling the sharding DDL migration among multiple DM-workers can be concluded as follows:

- Based on the task configuration and DM cluster deployment topology information, a logical sharding group is built in `DM-master` to coordinate DDL migration. The group members are DM-workers that handle each sub-task divided from the migration task).
- After receiving the DDL statement from the binlog event, each DM-worker sends the DDL information to `DM-master`.
- `DM-master` creates or updates the DDL lock based on the DDL information received from each DM-worker and the sharding group information.
- If all members of the sharding group receive a same specific DDL statement, this indicates that all DML statements before the DDL execution on the upstream sharded tables have been completely migrated, and this DDL statement can be executed. Then DM can continue to migrate the subsequent DML statements.
- After being converted by the table router, the DDL statement of the upstream sharded tables must be consistent with the DDL statement to be executed in the downstream. Therefore, this DDL statement only needs to be executed once by the DDL owner and all other DM-workers can ignore this DDL statement.

In the above example, only one sharded table needs to be merged in the upstream MySQL instance corresponding to each DM-worker. But in actual scenarios, there might be multiple

sharded tables in multiple sharded schemas to be merged in one MySQL instance. And when this happens, it becomes more complex to coordinate the sharding DDL migration.

Assume that there are two sharded tables, namely `table_1` and `table_2`, to be merged in one MySQL instance:

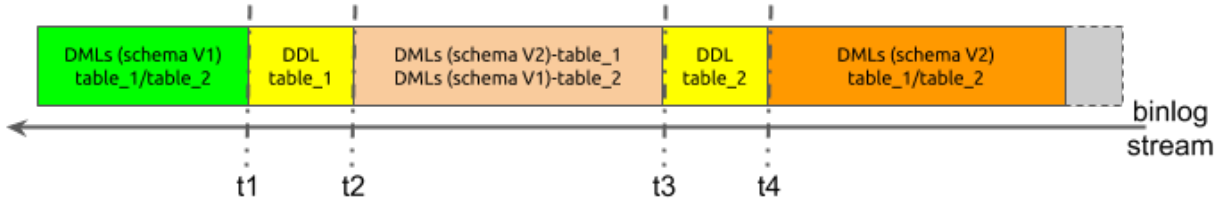

Figure 464: shard-ddl-example-2

Because data comes from the same MySQL instance, all the data is obtained from the same binlog stream. In this case, the time sequence is as follows:

1. The sync unit in DM-worker receives the DML statements of `schema V1` from both sharded tables when the migration begins.
2. At `t1`, the sync unit in DM-worker receives the DDL statements of `table_1`.
3. From `t2` to `t3`, the received data includes the DML statements of `schema V2` from `table_1` and the DML statements of `schema V1` from `table_2`.
4. At `t3`, the sync unit in DM-worker receives the DDL statements of `table_2`.
5. From `t4` on, the sync unit in DM-worker receives the DML statements of `schema V2` from both tables.

If the DDL statements are not processed particularly during the data migration, when the DDL statement of `table_1` is migrated to the downstream and changes the downstream table schema, the DML statement of `schema V1` from `table_2` cannot be migrated successfully. Therefore, within a single DM-worker, a logical sharding group similar to that within `DM-master` is created, except that members of this group are different sharded tables in the same upstream MySQL instance.

But when a DM-worker coordinates the migration of the sharding group within itself, it is not totally the same as that performed by `DM-master`. The reasons are as follows:

- When the DM-worker receives the DDL statement of `table_1`, it cannot pause the migration and needs to continue parsing the binlog to get the subsequent DDL statements of `table_2`. This means it needs to continue parsing between `t2` and `t3`.
- During the binlog parsing process between `t2` and `t3`, the DML statements of `schema V2` from `table_1` cannot be migrated to the downstream until the sharding DDL statement is migrated and successfully executed.

In DM, the simplified migration process of sharding DDL statements within the DM worker is as follows:

1. When receiving the DDL statement of `table_1` at `t1`, the DM-worker records the DDL information and the current position of the binlog.
2. DM-worker continues parsing the binlog between `t2` and `t3`.
3. DM-worker ignores the DML statement with the `schema V2` schema that belongs to `table_1`, and migrates the DML statement with the `schema V1` schema that belongs to `table_2` to the downstream.
4. When receiving the DDL statement of `table_2` at `t3`, the DM-worker records the DDL information and the current position of the binlog.
5. Based on the information of the migration task configuration and the upstream schemas and tables, the DM-worker decides that the DDL statements of all sharded tables in the MySQL instance have been received and migrates them to the downstream to modify the downstream table schema.
6. DM-worker sets the starting point of parsing the new binlog stream to be the position saved at Step #1.
7. DM-worker resumes parsing the binlog between `t2` and `t3`.
8. DM-worker migrates the DML statement with the `schema V2` schema that belongs to `table_1` to the downstream, and ignores the DML statement with the `schema V1` schema that belongs to `table_2`.
9. After parsing the binlog position saved at Step #4, the DM-worker decides that all DML statements that have been ignored in Step #3 have been migrated to the downstream again.
10. DM-worker resumes the migration starting from the binlog position at `t4`.

You can conclude from the above analysis that DM mainly uses two-level sharding groups for coordination and control when handling migration of the sharding DDL. Here is the simplified process:

1. Each DM-worker independently coordinates the DDL statements migration for the corresponding sharding group composed of multiple sharded tables within the upstream MySQL instance.
2. After the DM-worker receives the DDL statements of all sharded tables, it sends the DDL information to `DM-master`.
3. `DM-master` coordinates the DDL migration of the sharding group composed of the DM-workers based on the received DDL information.
4. After receiving the DDL information from all DM-workers, `DM-master` requests the DDL lock owner (a specific DM-worker) to execute the DDL statement.
5. The DDL lock owner executes the DDL statement and returns the result to `DM-master` ↪ . Then the owner restarts the migration of the previously ignored DML statements during the internal coordination of DDL migration.
6. After `DM-master` confirms that the owner has successfully executed the DDL statement, it asks all other DM-workers to continue the migration.

7. All other DM-workers separately restart the migration of the previously ignored DML statements during the internal coordination of DDL migration.
8. After finishing migrating the ignored DML statements again, all DM-workers resume the normal migration process.

13.6.7.1.3 Merge and Migrate Data from Sharded Tables in Optimistic Mode

This document introduces the sharding support feature provided by Data Migration (DM) in the optimistic mode. This feature allows you to merge and migrate the data of tables with the same or different table schema(s) in the upstream MySQL or MariaDB instances into one same table in the downstream TiDB.

> **Note:**
>
> If you do not have an in-depth understanding of the optimistic mode and its restrictions, it is **NOT** recommended to use this mode. Otherwise, migration interruption or even data inconsistency might occur.

Background

DM supports executing DDL statements on sharded tables online, which is called sharding DDL, and uses the "pessimistic mode" by default. In this mode, when a DDL statement is executed in an upstream sharded table, data migration of this table is paused until the same DDL statement is executed in all other sharded tables. Only by then this DDL statement is executed in the downstream and data migration resumes.

The pessimistic mode guarantees that the data migrated to the downstream is always correct, but it pauses the data migration, which is bad for making A/B changes in the upstream. In some cases, users might spend a long time executing DDL statements in a single sharded table and change the schemas of other sharded tables only after a period of validation. In the pessimistic mode, these DDL statements block data migration and cause many binlog events to pile up.

Therefore, an "optimistic mode" is needed. In this mode, a DDL statement executed on a sharded table is automatically converted to a statement that is compatible with other sharded tables, and then immediately migrated to the downstream. In this way, the DDL statement does not block any sharded table from executing DML migration.

Configuration of the optimistic mode

To use the optimistic mode, specify the `shard-mode` item in the task configuration file as `optimistic`. You can restrict the behavior of the optimistic mode by enabling the `strict -optimistic-shard-mode` configuration. For the detailed sample configuration file, see DM Advanced Task Configuration File.

Restrictions

It takes some risks to use the optimistic mode. Follow these rules when you use it:

- Ensure that the schema of every sharded table is consistent with each other before and after you execute a batch of DDL statements.
- If you perform an A/B test, perform the test **ONLY** on one sharded table.
- After the A/B test is finished, migrate only the most direct DDL statement(s) to the final schema. Do not re-execute every right or wrong step of the test.

  For example, if you have executed `ADD COLUMN A INT; DROP COLUMN A; ADD COLUMN A FLOAT;` in a sharded table, you only need to execute `ADD COLUMN A FLOAT` in other sharded tables. You do not need to execute all of the three DDL statements again.
- Observe the status of the DM migration when executing the DDL statement. When an error is reported, you need to determine whether this batch of DDL statements will cause data inconsistency.

In the optimistic mode, most of the DDL statements executed in the upstream are automatically migrated to the downstream with no extra effort required. These DDL statements are called "Type 1 DDL".

DDL statements that change the column name, the column type, or the column default value are called "Type 2 DDL". When you execute Type 2 DDL statements in the upstream, make sure that you execute the DDL statements in all sharded tables in the same order.

Some examples of Type 2 DDL statements are as follows:

- Alter the type of a column: `ALTER TABLE table_name MODIFY COLUMN column_name VARCHAR(20).`
- Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO column_2;.`
- Add a `NOT NULL` column without a default value: `ALTER TABLE table_name ADD COLUMN column_1 NOT NULL;.`
- Rename an index: `ALTER TABLE table_name RENAME INDEX index_1 TO index_2;.`

When the sharded tables execute the DDL statements above, if `strict-optimistic-shard-mode: true` is set, the task is directly interrupted and an error is reported. If `strict-optimistic-shard-mode: false` is set or not specified, different execution order of the DDL statements in sharded tables will cause migration interruption. For example:

- Shard 1 renames a column and then alters the column type:
  1. Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO column_2;.`

2. Alter the column type: `ALTER TABLE table_name MODIFY COLUMN column_3 VARCHAR(20);`.

- Shard 2 alters a column type and then renames the column:

1. Alter a column type: `ALTER TABLE table_name MODIFY COLUMN column_3 VARCHAR(20)`.
2. Rename a column: `ALTER TABLE table_name RENAME COLUMN column_1 TO column_2;`.

In addition, the following restrictions apply to both the optimistic mode and the pessimistic mode:

- `DROP TABLE` or `DROP DATABASE` is not supported.
- `TRUNCATE TABLE` is not supported.
- Each DDL statement must involve operations on only one table.
- The DDL statement that is not supported in TiDB is also not supported in DM.
- The default value of a newly added column must not contain `current_timestamp` , `rand()`, `uuid()`; otherwise, data inconsistency between the upstream and the downstream might occur.

Risks

When you use the optimistic mode for a migration task, a DDL statement is migrated to the downstream immediately. If this mode is misused, data inconsistency between the upstream and the downstream might occur.

Operations that cause data inconsistency

- The schema of each sharded table is incompatible with each other. For example:
  - Two columns of the same name are added to two sharded tables respectively, but the columns are of different types.
  - Two columns of the same name are added to two sharded tables respectively, but the columns have different default values.
  - Two generated columns of the same name are added to two sharded tables respectively, but the columns are generated using different expressions.
  - Two indexes of the same name are added to two sharded tables respectively, but the keys are different.
  - Other different table schemas with the same name.
- Execute the DDL statement that can corrupt data in the sharded table and then try to roll back.

  For example, drop a column `X` and then add this column back.

Example

Merge and migrate the following three sharded tables to TiDB:

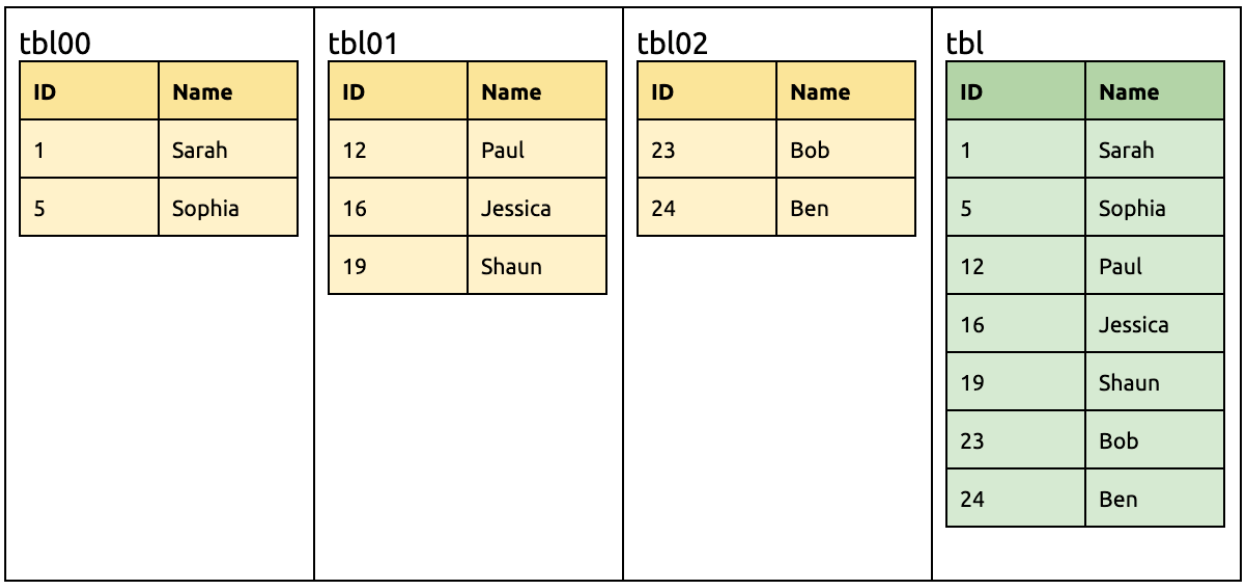

Figure 465: optimistic-ddl-fail-example-1

Add a new column `Age` in `tbl01` and set the default value of the column to `0`:

```
ALTER TABLE `tbl01` ADD COLUMN `Age` INT DEFAULT 0;
```

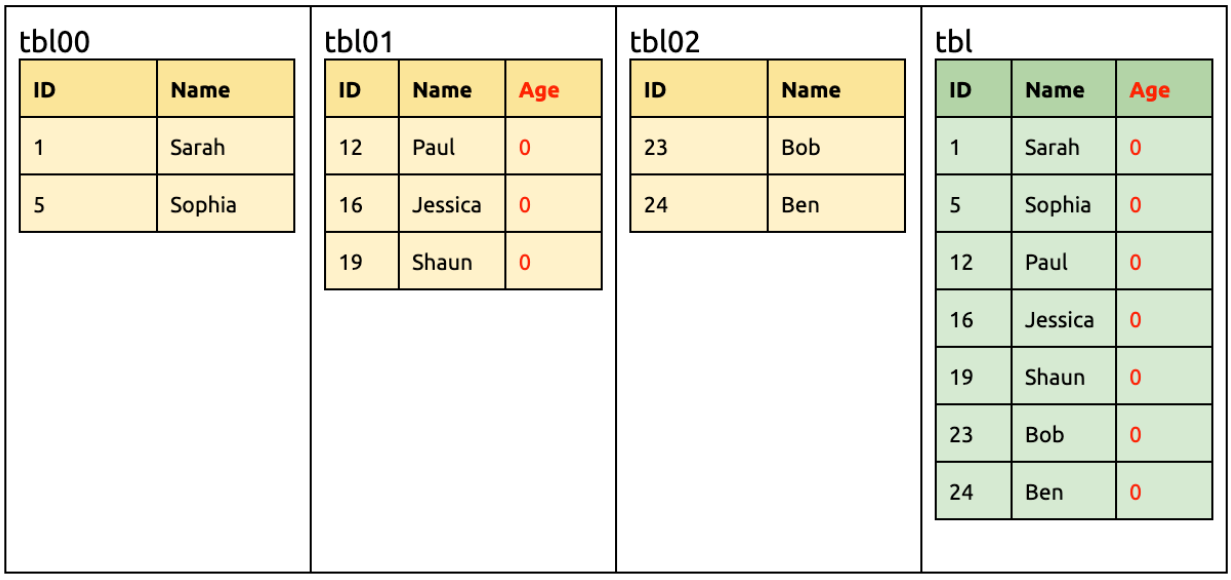

Figure 466: optimistic-ddl-fail-example-2

Add a new column `Age` in `tbl00` and set the default value of the column to `-1`:

```
ALTER TABLE `tbl00` ADD COLUMN `Age` INT DEFAULT -1;
```

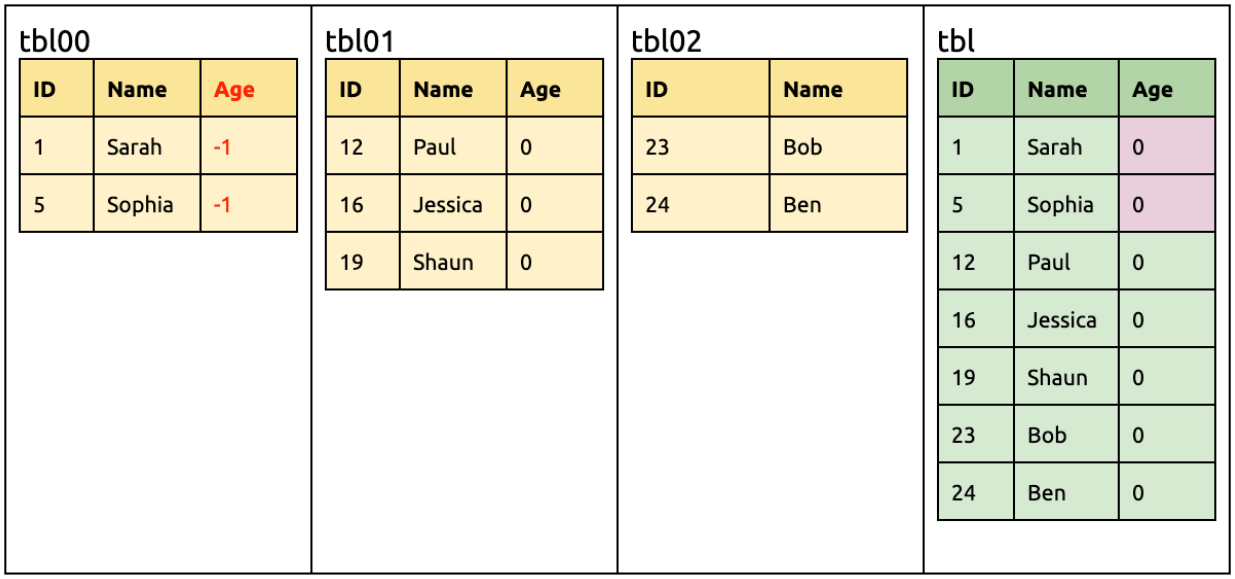

Figure 467: optimistic-ddl-fail-example-3

By then, the `Age` column of `tbl00` is inconsistent because `DEFAULT 0` and `DEFAULT -1` are incompatible with each other. In this situation, DM will report the error, but you have to manually fix the data inconsistency.

Implementation principle

In the optimistic mode, after DM-worker receives the DDL statement from the upstream, it forwards the updated table schema to DM-master. DM-worker tracks the current schema of each sharded table, and DM-master merges these schemas into a composite schema that is compatible with DML statements of every sharded table. Then DM-master migrates the corresponding DDL statement to the downstream. DML statements are directly migrated to the downstream.

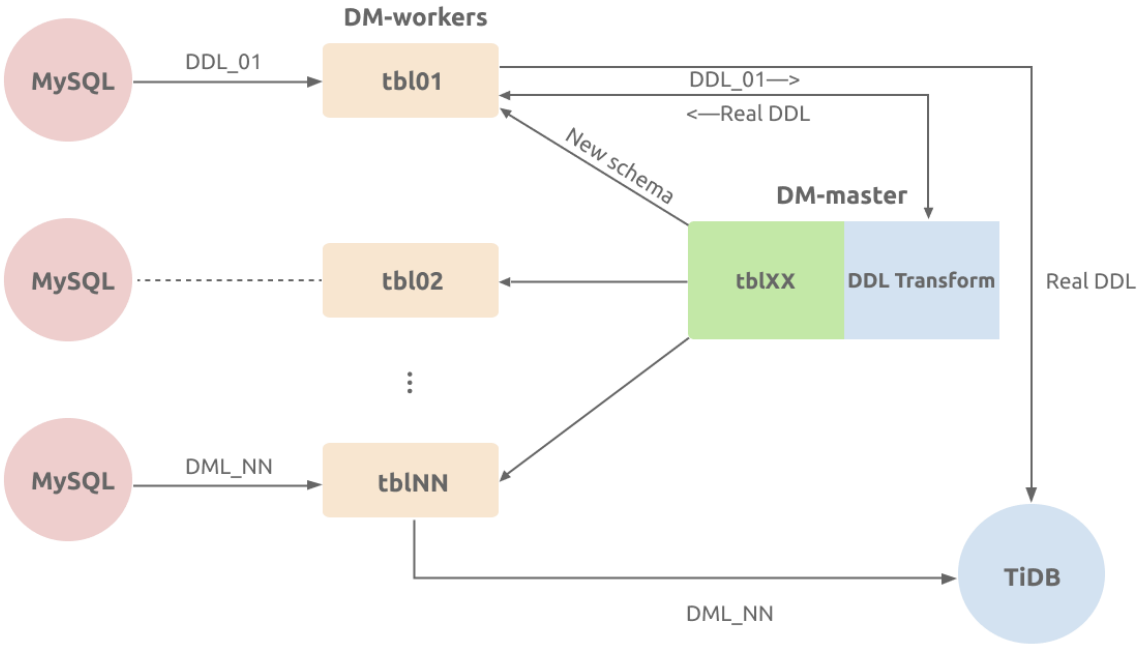

Figure 468: optimistic-ddl-flow

Examples

Assume the upstream MySQL has three sharded tables (`tbl00`, `tbl01`, and `tbl02`). Merge and migrate these sharded tables to the `tbl` table in the downstream TiDB. See the following image:

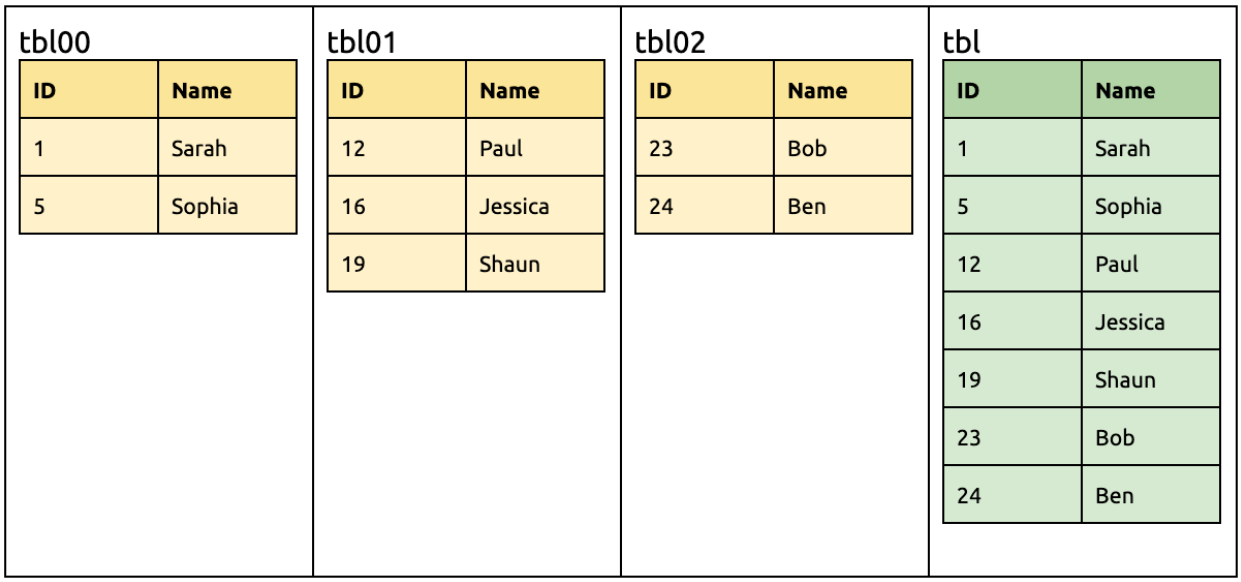

Figure 469: optimistic-ddl-example-1

Add a `Level` column in the upstream:

```
ALTER TABLE `tbl00` ADD COLUMN `Level` INT;
```

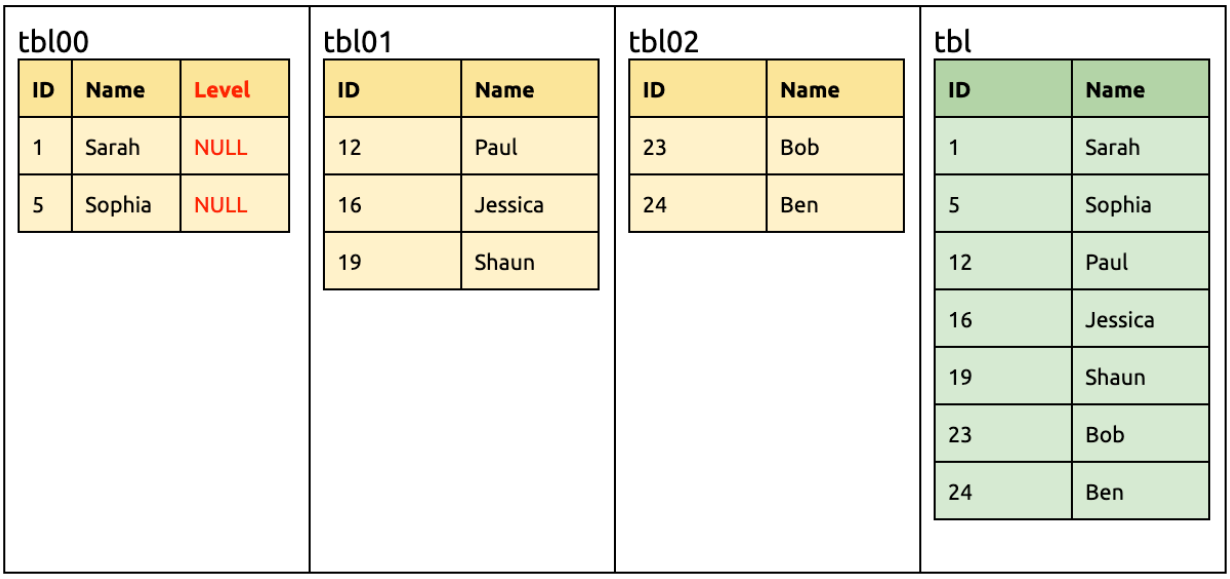

Figure 470: optimistic-ddl-example-2

Then TiDB will receive the DML statement from `tbl00` (with the `Level` column) and the DML statement from the `tbl01` and `tbl02` tables (without the `Level` column).

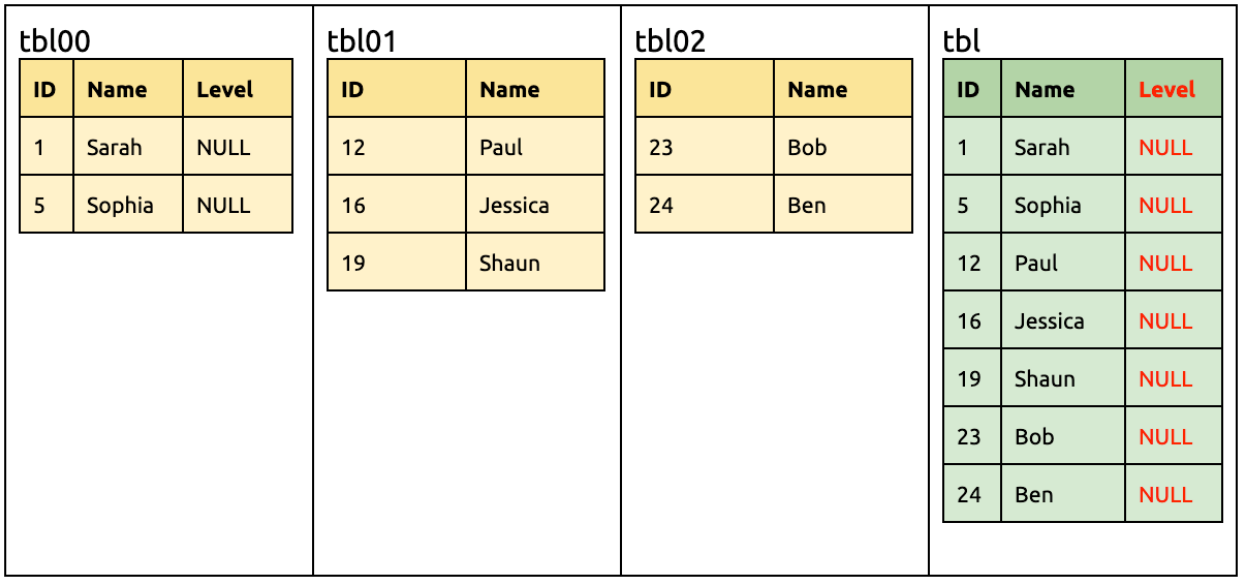

Figure 471: optimistic-ddl-example-3

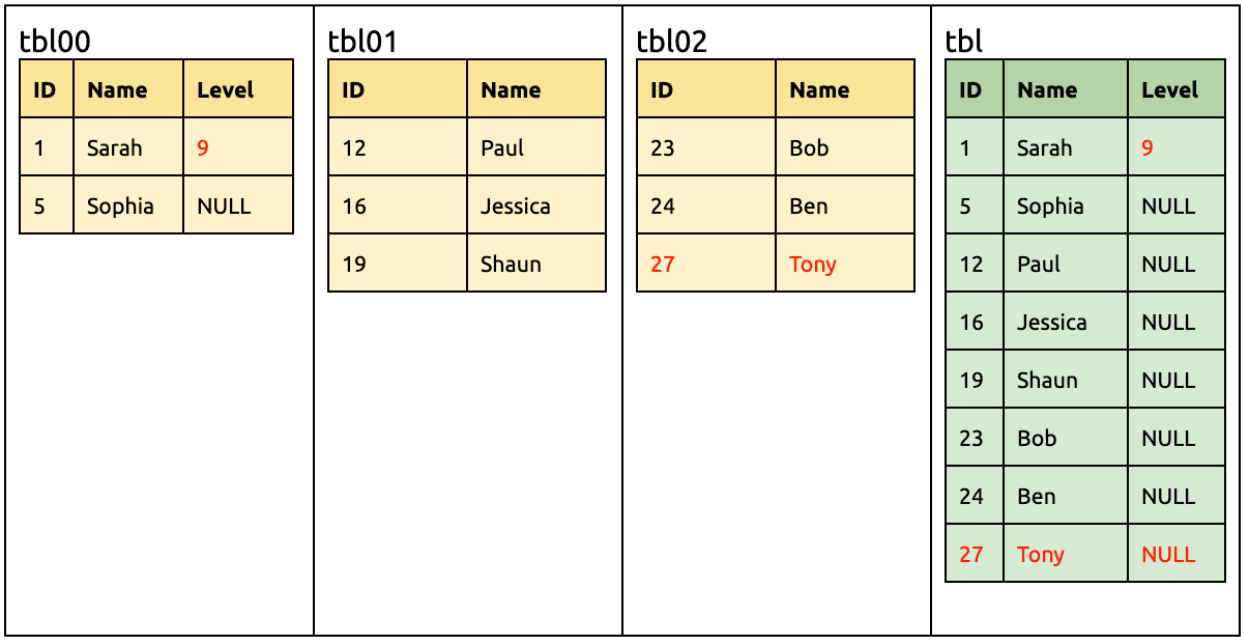
The following DML statements can be migrated to the downstream without any modification:

```
UPDATE `tbl00` SET `Level` = 9 WHERE `ID` = 1;
INSERT INTO `tbl02` (`ID`, `Name`) VALUES (27, 'Tony');
```



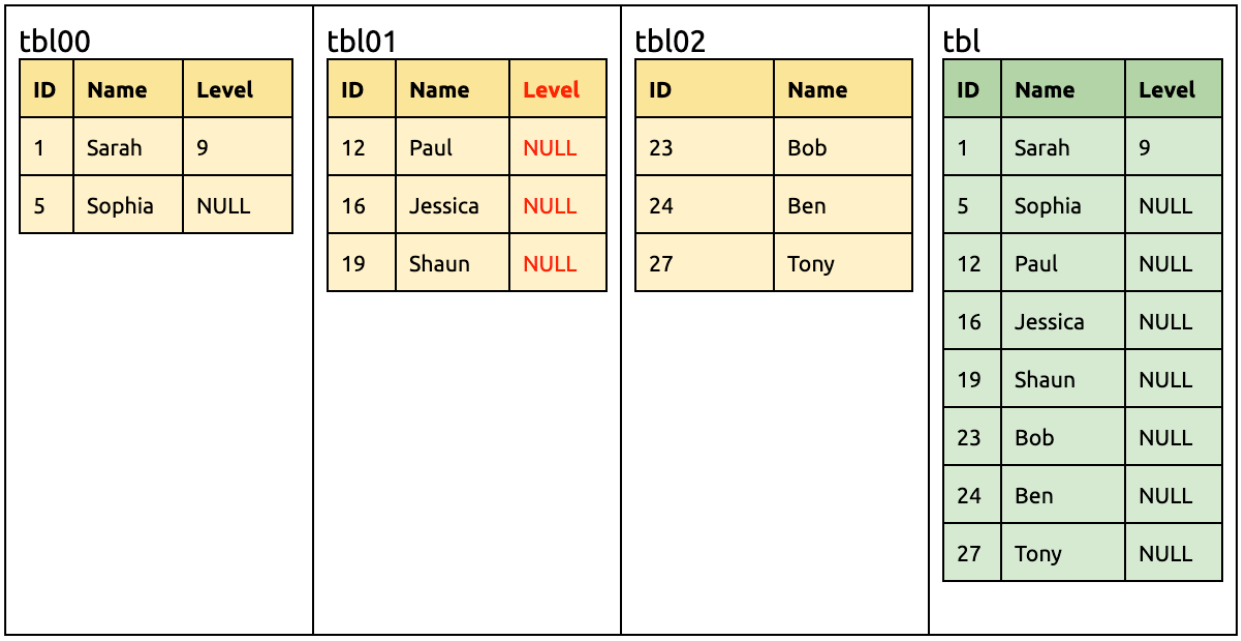


Figure 472: optimistic-ddl-example-4

Also add a `Level` column in `tbl01`:

```
ALTER TABLE `tbl01` ADD COLUMN `Level` INT;
```

tbl00

ID	Name	Level
1	Sarah	9
5	Sophia	NULL

tbl01

ID	Name	Level
12	Paul	NULL
16	Jessica	NULL
19	Shaun	NULL

tbl02

ID	Name
23	Bob
24	Ben
27	Tony

tbl

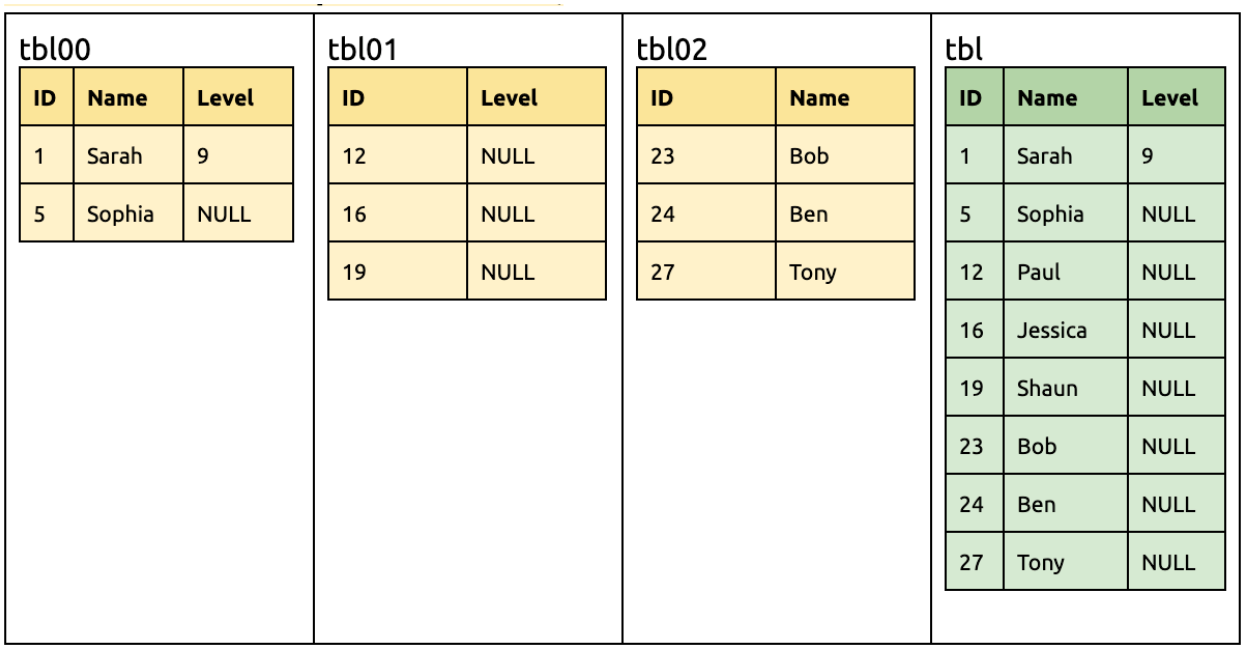
ID	Name	Level
1	Sarah	9
5	Sophia	NULL
12	Paul	NULL
16	Jessica	NULL
19	Shaun	NULL
23	Bob	NULL
24	Ben	NULL
27	Tony	NULL

Figure 473: optimistic-ddl-example-5

At this time, the downstream already have had the same `Level` column, so DM-master performs no operation after comparing the table schemas.

Drop a `Name` column in `tbl01`:

```
ALTER TABLE `tbl01` DROP COLUMN `Name`;
```



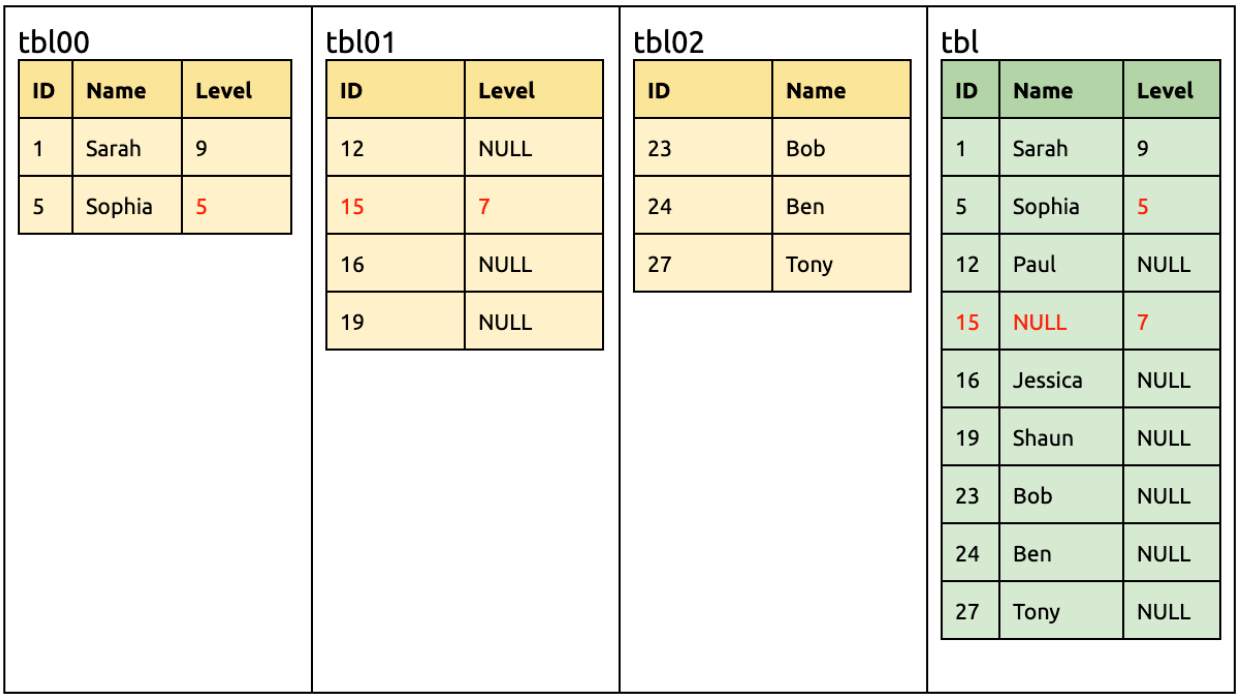


Figure 474: optimistic-ddl-example-6

Then the downstream will receive the DML statements from `tbl00` and `tbl02` with the `Name` column, so this column is not immediately dropped.

In the same way, all DML statements can still be migrated to the downstream:

```
INSERT INTO `tbl01` (`ID`, `Level`) VALUES (15, 7);
UPDATE `tbl00` SET `Level` = 5 WHERE `ID` = 5;
```

tbl00

ID	Name	Level
1	Sarah	9
5	Sophia	5

tbl01

ID	Level
12	NULL
15	7
16	NULL
19	NULL

tbl02

ID	Name
23	Bob
24	Ben
27	Tony

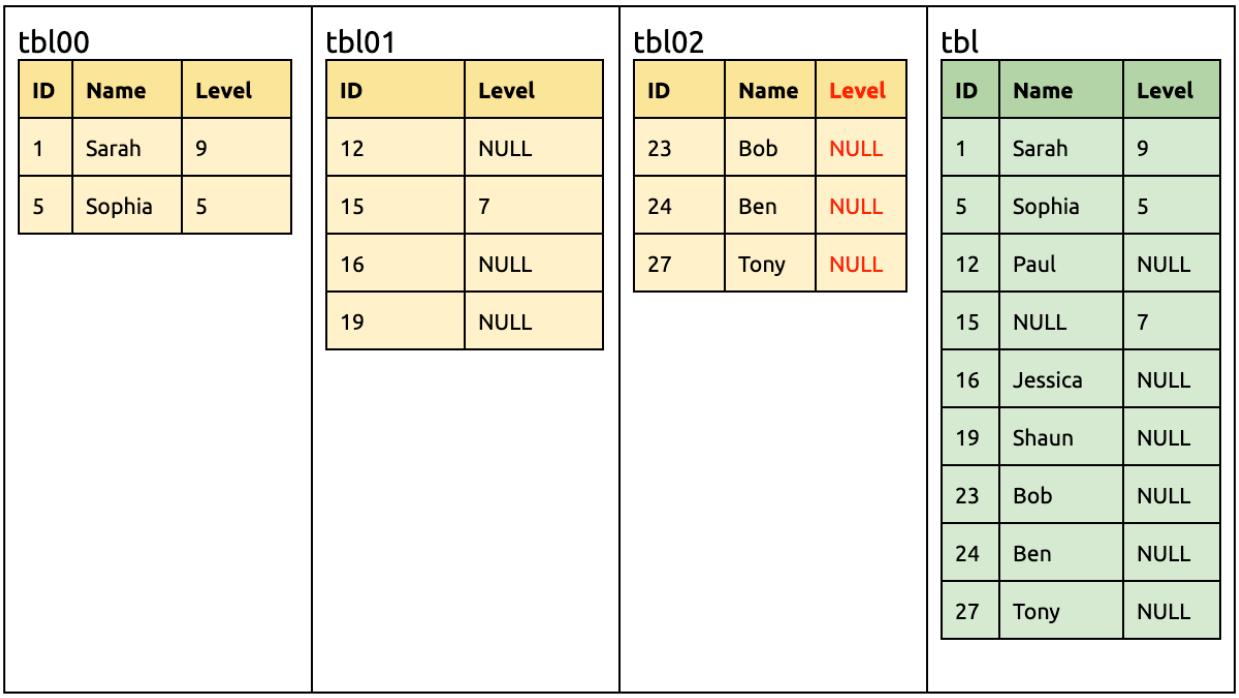
tbl

ID	Name	Level
1	Sarah	9
5	Sophia	5
12	Paul	NULL
15	NULL	7
16	Jessica	NULL
19	Shaun	NULL
23	Bob	NULL
24	Ben	NULL
27	Tony	NULL

Figure 475: optimistic-ddl-example-7

Add a `Level` column in `tbl02`:

```
ALTER TABLE `tbl02` ADD COLUMN `Level` INT;
```



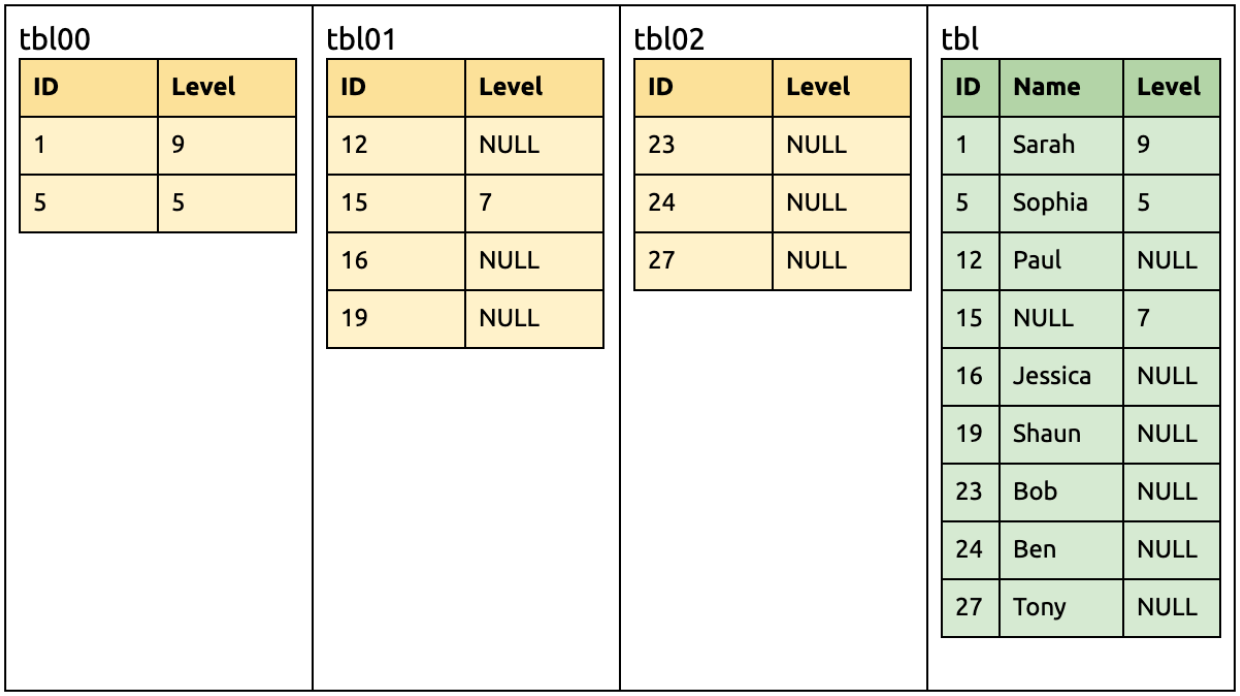


Figure 476: optimistic-ddl-example-8

By then, all sharded tables have the `Level` column.

Drop the `Name` columns in `tbl00` and `tbl02` respectively:

```
ALTER TABLE `tbl00` DROP COLUMN `Name`;
ALTER TABLE `tbl02` DROP COLUMN `Name`;
```

tbl00

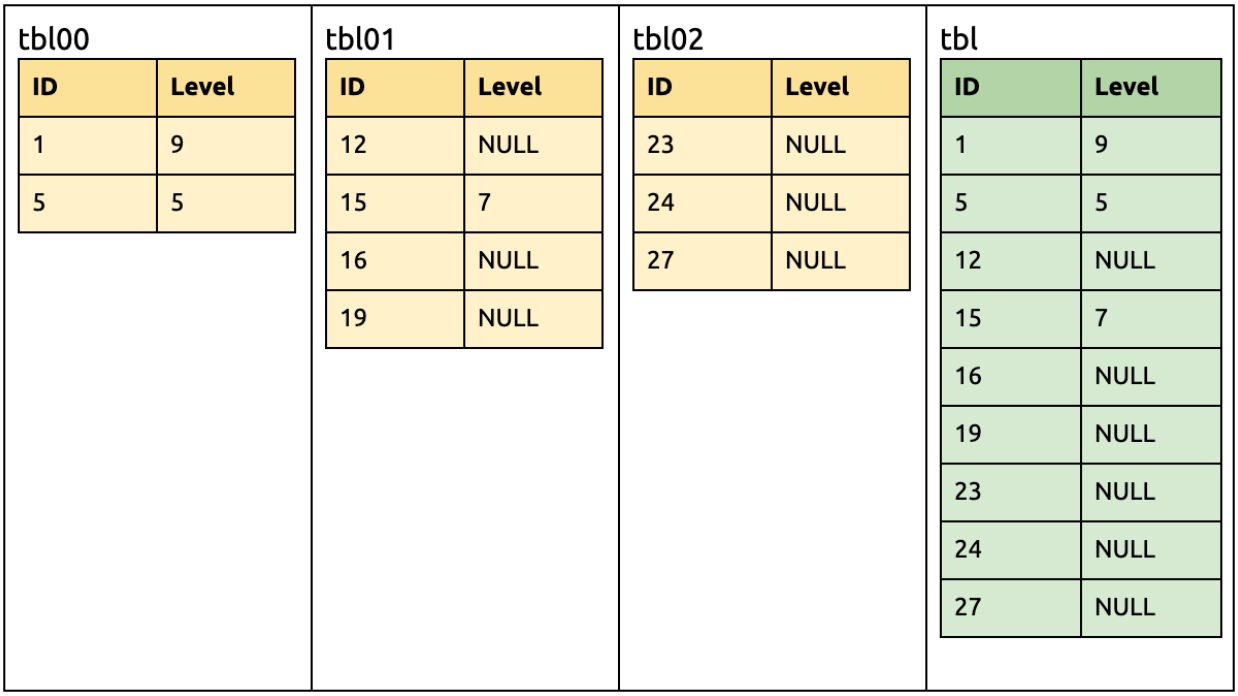
ID	Level
1	9
5	5

tbl01

ID	Level
12	NULL
15	7
16	NULL
19	NULL

tbl02

ID	Level
23	NULL
24	NULL
27	NULL



tbl

ID	Name	Level
1	Sarah	9
5	Sophia	5
12	Paul	NULL
15	NULL	7
16	Jessica	NULL
19	Shaun	NULL
23	Bob	NULL
24	Ben	NULL
27	Tony	NULL

Figure 477: optimistic-ddl-example-9

By then, the `Name` columns are dropped from all sharded tables and can be safely dropped in the downstream:

```
ALTER TABLE `tbl` DROP COLUMN `Name`;
```

tbl00

ID	Level
1	9
5	5

tbl01

ID	Level
12	NULL
15	7
16	NULL
19	NULL

tbl02

ID	Level
23	NULL
24	NULL
27	NULL

tbl

ID	Level
1	9
5	5
12	NULL
15	7
16	NULL
19	NULL
23	NULL
24	NULL
27	NULL

13.6.7.1.4 Handle Sharding DDL Locks Manually in DM

DM uses the sharding DDL lock to ensure operations are performed in the correct order. This locking mechanism resolves sharding DDL locks automatically in most cases, but you need to use the `shard-ddl-lock` command to manually handle the abnormal DDL locks in some abnormal scenarios.

Note:

- This document only applies to the processing of sharding DDL lock in pessimistic coordination mode.
- The commands in the Command usage sections in this document are in interactive mode. In command-line mode, you need to add the escape characters to avoid an error report.
- Do not use `shard-ddl-lock unlock` unless you are totally aware of the possible impacts brought by the command and you can accept them.
- Before manually handling the abnormal DDL locks, make sure that you have already read the DM shard merge principles.

Command

`shard-ddl-lock`

You can use this command to view the DDL lock and request DM-master to release the specified DDL lock. This command is only supported in DM v6.0 and later. For earlier versions, you must use the `show-ddl-locks` and `unlock-ddl-locks` commands.

```
shard-ddl-lock -h
```

```
maintain or show shard-ddl locks information
Usage:
  dmctl shard-ddl-lock [task] [flags]
  dmctl shard-ddl-lock [command]
Available Commands:
  unlock    Unlock un-resolved DDL locks forcely
Flags:
  -h, --help help for shard-ddl-lock
Global Flags:
  -s, --source strings MySQL Source ID.
Use "dmctl shard-ddl-lock [command] --help" for more information about a
    ↪ command.
```

Arguments description

- `shard-ddl-lock [task] [flags]`: view the DDL lock information on the current DM-master.
- `shard-ddl-lock [command]`: request DM-master to release the specified DDL lock. `[command]` only accepts `unlock` as a value.

Usage examples

`shard-ddl-lock [task] [flags]`

You can use `shard-ddl-lock [task] [flags]` to view the DDL lock information on the current DM-master. For example:

```
shard-ddl-lock test
```

Expected output

```
{
    "result": true,                                 # The result of the
       ↪ query for the lock information.
    "msg": "",                                      # The additional message
       ↪  for the failure to query the lock information or other
       ↪ descriptive information (for example, the lock task does not exist
       ↪ ).
```

```
    "locks": [                                  # The existing lock
        ↪ information list.
        {
            "ID": "test-`shard_db`.`shard_table`",   # The lock ID, which is
                ↪ made up of the current task name and the schema/table
                ↪ information corresponding to the DDL.
            "task": "test",                     # The name of the task
                ↪ to which the lock belongs.
            "mode": "pessimistic"               # The shard DDL mode.
                ↪ Can be set to "pessimistic" or "optimistic".
            "owner": "mysql-replica-01",        # The owner of the lock
                ↪ (the ID of the first source that encounters this DDL
                ↪ operation in the pessimistic mode), which is always empty
                ↪ in the optimistic mode.
            "DDLs": [                           # The list of DDL
                ↪ operations corresponding to the lock in the pessimistic
                ↪ mode, which is always empty in the optimistic mode.
                "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` DROP
                    ↪ COLUMN `c2`;"
            ],
            "synced": [                         # The list of sources
                ↪ that have received all sharding DDL events in the
                ↪ corresponding MySQL instance.
                "mysql-replica-01"
            ],
            "unsynced": [                       # The list of sources
                ↪ that have not yet received all sharding DDL events in the
                ↪ corresponding MySQL instance.
                "mysql-replica-02"
            ]
        }
    ]
}
```

`shard-ddl-lock unlock`

This command actively requests `DM-master` to unlock the specified DDL lock, including requesting the owner to execute the DDL statement, requesting all other DM-workers that are not the owner to skip the DDL statement, and removing the lock information on `DM-master`.

Note:

> Currently, `shard-ddl-lock unlock` takes effect only for the lock in the `pessimistic` mode.

```
shard-ddl-lock unlock -h
```

```
Unlock un-resolved DDL locks forcely

Usage:
  dmctl shard-ddl-lock unlock <lock-id> [flags]

Flags:
  -a, --action string  accept skip/exec values which means whether to skip
      ↪ or execute ddls (default "skip")
  -d, --database string database name of the table
  -f, --force-remove   force to remove DDL lock
  -h, --help           help for unlock
  -o, --owner string   source to replace the default owner
  -t, --table string   table name

Global Flags:
  -s, --source strings MySQL Source ID.
```

`shard-ddl-lock unlock` accepts the following arguments:

- `-o, --owner`:
  - Flag; string; optional
  - If it is not specified, this command requests for the default owner (the owner in the result of `shard-ddl-lock`) to execute the DDL statement; if it is specified, this command requests for the MySQL source (the alternative of the default owner) to execute the DDL statement.
  - The new owner should not be specified unless the original owner is already removed from the cluster.
- `-f, --force-remove`:
  - Flag; boolean; optional
  - If it is not specified, this command removes the lock information only when the owner succeeds to execute the DDL statement; if it is specified, this command forcefully removes the lock information even though the owner fails to execute the DDL statement (after doing this you cannot query or operate on the lock again).
- `lock-id`:

- Non-flag; string; required
- It specifies the ID of the DDL lock that needs to be unlocked (the `ID` in the result of `shard-ddl-lock`).

The following is an example of the `shard-ddl-lock unlock` command:

```
shard-ddl-lock unlock test-`shard_db`.`shard_table`
```

```
{
    "result": true,                                     # The result of the
        ↪ unlocking operation.
    "msg": "",                                          # The additional message
        ↪  for the failure to unlock the lock.
}
```

Supported scenarios

Currently, the `shard-ddl-lock unlock` command only supports handling sharding DDL locks in the following two abnormal scenarios.

Scenario 1: Some MySQL sources are removed

The reason for the abnormal lock

Before `DM-master` tries to automatically unlock the sharding DDL lock, all the MySQL sources need to receive the sharding DDL events (for details, see shard merge principles). If the sharding DDL event is already in the migration process, and some MySQL sources have been removed and are not to be reloaded (these MySQL sources have been removed according to the application demand), then the sharding DDL lock cannot be automatically migrated and unlocked because not all the DM-workers can receive the DDL event.

> **Note:**
>
> If you need to make some DM-workers offline when not in the process of migrating sharding DDL events, a better solution is to use `stop-task` to stop the running tasks first, make the DM-workers go offline, remove the corresponding configuration information from the task configuration file, and finally use `start-task` and the new task configuration to restart the migration task.

Manual solution

Suppose that there are two instances `MySQL-1` (`mysql-replica-01`) and `MySQL-2` (`mysql-replica-02`) in the upstream, and there are two tables `shard_db_1.shard_table_1` and `shard_db_1.shard_table_2` in `MySQL-1` and two tables `shard_db_2.shard_table_1`

and `shard_db_2.shard_table_2` in `MySQL-2`. Now we need to merge the four tables and migrate them into the table `shard_db.shard_table` in the downstream TiDB.

The initial table structure is:

```
SHOW CREATE TABLE shard_db_1.shard_table_1;
+---------------+-----------------------------------------+
| Table         | Create Table                            |
+---------------+-----------------------------------------+
| shard_table_1 | CREATE TABLE `shard_table_1` (
  `c1` int(11) NOT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+---------------+-----------------------------------------+
```

The following DDL operation will be executed on the upstream sharded tables to alter the table structure:

```
ALTER TABLE shard_db_*.shard_table_* ADD COLUMN c2 INT;
```

The operation processes of MySQL and DM are as follows:

1. The corresponding DDL operations are executed on the two sharded tables of `mysql-replica-01` to alter the table structures.

   ```
   ALTER TABLE shard_db_1.shard_table_1 ADD COLUMN c2 INT;
   ```

   ```
   ALTER TABLE shard_db_1.shard_table_2 ADD COLUMN c2 INT;
   ```

2. DM-worker sends the received DDL information of the two sharded tables of `mysql-replica-01` to DM-master, and DM-master creates the corresponding DDL lock.

3. Use `shard-ddl-lock` to check the information of the current DDL lock.

   ```
   » shard-ddl-lock test
   {
       "result": true,
       "msg": "",
       "locks": [
           {
               "ID": "test-`shard_db`.`shard_table`",
               "task": "test",
               "mode": "pessimistic"
               "owner": "mysql-replica-01",
               "DDLs": [
                   "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` ADD
                       ↪  COLUMN `c2` int(11);"
   ```

```
            ],
            "synced": [
                "mysql-replica-01"
            ],
            "unsynced": [
                "mysql-replica-02"
            ]
        }
    ]
}
```

4. Due to the application demand, the data corresponding to `mysql-replica-02` is no longer needed to be migrated to the downstream TiDB, and `mysql-replica-02` is removed.

5. The lock whose ID is `test-`shard_db`.`shard_table`` on `DM-master` cannot receive the DDL information of `mysql-replica-02`.

    - The returned result `unsynced` by `shard-ddl-lock` has always included the information of `mysql-replica-02`.

6. Use `shard-ddl-lock unlock` to request `DM-master` to actively unlock the DDL lock.

    - If the owner of the DDL lock has gone offline, you can use the parameter `--owner` to specify another DM-worker as the new owner to execute the DDL.
    - If any MySQL source reports an error, `result` will be set to `false`, and at this point you should check carefully if the errors of each MySQL source is acceptable and within expectations.

    ```
    shard-ddl-lock unlock test-`shard_db`.`shard_table`
    ```

    ```
    {
        "result": true,
        "msg": ""
    ```

7. Use `shard-ddl-lock` to confirm if the DDL lock is unlocked successfully.

```
» shard-ddl-lock test
{
    "result": true,
    "msg": "no DDL lock exists",
    "locks": [
    ]
}
```

8. Check whether the table structure is altered successfully in the downstream TiDB.

```
mysql> SHOW CREATE TABLE shard_db.shard_table;
+-------------+-----------------------------------------------------+
| Table       | Create Table                                        |
+-------------+-----------------------------------------------------+
| shard_table | CREATE TABLE `shard_table` (
  `c1` int(11) NOT NULL,
  `c2` int(11) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+-------------+-----------------------------------------------------+
```

9. Use `query-status` to confirm if the migration task is normal.

Impact

After you have manually unlocked the lock by using `shard-ddl-lock unlock`, if you don't deal with the offline MySQL sources included in the task configuration information, the lock might still be unable to be migrated automatically when the next sharding DDL event is received.

Therefore, after you have manually unlocked the DDL lock, you should perform the following operations:

1. Use `stop-task` to stop the running tasks.
2. Update the task configuration file, and remove the related information of the offline MySQL source from the configuration file.
3. Use `start-task` and the new task configuration file to restart the task.

> **Note:**
>
> After you run `shard-ddl-lock unlock`, if the MySQL source that went offline is reloaded and the DM-worker tries to migrate the data of the sharded tables, a match error between the data and the downstream table structure might occur.

Scenario 2: Some DM-workers stop abnormally or the network failure occurs during the DDL unlocking process

The reason for the abnormal lock

After `DM-master` receives the DDL events of all DM-workers, automatically running `unlock DDL lock` mainly include the following steps:

1. Ask the owner of the lock to execute the DDL and update the checkpoints of corresponding sharded tables.
2. Remove the DDL lock information stored on `DM-master` after the owner successfully executes the DDL.
3. Ask all other non-owners to skip the DDL and update the checkpoints of corresponding sharded tables after the owner successfully executes the DDL.
4. DM-master removes the corresponding DDL lock information after all the owners or non-owners' operations are successful.

Currently, the above unlocking process is not atomic. If the non-owner skips the DDL operation successfully, the DM-worker where the non-owner is located stops abnormally or a network anomaly occurs with the downstream TiDB, which can cause the checkpoint updating to fail.

When the MySQL source corresponding to the non-owner restores data migration, the non-owner tries to request the DM-master to re-coordinate the DDL operation that has been coordinated before the exception occurs and will never receives the corresponding DDL operation from other MySQL sources. This can cause the DDL operation to automatically unlock the corresponding lock.

Manual solution

Suppose that now we have the same upstream and downstream table structures and the same demand for merging tables and migration as in the manual solution of Some MySQL sources are removed.

When `DM-master` automatically executes the unlocking process, the owner (`mysql-replica-01`) successfully executes the DDL and continues the migration process. However, in the process of requesting the non-owner (`mysql-replica-02`) to skip the DDL operation, the checkpoint fails to update after the DM-worker skips the DDL operation because the corresponding DM-worker was restarted.

After the data migration subtask corresponding to `mysql-replica-02` restores, a new lock is created on the DM-master, but other MySQL sources have executed or skipped DDL operations and are performing subsequent migration.

The operation processes are:

1. Use `shard-ddl-lock` to confirm if the corresponding lock of the DDL exists on `DM-master`.

   Only `mysql-replica-02` is at the `synced` state.

```
» shard-ddl-lock
{
    "result": true,
    "msg": "",
    "locks": [
        {
```

```
            "ID": "test-`shard_db`.`shard_table`",
            "task": "test",
            "mode": "pessimistic"
            "owner": "mysql-replica-02",
            "DDLs": [
                "USE `shard_db`; ALTER TABLE `shard_db`.`shard_table` ADD
                    ↪  COLUMN `c2` int(11);"
            ],
            "synced": [
                "mysql-replica-02"
            ],
            "unsynced": [
                "mysql-replica-01"
            ]
        }
    ]
}
```

2. Use `shard-ddl-lock` to ask `DM-master` to unlock the lock.

    - During the unlocking process, the owner tries to execute the DDL operation to the downstream again (the original owner before restarting has executed the DDL operation to the downstream once). Make sure that the DDL operation can be executed multiple times.

```
shard-ddl-lock unlock test-`shard_db`.`shard_table`
{
    "result": true,
    "msg": "",
}
```

3. Use `shard-ddl-lock` to confirm if the DDL lock has been successfully unlocked.
4. Use `query-status` to confirm if the migration task is normal.

Impact

After manually unlocking the lock, the following sharding DDL can be migrated automatically and normally.

13.6.7.2 Migrate from Databases that Use GH-ost/PT-osc

In production scenarios, table locking during DDL execution can block the reads from or writes to the database to a certain extent. Therefore, online DDL tools are often used to execute DDLs to minimize the impact on reads and writes. Common DDL tools are gh-ost and pt-osc.

When using DM to migrate data from MySQL to TiDB, you can enable online-ddl to allow collaboration of DM and gh-ost or pt-osc. For details about how to enable online-ddl and the workflow after enabling this option, see Continuous Replication with gh-ost or pt-osc. This document focuses on the collaboration details of DM and online DDL tools.

13.6.7.2.1 Working details for DM with online DDL tools

This section describes the working details for DM with the online DDL tools gh-ost and pt-osc when implementing online-schema-change.

13.6.7.2.2 online-schema-change: gh-ost

When gh-ost implements online-schema-change, 3 types of tables are created:

- gho: used to apply DDLs. When the data is fully replicated and the gho table is consistent with the origin table, the origin table is replaced by renaming.
- ghc: used to store information that is related to online-schema-change.
- del: created by renaming the origin table.

In the process of migration, DM divides the above tables into 3 categories:

- ghostTable: `_*_gho`
- trashTable: `_*_ghc`, `_*_del`
- realTable: the origin table that executes online-ddl.

The SQL statements mostly used by gh-ost and the corresponding operation of DM are as follows:

1. Create the `_ghc` table:

```
Create /* gh-ost */ table `test`.`_test4_ghc` (
                    id bigint auto_increment,
                    last_update timestamp not null DEFAULT CURRENT_
                        ↪ TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
                    hint varchar(64) charset ascii not null,
                    value varchar(4096) charset ascii not null,
                    primary key(id),
                    unique key hint_uidx(hint)
            ) auto_increment=256 ;
```

   DM does not create the `_test4_ghc` table.

2. Create the `_gho` table:

```
Create /* gh-ost */ table `test`.`_test4_gho` like `test`.`test4` ;
```

DM does not create the `_test4_gho` table. DM deletes the `dm_meta.{task_name}_onlineddl` record in the downstream according to `ghost_schema`, `ghost_table`, and the `server_id` of `dm_worker`, and clears the related information in memory.

```
DELETE FROM dm_meta.{task_name}_onlineddl WHERE id = {server_id} and
    ↪ ghost_schema = {ghost_schema} and ghost_table = {ghost_table};
```

3. Apply the DDL that needs to be executed in the `_gho` table:

```
Alter /* gh-ost */ table `test`.`_test4_gho` add column cl1 varchar
    ↪ (20) not null ;
```

DM does not perform the DDL operation of `_test4_gho`. It records this DDL in `dm_meta.{task_name}_onlineddl` and memory.

```
REPLACE INTO dm_meta.{task_name}_onlineddl (id, ghost_schema , ghost_
    ↪ table , ddls) VALUES (......);
```

4. Write data to the `_ghc` table, and replicate the origin table data to the `_gho` table:

```
INSERT /* gh-ost */ INTO `test`.`_test4_ghc` VALUES (......);
INSERT /* gh-ost `test`.`test4` */ ignore INTO `test`.`_test4_gho` (`
    ↪ id`, `date`, `account_id`, `conversion_price`, `ocpc_matched_
    ↪ conversions`, `ad_cost`, `cl2`)
  (SELECT `id`, `date`, `account_id`, `conversion_price`, `ocpc_matched
      ↪ _conversions`, `ad_cost`, `cl2` FROM `test`.`test4` FORCE INDEX
      ↪  (`PRIMARY`)
    WHERE (((`id` > _binary'1') OR ((`id` = _binary'1'))) AND ((`id` <
        ↪ _binary'2') OR ((`id` = _binary'2')))) lock IN share mode
  )   ;
```

DM does not execute DML statements that are not for **realtable**.

5. After the migration is completed, both the origin table and `_gho` table are renamed, and the online DDL operation is completed:

```
Rename /* gh-ost */ table `test`.`test4` to `test`.`_test4_del`, `test
    ↪ `.`_test4_gho` to `test`.`test4`;
```

DM performs the following two operations:

- DM splits the above `rename` operation into two SQL statements.

```
rename test.test4 to test._test4_del;
rename test._test4_gho to test.test4;
```

- DM does not execute `rename to _test4_del`. When executing `rename ghost_table to origin table`, DM takes the following steps:

- Read the DDL recorded in memory in Step 3
- Replace `ghost_table` and `ghost_schema` with `origin_table` and its corresponding schema
- Execute the DDL that has been replaced

```
alter table test._test4_gho add column cl1 varchar(20) not null;
-- Replaced with:
alter table test.test4 add column cl1 varchar(20) not null;
```

Note:

The specific SQL statements of gh-ost vary with the parameters used in the execution. This document only lists the major SQL statements. For more details, refer to the gh-ost documentation.

13.6.7.2.3 online-schema-change: pt

When pt-osc implements online-schema-change, 2 types of tables are created:

- `new`: used to apply DDL. When the data is fully replicated and the `new` table is consistent with the origin table, the origin table is replaced by renaming.
- `old`: created by renaming the origin table.
- 3 kinds of Trigger: `pt_osc_*_ins`, `pt_osc_*_upd`, `pt_osc_*_del`. In the process of pt_osc, the new data generated by the origin table is replicated to `new` by the Trigger.

In the process of migration, DM divides the above tables into 3 categories:

- ghostTable: `_*_new`
- trashTable: `_*_old`
- realTable: the origin table that executes online-ddl.

The SQL statements mostly used by pt-osc and the corresponding operation of DM are as follows:

1. Create the `_new` table:

```
CREATE TABLE `test`.`_test4_new` ( id int(11) NOT NULL AUTO_INCREMENT,
date date DEFAULT NULL, account_id bigint(20) DEFAULT NULL, conversion
    ↪ _price decimal(20,3) DEFAULT NULL, ocpc_matched_conversions
    ↪ bigint(20) DEFAULT NULL, ad_cost decimal(20,3) DEFAULT NULL,cl2
    ↪ varchar(20) COLLATE utf8mb4_bin NOT NULL,cl1 varchar(20) COLLATE
    ↪  utf8mb4_bin NOT NULL,PRIMARY KEY (id) ) ENGINE=InnoDB AUTO_
    ↪ INCREMENT=3 DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin ;
```

DM does not create the `_test4_new` table. DM deletes the `dm_meta.{task_name}_onlineddl` record in the downstream according to `ghost_schema`, `ghost_table`, and the `server_id` of `dm_worker`, and clears the related information in memory.

```
DELETE FROM dm_meta.{task_name}_onlineddl WHERE id = {server_id} and
    ↪ ghost_schema = {ghost_schema} and ghost_table = {ghost_table};
```

2. Execute DDL in the `_new` table:

```
ALTER TABLE `test`.`_test4_new` add column c3 int;
```

DM does not perform the DDL operation of `_test4_new`. Instead, it records this DDL in `dm_meta.{task_name}_onlineddl` and memory.

```
REPLACE INTO dm_meta.{task_name}_onlineddl (id, ghost_schema , ghost_
    ↪ table , ddls) VALUES (......);
```

3. Create 3 Triggers used for data migration:

```
CREATE TRIGGER `pt_osc_test_test4_del` AFTER DELETE ON `test`.`test4`
    ↪ ...... ;
CREATE TRIGGER `pt_osc_test_test4_upd` AFTER UPDATE ON `test`.`test4`
    ↪ ...... ;
CREATE TRIGGER `pt_osc_test_test4_ins` AFTER INSERT ON `test`.`test4`
    ↪ ...... ;
```

DM does not execute Trigger operations that are not supported in TiDB.

4. Replicate the origin table data to the `_new` table:

```
INSERT LOW_PRIORITY IGNORE INTO `test`.`_test4_new` (`id`, `date`, `
    ↪ account_id`, `conversion_price`, `ocpc_matched_conversions`, `ad_
    ↪ cost`, `cl2`, `cl1`) SELECT `id`, `date`, `account_id`, `
    ↪ conversion_price`, `ocpc_matched_conversions`, `ad_cost`, `cl2`,
    ↪ `cl1` FROM `test`.`test4` LOCK IN SHARE MODE /*pt-online-schema-
    ↪ change 3227 copy table*/
```

DM does not execute the DML statements that are not for **realtable**.

5. After the data migration is completed, the origin table and `_new` table are renamed, and the online DDL operation is completed:

```
RENAME TABLE `test`.`test4` TO `test`.`_test4_old`, `test`.`_test4_new`
    ↪  TO `test`.`test4`
```

DM performs the following two operations:

- DM splits the above `rename` operation into two SQL statements:

```
rename test.test4 to test._test4_old;
rename test._test4_new to test.test4;
```

- DM does not execute `rename to _test4_old`. When executing `rename ghost_table to origin table`, DM takes the following steps:
  - Read the DDL recorded in memory in Step 2
  - Replace `ghost_table` and `ghost_schema` with `origin_table` and its corresponding schema
  - Execute the DDL that has been replaced

```
ALTER TABLE `test`.`_test4_new` add column c3 int;
-- Replaced with:
ALTER TABLE `test`.`test4` add column c3 int;
```

6. Delete the `_old` table and 3 Triggers of the online DDL operation:

```
DROP TABLE IF EXISTS `test`.`_test4_old`;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_del` AFTER DELETE ON `test
    ↪ `.`test4` ..... ;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_upd` AFTER UPDATE ON `test
    ↪ `.`test4` ..... ;
DROP TRIGGER IF EXISTS `pt_osc_test_test4_ins` AFTER INSERT ON `test
    ↪ `.`test4` ..... ;
```

DM does not delete `_test4_old` and Triggers.

Note:

The specific SQL statements of pt-osc vary with the parameters used in the execution. This document only lists the major SQL statements. For more details, refer to the pt-osc documentation.

13.6.7.2.4 Other online schema change tools

In some cases, you might need to change the default behavior of your online schema change tool. For example, you might use customized names for `ghost table` and `trash table`. In other cases, you might want to use other tools instead of gh-ost or pt-osc, with the same working principles and change processes.

To achieve such customized needs, you need to write regular expressions to match the names of the `ghost table` and `trash table`.

Starting from v2.0.7, DM experimentally supports the modified online schema change tools. By setting `online-ddl=true` in the DM task configuration and configuring `shadow-table-rules` and `trash-table-rules`, you can match the modified temporary tables with regular expressions.

For example, if you use a customized pt-osc with the name of `ghost table` being `_{origin_table}_pcnew` and the name of `trash table` being `_{origin_table}_pcold`, you can set the custom rules as follows:

```
online-ddl: true
shadow-table-rules: ["^_(.+)_(?:pcnew)$"]
trash-table-rules: ["^_(.+)_(?:pcold)$"]
```

13.6.7.3 Migrate Data to a Downstream TiDB Table with More Columns

This document provides the additional steps to be taken when you migrate data to a downstream TiDB table with more columns than the corresponding upstream table. For regular migration steps, see the following migration scenarios:

- Migrate Small Datasets from MySQL to TiDB
- Migrate Large Datasets from MySQL to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

13.6.7.3.1 Use DM to migrate data to a downstream TiDB table with more columns

When replicating the upstream binlog, DM tries to use the current table schema of the downstream to parse the binlog and generate the corresponding DML statements. If the column number of the table in the upstream binlog does not match the column number in the downstream table schema, the following error occurs:

```
"errors": [
    {
        "ErrCode": 36027,
        "ErrClass": "sync-unit",
        "ErrScope": "internal",
        "ErrLevel": "high",
        "Message": "startLocation: [position: (mysql-bin.000001, 2022), gtid-
            ↪ set:09bec856-ba95-11ea-850a-58f2b4af5188:1-9 ], endLocation: [
            ↪  position: (mysql-bin.000001, 2022), gtid-set: 09bec856-ba95
            ↪ -11ea-850a-58f2b4af5188:1-9]: gen insert sqls failed, schema:
            ↪ log, table: messages: Column count doesn't match value count:
            ↪ 3 (columns) vs 2 (values)",
        "RawCause": "",
        "Workaround": ""
```

```
    }
]
```

The following is an example upstream table schema:

```
#### Upstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
)
```

The following is an example downstream table schema:

```
#### Downstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  `message` varchar(255) DEFAULT NULL, # This is the additional column that
    ↪ only exists in the downstream table.
  PRIMARY KEY (`id`)
)
```

When DM tries to use the downstream table schema to parse the binlog event generated by the upstream, DM reports the above `Column count doesn't match` error.

In such cases, you can use the `binlog-schema` command to set a table schema for the table to be migrated from the data source. The specified table schema needs to correspond to the binlog event data to be replicated by DM. If you are migrating sharded tables, for each sharded table, you need to set a table schema in DM to parse binlog event data. The steps are as follows:

1. Create a SQL file in DM and add the `CREATE TABLE` statement that corresponds to the upstream table schema to the file. For example, save the following table schema to `log.messages.sql`. For DM v6.0 or later versions, you can update the table schema by adding the `--from-source` or `--from-target` flag without creating a SQL file. For details, see Manage Table Schemas of Tables to be Migrated.

   ```
   # Upstream table schema
   CREATE TABLE `messages` (
   `id` int(11) NOT NULL,
   PRIMARY KEY (`id`)
   )
   ```

2. Use the `binlog-schema` command to set the table schema for the table to be migrated from the data source. At this time, the data migration task should be in the Paused state due to the above `Column count doesn't match` error.

```
tiup dmctl --master-addr ${advertise-addr} binlog-schema update -s ${
    ↪ source-id} ${task-name} ${database-name} ${table-name} ${schema-
    ↪ file}
```

The descriptions of parameters in this command are as follows:

Parameter	Description
- ↪ master ↪ - ↪ addr ↪	Specifies ${ ↪ advertise ↪ - ↪ addr ↪ } of any DM-master node in the cluster where dmctl is to be connected. ${ ↪ advertise ↪ - ↪ addr ↪ } indicates the address that DM-master advertises to the outside world.

Parameter	Description
`binlog -schema set`	Manually set the schema information.
`-s`	Specifies the source. `${source-id}` indicates the source ID of MySQL data.

Parameter	Description
`${ task - name }`	Specifies the name of the migration task defined in the `task.yaml` configuration file of the data migration task.

Parameter	Description
${ ↪ database ↪ - ↪ name ↪ } ↪	Specifies the database. ${ ↪ database ↪ - ↪ name ↪ } indicates the name of the upstream database.
${ ↪ table ↪ - ↪ name ↪ } ↪	Specifies the name of the upstream table.
${ ↪ schema ↪ - ↪ file ↪ } ↪	Specifies the table schema file to be set.

For example:

```
tiup dmctl --master-addr 172.16.10.71:8261 binlog-schema update -s
    ↪ mysql-01 task-test -d log -t message log.message.sql
```

3. Use the `resume-task` command to resume the migration task in the Paused state.

```
tiup dmctl --master-addr ${advertise-addr} resume-task ${task-name}
```

4. Use the `query-status` command to confirm that the data migration task is running correctly.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

13.6.7.4 Continuous Data Validation in DM

This document describes how to use continuous data validation in DM, its working principles, and its limitations.

13.6.7.4.1 User scenario

In the process of incrementally migrating data from the upstream database to the downstream database, there is a small probability that the flow of data leads to data corruption or data loss. For scenarios where data consistency is required, such as the credit and securities industries, after the migration is complete, you can perform full data validation to ensure data consistency.

However, in incremental migration scenarios, the upstream and downstream are continuously writing data. Because data is constantly changing in the upstream and downstream, it is difficult to perform full data validation (for example, use sync-diff-inspector) to all data in the tables.

In incremental migration scenarios, you can use the continuous data validation feature in DM. This feature ensures data integrity and consistency during incremental migration where data is continuously written into the downstream.

13.6.7.4.2 Enable continuous data validation

You can enable continuous data validation using either of the following methods:

- Enable in the task configuration file.
- Enable using dmctl.

Method 1: Enable in the task configuration file

To enable continuous data validation, add the following configuration items to the task configuration file:

```
#### Add the following configuration items to the upstream database that
   ↪ needs to be validated:
mysql-instances:
  - source-id: "mysql1"
    block-allow-list: "bw-rule-1"
    validator-config-name: "global"
validators:
  global:
```

```
mode: full # "fast" is also allowed. "none" is the default mode, which
    ↪ means no validation is performed.
worker-count: 4 # The number of validation workers in the background.
    ↪ The default value is 4.
row-error-delay: 30m # If a row cannot pass the validation within the
    ↪ specified time, it will be marked as an error row. The default
    ↪ value is 30m, which means 30 minutes.
```

The configuration items are described as follows:

- `mode`: validation mode. The possible values are `none`, `full`, and `fast`.
    - `none`: the default value, which means no validation is performed.
    - `full`: compares the changed row and the row obtained in the downstream database.
    - `fast`: only checks if the changed row exists in the downstream database.
- `worker-count`: the number of validation workers in the background. Each worker is a goroutine.
- `row-error-delay`: if a row cannot pass the validation within the specified time, it will be marked as an error row. The default value is 30 minutes.

For the complete configuration, refer to DM Advanced Task Configuration File.

Method 2: Enable using dmctl

To enable continuous data validation, run the `dmctl validation start` command:

```
Usage:
  dmctl validation start [--all-task] [task-name] [flags]

Flags:
      --all-task          whether applied to all tasks
  -h, --help              help for start
      --mode string       specify the mode of validation: full (default),
        ↪ fast; this flag will be ignored if the validation task has been
        ↪ ever enabled but currently paused (default "full")
      --start-time string specify the start time of binlog for validation, e
        ↪ .g. '2021-10-21 00:01:00' or 2021-10-21T00:01:00
```

- `--mode`: specify the validation mode. The possible values are `fast` and `full`.
- `--start-time`: specify the start time for validation. The format follows `2021-10-21 00:01:00` or `2021-10-21T00:01:00`.
- `task`: specify the name of the task to enable continuous validation for. You can use `--all-task` to enable validation for all tasks.

For example:

```
dmctl --master-addr=127.0.0.1:8261 validation start --start-time 2021-10-21
    ↪ T00:01:00 --mode full my_dm_task
```

13.6.7.4.3 Use continuous data validation

When you use continuous data validation, you can use dmctl to view the status of the validation and to handle the error rows. "Error rows" refers to the rows that are found to be inconsistent between the upstream and downstream databases.

View the validation status

You can view the validation status using either of the following methods:

Method 1: run the `dmctl query-status <task-name>` command. If continuous data validation is enabled, the validation result is displayed in the `validation` field of each subtask. Example output:

```
"subTaskStatus": [
    {
        "name": "test",
        "stage": "Running",
        "unit": "Sync",
        "result": null,
        "unresolvedDDLLockID": "",
        "sync": {
            ...
        },
        "validation": {
            "task": "test", // Task name
            "source": "mysql-01", // Source id
            "mode": "full", // Validation mode
            "stage": "Running", // Current stage. "Running" or "Stopped".
            "validatorBinlog": "(mysql-bin.000001, 5989)", // The binlog
                ↪ position of the validation
            "validatorBinlogGtid": "1642618e-cf65-11ec-9e3d-0242ac110002
                ↪ :1-30", // The GTID position of the validation
            "cutoverBinlogPos": "", // The specified binlog position for
                ↪ cutover
            "cutoverBinlogGTID": "1642618e-cf65-11ec-9e3d-0242ac110002:1-30",
                ↪  // The specified GTID position for cutover
            "result": null, // When the validation is abnormal, show the
                ↪ error message
            "processedRowsStatus": "insert/update/delete: 0/0/0", //
                ↪ Statistics of the processed binlog rows.
```

```
            "pendingRowsStatus": "insert/update/delete: 0/0/0", // Statistics
               ↪  of the binlog rows that are not validated yet or that fail
               ↪  to be validated but are not marked as "error rows"
            "errorRowsStatus": "new/ignored/resolved: 0/0/0" // Statistics of
               ↪  the error rows. The three statuses are explained in the
               ↪ next section.
        }
    }
]
```

Method 2: run the `dmctl validation status <taskname>` command.

```
dmctl validation status [--table-stage stage] <task-name> [flags]
Flags:
  -h, --help              help for status
      --table-stage string filter validation tables by stage: running/
         ↪ stopped
```

In the preceding command, you can use `--table-stage` to filter the tables that are being validated or stop validation. Example output:

```
{
    "result": true,
    "msg": "",
    "validators": [
        {
            "task": "test",
            "source": "mysql-01",
            "mode": "full",
            "stage": "Running",
            "validatorBinlog": "(mysql-bin.000001, 6571)",
            "validatorBinlogGtid": "",
            "cutoverBinlogPos": "(mysql-bin.000001, 6571)",
            "cutoverBinlogGTID": "",
            "result": null,
            "processedRowsStatus": "insert/update/delete: 2/0/0",
            "pendingRowsStatus": "insert/update/delete: 0/0/0",
            "errorRowsStatus": "new/ignored/resolved: 0/0/0"
        }
    ],
    "tableStatuses": [
        {
            "source": "mysql-01", // Source id
            "srcTable": "`db`.`test1`", // Source table name
            "dstTable": "`db`.`test1`", // Target table name
            "stage": "Running", // Validation status
```

```
            "message": "" // Error message
        }
    ]
}
```

If you want to view the details of the error rows, such as error types and error time, run the `dmctl validation show-error` command:

```
Usage:
  dmctl validation show-error [--error error-state] <task-name> [flags]

Flags:
      --error string filtering type of error: all, ignored, or unprocessed (
          ↪ default "unprocessed")
  -h, --help         help for show-error
```

Example output:

```
{
    "result": true,
    "msg": "",
    "error": [
        {
            "id": "1", // Error row id, which will be used in processing
                ↪ error rows
            "source": "mysql-replica-01", // Source id
            "srcTable": "`validator_basic`.`test`", // Source table of the
                ↪ error row
            "srcData": "[0, 0]", // Data of the error row in the source table
            "dstTable": "`validator_basic`.`test`", // Target table of the
                ↪ error row
            "dstData": "[]", // Data of the error row in the target table
            "errorType": "Expected rows not exist", // Error type
            "status": "NewErr", // Error status
            "time": "2022-07-04 13:33:02", // Discovery time of the error row
            "message": "" // Additional information
        }
    ]
}
```

Handle error rows

After continuous data validation returns error rows, you need to manually handle the error rows.

When continuous data validation finds error rows, the validation does not stop immediately. Instead, it records the error rows for you to handle. Before the error rows are

processed, the default status is `unprocessed`. If you manually correct the error rows in the downstream, the validation does not automatically retrieve the latest status of the corrected data. The error rows are still recorded in the `error` field.

If you do not want to see an error row in the validation status, or if you want to mark an error row as resolved, you can locate the error row id using the `validation show-error` command and subsequently handle it with the given error id:

dmctl provides three error handling commands:

- `clear-error`: clear the error row. The `show-error` command does not show the error row anymore.

```
Usage:
  dmctl validation clear-error <task-name> <error-id|--all> [flags]

Flags:
      --all   all errors
  -h, --help  help for clear-error
```

- `ignore-error`: ignore the error row. This error row is marked as "ignored".

```
Usage:
  dmctl validation ignore-error <task-name> <error-id|--all> [flags]

Flags:
      --all   all errors
  -h, --help  help for ignore-error
```

- `resolve-error`: the error row is manually handled and marked as "resolved".

```
Usage:
  dmctl validation resolve-error <task-name> <error-id|--all> [flags]

Flags:
      --all   all errors
  -h, --help  help for resolve-error
```

13.6.7.4.4 Stop continuous data validation

To stop the continuous data validation, run the `validation stop` command:

```
Usage:
  dmctl validation stop [--all-task] [task-name] [flags]

Flags:
      --all-task  whether applied to all tasks
  -h, --help      help for stop
```

For detailed usage, refer to `dmctl validation start`.

13.6.7.4.5 Set the cutover point for continuous data validation

Before switching the application to another database, you might need to perform continuous data validation immediately after the data is replicated to a specific position to ensure data integrity. To achieve this, you can set this specific position as the cutover point for continuous validation.

To set the cutover point for continuous data validation, use the `validation update` command:

```
Usage:
  dmctl validation update <task-name> [flags]

Flags:
      --cutover-binlog-gtid string specify the cutover binlog gtid for
         ↪ validation, only valid when source config's gtid is enabled, e.g
         ↪ . '1642618e-cf65-11ec-9e3d-0242ac110002:1-30'
      --cutover-binlog-pos string specify the cutover binlog name for
         ↪ validation, should include binlog name and pos in brackets, e.g.
         ↪  '(mysql-bin.000001, 5989)'
  -h, --help                     help for update
```

- `--cutover-binlog-gtid`: specifies the cutover position for validation, in the format of `1642618e-cf65-11ec-9e3d-0242ac110002:1-30`. Only valid when GTID is enabled in the upstream cluster.
- `--cutover-binlog-pos`: specifies the cutover position for validation, in the format of `(mysql-bin.000001, 5989)`.
- `task-name`: the name of the task for continuous data validation. This parameter is **required**.

13.6.7.4.6 Implementation

The architecture of continuous data validation (validator) in DM is as follows:

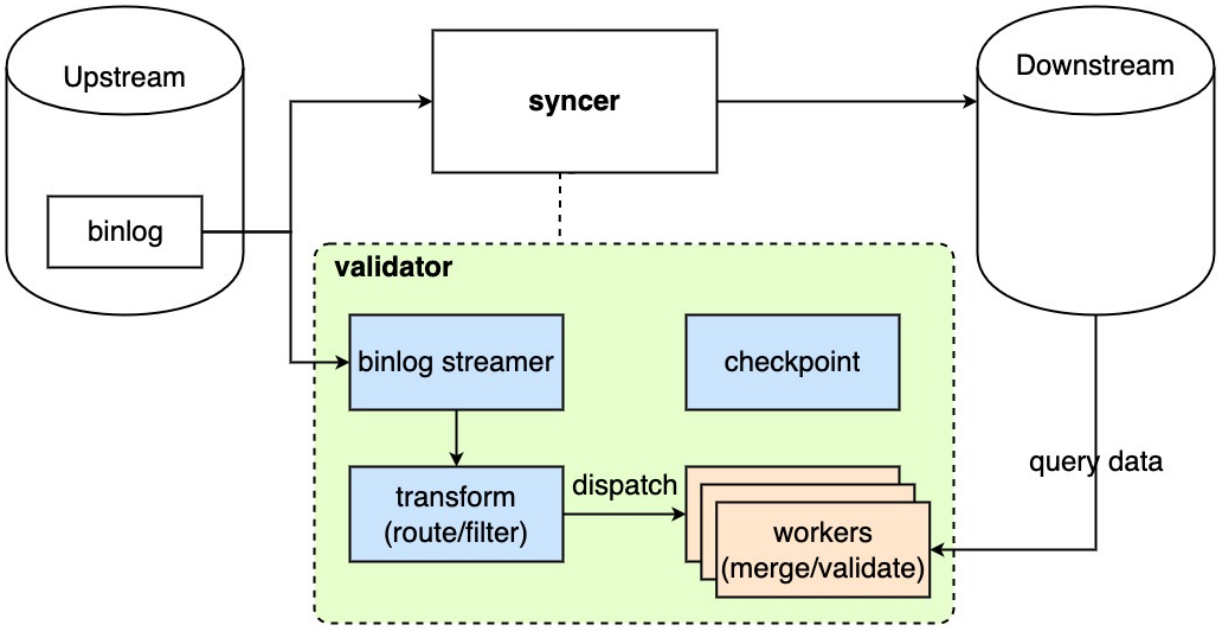

Figure 479: validator summary

The lifecycle of continuous data validation is as follows:

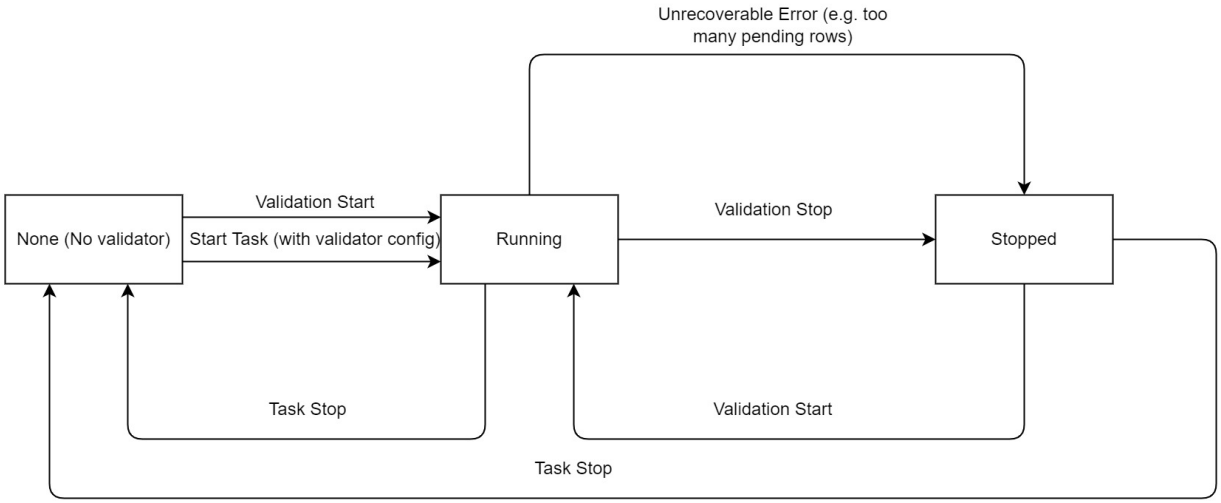

Figure 480: validator lifecycle

The detailed implementation of continuous data validation is as follows:

1. The validator pulls a binlog event from the upstream and gets the changed rows:

- The validator only checks a event that has been incrementally migrated by the syncer. If the event has not been processed by the syncer, the validator pauses and waits for the syncer to complete processing.
- If the event has been processed by the syncer, the validator moves on to the following steps.

2. The validator parses the binlog event and filters out the rows based on the block and allow lists, the table filters, and table routing. After that, the validator submits the changed rows to the validation worker that runs in the background.
3. The validation worker merges the changed rows that affect the same table and the same primary key to avoid validating "expired" data. The changed rows are cached in memory.
4. When the validation worker has accumulated a certain number of changed rows or when a certain time interval is passed, the validation worker queries the downstream database using the primary keys to get the current data and compares it with the changed rows.
5. The validation worker performs the data validation. If the validation mode is `full`, the validation worker compares data of the changed rows with data of the downstream database. if the validation mode is `fast`, the validation worker only checks the existence of the changed rows.

    - If the changed rows pass the validation, the changed row is removed from the memory.
    - If the changed rows fail the validation, the validator does not report an error immediately but waits for a certain time interval before validating the row again.
    - If a changed row cannot pass the validation within the specified time (specified by the user), the validator marks the row as an error row and writes it to the meta database in the downstream. You can view the information of error rows by querying the migration task. For details, refer to View the validation status and Handle error rows.

13.6.7.4.7 Limitations

- The source table to be validated must have a primary key or a not-null unique key.
- When DM migrates DDL from the upstream database, the following limitations apply:

    - The DDL must not change the primary key, or change the order of columns, or delete existing columns.
    - The table must not be dropped.

- Does not support tasks that use expressions to filter events.
- The precision of floating-point numbers is different between TiDB and MySQL. Differences smaller than 10^-6 are considered equal.
- Does not support the following data types:

    - JSON
    - Binary data

13.6.7.5 Cluster Upgrade

13.6.7.5.1 Maintain a DM Cluster Using TiUP

This document introduces how to maintain a DM cluster using the TiUP DM component.

If you have not deployed a DM cluster yet, you can refer to Deploy a DM Cluster Using TiUP for instructions.

> **Note:**
>
> - Make sure that the ports among the following components are interconnected
>   - The `peer_port` (`8291` by default) among the DM-master nodes are interconnected.
>   - Each DM-master node can connect to the `port` of all DM-worker nodes (`8262` by default).
>   - Each DM-worker node can connect to the `port` of all DM-master nodes (`8261` by default).
>   - The TiUP nodes can connect to the `port` of all DM-master nodes (`8261` by default).
>   - The TiUP nodes can connect to the `port` of all DM-worker nodes (`8262` by default).

For the help information of the TiUP DM component, run the following command:

```
tiup dm --help
```

```
Deploy a DM cluster for production

Usage:
  tiup dm [flags]
  tiup dm [command]

Available Commands:
  deploy     Deploy a DM cluster for production
  start      Start a DM cluster
  stop       Stop a DM cluster
  restart    Restart a DM cluster
  list       List all clusters
  destroy    Destroy a specified DM cluster
  audit      Show audit log of cluster operation
  exec       Run shell command on host in the dm cluster
```

```
  edit-config Edit DM cluster config
  display     Display information of a DM cluster
  reload      Reload a DM cluster's config and restart if needed
  upgrade     Upgrade a specified DM cluster
  patch       Replace the remote package with a specified package and restart
     ↪  the service
  scale-out   Scale out a DM cluster
  scale-in    Scale in a DM cluster
  import      Import an exist DM 1.0 cluster from dm-ansible and re-deploy
     ↪ 2.0 version
  help        Help about any command

Flags:
  -h, --help            help for tiup-dm
      --native-ssh      Use the native SSH client installed on local system
         ↪ instead of the build-in one.
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -v, --version         version for tiup-dm
      --wait-timeout int Timeout in seconds to wait for an operation to
         ↪ complete, ignored for operations that don't fit. (default 60)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup dm list
```

```
Name  User  Version Path                                       PrivateKey
----  ----  ------- ----                                       ----------
prod-cluster tidb ${version} /root/.tiup/storage/dm/clusters/test /root/.
   ↪ tiup/storage/dm/clusters/test/ssh/id_rsa
```

Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup dm start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup dm list`.

Check the cluster status

TiUP provides the `tiup dm display` command to view the status of each component in the cluster. With this command, you do not have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup dm display prod-cluster
```

```
dm Cluster: prod-cluster
dm Version: ${version}
ID                  Role        Host        Ports     OS/Arch      Status
   ↪ Data Dir                          Deploy Dir
--                  ----        ----        -----     -------      ------
   ↪ --------                          ----------
172.19.0.101:9093 alertmanager 172.19.0.101 9093/9094 linux/x86_64 Up    /
   ↪ home/tidb/data/alertmanager-9093 /home/tidb/deploy/alertmanager-9093

   ↪                                 /home/tidb/deploy/grafana-3000
172.19.0.101:9090 prometheus 172.19.0.101 9090     linux/x86_64 Up       /
   ↪ home/tidb/data/prometheus-9090 /home/tidb/deploy/prometheus-9090
```

The `Status` column uses `Up` or `Down` to indicate whether the service is running normally.

For the DM-master component, `|L` might be appended to a status, which indicates that the DM-master node is a Leader. For the DM-worker component, `Free` indicates that the current DM-worker node is not bound to an upstream.

Scale in a cluster

Scaling in a cluster means making some node(s) offline. This operation removes the specified node(s) from the cluster and deletes the remaining data files.

When you scale in a cluster, DM operations on DM-master and DM-worker components are performed in the following order:

1. Stop component processes.
2. Call the API for DM-master to delete the `member`.
3. Clean up the data files related to the node.

The basic usage of the scale-in command:

```
tiup dm scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two arguments: the cluster name and the node ID. The node ID can be obtained by using the `tiup dm display` command in the previous section.

For example, to scale in the DM-worker node on `172.16.5.140` (similar to scaling in DM-master), run the following command:

```
tiup dm scale-in prod-cluster -N 172.16.5.140:8262
```

Scale out a cluster

The scale-out operation has an inner logic similar to that of deployment: the TiUP DM component first ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

For example, to scale out a DM-worker node in the `prod-cluster` cluster, take the following steps (scaling out DM-master has similar steps):

1. Create a `scale.yaml` file and add information of the new worker node:

> **Note:**
> You need to create a topology file, which includes only the description of the new nodes, not the existing nodes. For more configuration items (such as the deployment directory), refer to this TiUP configuration parameter example.

```
---

worker_servers:
  - host: 172.16.5.140
```

2. Perform the scale-out operation. TiUP DM adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup dm scale-out prod-cluster scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup dm display prod-cluster`.

Rolling upgrade

Note:

Since v2.0.5, dmctl support Export and Import Data Sources and Task Configuration of Clusters.

Before upgrading, you can use `config export` to export the configuration files of clusters. After upgrading, if you need to downgrade to an earlier version, you can first redeploy the earlier cluster and then use `config import` to import the previous configuration files.

For clusters earlier than v2.0.5, you can use dmctl (>= v2.0.5 and < v8.0.0) to export and import the data source and task configuration files.

For clusters later than v2.0.2, currently, it is not supported to automatically import the configuration related to relay worker. You can use `start-relay` command to manually start relay log.

The rolling upgrade process is made as transparent as possible to the application, and does not affect the business. The operations vary with different nodes.

Upgrade command

You can run the `tiup dm upgrade` command to upgrade a DM cluster. For example, the following command upgrades the cluster to `${version}`. Modify `${version}` to your needed version before running this command:

Note:

Starting from v8.0.0, DM removes the fixed secret key for encryption and decryption and enables you to customize a secret key for encryption and decryption. If encrypted passwords are used in data source configurations and migration task configurations before the upgrade, you need to refer to the upgrade steps in Customize a Secret Key for DM Encryption and Decryption for additional operations.

```
tiup dm upgrade prod-cluster ${version}
```

Update configuration

If you want to dynamically update the component configurations, the TiUP DM component saves a current configuration for each cluster. To edit this configuration, execute the `tiup dm edit-config <cluster-name>` command. For example:

```
tiup dm edit-config prod-cluster
```

TiUP DM opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano` ↪ . After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup dm reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup dm patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  tiup dm patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the role
      --transfer-timeout int Timeout in seconds when transferring dm-master
          ↪ leaders (default 600)

Global Flags:
      --native-ssh      Use the native SSH client installed on local system
          ↪ instead of the build-in one.
      --ssh-timeout int  Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
      --wait-timeout int Timeout in seconds to wait for an operation to
          ↪ complete, ignored for operations that don't fit. (default 60)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

If a DM-master hotfix package is in `/tmp/dm-master-hotfix.tar.gz` and you want to replace all the DM-master packages in the cluster, run the following command:

```
tiup dm patch prod-cluster /tmp/dm-master-hotfix.tar.gz -R dm-master
```

You can also replace only one DM-master package in the cluster:

```
tiup dm patch prod-cluster /tmp/dm--hotfix.tar.gz -N 172.16.4.5:8261
```

Import and upgrade a DM 1.0 cluster deployed using DM-Ansible

Note:

- TiUP does not support importing the DM Portal component in a DM 1.0 cluster.
- You need to stop the original cluster before importing.
- Don't run `stop-task` for tasks that need to be upgraded to 2.0.
- TiUP only supports importing to a DM cluster of v2.0.0-rc.2 or a later version.
- The `import` command is used to import data from a DM 1.0 cluster to a new DM 2.0 cluster. If you need to import DM migration tasks to an existing DM 2.0 cluster, refer to Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+.
- The deployment directories of some components are different from those of the original cluster. You can execute the `display` command to view the details.
- Run `tiup update --self && tiup update dm` before importing to make sure that the TiUP DM component is the latest version.
- Only one DM-master node exists in the cluster after importing. Refer to Scale out a cluster to scale out the DM-master.

Before TiUP is released, DM-Ansible is often used to deploy DM clusters. To enable TiUP to take over the DM 1.0 cluster deployed by DM-Ansible, use the `import` command.

For example, to import a cluster deployed using DM Ansible:

```
tiup dm import --dir=/path/to/dm-ansible --cluster-version ${version}
```

Execute `tiup list dm-master` to view the latest cluster version supported by TiUP.

The process of using the `import` command is as follows:

1. TiUP generates a topology file `topology.yml` based on the DM cluster previously deployed using DM-Ansible.
2. After confirming that the topology file has been generated, you can use it to deploy the DM cluster of v2.0 or later versions.

After the deployment is completed, you can execute the `tiup dm start` command to start the cluster and begin the process of upgrading the DM kernel.

View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
  tiup dm audit [audit-id] [flags]

Flags:
  -h, --help help for audit
```

If the `[audit-id]` argument is not specified, the command shows a list of commands that have been executed. For example:

```
tiup dm audit
```

```
ID     Time                Command
--     ----                -------
4D5kQY 2020-08-13T05:38:19Z tiup dm display test
4D5kNv 2020-08-13T05:36:13Z tiup dm list
4D5kNr 2020-08-13T05:36:10Z tiup dm deploy -p prod-cluster ${version} ./
   ↪ examples/dm/minimal.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` argument as follows:

```
tiup dm audit 4D5kQY
```

Run commands on a host in the DM cluster

To run commands on a host in the DM cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
  tiup dm exec <cluster-name> [flags]

Flags:
      --command string the command run on cluster host (default "ls")
  -h, --help           help for exec
  -N, --node strings   Only exec on host with specified nodes
  -R, --role strings   Only exec on host with specified roles
      --sudo           use root permissions (default false)
```

For example, to execute `ls /tmp` on all DM nodes, run the following command:

```
tiup dm exec prod-cluster --command='ls /tmp'
```

dmctl

TiUP integrates the DM cluster controller `dmctl`.

Run the following command to use dmctl:

```
tiup dmctl [args]
```

Specify the version of dmctl. Modify `${version}` to your needed version before running this command:

```
tiup dmctl:${version} [args]
```

The previous dmctl command to add a source is `dmctl --master-addr master1:8261 operate-source create /tmp/source1.yml`. After dmctl is integrated into TiUP, the command is:

```
tiup dmctl --master-addr master1:8261 operate-source create /tmp/source1.
    ↪ yml
```

Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--native-ssh` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup dm deploy <cluster-name> <version> <topo> --native-ssh`. Fill in the name of your cluster for `<cluster-name>`, the DM version to be deployed (such as `v8.4.0`) for `<version>` , and the topology file name for `<topo>`.
- Start a cluster: `tiup dm start <cluster-name> --native-ssh`.
- Upgrade a cluster: `tiup dm upgrade ... --native-ssh`

You can add `--native-ssh` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
##### or
export TIUP_NATIVE_SSH=1
##### or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--native-ssh` at the same time, `--native-ssh` has higher priority.

> **Note:**
>
> During the process of cluster deployment, if you need to use a password for connection or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

13.6.7.5.2 Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+

This document introduces how to manually upgrade the TiDB DM tool from v1.0.x to v2.0+. The main idea is to use the global checkpoint information in v1.0.x to start a new data migration task in the v2.0+ cluster.

For how to automatically upgrade the TiDB DM tool from v1.0.x to v2.0+, refer to Using TiUP to automatically import the 1.0 cluster deployed by DM-Ansible.

> **Note:**
>
> - Currently, upgrading DM from v1.0.x to v2.0+ is not supported when the data migration task is in the process of full export or full import.
> - As the gRPC protocol used for interaction between the components of the DM cluster is updated greatly, you need to make sure that the DM components (including dmctl) use the same version before and after the upgrade.
> - Because the metadata storage of the DM cluster (such as checkpoint, shard DDL lock status, and online DDL metadata) is updated greatly, the metadata of v1.0.x cannot be reused automatically in v2.0+. So you need to make sure the following requirements are satisfied before performing the upgrade operation:
>   - All data migration tasks are not in the process of shard DDL coordination.
>   - All data migration tasks are not in the process of online DDL coordination.

The steps for manual upgrade are as follows.

Step 1: Prepare v2.0+ configuration file

The prepared configuration files of v2.0+ include the configuration files of the upstream database and the configuration files of the data migration task.

Upstream database configuration file

In v2.0+, the upstream database configuration file is separated from the process configuration of the DM-worker, so you need to obtain the source configuration based on the v1.0.x DM-worker configuration.

> **Note:**
>
> If `enable-gtid` in the source configuration is enabled during the upgrade from v1.0.x to v2.0+, you need to parse the binlog or relay log file to obtain the GTID sets corresponding to the binlog position.

Upgrade a v1.0.x cluster deployed by DM-Ansible

Assume that the v1.0.x DM cluster is deployed by DM-Ansible, and the following `dm_worker_servers` configuration is in the `inventory.ini` file:

```
[dm_master_servers]
dm_worker1 ansible_host=172.16.10.72 server_id=101 source_id="mysql-replica-01" mysql_host=172.16.10.81 mysql_user=root mysql_password='VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=' mysql_port=3306
dm_worker2 ansible_host=172.16.10.73 server_id=102 source_id="mysql-replica-02" mysql_host=172.16.10.82 mysql_user=root mysql_password='VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=' mysql_port=3306
```

Then you can convert it to the following two source configuration files:

```
##### The source configuration corresponding to the original dm_worker1. For example, it is named as source1.yaml.
server-id: 101                                # Corresponds to the original `server_id`.
source-id: "mysql-replica-01"                 # Corresponds to the original `source_id`.
from:
  host: "172.16.10.81"                        # Corresponds to the original `mysql_host`.
  port: 3306                                  # Corresponds to the original `mysql_port`.
  user: "root"                                # Corresponds to the original `mysql_user`.
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=" # Corresponds to the original `mysql_password`.
```

```
##### The source configuration corresponding to the original dm_worker2. For
    ↪  example, it is named as source2.yaml.
server-id: 102                                # Corresponds to the original `
    ↪ server_id`.
source-id: "mysql-replica-02"                 # Corresponds to the original `
    ↪ source_id`.
from:
  host: "172.16.10.82"                        # Corresponds to the original `
      ↪ mysql_host`.
  port: 3306                                  # Corresponds to the original `
      ↪ mysql_port`.
  user: "root"                                # Corresponds to the original `
      ↪ mysql_user`.
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=" # Corresponds to the original
      ↪  `mysql_password`.
```

Upgrade a v1.0.x cluster deployed by binary

Assume that the v1.0.x DM cluster is deployed by binary, and the corresponding DM-worker configuration is as follows:

```
log-level = "info"
log-file = "dm-worker.log"
worker-addr = ":8262"
server-id = 101
source-id = "mysql-replica-01"
flavor = "mysql"
[from]
host = "172.16.10.81"
user = "root"
password = "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU="
port = 3306
```

Then you can convert it to the following source configuration file:

```
server-id: 101                                # Corresponds to the original `
    ↪ server-id`.
source-id: "mysql-replica-01"                 # Corresponds to the original `
    ↪ source-id`.
flavor: "mysql"                               # Corresponds to the original `
    ↪ flavor`.
from:
  host: "172.16.10.81"                        # Corresponds to the original `
      ↪ from.host`.
  port: 3306                                  # Corresponds to the original `
      ↪ from.port`.
```

```
user: "root"                                    # Corresponds to the original `
    ↪ from.user`.
password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=" # Corresponds to the original
    ↪  `from.password`.
```

Data migration task configuration file

For data migration task configuration guide, v2.0+ is basically compatible with v1.0.x. You can directly copy the configuration of v1.0.x.

Step 2: Deploy the v2.0+ cluster

> **Note:**
>
> Skip this step if you have other v2.0+ clusters available.

Use TiUP to deploy a new v2.0+ cluster according to the required number of nodes.

Step 3: Stop the v1.0.x cluster

If the original v1.0.x cluster is deployed by DM-Ansible, you need to use DM-Ansible to stop the v1.0.x cluster.

If the original v1.0.x cluster is deployed by binary, you can stop the DM-worker and DM-master processes directly.

Step 4: Upgrade data migration task

1. Use the `operate-source` command to load the upstream database source configuration from step 1 into the v2.0+ cluster.
2. In the downstream TiDB cluster, obtain the corresponding global checkpoint information from the incremental checkpoint table of the v1.0.x data migration task.

    - Assume that the v1.0.x data migration configuration does not specify `meta-schema` (or specify its value as the default `dm_meta`), and the corresponding task name is `task_v1`, the corresponding checkpoint information is in the `dm_meta`.`task_v1_syncer_checkpoint` table of the downstream TiDB.
    - Use the following SQL statements to obtain the global checkpoint information of all upstream database sources corresponding to the data migration task.

```
> SELECT `id`, `binlog_name`, `binlog_pos` FROM `dm_meta`.`task_v1
    ↪ _syncer_checkpoint` WHERE `is_global`=1;
+-----------------+------------------------+------------+
| id              | binlog_name            | binlog_pos |
+-----------------+------------------------+------------+
```

```
| mysql-replica-01 | mysql-bin|000001.000123 | 15847 |
| mysql-replica-02 | mysql-bin|000001.000456 | 10485 |
+------------------+--------------------------+-----------+
```

3. Update the v1.0.x data migration task configuration file to start a new v2.0+ data migration task.

    - If the data migration task configuration file of v1.0.x is `task_v1.yaml`, copy it and rename it to `task_v2.yaml`.
    - Make the following changes to `task_v2.yaml`:
        - Modify `name` to a new name, such as `task_v2`.
        - Change `task-mode` to `incremental`.
        - Set the starting point of incremental replication for each source according to the global checkpoint information obtained in step 2. For example:

```
mysql-instances:
  - source-id: "mysql-replica-01"   # Corresponds to the `id`
      ↪ of the checkpoint information.
    meta:
      binlog-name: "mysql-bin.000123" # Corresponds to the `
          ↪ binlog_name` in the checkpoint information,
          ↪ excluding the part of `|000001`.
      binlog-pos: 15847             # Corresponds to `binlog_
          ↪ pos` in the checkpoint information.

  - source-id: "mysql-replica-02"
    meta:
      binlog-name: "mysql-bin.000456"
      binlog-pos: 10485
```

> **Note:**
> If `enable-gtid` is enabled in the source configuration, currently you need to parse the binlog or relay log file to obtain the GTID sets corresponding to the binlog position, and set it to `binlog-gtid` in the `meta`.

4. Use the `start-task` command to start the upgraded data migration task through the v2.0+ data migration task configuration file.

5. Use the `query-status` command to confirm whether the data migration task is running normally.

If the data migration task runs normally, it indicates that the DM upgrade to v2.0+ is successful.

13.6.7.6 Tools

13.6.7.6.1 Use WebUI to Manage DM migration tasks

DM WebUI is a web-based GUI platform for managing TiDB Data Migration (DM) tasks. This platform provides a simple and intuitive way to manage a large number of migration tasks, which frees you from using the dmctl command-line tool.

This document introduces how to access DM WebUI, the prerequisites, the use cases of each page on the interface, and the attention points.

> **Warning:**
>
> - DM WebUI is currently an experimental feature. It is not recommended to use it in the production environment.
> - The lifecycle of `task` in DM WebUI has been changed, and it is not recommended to use DM WebUI and dmctl at the same time.

DM WebUI has the following pages:

- **Migration**
  - **Task**: Provides an entry to task creation, and displays the detailed information of each migration task. This page helps you monitor, create, delete, and configure migration tasks.
  - **Source**: Configures the information of upstream data source for a migration task. On this page, you can manage the upstream configuration in a data migration environment, including creating and deleting upstream configuration, monitoring the task status corresponding to the upstream configuration, and modifying upstream configuration.
  - **Replication Detail**: Displays the detailed status information of migration tasks. On this page, you can view the detailed configuration and status information based on a specified filter, including the configuration information and database names of the upstream and downstream, the relation of source tables and target tables.
- **Cluster**
  - **Members**: Displays the list of all master and worker nodes in the DM cluster, and the binding relationship between worker nodes and the source. On this page, you can view the configuration information of the current DM cluster and the status information of each worker. In addition, basic management is also provided on this page.

The interface is as follows:

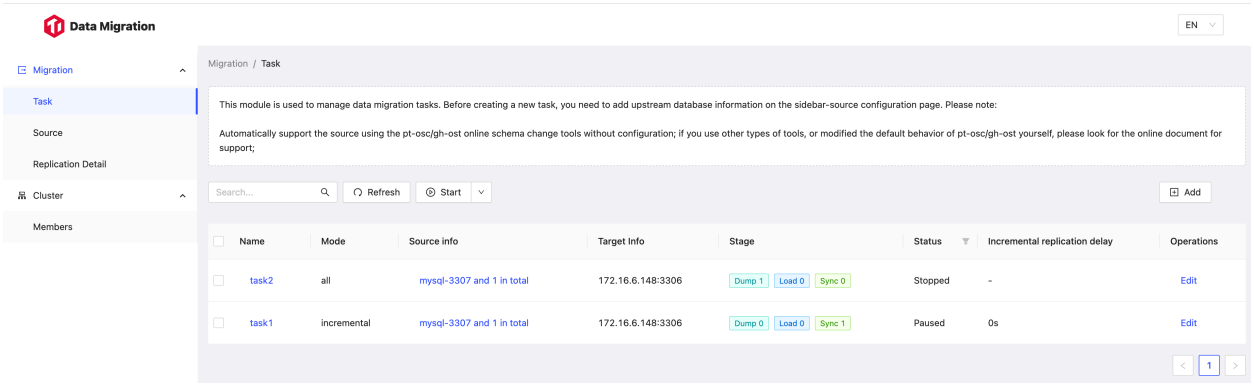

Figure 481: webui

Access method

When OpenAPI is enabled, you can access the DM WebUI from any master node of the DM cluster. The access port is `8261` by default and is the same as that of DM OpenAPI. Here is an example of an access address: `http://{master_ip}:{master_port}/dashboard/`.

Migration

Migration includes **Source**, **Task**, and **Replication Detail** pages.

Source

Before creating a migration task, you need to create the data source information of the upstream for the replication task. You can create the upstream configuration in the **Source** page. When creating sources, pay attention to the following items:

- If there is a auto failover between primary and secondary instance, enable GTID in the upstream MySQL and set GTID to `True` when creating the upstream configuration; otherwise, the migration task will be interrupted during the failover (except for AWS Aurora).
- If a MySQL instance needs to be temporarily offline, you can disable the instance. However, when the MySQL instance is being disabled, other MySQL instances running migration tasks should not execute DDL operations; otherwise, the disabled instance cannot properly migrate data after it is enabled.
- When multiple migration tasks use the same upstream, it might cause additional stress. Enabling relay log can reduce the impact on the upstream, so it is recommended to enable relay log.

Task

You can view the migration task details on the **Task** page, and create migration tasks.

View migration task details

In the task list, click the task name to view the Details page from the right. The Details page displays more detailed task status information. On this page, you can view the status of each sub-task and the current configuration information of the migration task.

In DM, each sub-task of a migration task might be at different stages, namely full dump -> full import (load) -> incremental replication (sync). Therefore, the current stage of a task is displayed with the statistics of the sub-task statuses, which can help you better understand the running status of the task.

Create migration tasks

To create a migration task on this page, click the **Add** button on the top right corner. You can use one of the following methods to create a migration task:

- By following the WebUI instruction. Fill in the required information step by step on the WebUI. This method is suitable for beginners and for daily use.
- By using a configuration file. Paste or write a JSON-formatted configuration file to create a migration task. This method supports adjusting more parameters and is suitable for advanced users.

Replication detail

You can view the status of the migration rules configured for a migration task on the **Replication Detail** page. This page supports querying by task, source, and database name.

The query result contains the corresponding information of the upstream table and the downstream table, so be careful using `.*` in case that too many query results slow down the page response.

Cluster

Members

The **Members** page displays all the master and worker nodes in the DM cluster, and the binding relationship between worker nodes and the source.

13.6.7.6.2 Maintain DM Clusters Using dmctl

> **Note:**
>
> For DM clusters deployed using TiUP, you are recommended to directly use `tiup dmctl` to maintain the clusters.

dmctl is a command line tool used to maintain DM clusters. It supports both the interactive mode and the command mode.

Interactive mode

Enter the interactive mode to interact with DM-master:

> **Note:**
>
> The interactive mode does not support Bash features. For example, you need to directly pass string flags instead of passing them in quotes.

```
./dmctl --master-addr 172.16.30.14:8261
```

```
Welcome to dmctl
Release Version: ${version}
Git Commit Hash: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
Git Branch: release-x.x

Go Version: go version gox.xx linux/amd64

» help
DM control

Usage:
  dmctl [command]

Available Commands:
  binlog        manage or show binlog operations
  binlog-schema manage or show table schema in schema tracker
  check-task    Checks the configuration file of the task
  config        manage config operations
  encrypt       Encrypts plain text to cipher text
  help          Gets help about any command
  list-member   Lists member information
  offline-member Offlines member which has been closed
  operate-leader `evict`/`cancel-evict` the leader
  operate-source `create`/`stop`/`show` upstream MySQL/MariaDB source
  pause-relay   Pauses DM-worker's relay unit
  pause-task    Pauses a specified running task or all (sub)tasks bound to a
    ↪ source
  purge-relay   Purges relay log files of the DM-worker according to the
    ↪ specified filename
  query-status  Queries task status
  resume-relay  Resumes DM-worker's relay unit
  resume-task   Resumes a specified paused task or all (sub)tasks bound to a
    ↪ source
```

```
  shard-ddl-lock maintain or show shard-ddl locks information
  start-relay   Starts workers pulling relay log for a source
  start-task    Starts a task as defined in the configuration file
  stop-relay    Stops workers pulling relay log for a source
  stop-task     Stops a specified task or all (sub)tasks bound to a source
  transfer-source Transfers a upstream MySQL/MariaDB source to a free worker

Flags:
  -h, --help          Help for dmctl.
  -s, --source strings MySQL Source ID.

Use "dmctl [command] --help" for more information about a command.
```

Command mode

The command mode differs from the interactive mode in that you need to append the task operation right after the dmctl command. The parameters of the task operation in the command mode are the same as those in the interactive mode.

Note:

- A dmctl command must be followed by only one task operation.
- Starting from v2.0.4, DM supports reading the `-master-addr` parameter from the environment variable `DM_MASTER_ADDR`.

```
./dmctl --master-addr 172.16.30.14:8261 start-task task.yaml
./dmctl --master-addr 172.16.30.14:8261 stop-task task
./dmctl --master-addr 172.16.30.14:8261 query-status

export DM_MASTER_ADDR="172.16.30.14:8261"
./dmctl query-status
```

```
Available Commands:
  binlog        manage or show binlog operations
  binlog-schema manage or show table schema in schema tracker
  check-task    Checks the configuration file of the task
  config        manage config operations
  encrypt       Encrypts plain text to cipher text
  help          Gets help about any command
  list-member   Lists member information
  offline-member Offlines member which has been closed
  operate-leader `evict`/`cancel-evict` the leader
```

```
  operate-source `create`/`stop`/`show` upstream MySQL/MariaDB source
  pause-relay   Pauses DM-worker's relay unit
  pause-task    Pauses a specified running task or all (sub)tasks bound to a
     ↪ source
  purge-relay   Purges relay log files of the DM-worker according to the
     ↪ specified filename
  query-status  Queries task status
  resume-relay  Resumes DM-worker's relay unit
  resume-task   Resumes a specified paused task or all (sub)tasks bound to a
     ↪ source
  shard-ddl-lock maintain or show shard-ddl locks information
  start-relay   Starts workers pulling relay log for a source
  start-task    Starts a task as defined in the configuration file
  stop-relay    Stops workers pulling relay log for a source
  stop-task     Stops a specified task or all (sub)tasks bound to a source
  transfer-source Transfers a upstream MySQL/MariaDB source to a free worker

Flags:
      --config string     Path to config file.
  -h, --help              help for dmctl
      --master-addr string Master API server address, this parameter is
         ↪ required when interacting with the dm-master
      --rpc-timeout string RPC timeout, default is 10m. (default "10m")
  -s, --source strings    MySQL Source ID.
      --ssl-ca string     Path of file that contains list of trusted SSL CAs
         ↪  for connection.
      --ssl-cert string   Path of file that contains X509 certificate in PEM
         ↪  format for connection.
      --ssl-key string    Path of file that contains X509 key in PEM format
         ↪ for connection.
  -V, --version           Prints version and exit.

Use "dmctl [command] --help" for more information about a command.
```

13.6.7.7 Performance Tuning

13.6.7.7.1 DM 5.4.0 Benchmark Report

The benchmark data of TiDB Data Migration (DM) v5.4.0 is nearly the same as that of DM v5.3.0. To learn the test purpose, environment, scenarios, and results of DM v5.3.0, refer to DM 5.3.0 Benchmark Report.

13.6.7.7.2 Optimize Configuration of DM

This document introduces how to optimize the configuration of the data migration task to improve the performance of data migration.

Full data export

`mydumpers` is the configuration item related to full data export. This section describes how to configure performance-related options.

`rows`

Setting the `rows` option enables concurrently exporting data from a single table using multi-thread. The value of `rows` is the maximum number of rows contained in each exported chunk. After this option is enabled, DM selects a column as the split benchmark when the data of a MySQL single table is concurrently exported. This column can be one of the following columns: the primary key column, the unique index column, and the normal index column (ordered from highest priority to lowest). Make sure this column is of integer type (for example, `INT`, `MEDIUMINT`, `BIGINT`).

The value of `rows` can be set to 10000. You can change this value according to the total number of rows in the table and the performance of the database. In addition, you need to set `threads` to control the number of concurrent threads. By default, the value of `threads` is 4. You can adjust this value as needed.

`chunk-filesize`

During full backup, DM splits the data of each table into multiple chunks according to the value of the `chunk-filesize` option. Each chunk is saved in a file with a size of about `chunk-filesize`. In this way, data is split into multiple files and you can use the parallel processing of the DM Load unit to improve the import speed. The default value of this option is 64 (in MB). Normally, you do not need to set this option. If you set it, adjust the value of this option according to the size of the full data.

Note:

- You cannot update the value of `mydumpers` after the migration task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using dmctl, update the configuration file, and re-create the task.
- `mydumpers.threads` can be replaced with the `mydumper-thread` configuration item for simplicity.
- If `rows` is set, DM ignores the value of `chunk-filesize`.

Full data import

`loaders` is the configuration item related to full data import. This section describes how to configure performance-related options.

`pool-size`

The `pool-size` option determines the number of threads in the DM Load unit. The default value is 16. Normally, you do not need to set this option. If you set it, adjust the value of this option according to the size of the full data and the performance of the database.

Note:

- You cannot update the value of `loaders` after the migration task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using dmctl, update the configuration file, and re-create the task.
- `loaders.pool-size` can be replaced with the `loader-thread` configuration item for simplicity.

Incremental data replication

`syncers` is the configuration item related to incremental data replication. This section describes how to configure performance-related options.

`worker-count`

`worker-count` determines the number of threads for concurrent replication of DMLs in the DM Sync unit. The default value is 16. To speed up data replication, increase the value of this option appropriately.

`batch`

`batch` determines the number of DMLs included in each transaction when the data is replicated to the downstream database during the DM Sync unit. The default value is 100. Normally, you do not need to change the value of this option.

Note:

- You cannot update the value of `syncers` after the replication task is created. Be sure about the value of each option before creating the task. If you need to update the value, stop the task using dmctl, update the configuration file, and re-create the task.
- `syncers.worker-count` can be replaced with the `syncer-thread` configuration item for simplicity.
- You can change the values of `worker-count` and `batch` according to the actual scenario. For example, if there is a high network delay between DM and the downstream database, you can increase the value of `worker-count` and decrease the value of `batch` appropriately.

13.6.7.7.3 DM Cluster Performance Test

This document describes how to build a test scenario to do a performance test on the DM cluster, including the speed test and latency test regarding data migration.

Migration data flow

You can use a simple migration data flow, that is, MySQL -> DM -> TiDB, to test the data migration performance of the DM cluster.

Deploy test environment

- Deploy the TiDB test cluster using TiUP, with all default configurations.
- Deploy the MySQL service. Enable the `ROW` mode for binlog, and use default configurations for other configuration items.
- Deploy a DM cluster, with a DM-worker and a DM-master.

Performance test

Table schema

Use tables with the following schema for the performance test:

```
CREATE TABLE `sbtest` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `k` int(11) NOT NULL DEFAULT '0',
  `c` char(120) CHARSET utf8mb4 COLLATE utf8mb4_bin NOT NULL DEFAULT '',
  `pad` char(60) CHARSET utf8mb4 COLLATE utf8mb4_bin NOT NULL DEFAULT '',
  PRIMARY KEY (`id`),
  KEY `k_1` (`k`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

Full import benchmark case

Generate test data

Use `sysbench` to create test tables upstream and generate test data for full import. Execute the following `sysbench` command to generate test data:

```
sysbench --test=oltp_insert --tables=4 --mysql-host=172.16.4.40 --mysql-
    ↪ port=3306 --mysql-user=root --mysql-db=dm_benchmark --db-driver=mysql
    ↪  --table-size=50000000 prepare
```

Create a data migration task

1. Create an upstream MySQL source and set `source-id` to `source-1`. For details, see Load the Data Source Configurations.
2. Create a migration task (in `full` mode). The following is a task configuration template:

“‘yaml

name: test-full
task-mode: full

Configure the migration task using the TiDB information of your actual test environment. target-database: host: “192.168.0.1” port: 4000 user: “root” password: “”

mysql-instances: - source-id: “source-1” block-allow-list: “instance” mydumper-config-name: “global” loader-thread: 16

Configure the name of the database where sysbench generates data. block-allow-list: instance: do-dbs: [“dm_benchmark”]

mydumpers: global: rows: 32000 threads: 32 “‘

For details about how to create a migration task, see Create a Data Migration Task.

Note:

- To enable concurrently exporting data from a single table using multi-thread, you can use the `rows` option in the `mydumpers` configuration item. This speeds up data export.
- To test the performance under different configurations, you can tune `loader-thread` in the `mysql-instances` configuration, as well as `rows` and `threads` in the `mydumpers` configuration item.

Get test results

Observe the DM-worker log. When you see `all data files have been finished`, it means that full data has been imported. In this case, you can see the time consumed to import data. The sample log is as follows:

```
[INFO] [loader.go:604] ["all data files have been finished"] [task=test] [
    ↪ unit=load] ["cost time"=52.439796ms]
```

According to the size of the test data and the time consumed to import data, you can calculate the migration speed of the full data.

Incremental replication benchmark case

Initialize tables

Use `sysbench` to create test tables in the upstream.

Create a data migration task

1. Create the source of the upstream MySQL. Set `source-id` to `source-1` (if the source has been created in the full import benchmark case, you do not need to create it again). For details, see Load the Data Source Configurations.

2. Create a DM migration task (in `all` mode). The following is an example of the task configuration file:

“‘yaml
name: test-all
task-mode: all

Configure the migration task using the TiDB information of your actual test environment. target-database: host: “192.168.0.1” port: 4000 user: “root” password: “”

mysql-instances: - source-id: “source-1” block-allow-list: “instance” syncer-config-name: “global”

Configure the name of the database where sysbench generates data. block-allow-list: instance: do-dbs: [“dm_benchmark”]

syncers: global: worker-count: 16 batch: 100 “‘

For details about how to create a data migration task, see Create a Data Migration Task.

> **Note:**
>
> To test the performance under different configurations, you can tune `worker-count` and `batch` in the `syncers` configuration item.

Generate incremental data

To continuously generate incremental data in the upstream, run the `sysbench` command:

```
sysbench --test=oltp_insert --tables=4 --num-threads=32 --mysql-host
    ↪ =172.17.4.40 --mysql-port=3306 --mysql-user=root --mysql-db=dm_
    ↪ benchmark --db-driver=mysql --report-interval=10 --time=1800 run
```

> **Note:**
>
> You can test the data migration performance under different scenarios by using different `sysbench` statements.

Get test results

To observe the migration status of DM, you can run the `query-status` command. To observe the monitoring metrics of DM, you can use Grafana. Here the monitoring metrics refer to `finished sqls jobs` (the number of jobs finished per unit time), and other related metrics. For more information, see Binlog Migration Monitoring Metrics.

13.6.7.7.4 Handle Performance Issues of TiDB Data Migration

This document introduces common performance issues that might exist in DM and how to deal with them.

Before diagnosing an issue, you can refer to the DM Benchmark Report.

When diagnosing and handling performance issues, make sure that:

- The DM monitoring component is correctly configured and installed.
- You can view monitoring metrics on the Grafana monitoring dashboard.
- The component you diagnose works well; otherwise, possible monitoring metrics exceptions might interfere with the diagnosis of performance issues.

In the case of a large latency in the data migration, to quickly figure out whether the bottleneck is inside the DM component or in the TiDB cluster, you can first check `DML queue remain length` in Write SQL Statements to Downstream.

relay log unit

To diagnose performance issues in the relay log unit, you can check the `binlog file gap between master and relay` monitoring metric. For more information about this metric, refer to monitoring metrics of the relay log. If this metric is greater than 1 for a long time, it usually indicates that there is a performance issue; if this metric is 0, it usually indicates that there is no performance issue.

If the value of `binlog file gap between master and relay` is 0, but you suspect that there is a performance issue, you can check `binlog pos`. If `master` in this metric is much larger than `relay`, a performance issue might exist. In this case, diagnose and handle this issue accordingly.

Read binlog data

`read binlog event duration` refers to the duration that the relay log reads binlog from the upstream database (MySQL/MariaDB). Ideally, this metric is close to the network latency between DM-worker and MySQL/MariaDB instances.

- For data migration in one data center, reading binlog data is not a performance bottleneck. If the value of `read binlog event duration` is too large, check the network connection between DM-worker and MySQL/MariaDB.

- For data migration in the geo-distributed environment, try to deploy DM-worker and MySQL/MariaDB in one data center, while deploying the TiDB cluster in the target data center.

The process of reading binlog data from the upstream database includes the following sub-processes:

- The upstream MySQL/MariaDB reads the binlog data locally and sends it through the network. When no exception occurs in the MySQL/MariaDB load, this sub-process usually does not become a bottleneck.
- The binlog data is transferred from the machine where MySQL/MariaDB is located to the machine where DM-worker is located via the network. Whether this sub-process becomes a bottleneck mainly depends on the network connection between DM-worker and the upstream MySQL/MariaDB.
- DM-worker reads binlog data from the network data stream and constructs it as a binlog event. When no exception occurs in the DM-worker load, this sub-process usually does not become a bottleneck.

> **Note:**
>
> If the value of `read binlog event duration` is large, another possible reason is that the upstream MySQL/MariaDB has a low load. This means that no binlog event needs to be sent to DM for a period of time, and the relay log unit stays in a wait state, thus this value includes additional waiting time.

binlog data decoding and verification

After reading the binlog event into the DM memory, DM's relay processing unit decodes and verifies data. This usually does not lead to performance bottleneck; therefore, there is no related performance metric on the monitoring dashboard by default. If you need to view this metric, you can manually add a monitoring item in Grafana. This monitoring item corresponds to `dm_relay_read_transform_duration`, a metric from Prometheus.

Write relay log files

When writing a binlog event to a relay log file, the relevant performance metric is `write relay log duration`. This value should be microseconds when `binlog event size` is not too large. If `write relay log duration` is too large, check the write performance of the disk. To avoid low write performance, use local SSDs for DM-worker.

Load unit

The main operations of the Load unit are to read the SQL file data from the local and write it to the downstream. The related performance metric is `transaction execution latency`. If this value is too large, check the downstream performance by checking the

monitoring of the downstream database. You can also check whether there is a large network latency between DM and the downstream database.

Binlog replication unit

To diagnose performance issues in the Binlog replication unit, you can check the `binlog file gap between master and syncer` monitoring metric. For more information about this metric, refer to monitoring metrics of the Binlog replication.

- If this metric is greater than 1 for a long time, it usually indicates that there is a performance issue.
- If this metric is 0, it usually indicates that there is no performance issue.

When `binlog file gap between master and syncer` is greater than 1 for a long time, check `binlog file gap between relay and syncer` to figure out which unit the latency mainly exists in. If this value is usually 0, the latency might exist in the relay log unit. Then you can refer to relay log unit to resolve this issue; otherwise, continue checking the Binlog replication unit.

Read binlog data

The Binlog replication unit decides whether to read the binlog event from the upstream MySQL/MariaDB or from the relay log file according to the configuration. The related performance metric is `read binlog event duration`, which generally ranges from a few microseconds to tens of microseconds.

- If DM's Binlog replication processing unit reads the binlog event from upstream MySQL/MariaDB, to locate and resolve the issue, refer to read binlog data in the "relay log unit" section.
- If DM's Binlog replication processing unit reads the binlog event from the relay log file, when `binlog event size` is not too large, the value of `read binlog event duration` ↪ should be microseconds. If `read binlog event duration` is too large, check the read performance of the disk. To avoid low write performance, use local SSDs for DM-worker.

binlog event conversion

The Binlog replication unit constructs DML, parses DDL, and performs table router conversion from binlog event data. The related metric is `transform binlog event duration`.

The duration is mainly affected by the write operations upstream. Take the `INSERT` ↪ `INTO` statement as an example, the time consumed to convert a single `VALUES` greatly differs from that to convert a lot of `VALUES`. The time consumed might range from tens of microseconds to hundreds of microseconds. However, usually this is not a bottleneck of the system.

Write SQL statements to downstream

When the Binlog replication unit writes the converted SQL statements to the downstream, the related performance metrics are `DML queue remain length` and `transaction execution latency`.

After constructing SQL statements from binlog event, DM uses `worker-count` queues to concurrently write these statements to the downstream. However, to avoid too many monitoring entries, DM performs the modulo `8` operation on the IDs of concurrent queues. This means that all concurrent queues correspond to one item from `q_0` to `q_7`.

`DML queue remain length` indicates in the concurrent processing queue, the number of DML statements that have not been consumed and have not started to be written downstream. Ideally, the curves corresponding to each `q_*` are almost the same. If not, it indicates that the concurrent load is extremely unbalanced.

If the load is not balanced, confirm whether tables need to be migrated have primary keys or unique keys. If these keys do not exist, add the primary keys or the unique keys; if these keys do exist while the load is not balanced, upgrade DM to v1.0.5 or later versions.

- When there is no noticeable latency in the entire data migration link, the corresponding curve of `DML queue remain length` is almost always 0, and the maximum does not exceed the value of `batch` in the task configuration file.
- If you find a noticeable latency in the data migration link, and the curve of `DML queue remain length` corresponding to each `q_*` is almost the same and is almost always 0, it means that DM fails to read, convert, or concurrently write the data from the upstream in time (the bottleneck might be in the relay log unit). For troubleshooting, refer to the previous sections of this document.

If the corresponding curve of `DML queue remain length` is not 0 (usually the maximum is not more than 1024), it indicates that there is a bottleneck when writing SQL statements to the downstream. You can use `transaction execution latency` to view the time consumed to execute a single transaction to the downstream.

`transaction execution latency` is usually tens of milliseconds. If this value is too large, check the downstream performance based on the monitoring of the downstream database. You can also check whether there is a large network latency between DM and the downstream database.

To view the time consumed to write a single statement such as `BEGIN`, `INSERT`, `UPDATE`, `DELETE`, or `COMMIT` to the downstream, you can also check `statement execution latency`.

13.6.7.8 Manage Data Sources

13.6.7.8.1 Switch DM-worker Connection between Upstream MySQL Instances

When the upstream MySQL instance that DM-worker connects to needs downtime maintenance or when the instance crashes unexpectedly, you need to switch the DM-worker connection to another MySQL instance within the same migration group.

Note:

- You can switch the DM-worker connection to only an instance within the same primary-secondary migration cluster.
- The MySQL instance to be newly connected to must have the binlog required by DM-worker.
- DM-worker must operate in the GTID sets mode, which means you must specify `enable-gtid: true` in the corresponding source configuration file.
- The connection switch only supports the following two scenarios. Strictly follow the procedures for each scenario. Otherwise, you might have to re-deploy the DM cluster according to the newly connected MySQL instance and perform the data migration task all over again.

For more details on GTID set, refer to MySQL documentation.

Switch DM-worker connection via virtual IP

When DM-worker connects the upstream MySQL instance via a virtual IP (VIP), switching the VIP connection to another MySQL instance means switching the MySQL instance connected to DM-worker, without the upstream connection address changed.

Note:

Make necessary changes to DM in this scenario. Otherwise, when you switch the VIP connection to another MySQL instance, DM might connect to the new and old MySQL instances at the same time in different connections. In this situation, the binlog replicated to DM is not consistent with other upstream status that DM receives, causing unpredictable anomalies and even data damage.

To switch one upstream MySQL instance (when DM-worker connects to it via a VIP) to another, perform the following steps:

1. Use the `query-status` command to get the GTID sets (`syncerBinlogGtid`) corresponding to the binlog that the current processing unit of binlog replication has replicated to the downstream. Mark the sets as `gtid-S`.
2. Use the `SELECT @@GLOBAL.gtid_purged;` command on the new MySQL instance to get the GTID sets corresponding to the purged binlogs. Mark the sets as `gtid-P`.

3. Use the `SELECT @@GLOBAL.gtid_executed;` command on the new MySQL instance to get the GTID sets corresponding to all successfully executed transactions. Mark the sets as `gtid-E`.
4. Make sure that the following conditions are met. Otherwise, you cannot switch the DM-work connection to the new MySQL instance:

    - `gtid-S` contains `gtid-P`. `gtid-P` can be empty.
    - `gtid-E` contains `gtid-S`.

5. Use `pause-task` to pause all running tasks of data migration.
6. Change the VIP for it to direct at the new MySQL instance.
7. Use `resume-task` to resume the previous migration task.

Change the address of the upstream MySQL instance that DM-worker connects to

To make DM-worker connect to a new MySQL instance in the upstream by modifying the DM-worker configuration, perform the following steps:

1. Use the `query-status` command to get the GTID sets (`syncerBinlogGtid`) corresponding to the binlog that the current processing unit of binlog replication has replicated to the downstream. Mark this sets as `gtid-S`.
2. Use the `SELECT @@GLOBAL.gtid_purged;` command on the new MySQL instance to get the GTID sets corresponding to the purged binlogs. Mark this sets as `gtid-P`.
3. Use the `SELECT @@GLOBAL.gtid_executed;` command on the new MySQL instance to get the GTID sets corresponding to all successfully executed transactions. Mark this sets as `gtid-E`.
4. Make sure that the following conditions are met. Otherwise, you cannot switch the DM-work connection to the new MySQL instance:

    - `gtid-S` contains `gtid-P`. `gtid-P` can be empty.
    - `gtid-E` contains `gtid-S`.

5. Use `stop-task` to stop all running tasks of data migration.
6. Use the `operator-source stop` command to remove the source configuration corresponding to the address of the old MySQL instance from the DM cluster.
7. Update the address of the MySQL instance in the source configuration file and use the `operate-source create` command to reload the new source configuration in the DM cluster.
8. Use `start-task` to restart the migration task.

13.6.7.9 Manage Tasks

13.6.7.9.1 Handle Failed DDL Statements in TiDB Data Migration

This document introduces how to handle failed DDL statements when you're using the TiDB Data Migration (DM) tool to migrate data.

Currently, TiDB is not completely compatible with all MySQL syntax (see the DDL statements supported by TiDB). Therefore, when DM is migrating data from MySQL to TiDB and TiDB does not support the corresponding DDL statement, an error might occur and break the migration process. In this case, you can use the `binlog` command of DM to resume the migration.

Restrictions

Do not use this command in the following situations:

- It is unacceptable in the actual production environment that the failed DDL statement is skipped in the downstream TiDB.
- The failed DDL statement cannot be replaced with other DDL statements.
- Other DDL statements must not be injected into the downstream TiDB.

For example, `DROP PRIMARY KEY`. In this scenario, you can only create a new table in the downstream with the new table schema (after executing the DDL statement), and re-import all the data into this new table.

Supported scenarios

During the migration, the DDL statement unsupported by TiDB is executed in the upstream and migrated to the downstream, and as a result, the migration task gets interrupted.

- If it is acceptable that this DDL statement is skipped in the downstream TiDB, then you can use `binlog skip <task-name>` to skip migrating this DDL statement and resume the migration.
- If it is acceptable that this DDL statement is replaced with other DDL statements, then you can use `binlog replace <task-name>` to replace this DDL statement and resume the migration.
- If it is acceptable that other DDL statements are injected to the downstream TiDB, then you can use `binlog inject <task-name>` to inject other DDL statements and resume the migration.

Commands

When you use dmctl to manually handle the failed DDL statements, the commonly used commands include `query-status` and `binlog`.

query-status

The `query-status` command is used to query the current status of items such as the subtask and the relay unit in each MySQL instance. For details, see query status.

binlog

The `binlog` command is used to manage and show binlog operations. This command is only supported in DM v6.0 and later versions. For earlier versions, use the `handle-error` command.

The usage of `binlog` is as follows:

```
binlog -h
```

```
manage or show binlog operations

Usage:
  dmctl binlog [command]

Available Commands:
  inject    inject the current error event or a specific binlog position (
    ↪ binlog-pos) with some ddls
  list      list error handle command at binlog position (binlog-pos) or
    ↪ after binlog position (binlog-pos)
  replace   replace the current error event or a specific binlog position (
    ↪ binlog-pos) with some ddls
  revert    revert the current binlog operation or a specific binlog
    ↪ position (binlog-pos) operation
  skip      skip the current error event or a specific binlog position (
    ↪ binlog-pos) event

Flags:
  -b, --binlog-pos string position used to match binlog event if matched the
    ↪  binlog operation will be applied. The format like "mysql-bin
    ↪ |000001.000003:3270"
  -h, --help            help for binlog

Global Flags:
  -s, --source strings MySQL Source ID.

Use "dmctl binlog [command] --help" for more information about a command.
```

`binlog` supports the following sub-commands:

- `inject`: injects DDL statements into the current error event or a specific binlog position. To specify the binlog position, refer to `-b, --binlog-pos`.
- `list`: lists all valid `inject`, `skip`, and `replace` operations at the current binlog position or after the current binlog position. To specify the binlog position, refer to `-b, --binlog-pos`.
- `replace`: replaces the DDL statement at a specific binlog position with another DDL statement. To specify the binlog position, refer to `-b, --binlog-pos`.
- `revert`: reverts the `inject`, `skip` or `replace` operation at a specified binlog operation, only if the previous operation does not take effect. To specify the binlog position, refer to `-b, --binlog-pos`.
- `skip`: skips the DDL statement at a specific binlog position. To specify the binlog position, refer to `-b, --binlog-pos`.

`binlog` supports the following flags:

- `-b, --binlog-pos`:
  - Type: string.
  - Specifies a binlog position. When the position of the binlog event matches `binlog -pos`, the operation is executed. If it is not specified, DM automatically sets `binlog-pos` to the currently failed DDL statement.
  - Format: `binlog-filename:binlog-pos`, for example, `mysql-bin|000001.000003:3270`.
  - After the migration returns an error, the binlog position can be obtained from `position` in `startLocation` returned by `query-status`. Before the migration returns an error, the binlog position can be obtained by using `SHOW BINLOG EVENTS` in the upstream MySQL instance.
- `-s, --source`:
  - Type: string.
  - Specifies the MySQL instance in which the preset operation is to be executed.

Usage examples

Skip DDL if the migration gets interrupted

If you need to skip the DDL statement when the migration gets interrupted, run the `binlog skip` command:

```
binlog skip -h
```

```
skip the current error event or a specific binlog position (binlog-pos)
   ↪ event

Usage:
  dmctl binlog skip <task-name> [flags]

Flags:
  -h, --help help for skip

Global Flags:
  -b, --binlog-pos string position used to match binlog event if matched the
     ↪  binlog operation will be applied. The format like "mysql-bin
     ↪ |000001.000003:3270"
  -s, --source strings   MySQL Source ID.
```

Non-shard-merge scenario

Assume that you need to migrate the upstream table `db1.tbl1` to the downstream TiDB. The initial table schema is:

```
SHOW CREATE TABLE db1.tbl1;
```

```
+-------+-----------------------------------------------+
| Table | Create Table                                  |
+-------+-----------------------------------------------+
| tbl1 | CREATE TABLE `tbl1` (
  `c1` int(11) NOT NULL,
  `c2` decimal(11,3) DEFAULT NULL,
  PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-------+-----------------------------------------------+
```

Now, the following DDL statement is executed in the upstream to alter the table schema (namely, alter DECIMAL(11, 3) of c2 into DECIMAL(10, 3)):

```
ALTER TABLE db1.tbl1 CHANGE c2 c2 DECIMAL (10, 3);
```

Because this DDL statement is not supported by TiDB, the migration task of DM gets interrupted. Execute the `query-status <task-name>` command, and you can see the following error:

```
ERROR 8200 (HY000): Unsupported modify column: can't change decimal column
    ↪ precision
```

Assume that it is acceptable in the actual production environment that this DDL statement is not executed in the downstream TiDB (namely, the original table schema is retained). Then you can use `binlog skip <task-name>` to skip this DDL statement to resume the migration. The procedures are as follows:

1. Execute `binlog skip <task-name>` to skip the currently failed DDL statement:

```
» binlog skip test
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

2. Execute `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
```

```
            ]
        }
    ]
}
```

You can see that the task runs normally and the wrong DDL is skipped.

Shard merge scenario

Assume that you need to merge and migrate the following four tables in the upstream to one same table `shard_db`.`shard_table` in the downstream. The task mode is "pessimistic".

- MySQL instance 1 contains the shard_db_1 schema, which includes the shard_table_1 and shard_table_2 tables.
- MySQL instance 2 contains the shard_db_2 schema, which includes the shard_table_1 and shard_table_2 tables.

The initial table schema is:

```
SHOW CREATE TABLE shard_db.shard_table;
```

```
+--
    ↪ -----+-----------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-----------------------------------------------------------------
    ↪
| tb    | CREATE TABLE `shard_table` (
  `id` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
    ↪ -----+-----------------------------------------------------------------
    ↪
```

Now, execute the following DDL statement to all upstream sharded tables to alter their character set:

```
ALTER TABLE `shard_db_*`.`shard_table_*` CHARACTER SET LATIN1 COLLATE
    ↪ LATIN1_DANISH_CI;
```

Because this DDL statement is not supported by TiDB, the migration task of DM gets interrupted. Execute the `query-status` command, and you can see the following errors reported by the `shard_db_1.shard_table_1` table in MySQL instance 1 and the `shard_db_2.shard_table_1` table in MySQL instance 2:

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_1`
        ↪ CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_1`
        ↪ CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

Assume that it is acceptable in the actual production environment that this DDL statement is not executed in the downstream TiDB (namely, the original table schema is retained). Then you can use `binlog skip <task-name>` to skip this DDL statement to resume the migration. The procedures are as follows:

1. Execute `binlog skip <task-name>` to skip the currently failed DDL statements in MySQL instance 1 and 2:

    ```
    » binlog skip test
    ```

    ```
    {
        "result": true,
        "msg": "",
        "sources": [
            {
                "result": true,
                "msg": "",
                "source": "mysql-replica-01",
                "worker": "worker1"
            },
            {
                "result": true,
                "msg": "",
                "source": "mysql-replica-02",
                "worker": "worker2"
            }
        ]
    }
    ```

2. Execute the `query-status` command, and you can see the errors reported by the `shard_db_1.shard_table_2` table in MySQL instance 1 and the `shard_db_2.shard_table_2` table in MySQL instance 2:

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_2` CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_2` CHARACTER SET UTF8 COLLATE UTF8_UNICODE_CI",
    "RawCause": "[ddl:8200]Unsupported modify charset from latin1 to utf8"
}
```

3. Execute `binlog skip <task-name>` again to skip the currently failed DDL statements in MySQL instance 1 and 2:

```
» handle-error test skip
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

4. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",

                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
            ]
        },
        {
```

```
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-02",
                "worker": "worker2",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
            ]
        }
    ]
}
```

You can see that the task runs normally with no error and all four wrong DDL statements are skipped.

Replace DDL if the migration gets interrupted

If you need to replace the DDL statement when the migration gets interrupted, run the `binlog replace` command:

```
binlog replace -h
```

```
replace the current error event or a specific binlog position (binlog-pos)
    ↪ with some ddls

Usage:
  dmctl binlog replace <task-name> <replace-sql1> <replace-sql2>... [flags]

Flags:
  -h, --help help for replace

Global Flags:
  -b, --binlog-pos string position used to match binlog event if matched the
     ↪  binlog operation will be applied. The format like "mysql-bin
     ↪ |000001.000003:3270"
  -s, --source strings   MySQL Source ID.
```

Non-shard-merge scenario

Assume that you need to migrate the upstream table `db1.tbl1` to the downstream TiDB. The initial table schema is:

```
SHOW CREATE TABLE db1.tbl1;
```

```
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| tb    | CREATE TABLE `tbl1` (
  `id` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
```

Now, perform the following DDL operation in the upstream to add a new column with the UNIQUE constraint:

```
ALTER TABLE `db1`.`tbl1` ADD COLUMN new_col INT UNIQUE;
```

Because this DDL statement is not supported by TiDB, the migration task gets interrupted. Execute the `query-status` command, and you can see the following error:

```
{
    "Message": "cannot track DDL: ALTER TABLE `db1`.`tbl1` ADD COLUMN `new_
        ↪ col` INT UNIQUE KEY",
    "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
        ↪ UNIQUE KEY when altering 'db1.tbl1'",
}
```

You can replace this DDL statement with two equivalent DDL statements. The steps are as follows:

1. Replace the wrong DDL statement by the following command:

```
» binlog replace test "ALTER TABLE `db1`.`tbl1` ADD COLUMN `new_col`
    ↪ INT;ALTER TABLE `db1`.`tbl1` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

2. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
```

```
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
                        ],
                        "unresolvedGroups": [
                        ],
                        "synced": true,
                        "binlogType": "remote",
                        "totalRows": "4",
                        "totalRps": "0",
                        "recentRps": "0"
                    }
                }
            ]
        }
    ]
}
```

You can see that the task runs normally and the wrong DDL statement is replaced by new DDL statements that execute successfully.

Shard merge scenario

Assume that you need to merge and migrate the following four tables in the upstream to one same table `` `shard_db`.`shard_table` `` in the downstream. The task mode is "pessimistic".

- In the MySQL instance 1, there is a schema `shard_db_1`, which has two tables `shard_table_1` and `shard_table_2`.
- In the MySQL instance 2, there is a schema `shard_db_2`, which has two tables `shard_table_1` and `shard_table_2`.

The initial table schema is:

```
SHOW CREATE TABLE shard_db.shard_table;
```

```
+--
    ↪ -----+-----------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-----------------------------------------------------------------------
    ↪
| tb    | CREATE TABLE `shard_table` (
  `id` int(11) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin |
+--
    ↪ -----+-----------------------------------------------------------------------
    ↪
```

Now, perform the following DDL operation to all upstream sharded tables to add a new column with the UNIQUE constraint:

```
ALTER TABLE `shard_db_*`.`shard_table_*` ADD COLUMN new_col INT UNIQUE;
```

Because this DDL statement is not supported by TiDB, the migration task gets interrupted. Execute the `query-status` command, and you can see the following errors reported by the `shard_db_1.shard_table_1` table in MySQL instance 1 and the `shard_db_2.shard_table_1` table in MySQL instance 2:

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_1`.`shard_table_1`
        ↪ ADD COLUMN `new_col` INT UNIQUE KEY",
    "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
        ↪ UNIQUE KEY when altering 'shard_db_1.shard_table_1'",
}
```

```
{
    "Message": "cannot track DDL: ALTER TABLE `shard_db_2`.`shard_table_1`
        ↪ ADD COLUMN `new_col` INT UNIQUE KEY",
```

```
    "RawCause": "[ddl:8200]unsupported add column 'new_col' constraint
       ↪ UNIQUE KEY when altering 'shard_db_2.shard_table_1'",
}
```

You can replace this DDL statement with two equivalent DDL statements. The steps are as follows:

1. Replace the wrong DDL statements respectively in MySQL instance 1 and MySQL instance 2 by the following commands:

```
» binlog replace test -s mysql-replica-01 "ALTER TABLE `shard_db_1`.`
   ↪ shard_table_1` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_
   ↪ 1`.`shard_table_1` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

```
» binlog replace test -s mysql-replica-02 "ALTER TABLE `shard_db_2`.`
   ↪ shard_table_1` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_
   ↪ 2`.`shard_table_1` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

2. Use `query-status <task-name>` to view the task status, and you can see the following errors reported by the `shard_db_1.shard_table_2` table in MySQL instance 1 and the `shard_db_2.shard_table_2` table in MySQL instance 2:

```
{
    "Message": "detect inconsistent DDL sequence from source ... ddls:
        ↪ [ALTER TABLE `shard_db`.`tb` ADD COLUMN `new_col` INT UNIQUE
        ↪ KEY] source: `shard_db_1`.`shard_table_2`], right DDL
        ↪ sequence should be ..."
}
```

```
{
    "Message": "detect inconsistent DDL sequence from source ... ddls:
        ↪ [ALTER TABLE `shard_db`.`tb` ADD COLUMN `new_col` INT UNIQUE
        ↪ KEY] source: `shard_db_2`.`shard_table_2`], right DDL
        ↪ sequence should be ..."
}
```

3. Execute `handle-error <task-name> replace` again to replace the wrong DDL statements in MySQL instance 1 and 2:

```
» binlog replace test -s mysql-replica-01 "ALTER TABLE `shard_db_1`.`
    ↪ shard_table_2` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_
    ↪ 1`.`shard_table_2` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

```
» binlog replace test -s mysql-replica-02 "ALTER TABLE `shard_db_2`.`
    ↪ shard_table_2` ADD COLUMN `new_col` INT;ALTER TABLE `shard_db_
    ↪ 2`.`shard_table_2` ADD UNIQUE(`new_col`)";
```

```
{
    "result": true,
    "msg": "",
```

```
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

4. Use `query-status <task-name>` to view the task status:

```
» query-status test
```

See the execution result.

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "sourceStatus": {
                "source": "mysql-replica-01",
                "worker": "worker1",
                "result": null,
                "relayStatus": null
            },
            "subTaskStatus": [
                {
                    "name": "test",
                    "stage": "Running",
                    "unit": "Sync",
                    "result": null,
                    "unresolvedDDLLockID": "",
                    "sync": {
                        "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-10",
                        "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                            ↪ 2388)",
                        "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                            ↪ de45f57:1-4",
                        "blockingDDLs": [
```

```
                ],
                "unresolvedGroups": [
                ],
                "unresolvedGroups": [
                ],
                "synced": true,
                "binlogType": "remote",
                "totalRows": "4",
                "totalRps": "0",
                "recentRps": "0"
            }
        }
    ]
},
{
    "result": true,
    "msg": "",
    "sourceStatus": {
        "source": "mysql-replica-02",
        "worker": "worker2",
        "result": null,
        "relayStatus": null
    },
    "subTaskStatus": [
        {
            "name": "test",
            "stage": "Running",
            "unit": "Sync",
            "result": null,
            "unresolvedDDLLockID": "",
            "sync": {
                "masterBinlog": "(DESKTOP-T561TSO-bin.000001,
                    ↪ 2388)",
                "masterBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                    ↪ de45f57:1-10",
                "syncerBinlog": "(DESKTOP-T561TSO-bin.000001,
                    ↪ 2388)",
                "syncerBinlogGtid": "143bdef3-dd4a-11ea-8b00-00155
                    ↪ de45f57:1-4",
                "blockingDDLs": [
                ],
                "unresolvedGroups": [
                ],
                "unresolvedGroups": [
                ],
```

```
                    "synced": try,
                    "binlogType": "remote",
                    "totalRows": "4",
                    "totalRps": "0",
                    "recentRps": "0"
                }
            }
        ]
    }
]
}
```

You can see that the task runs normally with no error and all four wrong DDL statements are replaced.

Other commands

For the usage of other commands of `binlog`, refer to the `binlog skip` and `binlog replace` examples above.

13.6.7.9.2 Manage Table Schemas of Tables to Be Migrated Using TiDB Data Migration

This document describes how to manage the schema of the table in DM during migration using dmctl.

When DM performs incremental replication, it first reads the upstream binlog, then creates SQL statements and executes them in the downstream. However, the upstream binlog does not contain the complete table schema. To generate the SQL statements, DM maintains internally the schema information of the table to be migrated. This is called the internal table schema.

To deal with some special occasions, or to handle migration interruptions caused by mismatch of the table schemas, DM provides the `binlog-schema` command to obtain, modify, and delete the internal table schema.

Implementation principles

The internal table schema comes from the following sources:

- For full data migration (`task-mode=all`), the migration task goes through three stages: dump/load/sync, which means full export, full import, and incremental replication. In the dump stage, DM exports the table schema information along with the data and automatically creates the corresponding table in the downstream. In the sync stage, this table schema is used as the starting table scheme for incremental replication.
- In the sync stage, when DM handles DDL statements such as `ALTER TABLE`, it updates the internal table schema at the same time.

- If the task is an incremental migration (`task-mode=incremental`), in which the downstream has completed creating the table to be migrated, DM obtains the table schema information from the downstream database. This behavior varies with DM versions.

For incremental replication, schema maintenance is complicated. During the whole data replication, the following four table schemas are involved. These schemas might be the consistent or inconsistent with one another:

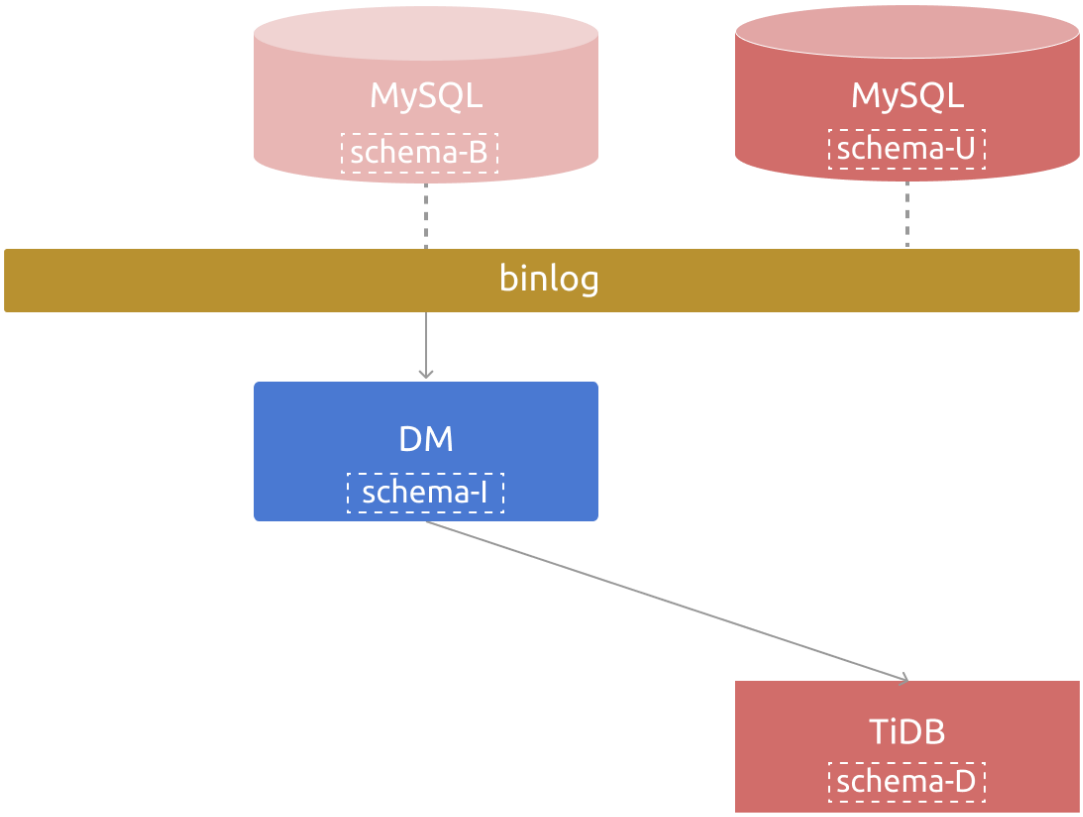

Figure 482: schema

- The upstream table schema at the current time, identified as `schema-U`.
- The table schema of the binlog event currently being consumed by DM, identified as `schema-B`. This schema corresponds to the upstream table schema at a historical time.
- The table schema currently maintained in DM (the schema tracker component), identified as `schema-I`.
- The table schema in the downstream TiDB cluster, identified as `schema-D`.

In most cases, the preceding four table schemas are consistent.

When the upstream database performs a DDL operation to change the table schema, `schema-U` is changed. By applying the DDL operation to the internal schema tracker component and the downstream TiDB cluster, DM updates `schema-I` and `schema-D` in an orderly manner to keep them consistent with `schema-U`. Therefore, DM can then normally consume the binlog event corresponding to the `schema-B` table schema. That is, after the DDL operation is successfully migrated, `schema-U`, `schema-B`, `schema-I`, and `schema-D` are still consistent.

Note the following situations that might cause inconsistency:

- During the migration with optimistic mode sharding DDL support enabled, the `schema-D` of the downstream table might be inconsistent with the `schema-B` and `schema-I` of some upstream sharded tables. In such cases, DM still keeps `schema-I` and `schema-B` consistent to ensure that the binlog event corresponding to DML can be parsed normally.
- When the downstream table has more columns than the upstream table, `schema-D` might be inconsistent with `schema-B` and `schema-I`. In the full data migration (`task-mode=all`), DM automatically handles inconsistency. In the incremental migration (`task-mode=incremental`), because the task is on a first start and there is no internal schema information yet, DM automatically reads the downstream schema (`schema-D`) and updates `schema-I` (this behavior varies with DM versions). After that, if DM uses `schema-I` to parse `schema-B`'s binlog, it will report `Column count doesn't match value count` error. For details, refer to Migrate Data to a Downstream TiDB Table with More Columns.

You can run the `binlog-schema` command to obtain, modify, or delete the `schema-I` table schema maintained in DM.

> **Note:**
>
> The `binlog-schema` command is supported only in DM v6.0 or later versions. For earlier versions, you must use the `operate-schema` command.

Command

```
help binlog-schema
```

```
manage or show table schema in schema tracker

Usage:
  dmctl binlog-schema [command]
```

```
Available Commands:
  delete     delete table schema structure
  list       show table schema structure
  update     update tables schema structure

Flags:
  -h, --help help for binlog-schema

Global Flags:
  -s, --source strings MySQL Source ID.

Use "dmctl binlog-schema [command] --help" for more information about a
    ↪ command.
```

Note:

- Because a table schema might change during data migration, to obtain a predictable table schema, currently the `binlog-schema` command can be used only when the data migration task is in the `Paused` state.
- To avoid data loss due to mishandling, it is **strongly recommended** to get and backup the table schema firstly before you modify the schema.

Parameters

- `delete`: Deletes the table schema.
- `list`: Lists the table schema.
- `update`: Updates the table schema.
- `-s` or `--source`:
  - Required.
  - Specifies the MySQL source that the operation is applied to.

Usage example

Get the table schema

To get the table schema, run the `binlog-schema list` command:

```
help binlog-schema list
```

```
show table schema structure
```

```
Usage:
  dmctl binlog-schema list <task-name> <database> <table> [flags]

Flags:
  -h, --help help for list

Global Flags:
  -s, --source strings MySQL Source ID.
```

If you want to get the table schema of the `db_single`.`t1` table corresponding to the mysql-replica-01 MySQL source in the db_single task, run the following command:

```
binlog-schema list -s mysql-replica-01 task_single db_single t1
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "CREATE TABLE `t1` ( `c1` int(11) NOT NULL, `c2` int(11)
                ↪ DEFAULT NULL, PRIMARY KEY (`c1`)) ENGINE=InnoDB DEFAULT
                ↪ CHARSET=latin1 COLLATE=latin1_bin",
            "source": "mysql-replica-01",
            "worker": "127.0.0.1:8262"
        }
    ]
}
```

Update the table schema

To update the table schema, run the binlog-schema update command:

```
help binlog-schema update
```

```
update tables schema structure

Usage:
  dmctl binlog-schema update <task-name> <database> <table> [schema-file] [
     ↪ flags]

Flags:
      --flush       flush the table info and checkpoint immediately (default
         ↪  true)
      --from-source use the schema from upstream database as the schema of
         ↪ the specified tables
```

```
      --from-target use the schema from downstream database as the schema of
          ↪ the specified tables
  -h, --help        help for update
      --sync        sync the table info to master to resolve shard ddl lock,
          ↪ only for optimistic mode now (default true)

Global Flags:
  -s, --source strings MySQL Source ID.
```

If you want to set the table schema of the `db_single`.`t1` table corresponding to the mysql-replica-01 MySQL source in the db_single task as follows:

```
CREATE TABLE `t1` (
    `c1` int(11) NOT NULL,
    `c2` bigint(11) DEFAULT NULL,
    PRIMARY KEY (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_bin
```

Save the CREATE TABLE statement above as a file (for example, db_single.t1-schema.sql), and run the following command:

```
operate-schema set -s mysql-replica-01 task_single -d db_single -t t1 db_
    ↪ single.t1-schema.sql
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "127.0.0.1:8262"
        }
    ]
}
```

Delete the table schema

To delete the table schema, run the binlog-schema delete command:

```
help binlog-schema delete
```

```
delete table schema structure

Usage:
  dmctl binlog-schema delete <task-name> <database> <table> [flags]
```

```
Flags:
  -h, --help  help for delete

Global Flags:
  -s, --source strings MySQL Source ID.
```

> **Note:**
>
> After the table schema maintained in DM is deleted, if a DDL/DML statement related to this table needs to be migrated to the downstream, DM will try to get the table schema from the following three sources in an orderly manner:
>
> - The `table_info` field in the checkpoint table
> - The meta information in the optimistic sharding DDL
> - The corresponding table in the downstream TiDB

If you want to delete the table schema of the `` `db_single`.`t1` `` table corresponding to the `mysql-replica-01` MySQL source in the `db_single` task, run the following command:

```
binlog-schema delete -s mysql-replica-01 task_single db_single t1
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "127.0.0.1:8262"
        }
    ]
}
```

13.6.7.10 Export and Import Data Sources and Task Configuration of Clusters

`config` command is used to export and import data sources and task configuration of clusters.

> **Note:**
>
> For clusters earlier than v2.0.5, you can use dmctl (>= v2.0.5 and < v8.0.0) to export and import the data source and task configuration files.

```
» help config
Commands to import/export config
Usage:
  dmctl config [command]
Available Commands:
  export     Export the configurations of sources and tasks.
  import     Import the configurations of sources and tasks.
Flags:
  -h, --help help for config
Global Flags:
  -s, --source strings MySQL Source ID.
Use "dmctl config [command] --help" for more information about a command.
```

13.6.7.10.1 Export the data source and task configuration of clusters

You can use `export` command to export the data source and task configuration of clusters to specified files.

```
config export [--dir directory]
```

Parameter explanation

- `dir`:
  - optional
  - specifies the file path for exporting
  - the default value is `./configs`

Returned results

```
config export -d /tmp/configs
```

```
export configs to directory `/tmp/configs` succeed
```

13.6.7.10.2 import the data source and task configuration of clusters

You can use `import` command to import the data source and task configuration of clusters from specified files.

```
config import [--dir directory]
```

> **Note:**
>
> For clusters later than v2.0.2, currently, it is not supported to automatically import the configuration related to relay worker. You can use `start-relay` command to manually start relay log.

Parameter explanation

- `dir`:
  - optional
  - specifies the file path for importing
  - the default value is `./configs`

Returned results

```
config import -d /tmp/configs
```

```
start creating sources
start creating tasks
import configs from directory `/tmp/configs` succeed
```

13.6.7.11 Handle Alerts in TiDB Data Migration

This document introduces how to deal with the alert information in DM.

13.6.7.11.1 Alerts related to high availability

`DM_master_all_down`

- Description:

  If all DM-master nodes are offline, this alert is triggered.

- Solution:

  You can take the following steps to handle the alert:

1. Check the environment of the cluster.
2. Check the logs of all DM-master nodes for troubleshooting.

`DM_worker_offline`

- Description:

  If a DM-worker node is offline for more than one hour, this alert is triggered. In a high-availability architecture, this alert might not directly interrupt the task but increases the risk of interruption.

- Solution:

  You can take the following steps to handle the alert:

  1. View the working status of the corresponding DM-worker node.
  2. Check whether the node is connected.
  3. Troubleshoot errors through logs.

`DM_DDL_error`

- Description:

  This error occurs when DM is processing the sharding DDL operations.

- Solution:

  Refer to Troubleshoot DM.

`DM_pending_DDL`

- Description:

  If a sharding DDL operation is pending for more than one hour, this alert is triggered.

- Solution:

  In some scenarios, the pending sharding DDL operation might be what users expect. Otherwise, refer to Handle Sharding DDL Locks Manually in DM for solution.

13.6.7.11.2 Alert rules related to task status

`DM_task_state`

- Description:

  When a sub-task of DM-worker is in the `Paused` state for over 20 minutes, an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

13.6.7.11.3 Alert rules related to relay log

`DM_relay_process_exits_with_error`

- Description:

  When the relay log processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_remain_storage_of_relay_log`

- Description:

  When the free space of the disk where the relay log is located is less than 10G, an alert is triggered.

- Solutions:

  You can take the following methods to handle the alert:

  - Delete unwanted data manually to increase free disk space.
  - Reconfigure the automatic data purge strategy of the relay log or purge data manually.
  - Execute the command `pause-relay` to pause the relay log pulling process. After there is enough free disk space, resume the process by running the command `resume-relay`. Note that you must not purge upstream binlog files that have not been pulled after the relay log pulling process is paused.

`DM_relay_log_data_corruption`

- Description:

  When the relay log processing unit validates the binlog event read from the upstream and detects abnormal checksum information, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_fail_to_read_binlog_from_master`

- Description:

  If an error occurs when the relay log processing unit tries to read the binlog event from the upstream, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_fail_to_write_relay_log`

- Description:

  If an error occurs when the relay log processing unit tries to write the binlog event into the relay log file, this unit moves to the `Paused` state, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_binlog_file_gap_between_master_relay`

- Description:

  When the number of the binlog files in the current upstream MySQL/MariaDB exceeds that of the latest binlog files pulled by the relay log processing unit by **more than** 1 for 10 minutes, and an alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

13.6.7.11.4 Alert rules related to Dump/Load

`DM_dump_process_exists_with_error`

- Description:

  When the Dump processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_load_process_exists_with_error`

- Description:

  When the Load processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

13.6.7.11.5 Alert rules related to binlog replication

`DM_sync_process_exists_with_error`

- Description:

  When the binlog replication processing unit encounters a non-autorecoverable error (for example, binlog files not found), or when it encounters multiple recoverable errors (for example, network problems) in a short period of time (for example, more than 3 times in 2 minutes), this alert is triggered.

- Solution:

  Refer to Troubleshoot DM.

`DM_binlog_file_gap_between_master_syncer`

- Description:

  When the number of the binlog files in the current upstream MySQL/MariaDB exceeds that of the latest binlog files processed by the relay log processing unit by **more than** 1 for 10 minutes, an alert is triggered.

- Solution:

  Refer to Handle Performance Issues.

`DM_binlog_file_gap_between_relay_syncer`

- Description:

  When the number of the binlog files in the current relay log processing unit exceeds that of the latest binlog files processed by the binlog replication processing unit by **more than** 1 for 10 minutes, an alert is triggered.

- Solution:

  Refer to Handle Performance Issues.

13.6.7.12 Daily Check for TiDB Data Migration

This document summarizes how to perform a daily check on TiDB Data Migration (DM).

- Method 1: Execute the `query-status` command to check the running status of the task and the error output (if any). For details, see Query Status.
- Method 2: If Prometheus and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. For example, suppose that the Grafana's address is `172.16.10.71`, go to http://172.16.10.71:3000, enter the Grafana dashboard, and select the DM Dashboard to check monitoring metrics of DM. For more information of these metrics, see DM Monitoring Metrics.
- Method 3: Check the running status of DM and the error (if any) using the log file.
    - DM-master log directory: It is specified by the `--log-file` DM-master process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-master node.
    - DM-worker log directory: It is specified by the `--log-file` DM-worker process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-worker node.

13.6.8 Reference

13.6.8.1 Architecture

13.6.8.1.1 DM-worker Introduction

DM-worker is a tool used to migrate data from MySQL/MariaDB to TiDB.

It has the following features:

- Acts as a secondary database of any MySQL or MariaDB instance
- Reads the binlog events from MySQL/MariaDB and persists them to the local storage
- A single DM-worker supports migrating the data of one MySQL/MariaDB instance to multiple TiDB instances
- Multiple DM-workers support migrating the data of multiple MySQL/MariaDB instances to one TiDB instance

DM-worker processing unit

A DM-worker task contains multiple logic units, including relay log, the dump processing unit, the load processing unit, and binlog replication.

Relay log

The relay log persistently stores the binlog data from the upstream MySQL/MariaDB and provides the feature of accessing binlog events for the binlog replication.

Its rationale and features are similar to the relay log of MySQL. For details, see MySQL Relay Log.

Dump processing unit

The dump processing unit dumps the full data from the upstream MySQL/MariaDB to the local disk.

Load processing unit

The load processing unit reads the dumped files of the dump processing unit and then loads these files to the downstream TiDB.

Binlog replication/sync processing unit

Binlog replication/sync processing unit reads the binlog events of the upstream MySQL/-MariaDB or the binlog events of the relay log, transforms these events to SQL statements, and then applies these statements to the downstream TiDB.

Privileges required by DM-worker

This section describes the upstream and downstream database users' privileges required by DM-worker, and the user privileges required by the respective processing unit.

Upstream database user privileges

The upstream database (MySQL/MariaDB) user must have the following privileges:

Privilege	Scope
`SELECT`	Tables
`RELOAD`	Global
`REPLICATION SLAVE`	Global
`REPLICATION CLIENT`	Global

If you need to migrate the data from `db1` to TiDB, execute the following `GRANT` statement:

```
GRANT RELOAD,REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO 'your_user'@'
    ↪ your_wildcard_of_host';
GRANT SELECT ON db1.* TO 'your_user'@'your_wildcard_of_host';
```

If you also need to migrate the data from other databases into TiDB, make sure the same privileges are granted to the user of the respective databases.

Downstream database user privileges

The downstream database (TiDB) user must have the following privileges:

Privilege	Scope
`SELECT`	Tables
`INSERT`	Tables
`UPDATE`	Tables

Privilege	Scope
DELETE	Tables
CREATE	Databases, tables
DROP	Databases, tables
ALTER	Tables
INDEX	Tables

Execute the following GRANT statement for the databases or tables that you need to migrate:

```
GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,ALTER,INDEX ON db.table TO '
    ↪ your_user'@'your_wildcard_of_host';
GRANT ALL ON dm_meta.* TO 'your_user'@'your_wildcard_of_host';
```

Minimal privilege required by each processing unit

Processing unit	Minimal upstream (MySQL/MariaDB) privilege	Minimal downstream (TiDB) privilege	Minimal system privilege
Relay log	REPLICATION SLAVE (reads the binlog)REPLICATION ↪ CLIENT (show master ↪ status, show slave status)	NULL	Read/Write local files
Dump	SELECTRELOAD (flushes tables with Read lock and unlocks tables)	NULL	Write local files
Load	NULL	SELECT (Query the checkpoint history)CREATE (creates a database/table)DELETE ↪ (deletes checkpoint)INSERT (Inserts the Dump data)	Read/Write local files

Processing unit	Minimal upstream (MySQL/MariaDB) privilege	Minimal downstream (TiDB) privilege	Minimal system privilege
Binlog replication	`REPLICATION SLAVE` (reads the binlog)`REPLICATION CLIENT` (`show master status`, `show slave status`)	`SELECT` (shows the index and column)`INSERT` (DML)`UPDATE` (DML)`DELETE` (DML)`CREATE` (creates a database/table)`DROP` (drops databases/tables)`ALTER` (alters a table)`INDEX` (creates/drops an index)	Read/Write local files

Note:

These privileges are not immutable and they change as the request changes.

13.6.8.1.2 DM Safe Mode

Safe mode is a special operation mode for DM to perform incremental replication. In safe mode, when the DM incremental replication component replicates binlog events, DM forcibly rewrites all the `INSERT` and `UPDATE` statements before executing them in the downstream.

During safe mode, one binlog event can be replicated repeatedly to the downstream with idempotence guaranteed. Thus, the incremental replication is *safe*.

After resuming a data replication task from a checkpoint, DM might repeatedly replicate some binlog events, which leads to the following issues:

- During incremental replication, the operation of executing DML and the operation of writing checkpoints are not simultaneous. The operation of writing checkpoints and

writing data into the downstream database is not atomic. Therefore, **when DM exits abnormally, checkpoints might only record the restoration point before the exit point**.

- When DM restarts a replication task and resumes incremental replication from a checkpoint, some data between the checkpoint and the exit point might already be processed before the abnormal exit. This causes **some SQL statements to be executed repeatedly**.
- If an `INSERT` statement is executed repeatedly, the primary key or the unique index might encounter a conflict, which leads to a replication failure. If an `UPDATE` statement is executed repeatedly, the filter condition might not be able to locate the previously updated records.

In safe mode, DM can rewrite SQL statements to resolve the preceding issues.

Working principle

In safe mode, DM guarantees the idempotency of binlog events by rewriting SQL statements. Specifically, the following SQL statements are rewritten:

- `INSERT` statements are rewritten to `REPLACE` statements.
- `UPDATE` statements are analyzed to obtain the value of the primary key or the unique index of the row updated. `UPDATE` statements are then rewritten to `DELETE` + `REPLACE` statements in the following two steps: DM deletes the old record using the primary key or unique index, and inserts the new record using the `REPLACE` statement.

`REPLACE` is a MySQL-specific syntax for inserting data. When you insert data using `REPLACE`, and the new data and existing data have a primary key or unique constraint conflict, MySQL deletes all the conflicting records and executes the insert operation, which is equivalent to "force insert". For details, see REPLACE statement in MySQL documentation.

Assume that a `dummydb.dummytbl` table has a primary key `id`. Execute the following SQL statements repeatedly on this table:

```
INSERT INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123, 999, '
    ↪ abc');
UPDATE dummydb.dummytbl SET int_value = 888999 WHERE int_value = 999; --
    ↪ Suppose there is no other record with int_value = 999
UPDATE dummydb.dummytbl SET id = 999 WHERE id = 888; -- Update the primary
    ↪ key
```

With safe mode enabled, when the preceding SQL statements are executed again in the downstream, they are rewritten as follows:

```
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123, 999,
    ↪ 'abc');
DELETE FROM dummydb.dummytbl WHERE id = 123;
```

```
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (123,
    ↪ 888999, 'abc');
DELETE FROM dummydb.dummytbl WHERE id = 888;
REPLACE INTO dummydb.dummytbl (id, int_value, str_value) VALUES (999,
    ↪ 888888, 'abc888');
```

In the preceding statements, `UPDATE` is rewritten as `DELETE` + `REPLACE`, rather than `DELETE` + `INSERT`. If `INSERT` is used here, when you insert a duplicate record with `id = 999`, the database reports a primary key conflict. This is why `REPLACE` is used instead. The new record will replace the existing record.

By rewriting SQL statements, DM overwrites the existing row data using the new row data when performing duplicate insert or update operations. This guarantees that insert and update operations are executed repeatedly.

Enable safe mode

You can enable safe mode either automatically or manually. This section describes the detailed steps.

Automatically enable

When DM resumes an incremental replication task from a checkpoint (For example, DM worker restart or network reconnection), DM automatically enables safe mode for a period (60 seconds by default).

Whether to enable safe mode is related to `safemode_exit_point` in the checkpoint. When an incremental replication task is paused abnormally, DM tries to replicate all DML statements in the memory to the downstream and records the latest binlog position among the DML statements as `safemode_exit_point`, which is saved to the last checkpoint.

The detailed logic is as follows:

- If the checkpoint contains `safemode_exit_point`, the incremental replication task is paused abnormally. When DM resumes the task, the binlog position of the checkpoint to be resumed (**begin position**) is earlier than `safemode_exit_point`, which represents the binlog events between the begin position and the `safemode_exit_point` might have been processed in the downstream. So, during the resume process, some binlog events might be executed repeatedly. Therefore, enabling safe mode can make these binlog positions **safe**. After the binlog position exceeds the `safemode_exit_point`, DM automatically disables safe mode unless safe mode is enabled manually.
- If the checkpoint does not contain `safemode_exit_point`, there are two cases:
    1. This is a new task, or this task is paused as expected.
    2. This task is paused abnormally but DM fails to record `safemode_exit_point`, or the DM process exits abnormally.

In the second case, DM does not know which binlog events after the checkpoint are executed in the downstream. To ensure that repeatedly executed binlog events do not cause any problems, DM automatically enables safe mode during the first two checkpoint intervals. The default interval between two checkpoints is 30 seconds, which means when a normal incremental replication task starts, safe mode is enforced for the first 60 seconds (2 * 30 seconds).

Usually, it is not recommended to change the checkpoint interval to adjust the safe mode period at the beginning of the incremental replication task. However, if you do need a change, you can manually enable safe mode (recommended) or change the `checkpoint-flush-interval` item in syncer configuration.

Manually enable

You can set the `safe-mode` item in the syncer configuration to enable safe mode during the entire replication process. `safe-mode` is a bool type parameter and is `false` by default. If it is set to `true`, DM enables safe mode for the whole incremental replication process.

The following is a task configuration example with safe mode enabled:

```
syncers:                           # The running configurations of the sync
   ↪ processing unit.
  global:                          # Configuration name.
    # Other configuration items are not provided in this example.
    safe-mode: true                # Enables safe mode for the whole
       ↪ incremental replication process.
    # Other configuration items are not provided in this example.
##### ----------- Instance configuration -----------
mysql-instances:
  -
    source-id: "mysql-replica-01"
    # Other configuration items are not provided in this example.
    syncer-config-name: "global"       # Name of the syncers configuration.
```

Notes for safe mode

If you want to enable safe mode during the entire replication process for safety reasons, be aware of the following:

- **Incremental replication in safe mode consumes extra overhead.** Frequent `DELETE` + `REPLACE` operations result in frequent changes to primary keys or unique indexes, which creates a greater performance overhead than executing `UPDATE` statements only.
- **Safe mode forces the replacement of records with the same primary key, which might result in data loss in the downstream.** When you merge and migrate shards from the upstream to the downstream, incorrect configuration might lead to a large number of primary key or unique key conflicts. If safe mode is enabled in

this situation, the downstream might lose lots of data without showing any exception, resulting in severe data inconsistency.

- **Safe mode relies on the primary key or unique index to detect conflicts.** If the downstream table has no primary key or unique index, DM cannot use `REPLACE` ↪ to replace and insert records. In this case, even if safe mode is enabled and DM rewrites `INSERT` to `REPLACE` statements, duplicate records are still inserted into the downstream.

In summary, if the upstream database has data with duplicate primary keys, and your application tolerates loss of duplicate records and performance overhead, you can enable safe mode to ignore data duplication.

13.6.8.1.3 Data Migration Relay Log

The Data Migration (DM) relay log consists of several sets of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

After relay log is enabled, DM-worker automatically migrates the upstream binlog to the local configuration directory (the default migration directory is `<deploy_dir>/<relay_log>` if DM is deployed using TiUP). The default value of `<relay_log>` is `relay-dir` and can be modified in Upstream Database Configuration File. Since v5.4.0, you can configure the local configuration directory through `relay-dir` in the DM-worker configuration file, which takes precedence over the configuration file of the upstream database.

User scenarios

In MySQL, storage space is limited, so the binlog is automatically purged when the maximum retention time is reached. After the upstream database purges the binlog, DM fails to pull the purged binlog and the migration task fails. For each migration task, DM creates a connection in the upstream to pull binlog. Too many connections might cause a heavy workload on the upstream database.

When the relay log is enabled, multiple migration task with the same upstream database can reuse the relay log that has been pulled to the local disk. This **relieves the pressure on the upstream database**.

For full and incremental data migration tasks (`task-mode=all`), DM needs to first migrate full data and then perform incremental migration based on binlog. If the full migration phase takes long, the upstream binlog might be purged, which results in incremental migration failure. To avoid this situation, you can enable the relay log feature so that DM automatically retains enough log in the local disk and **ensures the incremental migration task can be performed normally**.

It is generally recommended to enable relay log, but be aware of the following potential issue:

Because relay log must be written to the disk, it consumes external IO and CPU resources. This prolongs the whole data replication process and increases the data replication latency. For **latency-sensitive** scenarios, it is not recommended to enable relay log.

Note:

In DM v2.0.7 and later versions, relay log writes are optimized. The latency and CPU resource consumption is relatively low.

Use relay log

This section describes how to enable and disable relay log, query relay log status, and purge relay log.

Enable and disable relay log

In v5.4.0 and later versions, you can enable relay log by setting `enable-relay` to `true`. Since v5.4.0, when binding the upstream data source, DM-worker checks the `enable-relay` item in the configuration of the data source. If `enable-relay` is `true`, the relay log feature is enabled for this data source.

For the detailed configuration method, see Upstream Database Configuration File.

In addition, you can also dynamically adjust the `enable-relay` configuration of the data source using the `start-relay` or `stop-relay` command to enable or disable relay log in time.

```
start-relay -s mysql-replica-01
```

```
{
    "result": true,
    "msg": ""
}
```

Note:

In DM v2.0.x later than DM v2.0.2 and in v5.3.0, the configuration item `enable-relay` in the source configuration file is no longer valid, and you can only use `start-relay` and `stop-relay` to enable and disable relay log. If DM finds that `enable-relay` is set to `true` when loading the data source configuration, it outputs the following message:

```
Please use `start-relay` to specify which workers should pull
    ↪ relay log of relay-enabled sources.
```

Warning:

This startup method is marked as deprecated in v6.1 and might be removed in a future release. You can see the following prompt in the output of the relevant command: `start-relay/stop-relay with worker name will be deprecated soon. You can try stopping relay first and use start-relay without worker name instead.`

In the command `start-relay`, you can configure one or more DM-workers to migrate relay logs for the specified data source, but the DM-workers specified in the parameter must be free or have been bound to the upstream data source. Examples are as follows:

```
start-relay -s mysql-replica-01 worker1 worker2
```

```
{
    "result": true,
    "msg": ""
}
```

```
stop-relay -s mysql-replica-01 worker1 worker2
```

```
{
    "result": true,
    "msg": ""
}
```

In DM versions earlier than v2.0.2 (not including v2.0.2), DM checks the configuration item `enable-relay` in the source configuration file when binding a DM-worker to an upstream data source. If `enable-relay` is set to `true`, DM enables the relay log feature for the data source.

See Upstream Database Configuration File for how to set the configuration item `enable-relay`.

Query relay log status

You can use the command `query-status -s` to query the status of the relay log:

```
query-status -s mysql-replica-01
```

Expected output

```
{
    "result": true,
    "msg": "",
```

```
"sources": [
    {
        "result": true,
        "msg": "no sub task started",
        "sourceStatus": {
            "source": "mysql-replica-01",
            "worker": "worker2",
            "result": null,
            "relayStatus": {
                "masterBinlog": "(mysql-bin.000005, 916)",
                "masterBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ :1-28",
                "relaySubDir": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ .000001",
                "relayBinlog": "(mysql-bin.000005, 4)",
                "relayBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ :1-28",
                "relayCatchUpMaster": false,
                "stage": "Running",
                "result": null
            }
        },
        "subTaskStatus": [
        ]
    },
    {
        "result": true,
        "msg": "no sub task started",
        "sourceStatus": {
            "source": "mysql-replica-01",
            "worker": "worker1",
            "result": null,
            "relayStatus": {
                "masterBinlog": "(mysql-bin.000005, 916)",
                "masterBinlogGtid": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ :1-28",
                "relaySubDir": "09bec856-ba95-11ea-850a-58f2b4af5188
                    ↪ .000001",
                "relayBinlog": "(mysql-bin.000005, 916)",
                "relayBinlogGtid": "",
                "relayCatchUpMaster": true,
                "stage": "Running",
                "result": null
            }
        },
```

```
            "subTaskStatus": [
            ]
        }
    ]
}
```

Pause and resume relay log

You can use the command `pause-relay` to pause the pulling process of relay logs and use the command `resume-relay` to resume the process. You need to specify the `source-id` of the upstream data source when executing these two commands. See the following examples:

```
pause-relay -s mysql-replica-01 -s mysql-replica-02
```

Expected output

```
{
    "op": "PauseRelay",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

```
resume-relay -s mysql-replica-01
```

Expected output

```
{
    "op": "ResumeRelay",
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
```

```
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        }
    ]
}
```

Purge relay logs

DM provides two ways to purge relay logs: manual purge and automatic purge. Neither of these two methods purges active relay logs.

Note:

- Active relay log: The relay log is being used by a data migration task. An active relay log is currently only updated and written in the Syncer Unit. If a data migration task in All mode spends more time on full export/import than the expiration time configured in the purge of the data source, the relay log is still purged.
- Expired relay log: The difference between the last modification time of the relay log file and the current time is greater than the value of the `expires` field in the configuration file.

Automatic purge

You can enable automatic purge and configure its strategy in the source configuration file. See the following example:

```
##### relay log purge strategy
purge:
    interval: 3600
    expires: 24
    remain-space: 15
```

- `purge.interval`
    - The interval of automatic purge in the background, in seconds.
    - "3600" by default, indicating a background purge task is performed every 3600 seconds.
- `purge.expires`

    - The number of hours for which the relay log (that has been previously written to the relay processing unit, and that is not being used or will not be read later by the currently running data migration task) can be retained before being purged in the automatic background purge.
    - "0" by default, indicating data purge is not performed according to the update time of the relay log.

- `purge.remain-space`

    - The amount of remaining disk space in GB less than which the specified DM-worker machine tries to purge the relay log that can be purged securely in the automatic background purge. If it is set to `0`, data purge is not performed according to the remaining disk space.
    - "15" by default, indicating when the available disk space is less than 15 GB, DM-master tries to purge the relay log securely.

Manual purge

Manual purge means using the `purge-relay` command provided by dmctl to specify `subdir` and the binlog name thus to purge all the relay logs **before** the specified binlog. If the `-subdir` option in the command is not specified, all relay logs **before** the current relay log sub-directory are purged.

Assuming that the directory structure of the current relay log is as follows:

```
$ tree .
.
|-- deb76a2b-09cc-11e9-9129-5242cf3bb246.000001
|   |-- mysql-bin.000001
|   |-- mysql-bin.000002
|   |-- mysql-bin.000003
|   `-- relay.meta
|-- deb76a2b-09cc-11e9-9129-5242cf3bb246.000003
|   |-- mysql-bin.000001
|   `-- relay.meta
|-- e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
|   |-- mysql-bin.000001
|   `-- relay.meta
`-- server-uuid.index

$ cat server-uuid.index
deb76a2b-09cc-11e9-9129-5242cf3bb246.000001
e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
deb76a2b-09cc-11e9-9129-5242cf3bb246.000003
```

- Executing the following `purge-relay` command in dmctl purges all relay log files **before** `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002/mysql-bin.000001`, which

are all relay log files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000001`. Files in `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002` and `deb76a2b-09cc-11e9-9129-5242cf3bb246.000003` are retained.

```
purge-relay -s mysql-replica-01 --filename mysql-bin.000001 --sub-dir
    ↪ e4e0e8ab-09cc-11e9-9220-82cc35207219.000002
```

- Executing the following `purge-relay` command in dmctl purges all relay log files **before the current** (`deb76a2b-09cc-11e9-9129-5242cf3bb246.000003`) directory's `mysql-bin.000001`, which are all relay log files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000001` and `e4e0e8ab-09cc-11e9-9220-82cc35207219.000002`. Files in `deb76a2b-09cc-11e9-9129-5242cf3bb246.000003` are retained.

```
purge-relay -s mysql-replica-01 --filename mysql-bin.000001
```

Internal mechanism of relay log

This section introduces the internal mechanism of relay log.

Directory structure

An example of the directory structure of the local storage for a relay log:

```
<deploy_dir>/<relay_log>/
|-- 7e427cc0-091c-11e9-9e45-72b7c59d52d7.000001
|   |-- mysql-bin.000001
|   |-- mysql-bin.000002
|   |-- mysql-bin.000003
|   |-- mysql-bin.000004
|   `-- relay.meta
|-- 842965eb-091c-11e9-9e45-9a3bff03fa39.000002
|   |-- mysql-bin.000001
|   `-- relay.meta
`-- server-uuid.index
```

- `subdir`:
    - DM-worker stores the binlog migrated from the upstream database in the same directory. Each directory is a `subdir`.
    - `subdir` is named in the format of `<Upstream database UUID>.<Local subdir serial number>`.
    - After a switch between primary and secondary instances in the upstream, DM-worker generates a new `subdir` directory with an incremental serial number.
    - In the above example, for the `7e427cc0-091c-11e9-9e45-72b7c59d52d7.000001` directory, `7e427cc0-091c-11e9-9e45-72b7c59d52d7` is the upstream database UUID and `000001` is the local `subdir` serial number.

- `server-uuid.index`: records a list of the currently available `subdir` directories.
- `relay.meta`: stores the information of the migrated binlog in each `subdir`. For example,

```
cat c0149e17-dff1-11e8-b6a8-0242ac110004.000001/relay.meta
```

```
binlog-name = "mysql-bin.000010"                          # The name of the
    ↪ currently migrated binlog.
binlog-pos = 63083620                                     # The position of
    ↪ the currently migrated binlog.
binlog-gtid = "c0149e17-dff1-11e8-b6a8-0242ac110004:1-3328" # GTID of
    ↪ the currently migrated binlog.
```

There might also be multiple GTIDs:

```
cat 92acbd8a-c844-11e7-94a1-1866daf8accc.000001/relay.meta
```

```
binlog-name = "mysql-bin.018393"
binlog-pos = 277987307
binlog-gtid = "3ccc475b-2343-11e7-be21-6c0b84d59f30:1-14,406a3f61-690d
    ↪ -11e7-87c5-6c92bf46f384:1-94321383,53bfca22-690d-11e7-8a62-18
    ↪ ded7a37b78:1-495,686e1ab6-c47e-11e7-a42c-6c92bf46f384
    ↪ :1-34981190,03fc0263-28c7-11e7-a653-6c0b84d59f30:1-7041423,05474
    ↪ d3c-28c7-11e7-8352-203db246dd3d:1-170,10b039fc-c843-11e7-8f6a
    ↪ -1866daf8d810:1-308290454"
```

The position where DM receives the binlog

- DM obtains the earliest position that each migration task needs from the saved checkpoint (in the downstream `dm_meta` schema by default). If this position is later than any of the following positions, DM starts to migrate from this position.
- If the local relay log is valid, which means that the relay log contains valid `server-uuid.index`, `subdir`, and `relay.meta` files, DM-worker recovers the migration from the position recorded in `relay.meta`.
- If there is no valid local relay log, but the upstream data source configuration file specifies `relay-binlog-name` or `relay-binlog-gtid`:
  - In non-GTID mode, if `relay-binlog-name` is specified, DM-worker starts to migrate from the specified binlog file.
  - In GTID mode, if `relay-binlog-gtid` is specified, DM-worker starts to migrate from the specified GTID.
- If there is no valid local relay log and the `relay-binlog-name` or `relay-binlog-gtid` is not specified in the DM configuration file:

- In non-GTID mode, DM-worker starts to migrate from the earliest binlog that each subtask is migrating, until the latest binlog is migrated.
- In GTID mode, DM-worker starts to migrate from the earliest GTID that each subtask is migrating, until the latest GTID is migrated.

> **Note:**
>
> If the upstream relay log is purged, an error occurs. In this case, you need to configure `relay-binlog-gtid` to specify the start position of the migration.

13.6.8.1.4 Special Handling of DM DDLs

When TiDB Data Migration (DM) migrates data, it parses the DDL statements and handles them according to the statement type and the current migration stage.

Skip DDL statements

The following statements are not supported by DM, so DM skips them directly after parsing.

```
<tr>
    <th>Description</th>
    <th>SQL</th>
</tr>
<tr>
    <td>transaction</td>
    <td><code>^SAVEPOINT</code></td>
</tr>
<tr>
    <td>skip all flush sqls</td>
    <td><code>^FLUSH</code></td>
</tr>
<tr>
    <td rowspan="3">table maintenance</td>
    <td><code>^OPTIMIZE\\s+TABLE</code></td>
</tr>
<tr>
    <td><code>^ANALYZE\\s+TABLE</code></td>
</tr>
<tr>
    <td><code>^REPAIR\\s+TABLE</code></td>
</tr>
<tr>
    <td>temporary table</td>
```

```
    <td><code>^DROP\\s+(\\/\\*\\!40005\\s+)?TEMPORARY\\s+(\\*\\/\\s+)?TABLE
       ↪ </code></td>
</tr>
<tr>
    <td rowspan="2">trigger</td>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?TRIGGER</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+TRIGGER</code></td>
</tr>
<tr>
    <td rowspan="3">procedure</td>
    <td><code>^DROP\\s+PROCEDURE</code></td>
</tr>
<tr>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?PROCEDURE</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+PROCEDURE</code></td>
</tr>
<tr>
    <td rowspan="3">view</td>
    <td><code>^CREATE\\s*(OR REPLACE)?\\s+(ALGORITHM\\s?=.+?)?(DEFINER\\s
       ↪ ?=.+?)?\\s+(SQL SECURITY DEFINER)?VIEW</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+VIEW</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+(ALGORITHM\\s?=.+?)?(DEFINER\\s?=.+?)?(SQL SECURITY
       ↪ DEFINER)?VIEW</code></td>
</tr>
<tr>
    <td rowspan="4">function</td>
    <td><code>^CREATE\\s+(AGGREGATE)?\\s*?FUNCTION</code></td>
</tr>
<tr>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?FUNCTION</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+FUNCTION</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+FUNCTION</code></td>
</tr>
```

```
<tr>
    <td rowspan="3">tableSpace</td>
    <td><code>^CREATE\\s+TABLESPACE</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+TABLESPACE</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+TABLESPACE</code></td>
</tr>
<tr>
    <td rowspan="3">event</td>
    <td><code>^CREATE\\s+(DEFINER\\s?=.+?)?EVENT</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+(DEFINER\\s?=.+?)?EVENT</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+EVENT</code></td>
</tr>
<tr>
    <td rowspan="7">account management</td>
    <td><code>^GRANT</code></td>
</tr>
<tr>
    <td><code>^REVOKE</code></td>
</tr>
<tr>
    <td><code>^CREATE\\s+USER</code></td>
</tr>
<tr>
    <td><code>^ALTER\\s+USER</code></td>
</tr>
<tr>
    <td><code>^RENAME\\s+USER</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+USER</code></td>
</tr>
<tr>
    <td><code>^DROP\\s+USER</code></td>
</tr>
```

Rewrite DDL statements

The following statements are rewritten before being replicated to the downstream.

Original statement	Rewritten statement
`^CREATE DATABASE...`	`^CREATE DATABASE...IF NOT EXISTS`
`^CREATE TABLE...`	`^CREATE TABLE..IF NOT EXISTS`
`^DROP DATABASE...`	`^DROP DATABASE...IF EXISTS`
`^DROP TABLE...`	`^DROP TABLE...IF EXISTS`
`^DROP INDEX...`	`^DROP INDEX...IF EXISTS`

Shard merge migration tasks

When DM merges and migrates tables in pessimistic or optimistic mode, the behavior of DDL replication is different from that in other scenarios. For details, refer to Pessimistic Mode and Optimistic Mode.

Online DDL

The Online DDL feature also handles DDL events in a special way. For details, refer to Migrate from Databases that Use GH-ost/PT-osc.

13.6.8.2 Mechanism

13.6.8.2.1 DML Replication Mechanism in Data Migration

This document introduces how the core processing unit Sync in DM processes DML statements read from the data source or relay log. This document introduces the complete processing flow of DML events in DM, including the logic of binlog reading, filtering, routing, transformation, optimization, and execution. This document also explains the DML optimization logic and DML execution logic in detail.

DML processing flow

The Sync unit processes DML statements as follows:

1. Read the binlog event from the MySQL, MariaDB, or relay log.
2. Transform the binlog event read from the data source:
    1. Binlog filter: filter binlog events according to binlog expressions, configured by `filters`.
    2. Table routing: transform the "database/table" name according to the "database/table" routing rule, configured by `routes`.
    3. Expression filter: filter binlog events according to SQL expressions, configured by `expression-filter`.
3. Optimize the DML execution plan:

1. Compactor: merge multiple operations on the same record (with the same primary key) into one operation. This feature is enabled by `syncer.compact`.
2. Causality: perform conflict detection on different records (with different primary keys) to improve the concurrency of replication.
3. Merger: merge multiple binlog events into one DML statement, enabled by `syncer.multiple-rows`.

4. Execute the DML to the downstream.

5. Periodically save the binlog position or GTID to the checkpoint.

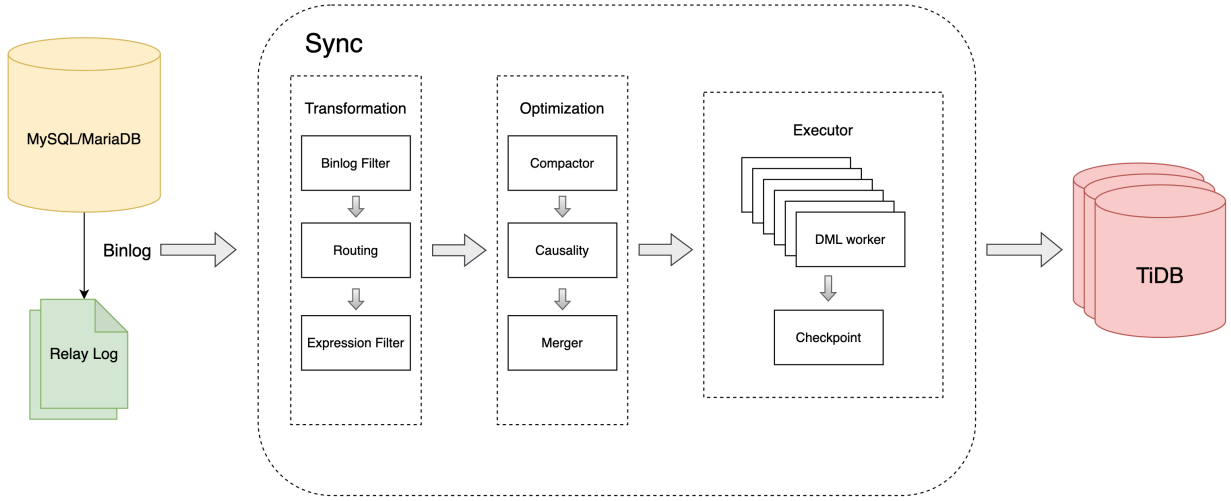

Figure 483: DML processing logic

DML optimization logic

The Sync unit implements the DML optimization logic through three steps: Compactor, Causality, and Merger.

Compactor

According to the binlog records of the upstream, DM captures the changes of the records and replicates them to the downstream. When the upstream makes multiple changes to the same record (`INSERT`/`UPDATE`/`DELETE`) in a short period of time, DM can compress multiple changes into one change through Compactor to reduce the pressure on the downstream and improve the throughput. For example:

```
INSERT + UPDATE => INSERT
INSERT + DELETE => DELETE
UPDATE + UPDATE => UPDATE
UPDATE + DELETE => DELETE
DELETE + INSERT => UPDATE
```

The Compactor feature is disabled by default. To enable it, you can set `syncer.compact` to `true` in the `sync` configuration module of the replication task, as shown below:

```
syncers:                          # The configuration parameters of the sync
    ↪ processing unit
  global:                         # Configuration name
    ...                            # Other configurations are omitted
    compact: true
```

Causality

The sequential replication model of MySQL binlog requires that binlog events be replicated in the order of binlog. This replication model cannot meet the requirements of high QPS and low replication latency. In addition, because not all operations involved in binlog have conflicts, sequential replication is not necessary in those cases.

DM recognizes the binlog that needs to be executed sequentially through conflict detection, and ensures that these binlog are executed sequentially while maximizing the concurrency of other binlog. This helps improve the performance of binlog replication.

Causality adopts an algorithm similar to the union-find algorithm to classify each DML and group DMLs that are related to each other.

Merger

According to the MySQL binlog protocol, each binlog corresponds to a change operation of one row of data. Through Merger, DM can merge multiple binlogs into one DML and execute it to the downstream, reducing the network interaction. For example:

```
  INSERT tb(a,b) VALUES(1,1);
+ INSERT tb(a,b) VALUES(2,2);
= INSERT tb(a,b) VALUES(1,1),(2,2);
  UPDATE tb SET a=1, b=1 WHERE a=1;
+ UPDATE tb SET a=2, b=2 WHERE a=2;
= INSERT tb(a,b) VALUES(1,1),(2,2) ON DUPLICATE UPDATE a=VALUES(a), b=VALUES
    ↪ (b)
  DELETE tb WHERE a=1
+ DELETE tb WHERE a=2
= DELETE tb WHERE (a) IN (1),(2);
```

The Merger feature is disabled by default. To enable it, you can set `syncer.multiple-rows` to `true` in the `sync` configuration module of the replication task, as shown below:

```
syncers:                          # The configuration parameters of the sync
    ↪ processing unit
  global:                         # Configuration name
    ...                            # Other configurations are omitted
    multiple-rows: true
```

DML execution logic

After the Sync unit optimizes the DML, it performs the execution logic.

DML generation

DM has an embedded schema tracker that records the schema information of the upstream and downstream:

- When DM receives a DDL statement, DM updates the table schema of the internal schema tracker.
- When DM receives a DML statement, DM generates the corresponding DML according to the table schema of the schema tracker.

The logic of generating DML is as follows:

1. The Sync unit records the initial table structure of the upstream:
    - When starting a full and incremental task, Sync uses the **table structure exported during the upstream full data migration** as the initial table structure of the upstream.
    - When starting an incremental task, because MySQL binlog does not record the table structure information, Sync uses the **table structure of the corresponding table in the downstream** as the initial table structure of the upstream.
2. The user's upstream and downstream table structures might be inconsistent, for example, the downstream might have additional columns than the upstream, or the upstream and downstream primary keys are inconsistent. Therefore, to ensure the correctness of data replication, DM records the **primary key and unique key information of the corresponding table in the downstream**.
3. DM generates DML:
    - Use the **the upstream table structure recorded in the schema tracker** to generate the column names of the DML statement.
    - Use the **column values recorded in the binlog** to generate the column values of the DML statement.
    - Use the **downstream primary key or unique key recorded in the schema tracker** to generate the `WHERE` condition of the DML statement. When the table structure has no unique key, DM uses all the column values recorded in the binlog as the `WHERE` condition.

Worker count

Causality can divide binlog into multiple groups through conflict detection and execute them concurrently to the downstream. DM controls the concurrency by setting `worker-count`. When the CPU usage of the downstream TiDB is not high, increasing the concurrency can effectively improve the throughput of data replication.

You can modify the number of threads that concurrently migrate DML by modifying the `syncer.worker-count` configuration item.

Batch

DM batches multiple DMLs into a single transaction and executes it to the downstream. When a DML worker receives a DML, it adds the DML to the cache. When the number of DMLs in the cache reaches the preset threshold, or the DML worker does not receive DML for a long time, the DML worker executes the DMLs in the cache to the downstream.

You can modify the number of DMLs contained in a transaction by modifying the `syncer.batch` configuration item.

checkpoint

The operation of executing DML and updating checkpoint is not atomic.

In DM, checkpoint is updated every 30 seconds by default. Because there are multiple DML worker processes, the checkpoint process calculates the binlog position of the earliest replication progress of all DML workers, and uses this position as the current replication checkpoint. All binlogs earlier than this position are guaranteed to be successfully executed to the downstream.

Notes

Transaction consistency

DM replicates data at the row level and does not guarantee transaction consistency. In DM, an upstream transaction is split into multiple rows and distributed to different DML workers for concurrent execution. Therefore, when the DM replication task reports an error and pauses, or when the user manually pauses the task, the downstream might be in an intermediate state. That is, the DML statements in an upstream transaction might be partially replicated to the downstream, which might cause the downstream to be in an inconsistent state.

To ensure that the downstream is in a consistent state when the task is paused as much as possible, starting from DM v5.3.0, DM waits for 10 seconds before pausing the task to ensure that all transactions from the upstream are replicated to the downstream. However, if a transaction is not replicated to the downstream within 10 seconds, the downstream might still be in an inconsistent state.

Safe mode

The operation of DML execution and checkpoint update is not atomic, and the operation of checkpoint update and writing data to the downstream is also not atomic. When DM exits abnormally, the checkpoint might only record a recovery point before the exit time. Therefore, when the task is restarted, DM might write the same data multiple times, which means that DM actually provides the “at least once processing” logic, and the same data might be processed more than once.

To make sure the data is reentrant, DM enters the safe mode when it restarts from an abnormal exit.

When the safe mode is enabled, to make sure that data can be processed multiple times, DM performs the following conversions:

- Rewrite the `INSERT` statement of the upstream to the `REPLACE` statement.
- Rewrite the `UPDATE` statement of the upstream to the `DELETE` + `REPLACE` statement.

Exactly-once processing

Currently, DM only guarantees eventual consistency and does not support "exactly-once processing" and "keeping the original order of transactions".

13.6.8.3 Command Line

13.6.8.3.1 TiDB Data Migration Command-line Flags

This document introduces DM's command-line flags.

DM-master

`--advertise-addr`

- The external address of DM-master used to receive client requests
- The default value is `"{master-addr}"`
- Optional flag. It can be in the form of `"domain-name:port"`

`--advertise-peer-urls`

- The external address for communication between DM-master nodes
- The default value is `"{peer-urls}"`
- Optional flag. It can be in the form of `"http(s)://domain-name:port"`

`--config`

- The configuration file path of DM-master
- The default value is `""`
- Optional flag

`--data-dir`

- The directory used to store data of DM-master
- The default value is `"default.{name}"`
- Optional flag

`--initial-cluster`

- The `"{node name}={external address}"` list used to bootstrap DM-master cluster
- The default value is `"{name}={advertise-peer-urls}"`
- This flag needs to be specified if the `join` flag is not specified. A configuration example of a 3-node cluster is `"dm-master-1=http://172.16.15.11:8291,dm-master-2=http ↪ ://172.16.15.12:8291,dm-master-3=http://172.16.15.13:8291"`

`--join`

- The existing cluster's `advertise-addr` list when a DM-master node joins this cluster
- The default value is `""`
- This flag needs to be specified if the `initial-cluster` flag is not specified. Suppose a new node joins a cluster that has 2 nodes, a configuration example is `"172.16.15.11:8261,172.16.15.12:8261"`

`--log-file`

- The output file name of the log
- The default value is `""`
- Optional flag

`-L`

- The log level
- The default value is `"info"`
- Optional flag

`--master-addr`

- The address on which DM-master listens to the client's requests
- The default value is `""`
- Required flag

`--name`

- The name of a DM-master node
- The default value is `"dm-master-{hostname}"`
- Required flag

`--peer-urls`

- The listening address for communications between DM-master nodes
- The default value is `"http://127.0.0.1:8291"`

- Required flag

`--secret-key-path`

- The path of the customized secret key for encryption and decryption
- The default value is `""`
- Optional flag

DM-worker

`--advertise-addr`

- The external address of DM-worker used to receive client requests
- The default value is `"{worker-addr}"`
- Optional flag. It can be in the form of `"domain-name:port"`

`--config`

- The configuration file path of DM-worker
- The default value is `""`
- Optional flag

`--join`

- The `{advertise-addr}` list of DM-master nodes in a cluster when a DM-worker registers to this cluster
- The default value is `""`
- Required flag. A configuration example of 3-node (DM-master node) cluster is `"172.16.15.11:8261,172.16.15.12:8261,172.16.15.13:8261"`

`--log-file`

- The output file name of the log
- The default value is `""`
- Optional flag

`-L`

- The log level
- The default value is `"info"`
- Optional flag

`--name`

- The name of a DM-worker node
- The default value is `"{advertise-addr}"`
- Required flag

`--worker-addr`

- The address on which DM-worker listens to the client's requests
- The default value is `""`
- Required flag

dmctl

`--config`

- The configuration file path of dmctl
- The default value is `""`
- Optional flag

`--master-addr`

- The `{advertise-addr}` of any DM-master node in the cluster to be connected by dmctl
- The default value is `""`
- It is a required flag when dmctl interacts with DM-master

13.6.8.4 Configuration Files

13.6.8.4.1 Data Migration Configuration File Overview

This document gives an overview of configuration files of DM (Data Migration).

DM process configuration files

- `dm-master.toml`: The configuration file of running the DM-master process, including the topology information and the logs of the DM-master. For more details, refer to DM-master Configuration File.
- `dm-worker.toml`: The configuration file of running the DM-worker process, including the topology information and the logs of the DM-worker. For more details, refer to DM-worker Configuration File.
- `source.yaml`: The configuration of the upstream database such as MySQL and MariaDB. For more details, refer to Upstream Database Configuration File.

DM migration task configuration

Data migration task creation

You can take the following steps to create a data migration task:

1. Load the data source configuration into the DM cluster using dmctl.
2. Refer to the description in the Task Configuration Guide and create the configuration file `your_task.yaml`.
3. Create the data migration task using dmctl.

Important concepts

This section shows description of some important concepts.

Concept	Description	Configuration File
`source-id`	Uniquely represents a MySQL or MariaDB instance, or a migration group with the primary-secondary structure. The maximum length of `source-id` is 32.	`source_id` of `source.yaml`; `source-id` of `task.yaml`
DM-master ID	Uniquely represents a DM-master (by the `master-addr` parameter of `dm-master.toml`)	`master-addr` of `dm-master.toml`

Concept	Description	Configuration File
DM-worker ID	Uniquely represents a DM-worker (by the `worker-addr` parameter of `dm-worker.toml`)	`worker-addr` of `dm-worker.toml`

13.6.8.4.2 Upstream Database Configuration File of TiDB Data Migration

This document introduces the configuration file of the upstream database, including a configuration file template and the description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of the upstream database:

```
source-id: "mysql-replica-01"

##### Whether to enable GTID.
enable-gtid: false

##### Whether to enable relay log.
enable-relay: false
relay-binlog-name: ""  # The file name from which DM-worker starts to pull the binlog.
relay-binlog-gtid: ""  # The GTID from which DM-worker starts to pull the binlog.
##### relay-dir: "relay-dir" # The directory used to store relay log. The default value is "relay-dir". This configuration item is marked as deprecated since v6.1 and replaced by a parameter of the same name in the dm-worker configuration.

from:
  host: "127.0.0.1"
  port: 3306
  user: "root"
  password: "ZqMLjZ2j5khNelDEfDoUhkD5aV5fIJOe0fiog9w=" # The user password of the upstream database. It is recommended to use the password
```

```
    ↪ encrypted with dmctl.
  security:                   # The TLS configuration of the upstream
    ↪ database
    ssl-ca: "/path/to/ca.pem"
    ssl-cert: "/path/to/cert.pem"
    ssl-key: "/path/to/key.pem"

##### purge:
#####  interval: 3600
#####  expires: 0
#####  remain-space: 15

##### checker:
#####  check-enable: true
#####  backoff-rollback: 5m0s
#####  backoff-max: 5m0s    # The maximum value of backoff, should be larger
   ↪  than 1s

##### Configure binlog event filters. New in DM v2.0.2
##### case-sensitive: false
##### filters:
##### - schema-pattern: dmctl
#####  table-pattern: t_1
#####  events: []
#####  sql-pattern:
#####  - alter table .* add column `aaa` int
#####  action: Ignore
```

> **Note:**
>
> In DM v2.0.1, DO NOT set `enable-gtid` and `enable-relay` to `true` at the same time. Otherwise, it may cause loss of incremental data.

Configuration parameters

This section describes each configuration parameter in the configuration file.

Global configuration

Parameter	Description
`source-id`	Represents a MySQL instance ID.

Parameter	Description
`enable-gtid`	Determines whether to pull binlog from the upstream using GTID. The default value is `false`. In general, you do not need to configure `enable-gtid` manually. However, if GTID is enabled in the upstream database, and the primary/secondary switch is required, you need to set `enable-gtid` to `true`.
`enable-relay`	Determines whether to enable the relay log feature. The default value is `false`. This parameter takes effect from v5.4. Additionally, you can enable relay log dynamically using the `start-relay` command.
`relay-binlog` ↪ `-name`	Specifies the file name from which DM-worker starts to pull the binlog. For example, `"mysql-bin.000002"`. It only works when `enable_gtid` is `false`. If this parameter is not specified, DM-worker will start pulling from the earliest binlog file being replicated. Manual configuration is generally not required.
`relay-binlog` ↪ `-gtid`	Specifies the GTID from which DM-worker starts to pull the binlog. For example, `"e9a1fc22-ec08-11e9-b2ac-0242` ↪ `ac110003:1-7849"`. It only works when `enable_gtid` is `true`. If this parameter is not specified, DM-worker will start pulling from the latest GTID being replicated. Manual configuration is generally not required.
`relay-dir`	Specifies the relay log directory.
`host`	Specifies the host of the upstream database.
`port`	Specifies the port of the upstream database.
`user`	Specifies the username of the upstream database.
`password`	Specifies the user password of the upstream database. It is recommended to use the password encrypted with dmctl.

Parameter	Description
`security`	Specifies the TLS config of the upstream database. The configured file paths of the certificates must be accessible to all nodes. If the configured file paths are local paths, then all the nodes in the cluster need to store a copy of the certificates in the same path of each host.

Relay log cleanup strategy configuration (`purge`)

Generally, there is no need to manually configure these parameters unless there is a large amount of relay logs and disk capacity is insufficient.

Parameter	Description	Default value
`interval`	Sets the time interval at which relay logs are regularly checked for expiration, in seconds.	`3600`
`expires`	Sets the expiration time for relay logs, in hours. The relay log that is not written by the relay processing unit, or does not need to be read by the existing data migration task will be deleted by DM if it exceeds the expiration time. If this parameter is not specified, the automatic purge is not performed.	`0`
`remain-space`	Sets the minimum amount of free disk space, in gigabytes. When the available disk space is smaller than this value, DM-worker tries to delete relay logs.	`15`

> **Note:**
>
> The automatic data purge strategy only takes effect when `interval` is not 0 and at least one of the two configuration items `expires` and `remain-space` is not 0.

Task status checker configuration (`checker`)

DM periodically checks the current task status and error message to determine if resuming the task will eliminate the error. If needed, DM automatically retries to resume the task.

DM adjusts the checking interval using the exponential backoff strategy. Its behaviors can be adjusted by the following configuration.

Parameter	Description
`check-enable`	Whether to enable this feature.
`backoff-rollback`	If the current checking interval of backoff strategy is larger than this value and the task status is normal, DM will try to decrease the interval.
`backoff-max`	The maximum value of checking interval of backoff strategy, must be larger than 1 second.

Binlog event filter

Starting from DM v2.0.2, you can configure binlog event filters in the source configuration file.

Parameter	Description
`case-sensitive`	Determines whether the filtering rules are case-sensitive. The default value is `false`.
`filters`	Sets binlog event filtering rules. For details, see Binlog event filter parameter explanation.

13.6.8.4.3 DM Advanced Task Configuration File

This document introduces the advanced task configuration file of Data Migration (DM), including global configuration and instance configuration.

Important concepts

For description of important concepts including `source-id` and the DM-worker ID, see Important concepts.

Task configuration file template (advanced)

The following is the task configuration file template which allows you to perform **advanced** data migration tasks.

```
---

##### ----------- Global configuration -----------
###### ********* Basic configuration *********
name: test                  # The name of the task. Should be globally
   ↪ unique.
```

```
task-mode: all              # The task mode. Can be set to `full`(only
    ↪ migrates full data)/`incremental`(replicates binlogs synchronously)/`
    ↪ all` (replicates both full data and incremental binlogs).
shard-mode: "pessimistic"   # The shard merge mode. Optional modes are ""/"
    ↪ pessimistic"/"optimistic". The "" mode is used by default which means
    ↪  sharding DDL merge is disabled. If the task is a shard merge task,
    ↪ set it to the "pessimistic" mode.
                            # After understanding the principles and
                               ↪ restrictions of the "optimistic" mode,
                               ↪ you can set it to the "optimistic" mode.
strict-optimistic-shard-mode: false # Only takes effect in the optimistic
    ↪ mode. This configuration restricts the behavior of the optimistic
    ↪ mode. The default value is false. Introduced in v7.2.0. For details,
    ↪ see https://docs.pingcap.com/tidb/v7.2/feature-shard-merge-optimistic
meta-schema: "dm_meta"      # The downstream database that stores the `meta`
    ↪  information.
timezone: "Asia/Shanghai"   # The timezone used in SQL Session. By default,
    ↪ DM uses the global timezone setting in the target cluster, which
    ↪ ensures the correctness automatically. A customized timezone does not
    ↪  affect data migration but is unnecessary.
case-sensitive: false       # Determines whether the schema/table is case-
    ↪ sensitive.
online-ddl: true            # Supports automatic processing of upstream "gh-
    ↪ ost" and "pt".
online-ddl-scheme: "gh-ost" # `online-ddl-scheme` is deprecated, so it is
    ↪ recommended to use `online-ddl`.
clean-dump-file: true       # Whether to clean up the files generated during
    ↪  data dump. Note that these include `metadata` files.
collation_compatible: "loose" # The mode to sync the default collation in `
    ↪ CREATE` SQL statements. The supported values are "loose" (by default)
    ↪  or "strict". When the value is "strict", DM explicitly appends the
    ↪ corresponding collation of the upstream to the SQL statements; when
    ↪ the value is "loose", DM does not modify the SQL statements. In "
    ↪ strict" mode, if the downstream does not support the default
    ↪ collation in the upstream, the downstream might report an error.
ignore-checking-items: []   # Ignorable checking items. For the complete
    ↪ list of ignorable checking items, see DM precheck: https://docs.

    ssl-ca: "/path/to/ca.pem"
    ssl-cert: "/path/to/cert.pem"
    ssl-key: "/path/to/key.pem"

###### ******** Feature configuration set **********
##### The routing mapping rule set between the upstream and downstream
   ↪ tables.
routes:
  route-rule-1:              # The name of the routing mapping rule.
    schema-pattern: "test_*" # The pattern of the upstream schema name,
      ↪ wildcard characters (*?) are supported.
```

```
    table-pattern: "t_*"     # The pattern of the upstream table name,
       ↪ wildcard characters (*?) are supported.
    target-schema: "test"    # The name of the downstream schema.
    target-table: "t"        # The name of the downstream table.
    # Optional. Used for extracting the source information of sharded
       ↪ schemas and tables and writing the information to the user-defined
       ↪  columns in the downstream. If these options are configured, you
       ↪ need to manually create a merged table in the downstream. For
       ↪ details, see description of table routing in <https://docs.pingcap
       ↪ .com/tidb/dev/dm-table-routing>.
    # extract-table:                                  # Extracts and writes
       ↪ the table name suffix without the t_ part to the c-table column of
       ↪  the merged table. For example, 01 is extracted and written to the
       ↪  c-table column for the sharded table t_01.
    #   table-regexp: "t_(.*)"
    #   target-column: "c_table"
    # extract-schema:                                 # Extracts and writes
       ↪ the schema name suffix without the test_ part to the c_schema
       ↪ column of the merged table. For example, 02 is extracted and
       ↪ written to the c_schema column for the sharded schema test_02.
    #   schema-regexp: "test_(.*)"
    #   target-column: "c_schema"
    # extract-source:                                 # Extracts and writes
       ↪ the source instance information to the c_source column of the
       ↪ merged table. For example, mysql-replica-01 is extracted and
       ↪ written to the c_source column for the data source mysql-replica
       ↪ -01.
    #   source-regexp: "(.*)"
    #   target-column: "c_source"
  route-rule-2:
    schema-pattern: "test_*"
    target-schema: "test"

##### The binlog event filter rule set of the matched table of the upstream
   ↪ database instance.
filters:
  filter-rule-1:                          # The name of the filtering rule.
    schema-pattern: "test_*"              # The pattern of the upstream
       ↪ schema name, wildcard characters (*?) are supported.
    table-pattern: "t_*"                  # The pattern of the upstream
       ↪ schema name, wildcard characters (*?) are supported.
    events: ["truncate table", "drop table"] # What event types to match.
    action: Ignore                        # Whether to migrate (Do) or
       ↪ ignore (Ignore) the binlog that matches the filtering rule.
  filter-rule-2:
```

```
    schema-pattern: "test_*"
    events: ["all dml"]
    action: Do

expression-filter:              # Defines the filter rules for row changes
   ↪ when migrating data. Supports defining multiple rules.
  # Filter the value of inserted `c` in `expr_filter`.`tbl` when it is even.
  even_c:                       # The name of the filter rule.
    schema: "expr_filter"       # The name of upstream database to be
       ↪ matched. Wildcard match or regular match is not supported.
    table: "tbl"                # The name of upstream table to be matched.
       ↪  Wildcard match or regular match is not supported.
    insert-value-expr: "c % 2 = 0"

##### The filter rule set of tables to be migrated from the upstream
   ↪ database instance. You can set multiple rules at the same time.
block-allow-list:               # Use black-white-list if the DM version is
   ↪  earlier than or equal to v2.0.0-beta.2.
  bw-rule-1:                    # The name of the block allow list rule.
    do-dbs: ["~^test.*", "user"] # The allow list of upstream schemas needs
       ↪ to be migrated.
    ignore-dbs: ["mysql", "account"] # The block list of upstream schemas
       ↪ needs to be migrated.
    do-tables:                  # The allow list of upstream tables needs
       ↪ to be migrated.
    - db-name: "~^test.*"
      tbl-name: "~^t.*"
    - db-name: "user"
      tbl-name: "information"
  bw-rule-2:                    # The name of the block allow list rule.
    ignore-tables:              # The block list of upstream tables needs
       ↪ to be migrated.
    - db-name: "user"
      tbl-name: "log"

##### Configuration arguments of the dump processing unit.
mydumpers:
  global:                       # The configuration name of the processing
     ↪ unit.
    threads: 4                  # The number of threads that access the
       ↪ upstream when the dump processing unit performs the precheck and
       ↪ exports data from the upstream database (4 by default)
    chunk-filesize: 64          # The size of the file generated by the
       ↪ dump processing unit (64 MB by default).
    extra-args: "--consistency none" # Other arguments of the dump
```

```
      ↪ processing unit. You do not need to manually configure table-list
      ↪ in `extra-args`, because it is automatically generated by DM.

##### Configuration arguments of the load processing unit.
loaders:
  global:                       # The configuration name of the processing
    ↪ unit.
    pool-size: 16               # The number of threads that concurrently
      ↪ execute dumped SQL files in the load processing unit (16 by
      ↪ default). When multiple instances are migrating data to TiDB at
      ↪ the same time, slightly reduce the value according to the load.
    # The directory that stores full data exported from the upstream ("./
      ↪ dumped_data" by default).
    # Supoprts a local filesystem path or an Amazon S3 path. For example, "
      ↪ s3://dm_bucket/dumped_data?endpoint=s3-website.us-east-2.amazonaws
      ↪ .com&access_key=s3accesskey&secret_access_key=s3secretkey&force_
      ↪ path_style=true"
    dir: "./dumped_data"

    # The import mode during the full import phase. The following modes are
      ↪ supported:
    # - "logical" (default). Uses TiDB Lightning's logical import mode to
      ↪ import data. Document: https://docs.pingcap.com/tidb/stable/tidb-
      ↪ lightning-logical-import-mode
    # - "physical". Uses TiDB Lightning's physical import mode to import
      ↪ data. Document: https://docs.pingcap.com/tidb/stable/tidb-
      ↪ lightning-physical-import-mode
    #   The "physical" mode is still an experimental feature and is not
      ↪ recommended in production.
    import-mode: "logical"
    #  Methods to resolve conflicts in logical import.
    # - "replace" (default). Uses the new data to replace the existing data.
    # - "ignore". Keeps the existing data, and ignores the new data.
    # - "error". Reports errors when inserting duplicated data, and then
      ↪ stops the replication task.
    on-duplicate-logical: "replace"

    #  Methods to resolve conflicts in physical import.
    # - "none". Corresponds to the "none" strategy of conflict detection in
      ↪ TiDB Lightning's physical import.
    #   (https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
      ↪ mode-usage#conflict-detection).
    #   Conflicting data is not resolved in this method. "none" has the best
      ↪ performance, but
    #   might lead to inconsistent data in the downstream database.
```

```
# - "manual". Corresponds to the "replace" strategy of conflict
    ↪ detection in TiDB Lightning's physical import.
#   (https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
    ↪ mode-usage#conflict-detection).
#   When the import encounter conflicting data, DM removes all
    ↪ conflicting records from
#   the target table and records the data in the `${meta-schema}_${name}.
    ↪ conflict_error_v3`
#   table. In this configuration file, the conflicting data is recorded
    ↪ in the
#   `dm_meta_test.conflict_error_v3` table. When the full import phase is
    ↪  completed, the
#   tasks is paused and you are prompted to query this table and manually
    ↪  resolve the
#   conflicts. You need to resume the task and enter the incremental
    ↪ phase using the `resume-task` command.
on-duplicate-physical: "none"
# The directory used for local KV sorting in the physical import mode.
    ↪ The default value of this
# configuration is the same as the `dir` configuration. For details,
    ↪ refer to TiDB Lightning document: https://docs.pingcap.com/tidb/
    ↪ stable/tidb-lightning-physical-import-mode#environment-
    ↪ requirements
sorting-dir-physical: "./dumped_data"
# Disk quota. Corresponds to the disk-quota configuration of TiDB
    ↪ Lightning. For details, refer to TiDB Lightning document: https://
    ↪ docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-mode-
    ↪ usage#configure-disk-quota-new-in-v620
disk-quota-physical: "0"
# DM performs `ADMIN CHECKSUM TABLE <table>` for each table to verify
    ↪ data integrity after the import.
# - "required" (default): performs admin checksum after the import. If
    ↪ checksum fails,
#   DM pauses the task and you need to manually handle the failure.
# - "optional": performs admin checksum after the import. If checksum
    ↪ fails, DM logs a
#   warning and continues to migrate data. The task is not paused.
# - "off": does not perform admin checksum after the import.
# If checksum fails, the import is abnormal, which means the data is
    ↪ inconsistent or lost.
# Therefore, it is recommended to always enable checksum.
checksum-physical: "required"
# Only available for physical import. Determines whether to perform the
    ↪ `ANALYZE TABLE <table>` operation for each table after the
    ↪ CHECKSUM process is completed.
```

```
    # - "required" (default). Indicates that the Analyze operation will be
       ↪ performed after the import is complete. If the analysis fails, the
       ↪  task will pause and require manual processing by the user.
    # - "optional". Indicates that the data will be analyzed after the
       ↪ import is complete. If the analysis fails, a warning log will be
       ↪ printed and the task will not be paused.
    # - "off". Indicates that no data analysis will be performed after the
       ↪ import is complete.
    # Analyze only affects statistics data and it is recommended that
       ↪ Analyze is set to off in most scenarios.
    analyze: "off"
    # Only available for physical import. The concurrency of sending KV data
       ↪  to TiKV. This can be increased when the direct network transfer
       ↪ speed between dm-worker and TiKV exceeds 10,000 Mb/s.
    # range-concurrency: 16
    # Only available for physical import mode. Whether to enable compression
       ↪  when sending KV data to TiKV. Currently, only Gzip compression is
       ↪  supported and can be specified using either "gzip" or "gz".
       ↪ Compression is not enabled by default.
    # compress-kv-pairs: ""
    # One or more PD server addresses. If no address is specified, use the
       ↪ PD address information from the TiDB query by default.
    # pd-addr: "192.168.0.1:2379"

##### Configuration arguments of the sync processing unit.
syncers:
  global:                       # The configuration name of the processing
     ↪ unit.
    worker-count: 16            # The number of concurrent threads that
       ↪ apply binlogs which have been transferred to the local (16 by
       ↪ default). Adjusting this parameter has no effect on the
       ↪ concurrency of upstream pull logs, but has a significant effect on
       ↪  the downstream database.
    batch: 100                  # The number of SQL statements in a
       ↪ transaction batch that the sync processing unit replicates to the
       ↪ downstream database (100 by default). Generally, it is recommended
       ↪  to set the value less than 500.
    enable-ansi-quotes: true    # Enable this argument if `sql-mode: "ANSI_
       ↪ QUOTES"` is set in the `session`

    # If set to true, `INSERT` statements from upstream are rewritten to `
       ↪ REPLACE` statements, and `UPDATE` statements are rewritten to `
       ↪ DELETE` and `REPLACE` statements. This ensures that DML statements
       ↪  can be imported repeatedly during data migration when there is
       ↪ any primary key or unique index in the table schema.
```

```
    safe-mode: false
    # The duration of the automatic safe mode.
    # If this value is not set or set to "", the default value is twice of `
       ↪ checkpoint-flush-interval` (30s by default), which is 60s.
    # If this value is set to "0s", DM reports an error when it
       ↪ automatically enters the safe mode.
    # If this value is set to a normal value, such as "1m30s", when the task
       ↪  pauses abnormally, when DM fails to
    # record safemode_exit_point, or when DM exits unexpectedly, the
       ↪ duration of the automatic safe mode is set to
    # 1 minute 30 seconds.
    safe-mode-duration: "60s"

    # If set to true, DM compacts as many upstream statements on the same
       ↪ rows as possible into a single statements without increasing
       ↪ latency.
    # For example, `INSERT INTO tb(a,b) VALUES(1,1); UPDATE tb SET b=11
       ↪ WHERE a=1`;` will be compacted to `INSERT INTO tb(a,b) VALUES
       ↪ (1,11);`, where "a" is the primary key
    # `UPDATE tb SET b=1 WHERE a=1; UPDATE tb(a,b) SET b=2 WHERE a=1;` will
       ↪ be compacted to `UPDATE tb(a,b) SET b=2 WHERE a=1;`, where "a" is
       ↪ the primary key
    # `DELETE FROM tb WHERE a=1; INSERT INTO tb(a,b) VALUES(1,1);` will be
       ↪ compacted to `REPLACE INTO tb(a,b) VALUES(1,1);`, where "a" is the
       ↪  primary key
    compact: false
    # If set to true, DM combines as many statements of the same type as
       ↪ possible into a single statement and generates a single SQL
       ↪ statement with multiple rows of data.
    # For example, `INSERT INTO tb(a,b) VALUES(1,1); INSERT INTO tb(a,b)
       ↪ VALUES(2,2);` will become `INSERT INTO tb(a,b) VALUES(1,1),(2,2);`
    # `UPDATE tb SET b=11 WHERE a=1; UPDATE tb(a,b) set b=22 WHERE a=2;`
       ↪ will become `INSERT INTO tb(a,b) VALUES(1,11),(2,22) ON DUPLICATE
       ↪ KEY UPDATE a=VALUES(a), b= VALUES(b);`, where "a" is the primary
       ↪ key
    # `DELETE FROM tb WHERE a=1; DELETE FROM tb WHERE a=2` will become `
       ↪ DELETE FROM tb WHERE (a) IN (1),(2)`, where "a" is the primary key
    multiple-rows: true

##### Configuration arguments of continuous data validation (validator).
validators:
  global:             # Configuration name.
    # full: validates the data in each row is correct.
    # fast: validates whether the row is successfully migrated to the
       ↪ downstream.
```

```
    # none: does not validate the data.
    mode: full        # Possible values are "full", "fast", and "none". The
       ↪ default value is "none", which does not validate the data.
    worker-count: 4   # The number of validation workers in the background.
       ↪ The default value is 4.
    row-error-delay: 30m # If a row cannot pass the validation within the
       ↪ specified time, it will be marked as an error row. The default
       ↪ value is 30m, which means 30 minutes.

##### ----------- Instance configuration -----------
mysql-instances:
  -
    source-id: "mysql-replica-01"            # The `source-id` in source.
       ↪ toml.
    meta:                                    # The position where the
       ↪ binlog replication starts when `task-mode` is `incremental` and
       ↪ the downstream database checkpoint does not exist. If the
       ↪ checkpoint exists, the checkpoint is used. If neither the `meta`
       ↪ configuration item nor the downstream database checkpoint exists,
       ↪ the migration starts from the latest binlog position of the
       ↪ upstream.

      binlog-name: binlog.000001

    ↪ according to the load.
  syncer-thread: 16                         # The number of threads that
    ↪ the sync processing unit uses for replicating incremental data. `
    ↪ syncer-thread` corresponds to the `worker-count` configuration
    ↪ item of the syncers configuration. `syncer-thread` has overriding
    ↪ priority when the two items are both configured. When multiple
    ↪ instances are migrating data to TiDB at the same time, reduce the
    ↪ value according to the load.
```

Configuration order

From the sample configuration file, you can see that the configuration file contains two parts: `Global configuration` and `Instance configuration`, where the `Global configuration` contains `Basic configuration` and `Feature configuration set`. The configuration order is as follows:

1. Edit the global configuration.
2. Edit the instance configuration based on the global configuration.

Global configuration

Basic configuration

Refer to the comments in the template to see more details. Detailed explanations about `task-mode` are as follows:

- Description: the task mode that can be used to specify the data migration task to be executed.

- Value: string (`full`, `incremental`, or `all`).
    - `full` only makes a full backup of the upstream database and then imports the full data to the downstream database.
    - `incremental`: Only replicates the incremental data of the upstream database to the downstream database using the binlog. You can set the `meta` configuration item of the instance configuration to specify the starting position of incremental replication.
    - `all`: `full` + `incremental`. Makes a full backup of the upstream database, imports the full data to the downstream database, and then uses the binlog to make an incremental replication to the downstream database starting from the exported position during the full backup process (binlog position).

Feature configuration set

Arguments in each feature configuration set are explained in the comments in the template.

Parameter	Description
`routes`	The routing mapping rule set between the upstream and downstream tables. If the names of the upstream and downstream schemas and tables are the same, this item does not need to be configured. See Table Routing for usage scenarios and sample configurations.
`filters`	The binlog event filter rule set of the matched table of the upstream database instance. If binlog filtering is not required, this item does not need to be configured. See Binlog Event Filter for usage scenarios and sample configurations.
`block-allow-list`	The filter rule set of the block allow list of the matched table of the upstream database instance. It is recommended to specify the schemas and tables that need to be migrated through this item, otherwise all schemas and tables are migrated. See Binlog Event Filter and Block & Allow Lists for usage scenarios and sample configurations.

Parameter	Description
`mydumpers`	Configuration arguments of dump processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure `thread` only using `mydumper-thread`.
`loaders`	Configuration arguments of load processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure `pool-size` only using `loader-thread`.
`syncers`	Configuration arguments of sync processing unit. If the default configuration is sufficient for your needs, this item does not need to be configured. Or you can configure `worker-count` only using `syncer-thread`.

Instance configuration

This part defines the subtask of data migration. DM supports migrating data from one or multiple MySQL instances in the upstream to the same instance in the downstream.

For the configuration details of the above options, see the corresponding part in Feature configuration set, as shown in the following table.

Option	Corresponding part
`route-rules`	`routes`
`filter-rules`	`filters`
`block-allow-list`	`block-allow-list`
`mydumper-config-name`	`mydumpers`
`loader-config-name`	`loaders`
`syncer-config-name`	`syncers`

13.6.8.4.4 DM-master Configuration File

This document introduces the configuration of DM-master, including a configuration file template and a description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of DM-master.

```
name = "dm-master"

##### log configuration
```

```
log-level = "info"
log-file = "dm-master.log"

##### DM-master listening address
master-addr = ":8261"
advertise-addr = "127.0.0.1:8261"

##### URLs for peer traffic
peer-urls = "http://127.0.0.1:8291"
advertise-peer-urls = "http://127.0.0.1:8291"

##### cluster configuration
initial-cluster = "master1=http://127.0.0.1:8291,master2=http
    ↪ ://127.0.0.1:8292,master3=http://127.0.0.1:8293"
join = ""

ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/cert.pem"
ssl-key = "/path/to/key.pem"
cert-allowed-cn = ["dm"]

secret-key-path = "/path/to/secret/key"
```

Configuration parameters

This section introduces the configuration parameters of DM-master.

Global configuration

Parameter	Description
`name`	The name of the DM-master.
`log-level`	Specifies a log level from `debug`, `info`, `warn`, `error`, and `fatal`. The default log level is `info`.
`log-file`	Specifies the log file directory. If the parameter is not specified, the logs are printed onto the standard output.
`master-addr`	Specifies the address of DM-master which provides services. You can omit the IP address and specify the port number only, such as ":8261".
`advertise-addr`	Specifies the address that DM-master advertises to the outside world.
`peer-urls`	Specifies the peer URL of the DM-master node.

Parameter	Description
`advertise-peer-urls`	Specifies the peer URL that DM-master advertises to the outside world. The value of `advertise-peer-urls` is by default the same as that of `peer-urls`.
`initial-cluster`	The value of `initial-cluster` is the combination of the `advertise-peer-urls` value of all DM-master nodes in the initial cluster.
`join`	The value of `join` is the combination of the `advertise-peer-urls` value of the existed DM-master nodes in the cluster. If the DM-master node is newly added, replace `initial-cluster` with `join`.
`ssl-ca`	The path of the file that contains list of trusted SSL CAs for DM-master to connect with other components.
`ssl-cert`	The path of the file that contains X509 certificate in PEM format for DM-master to connect with other components.
`ssl-key`	The path of the file that contains X509 key in PEM format for DM-master to connect with other components.
`cert-allowed-cn`	Common Name list.
`secret-key-path`	The file path of the secret key, which is used to encrypt and decrypt upstream and downstream passwords. The file must contain a 64-character hexadecimal AES-256 secret key. One way to generate this key is by calculating SHA256 checksum of random data, such as head -n 256 /dev/urandom | sha256sum. For more information, see Customize a secret key for DM encryption and decryption.

13.6.8.4.5 DM-worker Configuration File

This document introduces the configuration of DM worker, including a configuration file template and a description of each configuration parameter in this file.

Configuration file template

The following is a configuration file template of the DM-worker:

```
##### Worker Configuration.
```

```
name = "worker1"

##### Log configuration.
log-level = "info"
log-file = "dm-worker.log"

##### DM-worker listen address.
worker-addr = ":8262"
advertise-addr = "127.0.0.1:8262"
join = "http://127.0.0.1:8261,http://127.0.0.1:8361,http://127.0.0.1:8461"

keepalive-ttl = 60
relay-keepalive-ttl = 1800 # New in DM v2.0.2.
##### relay-dir = "relay_log" # New in 5.4.0. When you use a relative path,
    ↪ check the deployment and start method of DM-worker to determine the
    ↪ full path.

ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/cert.pem"
ssl-key = "/path/to/key.pem"
cert-allowed-cn = ["dm"]
```

Configuration parameters

Global

Parameter	Description
`name`	The name of the DM-worker.
`log-level`	Specifies a log level from `debug`, `info`, `warn`, `error`, and `fatal`. The default log level is `info`.
`log-file`	Specifies the log file directory. If this parameter is not specified, the logs are printed onto the standard output.
`worker-addr`	Specifies the address of DM-worker which provides services. You can omit the IP address and specify the port number only, such as ":8262".
`advertise-addr`	Specifies the address that DM-worker advertises to the outside world.
`join`	Corresponds to one or more `master-addrs` in the DM-master configuration file.

Parameter	Description
keepalive- ↪ ttl	The keepalive time (in seconds) of a DM-worker node to the DM-master node if the upstream data source of the DM-worker node does not enable the relay log. The default value is 60s.
relay- ↪ keepalive ↪ -ttl	The keepalive time (in seconds) of a DM-worker node to the DM-master node if the upstream data source of the DM-worker node enables the relay log. The default value is 1800s. This parameter is added since DM v2.0.2.
relay-dir	When relay log is enabled in the bound upstream data source, DM-worker stores the relay log in this directory. This parameter is new in v5.4.0 and takes precedence over the configuration of the upstream data source.
ssl-ca	The path of the file that contains list of trusted SSL CAs for DM-worker to connect with other components.
ssl-cert	The path of the file that contains X509 certificate in PEM format for DM-worker to connect with other components.
ssl-key	The path of the file that contains X509 key in PEM format for DM-worker to connect with other components.
cert-allowed ↪ -cn	Common Name list.

13.6.8.4.6 Table Selector of TiDB Data Migration

Table selector provides a match rule based on wildcard characters for schema/table. To match a specified table, configure schema-pattern/table-pattern.

Wildcard character

Table selector uses the following two wildcard characters in schema-pattern/table-
↪ pattern:

- The asterisk character (*, also called "star")
  - * matches zero or more characters. For example, doc* matches doc and document but not dodo.
  - * can only be placed at the end of the word. For example, doc* is supported, while do*c is not supported.

- The question mark (`?`)

  `?` matches exactly one character except the empty character.

Match rules

- `schema-pattern` cannot be empty.
- `table-pattern` can be empty. When you configure it as empty, only `schema` is matched according to `schema-pattern`.
- When `table-pattern` is not empty, the `schema` is matched according to `schema-pattern` and `table` is matched according to `table-pattern`. Only when both `schema` and `table` are successfully matched, you can get the match result.

Usage examples

- Matching all schemas and tables that have a `schema_` prefix in the schema name:

```
schema-pattern: "schema_*"
table-pattern: ""
```

- Matching all tables that have a `schema_` prefix in the schema name and a `table_` prefix in the table name:

```
schema-pattern = "schema_*"
table-pattern = "table_*"
```

13.6.8.5 Maintain DM Clusters Using OpenAPI

DM provides the OpenAPI feature for easily querying and operating the DM cluster, which is similar to the feature of dmctl tools.

To enable OpenAPI, perform one of the following operations:

- If your DM cluster has been deployed directly using binary, add the following configuration to the DM-master configuration file.

```
openapi = true
```

- If your DM cluster has been deployed using TiUP, add the following configuration to the topology file:

```
server_configs:
  master:
    openapi: true
```

Note:

- DM provides the specification document that meets the OpenAPI 3.0.0 standard. This document contains all the request parameters and returned values. You can copy the document yaml and preview it in Swagger Editor.
- After you deploy the DM-master nodes, you can access `http://{master-addr}/api/v1/docs` to preview the documentation online.
- Some features supported in the configuration file are not supported in OpenAPI. Their capabilities are not fully aligned. In a production environment, it is recommended to use the configuration file.

You can use the APIs to perform the following maintenance operations on the DM cluster:

13.6.8.5.1 APIs for managing clusters

- Get the information of a DM-master node
- Stop a DM-master node
- Get the information of a DM-worker node
- Stop a DM-worker node

13.6.8.5.2 APIs for managing data sources

- Create a data source
- Get a data source
- Delete the data source
- Update a data source
- Enable a data source
- Disable a data source
- Get the information of a data source
- Get the data source list
- Start the relay-log feature for data sources
- Stop the relay-log feature for data sources
- Purge relay-log files that are no longer required
- Change the bindings between the data source and DM-workers
- Get the list of schema names of a data source
- Get the list of table names of a specified schema in a data source

13.6.8.5.3 APIs for managing replication tasks

- Create a replication task
- Get a replication task
- Delete a replication task
- Update a replication task
- Start a replication task
- Stop a replication task
- Get the information of a replication task
- Get the replication task list
- Get the migration rules of a replication task
- Get the list of schema names of the data source that is associated with a replication task
- Get the list of table names of a specified schema in the data source that is associated with a replication task
- Get the CREATE statement for schemas of the data source that is associated with a replication task
- Update the CREATE statement for schemas of the data source that is associated with a replication task
- Delete a schema of the data source that is associated with a replication task

The following sections describe the specific usage of the APIs.

13.6.8.5.4 API error message template

After sending an API request, if an error occurs, the returned error message is in the following format:

```
{
    "error_msg": "",
    "error_code": ""
}
```

From the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

13.6.8.5.5 Get the information of a DM-master node

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/cluster/masters`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/cluster/masters' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
      "name": "master1",
      "alive": true,
      "leader": true,
      "addr": "127.0.0.1:8261"
    }
  ]
}
```

13.6.8.5.6 Stop a DM-master node

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

`DELETE /api/v1/cluster/masters/{master-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/cluster/masters/master1' \
  -H 'accept: */*'
```

13.6.8.5.7 Get the information of a DM-worker node

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/cluster/workers`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/cluster/workers' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
      "name": "worker1",
      "addr": "127.0.0.1:8261",
      "bound_stage": "bound",
      "bound_source_name": "mysql-01"
    }
  ]
}
```

13.6.8.5.8 Stop a DM-worker node

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

`DELETE /api/v1/cluster/workers/{worker-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/cluster/workers/worker1' \
  -H 'accept: */*'
```

13.6.8.5.9 Create a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Request URI

`POST /api/v1/sources`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
```

```
  "enable": true,
  "enable_gtid": false,
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
    "expires": 0,
    "remain_space": 15
  }
}'
```

```
{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
  "enable": true,
  "enable_gtid": false,
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
    "expires": 0,
    "remain_space": 15
  },
  "status_list": [
    {
      "source_name": "mysql-replica-01",
      "worker_name": "worker-1",
      "relay_status": {
        "master_binlog": "(mysql-bin.000001, 1979)",
        "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
```

```
      "relay_dir": "./sub_dir",
      "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
      "relay_catch_up_master": true,
      "stage": "Running"
    },
    "error_msg": "string"
  }
 ]
}
```

13.6.8.5.10 Get a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Request URI

`GET /api/v1/sources/{source-name}`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/source-1?with_status=true' \
  -H 'accept: application/json'
```

```
{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
  "enable_gtid": false,
  "enable": false,
  "flavor": "mysql",
  "task_name_list": [
    "task1"
  ],
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
```

```
    "expires": 0,
    "remain_space": 15
  },
  "status_list": [
    {
      "source_name": "mysql-replica-01",
      "worker_name": "worker-1",
      "relay_status": {
        "master_binlog": "(mysql-bin.000001, 1979)",
        "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_dir": "./sub_dir",
        "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_catch_up_master": true,
        "stage": "Running"
      },
      "error_msg": "string"
    }
  ],
  "relay_config": {
    "enable_relay": true,
    "relay_binlog_name": "mysql-bin.000002",
    "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
    "relay_dir": "./relay_log"
  }
}
```

13.6.8.5.11 Delete the data source

This API is a synchronous interface. If the request is successful, the status code of the returned body is 204.

Request URI

`DELETE /api/v1/sources/{source-name}`

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01?force=true' \
  -H 'accept: application/json'
```

13.6.8.5.12 Update a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding data source is returned.

Note:

When you use this API to update the data source configuration, make sure that there are no running tasks under the current data source.

Request URI

`PUT /api/v1/sources/{source-name}`

Example

```
curl -X 'PUT' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{
  "source": {
    "source_name": "mysql-01",
    "host": "127.0.0.1",
    "port": 3306,
    "user": "root",
    "password": "123456",
    "enable_gtid": false,
    "enable": false,
    "flavor": "mysql",
    "task_name_list": [
      "task1"
    ],
    "security": {
      "ssl_ca_content": "",
      "ssl_cert_content": "",
      "ssl_key_content": "",
      "cert_allowed_cn": [
        "string"
      ]
    },
    "purge": {
      "interval": 3600,
      "expires": 0,
      "remain_space": 15
    },
    "relay_config": {
      "enable_relay": true,
      "relay_binlog_name": "mysql-bin.000002",
```

```
    "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
    "relay_dir": "./relay_log"
   }
  }
}'
```

```
{
  "source_name": "mysql-01",
  "host": "127.0.0.1",
  "port": 3306,
  "user": "root",
  "password": "123456",
  "enable": true,
  "enable_gtid": false,
  "security": {
    "ssl_ca_content": "",
    "ssl_cert_content": "",
    "ssl_key_content": "",
    "cert_allowed_cn": [
      "string"
    ]
  },
  "purge": {
    "interval": 3600,
    "expires": 0,
    "remain_space": 15
  }
}
```

13.6.8.5.13 Enable a data source

This is a synchronous interface that enables a data source on a successful request and starts all subtasks of the task that rely on this data source in batch.

Request URI

`POST /api/v1/sources/{source-name}/enable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/enable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json'
```

13.6.8.5.14 Disable a data source

This is a synchronous interface that deactivates this data source on a successful request and stops all subtasks of the task that rely on it in batch.

Request URI

`POST /api/v1/sources/{source-name}/disable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/disable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json'
```

13.6.8.5.15 Get the data source list

This API is a synchronous interface. If the request is successful, the data source list is returned.

Request URI

`GET /api/v1/sources`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources?with_status=true' \
  -H 'accept: application/json'
```

```
{
  "data": [
    {
      "enable_gtid": false,
      "host": "127.0.0.1",
      "password": "******",
      "port": 3306,
      "purge": {
        "expires": 0,
        "interval": 3600,
        "remain_space": 15
      },
      "security": null,
      "source_name": "mysql-01",
      "user": "root"
    },
    {
      "enable_gtid": false,
      "host": "127.0.0.1",
```

```
      "password": "******",
      "port": 3307,
      "purge": {
        "expires": 0,
        "interval": 3600,
        "remain_space": 15
      },
      "security": null,
      "source_name": "mysql-02",
      "user": "root"
    }
  ],

}
```

13.6.8.5.16 Get the information of a data source

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/sources/{source-name}/status`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-replica-01/status' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
      "source_name": "mysql-replica-01",
      "worker_name": "worker-1",
      "relay_status": {
        "master_binlog": "(mysql-bin.000001, 1979)",
        "master_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_dir": "./sub_dir",
        "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
        "relay_catch_up_master": true,
        "stage": "Running"
      },
      "error_msg": "string"
    }
  ]
```

```
}
```

13.6.8.5.17 Start the relay-log feature for data sources

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a data source.

Request URI

`POST /api/v1/sources/{source-name}/relay/enable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/enable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "worker_name_list": [
    "worker-1"
  ],
  "relay_binlog_name": "mysql-bin.000002",
  "relay_binlog_gtid": "e9a1fc22-ec08-11e9-b2ac-0242ac110003:1-7849",
  "relay_dir": "./relay_log"
}'
```

13.6.8.5.18 Stop the relay-log feature for data sources

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a data source.

Request URI

`POST /api/v1/sources/{source-name}/relay/disable`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/disable' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "worker_name_list": [
    "worker-1"
  ]
}'
```

13.6.8.5.19 Purge relay log files that are no longer required

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a data source.

Request URI

`POST /api/v1/sources/{source-name}/relay/purge`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/relay/purge' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "relay_binlog_name": "mysql-bin.000002",
  "relay_dir": "string"
}'
```

13.6.8.5.20 Change the bindings between the data source and DM-workers

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn about its latest status, You can get the information of a DM-worker node.

Request URI

`POST /api/v1/sources/{source-name}/transfer`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/sources/mysql-01/transfer' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "worker_name": "worker-1"
}'
```

13.6.8.5.21 Get the list of schema names of a data source

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

`GET /api/v1/sources/{source-name}/schemas`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/source-1/schemas' \
  -H 'accept: application/json'
```

```
[
  "db1"
]
```

13.6.8.5.22 Get the list of table names of a specified schema in a data source

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

`GET /api/v1/sources/{source-name}/schemas/{schema-name}`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/sources/source-1/schemas/db1' \
  -H 'accept: application/json'
```

```
[
  "table1"
]
```

13.6.8.5.23 Create a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200. A successful request will return the information of the corresponding replication task.

Request URI

`POST /api/v1/tasks`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/tasks' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{

13.6.8.5.24 Get a replication task

This API is a synchronous interface. If the request is successful, the information of the corresponding replication task is returned.

Request URI

`GET /api/v1/tasks/{task-name}?with_status=true`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1?with_status=true' \
  -H 'accept: application/json'
```

```
{
  "name": "task-1",
  "task_mode": "all",
  "shard_mode": "pessimistic",
  "meta_schema": "dm-meta",
  "enhance_online_schema_change": true,

      }
    ]
  }
}
```

13.6.8.5.25 Delete a replication task

This interface is a synchronous interface and the Status Code of the returned body is 204 upon successful request.

Request URI

`DELETE /api/v1/tasks/{task-name}`

Example

```
curl -X 'DELETE' \
```

```
  'http://127.0.0.1:8261/api/v1/tasks/task-1' \
  -H 'accept: application/json'
```

13.6.8.5.26 Update a replication task

This interface is a synchronous interface and a successful request returns the information of the task.

> **Note:**
>
> When you use this API to update the task configuration, make sure that the task is stopped and has run into incremental sync and that only some of the fields can be updated.

Request URI

`PUT /api/v1/tasks/{task-name}`

Example

```
curl -X 'PUT' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1' \
  -H 'accept: application/json' \
  -H 'Content-Type: application/json' \
  -d '{
  "task": {
    "name": "task-1",
    "task_mode": "all",

      }
    ]
  }
}
```

13.6.8.5.27 Start a replication task

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 204. To learn the latest status of a task, You can get the information of a replication task.

Request URI

`POST /api/v1/tasks/{task-name}/start`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/start' \
  -H 'accept: */*'
```

13.6.8.5.28 Stop a replication task

This API is an asynchronous interface. If the request is successful, the status code of the returned body is 200. To learn the latest status of a task, You can get the information of a replication task.

Request URI

`POST /api/v1/tasks/{task-name}/stop`

Example

```
curl -X 'POST' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/stop' \
  -H 'accept: */*'
```

13.6.8.5.29 Get the information of a replication task

This API is a synchronous interface. If the request is successful, the information of the corresponding node is returned.

Request URI

`GET /api/v1/tasks/task-1/status`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/status?stage=running' \
  -H 'accept: application/json'
```

```
{
  "total": 1,
  "data": [
    {
```

```
    "name": "string",
    "source_name": "string",
    "worker_name": "string",
    "stage": "running",
    "unit": "sync",
    "unresolved_ddl_lock_id": "string",

      "binlog_type": "string",
      "seconds_behind_master": 0
    }
  }
]
```

```
}
```

13.6.8.5.30 Get the replication task list

This API is a synchronous interface and a successful request returns a list of the corresponding tasks.

Request URI

`GET /api/v1/tasks`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks' \
  -H 'accept: application/json'
```

```
{

        }
      ]
    }
  }
 ]
}
```

13.6.8.5.31 Get the migration rules of a replication task

This API is a synchronous interface and a successful request returns a list of the migration rules of this task.

Request URI

`GET /api/v1/tasks/{task-name}/sources/{source-name}/migrate_targets`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/migrate_
     ↪ targets' \
  -H 'accept: application/json'
```

```
{
  "total": 0,
  "data": [
```

```
    {
      "source_schema": "db1",
      "source_table": "tb1",
      "target_schema": "db1",
      "target_table": "tb1"
    }
  ]
}
```

13.6.8.5.32 Get the list of schema names of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

`GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas' \
  -H 'accept: application/json'
```

```
[
  "db1"
]
```

13.6.8.5.33 Get the list of table names of a specified schema in the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding list is returned.

Request URI

`GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-name`
`↪ }`

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1' \
  -H 'accept: application/json'
```

```
[
  "table1"
]
```

13.6.8.5.34 Get the CREATE statement for schemas of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the corresponding CREATE statement is returned.

Request URI

```
GET /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-name
↪ }/{table-name}
```

Example

```
curl -X 'GET' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1/
     ↪ table1' \
  -H 'accept: application/json'
```

```
{
  "schema_name": "db1",
  "table_name": "table1",
  "schema_create_sql": "CREATE TABLE `t1` (`id` int(11) NOT NULL AUTO_
     ↪ INCREMENT,PRIMARY KEY (`id`) /*T![clustered_index] CLUSTERED */)
     ↪ ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin"
}
```

13.6.8.5.35 Update the CREATE statement for schemas of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200.

Request URI

```
POST /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-
↪ name}/{table-name}
```

Example

```
curl -X 'PUT' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/task-1/schemas/db1/
     ↪ table1' \
  -H 'accept: */*' \
  -H 'Content-Type: application/json' \
  -d '{
  "sql_content": "CREATE TABLE `t1` ( `c1` int(11) DEFAULT NULL, `c2` int
     ↪ (11) DEFAULT NULL, `c3` int(11) DEFAULT NULL) ENGINE=InnoDB DEFAULT
     ↪ CHARSET=utf8mb4 COLLATE=utf8mb4_bin;",
  "flush": true,
  "sync": true
```

```
}'
```

13.6.8.5.36 Delete a schema of the data source that is associated with a replication task

This API is a synchronous interface. If the request is successful, the status code of the returned body is 200.

Request URI

```
DELETE /api/v1/tasks/{task-name}/sources/{source-name}/schemas/{schema-
↪ name}/{table-name}
```

Example

```
curl -X 'DELETE' \
  'http://127.0.0.1:8261/api/v1/tasks/task-1/sources/source-1/schemas/db1/
     ↪ table1' \
  -H 'accept: */*'
```

13.6.8.6 Compatibility Catalog of TiDB Data Migration

DM supports migrating data from different sources to TiDB clusters. Based on the data source type, DM has four compatibility levels:

- **Generally available (GA)**: The application scenario has been verified and passed the GA test.
- **Experimental**: Although the application scenario has been verified, the test does not cover all scenarios or involves only a limited number of users. The application scenario might encounter problems occasionally.
- **Not tested**: DM is expected to be always compatible with MySQL during iteration. However, due to resource constraints, not all MySQL forks are tested with DM. Therefore, the *not tested* source or target is technically compatible with DM, but is not fully tested, which means you need to verify its compatibility before you use.
- **Incompatible**: DM is proved to be incompatible with the data source and the application is not recommended for use in production environments.

13.6.8.6.1 Data sources

Data source	Compatibility level	Remarks
MySQL 5.5	Not tested	
MySQL 5.6	GA	

Data source	Compatibility level	Remarks
MySQL 5.7	GA	
MySQL 8.0	GA	Does not support binlog transaction compression Transaction_payload_e
MariaDB < 10.1.2	Incompatible	Incompatible with binlog of the time type
MariaDB 10.1.2 ~ 10.5.10	Experimental	
MariaDB > 10.5.10	Incompatible	Permission errors reported in the check procedure

13.6.8.6.2 Target databases

> **Warning:**
>
> DM v5.3.0 is not recommended. If you have enabled GTID replication but do not enable relay log in DM v5.3.0, data replication fails with low probability.

Target database	Compatibility level	DM version
TiDB 6.0	GA	5.3.1
TiDB 5.4	GA	5.3.1
TiDB 5.3	GA	5.3.1
TiDB 5.2	GA	2.0.7, recommended: 5.4
TiDB 5.1	GA	2.0.4, recommended: 5.4
TiDB 5.0	GA	2.0.4, recommended: 5.4
TiDB 4.x	GA	2.0.1, recommended: 2.0.7
TiDB 3.x	GA	2.0.1, recommended: 2.0.7
MySQL	Experimental	
MariaDB	Experimental	

13.6.8.7 Secure

13.6.8.7.1 Enable TLS for DM Connections

This document describes how to enable encrypted data transmission for DM connections, including connections between the DM-master, DM-worker, and dmctl components, and connections between DM and the upstream or downstream database.

Enable encrypted data transmission between DM-master, DM-worker, and dmctl

This section introduces how to enable encrypted data transmission between DM-master, DM-worker, and dmctl.

Configure and enable encrypted data transmission

1. Prepare certificates.

   It is recommended to prepare a server certificate for DM-master and DM-worker separately. Make sure that the two components can authenticate each other. You can choose to share one client certificate for dmctl.

   To generate self-signed certificates, you can use `openssl`, `cfssl` and other tools based on `openssl`, such as `easy-rsa`.

   If you choose `openssl`, you can refer to generating self-signed certificates.

2. Configure certificates.

> **Note:**
> You can configure DM-master, DM-worker, and dmctl to use the same set of certificates.

- DM-master

  Configure in the configuration file or command-line arguments:

```
ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/master-cert.pem"
ssl-key = "/path/to/master-key.pem"
```

- DM-worker

  Configure in the configuration file or command-line arguments:

```
ssl-ca = "/path/to/ca.pem"
ssl-cert = "/path/to/worker-cert.pem"
ssl-key = "/path/to/worker-key.pem"
```

- dmctl

  After enabling encrypted transmission in a DM cluster, if you need to connect to the cluster using dmctl, specify the client certificate. For example:

```
./dmctl --master-addr=127.0.0.1:8261 --ssl-ca /path/to/ca.pem --ssl
    ↪ -cert /path/to/client-cert.pem --ssl-key /path/to/client-key
    ↪ .pem
```

Verify component caller's identity

The Common Name is used for caller verification. In general, the callee needs to verify the caller's identity, in addition to verifying the key, the certificates, and the CA provided by the caller. For example, DM-worker can only be accessed by DM-master, and other visitors are blocked even though they have legitimate certificates.

To verify component caller's identity, you need to mark the certificate user identity using `Common Name` (CN) when generating the certificate, and to check the caller's identity by configuring the `Common Name` list for the callee.

- DM-master

  Configure in the configuration file or command-line arguments:

```
cert-allowed-cn = ["dm"]
```

- DM-worker

  Configure in the configuration file or command-line arguments:

```
cert-allowed-cn = ["dm"]
```

Reload certificates

To reload the certificates and the keys, DM-master, DM-worker, and dmctl reread the current certificates and the key files each time a new connection is created.

When the files specified by `ssl-ca`, `ssl-cert` or `ssl-key` are updated, restart DM components to reload the certificates and the key files and reconnect with each other.

Enable encrypted data transmission between DM components and the upstream or downstream database

This section introduces how to enable encrypted data transmission between DM components and the upstream or downstream database.

Enable encrypted data transmission for upstream database

1. Configure the upstream database, enable the encryption support, and set the server certificate. For detailed operations, see Using encrypted connections.
2. Set the MySQL client certificate in the source configuration file:

> **Note:**
> Make sure that all DM-master and DM-worker components can read the certificates and the key files via specified paths.

```
from:
    security:
        ssl-ca: "/path/to/mysql-ca.pem"
        ssl-cert: "/path/to/mysql-cert.pem"
        ssl-key: "/path/to/mysql-key.pem"
```

Enable encrypted data transmission for downstream TiDB

1. Configure the downstream TiDB to use encrypted connections. For detailed operations, refer to Configure TiDB server to use secure connections.
2. Set the TiDB client certificate in the task configuration file:

Note:

Make sure that all DM-master and DM-worker components can read the certificates and the key files via specified paths.

```
target-database:
    security:
        ssl-ca: "/path/to/tidb-ca.pem"
        ssl-cert: "/path/to/tidb-client-cert.pem"
        ssl-key: "/path/to/tidb-client-key.pem"
```

13.6.8.7.2 Generate Self-signed Certificates for TiDB Data Migration

This document provides an example of using `openssl` to generate a self-signed certificate for TiDB Data Migration (DM). You can also generate certificates and keys that meet requirements according to your demands.

Assume that the topology of the instance cluster is as follows:

Name	Host IP	Services
node1	172.16.10.11	DM-master1
node2	172.16.10.12	DM-master2
node3	172.16.10.13	DM-master3
node4	172.16.10.14	DM-worker1
node5	172.16.10.15	DM-worker2
node6	172.16.10.16	DM-worker3

Install OpenSSL

- For Debian or Ubuntu OS:

```
apt install openssl
```

- For RedHat or CentOS OS:

```
yum install openssl
```

You can also refer to OpenSSL's official download document for installation.

Generate the CA certificate

A certificate authority (CA) is a trusted entity that issues digital certificates. In practice, contact your administrator to issue the certificate or use a trusted CA. CA manages multiple certificate pairs. Here you only need to generate an original pair of certificates as follows.

1. Generate the CA key:

```
openssl genrsa -out ca-key.pem 4096
```

2. Generate the CA certificates:

```
openssl req -new -x509 -days 1000 -key ca-key.pem -out ca.pem
```

3. Validate the CA certificates:

```
openssl x509 -text -in ca.pem -noout
```

Issue certificates for individual components

Certificates that might be used in the cluster

- The `master` certificate used by DM-master to authenticate DM-master for other components.
- The `worker` certificate used by DM-worker to authenticate DM-worker for other components.
- The `client` certificate used by dmctl to authenticate clients for DM-master and DM-worker.

Issue certificates for DM-master

To issue a certificate to a DM-master instance, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out master-key.pem 2048
```

2. Make a copy of the OpenSSL configuration template file (Refer to the actual location of your template file because it might have more than one location):

```
cp /usr/lib/ssl/openssl.cnf .
```

If you do not know the actual location, look for it in the root directory:

```
find / -name openssl.cnf
```

3. Edit `openssl.cnf`, add `req_extensions = v3_req` under the `[ req ]` field, and add `subjectAltName = @alt_names` under the `[ v3_req ]` field. Finally, create a new field and edit the information of `Subject Alternative Name` (SAN) according to the cluster topology description above.

```
[ alt_names ]
IP.1 = 127.0.0.1
IP.2 = 172.16.10.11
IP.3 = 172.16.10.12
IP.4 = 172.16.10.13
```

The following checking items of SAN are currently supported:

- IP
- DNS
- URI

> **Note:**
> If a special IP such as `0.0.0.0` is to be used for connection or communication, you must also add it to `alt_names`.

4. Save the `openssl.cnf` file, and generate the certificate request file: (When giving input to `Common Name (e.g. server FQDN or YOUR name)[]:`, you assign a Common Name (CN) to the certificate, such as `dm`. It is used by the server to validate the identity of the client. Each component does not enable the validation by default. You can enable it in the configuration file.)

```
openssl req -new -key master-key.pem -out master-cert.pem -config
    ↪ openssl.cnf
```

5. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA ca.pem -CAkey ca-key.pem -
    ↪ CAcreateserial -in master-cert.pem -out master-cert.pem -
    ↪ extensions v3_req -extfile openssl.cnf
```

6. Verify that the certificate includes the SAN field (optional):

```
openssl x509 -text -in master-cert.pem -noout
```

7. Confirm that the following files exist in your current directory:

```
ca.pem
master-cert.pem
master-key.pem
```

> **Note:**
>
> The process of issuing certificates for the DM-worker instance is similar and will not be repeated in this document.

Issue certificates for the client (dmctl)

To issue a certificate to the client (dmctl), perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out client-key.pem 2048
```

2. Generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key client-key.pem -out client-cert.pem
```

3. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA ca.pem -CAkey ca-key.pem -
    ↪ CAcreateserial -in client-cert.pem -out client-cert.pem
```

13.6.8.8 Monitoring and Alerts

13.6.8.8.1 Data Migration Monitoring Metrics

If your DM cluster is deployed using TiUP, the monitoring system is also deployed at the same time. This document describes the monitoring metrics provided by DM-worker.

Task

In the Grafana dashboard, the default name of DM is `DM-task`.

`overview`

`Overview` contains some monitoring metrics of all the DM-worker and DM-master instances or sources in the currently selected task. The current default alert rule is only for a single DM-worker/DM-master instance/source.

Metric name	Description	Alert	Severity level
task state	The state of subtasks for migration	N/A	N/A
storage capacity	The total storage capacity of the disk occupied by relay logs	N/A	N/A
storage remain	The remaining storage capacity of the disk occupied by relay logs	N/A	N/A
binlog file gap between master and relay	The number of binlog files by which the `relay` processing unit is behind the upstream master	N/A	N/A
load progress	The percentage of the completed loading process of the load unit. The value is between 0%~100%	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and syncer	The number of binlog files by which the binlog replication unit is behind the upstream master	N/A	N/A
shard lock resolving	Whether the current subtask is waiting for sharding DDL migration. A value greater than 0 means that the current subtask is waiting for sharding DDL migration	N/A	N/A

Operation errors

Metric name	Description	Alert	Severity level
before any operate error	The number of errors before any operation	N/A	N/A
source bound error	The number of errors of data source binding operations	N/A	N/A

Metric name	Description	Alert	Severity level
start error	The number of errors during the start of a subtask	N/A	N/A
pause error	The number of errors during the pause of a subtask	N/A	N/A
resume error	The number of errors during the resuming of a subtask	N/A	N/A
auto-resume error	The number of errors during the auto-resuming of a subtask	N/A	N/A
update error	The number of errors during the update of a subtask	N/A	N/A
stop error	The number of errors during the stop of a subtask	N/A	N/A

High availability

Metric name	Description	Alert	Severity level
number of dm-masters start leader com-po-nents per minute	The number of DM-master attempts to enable leader related components per minute	N/A	N/A
number of work-ers in differ-ent state	The number of DM-workers in different states	Some DM-worker(s) has (have) been offline for more than one hour	critical
workers' state	The state of the DM-worker	N/A	N/A
number of worker event error	The number of different types of DM-worker errors	N/A	N/A
shard ddl error per minute	The number of different types of sharding DDL errors per minute	Any shard-ing DDL error occurs	critical

Metric name	Description	Alert	Severity level
number of pending sharding DDL operations	The number of pending sharding DDL operations	Any pending sharding DDL operation has existed for more than one hour	critical

Task state

Metric name	Description	Alert	Severity level
task state	The state of subtasks	An alert occurs when the subtask has been in the `Paused` state for more than 20 minutes	critical

Dump/Load unit

The following metrics show only when `task-mode` is in the `full` or `all` mode.

Metric name	Description	Alert	Severity level
dump progress	The percentage of the completed dumping process of the dump unit. The value range is 0%~100%	N/A	N/A
load progress	The percentage of the completed loading process of the load unit. The value range is 0%~100%	N/A	N/A
checksum progress	The percentage of the completed checksum process after the load unit finishes dumping. The value range is 0%~100%	N/A	N/A

Metric name	Description	Alert	Severity level
total bytes for load unit	The bytes processed in the parsing, in generating data KV, and in generating index KV stages of the import process by the load unit	N/A	N/A
chunk process duration	The duration of the load unit processing the data source file chunk (in seconds)	N/A	N/A
data file size	The total size of the data files (includes the `INSERT INTO` statement) in the full data imported by the load unit	N/A	N/A
dump process exits with error	The dump unit encounters an error within the DM-worker and exits	Immediate alerts	critical
load process exits with error	The load unit encounters an error within the DM-worker and exits	Immediate alerts	critical

Binlog replication

The following metrics show only when `task-mode` is in the `incremental` or `all` mode.

Metric name	Description	Alert	Severity level
remaining time to sync	The predicted remaining time it takes for `syncer` to be completely migrated with the upstream master (in minutes)	N/A	N/A
replicate lag gauge	The latency time it takes to replicate the binlog from upstream to downstream (in seconds)	N/A	N/A
replicate lag histogram	The histogram of replicating the binlog from upstream to downstream (in seconds). Note that due to different statistical mechanisms, the data might be inaccurate	N/A	N/A

Metric name	Description	Alert	Severity level
process exist with error	The binlog replication unit encounters an error within the DM-worker and exits	Immediate alerts	critical

Metric name	Description	Alert	Severity level
binlog file gap between master and syncer	The number of binlog files by which the `syncer` processing unit is behind the upstream master	An alert occurs when the number of binlog files by which the `syncer` processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical

Metric name	Description	Alert	Severity level
binlog file gap between relay and syncer	The number of binlog files by which `syncer` is behind `relay`	An alert occurs when the number of binlog files by which the `syncer` ↪ processing unit is behind the `relay` processing unit exceeds one (>1) and the condition lasts over 10 minutes	critical

Metric name	Description	Alert	Severity level
binlog event QPS	The number of binlog events received per unit of time (this number does not include the events that need to be skipped)	N/A	N/A
skipped binlog event QPS	The number of binlog events received per unit of time that need to be skipped	N/A	N/A
read binlog event duration	The duration that the binlog replication unit reads the binlog from the relay log or the upstream MySQL (in seconds)	N/A	N/A
transform binlog event duration	The duration that the binlog replication unit parses and transforms the binlog into SQL statements (in seconds)	N/A	N/A

Metric name	Description	Alert	Severity level
dispatch binlog event duration	The duration that the binlog replication unit dispatches a binlog event (in seconds)	N/A	N/A
transaction execution latency	The duration that the binlog replication unit executes the transaction to the downstream (in seconds)	N/A	N/A
binlog event size	The size of a binlog event that the binlog replication unit reads from the relay log or the upstream MySQL	N/A	N/A
DML queue remain length	The length of the remaining DML job queue	N/A	N/A
total sqls jobs	The number of newly added jobs per unit of time	N/A	N/A
finished sqls jobs	The number of finished jobs per unit of time	N/A	N/A

Metric name	Description	Alert	Severity level
statement execution latency	The duration that the binlog replication unit executes the statement to the downstream (in seconds)	N/A	N/A
add job duration	The duration that the binlog replication unit adds a job to the queue (in seconds)	N/A	N/A
DML conflict detect duration	The duration that the binlog replication unit detects the conflict in DML (in seconds)	N/A	N/A
skipped event duration	The duration that the binlog replication unit skips a binlog event (in seconds)	N/A	N/A
unsynced tables	The number of tables that have not received the shard DDL statement in the current subtask	N/A	N/A

Metric name	Description	Alert	Severity level
shard lock resolving	Whether the current subtask is waiting for the shard DDL lock to be resolved. A value greater than 0 indicates that it is waiting for the shard DDL lock to be resolved	N/A	N/A
ideal QPS	The highest QPS that can be achieved when the running time of DM is 0	N/A	N/A
binlog event row	The number of rows in a binlog event	N/A	N/A
finished transaction total	The number of finished transactions in total	N/A	N/A
replication transaction batch	The number of sql rows in the transaction executed to the downstream	N/A	N/A
flush checkpoints time interval	The time interval for flushing the checkpoints (in seconds)	N/A	N/A

Relay log

> **Note:**
>
> Currently, DM v2.0 does not support enabling the relay log feature.

Metric name	Description	Alert	Severity level
storage capacity	The storage capacity of the disk occupied by the relay log	N/A	N/A
storage remain	The remaining storage capacity of the disk occupied by the relay log	An alert is needed once the value is smaller than 10G	critical
process exits with error	The relay log encounters an error within the DM-worker and exits	Immediate alerts	critical
relay log data corruption	The number of corrupted relay log files	Immediate alerts	emergency

Metric name	Description	Alert	Severity level
fail to read binlog from master	The number of errors encountered when the relay log reads the binlog from the upstream MySQL	Immediate alerts	critical
fail to write relay log	The number of errors encountered when the relay log writes the binlog to disks	Immediate alerts	critical
binlog file index	The largest index number of relay log files. For example, “value = 1” indicates “relay-log.000001”	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and relay	The number of binlog files in the relay log that are behind the upstream master	An alert occurs when the number of binlog files by which the `relay` processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical
binlog pos	The write offset of the latest relay log file	N/A	N/A

Metric name	Description	Alert	Severity level
read binlog event duration	The duration that the relay log reads binlog from the upstream MySQL (in seconds)	N/A	N/A
write relay log duration	The duration that the relay log writes binlog into the disks each time (in seconds)	N/A	N/A
binlog event size	The size of a single binlog event that the relay log writes into the disks	N/A	N/A

Instance

In the Grafana dashboard, the default name of an instance is `DM-instance`.

Relay log

Metric name	Description	Alert	Severity level
storage capacity	The total storage capacity of the disk occupied by the relay log	N/A	N/A

Metric name	Description	Alert	Severity level
storage remain	The remaining storage capacity within the disk occupied by the relay log	An alert occurs once the value is smaller than 10G	critical
process exits with error	The relay log encounters an error in DM-worker and exits	Immediate alerts	critical
relay log data corruption	The number of corrupted relay logs	Immediate alerts	emergency
fail to read binlog from master	The number of errors encountered when relay log reads the binlog from the upstream MySQL	Immediate alerts	critical
fail to write relay log	The number of errors encountered when the relay log writes the binlog to disks	Immediate alerts	critical

Metric name	Description	Alert	Severity level
binlog file index	The largest index number of relay log files. For example, “value = 1” indicates “relay-log.000001”	N/A	N/A

Metric name	Description	Alert	Severity level
binlog file gap between master and relay	The number of binlog files by which the `relay` processing unit is behind the upstream master	An alert occurs when the number of binlog files by which the `relay` processing unit is behind the upstream master exceeds one (>1) and the condition lasts over 10 minutes	critical
binlog pos	The write offset of the latest relay log file	N/A	N/A

Metric name	Description	Alert	Severity level
read binlog duration	The duration that the relay log reads the binlog from the upstream MySQL (in seconds)	N/A	N/A
write relay log duration	The duration that the relay log writes the binlog into the disk each time (in seconds)	N/A	N/A
binlog size	The size of a single binlog event that the relay log writes into the disks	N/A	N/A

Task

Metric name	Description	Alert	Severity level
task state	The state of subtasks for migration	An alert occurs when the sub-task has been paused for more than 10 min-utes	critical

Metric name	Description	Alert	Severity level
load progress	The percentage of the completed loading process of the load unit. The value range is 0%~100%	N/A	N/A
binlog file gap between master and syncer	The number of binlog files by which the binlog replication unit is behind the upstream master	N/A	N/A
shard lock resolving	Whether the current subtask is waiting for sharding DDL migration. A value greater than 0 means that the current subtask is waiting for sharding DDL migration	N/A	N/A

13.6.8.8.2 DM Alert Information

The alert system is deployed by default when you deploy a DM cluster using TiUP.

For more information about DM alert rules and the solutions, refer to handle alerts.

Both DM alert information and monitoring metrics are based on Prometheus. For more

information about their relationship, refer to DM monitoring metrics.

13.6.8.9 Handle Errors in TiDB Data Migration

This document introduces the error system and how to handle common errors when you use DM.

13.6.8.9.1 Error system

In the error system, usually, the information of a specific error is as follows:

- `code`: error code.

  DM uses the same error code for the same error type. An error code does not change as the DM version changes.

  Some errors might be removed during the DM iteration, while the error codes are not. DM uses a new error code instead of an existing one for a new error.

- `class`: error type.

  It is used to mark the component where an error occurs (error source).

  The following table displays all error types, error sources, and error samples.

  |

  Error Type

```
|   Error Source          | Error Sample
   ↪                                                |
```

  :———— | :———————— | :————————————

```
relay-event-lib| Executing the basic functions of the relay module | [code=28001:
↪ class=relay-event-lib:scope=internal:level=high] parse server-uuid.
↪ index |

↪ scheduler:scope=internal:level=high],"the scheduler has not started"
|
dmctl | An error occurs within dmctl or when it interacts with other components |
[code=48001:class=dmctl:scope=internal:level=high],"can not create grpc
↪  connection" |
```

- `scope`: Error scope.

  It is used to mark the scope and source of DM objects when an error occurs. `scope` includes four types: `not-set`, `upstream`, `downstream`, and `internal`.

  If the logic of the error directly involves requests between upstream and downstream databases, the scope is set to `upstream` or `downstream`; otherwise, it is currently set to `internal`.

- `level`: Error level.

  The severity level of the error, including `low`, `medium`, and `high`.

  - The `low` level error usually relates to user operations and incorrect inputs. It does not affect migration tasks.
  - The `medium` level error usually relates to user configurations. It affects some newly started services; however, it does not affect the existing DM migration status.
  - The `high` level error usually needs your attention, since you need to resolve it to avoid the possible interruption of a migration task.

- `message`: Error descriptions.

  Detailed descriptions of the error. To wrap and store every additional layer of error message on the error call chain, the errors.Wrap mode is adopted. The message description wrapped at the outermost layer indicates the error in DM and the message description wrapped at the innermost layer indicates the error source.

- `workaround`: Error handling methods (optional)

  The handling methods for this error. For some confirmed errors (such as configuration errors), DM gives the corresponding manual handling methods in `workaround`.

- Error stack information (optional)

  Whether DM outputs the error stack information depends on the error severity and the necessity. The error stack records the complete stack call information when the error occurs. If you cannot figure out the error cause based on the basic information and the error message, you can trace the execution path of the code when the error occurs using the error stack.

For the complete list of error codes, refer to the error code lists.

13.6.8.9.2 Troubleshooting

If you encounter an error while running DM, take the following steps to troubleshoot this error:

1. Execute the `query-status` command to check the task running status and the error output.
2. Check the log files related to the error. The log files are on the DM-master and DM-worker nodes. To get key information about the error, refer to the error system. Then check the Handle Common Errors section to find the solution.
3. If the error is not covered in this document, and you cannot solve the problem by checking the log or monitoring metrics, get support from PingCAP or the community.
4. After the error is resolved, restart the task using dmctl.

```
resume-task ${task name}
```

However, you need to reset the data migration task in some cases. For details, refer to Reset the Data Migration Task.

13.6.8.9.3 Handle common errors

|

Error Code

Error Description	How to Handle
`code=10001`	Abnormal database operation.	Further analyze the error message and error stack.
`code=10002`	The `bad connection` error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is not sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, check the network or TiDB status.
`code=10003`	The `invalid connection` error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is partly sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, further check the error message and analyze the information based on the actual situation.
`code=10005`	Occurs when performing the `QUERY` type SQL statements.	
`code=10006`	Occurs when performing the `EXECUTE` type SQL statements, including DDL statements and DML statements of the `INSERT`, `UPDATE`or `DELETE` type. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.	
`code=11006`	Occurs when the built-in parser of DM parses the incompatible DDL statements.	Refer to Data Migration - incompatible DDL statements for solution.
`code=20010`	Occurs when decrypting the database password that is provided in task configuration.	Check whether the downstream database password provided in the configuration task is correctly encrypted using dmctl.
`code=26002`	The task check fails to establish database connection. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.	Check whether the machine where DM-master is located has permission to access the upstream.
`code=32001`	Abnormal dump processing unit	If the error message contains `mydumper: argument list too long.`, configure the table to be exported by manually adding the `--regex` regular expression in the Mydumper argument `extra-args` in the `task.yaml` file according to the block-allow list. For example, to export all tables named `hello`, add `--regex '.*\\.hello$'`; to export all tables, add `--regex '.*'`.
`code=38008`	An error occurs in the gRPC communication among DM components.	Check `class`. Find out the error occurs in the interaction of which components. Determine the type of communication error. If the error occurs when establishing gRPC connection, check

whether the communication server is working normally. |

What can I do when a migration task is interrupted with the `invalid connection` error returned?

Reason

The `invalid connection` error indicates that anomalies have occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy) and that a part of the data for the current request has been sent to TiDB.

Solutions

Because DM has the feature of concurrently migrating data to the downstream in migration tasks, several errors might occur when a task is interrupted. You can check these errors by using `query-status`.

- If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
- If DM does not or fails to retry automatically because of version problems, use `stop-task` to stop the task and then use `start-task` to restart the task.

A migration task is interrupted with the `driver: bad connection` error returned

Reason

The `driver: bad connection` error indicates that anomalies have occurred in the connection between DM and the upstream TiDB database (such as network failure and TiDB restart) and that the data of the current request has not yet been sent to TiDB at that moment.

Solution

The current version of DM automatically retries on error. If you use the previous version which does not support automatically retry, you can execute the `stop-task` command to stop the task. Then execute `start-task` to restart the task.

The relay unit throws error `event from * in * diff from passed-in event *` or a migration task is interrupted with failing to get or parse binlog errors like `get binlog error ERROR 1236 (HY000)` and `binlog checksum mismatch, data may be corrupted` returned

Reason

During the DM process of relay log pulling or incremental replication, this two errors might occur if the size of the upstream binlog file exceeds **4 GB**.

Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the size of the binlog file, and store the replicated binlog positions as checkpoints. However, the official MySQL uses `uint32` to store binlog positions. This means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

Solutions

For relay units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the DM-worker.

3. Copy the corresponding binlog file in the upstream to the relay log directory as the relay log file.

4. In the relay log directory, update the corresponding `relay.meta` file to pull from the next binlog file. If you have specified `enable_gtid` to `true` for the DM-worker, you need to modify the GTID corresponding to the next binlog file when updating the `relay.meta` file. Otherwise, you don't need to modify the GTID.

   Example: when the error occurs, `binlog-name = "mysql-bin.004451"` and `binlog-pos = 2453`. Update them respectively to `binlog-name = "mysql-bin.004452"` and `binlog-pos = 4`, and update `binlog-gtid` to `f0e914ef-54cf-11e7-813d-6c92bf2fa791:1-138218058`.

5. Restart the DM-worker.

For binlog replication processing units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the migration task using `stop-task`.

3. Update the `binlog_name` in the global checkpoints and in each table checkpoint of the downstream `dm_meta` database to the name of the binlog file in error; update `binlog_pos` to a valid position value for which migration has completed, for example, 4.

   Example: the name of the task in error is `dm_test`, the corresponding `source-id` is `replica-1`, and the corresponding binlog file is `mysql-bin|000001.004451`. Execute the following command:

   ```
   UPDATE dm_test_syncer_checkpoint SET binlog_name='mysql-bin|000001.004451', binlog_pos = 4 WHERE id='replica-1';
   ```

4. Specify `safe-mode: true` in the `syncers` section of the migration task configuration to ensure re-entrant.

5. Start the migration task using `start-task`.

6. View the status of the migration task using `query-status`. You can restore `safe-mode` to the original value and restart the migration task when migration is done for the original error-triggering relay log files.

`Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you query the task or check the log

For database related passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. For how to encrypt the plaintext password, see Encrypt the database password using dmctl.

In addition, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data migration task.

The `load` processing unit reports the error `packet for query is too large. Try adjusting the 'max_allowed_packet' variable`

Reasons

- Both MySQL client and MySQL/TiDB server have the quota limits for `max_allowed_packet`. If any `max_allowed_packet` exceeds a limit, the client receives the error message. Currently, for the latest version of DM and TiDB server, the default value of `max_allowed_packet` is `64M`.
- The full data import processing unit in DM does not support splitting the SQL file exported by the Dump processing unit in DM.

Solutions

- It is recommended to set the `statement-size` option of `extra-args` for the Dump processing unit:

  According to the default `--statement-size` setting, the default size of `Insert Statement` generated by the Dump processing unit is about `1M`. With this default setting, the load processing unit does not report the error `packet for query is too large. Try adjusting the 'max_allowed_packet' variable` in most cases.

  Sometimes you might receive the following `WARN` log during the data dump. This `WARN` log does not affect the dump process. This only means that wide tables are dumped.

  ```
  Row bigger than statement_size for xxx
  ```

- If the single row of the wide table exceeds `64M`, you need to modify the following configurations and make sure the configurations take effect.
  - Execute `set @@global.max_allowed_packet=134217728` (`134217728` = 128 MB) in the TiDB server.
  - First add the `max-allowed-packet: 134217728` (128 MB) to the `target-database` section in the DM task configuration file. Then, execute the `stop-task` command and execute the `start-task` command.

13.6.8.10 TiDB Data Migration Glossary

This document lists the terms used in the logs, monitoring, configurations, and documentation of TiDB Data Migration (DM).

13.6.8.10.1 B

Binlog

In TiDB DM, binlogs refer to the binary log files generated in the TiDB database. It has the same indications as that in MySQL or MariaDB. Refer to MySQL Binary Log and MariaDB Binary Log for details.

Binlog event

Binlog events are information about data modification made to a MySQL or MariaDB server instance. These binlog events are stored in the binlog files. Refer to MySQL Binlog Event and MariaDB Binlog Event for details.

Binlog event filter

Binlog event filter is a more fine-grained filtering feature than the block and allow lists filtering rule. Refer to binlog event filter for details.

Binlog position

The binlog position is the offset information of a binlog event in a binlog file. Refer to MySQL `SHOW BINLOG EVENTS` and MariaDB `SHOW BINLOG EVENTS` for details.

Binlog replication processing unit/sync unit

Binlog replication processing unit is the processing unit used in DM-worker to read upstream binlogs or local relay logs, and to migrate these logs to the downstream. Each subtask corresponds to a binlog replication processing unit. In the current documentation, the binlog replication processing unit is also referred to as the sync processing unit.

Block & allow table list

Block & allow table list is the feature that filters or only migrates all operations of some databases or some tables. Refer to block & allow table lists for details. This feature is similar to MySQL Replication Filtering and MariaDB Replication Filters.

13.6.8.10.2 C

Checkpoint

A checkpoint indicates the position from which a full data import or an incremental replication task is paused and resumed, or is stopped and restarted.

- In a full import task, a checkpoint corresponds to the offset and other information of the successfully imported data in a file that is being imported. A checkpoint is updated synchronously with the data import task.

- In an incremental replication, a checkpoint corresponds to the binlog position and other information of a binlog event that is successfully parsed and migrated to the downstream. A checkpoint is updated after the DDL operation is successfully migrated or 30 seconds after the last update.

In addition, the `relay.meta` information corresponding to a relay processing unit works similarly to a checkpoint. A relay processing unit pulls the binlog event from the upstream and writes this event to the relay log, and writes the binlog position or the GTID information corresponding to this event to `relay.meta`.

13.6.8.10.3 D

Dump processing unit/dump unit

The dump processing unit is the processing unit used in DM-worker to export all data from the upstream. Each subtask corresponds to a dump processing unit.

13.6.8.10.4 G

GTID

The GTID is the global transaction ID of MySQL or MariaDB. With this feature enabled, the GTID information is recorded in the binlog files. Multiple GTIDs form a GTID set. Refer to MySQL GTID Format and Storage and MariaDB Global Transaction ID for details.

13.6.8.10.5 L

Load processing unit/load unit

The load processing unit is the processing unit used in DM-worker to import the fully exported data to the downstream. Each subtask corresponds to a load processing unit. In the current documentation, the load processing unit is also referred to as the import processing unit.

13.6.8.10.6 M

Migrate/migration

The process of using the TiDB Data Migration tool to copy the **full data** of the upstream database to the downstream database.

In the case of clearly mentioning “full”, not explicitly mentioning “full or incremental”, and clearly mentioning “full + incremental”, use migrate/migration instead of replicate/replication.

13.6.8.10.7 R

Relay log

The relay log refers to the binlog files that DM-worker pulls from the upstream MySQL or MariaDB, and stores in the local disk. The format of the relay log is the standard binlog file, which can be parsed by tools such as mysqlbinlog of a compatible version. Its role is similar to MySQL Relay Log and MariaDB Relay Log.

For more details such as the relay log's directory structure, initial migration rules, and data purge in TiDB DM, see TiDB DM relay log.

Relay processing unit

The relay processing unit is the processing unit used in DM-worker to pull binlog files from the upstream and write data into relay logs. Each DM-worker instance has only one relay processing unit.

Replicate/replication

The process of using the TiDB Data Migration tool to copy the **incremental data** of the upstream database to the downstream database.

In the case of clearly mentioning "incremental", use replicate/replication instead of migrate/migration.

13.6.8.10.8 S

Safe mode

Safe mode is the mode in which DML statements can be imported more than once when the primary key or unique index exists in the table schema. In this mode, some statements from the upstream are migrated to the downstream only after they are re-written. The `INSERT` statement is re-written as `REPLACE`; the `UPDATE` statement is re-written as `DELETE` and `REPLACE`.

This mode is enabled in any of the following situations:

- The safe mode remains enabled when the `safe-mode` parameter in the task configuration file is set to `true`.
- In shard merge scenarios, the safe mode remains enabled before DDL statements are replicated in all sharded tables.
- If the argument `--consistency none` is configured for the dump processing unit of a full migration task, it cannot be determined whether the binlog changes at the beginning of the export affect the exported data or not. Therefore, the safe mode remains enabled for the incremental replication of these binlog changes.
- If the task is paused by error and then resumed, the operations on some data might be executed twice.

Shard DDL

The shard DDL is the DDL statement that is executed on the upstream sharded tables. It needs to be coordinated and migrated by TiDB DM in the process of merging the sharded tables. In the current documentation, the shard DDL is also referred to as the sharding DDL.

Shard DDL lock

The shard DDL lock is the lock mechanism that coordinates the migration of shard DDL. Refer to the implementation principles of merging and migrating data from sharded tables in the pessimistic mode for details. In the current documentation, the shard DDL lock is also referred to as the sharding DDL lock.

Shard group

A shard group is all the upstream sharded tables to be merged and migrated to the same table in the downstream. Two-level shard groups are used for implementation of TiDB DM. Refer to the implementation principles of merging and migrating data from sharded tables in the pessimistic mode for details. In the current documentation, the shard group is also referred to as the sharding group.

Subtask

The subtask is a part of a data migration task that is running on each DM-worker instance. In different task configurations, a single data migration task might have one subtask or multiple subtasks.

Subtask status

The subtask status is the status of a data migration subtask. The current status options include `New`, `Running`, `Paused`, `Stopped`, and `Finished`. Refer to subtask status for more details about the status of a data migration task or subtask.

13.6.8.10.9 T

Table routing

The table routing feature enables DM to migrate a certain table of the upstream MySQL or MariaDB instance to the specified table in the downstream, which can be used to merge and migrate sharded tables. Refer to table routing for details.

Task

The data migration task, which is started after you successfully execute a `start-task` ↪ command. In different task configurations, a single migration task can run on a single DM-worker instance or on multiple DM-worker instances at the same time.

Task status

The task status refers to the status of a data migration task. The task status depends on the statuses of all its subtasks. Refer to subtask status for details.

13.6.8.11 Example

13.6.8.11.1 Migrate Data Using Data Migration

This guide shows how to migrate data using the Data Migration (DM) tool.

Step 1: Deploy the DM cluster

It is recommended to deploy the DM cluster using TiUP. You can also deploy the DM cluster using binary for trial or test.

Note:

- For database passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. See Encrypt the database password using dmctl.
- The user of the upstream and downstream databases must have the corresponding read and write privileges.

Step 2: Check the cluster information

After the DM cluster is deployed using TiUP, the configuration information is like what is listed below.

- The configuration information of related components in the DM cluster:

Component	Host	Port
dm_worker1	172.16.10.72	8262
dm_worker2	172.16.10.73	8262
dm_master	172.16.10.71	8261

- The information of upstream and downstream database instances:

Database instance	Host	Port	Username	Encrypted password
Upstream MySQL-1	172.16.10.81	3306	root	VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=
Upstream MySQL-2	172.16.10.82	3306	root	VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU=
Downstream TiDB	172.16.10.83	4000	root	

The list of privileges needed on the MySQL host can be found in the precheck documentation.

Step 3: Create data source

1. Write MySQL-1 related information to `conf/source1.yaml`:

```
# MySQL1 Configuration.

source-id: "mysql-replica-01"
# This indicates that whether DM-worker uses Global Transaction
    ↪ Identifier (GTID) to pull binlog. Before you use this
    ↪ configuration item, make sure that the GTID mode is enabled in
    ↪ the upstream MySQL.
enable-gtid: false

from:
  host: "172.16.10.81"
  user: "root"
  password: "VjX8cEeTX+qcvZ3bPaO4h0C80pe/1aU="
  port: 3306
```

2. Execute the following command in the terminal, and use `tiup dmctl` to load the MySQL-1 data source configuration to the DM cluster:

```
tiup dmctl --master-addr 172.16.10.71:8261 operate-source create conf/
    ↪ source1.yaml
```

3. For MySQL-2, modify the relevant information in the configuration file and execute the same `dmctl` command.

Step 4: Configure the data migration task

The following example assumes that you need to migrate all the `test_table` table data in the `test_db` database of both the upstream MySQL-1 and MySQL-2 instances, to the downstream `test_table` table in the `test_db` database of TiDB, in the full data plus incremental data mode.

Edit the `task.yaml` task configuration file as below:

```
##### The task name. You need to use a different name for each of the
    ↪ multiple tasks that
##### run simultaneously.
name: "test"
##### The full data plus incremental data (all) migration mode.
task-mode: "all"
##### The downstream TiDB configuration information.
target-database:
  host: "172.16.10.83"
  port: 4000
  user: "root"
  password: ""
```

```
##### Configuration of all the upstream MySQL instances required by the
    ↪ current data migration task.
mysql-instances:
-
  # The ID of upstream instances or the migration group. You can refer to
     ↪ the configuration of `source_id` in the "inventory.ini" file or in
     ↪ the "dm-master.toml" file.
  source-id: "mysql-replica-01"
  # The configuration item name of the block and allow lists of the name of
     ↪ the
  # database/table to be migrated, used to quote the global block and allow
  # lists configuration that is set in the global block-allow-list below.
  block-allow-list: "global" # Use black-white-list if the DM version is
     ↪ earlier than or equal to v2.0.0-beta.2.
  # The configuration item name of the dump processing unit, used to quote
     ↪ the global configuration of the dump unit.
  mydumper-config-name: "global"

-
  source-id: "mysql-replica-02"
  block-allow-list: "global" # Use black-white-list if the DM version is
     ↪ earlier than or equal to v2.0.0-beta.2.
  mydumper-config-name: "global"

##### The global configuration of block and allow lists. Each instance can
    ↪ quote it by the
##### configuration item name.
block-allow-list:                 # Use black-white-list if the DM version
    ↪ is earlier than or equal to v2.0.0-beta.2.
  global:
    do-tables:                    # The allow list of upstream tables to be
       ↪ migrated.
    - db-name: "test_db"          # The database name of the table to be
       ↪ migrated.
      tbl-name: "test_table"      # The name of the table to be migrated.

##### The global configuration of the dump unit. Each instance can quote it
    ↪ by the configuration item name.
mydumpers:
  global:
    extra-args: ""
```

Step 5: Start the data migration task

To detect possible errors of data migration configuration in advance, DM provides the

precheck feature:

- DM automatically checks the corresponding privileges and configuration while starting the data migration task.
- You can also use the `check-task` command to manually precheck whether the upstream MySQL instance configuration satisfies the DM requirements.

For details about the precheck feature, see Precheck the upstream MySQL instance configuration.

> **Note:**
>
> Before starting the data migration task for the first time, you should have got the upstream configured. Otherwise, an error is reported while you start the task.

Run the `tiup dmctl` command to start the data migration tasks. `task.yaml` is the configuration file that is edited above.

```
tiup dmctl --master-addr 172.16.10.71:8261 start-task ./task.yaml
```

- If the above command returns the following result, it indicates the task is successfully started.

```
{
    "result": true,
    "msg": "",
    "workers": [
        {
            "result": true,
            "worker": "172.16.10.72:8262",
            "msg": ""
        },
        {
            "result": true,
            "worker": "172.16.10.73:8262",
            "msg": ""
        }
    ]
}
```

- If you fail to start the data migration task, modify the configuration according to the returned prompt and then run the `start-task task.yaml` command to restart the task.

Step 6: Check the data migration task

If you need to check the task state or whether a certain data migration task is running in the DM cluster, run the following command in `tiup dmctl`:

```
tiup dmctl --master-addr 172.16.10.71:8261 query-status
```

Step 7: Stop the data migration task

If you do not need to migrate data any more, run the following command in `tiup dmctl` to stop the task:

```
tiup dmctl --master-addr 172.16.10.71:8261 stop-task test
```

`test` is the task name that you set in the `name` configuration item of the `task.yaml` configuration file.

Step 8: Monitor the task and check logs

Assuming that Prometheus, Alertmanager, and Grafana are successfully deployed along with the DM cluster deployment using TiUP, and the Grafana address is `172.16.10.71`. To view the alert information related to DM, you can open http://172.16.10.71:9093 in a browser and enter into Alertmanager; to check monitoring metrics, go to http://172.16.10.71:3000, and choose the DM dashboard.

While the DM cluster is running, DM-master, DM-worker, and dmctl output the monitoring metrics information through logs. The log directory of each component is as follows:

- DM-master log directory: It is specified by the `--log-file` DM-master process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-master node.
- DM-worker log directory: It is specified by the `--log-file` DM-worker process parameter. If DM is deployed using TiUP, the log directory is `{log_dir}` in the DM-worker node.

13.6.8.11.2 Create a Data Migration Task

This document describes how to create a simple data migration task after the DM cluster is successfully deployed.

Sample scenario

Suppose that you create a data migration task based on this sample scenario:

- Deploy two MySQL instances with binlog enabled and one TiDB instance locally
- Use a DM-master of the DM cluster to manage the cluster and data migration tasks.

The information of each node is as follows.

Instance	Server Address	Port
MySQL1	127.0.0.1	3306
MySQL2	127.0.0.1	3307
TiDB	127.0.0.1	4000
DM-master	127.0.0.1	8261

Based on this scenario, the following sections describe how to create a data migration task.

Start upstream MySQL

Prepare 2 runnable MySQL instances. You can also use Docker to quickly start MySQL. The commands are as follows:

```
docker run --rm --name mysql-3306 -p 3306:3306 -e MYSQL_ALLOW_EMPTY_PASSWORD
    ↪ =true mysql:5.7.22 --log-bin=mysql-bin --port=3306 --bind-address
    ↪ =0.0.0.0 --binlog-format=ROW --server-id=1 --gtid_mode=ON --enforce-
    ↪ gtid-consistency=true > mysql.3306.log 2>&1 &
docker run --rm --name mysql-3307 -p 3307:3307 -e MYSQL_ALLOW_EMPTY_PASSWORD
    ↪ =true mysql:5.7.22 --log-bin=mysql-bin --port=3307 --bind-address
    ↪ =0.0.0.0 --binlog-format=ROW --server-id=1 --gtid_mode=ON --enforce-
    ↪ gtid-consistency=true > mysql.3307.log 2>&1 &
```

Prepare data

- Write example data into mysql-3306:

```
drop database if exists `sharding1`;
create database `sharding1`;
use `sharding1`;
create table t1 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
create table t2 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
insert into t1 (id, uid, name) values (1, 10001, 'Gabriel García
    ↪ Márquez'), (2 ,10002, 'Cien años de soledad');
insert into t2 (id, uid, name) values (3,20001, 'José Arcadio Buendía'
    ↪ ), (4,20002, 'Úrsula Iguarán'), (5,20003, 'José Arcadio');
```

- Write example data into mysql-3307:

```
drop database if exists `sharding2`;
create database `sharding2`;
use `sharding2`;
```

```
create table t2 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
create table t3 (id bigint, uid int, name varchar(80), info varchar
    ↪ (100), primary key (`id`), unique key(`uid`)) DEFAULT CHARSET=
    ↪ utf8mb4;
insert into t2 (id, uid, name, info) values (6, 40000, 'Remedios
    ↪ Moscote', '{}');
insert into t3 (id, uid, name, info) values (7, 30001, 'Aureliano José
    ↪ ', '{}'), (8, 30002, 'Santa Sofía de la Piedad', '{}'), (9,
    ↪ 30003, '17 Aurelianos', NULL);
```

Start downstream TiDB

To run a TiDB server, use the following command:

```
wget https://download.pingcap.org/tidb-community-server-v8.4.0-linux-amd64.
    ↪ tar.gz
tar -xzvf tidb-latest-linux-amd64.tar.gz
mv tidb-latest-linux-amd64/bin/tidb-server ./
./tidb-server
```

> **Warning:**
>
> The deployment method of TiDB in this document **do not apply** to production or development environments.

Configure the MySQL data source

Before starting a data migration task, you need to configure the MySQL data source.

Encrypt the password

> **Note:**
>
> - You can skip this step if the database does not have a password.
> - You can use the plaintext password to configure the source information in DM v1.0.6 and later versions.

For safety reasons, it is recommended to configure and use encrypted passwords. You can use dmctl to encrypt the MySQL/TiDB password. Suppose the password is "123456":

> **Note:**
>
> Starting from v8.0.0, you must configure `secret-key-path` for DM-master before using the `dmctl encrypt` command.

```
./dmctl encrypt "123456"
```

```
fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg=
```

Save this encrypted value, and use it for creating a MySQL data source in the following steps.

Edit the source configuration file

Write the following configurations to `conf/source1.yaml`.

```
##### MySQL1 Configuration.

source-id: "mysql-replica-01"

##### Indicates whether GTID is enabled
enable-gtid: true

from:
  host: "127.0.0.1"
  user: "root"
  password: "fCxfQ9XKCezSzuCD0Wf5dUD+LsKegSg="
  port: 3306
```

In MySQL2 data source, copy the above configurations to `conf/source2.yaml`. You need to change `name` to `mysql-replica-02` and change `password` and `port` to appropriate values.

Create a source

To load the data source configurations of MySQL1 into the DM cluster using dmctl, run the following command in the terminal:

```
./dmctl --master-addr=127.0.0.1:8261 operate-source create conf/source1.
    ↪ yaml
```

For MySQL2, replace the configuration file in the above command with that of MySQL2.

Create a data migration task

After importing prepared data, there are several sharded tables on both MySQL1 and MySQL2 instances. These tables have identical structure and the same prefix “t” in the

table names; the databases where these tables are located are all prefixed with "sharding"; and there is no conflict between the primary keys or the unique keys (in each sharded table, the primary keys or the unique keys are different from those of other tables).

Now, suppose that you need to migrate these sharded tables to the `db_target.t_target` table in TiDB. The steps are as follows.

1. Create the configuration file of the task:

```
---
name: test
task-mode: all
shard-mode: "pessimistic"
target-database:
  host: "127.0.0.1"
  port: 4000
  user: "root"
  password: "" # It is recommended to use password encrypted with dmctl
     ↪  if the password is not empty.

mysql-instances:
  - source-id: "mysql-replica-01"
    block-allow-list: "instance" # This configuration applies to DM
       ↪ versions higher than v2.0.0-beta.2. Use black-white-list
       ↪ otherwise.
    route-rules: ["sharding-route-rules-table", "sharding-route-rules-
       ↪ schema"]
    mydumper-thread: 4
    loader-thread: 16
    syncer-thread: 16
  - source-id: "mysql-replica-02"
    block-allow-list: "instance" # This configuration applies to DM
       ↪ versions higher than v2.0.0-beta.2. Use black-white-list
       ↪ otherwise.
    route-rules: ["sharding-route-rules-table", "sharding-route-rules-
       ↪ schema"]
    mydumper-thread: 4
    loader-thread: 16
    syncer-thread: 16
block-allow-list: # This configuration applies to DM versions higher
    ↪ than v2.0.0-beta.2. Use black-white-list otherwise.
  instance:
    do-dbs: ["~^sharding[\\d]+"]
    do-tables:
    - db-name: "~^sharding[\\d]+"
      tbl-name: "~^t[\\d]+"
```

```
routes:
  sharding-route-rules-table:
    schema-pattern: sharding*
    table-pattern: t*
    target-schema: db_target
    target-table: t_target
  sharding-route-rules-schema:
    schema-pattern: sharding*
    target-schema: db_target
```

2. To create a task using dmctl, write the above configurations to the `conf/task.yaml` file:

```
./dmctl --master-addr 127.0.0.1:8261 start-task conf/task.yaml
```

```
{
    "result": true,
    "msg": "",
    "sources": [
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-01",
            "worker": "worker1"
        },
        {
            "result": true,
            "msg": "",
            "source": "mysql-replica-02",
            "worker": "worker2"
        }
    ]
}
```

Now, you have successfully created a task to migrate the sharded tables from the MySQL1 and MySQL2 instances to TiDB.

Verify data

You can modify data in the upstream MySQL sharded tables. Then use sync-diff-inspector to check whether the upstream and downstream data are consistent. Consistent data means that the migration task works well, which also indicates that the cluster works well.

13.6.8.11.3 Best Practices of Data Migration in the Shard Merge Scenario

This document describes the features and limitations of TiDB Data Migration (DM) in the shard merge scenario and provides a data migration best practice guide for your application (the default "pessimistic" mode is used).

Use a separate data migration task

In the Merge and Migrate Data from Sharded Tables document, the definition of "sharding group" is given: A sharding group consists of all upstream tables that need to be merged and migrated into the same downstream table.

The current sharding DDL mechanism has some usage restrictions to coordinate the schema changes brought by DDL operations in different sharded tables. If these restrictions are violated due to unexpected reasons, you need to handle sharding DDL locks manually in DM, or even redo the entire data migration task.

To mitigate the impact on data migration when an exception occurs, it is recommended to merge and migrate each sharding group as a separate data migration task. **This might enable that only a small number of data migration tasks need to be handled manually while others remain unaffected.**

Handle sharding DDL locks manually

You can easily conclude from Merge and Migrate Data from Sharded Tables that DM's sharding DDL lock is a mechanism for coordinating the execution of DDL operations to the downstream from multiple upstream sharded tables.

Therefore, when you find any sharding DDL lock on `DM-master` through `shard-ddl-lock` command, or any `unresolvedGroups` or `blockingDDLs` on some DM-workers through `query-status` command, do not rush to manually release the sharding DDL lock through `shard-ddl-lock unlock` commands.

Instead, you can:

- Follow the corresponding manual solution to handle the scenario if the failure of automatically releasing the sharding DDL lock is one of the listed abnormal scenarios.
- Redo the entire data migration task if it is an unsupported scenario: First, empty the data in the downstream database and the `dm_meta` information associated with the migration task; then, re-execute the full and incremental data replication.

Handle conflicts between primary keys or unique indexes across multiple sharded tables

Data from multiple sharded tables might cause conflicts between the primary keys or unique indexes. You need to check each primary key or unique index based on the sharding logic of these sharded tables. The following are three cases related to primary keys or unique indexes:

- Shard key: Usually, the same shard key only exists in one sharded table, which means no data conflict is caused on shard key.

- Auto-increment primary key: The auto-increment primary key of each sharded tables counts separately, so their range might overlap. In this case, you need to refer to the next section Handle conflicts of auto-increment primary key to solve it.
- Other primary keys or unique indexes: you need to analyze them based on the business logic. If data conflict, you can also refer to the next section Handle conflicts of auto-increment primary key to solve it.

Handle conflicts of auto-increment primary key

This section introduces two recommended solutions to handle conflicts of auto-increment primary key.

Remove the `PRIMARY KEY` attribute from the column

Assume that the upstream schemas are as follows:

```
CREATE TABLE `tbl_no_pk` (
  `auto_pk_c1` bigint(20) NOT NULL,
  `uk_c2` bigint(20) NOT NULL,
  `content_c3` text,
  PRIMARY KEY (`auto_pk_c1`),
  UNIQUE KEY `uk_c2` (`uk_c2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

If the following requirements are satisfied:

- The `auto_pk_c1` column has no impact on the application and does not depend on the column's `PRIMARY KEY` attribute.
- The `uk_c2` column has the `UNIQUE KEY` attribute, and it is globally unique in all upstream sharded tables.

Then you can perform the following steps to fix the `ERROR 1062 (23000): Duplicate entry '***' for key 'PRIMARY'` error that is possibly caused by the `auto_pk_c1` column when you merge sharded tables.

1. Before the full data migration, create a table in the downstream database for merging and migrating data, and modify the `PRIMARY KEY` attribute of the `auto_pk_c1` column to normal index.

   ```
   CREATE TABLE `tbl_no_pk_2` (
     `auto_pk_c1` bigint(20) NOT NULL,
     `uk_c2` bigint(20) NOT NULL,
     `content_c3` text,
     INDEX (`auto_pk_c1`),
     UNIQUE KEY `uk_c2` (`uk_c2`)
   ) ENGINE=InnoDB DEFAULT CHARSET=latin1
   ```

2. Add the following configuration in `task.yaml` to skip the check of auto-increment primary key conflict:

```
ignore-checking-items: ["auto_increment_ID"]
```

3. Start the full and incremental data replication task.

4. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from the upstream has already been merged and migrated to the downstream database.

Use a composite primary key

Assume that the upstream schemas are as follows:

```
CREATE TABLE `tbl_multi_pk` (
  `auto_pk_c1` bigint(20) NOT NULL,
  `uuid_c2` bigint(20) NOT NULL,
  `content_c3` text,
  PRIMARY KEY (`auto_pk_c1`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

If the following requirements are satisfied:

- The application does not depend on the `PRIMARY KEY` attribute of the `auto_pk_c1` column.
- The composite primary key that consists of the `auto_pk_c1` and `uuid_c2` columns is globally unique.
- It is acceptable to use a composite primary key in the application.

Then you can perform the following steps to fix the `ERROR 1062 (23000): Duplicate entry '***' for key 'PRIMARY'` error that is possibly caused by the `auto_pk_c1` column when you merge sharded tables.

1. Before the full data migration, create a table in the downstream database for merging and migrating data. Do not specify the `PRIMARY KEY` attribute for the `auto_pk_c1` column, but use the `auto_pk_c1` and `uuid_c2` columns to make up a composite primary key.

```
CREATE TABLE `tbl_multi_pk_c2` (
  `auto_pk_c1` bigint(20) NOT NULL,
  `uuid_c2` bigint(20) NOT NULL,
  `content_c3` text,
  PRIMARY KEY (`auto_pk_c1`,`uuid_c2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

2. Start the full and incremental data migration task.

3. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from upstream has already been merged and migrated to the downstream database.

Special processing when the upstream RDS contains sharded tables

If the upstream data source is an RDS and it contains sharded tables, the table names in MySQL binlog might be invisible when connecting to a SQL client. For example, if the upstream is a UCloud distributed database, the table name in the binlog might have an extra prefix `_0001`. Therefore, you need to configure table routing based on the table names in binlog, instead of those in the SQL client.

Create/drop tables in the upstream

In Merge and Migrate Data from Sharded Tables, it is clear that the coordination of sharding DDL lock depends on whether the downstream database receives the DDL statements of all upstream sharded tables. In addition, DM currently **does not support** dynamically creating or dropping sharded tables in the upstream. Therefore, to create or drop sharded tables in the upstream, it is recommended to perform the following steps.

Create sharded tables in the upstream

If you need to create a new sharded table in the upstream, perform the following steps:

1. Wait for the coordination of all executed sharding DDL in the upstream sharded tables to finish.

2. Run `stop-task` to stop the data migration task.

3. Create a new sharded table in the upstream.

4. Make sure that the configuration in the `task.yaml` file allows the newly added sharded table to be merged in one downstream table with other existing sharded tables.

5. Run `start-task` to start the task.

6. Run `query-status` to verify whether the data migration task is successfully processed and whether the data from upstream has already been merged and migrated to the downstream database.

Drop sharded tables in the upstream

If you need to drop a sharded table in the upstream, perform the following steps:

1. Drop the sharded table, run `SHOW BINLOG EVENTS` to fetch the `End_log_pos` corresponding to the `DROP TABLE` statement in the binlog events, and mark it as *Pos-M*.

2. Run `query-status` to fetch the position (`syncerBinlog`) corresponding to the binlog event that has been processed by DM, and mark it as *Pos-S*.
3. When *Pos-S* is greater than *Pos-M*, it means that DM has processed all of the `DROP TABLE` statements, and the data of the table before dropping has been migrated to the downstream, so the subsequent operation can be performed. Otherwise, wait for DM to finish migrating the data.
4. Run `stop-task` to stop the task.
5. Make sure that the configuration in the `task.yaml` file ignores the dropped sharded table in the upstream.
6. Run `start-task` to start the task.
7. Run `query-status` to verify whether the data migration task is successfully processed.

Speed limits and traffic flow control

When data from multiple upstream MySQL or MariaDB instances is merged and migrated to the same TiDB cluster in the downstream, every DM-worker corresponding to each upstream instance executes full and incremental data replication concurrently. This means that the default degree of concurrency (`pool-size` in full data migration and `worker-count` in incremental data replication) accumulates as the number of DM-workers increases, which might overload the downstream database. In this case, you need to conduct a preliminary performance analysis based on TiDB and DM monitoring metrics and adjust the value of each concurrency parameter. In the future, DM is expected to support partially automated traffic flow control.

13.6.8.12 Troubleshoot

13.6.8.12.1 TiDB Data Migration FAQs

This document collects the frequently asked questions (FAQs) about TiDB Data Migration (DM).

Does DM support migrating data from Alibaba RDS or other cloud databases?

Currently, DM only supports decoding the standard version of MySQL or MariaDB binlog. It has not been tested for Alibaba Cloud RDS or other cloud databases. If you are confirmed that its binlog is in standard format, then it is supported.

It is a known issue that for an upstream table with no primary key in Alibaba Cloud RDS, its binlog still contains a hidden primary key column, which is inconsistent with the original table structure.

Here are some known incompatible issues:

- In **Alibaba Cloud RDS**, for an upstream table with no primary key, its binlog still contains a hidden primary key column, which is inconsistent with the original table structure.
- In **HUAWEI Cloud RDS**, directly reading binlog files is not supported. For more details, see Can HUAWEI Cloud RDS Directly Read Binlog Backup Files?

Does the regular expression of the block and allow list in the task configuration support `non-capturing (?!)`?

Currently, DM does not support it and only supports the regular expressions of the Golang standard library. See regular expressions supported by Golang via re2-syntax.

If a statement executed upstream contains multiple DDL operations, does DM support such migration?

DM will attempt to split a single statement containing multiple DDL change operations into multiple statements containing only one DDL operation, but might not cover all cases. It is recommended to include only one DDL operation in a statement executed upstream, or verify it in the test environment. If it is not supported, you can file an issue to the `pingcap/tiflow` repository.

How to handle incompatible DDL statements?

When you encounter a DDL statement unsupported by TiDB, you need to manually handle it using dmctl (skipping the DDL statement or replacing the DDL statement with a specified DDL statement). For details, see Handle failed DDL statements.

> **Note:**
>
> Currently, TiDB is not compatible with all the DDL statements that MySQL supports. See MySQL Compatibility.

Does DM replicate view-related DDL statements and DML statements to TiDB?

Currently, DM does not replicate view-related DDL statements to the downstream TiDB cluster, nor does it replicate view-related DML statements to the downstream TiDB cluster.

How to reset the data migration task?

When an exception occurs during data migration and the data migration task cannot be resumed, you need to reset the task and re-migrate the data:

1. Execute the `stop-task` command to stop the abnormal data migration task.
2. Purge the data migrated to the downstream.
3. Use one of the following ways to restart the data migration task.

- Specify a new task name in the task configuration file. Then execute `start-task {task-config-file}`.
- Execute `start-task --remove-meta {task-config-file}`.

How to handle the error returned by the DDL operation related to the gh-ost table, after `online-ddl: true` is set?

```
[unit=Sync] ["error information"="{\"msg\":\"[code=36046:class=sync-unit:scope=internal:level=high] online ddls on ghost table `xxx`.`_xxxx_gho`\\ngithub.com/pingcap/tiflow/pkg/terror.(*Error).Generate ......
```

The above error can be caused by the following reason:

In the last `rename ghost_table to origin table` step, DM reads the DDL information in memory, and restores it to the DDL of the origin table.

However, the DDL information in memory is obtained in either of the two ways:

- DM processes the gh-ost table during the `alter ghost_table` operation and records the DDL information of `ghost_table`;
- When DM-worker is restarted to start the task, DM reads the DDL from `dm_meta.{task_name}_onlineddl`.

Therefore, in the process of incremental replication, if the specified Pos has skipped the `alter ghost_table` DDL but the Pos is still in the online-ddl process of gh-ost, the ghost_table is not written into memory or `dm_meta.{task_name}_onlineddl` correctly. In such cases, the above error is returned.

You can avoid this error by the following steps:

1. Remove the `online-ddl-scheme` or `online-ddl` configuration of the task.
2. Configure `_{table_name}_gho`, `_{table_name}_ghc`, and `_{table_name}_del` in `block-allow-list.ignore-tables`.
3. Execute the upstream DDL in the downstream TiDB manually.
4. After the Pos is replicated to the position after the gh-ost process, re-enable the `online-ddl-scheme` or `online-ddl` configuration and comment out `block-allow-list.ignore-tables`.

How to add tables to the existing data migration tasks?

If you need to add tables to a data migration task that is running, you can address it in the following ways according to the stage of the task.

Note:

Because adding tables to an existing data migration task is complex, it is recommended that you perform this operation only when necessary.

In the `Dump` stage

Since MySQL cannot specify a snapshot for export, it does not support updating data migration tasks during the export and then restarting to resume the export through the checkpoint. Therefore, you cannot dynamically add tables that need to be migrated at the `Dump` stage.

If you really need to add tables for migration, it is recommended to restart the task directly using the new configuration file.

In the `Load` stage

During the export, multiple data migration tasks usually have different binlog positions. If you merge the tasks in the `Load` stage, they might not be able to reach consensus on binlog positions. Therefore, it is not recommended to add tables to a data migration task in the `Load` stage.

In the `Sync` stage

When the data migration task is in the `Sync` stage, if you add additional tables to the configuration file and restart the task, DM does not re-execute full export and import for the newly added tables. Instead, DM continues incremental replication from the previous checkpoint.

Therefore, if the full data of the newly added table has not been imported to the downstream, you need to use a separate data migration task to export and import the full data to the downstream.

Record the position information in the global checkpoint (`is_global=1`) corresponding to the existing migration task as `checkpoint-T`, such as `(mysql-bin.000100, 1234)`. Record the position information of the full export `metedata` (or the checkpoint of another data migration task in the `Sync` stage) of the table to be added to the migration task as `checkpoint-S`, such as `(mysql-bin.000099, 5678)`. You can add the table to the migration task by the following steps:

1. Use `stop-task` to stop an existing migration task. If the table to be added belongs to another running migration task, stop that task as well.
2. Use a MySQL client to connect the downstream TiDB database and manually update the information in the checkpoint table corresponding to the existing migration task to the smaller value between `checkpoint-T` and `checkpoint-S`. In this example, it is `(mysql- bin.000099, 5678)`.

- The checkpoint table to be updated is `{task-name}_syncer_checkpoint` in the `{dm_meta}` schema.
- The checkpoint rows to be updated match `id=(source-id)` and `is_global=1`.
- The checkpoint columns to be updated are `binlog_name` and `binlog_pos`.

3. Set `safe-mode: true` for the `syncers` in the task to ensure reentrant execution.
4. Start the task using `start-task`.
5. Observe the task status through `query-status`. When `syncerBinlog` exceeds the larger value of `checkpoint-T` and `checkpoint-S`, restore `safe-mode` to the original value and restart the task. In this example, it is `(mysql-bin.000100, 1234)`.

How to handle the error `packet for query is too large. Try adjusting the 'max_allowed_packet' variable` that occurs during the full import?

Set the parameters below to a value larger than the default 67108864 (64M).

- The global variable of the TiDB server: `max_allowed_packet`.
- The configuration item in the task configuration file: `target-database.max-allowed-packet`. For details, refer to DM Advanced Task Configuration File.

How to handle the error `Error 1054: Unknown column 'binlog_gtid' in 'field list'` that occurs when existing DM migration tasks of an DM 1.0 cluster are running on a DM 2.0 or newer cluster?

Since DM v2.0, if you directly run the `start-task` command with the task configuration file of the DM 1.0 cluster to continue the incremental data replication, the error `Error 1054: Unknown column 'binlog_gtid' in 'field list'` occurs.

This error can be handled by manually importing DM migration tasks of a DM 1.0 cluster to a DM 2.0 cluster.

Why does TiUP fail to deploy some versions of DM (for example, v2.0.0-hotfix)?

You can use the `tiup list dm-master` command to view the DM versions that TiUP supports to deploy. TiUP does not manage DM versions which are not shown by this command.

How to handle the error `parse mydumper metadata error: EOF` that occurs when DM is replicating data?

You need to check the error message and log files to further analyze this error. The cause might be that the dump unit does not produce the correct metadata file due to a lack of permissions.

Why does DM report no fatal error when replicating sharded schemas and tables, but downstream data is lost?

Check the configuration items `block-allow-list` and `table-route`:

- You need to configure the names of upstream databases and tables under `block-allow-list`. You can add "~" before `do-tables` to use regular expressions to match names.
- `table-route` uses wildcard characters instead of regular expressions to match table names. For example, `table_parttern_[0-63]` only matches 7 tables, from `table_parttern_0` to `table_pattern_6`.

Why does the `replicate lag` monitor metric show no data when DM is not replicating from upstream?

In DM 1.0, you need to enable `enable-heartbeat` to generate the monitor data. In DM 2.0 and later versions, it is expected to have no data in the monitor metric `replicate lag` because this feature is not supported.

How to handle the error `fail to initial unit Sync of subtask` when DM is starting a task, with the `RawCause` in the error message showing `context deadline exceeded`?

This is a known issue in DM 2.0.0 version and will be fixed in DM 2.0.1 version. It is likely to be triggered when a replication task has a lot of tables to process. If you use TiUP to deploy DM, you can upgrade DM to the nightly version to fix this issue. Or you can download the 2.0.0-hotfix version from the release page of DM on GitHub and manually replace the executable files.

How to handle the error `duplicate entry` when DM is replicating data?

You need to first check and confirm the following things:

- `disable-detect` is not configured in the replication task (in v2.0.7 and earlier versions).
- The data is not inserted manually or by other replication programs.
- No DML filter associated with this table is configured.

To facilitate troubleshooting, you can first collect general log files of the downstream TiDB instance and then ask for technical support at TiDB Community slack channel. The following example shows how to collect general log files:

```
##### Enable general log collection
curl -X POST -d "tidb_general_log=1" http://{TiDBIP}:10080/settings
##### Disable general log collection
curl -X POST -d "tidb_general_log=0" http://{TiDBIP}:10080/settings
```

When the `duplicate entry` error occurs, you need to check the log files for the records that contain conflict data.

Why do some monitoring panels show `No data point`?

It is normal for some panels to have no data. For example, when there is no error reported, no DDL lock, or the relay log feature is not enabled, the corresponding panels show `No data point`. For detailed description of each panel, see DM Monitoring Metrics.

In DM v1.0, why does the command `sql-skip` fail to skip some statements when the task is in error?

You need to first check whether the binlog position is still advancing after you execute `sql-skip`. If so, it means that `sql-skip` has taken effect. The reason why this error keeps occurring is that the upstream sends multiple unsupported DDL statements. You can use `sql-skip -s <sql-pattern>` to set a pattern to match these statements.

Sometimes, the error message contains the `parse statement` information, for example:

```
if the DDL is not needed, you can use a filter rule with \"*\" schema-
    ↪ pattern to ignore it.\n\t : parse statement: line 1 column 11 near \"
    ↪ EVENT `event_del_big_table` \r\nDISABLE\" %!(MISSING)(EXTRA string=
    ↪ ALTER EVENT `event_del_big_table` \r\nDISABLE
```

The reason for this type of error is that the TiDB parser cannot parse DDL statements sent by the upstream, such as `ALTER EVENT`, so `sql-skip` does not take effect as expected. You can add binlog event filters in the configuration file to filter those statements and set `schema-pattern: "*"`. Starting from DM v2.0.1, DM pre-filters statements related to `EVENT`.

Since DM v6.0, `binlog` replaces `sql-skip` and `handle-error`. You can use the `binlog` command instead to avoid this issue.

Why do `REPLACE` statements keep appearing in the downstream when DM is replicating?

You need to check whether the safe mode is automatically enabled for the task. If the task is automatically resumed after an error, or if there is high availability scheduling, then the safe mode is enabled because it is within 1 minutes after the task is started or resumed.

You can check the DM-worker log file and search for a line containing `change count`. If the `new count` in the line is not zero, the safe mode is enabled. To find out why it is enabled, check when it happens and if any errors are reported before.

In DM v2.0, why does the full import task fail if DM restarts during the task?

In DM v2.0.1 and earlier versions, if DM restarts before the full import completes, the bindings between upstream data sources and DM-worker nodes might change. For example, it is possible that the intermediate data of the dump unit is on DM-worker node A but the load unit is run by DM-worker node B, thus causing the operation to fail.

The following are two solutions to this issue:

- If the data volume is small (less than 1 TB) or the task merges sharded tables, take these steps:

    1. Clean up the imported data in the downstream database.
    2. Remove all files in the directory of exported data.
    3. Delete the task using dmctl and run the command `start-task --remove-meta` to create a new task.

After the new task starts, it is recommended to ensure that there is no redundant DM worker node and avoid restarting or upgrading the DM cluster during the full import.

- If the data volume is large (more than 1 TB), take these steps:

    1. Clean up the imported data in the downstream database.
    2. Deploy TiDB-Lightning to the DM worker nodes that process the data.
    3. Use the Local-backend mode of TiDB-Lightning to import data that DM dump units export.
    4. After the full import completes, edit the task configuration file in the following ways and restart the task:
        - Change `task-mode` to `incremental`.
        - Set the value of `mysql-instance.meta.pos` to the position recorded in the metadata file that the dump unit outputs.

Why does DM report the error `ERROR 1236 (HY000): The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION = 1, but the master has purged binary logs containing GTIDs that the slave requires.` if it restarts during an incremental task?

This error indicates that the upstream binlog position recorded in the metadata file output by the dump unit has been purged during the full migration.

If this issue occurs, you need to pause the task, delete all migrated data in the downstream database, and start a new task with the `--remove-meta` option.

You can avoid this issue in advance by configuring in the following ways:

1. Increase the value of `expire_logs_days` in the upstream MySQL database to avoid wrongly purging needed binlog files before the full migration task completes. If the data volume is large, it is recommended to use dumpling and TiDB-Lightning at the same time to speed up the task.
2. Enable the relay log feature for this task so that DM can read data from relay logs even though the binlog position is purged.

Why does the Grafana dashboard of a DM cluster display `failed to fetch dashboard` if the cluster is deployed using TiUP v1.3.0 or v1.3.1?

This is a known bug of TiUP, which is fixed in TiUP v1.3.2. The following are two solutions to this issue:

- Solution one:

    1. Upgrade TiUP to a later version using the command `tiup update --self && tiup update dm`.
    2. Scale in and then scale out Grafana nodes in the cluster to restart the Grafana service.

- Solution two:

    1. Back up the `deploy/grafana-$port/bin/public` folder.
    2. Download the TiUP DM offline package and unpack it.
    3. Unpack the `grafana-v4.0.3-**.tar.gz` in the offline package.
    4. Replace the folder `deploy/grafana-$port/bin/public` with the `public` folder in `grafana-v4.0.3-**.tar.gz`.
    5. Execute `tiup dm restart $cluster_name -R grafana` to restart the Grafana service.

In DM v2.0, why does the query result of the command `query-status` show that the Syncer checkpoint GTIDs are inconsecutive if the task has `enable-relay` and `enable-gtid` enabled at the same time?

This is a known bug in DM, which is fixed in DM v2.0.2. The bug is triggered when the following two conditions are fully met at the same time:

1. Parameters `enable-relay` and `enable-gtid` are set to `true` in the source configuration file.
2. The upstream database is a **MySQL secondary database**. If you execute the command `show binlog events in '<newest-binlog>' limit 2` to query the `previous_gtids` of the database, the result is inconsecutive, such as the following example:

```
mysql> show binlog events in 'mysql-bin.000005' limit 2;
+------------------+------+---------------+-----------+-------------+-------------------
| Log_name         | Pos  | Event_type    | Server_id | End_log_pos | Info
+------------------+------+---------------+-----------+-------------+-------------------
| mysql-bin.000005 |    4 | Format_desc   |    123452 |         123 | Server ver:
  5.7.32-35-log, Binlog ver: 4
| mysql-bin.000005 |  123 | Previous_gtids |    123452 |         194 | d3618e68
  -6052-11eb-a68b-0242ac110002:6-7
+------------------+------+---------------+-----------+-------------+-------------------
```

The bug occurs if you run `query-status <task>` in dmctl to query task information and find that `subTaskStatus.sync.syncerBinlogGtid` is inconsecutive but `subTaskStatus.sync.masterBinlogGtid` is consecutive. See the following example:

```
query-status test
{
    ...
    "sources": [
        {
```

```
        ...
        "sourceStatus": {
            "source": "mysql1",
            ...
            "relayStatus": {
                "masterBinlog": "(mysql-bin.000006, 744)",
                "masterBinlogGtid": "f8004e25-6067-11eb-9fa3-0242ac110003
                    ↪ :1-50",
                ...
            }
        },
        "subTaskStatus": [
            {
                ...
                "sync": {
                    ...
                    "masterBinlog": "(mysql-bin.000006, 744)",
                    "masterBinlogGtid": "f8004e25-6067-11eb-9fa3-0242
                        ↪ ac110003:1-50",
                    "syncerBinlog": "(mysql-bin|000001.000006, 738)",
                    "syncerBinlogGtid": "f8004e25-6067-11eb-9fa3-0242
                        ↪ ac110003:1-20:40-49",
                    ...
                    "synced": false,
                    "binlogType": "local"
                }
            }
        ]
    },
    {
        ...
        "sourceStatus": {
            "source": "mysql2",
            ...
            "relayStatus": {
                "masterBinlog": "(mysql-bin.000007, 1979)",
                "masterBinlogGtid": "ddb8974e-6064-11eb-8357-0242ac110002
                    ↪ :1-25",
                ...
            }
        },
        "subTaskStatus": [
            {
                ...
                "sync": {
```

```
                    "masterBinlog": "(mysql-bin.000007, 1979)",
                    "masterBinlogGtid": "ddb8974e-6064-11eb-8357-0242
                       ↪ ac110002:1-25",
                    "syncerBinlog": "(mysql-bin|000001.000008, 1979)",
                    "syncerBinlogGtid": "ddb8974e-6064-11eb-8357-0242
                       ↪ ac110002:1-25",
                    ...
                    "synced": true,
                    "binlogType": "local"
                }
            }
        ]
    }
  ]
}
```

In the example, the `syncerBinlogGtid` of the data source `mysql1` is inconsecutive. In this case, you can do one of the following to handle the data loss:

- If upstream binlogs from the current time to the position recorded in the metadata of the full export task have not been purged, you can take these steps:
    1. Stop the current task and delete all data sources with inconsecutive GTIDs.
    2. Set `enable-relay` to `false` in all source configuration files.
    3. For data sources with inconsecutive GTIDs (such as `mysql1` in the above example), change the task to an incremental task and configure related `mysql-instances.meta` with metadata information of each full export task, including the `binlog-name`, `binlog-pos`, and `binlog-gtid` information.
    4. Set `syncers.safe-mode` to `true` in `task.yaml` of the incremental task and restart the task.
    5. After the incremental task replicates all missing data to the downstream, stop the task and change `safe-mode` to `false` in the `task.yaml`.
    6. Restart the task again.
- If upstream binlogs have been purged but local relay logs remain, you can take these steps:
    1. Stop the current task.
    2. For data sources with inconsecutive GTIDs (such as `mysql1` in the above example), change the task to an incremental task and configure related `mysql-instances.meta` with metadata information of each full export task, including the `binlog-name`, `binlog-pos`, and `binlog-gtid` information.
    3. In the `task.yaml` of the incremental task, change the previous value of `binlog-gtid` to the previous value of `previous_gtids`. For the above example, change `1-y` to `6-y`.
    4. Set `syncers.safe-mode` to `true` in the `task.yaml` and restart the task.

5. After the incremental task replicates all missing data to the downstream, stop the task and change `safe-mode` to `false` in the `task.yaml`.
6. Restart the task again.
7. Restart the data source and set either `enable-relay` or `enable-gtid` to `false` in the source configuration file.

- If none of the above conditions is met or if the data volume of the task is small, you can take these steps:

    1. Clean up imported data in the downstream database.
    2. Restart the data source and set either `enable-relay` or `enable-gtid` to `false` in the source configuration file.
    3. Create a new task and run the command `start-task task.yaml --remove-meta` to migrate data from the beginning again.

For data sources that can be replicated normally (such as `mysql2` in the above example) in the first and second solutions above, configure related `mysql-instances.meta` with `syncerBinlog` and `syncerBinlogGtid` information from `subTaskStatus.sync` when setting the incremental task.

In DM v2.0, how do I handle the error "heartbeat config is different from previous used: serverID not equal" when switching the connection between DM-workers and MySQL instances in a virtual IP environment with the `heartbeat` feature enabled?

The `heartbeat` feature is disabled by default in DM v2.0 and later versions. If you enable the feature in the task configuration file, it interferes with the high availability feature. To solve this issue, you can disable the `heartbeat` feature by setting `enable-heartbeat` to `false` in the task configuration file, and then reload the task configuration file. DM will forcibly disable the `heartbeat` feature in subsequent releases.

Why does a DM-master fail to join the cluster after it restarts and DM reports the error "fail to start embed etcd, RawCause: member xxx has already been bootstrapped"?

When a DM-master starts, DM records the etcd information in the current directory. If the directory changes after the DM-master restarts, DM cannot get access to the etcd information, and thus the restart fails.

To solve this issue, you are recommended to maintain DM clusters using TiUP. In the case that you need to deploy using binary files, you need to configure `data-dir` with absolute paths in the configuration file of the DM-master, or pay attention to the current directory where you run the command.

Why DM-master cannot be connected when I use dmctl to execute commands?

When using dmctl execute commands, you might find the connection to DM master fails (even if you have specified the parameter value of `--master-addr` in the command), and the error message is like `RawCause: context deadline exceeded, Workaround: please check your network connection.`. But after checking the network connection using commands like `telnet <master-addr>`, no exception is found.

In this case, you can check the environment variable `https_proxy` (note that it is **https**). If this variable is configured, dmctl automatically connects the host and port specified by `https_proxy`. If the host does not have a corresponding `proxy` forwarding service, the connection fails.

To solve this issue, check whether `https_proxy` is mandatory. If not, cancel the setting. Otherwise, add the environment variable setting `https_proxy="" ./dmctl --master-addr "x.x.x.x:8261"` before the oringial dmctl commands.

> **Note:**
>
> The environment variables related to `proxy` include `http_proxy`, `https_proxy`, and `no_proxy`. If the connection error persists after you perform the above steps, check whether the configuration parameters of `http_proxy` and `no_proxy` are correct.

How to handle the returned error when executing start-relay command for DM versions from 2.0.2 to 2.0.6?

```
flush local meta, Rawcause: open relay-dir/xxx.000001/relay.metayyyy: no such file or directory
```

The above error might be made in the following cases:

- DM has been upgraded from v2.0.1 and earlier to v2.0.2 - v2.0.6, and relay log is started before the upgrade and restarted after the upgrade.
- Execute the stop-relay command to pause the relay log and then restart it.

You can avoid this error by the following options:

- Restart relay log:

```
» stop-relay -s sourceID workerName
» start-relay -s sourceID workerName
```

- Upgrade DM to v2.0.7 or later versions.

Why does the load unit report the `Unknown character set` error?

TiDB does not support all MySQL character sets. Therefore, DM reports this error if an unsupported character set is used when creating the table schema during a full import. To bypass this error, you can create the table schema in the downstream in advance using the character sets supported by TiDB according to the specific data.

13.6.8.12.2 Handle Errors in TiDB Data Migration

This document introduces the error system and how to handle common errors when you use DM.

Error system

In the error system, usually, the information of a specific error is as follows:

- `code`: error code.

  DM uses the same error code for the same error type. An error code does not change as the DM version changes.

  Some errors might be removed during the DM iteration, while the error codes are not. DM uses a new error code instead of an existing one for a new error.

- `class`: error type.

  It is used to mark the component where an error occurs (error source).

  The following table displays all error types, error sources, and error samples.

  |

  Error Type

Error Source	Error Sample
database	Database operations	[code=10003:class=database:scope=downstream:level=medium] database driver: invalid connection
functional	Underlying functions of DM	[code=11005:class=functional:scope=internal:level=high] not allowed operation: alter multiple tables in one statement
config	Incorrect configuration	[code=20005:class=config:scope=internal:level=medium] empty source-id not valid
binlog-op	Binlog operations	[code=22001:class=binlog-op:scope=internal:level=high] empty UUIDs not valid
checkpoint	checkpoint operations	[code=24002:class=checkpoint:scope=internal:level=high] save point bin.1234 is older than current pos bin.1371
task-check	Performing task check	[code=26003:class=task-check:scope=internal:level=medium] new table router error
relay-event-lib| Executing the basic functions of the relay module	[code=28001:class=relay-event-lib:scope=internal:level=high] parse server-uuid.index
relay-unit	relay processing unit	[code=30015:class=relay-unit:scope=upstream:level=high] TCPReader get event: ERROR 1236 (HY000): Could not open log file

```
dump-unit | dump processing unit | [code=32001:class=dump-unit:scope=internal
↪ :level=high] mydumper runs with error: CRITICAL **: 15:12:17.559:
↪ Error connecting to database: Access denied for user 'root'@'172.17.0.1'
↪  (using password: NO) |
load-unit | load processing unit | [code=34002:class=load-unit:scope=internal
↪ :level=high] corresponding ending of sql: ')' not found |
sync-unit | sync processing unit | [code=36027:class=sync-unit:scope=internal
↪ :level=high] Column count doesn't match value count: 9 (columns)vs
↪ 10 (values) |
dm-master | DM-master service | [code=38008:class=dm-master:scope=internal
↪ :level=high] grpc request error: rpc error: code = Unavailable desc
↪  = all SubConns are in TransientFailure, latest connection error:
↪ connection error: desc = "transport: Error while dialing dial tcp
↪ 172.17.0.2:8262: connect: connection refused" |
dm-worker | DM-worker service | [code=40066:class=dm-worker:scope=internal
↪ :level=high] ExecuteDDL timeout, try use query-status to query
↪ whether the DDL is still blocking |
dm-tracer | DM-tracer service | [code=42004:class=dm-tracer:scope=internal:

scheduler | Scheduling operations (of data migration tasks) | [code=46001:class=
↪ scheduler:scope=internal:level=high],"the scheduler has not started"
|
dmctl | An error occurs within dmctl or when it interacts with other components |
[code=48001:class=dmctl:scope=internal:level=high],"can not create grpc
↪  connection" |
```

- `scope`: Error scope.

  It is used to mark the scope and source of DM objects when an error occurs. `scope` includes four types: `not-set`, `upstream`, `downstream`, and `internal`.

  If the logic of the error directly involves requests between upstream and downstream databases, the scope is set to `upstream` or `downstream`; otherwise, it is currently set to `internal`.

- `level`: Error level.

  The severity level of the error, including `low`, `medium`, and `high`.

  - The `low` level error usually relates to user operations and incorrect inputs. It does not affect migration tasks.
  - The `medium` level error usually relates to user configurations. It affects some newly started services; however, it does not affect the existing DM migration status.
  - The `high` level error usually needs your attention, since you need to resolve it to avoid the possible interruption of a migration task.

- `message`: Error descriptions.

  Detailed descriptions of the error. To wrap and store every additional layer of error message on the error call chain, the errors.Wrap mode is adopted. The message description wrapped at the outermost layer indicates the error in DM and the message description wrapped at the innermost layer indicates the error source.

- `workaround`: Error handling methods (optional)

  The handling methods for this error. For some confirmed errors (such as configuration errors), DM gives the corresponding manual handling methods in `workaround`.

- Error stack information (optional)

  Whether DM outputs the error stack information depends on the error severity and the necessity. The error stack records the complete stack call information when the error occurs. If you cannot figure out the error cause based on the basic information and the error message, you can trace the execution path of the code when the error occurs using the error stack.

For the complete list of error codes, refer to the error code lists.

Troubleshooting

If you encounter an error while running DM, take the following steps to troubleshoot this error:

1. Execute the `query-status` command to check the task running status and the error output.
2. Check the log files related to the error. The log files are on the DM-master and DM-worker nodes. To get key information about the error, refer to the error system. Then check the Handle Common Errors section to find the solution.
3. If the error is not covered in this document, and you cannot solve the problem by checking the log or monitoring metrics, get support from PingCAP or the community.
4. After the error is resolved, restart the task using dmctl.

```
resume-task ${task name}
```

However, you need to reset the data migration task in some cases. For details, refer to Reset the Data Migration Task.

Handle common errors

|

Error Code

Error Description	How to Handle
code=10001	Abnormal database operation.	Further analyze the error message and error stack.
code=10002	The `bad connection` error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is not sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, check the network or TiDB status.
code=10003	The `invalid connection` error from the underlying database. It usually indicates that the connection between DM and the downstream TiDB instance is abnormal (possibly caused by network failure or TiDB restart) and the currently requested data is partly sent to TiDB.	DM provides automatic recovery for such error. If the recovery is not successful for a long time, further check the error message and analyze the information based on the actual situation.
code=10005	Occurs when performing the `QUERY` type SQL statements.	
code=10006	Occurs when performing the `EXECUTE` type SQL statements, including DDL statements and DML statements of the `INSERT`, `UPDATE`or `DELETE` type. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.	
code=11006	Occurs when the built-in parser of DM parses the incompatible DDL statements.	Refer to Data Migration - incompatible DDL statements for solution.
code=20010	Occurs when decrypting the database password that is provided in task configuration.	Check whether the downstream database password provided in the configuration task is correctly encrypted using dmctl.
code=26002	The task check fails to establish database connection. For more detailed error information, check the error message which usually includes the error code and error information returned for database operations.	Check whether the machine where DM-master is located has permission to access the upstream.
code=32001	Abnormal dump processing unit	If the error message contains `mydumper: argument list too long.`, configure the table to be exported by manually adding the `--regex` regular expression in the Mydumper argument `extra-args` in the `task.yaml` file according to the block-allow list. For example, to export all tables named `hello`, add `--regex '.*\\.hello$'`; to export all tables, add `--regex '.*'`.
code=38008	An error occurs in the gRPC communication among DM components.	Check `class`. Find out the error occurs in the interaction of which components. Determine the type of communication error. If the error occurs when establishing gRPC connection, check whether the communication server is working normally.

What can I do when a migration task is interrupted with the `invalid connection` error returned?

Reason

The `invalid connection` error indicates that anomalies have occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy) and that a part of the data for the current request has been sent to TiDB.

Solutions

Because DM has the feature of concurrently migrating data to the downstream in migration tasks, several errors might occur when a task is interrupted. You can check these errors by using `query-status`.

- If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
- If DM does not or fails to retry automatically because of version problems, use `stop-task` to stop the task and then use `start-task` to restart the task.

A migration task is interrupted with the `driver: bad connection` error returned

Reason

The `driver: bad connection` error indicates that anomalies have occurred in the connection between DM and the upstream TiDB database (such as network failure and TiDB restart) and that the data of the current request has not yet been sent to TiDB at that moment.

Solution

The current version of DM automatically retries on error. If you use the previous version which does not support automatically retry, you can execute the `stop-task` command to stop the task. Then execute `start-task` to restart the task.

The relay unit throws error `event from * in * diff from passed-in event *` or a migration task is interrupted with failing to get or parse binlog errors like `get binlog error ERROR 1236 (HY000)` and `binlog checksum mismatch, data may be corrupted` returned

Reason

During the DM process of relay log pulling or incremental replication, this two errors might occur if the size of the upstream binlog file exceeds **4 GB**.

Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the size of the binlog file, and store the replicated binlog positions as checkpoints. However, the official MySQL uses `uint32` to store binlog positions. This means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

Solutions

For relay units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the DM-worker.

3. Copy the corresponding binlog file in the upstream to the relay log directory as the relay log file.

4. In the relay log directory, update the corresponding `relay.meta` file to pull from the next binlog file. If you have specified `enable_gtid` to `true` for the DM-worker, you need to modify the GTID corresponding to the next binlog file when updating the `relay.meta` file. Otherwise, you don't need to modify the GTID.

   Example: when the error occurs, `binlog-name = "mysql-bin.004451"` and `binlog-pos = 2453`. Update them respectively to `binlog-name = "mysql-bin.004452"` and `binlog-pos = 4`, and update `binlog-gtid` to `f0e914ef-54cf-11e7-813d-6c92bf2fa791:1-138218058`.

5. Restart the DM-worker.

For binlog replication processing units, manually recover migration using the following solution:

1. Identify in the upstream that the size of the corresponding binlog file has exceeded 4GB when the error occurs.

2. Stop the migration task using `stop-task`.

3. Update the `binlog_name` in the global checkpoints and in each table checkpoint of the downstream `dm_meta` database to the name of the binlog file in error; update `binlog_pos` to a valid position value for which migration has completed, for example, 4.

   Example: the name of the task in error is `dm_test`, the corresponding s`source-id` is `replica-1`, and the corresponding binlog file is `mysql-bin|000001.004451`. Execute the following command:

   ```
   UPDATE dm_test_syncer_checkpoint SET binlog_name='mysql-bin|000001.004451', binlog_pos = 4 WHERE id='replica-1';
   ```

4. Specify `safe-mode: true` in the `syncers` section of the migration task configuration to ensure re-entrant.

5. Start the migration task using `start-task`.

6. View the status of the migration task using `query-status`. You can restore `safe-mode` to the original value and restart the migration task when migration is done for the original error-triggering relay log files.

`Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you query the task or check the log

For database related passwords in all the DM configuration files, it is recommended to use the passwords encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt it. For how to encrypt the plaintext password, see Encrypt the database password using dmctl.

In addition, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data migration task.

The `load` processing unit reports the error `packet for query is too large. Try adjusting the 'max_allowed_packet' variable`

Reasons

- Both MySQL client and MySQL/TiDB server have the quota limits for `max_allowed_packet`. If any `max_allowed_packet` exceeds a limit, the client receives the error message. Currently, for the latest version of DM and TiDB server, the default value of `max_allowed_packet` is `64M`.
- The full data import processing unit in DM does not support splitting the SQL file exported by the Dump processing unit in DM.

Solutions

- It is recommended to set the `statement-size` option of `extra-args` for the Dump processing unit:

  According to the default `--statement-size` setting, the default size of `Insert Statement` generated by the Dump processing unit is about `1M`. With this default setting, the load processing unit does not report the error `packet for query is too large. Try adjusting the 'max_allowed_packet' variable` in most cases.

  Sometimes you might receive the following `WARN` log during the data dump. This `WARN` log does not affect the dump process. This only means that wide tables are dumped.

  ```
  Row bigger than statement_size for xxx
  ```

- If the single row of the wide table exceeds `64M`, you need to modify the following configurations and make sure the configurations take effect.
  - Execute `set @@global.max_allowed_packet=134217728` (`134217728` = 128 MB) in the TiDB server.
  - First add the `max-allowed-packet: 134217728` (128 MB) to the `target-database` section in the DM task configuration file. Then, execute the `stop-task` command and execute the `start-task` command.

13.6.8.13 TiDB Data Migration Release Notes

Since DM v5.4, the Release Notes of TiDB Data Migration have been merged into TiDB Release Notes of the same version number.

- To read the DM Release Notes of v5.4 or a later version, see the DM related content in the corresponding TiDB Release Notes.
- To read the DM Release Notes of v5.3.0 or an earlier version, refer to the following links.

13.6.8.13.1 5.3

- 5.3.0

13.7 TiDB Lightning

13.7.1 TiDB Lightning Overview

TiDB Lightning is a tool used for importing data at TB scale to TiDB clusters. It is often used for initial data import to TiDB clusters.

TiDB Lightning supports the following file formats:

- Files exported by Dumpling
- CSV files
- Apache Parquet files generated by Amazon Aurora, Apache Hive, or Snowflake

TiDB Lightning can read data from the following sources:

- Local
- Amazon S3
- Google Cloud Storage

> **Note:**
>
> Compared with TiDB Lightning, the `IMPORT INTO` statement can be directly executed on TiDB nodes, supports automated distributed task scheduling and TiDB Global Sort, and offers significant improvements in deployment, resource utilization, task configuration convenience, ease of invocation and integration, high availability, and scalability. It is recommended that you consider using `IMPORT INTO` instead of TiDB Lightning in appropriate scenarios.

13.7.1.1 TiDB Lightning architecture

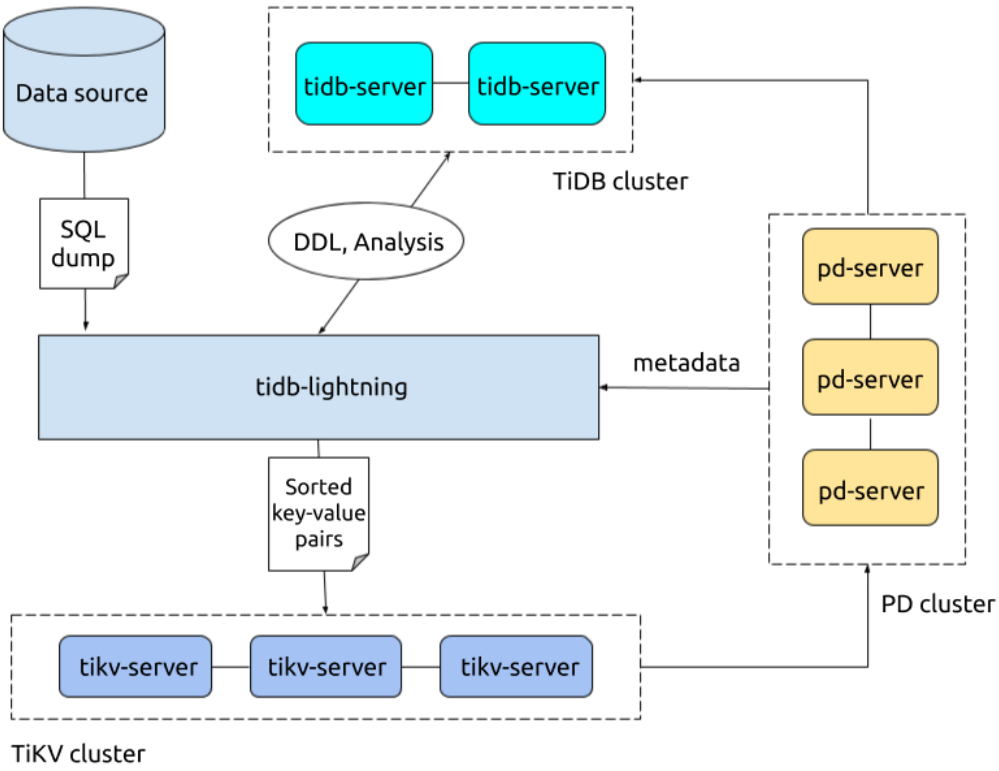

Figure 484: Architecture of TiDB Lightning tool set

TiDB Lightning supports two import modes, configured by `backend`. The import mode determines the way data is imported into TiDB.

- Physical Import Mode: TiDB Lightning first encodes data into key-value pairs and stores them in a local temporary directory, then uploads these key-value pairs to each TiKV node, and finally calls the TiKV Ingest interface to insert data into TiKV's RocksDB. If you need to perform initial import, consider the physical import mode, which has higher import speed. The backend for the physical import mode is `local`.
- Logical Import Mode: TiDB Lightning first encodes the data into SQL statements and then runs these SQL statements directly for data import. If the cluster to be imported is in production, or if the target table to be imported already contains data, use the logical import mode. The backend for the logical import mode is `tidb`.

Import mode	Physical Import Mode	Logical Import
Backend	`local`	`tidb`
Speed	Fast (100~500 GiB/hour)	Low (10~50 G
Resource consumption	High	Low
Network bandwidth consumption	High	Low
ACID compliance during import	No	Yes
Target tables	Must be empty	Can contain d
TiDB cluster version	>= 4.0.0	All
Whether the TiDB cluster can provide service during import	Limited service	Yes

The preceding performance data is used to compare the import performance difference between the two modes. The actual import speed is affected by various factors such as hardware configuration, table schema, and the number of indexes.

13.7.2 IMPORT INTO vs. TiDB Lightning

Many users have provided feedback that the deployment, configuration, and maintenance of TiDB Lightning are complex, especially in scenarios involving parallel importing of large datasets.

Based on the feedback, TiDB has gradually integrated some functionalities of TiDB Lightning into the `IMPORT INTO` SQL statement. You can directly import data by executing `IMPORT INTO`, thereby improving the efficiency of data import. In addition, `IMPORT INTO` supports some functionalities that TiDB Lightning does not, such as automatic distributed task scheduling and TiDB Global Sort.

`IMPORT INTO` is introduced in v7.2.0 and becomes generally available (GA) in v7.5.0. It will continue to be improved and optimized in future versions. Once the `IMPORT INTO` ↪ capability can fully replace TiDB Lightning, TiDB Lightning will be deprecated. At that time, relevant notification will be provided in advance in TiDB Release Notes and documentation.

13.7.2.1 Comparison between `IMPORT INTO` and TiDB Lightning

The following sections describe the differences between `IMPORT INTO` and TiDB Lightning in multiple dimensions.

13.7.2.1.1 Deployment cost

`IMPORT INTO`

`IMPORT INTO` does not require separate deployment. You can run it directly on TiDB nodes, which eliminates additional deployment work.

TiDB Lightning

By contrast, TiDB Lightning requires separate server deployment.

13.7.2.1.2 Resource utilization

`IMPORT INTO`

The `IMPORT INTO` task and other business workloads can share TiDB resources or utilize them at different times to fully leverage the TiDB resources. To ensure stable operation of business workloads while maintaining the performance and stability of the `IMPORT INTO` task, you can specify specific TiDB nodes dedicated to `IMPORT INTO` for data import.

When you use TiDB Global Sort, there is no need to mount large local disks. TiDB Global Sort can use Amazon S3 as the storage. Once the import task is completed, the temporary data stored on Amazon S3 for global sorting will be automatically deleted to save storage costs.

TiDB Lightning

You need separate servers to deploy and run TiDB Lightning. When no import tasks are executed, these resources remain idle. The total idle time is even longer in scenarios where import tasks are executed periodically, resulting in a waste of resources.

If the dataset to be imported is large, you also need to prepare large local disks to sort the data to be imported.

13.7.2.1.3 Task configuration and integration

`IMPORT INTO`

You can directly write SQL statements to submit import tasks, which are easy to call and integrate.

TiDB Lightning

By contrast, TiDB Lightning requires you to write task configuration files. These configuration files are complex and not easily called by third parties.

13.7.2.1.4 Task scheduling

`IMPORT INTO`

`IMPORT INTO` supports distributed execution. For example, when you import 40 TiB of source data files into one target table, after submitting the SQL statement, TiDB will automatically split the import task into multiple sub-tasks and schedule different TiDB nodes to execute these sub-tasks.

TiDB Lightning

By contrast, the configuration for TiDB Lightning is complex, inefficient, and prone to errors.

Assume that you start 10 TiDB Lightning instances to import data in parallel, then you need to create 10 TiDB Lightning configuration files. In each file, you need to configure the range of source files to be read by the corresponding TiDB Lightning instance. For example,

TiDB Lightning instance 1 reads the first 100 files, instance 2 reads the next 100 files, and so on.

In addition, you need to configure the shared metadata table and other configuration information for these 10 TiDB Lightning instances, which is complex.

13.7.2.1.5 Global Sort vs. local sort

`IMPORT INTO`

With TiDB Global Sort, `IMPORT INTO` can transmit tens of TiB of source data to multiple TiDB nodes, encode the data KV pairs and index KV pairs, and then transfer these pairs to Amazon S3 for global sorting before writing them into TiKV.

Because these KV pairs are globally sorted, data imported from various TiDB nodes into TiKV does not overlap, allowing it to be written directly into the RocksDB. This eliminates the need for TiKV to perform compaction operations, resulting in significant improvement in both write performance and stability of TiKV.

After the import is completed, the data used for global sorting on Amazon S3 will be automatically deleted, saving storage costs.

TiDB Lightning

TiDB Lightning only supports local sort. For example, for tens of TiB of source data, if TiDB Lightning does not have large local disks configured, or if multiple TiDB Lightning instances are used for parallel import, each TiDB Lightning instance can only use local disks to sort the data to be imported. Due to the inability to perform global sort, there will be an overlap between the data imported into TiKV by multiple TiDB Lightning instances, especially in scenarios where index data is more prevalent, triggering TiKV to perform compaction operations. Compaction operations are resource-intensive, which will lead to a decrease in TiKV's write performance and stability.

If you want to continue importing data later, you will need to keep the TiDB Lightning server and the disks on the server for the next import. The cost of using preallocated disks is relatively high, compared with `IMPORT INTO` using Amazon S3 on a pay-as-you-go basis.

13.7.2.1.6 Performance

Currently, there are no performance test comparison results under equivalent test environments between `IMPORT INTO` and TiDB Lightning.

When Amazon S3 is used as the storage for global sorting, the performance test results for `IMPORT INTO` are as follows:

Source dataset	Node configuration	Average import speed per TiDB node
40 TiB data (2.26 billion rows, 19 KiB per row)	10 TiDB (16C32G) nodes and 20 TiKV (16C27G) nodes	222 GiB/h

Source dataset	Node configuration	Average import speed per TiDB node
10 TiB data (565 million rows, 19 KiB per row)	5 TiDB (16C32G) nodes and 10 TiKV (16C27G) nodes	307 GiB/h

13.7.2.1.7 High availability

`IMPORT INTO`

After a TiDB node fails, tasks on that node are automatically transferred to the remaining TiDB nodes to continue running.

TiDB Lightning

After a TiDB Lightning instance node fails, you need to perform manual recovery of tasks on a new node based on previously recorded checkpoints.

13.7.2.1.8 Scalability

`IMPORT INTO`

Due to the use of Global Sort, data imported into TiKV does not overlap, resulting in better scalability compared with TiDB Lightning.

TiDB Lightning

Due to only supporting local sort, data imported into TiKV might overlap when new TiDB Lightning instances are added, resulting in more compaction operations for TiKV and limiting scalability relative to `IMPORT INTO`.

13.7.2.2 Functionalities not supported by `IMPORT INTO`

Currently, `IMPORT INTO` still lacks some functionalities and cannot fully replace TiDB Lightning in some scenarios, such as:

- Logical import

  Before importing data with `IMPORT INTO`, the target table must be empty. If you need to import data into a table that already contains data, it is recommended to use methods such as `LOAD DATA` or direct insertion. Starting from v8.0, TiDB supports bulk DML for executing large transactions.

- Conflict data handling

  `IMPORT INTO` currently does not support conflict data handling. Before the data import, you need to define the table schema properly to ensure that the data to be imported does not conflict with primary keys (PK) or unique keys (UK). Otherwise, it might cause task failures.

- Importing data into multiple target tables

  Currently, only one target table is allowed for one `IMPORT INTO` SQL statement. If you want to import data into multiple target tables, you need to submit multiple `IMPORT INTO` SQL statements.

In future versions, these functionalities will be supported by `IMPORT INTO`, along with additional enhancements to its capabilities, such as allowing modification of concurrency during task execution and adjusting throughput for writing to TiKV. This will make it more convenient for you to manage tasks.

13.7.2.3 Summary

Compared with TiDB Lightning, `IMPORT INTO`can be directly executed on TiDB nodes, supports automated distributed task scheduling and TiDB Global Sort, and offers significant improvements in deployment, resource utilization, task configuration convenience, ease of invocation and integration, high availability, and scalability. It is recommended that you consider using `IMPORT INTO` instead of TiDB Lightning in appropriate scenarios.

13.7.3 Compatibility of TiDB Lightning and IMPORT INTO with TiCDC and Log Backup

This document describes TiDB Lightning and `IMPORT INTO` compatibility with log backup and TiCDC, as well as some special usage scenarios.

13.7.3.1 `IMPORT INTO` vs. TiDB Lightning

`IMPORT INTO` integrates with the physical import mode of TiDB Lightning, but there are some differences. See `IMPORT INTO` vs. TiDB Lightning for details.

13.7.3.2 Compatibility with log backup and TiCDC

- TiDB Lightning logical import mode is compatible with log backup and TiCDC.
- TiDB Lightning physical import mode is not compatible with log backup and TiCDC. The reason is that physical import mode directly ingests encoded KV pairs of the source data to TiKV, causing TiKV not to generate corresponding change logs during this process. Without such change logs, the relevant data cannot be backed up via log backup and cannot be replicated by TiCDC.
- To use TiDB Lightning and TiCDC together in a cluster, see Compatibility with TiDB Lightning.
- `IMPORT INTO` is not compatible with log backup and TiCDC. The reason is that `IMPORT INTO` also ingests encoded KV pairs of the source data directly to TiKV.

13.7.3.3 Scenarios for TiDB Lightning logical import mode

If TiDB Lightning logical import mode can meet your application's performance requirements and your application requires imported tables to be backed up or replicated downstream using TiCDC, it is recommended to use TiDB Lightning logical import mode.

13.7.3.4 Scenarios for TiDB Lightning physical import mode

This section describes how to use TiDB Lightning together with log backup and TiCDC.

If TiDB Lightning logical import mode does not meet your application's performance requirements, you have to use TiDB Lightning physical import mode, and imported tables need to be backed up or replicated downstream using TiCDC, then the following scenarios are recommended.

13.7.3.4.1 Used with log backup

In this scenario, if PITR is enabled, the compatibility check will report an error after TiDB Lightning starts. If you are sure that these tables do not need backup, you can change the `Lightning.check-requirements` parameter in the TiDB Lightning configuration file to `false` and restart the import task.

Data imported using TiDB Lightning physical import mode cannot be backed up via log backup. If you need to back up the table, it is recommended to perform a table-level snapshot backup after the import, as described in Back up a table.

13.7.3.4.2 Used with TiCDC

Using TiCDC with physical import mode is not compatible in the short term, because TiCDC cannot keep up with the write speed of TiDB Lightning physical import mode, which might result in increasing cluster replication latency.

You can perform in different scenarios as follows:

- Scenario 1: the table does not need to be replicated downstream by TiCDC.

  In this scenario, if TiCDC changefeed is enabled, the compatibility check will report an error after TiDB Lightning starts. If you are sure that these tables do not need backup or log backup, you can change the `Lightning.check-requirements` parameter in the TiDB Lightning configuration file to `false` and restart the import task.

- Scenario 2: the table needs to be replicated downstream by TiCDC.

  In this scenario, if TiCDC changefeed is enabled, the compatibility check will report an error after TiDB Lightning starts. You need to change the `Lightning.check-requirements` parameter in the TiDB Lightning configuration file in the upstream TiDB cluster to `false` and restart the import task.

  After the import task for the upstream TiDB cluster is finished, use TiDB Lightning to import the same data in the downstream TiDB cluster. If you have databases such as

Redshift and Snowflake in the downstream, you can configure them to read CSV, SQL, or Parquet files from a cloud storage service and then write the data to the database.

13.7.3.5 Scenarios for `IMPORT INTO`

This section describes how to use `IMPORT INTO` together with log backup and TiCDC.

13.7.3.5.1 Used with log backup

In this scenario, if PITR is enabled, the compatibility check will report an error after you submit the `IMPORT INTO` statement. If you are sure that these tables do not need backup, you can include `DISABLE_PRECHECK` (introduced in v8.0.0) in `WithOptions` of that statement, and then resubmit it. In this way, the data import task ignores the compatibility check and imports the data directly.

Data imported using `IMPORT INTO` cannot be backed up via log backup. If you need to back up the table, it is recommended to perform a table-level snapshot backup after the import, as described in Back up a table.

13.7.3.5.2 Used with TiCDC

You can perform in different scenarios as follows:

- Scenario 1: the table does not need to be replicated downstream by TiCDC.

  In this scenario, if TiCDC changefeed is enabled, the compatibility check will report an error after you submit the `IMPORT INTO` statement. If you are sure that these tables do not need to be replicated by TiCDC, you can include `DISABLE_PRECHECK` (introduced in v8.0.0) in `WithOptions` of that statement, and then resubmit it. In this way, the data import task ignores the compatibility check and imports the data directly.

- Scenario 2: the table needs to be replicated downstream by TiCDC.

  In this scenario, if TiCDC changefeed is enabled, the compatibility check will report an error after you submit the `IMPORT INTO` statement. You can include `DISABLE_PRECHECK` (introduced in v8.0.0) in `WithOptions` of that statement, and then resubmit it. In this way, the data import task ignores the compatibility check and imports the data directly.

  After the import task for the upstream TiDB cluster is finished, use `IMPORT INTO` to import the same data in the downstream TiDB cluster. If you have databases such as Redshift and Snowflake in the downstream, you can configure them to read CSV, SQL, or Parquet files from a cloud storage service and then write the data to the database.

13.7.4 Quick Start for TiDB Lightning

This document provides a quick guide on getting started with TiDB Lightning by importing MySQL data into a TiDB cluster.

Warning:

The deployment method in this tutorial is only recommended for test and trial. **Do not apply it in the production or development environment.**

13.7.4.1 Step 1: Prepare full backup data

First, you can use dumpling to export data from MySQL.

1. Run `tiup --version` to check if TiUP is already installed. If TiUP is installed, skip this step. If TiUP is not installed, run the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Using TiUP to install Dumpling:

```
tiup install dumpling
```

3. To export data from MySQL, you can refer to the detailed steps provided in Use Dumpling to Export Data:

```
tiup dumpling -h 127.0.0.1 -P 3306 -u root -t 16 -F 256MB -B test -f '
    ↪ test.t[12]' -o /data/my_database/
```

In the above command:

- `-t 16`: Export data using 16 threads.
- `-F 256MB`: Split each table into multiple files, with each file approximately 256 MB in size.
- `-B test`: Export from the `test` database.
- `-f 'test.t[12]'`: Export only the two tables `test.t1` and `test.t2`.

The full backup data exported will be saved in the `/data/my_database` directory.

13.7.4.2 Step 2: Deploy the TiDB cluster

Before starting the data import, you need to deploy a TiDB cluster for the import. If you already have a TiDB cluster, you can skip this step.

For the steps on deploying a TiDB cluster, refer to the Quick Start Guide for the TiDB Database Platform.

13.7.4.3 Step 3: Install TiDB Lightning

Run the following command to install the latest version of TiDB Lightning:

```
tiup install tidb-lightning
```

13.7.4.4 Step 4: Start TiDB Lightning

> **Note:**
>
> The import method in this section is only suitable for testing and functional experience. For production environments, refer to Migrate Large Datasets from MySQL to TiDB

1. Create the configuration file `tidb-lightning.toml` and fill in the following settings based on your cluster information:

```
[lightning]
# Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# Configure the import mode
backend = "local"
# Sets the directory for temporarily storing the sorted key-value pairs
    ↪ . The target directory must be empty.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
# Local source data directory
data-source-dir = "/data/my_datasource/"

# Configures the wildcard rule. By default, all tables in the mysql,
    ↪ sys, INFORMATION_SCHEMA, PERFORMANCE_SCHEMA, METRICS_SCHEMA, and
    ↪ INSPECTION_SCHEMA system databases are filtered.
# If this item is not configured, the "cannot find schema" error occurs
    ↪  when system tables are imported.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
    ↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA
    ↪ .*']
[tidb]
# Information of the target cluster
```

```
host = "172.16.31.2"
port = 4000
user = "root"
password = "rootroot"
# Table schema information is fetched from TiDB via this status-port.
status-port = 10080
# The PD address of the cluster. Starting from v7.6.0, TiDB supports
    ↪ setting multiple PD addresses.
pd-addr = "172.16.31.3:2379,56.78.90.12:3456"
```

2. Run `tidb-lightning`. To avoid the program exiting due to the `SIGHUP` signal when starting the program directly in the command line using `nohup`, it is recommended to put the `nohup` command in a script. For example:

```
#!/bin/bash
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out &
```

13.7.4.5 Step 5: Check data integrity

After the import is completed, TiDB Lightning exits automatically. If the import is successful, you can find `tidb lightning exit` in the last line of the log file.

If any error occurs, refer to TiDB Lightning FAQs.

13.7.4.6 Summary

This tutorial briefly introduces what TiDB Lightning is and how to quickly deploy a TiDB Lightning cluster to import full backup data to the TiDB cluster.

For detailed features and usage about TiDB Lightning, refer to TiDB Lightning Overview.

13.7.5 Deploy TiDB Lightning

This document describes the hardware requirements of using TiDB Lightning to import data, and how to deploy it manually. Requirements on hardware resources vary with the import modes. For details, refer to the following docs:

- Physical Import Mode Requirements and Limitations
- Logical Import Mode Requirements and Limitations

13.7.5.1 Online deployment using TiUP (recommended)

1. Install TiUP using the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

This command automatically adds TiUP to the `PATH` environment variable. You need to start a new terminal session or run `source ~/.bashrc` before you can use TiUP. (According to your environment, you may need to run `source ~/.profile`. For the specific command, check the output of TiUP.)

2. Install TiDB Lightning using TiUP:

```
tiup install tidb-lightning
```

13.7.5.2 Manual deployment

13.7.5.2.1 Download TiDB Lightning binaries

Refer to Download TiDB Tools and download TiDB Lightning binaries. TiDB Lightning is completely compatible with early versions of TiDB. It is recommended to use the latest version of TiDB Lightning.

Unzip the TiDB Lightning binary package to obtain the `tidb-lightning` executable file:

```
tar -zxvf tidb-lightning-${version}-linux-amd64.tar.gz
chmod +x tidb-lightning
```

13.7.5.2.2 Upgrade TiDB Lightning

You can upgrade TiDB Lightning by replacing the binaries alone without further configurations. After the upgrade, you need to restart TiDB Lightning. For details, see How to properly restart TiDB Lightning.

If an import task is running, we recommend you to wait until it finishes before upgrading TiDB Lightning. Otherwise, there might be chances that you need to reimport from scratch, because there is no guarantee that checkpoints work across versions.

13.7.6 TiDB Lightning Requirements for the Target Database

Before using TiDB Lightning, you need to check whether the environment meets the requirements. This helps reduce errors during import and ensures import success.

13.7.6.1 Privileges of the target database

Based on the import mode and features enabled, the target database users should be granted with different privileges. The following table provides a reference.

```
<td></td>
<td>Feature</td>
<td>Scope</td>
<td>Required privilege</td>
<td>Remarks</td>
```

```
<td rowspan="2">Mandatory</td>
<td rowspan="2">Basic functions</td>
<td>Target table</td>
<td>CREATE, SELECT, INSERT, UPDATE, DELETE, DROP, ALTER</td>
<td>DROP is required only when tidb-lightning-ctl runs the checkpoint-
    ↪ destroy-all command</td>
```

```
<td>Target database</td>
<td>CREATE</td>
<td></td>
```

```
<td rowspan="4">Mandatory</td>
<td>Logical Import Mode</td>
<td>information_schema.columns</td>
<td>SELECT</td>
<td></td>
```

```
<td rowspan="3">Physical Import Mode</td>
<td>mysql.tidb</td>
<td>SELECT</td>
<td></td>
```

```
<td>-</td>
<td>SUPER</td>
<td></td>
```

```
<td>-</td>
<td>RESTRICTED_VARIABLES_ADMIN,RESTRICTED_TABLES_ADMIN</td>
<td>Required when the target TiDB enables SEM</td>
```

```
<td>Recommended</td>
<td>Conflict detection, max-error</td>
<td>Schema configured for lightning.task-info-schema-name</td>
<td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP</td>
<td>If not required, the value must be set to ""</td>
```

```
  <td>Optional</td>
  <td>Parallel import</td>
  <td>Schema configured for lightning.meta-schema-name</td>
  <td>SELECT, INSERT, UPDATE, DELETE, CREATE, DROP</td>
  <td>If not required, the value must be set to ""</td>
```

```
  <td>Optional</td>
  <td>checkpoint.driver = "mysql"</td>
  <td>checkpoint.schema setting</td>
  <td>SELECT,INSERT,UPDATE,DELETE,CREATE,DROP</td>
  <td>Required when checkpoint information is stored in databases, instead
     ↪ of files</td>
```

13.7.6.2 Storage space of the target database

The target TiKV cluster must have enough disk space to store the imported data. In addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has x 2 because:

- Indexes might take extra space.
- RocksDB has a space amplification effect.

It is difficult to calculate the exact data volume exported by Dumpling from MySQL. However, you can estimate the data volume by using the following SQL statement to summarize the `DATA_LENGTH` field in the information_schema.tables table:

```
-- Calculate the size of all schemas
SELECT
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(DATA_LENGTH)) AS 'Data Size',
  FORMAT_BYTES(SUM(INDEX_LENGTH)) 'Index Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_SCHEMA;

-- Calculate the 5 largest tables
SELECT
  TABLE_NAME,
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(data_length)) AS 'Data Size',
  FORMAT_BYTES(SUM(index_length)) AS 'Index Size',
```

```
  FORMAT_BYTES(SUM(data_length+index_length)) AS 'Total Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_NAME,
  TABLE_SCHEMA
ORDER BY
  SUM(DATA_LENGTH+INDEX_LENGTH) DESC
LIMIT
  5;
```

13.7.7 Data Sources

13.7.7.1 TiDB Lightning Data Sources

TiDB Lightning supports importing data from multiple data sources to TiDB clusters, including CSV, SQL, and Parquet files.

To specify the data source for TiDB Lightning, use the following configuration:

```
[mydumper]
#### Local source data directory or the URI of the external storage such as
    ↪ S3. For more information about the URI of the external storage, see
    ↪ https://docs.pingcap.com/tidb/dev/backup-and-restore-storages#uri-
    ↪ format.
data-source-dir = "/data/my_database"
```

When TiDB Lightning is running, it looks for all files that match the pattern of `data-source-dir`.

File	Type	Pattern
Schema file	Contains the CREATE TABLE DDL statement	${db_name}.${table_name}-schema.sql

File	Type	Pattern
Schema file	Contains the `CREATE` ↪ `DATABASE` ↪ DDL statement	`${db_` ↪ `name` ↪ `}-` ↪ `schema` ↪ `-` ↪ `create` ↪ `.` ↪ `sql`
Data file	If the data file contains data for a whole table, the file is imported into a table named `${db_` ↪ `name` ↪ `}.${` ↪ `table` ↪ `_` ↪ `name` ↪ `}`	${db_name}.${table_
Data file	If the data for a table is split into multiple data files, each data file must be suffixed with a number in its filename	${db_name}.${table_

File	Type	Pattern
Compressed file	If the file contains a compression suffix, such as `gzip`, `snappy`, or `zstd`, TiDB Lightning will decompress the file before importing it. Note that the Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.	${db_name}.${table_

TiDB Lightning processes data in parallel as much as possible. Because files must be read in sequence, the data processing concurrency is at the file level (controlled by `region-concurrency`). Therefore, when the imported file is large, the import performance is poor. It is recommended to limit the size of the imported file to no greater than 256 MiB to achieve the best performance.

13.7.7.1.1 Rename databases and tables

TiDB Lightning follows filename patterns to import data to the corresponding database and table. If the database or table names change, you can either rename the files and then import them, or use regular expressions to replace the names online.

Rename files in batch

If you are using Red Hat Linux or a distribution based on Red Hat Linux, you can use the `rename` command to batch rename files in the `data-source-dir` directory.

For example:

```
rename srcdb. tgtdb. *.sql
```

After you modify the database name, it is recommended that you delete the `${db_name}-schema-create.sql` file that contains the `CREATE DATABASE` DDL statement from the `data-source-dir` directory. If you want to modify the table name as well, you also need to modify the table name in the `${db_name}.${table_name}-schema.sql` file that contains the `CREATE TABLE` DDL statement.

Use regular expressions to replace names online

To use regular expressions to replace names online, you can use the `pattern` configuration within `[[mydumper.files]]` to match filenames, and replace `schema` and `table` with your desired names. For more information, see Match customized files.

The following is an example of using regular expressions to replace names online. In this example:

- The match rule for the data file `pattern` is `^({schema_regrex})\.({table_regrex})\.({file_serial_regrex})\.(csv|parquet|sql)`.
- Specify `schema` as `'$1'`, which means that the value of the first regular expression `schema_regrex` remains unchanged. Or specify `schema` as a string, such as `'tgtdb'`, which means a fixed target database name.
- Specify `table` as `'$2'`, which means that the value of the second regular expression `table_regrex` remains unchanged. Or specify `table` as a string, such as `'t1'`, which means a fixed target table name.
- Specify `type` as `'$3'`, which means the data file type. You can specify `type` as either `"table-schema"` (representing the `schema.sql` file) or `"schema-schema"` (representing the `schema-create.sql` file).

```
[mydumper]
data-source-dir = "/some-subdir/some-database/"
[[mydumper.files]]
pattern = '^(srcdb)\.(.*?)-schema-create\.sql'
schema = 'tgtdb'
type = "schema-schema"
[[mydumper.files]]
```

```
pattern = '^(srcdb)\.(.*?)-schema\.sql'
schema = 'tgtdb'
table = '$2'
type = "table-schema"
[[mydumper.files]]
pattern = '^(srcdb)\.(.*?)\.(?:[0-9]+)\.(csv|parquet|sql)'
schema = 'tgtdb'
table = '$2'
type = '$3'
```

If you are using `gzip` to back up data files, you need to configure the compression format accordingly. The matching rule of the data file `pattern` is `'^({schema_regrex})\.({table_regrex})\.({file_serial_regrex})\.(csv|parquet|sql)\.(gz)'`. You can specify `compression` as `'$4'` to represent the compressed file format. For example:

```
[mydumper]
data-source-dir = "/some-subdir/some-database/"
[[mydumper.files]]
pattern = '^(srcdb)\.(.*?)-schema-create\.(sql)\.(gz)'
schema = 'tgtdb'
type = "schema-schema"
compression = '$4'
[[mydumper.files]]
pattern = '^(srcdb)\.(.*?)-schema\.(sql)\.(gz)'
schema = 'tgtdb'
table = '$2'
type = "table-schema"
compression = '$4'
[[mydumper.files]]
pattern = '^(srcdb)\.(.*?)\.(?:[0-9]+)\.(sql)\.(gz)'
schema = 'tgtdb'
table = '$2'
type = '$3'
compression = '$4'
```

13.7.7.1.2 CSV

Schema

CSV files are schema-less. To import CSV files into TiDB, you must provide a table schema. You can provide schema by either of the following methods:

- Create files named `${db_name}.${table_name}-schema.sql` and `${db_name}-schema-create.sql` that contain DDL statements.
- Manually create the table schema in TiDB.

Configuration

You can configure the CSV format in the `[mydumper.csv]` section in the `tidb-lightning.toml` file. Most settings have a corresponding option in the `LOAD DATA` statement of MySQL.

```
[mydumper.csv]
#### The field separator. Can be one or multiple characters. The default is
    ↪ ','.
#### If the data might contain commas, it is recommended to use '|+|' or
    ↪ other uncommon
#### character combinations as a separator.
separator = ','
#### Quoting delimiter. Empty value means no quoting.
delimiter = '"'
#### Line terminator. Can be one or multiple characters. Empty value (
    ↪ default) means
#### both "\n" (LF) and "\r\n" (CRLF) are line terminators.
terminator = ''
#### Whether the CSV file contains a header.
#### If `header` is true, the first line is skipped and mapped
#### to the table columns.
header = true
#### Whether the CSV file contains any NULL value.
#### If `not-null` is true, all columns from CSV cannot be parsed as NULL.
not-null = false
#### When `not-null` is false (that is, CSV can contain NULL),
#### fields equal to this value will be treated as NULL.
null = '\N'
#### Whether to parse backslash as escape character.
backslash-escape = true
#### Whether to treat `separator` as the line terminator and trim all
    ↪ trailing separators.
trim-last-separator = false
```

If the input of a string field such as `separator`, `delimiter`, or `terminator` involves special characters, you can use a backslash to escape the special characters. The escape sequence must be a *double-quoted* string (`"⋯"`). For example, `separator = "\u001f"` means using the ASCII character `0X1F` as the separator.

You can use *single-quoted* strings (`'⋯'`) to suppress backslash escaping. For example, `terminator = '\n'` means using the two-character string, a backslash (\) followed by the letter `n`, as the terminator, rather than the LF `\n`.

For more details, see the TOML v1.0.0 specification.

`separator`

- Defines the field separator.
- Can be one or multiple characters, but must not be empty.
- Common values:
    - `','` for CSV (comma-separated values).
    - `"\t"` for TSV (tab-separated values).
    - `"\u0001"` to use the ASCII character `0x01`.
- Corresponds to the `FIELDS TERMINATED BY` option in the LOAD DATA statement.

`delimiter`

- Defines the delimiter used for quoting.
- If `delimiter` is empty, all fields are unquoted.
- Common values:
    - `'"'` quotes fields with double-quote. The same as RFC 4180.
    - `''` disables quoting.
- Corresponds to the `FIELDS ENCLOSED BY` option in the `LOAD DATA` statement.

`terminator`

- Defines the line terminator.
- If `terminator` is empty, both `"\n"` (Line Feed) and `"\r\n"` (Carriage Return + Line Feed) are used as the line terminator.
- Corresponds to the `LINES TERMINATED BY` option in the `LOAD DATA` statement.

`header`

- Whether *all* CSV files contain a header row.
- If `header` is `true`, the first row is used as the *column names*. If `header` is `false`, the first row is treated as an ordinary data row.

`not-null` and `null`

- The `not-null` setting controls whether all fields are non-nullable.
- If `not-null` is `false`, the string specified by `null` is transformed to the SQL NULL instead of a specific value.

- Quoting does not affect whether a field is null.

  For example, in the following CSV file:

```
A,B,C
\N,"\N",
```

  In the default settings (`not-null = false; null = '\N'`), the columns `A` and `B` are both converted to NULL after being imported to TiDB. The column `C` is an empty string `''` but not NULL.

`backslash-escape`

- Whether to parse backslash inside fields as escape characters.
- If `backslash-escape` is true, the following sequences are recognized and converted:

Sequence	Converted to
`\0`	Null character (`U+0000`)
`\b`	Backspace (`U+0008`)
`\n`	Line feed (`U+000A`)
`\r`	Carriage return (`U+000D`)
`\t`	Tab (`U+0009`)
`\Z`	Windows EOF (`U+001A`)

  In all other cases (for example, `\"`), the backslash is stripped, leaving the next character (`"`) in the field. The character left has no special roles (for example, delimiters) and is just an ordinary character.

- Quoting does not affect whether backslash is parsed as an escape character.
- Corresponds to the `FIELDS ESCAPED BY '\'` option in the `LOAD DATA` statement.

`trim-last-separator`

- Whether to treat `separator` as the line terminator and trim all trailing separators.

  For example, in the following CSV file:

```
A,,B,,
```

  - When `trim-last-separator = false`, this is interpreted as a row of 5 fields `('A', '', 'B', '', '')`.
  - When `trim-last-separator = true`, this is interpreted as a row of 3 fields `('A', '', 'B')`.

- This option is deprecated. Use the `terminator` option instead.

  If your existing configuration is:

```
separator = ','
trim-last-separator = true
```

  It is recommended to change the configuration to:

```
separator = ','
terminator = ",\n" # Use ",\n" or ",'\r\n" according to your actual
   ↪ file.
```

Non-configurable options

TiDB Lightning does not support every option supported by the `LOAD DATA` statement. For example:

- There cannot be line prefixes (`LINES STARTING BY`).
- The header cannot be skipped (`IGNORE n LINES`) and must be valid column names.

Strict format

TiDB Lightning works best when the input files have a uniform size of around 256 MiB. When the input is a single huge CSV file, TiDB Lightning can only process the file in one thread, which slows down the import speed.

This can be fixed by splitting the CSV into multiple files first. For the generic CSV format, there is no way to quickly identify where a row starts or ends without reading the whole file. Therefore, TiDB Lightning by default does *not* automatically split a CSV file. However, if you are certain that the CSV input adheres to certain restrictions, you can enable the `strict-format` setting to allow TiDB Lightning to split the file into multiple 256 MiB-sized chunks for parallel processing.

```
[mydumper]
strict-format = true
```

In a strict CSV file, every field occupies only a single line. In other words, one of the following must be true:

- Delimiter is empty.
- Every field does not contain the terminator itself. In the default configuration, this means every field does not contain CR (`\r`) or LF (`\n`).

If a CSV file is not strict, but `strict-format` is wrongly set to `true`, a field spanning multiple lines may be cut in half into two chunks, causing parse failure, or even quietly importing corrupted data.

Common configuration examples

CSV

The default setting is already tuned for CSV following RFC 4180.

```
[mydumper.csv]
separator = ',' # If the data might contain a comma (','), it is recommended
    ↪  to use '|+|' or other uncommon character combinations as the
    ↪ separator.
delimiter = '"'
header = true
not-null = false
null = '\N'
backslash-escape = true
```

Example content:

```
ID,Region,Count
1,"East",32
2,"South",\N
3,"West",10
4,"North",39
```

TSV

```
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
```

Example content:

```
ID    Region    Count
1     East      32
2     South     NULL
3     West      10
4     North     39
```

TPC-H DBGEN

```
[mydumper.csv]
separator = '|'

2|South|0|
3|West|10|
4|North|39|
```

13.7.7.1.3 SQL

When TiDB Lightning processes a SQL file, because TiDB Lightning cannot quickly split a single SQL file, it cannot improve the import speed of a single file by increasing concurrency. Therefore, when you import data from SQL files, avoid a single huge SQL file. TiDB Lightning works best when the input files have a uniform size of around 256 MiB.

13.7.7.1.4 Parquet

TiDB Lightning currently only supports Parquet files generated by Amazon Aurora, Apache Hive, and Snowflake. To identify the file structure in S3, use the following configuration to match all data files:

```
[[mydumper.files]]
#### The expression needed for parsing Amazon Aurora parquet files
pattern = '(?i)^(?:[^/]*/)*([a-z0-9\-_]+).([a-z0-9\-_]+)/(?:[^/]*/)*(?:[a-z0
    ↪ -9\-_.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

Note that this configuration only shows how to match the parquet files exported by Aurora snapshot. You need to export and process the schema file separately.

For more information on `mydumper.files`, refer to Match customized file.

13.7.7.1.5 Compressed files

TiDB Lightning currently supports compressed files exported by Dumpling or compressed files that follow the naming rules. Currently, TiDB Lightning supports the following compression algorithms: `gzip`, `snappy`, and `zstd`. When the file name follows the naming rules, TiDB Lightning automatically identifies the compression algorithm and imports the file after streaming decompression, without additional configuration.

Note:

- Because TiDB Lightning cannot concurrently decompress a single large compressed file, the size of the compressed file affects the import speed. It is recommended that a source file is no greater than 256 MiB after decompression.
- TiDB Lightning only imports individually compressed data files and does not support importing a single compressed file with multiple data files included.
- TiDB Lightning does not support `parquet` files compressed through another compression tool, such as `db.table.parquet.snappy`. If you want to compress `parquet` files, you can configure the compression format for the `parquet` file writer.
- TiDB Lightning v6.4.0 and later versions only support the following compressed data files: `gzip`, `snappy`, and `zstd`. Other types of files cause errors. If an unsupported compressed file exists in the directory where the source data file is stored, this will cause the task to report an error. You can move those unsupported files out of the import data directory to avoid such errors.
- The Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.

13.7.7.1.6 Match customized files

TiDB Lightning only recognizes data files that follow the naming pattern. In some cases, your data file might not follow the naming pattern, and thus data import is completed in a short time without importing any file.

To resolve this issue, you can use `[[mydumper.files]]` to match data files in your customized expression.

Take the Aurora snapshot exported to S3 as an example. The complete path of the Parquet file is `S3://some-bucket/some-subdir/some-database/some-database.some-table-part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet`.

Usually, `data-source-dir` is set to `S3://some-bucket/some-subdir/some-database/` to import the `some-database` database.

Based on the preceding Parquet file path, you can write a regular expression like `(?i)^(?:[^/]*/)*([a-z0-9\-_]+).([a-z0-9\-_]+)/(?:[^/]*/)*(?:[a-z0-9\-_.]+\.(parquet))$` to match the files. In the match group, `index=1` is `some-database`, `index=2` is `some-table`, and `index=3` is `parquet`.

You can write the configuration file according to the regular expression and the corresponding index so that TiDB Lightning can recognize the data files that do not follow the default naming convention. For example:

```
[[mydumper.files]]
#### The expression needed for parsing the Amazon Aurora parquet file
pattern = '(?i)^(?:[^/]*/)*([a-z0-9\-_]+).([a-z0-9\-_]+)/(?:[^/]*/)*(?:[a-z0
    ↪ -9\-_.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

- **schema**: The name of the target database. The value can be:
  - The group index obtained by using a regular expression, such as `$1`.
  - The name of the database that you want to import, such as `db1`. All matched files are imported into `db1`.
- **table**: The name of the target table. The value can be:
  - The group index obtained by using a regular expression, such as `$2`.
  - The name of the table that you want to import, such as `table1`. All matched files are imported into `table1`.
- **type**: The file type. Supports `sql`, `parquet`, and `csv`. The value can be:
  - The group index obtained by using a regular expression, such as `$3`.
- **key**: The file number, such as `001` in `${db_name}.${table_name}.001.csv`.
  - The group index obtained by using a regular expression, such as `$4`.

13.7.7.1.7 Import data from Amazon S3

The following examples show how to import data from Amazon S3 using TiDB Lightning. For more parameter configurations, see URI Formats of External Storage Services.

- Use the locally configured permissions to access S3 data:

```
tiup tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend
    ↪ =local --sorted-kv-dir=/tmp/sorted-kvs \
    -d 's3://my-bucket/sql-backup'
```

- Use the path-style request to access S3 data:

```
tiup tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend
    ↪ =local --sorted-kv-dir=/tmp/sorted-kvs \
    -d 's3://my-bucket/sql-backup?force-path-style=true&endpoint=http
        ↪ ://10.154.10.132:8088'
```

- Use a specific AWS IAM role ARN to access S3 data:

```
tiup tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend
    ↪ =local --sorted-kv-dir=/tmp/sorted-kvs \
    -d 's3://my-bucket/test-data?role-arn=arn:aws:iam::888888888888:
        ↪ role/my-role'
```

- Use access keys of an AWS IAM user to access S3 data:

```
tiup tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend
    ↪ =local --sorted-kv-dir=/tmp/sorted-kvs \
    -d 's3://my-bucket/test-data?access_key={my_access_key}&secret_
        ↪ access_key={my_secret_access_key}'
```

- Use the combination of AWS IAM role access keys and session tokens to access S3 data:

```
tiup tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend
    ↪ =local --sorted-kv-dir=/tmp/sorted-kvs \
    -d 's3://my-bucket/test-data?access_key={my_access_key}&secret_
        ↪ access_key={my_secret_access_key}&session-token={my_session_
        ↪ token}'
```

13.7.7.1.8 More resources

- Export to CSV files Using Dumpling
- LOAD DATA

13.7.8 Physical Import Mode

13.7.8.1 Physical Import Mode

Physical import mode is an efficient and fast import mode that inserts data directly into TiKV nodes as key-value pairs without going through the SQL interface. When using the physical import mode, a single instance of Lightning can import up to 10 TiB of data. The supported amount of imported data theoretically increases as the number of Lightning instances increases. It is verified by users that parallel importing based on Lightning can effectively handle up to 50 TiB of data.

Before you use the physical import mode, make sure to read Requirements and restrictions.

The backend for the physical import mode is `local`. You can modify it in `tidb-lightning.toml`:

```
toml [tikv-importer] # Set the import mode to "local" to use the physical
↪  import mode. backend = "local"
```

13.7.8.1.1 Implementation

1. Before importing data, TiDB Lightning automatically switches the TiKV nodes to "import mode", which improves write performance and stops auto-compaction. TiDB Lightning determines whether to pause global scheduling according to the TiDB Lightning version.

    - Starting from v7.1.0, you can control the scope of pausing scheduling by using the TiDB Lightning parameter `pause-pd-scheduler-scope`.
    - For TiDB Lightning versions between v6.2.0 and v7.0.0, the behavior of pausing global scheduling depends on the TiDB cluster version. When the TiDB cluster >= v6.1.0, TiDB Lightning pauses scheduling for the Region that stores the target table data. After the import is completed, TiDB Lightning recovers scheduling. For other versions, TiDB Lightning pauses global scheduling.
    - When TiDB Lightning < v6.2.0, TiDB Lightning pauses global scheduling.

2. TiDB Lightning creates table schemas in the target database and fetches the metadata.

    If you set `add-index-by-sql` to `true`, `tidb-lightning` adds indexes via the SQL interface, and drops all secondary indexes from the target table before importing the data. The default value is `false`, which is consistent with earlier versions.

3. Each table is divided into multiple contiguous **blocks**, so that TiDB Lightning can import data from large tables (greater than 200 GB) in parallel.

4. TiDB Lightning prepares an "engine file" for each block to handle key-value pairs. TiDB Lightning reads the SQL dump in parallel, converts the data source to key-value pairs in the same encoding as TiDB, sorts the key-value pairs and writes them to a local temporary storage file.

5. When an engine file is written, TiDB Lightning starts to split and schedule data on the target TiKV cluster, and then imports data to TiKV cluster.

    The engine file contains two types of engines: **data engine** and **index engine**. Each engine corresponds to a type of key-value pairs: row data and secondary index. Normally, row data is completely ordered in the data source, and the secondary index is unordered. Therefore, the data engine files are imported immediately after the corresponding block is written, and all index engine files are imported only after the entire table is encoded.

    Note that when `tidb-lightning` adds indexes via the SQL interface (that is, you set `add-index-by-sql` to `true`), the index engine will not write data because the secondary indexes of the target table have already been dropped in step 2.

6. After all engine files are imported, TiDB Lightning compares the checksum between the local data source and the downstream cluster, and ensures that the imported data is not corrupted. Then TiDB Lightning adds the previously dropped secondary indexes in step 2, or lets TiDB analyze the new data (`ANALYZE`) to optimize future operations.

Meanwhile, `tidb-lightning` adjusts the `AUTO_INCREMENT` value to prevent conflicts in the future.

The auto-increment ID is estimated by the **upper bound** of the number of rows, and is proportional to the total size of the table data file. Therefore, the auto-increment ID is usually larger than the actual number of rows. This is normal because the auto-increment ID is not necessarily contiguous.

7. After all steps are completed, TiDB Lightning automatically switches the TiKV nodes to "normal mode". If global scheduling is paused, TiDB Lightning also recovers global scheduling. After that, the TiDB cluster can provide services normally.

13.7.8.1.2 Requirements and restrictions

Environment requirements

Operating system:

It is recommended to use fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, tikv-server) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU:

It is recommended that you allocate CPU more than 32 cores and memory greater than 64 GiB to get better performance.

> **Note:**
>
> When you import a large amount of data, one concurrent import may consume about 2 GiB memory. The total memory usage can be `region-concurrency * 2 GiB`. `region-concurrency` is the same as the number of logical CPUs by default. If the memory size (GiB) is less than twice of the CPU or OOM occurs during the import, you can decrease `region-concurrency` to avoid OOM.

Storage: The `sorted-kv-dir` configuration item specifies the temporary storage directory for the sorted key-value files. The directory must be empty, and the storage space must be greater than the size of the dataset to be imported. For better import performance, it is recommended to use a directory different from `data-source-dir` and use flash storage and exclusive I/O for the directory.

Network: A 10Gbps Ethernet card is recommended.

Version requirements

- TiDB Lightning >= v4.0.3.
- TiDB >= v4.0.0.

Limitations

- Do not use the physical import mode to directly import data to TiDB clusters in production. It has severe performance implications. If you need to do so, refer to Pause scheduling on the table level.
- If your TiDB cluster has a latency-sensitive application and a low concurrency, it is strongly recommended that you **do not** use the physical import mode to import data into the cluster. This mode might have significant impact on the online application.
- Do not use multiple TiDB Lightning instances to import data to the same TiDB cluster by default. Use Parallel Import instead.
- When you use multiple TiDB Lightning to import data to the same target cluster, do not mix the import modes. That is, do not use the physical import mode and the logical import mode at the same time.
- During the process of importing data, do not perform DDL and DML operations in the target table. Otherwise the import will fail or the data will be inconsistent. At the same time, it is not recommended to perform read operations, because the data you read might be inconsistent. You can perform read and write operations after the import operation is completed.
- A single Lightning process can import a single table of 10 TiB at most. Parallel import can use 10 Lightning instances at most.

Tips for using with other components

- When you use TiDB Lightning with TiFlash, note the following:
    - Whether you have created a TiFlash replica for a table, you can use TiDB Lightning to import data to the table. However, the import might take longer than the normal import. The import time is influenced by the network bandwidth of the server TiDB Lightning is deployed on, the CPU and disk load on the TiFlash node, and the number of TiFlash replicas.
- TiDB Lightning character sets:
    - TiDB Lightning earlier than v5.4.0 cannot import tables of `charset=GBK`.
- When you use TiDB Lightning with TiCDC, note the following:
    - TiCDC cannot capture the data inserted in the physical import mode.
- When you use TiDB Lightning with BR, note the following:

- When BR backs up snapshots of tables that are being imported by TiDB Lightning, it might result in inconsistent backup data for those tables.
- When BR backs up data using AWS EBS volume snapshots, TiDB Lightning might fail to import data.
- Data imported in TiDB Lightning physical import mode does not support log backup and thereby cannot be restored by Point-in-Time Recovery (PITR).

13.7.8.2 Use Physical Import Mode

This document introduces how to use the physical import mode in TiDB Lightning, including writing the configuration file, tuning performance, and configuring disk quota.

There are limitations on the physical import mode. Before using the physical import mode, make sure to read Limitations.

13.7.8.2.1 Configure and use the physical import mode

You can use the following configuration file to execute data import using the physical import mode:

```
[lightning]
#### log
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14

#### Checks the cluster minimum requirements before start.
check-requirements = true

[mydumper]
#### The local data source directory or the URI of the external storage. For
   ↪  more information about the URI of the external storage, see https://
   ↪ docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
data-source-dir = "/data/my_database"

[conflict]
#### Starting from v7.3.0, a new version of strategy is introduced to handle
   ↪  conflicting data. The default value is "". Starting from v8.0.0,
   ↪ TiDB Lightning optimizes the conflict strategy for both physical and
   ↪ logical import modes.
#### - "": TiDB Lightning does not detect or handle conflicting data. If the
   ↪  source file contains conflicting primary or unique key records, the
   ↪ subsequent step reports an error.
```

```
#### - "error": when detecting conflicting primary or unique key records in
   ↪ the imported data, TiDB Lightning terminates the import and reports
   ↪ an error.
#### - "replace": when encountering conflicting primary or unique key
   ↪ records, TiDB Lightning retains the latest data and overwrites the
   ↪ old data.
####           The conflicting data are recorded in the `lightning_task_
   ↪ info.conflict_view` view of the target TiDB cluster.
####           In the `lightning_task_info.conflict_view` view, if the `is_
   ↪ precheck_conflict` field for a row is `0`, it means that the
   ↪ conflicting data recorded in that row is detected by postprocess
   ↪ conflict detection; if the `is_precheck_conflict` field for a row is
   ↪ `1`, it means that conflicting data recorded in that row is detected
   ↪ by pre-import conflict detection.
####           You can manually insert the correct records into the target
   ↪ table based on your application requirements. Note that the target
   ↪ TiKV must be v5.2.0 or later versions.
strategy = ""
#### Controls whether to enable pre-import conflict detection, which checks
   ↪ conflicts in data before importing it to TiDB. The default value is
   ↪ false, indicating that TiDB Lightning only checks conflicts after the
   ↪  import. If you set it to true, TiDB Lightning checks conflicts both
   ↪ before and after the import. This parameter can be used only in the
   ↪ physical import mode. In scenarios where the number of conflict
   ↪ records is greater than 1,000,000, it is recommended to set `precheck
   ↪ -conflict-before-import = true` for better performance in conflict
   ↪ detection. In other scenarios, it is recommended to disable it.
#### precheck-conflict-before-import = false
#### threshold = 10000
#### Starting from v8.1.0, there is no need to configure `max-record-rows`
   ↪ manually, because TiDB Lightning automatically assigns the value of `
   ↪ max-record-rows` with the value of `threshold`, regardless of the
   ↪ user input. `max-record-rows` will be deprecated in a future release.
#### max-record-rows = 10000

[tikv-importer]
#### Import mode. "local" means using the physical import mode.
backend = "local"

#### The `duplicate-resolution` parameter is deprecated starting from v8.0.0
   ↪  and will be removed in a future release. For more information, see <
   ↪ https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
   ↪ mode-usage#the-old-version-of-conflict-detection-deprecated-in-v800>.
#### If you set `duplicate-resolution = 'none'` and do not set `conflict.
   ↪ strategy`, TiDB Lightning will automatically assign `""` to `conflict
```

```
   ↪ .strategy`.
#### If you set `duplicate-resolution = 'remove'` and do not set `conflict.
   ↪ strategy`, TiDB Lightning will automatically assign "replace" to `
   ↪ conflict.strategy` and enable the new version of conflict detection.
#### The method to resolve the conflicting data.
duplicate-resolution = 'none'

#### The directory of local KV sorting.
sorted-kv-dir = "./some-dir"

#### Limits the bandwidth in which TiDB Lightning writes data into each TiKV
#### node in the physical import mode. 0 by default, which means no limit.
#### store-write-bwlimit = "128MiB"

#### Specifies whether Physical Import Mode adds indexes via SQL. The
   ↪ default value is `false`, which means that TiDB Lightning will encode
   ↪  both row data and index data into KV pairs and import them into TiKV
   ↪  together. This mechanism is consistent with that of the historical
   ↪ versions. If you set it to `true`, it means that TiDB Lightning adds
   ↪ indexes via SQL after importing the row data.
#### The benefit of adding indexes via SQL is that you can separately import
   ↪  data and import indexes, and import data more quickly. After the
   ↪ data is imported, even if the indexes fail to be added, it does not
   ↪ affect the consistency of the imported data.
#### add-index-by-sql = false

[tidb]
#### The information of the target cluster. The address of any tidb-server
   ↪ from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
#### Configure the password to connect to TiDB. Either plaintext or Base64
   ↪ encoded.
password = ""
#### Required. Table schema information is fetched from TiDB via this status
   ↪ -port.
status-port = 10080
#### Required. The address of any pd-server from the cluster. Starting from
   ↪ v7.6.0, TiDB supports setting multiple PD addresses.
pd-addr = "172.16.31.4:2379,56.78.90.12:3456"
#### tidb-lightning imports the TiDB library, and generates some logs.
#### Set the log level of the TiDB library.
log-level = "error"
```

```
[post-restore]
#### Specifies whether to perform `ADMIN CHECKSUM TABLE <table>` for each
   ↪ table to verify data integrity after importing.
#### The following options are available:
#### - "required" (default): Perform admin checksum after importing. If
   ↪ checksum fails, TiDB Lightning will exit with failure.
#### - "optional": Perform admin checksum. If checksum fails, TiDB Lightning
   ↪  will report a WARN log but ignore any error.
#### - "off": Do not perform checksum after importing.
#### Note that since v4.0.8, the default value has changed from "true" to "
   ↪ required".
#### # Note:
#### 1. Checksum failure usually means import exception (data loss or data
   ↪ inconsistency), so it is recommended to always enable Checksum.
#### 2. For backward compatibility, bool values "true" and "false" are also
   ↪ allowed for this field.
#### "true" is equivalent to "required" and "false" is equivalent to "off".
checksum = "required"

#### Specifies whether to perform `ANALYZE TABLE <table>` for each table
   ↪ after checksum is done.
#### Options available for this field are the same as `checksum`. However,
   ↪ the default value for this field is "optional".
analyze = "optional"
```

For the complete configuration file, refer to the configuration file and command line parameters.

13.7.8.2.2 Conflict detection

Conflicting data refers to two or more records with the same primary key or unique key column data. When the data source contains conflicting data and conflict detection feature is not turned on, the actual number of rows in the table is different from the total number of rows returned by the query using unique index.

There are two versions for conflict detection:

- The new version of conflict detection, controlled by the `conflict` configuration item.
- The old version of conflict detection (deprecated in v8.0.0 and will be removed in a future release), controlled by the `tikv-importer.duplicate-resolution` configuration item.

The new version of conflict detection

The meanings of configuration values are as follows:

Strategy	Default behavior of conflicting data	The corresponding SQL statement
`"` ↪ `replace` ↪ `"` ↪	Retaining the latest data and overwriting the old data	`REPLACE` ↪ ↪ `INTO` ↪ ↪ `...` ↪
`"` ↪ `error` ↪ `"` ↪	Terminating the import and reporting an error.	`INSERT` ↪ ↪ `INTO` ↪ ↪ `...` ↪

Strategy	Default behavior of conflicting data	The corresponding SQL statement
""	TiDB Lightning does not detect or handle conflicting data. If data with primary and unique key conflicts exists, the subsequent checksum step reports an error.	None

Strategy	Default behavior of conflicting data	The corresponding SQL statement

> **Note:**
>
> The conflict detection result in the physical import mode might differ from SQL-based import due to internal implementation and limitation of TiDB Lightning.

When the strategy is `"error"` and conflicting data is detected, TiDB Lightning reports an error and exits the import. When the strategy is `"replace"`, conflicting data is treated as conflict errors. If the `conflict.threshold` value is greater than `0`, TiDB Lightning tolerates the specified number of conflict errors. The default value is `9223372036854775807`, which means that almost all errors are tolerant. For more information, see error resolution.

The new version of conflict detection has the following limitations:

- Before importing, TiDB Lightning prechecks potential conflicting data by reading all data and encoding it. During the detection process, TiDB Lightning uses `tikv-importer.sorted-kv-dir` to store temporary files. After the detection is complete, TiDB Lightning retains the results for import phase. This introduces additional overhead for time consumption, disk space usage, and API requests to read the data.
- The new version of conflict detection only works in a single node, and does not apply to parallel imports and scenarios where the `disk-quota` parameter is enabled.

The new version of conflict detection controls whether to enable pre-import conflict detection via the `precheck-conflict-before-import` parameter. In cases where the original data contains a lot of conflicting data, the total time consumed by conflict detection before and after the import is less than that of the old version. Therefore, it is recommended to enable pre-import conflict detection in scenarios where the ratio of conflict records is greater than or equal to 1% and the local disk space is sufficient.

The old version of conflict detection (deprecated in v8.0.0)

Starting from v8.0.0, the old version of conflict detection (`tikv-importer.duplicate-resolution`) is deprecated. The `tikv-importer.duplicate-resolution` parameter

will be removed in a future release. If `tikv-importer.duplicate-resolution` is `remove` and `conflict.strategy` is not configured, TiDB Lightning automatically enables the new version of conflict detection by assigning the value of `conflict.strategy` to `"replace"` ↪ . Note that `tikv-importer.duplicate-resolution` and `conflict.strategy` cannot be configured at the same time, as it will result in an error.

- For versions between v7.3.0 and v7.6.0, TiDB Lightning enables the old version of conflict detection when `tikv-importer.duplicate-resolution` is not an empty string.
- For v7.2.0 and earlier versions, TiDB Lightning only supports the old version of conflict detection.

In the old version of conflict detection, TiDB Lightning offers two strategies:

- `remove` (recommended): records and removes all conflicting records from the target table to ensure a consistent state in the target TiDB.
- `none`: does not detect duplicate records. `none` has the best performance in the two strategies, but might lead to inconsistent data in the target TiDB.

Before v5.3, TiDB Lightning does not support conflict detection. If there is conflicting data, the import process fails at the checksum step. When conflict detection is enabled, if there is conflicting data, TiDB Lightning skips the checksum step (because it always fails).

Suppose an `order_line` table has the following schema:

```
CREATE TABLE IF NOT EXISTS `order_line` (
  `ol_o_id` int(11) NOT NULL,
  `ol_d_id` int(11) NOT NULL,
  `ol_w_id` int(11) NOT NULL,
  `ol_number` int(11) NOT NULL,
  `ol_i_id` int(11) NOT NULL,
  `ol_supply_w_id` int(11) DEFAULT NULL,
  `ol_delivery_d` datetime DEFAULT NULL,
  `ol_quantity` int(11) DEFAULT NULL,
  `ol_amount` decimal(6,2) DEFAULT NULL,
  `ol_dist_info` char(24) DEFAULT NULL,
  PRIMARY KEY (`ol_w_id`,`ol_d_id`,`ol_o_id`,`ol_number`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

If Lightning detects conflicting data during the import, you can query the `lightning_` ↪ `task_info.conflict_error_v3` table as follows:

```
mysql> select table_name,index_name,key_data,row_data from conflict_error_
    ↪ v3 limit 10;
+--
    ↪ ------------------+------------+----------+-----------------------------------
    ↪
```

```
| table_name       | index_name | key_data | row_data
   ↪                                                                |
+--
   ↪ ------------------+------------+----------+-----------------------------------
   ↪
| `tpcc`.`order_line` | PRIMARY | 21829216 | (2677, 10, 10, 11, 75656, 10,
   ↪ NULL, 5, 5831.97, "HT5DN3EVb6kWTd4L37bsbogj") |

```

You can manually identify the records that need to be retained and insert these records into the table.

13.7.8.2.3 Scope of pausing scheduling during import

Starting from v6.2.0, TiDB Lightning implements a mechanism to limit the impact of data import on online applications. With the new mechanism, TiDB Lightning does not pause the global scheduling, but only pauses scheduling for the Region that stores the target table data. This significantly reduces the impact of the import on online applications.

Starting from v7.1.0, you can control the scope of pausing scheduling by using the TiDB Lightning parameter `pause-pd-scheduler-scope`. The default value is `"table"`, which means that the scheduling is paused only for the Region that stores the target table data. When there is no business traffic in the cluster, it is recommended to set this parameter to `"global"` to avoid interference from other scheduling during the import.

TiDB Lightning does not support importing data into a table that already contains data.

The TiDB cluster must be v6.1.0 or later versions. For earlier versions, TiDB Lightning keeps the old behavior, which pauses scheduling globally and severely impacts the online application during the import.

By default, TiDB Lightning pauses the cluster scheduling for the minimum range possible. However, under the default configuration, the cluster performance still might be affected by fast import. To avoid this, you can configure the following options to control the import speed and other factors that might impact the cluster performance:

```
[tikv-importer]
#### Limits the bandwidth in which TiDB Lightning writes data into each TiKV
   ↪ node in the physical import mode.
store-write-bwlimit = "128MiB"

[tidb]
#### Use smaller concurrency to reduce the impact of Checksum and Analyze on
   ↪ the transaction latency.
distsql-scan-concurrency = 3
```

You can measure the impact of data import on TPCC results by simulating the online application using TPCC and importing data into a TiDB cluster using TiDB Lightning. The test result is as follows:

Concurrency	TPM	P99	P90	AVG
1	20%~30%	60%~80%	30%~50%	30%~40%
8	15%~25%	70%~80%	35%~45%	20%~35%
16	20%~25%	55%~85%	35%~40%	20%~30%
64	No significant impact			
256	No significant impact			

The percentage in the preceding table indicates the impact of data import on TPCC results.

- For the TPM column, the number indicates the percentage of TPM decrease.
- For the P99, P90, and AVG columns, the number indicates the percentage of latency increase.

The test results show that the smaller the concurrency, the larger the impact of data import on TPCC results. When the concurrency is 64 or more, the impact of data import on TPCC results is negligible.

Therefore, if your TiDB cluster has a latency-sensitive application and a low concurrency, it is strongly recommended **not** to use TiDB Lightning to import data into the cluster. This will cause a significant impact on the online application.

13.7.8.2.4 Performance tuning

The most direct and effective ways to improve import performance of the physical import mode are as follows:

- **Upgrade the hardware of the node where Lightning is deployed, especially the CPU and the storage device of `sorted-key-dir`.**
- **Use the parallel import feature to achieve horizontal scaling.**

TiDB Lightning provides some concurrency-related configurations to affect import performance in the physical import mode. However, from long-term experience, it is recommended to keep the following four configuration items in the default value. Adjusting the four configuration items does not bring significant performance boost.

```
[lightning]
#### The maximum concurrency of engine files.
#### Each table is split into one "index engine" to store indices, and
   ↪ multiple
#### "data engines" to store row data. These settings control the maximum
#### concurrent number for each type of engines.
#### The two settings controls the maximum concurrency of the two engine
   ↪ files.
index-concurrency = 2
table-concurrency = 6

#### The concurrency of data. The default value is the number of logical
   ↪ CPUs.
region-concurrency =

#### The maximum concurrency of I/O. When the concurrency is too high, the
   ↪ disk
#### cache may be frequently refreshed, causing the cache miss and read
   ↪ speed
#### to slow down. For different storage mediums, this parameter may need to
   ↪  be
#### adjusted to achieve the best performance.
io-concurrency = 5
```

During the import, each table is split into one "index engine" to store indices, and multiple "data engines" to store row data.

`index-concurrency` controls the maximum concurrency of the index engine. When you adjust `index-concurrency`, make sure that `index-concurrency * the number of ↪ source files of each table > region-concurrency` to ensure that the CPU is fully utilized. The ratio is usually between 1.5 ~ 2. Do not set `index-concurrency` too high and not lower than 2 (default). Too high `index-concurrency` causes too many pipelines to be built, which causes the index-engine import stage to pile up.

The same goes for `table-concurrency`. Make sure that `table-concurrency * the number of source files of each table > region-concurrency` to ensure that the CPU is fully utilized. A recommended value is around `region-concurrency * 4 / the number of source files of each table` and not lower than 4.

If the table is large, Lightning will split the table into multiple batches of 100 GiB. The concurrency is controlled by `table-concurrency`.

`index-concurrency` and `table-concurrency` has little effect on the import speed. You can leave them in the default value.

`io-concurrency` controls the concurrency of file read. The default value is 5. At any given time, only 5 handles are performing read operations. Because the file read speed is usually not a bottleneck, you can leave this configuration in the default value.

After the file data is read, Lightning needs to do some post-processing, such as encoding and sorting the data locally. The concurrency of these operations is controlled by `region-concurrency`. The default value is the number of CPU cores. You can leave this configuration in the default value. It is recommended to deploy Lightning on a separate server from other components. If you must deploy Lightning together with other components, you need to lower the value of `region-concurrency` according to the load.

The num-threads configuration of TiKV can also affect the performance. For new clusters, it is recommended to set `num-threads` to the number of CPU cores.

13.7.8.2.5 Configure disk quota New in v6.2.0

When you import data in the physical import mode, TiDB Lightning creates a large number of temporary files on the local disk to encode, sort, and split the original data. When the local disk space is insufficient, TiDB Lightning reports an error and exits because of write failure.

To avoid this situation, you can configure disk quota for TiDB Lightning. When the size of the temporary files exceeds the disk quota, TiDB Lightning pauses the process of reading the source data and writing temporary files. TiDB Lightning prioritizes writing the sorted key-value pairs to TiKV. After deleting the local temporary files, TiDB Lightning continues the import process.

To enable disk quota, add the following configuration to your configuration file:

```
[tikv-importer]
#### MaxInt64 by default, which is 9223372036854775807 bytes.
disk-quota = "10GB"
backend = "local"

[cron]
#### The interval of checking disk quota. 60 seconds by default.
check-disk-quota = "30s"
```

`disk-quota` limits the storage space used by TiDB Lightning. The default value is MaxInt64, which is 9223372036854775807 bytes. This value is much larger than the disk space you might need for the import, so leaving it as the default value is equivalent to not setting the disk quota.

`check-disk-quota` is the interval of checking disk quota. The default value is 60 seconds. When TiDB Lightning checks the disk quota, it acquires an exclusive lock for the relevant data, which blocks all the import threads. Therefore, if TiDB Lightning checks the disk quota before every write, it significantly slows down the write efficiency (as slow as a single-thread write). To achieve efficient write, disk quota is not checked before every write; instead, TiDB Lightning pauses all the import threads and checks the disk quota every `check-disk-quota` interval. That is, if the value of `check-disk-quota` is set to a large value, the disk space used by TiDB Lightning might exceed the disk quota you set, which leaves the disk quota ineffective. Therefore, it is recommended to set the value of `check-disk-quota` to a small value. The specific value of this item is determined by the environment in which TiDB Lightning is running. In different environments, TiDB Lightning writes temporary files at different speeds. Theoretically, the faster the speed, the smaller the value of `check-disk-quota` should be.

13.7.9 Logical Import Mode

13.7.9.1 Logical Import Mode Introduction

The logical import mode is one of the two import modes supported by TiDB Lightning. In the logical import mode, TiDB Lightning first encodes data into SQL statements and then runs the SQL statements to import data.

If your TiDB cluster already contains data and provides service for external applications, it is recommended to import data in the logical import mode. The behavior of the logical import mode is the same as executing normal SQL statements, and thus it guarantees ACID compliance.

The backend for the logical import mode is `tidb`.

13.7.9.1.1 Environment requirements

Operating system:

It is recommended to use fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, tikv-server) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU:

It is recommended that you allocate CPU more than 4 cores and memory greater than 8 GiB to get better performance. It is verified that TiDB Lightning does not have significant

memory usage (no more than 5 GiB) in the logical import mode. However, if you increase the value of `region-concurrency`, TiDB Lightning might consume more memory.

Network: A 1 Gbps or 10 Gbps Ethernet card is recommended.

13.7.9.1.2 Limitations

When you use multiple TiDB Lightning to import data to the same target, do not mix the backends. That is, do not use the physical import mode and the logical import mode to import data to a single TiDB cluster at the same time.

13.7.9.2 Use Logical Import Mode

This document introduces how to use the logical import mode in TiDB Lightning, including writing the configuration file and tuning performance.

13.7.9.2.1 Configure and use the logical import mode

You can use the logical import mode via the following configuration file to import data:

```
[lightning]
#### log
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14

#### Checks the cluster minimum requirements before start.
check-requirements = true

[mydumper]
#### The local data source directory or the URI of the external storage. For
   ↪  more information about the URI of the external storage, see https://
   ↪ docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
data-source-dir = "/data/my_database"

[tikv-importer]
#### Import mode. "tidb" means using the logical import mode.
backend = "tidb"

[tidb]
#### The information of the target cluster. The address of any tidb-server
   ↪ from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
```

```
#### Configure the password to connect to TiDB. Either plaintext or Base64
    ↪ encoded.
password = ""
#### tidb-lightning imports the TiDB library, and generates some logs.
#### Set the log level of the TiDB library.
log-level = "error"
```

For the complete configuration file, refer to TiDB Lightning Configuration.

13.7.9.2.2 Conflict detection

Conflicting data refers to two or more records with the same data in the PK or UK column. In the logical import mode, you can configure the strategy for handling conflicting data by setting the `conflict.strategy` configuration item. Based on the strategy, TiDB Lightning imports data with different SQL statements.

Strategy	Default behavior of conflicting data	The corresponding SQL statement
" ↪ `replace` ↪ " ↪	Replacing existing data with new data.	`REPLACE` ↪ ↪ `INTO` ↪ ↪ `...` ↪

Strategy	Default behavior of conflicting data	The corresponding SQL statement
`"` ↪ `ignore` ↪ `"` ↪	Keeping existing data and ignoring new data.	If `conflict` ↪ `.` ↪ `threshold` ↪ is greater than 0, `INSERT` ↪ ↪ `INTO` ↪ is used; if `conflict` ↪ `.` ↪ `threshold` ↪ is 0, `INSERT` ↪ ↪ `IGNORE` ↪ ↪ `INTO` ↪ ↪ `...` ↪ is used

Strategy	Default behavior of conflicting data	The corresponding SQL statement
`"` ↪ `error` ↪ `"` ↪	Terminating the import when conflicting data is detected.	`INSERT` ↪ ↪ `INTO` ↪ ↪ `...` ↪
`""`	Converted to `"` ↪ `error` ↪ `"` ↪ , which means terminating the import when conflicting data is detected.	None

When the strategy is `"error"`, errors caused by conflicting data directly terminate the import task. When the strategy is `"replace"` or `"ignore"`, you can control the maximum tolerant conflicts by configuring `conflict.threshold`. The default value is `10000`, which means that 10000 errors are tolerant.

When the strategy is `"ignore"`, conflicting data is recorded in the downstream `conflict_records` table. For further details, see Error report. Before v8.1.0, you can limit the records by configuring `conflict.max-record-rows`, and conflicting data that exceeds the limit is skipped and not recorded. Starting from v8.1.0, you need to configure `conflict.threshold` instead, because TiDB Lightning automatically assigns the value of `max-record-rows` with the value of `threshold`, regardless of the user input.

13.7.9.2.3 Performance tuning

- In the logical import mode, the performance of TiDB Lightning largely depends on the write performance of the target TiDB cluster. If the cluster hits a performance bottleneck, refer to Highly Concurrent Write Best Practices.
- If the target TiDB cluster does not hit a write bottleneck, consider increasing the value of `region-concurrency` in TiDB Lightning configuration. The default value of `region-concurrency` is the number of CPU cores. The meaning of `region-concurrency` is different between the physical import mode and the logical import mode. In the logical import mode, `region-concurrency` is the write concurrency.

  Example configuration:

  ```
  [lightning]
  region-concurrency = 32
  ```

- Adjusting the `raftstore.apply-pool-size` and `raftstore.store-pool-size` configuration items in the target TiDB cluster might improve the import speed.

13.7.10 TiDB Lightning Prechecks

Starting from TiDB 5.3.0, TiDB Lightning provides the ability to check the configuration before running a migration task. It is enabled by default. This feature automatically performs some routine checks for disk space and execution configuration. The main purpose is to ensure that the whole subsequent import process goes smoothly.

The following table describes each check item and detailed explanation.

Check Items	Supported Version	Description
Cluster version and status	>= 5.3.0	Check whether the cluster can be connected in the configuration, and whether the TiKV/PD/TiFlash version supports the physical import mode.

Check Items	Supported Version	Description
Permissions	>= 5.3.0	When the data source is cloud storage (Amazon S3), check whether TiDB Lightning has the necessary permissions and make sure that the import will not fail due to lack of permissions.

Check Items	Supported Version	Description
Disk space	>= 5.3.0	Check whether there is enough space on the local disk and on the TiKV cluster for importing data. TiDB Lightning samples the data sources and estimates the percentage of the index size from the sample result.

Check Items	Supported Version	Description
Region distribution status	>= 5.3.0	Check whether the Regions in the TiKV cluster are distributed evenly and whether there are too many empty Regions. If the number of empty Regions exceeds max(1000, number of tables * 3), i.e. greater than the bigger one of “1000”

Check Items	Supported Version	Description
Exceedingly Large CSV files in the data file	>= 5.3.0	When there are CSV files larger than 10 GiB in the backup file and auto-slicing is not enabled (Strict-Format=false), it will impact the import performance. The purpose of this check is to remind you to ensure the

Check Items	Supported Version	Description
Recovery from break-points	>= 5.3.0	This check ensures that no changes are made to the source file or schema in the database during the break-point recovery process that would result in importing the wrong data.

Check Items	Supported Version	Description
Import into an existing table	>= 5.3.0	When importing into an already created table, it checks, as much as possible, whether the source file matches the existing table. Check if the number of columns matches. If the source file has column names, check if the column

Check Items	Supported Version	Description
Whether the target table is empty	>= 5.3.1	TiDB Lightning automatically exits with an error if the target table is not empty. If parallel import mode is enabled (`parallel-import = true`), this check item will be skipped.

13.7.11 Table Filter

The TiDB migration tools operate on all the databases by default, but oftentimes only a subset is needed. For example, you only want to work with the schemas in the form of `foo*` and `bar*` and nothing else.

Since TiDB 4.0, all TiDB migration tools share a common filter syntax to define subsets. This document describes how to use the table filter feature.

13.7.11.1 Usage

13.7.11.1.1 CLI

Table filters can be applied to the tools using multiple `-f` or `--filter` command line parameters. Each filter is in the form of `db.table`, where each part can be a wildcard (further explained in the next section). The following lists the example usage.

- BR:

```
tiup br backup full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

```
tiup br restore full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

- Dumpling:

```
tiup dumpling -f 'foo*.*' -f 'bar*.*' -P 3306 -o /tmp/data/
```

- TiDB Lightning:

```
tiup tidb-lightning -f 'foo*.*' -f 'bar*.*' -d /tmp/data/ --backend
    ↪ tidb
```

13.7.11.1.2 TOML configuration files

Table filters in TOML files are specified as array of strings. The following lists the example usage.

- TiDB Lightning:

```
[mydumper]
filter = ['foo*.*', 'bar*.*']
```

- TiCDC:

```
[filter]
rules = ['foo*.*', 'bar*.*']

[[sink.dispatchers]]
matcher = ['db1.*', 'db2.*', 'db3.*']
dispatcher = 'ts'
```

13.7.11.2 Syntax

13.7.11.2.1 Plain table names

Each table filter rule consists of a "schema pattern" and a "table pattern", separated by a dot (`.`). Tables whose fully-qualified name matches the rules are accepted.

```
db1.tbl1
db2.tbl2
db3.tbl3
```

A plain name must only consist of valid identifier characters, such as:

- digits (`0` to `9`)
- letters (`a` to `z`, `A` to `Z`)
- `$`
- `_`
- non ASCII characters (U+0080 to U+10FFFF)

All other ASCII characters are reserved. Some punctuations have special meanings, as described in the next section.

13.7.11.2.2 Wildcards

Each part of the name can be a wildcard symbol described in fnmatch(3):

- `*` — matches zero or more characters
- `?` — matches one character
- `[a-z]` — matches one character between "a" and "z" inclusively
- `[!a-z]` — matches one character except "a" to "z".

```
db[0-9].tbl[0-9a-f][0-9a-f]
data.*
*.backup_*
```

"Character" here means a Unicode code point, such as:

- U+00E9 (é) is 1 character.
- U+0065 U+0301 (é) are 2 characters.
- U+1F926 U+1F3FF U+200D U+2640 U+FE0F (🤦🏿‍♀️) are 5 characters.

13.7.11.2.3 File import

To import a file as the filter rule, include an `@` at the beginning of the rule to specify the file name. The table filter parser treats each line of the imported file as additional filter rules.

For example, if a file `config/filter.txt` has the following content:

```
employees.*
*.WorkOrder
```

the following two invocations are equivalent:

```
tiup dumpling -f '@config/filter.txt'
tiup dumpling -f 'employees.*' -f '*.WorkOrder'
```

A filter file cannot further import another file.

13.7.11.2.4 Comments and blank lines

Inside a filter file, leading and trailing white-spaces of every line are trimmed. Furthermore, blank lines (empty strings) are ignored.

A leading `#` marks a comment and is ignored. `#` not at start of line is considered syntax error.

```
### this line is a comment
db.table  # but this part is not comment and may cause error
```

13.7.11.2.5 Exclusion

An `!` at the beginning of the rule means the pattern after it is used to exclude tables from being processed. This effectively turns the filter into a block list.

```
*.*
#^ note: must add the *.* to include all tables first
!*.Password
!employees.salaries
```

13.7.11.2.6 Escape character

To turn a special character into an identifier character, precede it with a backslash `\`.

```
db\.with\.dots.*
```

For simplicity and future compatibility, the following sequences are prohibited:

- `\` at the end of the line after trimming whitespaces (use `[ ]` to match a literal whitespace at the end).
- `\` followed by any ASCII alphanumeric character (`[0-9a-zA-Z]`). In particular, C-like escape sequences like `\0`, `\r`, `\n` and `\t` currently are meaningless.

13.7.11.2.7 Quoted identifier

Besides `\`, special characters can also be suppressed by quoting using `"` or `` ` ``.

```
"db.with.dots"."tbl\1"
`db.with.dots`.`tbl\2`
```

The quotation mark can be included within an identifier by doubling itself.

```
"foo""bar".`foo``bar`
### equivalent to:
foo\"bar.foo\`bar
```

Quoted identifiers cannot span multiple lines.

It is invalid to partially quote an identifier:

```
"this is "invalid*.*
```

13.7.11.2.8 Regular expression

In case very complex rules are needed, each pattern can be written as a regular expression delimited with `/`:

```
/^db\d{2,}$/./^tbl\d{2,}$/
```

These regular expressions use the Go dialect. The pattern is matched if the identifier contains a substring matching the regular expression. For instance, `/b/` matches `db01`.

> **Note:**
>
> Every `/` in the regular expression must be escaped as `\/`, including inside `[⋯]`. You cannot place an unescaped `/` between `\Q⋯\E`.

13.7.11.3 Multiple rules

When a table name matches none of the rules in the filter list, the default behavior is to ignore such unmatched tables.

To build a block list, an explicit `*.*` must be used as the first rule, otherwise all tables will be excluded.

```
### every table will be filtered out
tiup dumpling -f '!*.Password'

### only the "Password" table is filtered out, the rest are included.
tiup dumpling -f '*.*' -f '!*.Password'
```

In a filter list, if a table name matches multiple patterns, the last match decides the outcome. For instance:

```
### rule 1
employees.*
### rule 2
!*.dep*
### rule 3
*.departments
```

The filtered outcome is as follows:

Table name	Rule 1	Rule 2	Rule 3	Outcome
irrelevant.table				Default (reject)
employees.employees				Rule 1 (accept)
employees.dept_emp				Rule 2 (reject)
employees.departments				Rule 3 (accept)
else.departments				Rule 3 (accept)

Note:

In TiDB tools, the system schemas are always excluded in the default configuration. The system schemas are:

- `INFORMATION_SCHEMA`
- `PERFORMANCE_SCHEMA`
- `METRICS_SCHEMA`
- `INSPECTION_SCHEMA`
- `mysql`
- `sys`

13.7.12 TiDB Lightning Checkpoints

Importing a large database usually takes hours or days, and if such long running processes spuriously crashes, it can be very time-wasting to redo the previously completed tasks. To solve this, TiDB Lightning uses *checkpoints* to store the import progress, so that `tidb-lightning` continues importing from where it lefts off after restarting.

This document describes how to enable, configure, store, and control *checkpoints*.

13.7.12.1 Enable and configure checkpoints

```
[checkpoint]
### Whether to enable checkpoints.
### While importing data, TiDB Lightning records which tables have been imported, so
### even if TiDB Lightning or some other component crashes, you can start from a known
### good state instead of restarting from scratch.
enable = true

### Where to store the checkpoints.
###  - file: store as a local file (requires v2.1.1 or later)
###  - mysql: store into a remote MySQL-compatible database
driver = "file"

### The schema name (database name) to store the checkpoints
### Enabled only when `driver = "mysql"`.
### schema = "tidb_lightning_checkpoint"

### The data source name (DSN) indicating the location of the checkpoint storage.
### # For the "file" driver, the DSN is a path. If the path is not specified, Lightning would
### default to "/tmp/CHECKPOINT_SCHEMA.pb".
### # For the "mysql" driver, the DSN is a URL in the form of "USER:PASS@tcp(HOST:PORT)/".
### If the URL is not specified, the TiDB server from the [tidb] section is used to
### store the checkpoints. You should specify a different MySQL-compatible
### database server to reduce the load of the target TiDB cluster.
#dsn = "/tmp/tidb_lightning_checkpoint.pb"

### Whether to keep the checkpoints after all data are imported. If false, the
### checkpoints are deleted. Keeping the checkpoints can aid debugging but
### might leak metadata about the data source.
```

```
### keep-after-success = false
```

13.7.12.2 Checkpoints storage

TiDB Lightning supports two kinds of checkpoint storage: a local file or a remote MySQL-compatible database.

- With `driver = "file"`, checkpoints are stored in a local file at the path given by the `dsn` setting. Checkpoints are updated rapidly, so we highly recommend placing the checkpoint file on a drive with very high write endurance, such as a RAM disk.
- With `driver = "mysql"`, checkpoints can be saved in any databases compatible with MySQL 5.7 or later, including MariaDB and TiDB. By default, the checkpoints are saved in the target database.

While using the target database as the checkpoints storage, Lightning is importing large amounts of data at the same time. This puts extra stress on the target database and sometimes leads to communication timeout. Therefore, **it is strongly recommended to install a temporary MySQL server to store these checkpoints**. This server can be installed on the same host as `tidb-lightning` and can be uninstalled after the importer progress is completed.

13.7.12.3 Checkpoints control

If `tidb-lightning` exits abnormally due to unrecoverable errors (for example, data corruption), it refuses to reuse the checkpoints until the errors are resolved. This is to prevent worsening the situation. The checkpoint errors can be resolved using the `tidb-lightning-ctl` program.

13.7.12.3.1 `--checkpoint-error-destroy`

```
tidb-lightning-ctl --checkpoint-error-destroy='`schema`.`table`'
```

This option allows you to restart importing the table from scratch. The schema and table names must be quoted with backquotes and are case-sensitive.

- If importing the table `` `schema`.`table` `` failed previously, this option executes the following operations:
    1. DROPs the table `` `schema`.`table` `` from the target database, which means removing all imported data.
    2. Resets the checkpoints record of this table to be "not yet started".
- If there is no errors involving the table `` `schema`.`table` ``, this operation does nothing.

It is the same as applying the above on every table. This is the most convenient, safe and conservative solution to fix the checkpoint error problem:

```
tidb-lightning-ctl --checkpoint-error-destroy=all
```

13.7.12.3.2 `--checkpoint-error-ignore`

```
tidb-lightning-ctl --checkpoint-error-ignore='`schema`.`table`'
tidb-lightning-ctl --checkpoint-error-ignore=all
```

If importing the table `` `schema`.`table` `` failed previously, this clears the error status as if nothing ever happened. The `all` variant applies this operation to all tables.

> **Note:**
>
> Use this option only when you are sure that the error can indeed be ignored. If not, some imported data can be lost. The only safety net is the final "checksum" check, and thus you need to keep the "checksum" option always enabled when using `--checkpoint-error-ignore`.

13.7.12.3.3 `--checkpoint-remove`

```
tidb-lightning-ctl --checkpoint-remove='`schema`.`table`'
tidb-lightning-ctl --checkpoint-remove=all
```

This option simply removes all checkpoint information about one table or all tables, regardless of their status.

13.7.12.3.4 `--checkpoint-dump`

```
tidb-lightning-ctl --checkpoint-dump=output/directory
```

This option dumps the content of the checkpoint into the given directory, which is mainly used for debugging by the technical staff. This option is only enabled when `driver = "mysql ↪ "`.

13.7.13 Use TiDB Lightning to Import Data in Parallel

Since v5.3.0, the physical import mode of TiDB Lightning supports the parallel import of a single table or multiple tables. By simultaneously running multiple TiDB Lightning instances, you can import data in parallel from different single tables or multiple tables. In

this way, TiDB Lightning provides the ability to scale horizontally, which greatly reduces the time required to import large amount of data.

In technical implementation, TiDB Lightning records the meta data of each instance and the data of each imported table in the target TiDB, and coordinates the Row ID allocation range of different instances, the record of global Checksum, and the configuration changes and recovery of TiKV and PD.

You can use TiDB Lightning to import data in parallel in the following scenarios:

- Import sharded schemas and sharded tables. In this scenario, multiple tables from multiple upstream database instances are imported into the downstream TiDB database by different TiDB Lightning instances in parallel.
- Import single tables in parallel. In this scenario, single tables stored in a certain directory or cloud storage (such as Amazon S3) are imported into the downstream TiDB cluster by different TiDB Lightning instances in parallel. This is a new feature introduced in TiDB 5.3.0.

Note:

- Parallel import only supports initialized empty tables in TiDB and does not support migrating data to tables with data written by existing services. Otherwise, data inconsistencies may occur.
- Parallel import is usually used in the physical import mode. You need to configure `parallel-import = true`.
- Apply only one backend at a time when using multiple TiDB Lightning instances to import data to the same target. For example, you cannot import data to the same TiDB cluster in both the physical and logical import modes at the same time.

13.7.13.1 Considerations

To use parallel import, you need to configure `parallel-import = true`. When TiDB Lightning is started, it registers meta data in the downstream TiDB cluster and automatically detects whether there are other instances migrating data to the target cluster at the same time. If there is, it automatically enters the parallel import mode.

But when migrating data in parallel, you need to take the following into consideration:

- Handle conflicts between primary keys or unique indexes across multiple sharded tables
- Optimize import performance

13.7.13.1.1 Handle conflicts between primary keys or unique indexes

When using the physical import mode to import data in parallel, ensure that there are no primary key or unique index conflicts between data sources, and between the tables in the target TiDB cluster, and there are no data writes in the target table during import. Otherwise, TiDB Lightning will fail to guarantee the correctness of the imported data, and the target table will contain inconsistent indexes after the import is completed.

13.7.13.1.2 Optimize import performance

Because TiDB Lightning needs to upload the generated Key-Value data to the TiKV node where each copy of the corresponding Region is located, the import speed is limited by the size of the target cluster. It is recommended to ensure that the number of TiKV instances in the target TiDB cluster and the number of TiDB Lightning instances are greater than n:1 (n is the number of copies of the Region). At the same time, the following requirements should be met to achieve optimal import performance:

- Deploy each TiDB Lightning instance on a dedicated machine. Since one TiDB Lightning instance consumes all CPU resources by default, deploying multiple instances on a single machine cannot improve performance.
- The total size of source files for each TiDB Lightning instance performing parallel import should be smaller than 5 TiB
- The total number of TiDB Lightning instances should be smaller than 10.

When using TiDB Lightning to import shared databases and tables in parallel, choose an appropriate number of TiDB Lightning instances according to the amount of data.

- If the MySQL data volume is less than 2 TiB, you can use one TiDB Lightning instance for parallel import.
- If the MySQL data volume exceeds 2 TiB and the total number of MySQL instances is smaller than 10, it is recommended that you use one TiDB Lightning instance for each MySQL instance, and the number of parallel TiDB Lightning instances should not exceed 10.
- If the MySQL data volume exceeds 2 TiB and the total number of MySQL instances exceeds 10, it is recommended that you allocate 5 to 10 TiDB Lightning instances for importing the data exported by these MySQL instances.

Next, this document uses two examples to detail the operation steps of parallel import in different scenarios:

- Example 1: Use Dumpling + TiDB Lightning to import sharded databases and tables into TiDB in parallel
- Example 2: Import single tables in parallel

13.7.13.1.3 Restrictions

TiDB Lightning exclusively uses some resources when it is running. If you need to deploy multiple TiDB Lightning instances on a single machine (which is not recommended for production environments), or on a disk shared by multiple machines, be aware of the following usage restrictions.

- Set `tikv-importer.sorted-kv-dir` to a unique path for each TiDB Lightning instance. Multiple instances sharing the same path can lead to unintended behavior and may result in import failures or data errors.
- Store each TiDB Lightning checkpoint separately. For more information about checkpoint configurations, see TiDB Lightning Checkpoints.
    - If you set checkpoint.driver = "file" (default), make sure that the path to the checkpoint is unique for each instance.
    - If you set checkpoint.driver = "mysql", you need to set a unique schema for each instance.
- The log file for each TiDB Lightning should be set to a unique path. Sharing the same log file will impact log querying and troubleshooting.
- If you use the Web Interface or Debug API, you need to set `lightning.status-addr` to a unique address for each instance; otherwise, the TiDB Lightning process fails to start due to port conflict.

13.7.13.2 Example 1: Use Dumpling + TiDB Lightning to Import Sharded Databases and Tables into TiDB in Parallel

In this example, assume that the upstream is a MySQL cluster with 10 sharded tables, with a total size of 10 TiB. You can Use 5 TiDB Lightning instances to perform parallel import, and each instance imports 2 TiB. It is estimated that the total import time (excluding the time required for Dumpling export) can be reduced from about 40 hours to about 10 hours.

Assume that the upstream library is named `my_db`, and the name of each sharded table is `my_table_01` ~ `my_table_10`. You want to merge and import them into the downstream `my_db.my_table` table. The specific steps are described in the following sections.

13.7.13.2.1 Step 1: Use Dumpling to export data

Export two sharded tables on the 5 nodes where TiDB Lightning is deployed:

- If the two sharded tables are in the same MySQL instance, you can use the `--filter` ↪ parameter of Dumpling to directly export them. When using TiDB Lightning to import, you can specify `data-source-dir` as the directory where Dumpling exports data to;

- If the data of the two sharded tables are distributed on different MySQL nodes, you need to use Dumpling to separately export them. The exported data needs to be placed in the same parent directory but in different sub-directories. When using TiDB Lightning to perform parallel import, you need to specify `data-source-dir` as the parent directory.

For more information on how to use Dumpling to export data, see Dumpling.

13.7.13.2.2 Step 2: Configure TiDB Lightning data sources

Create a configuration file `tidb-lightning.toml`, and then add the following content:

```
[lightning]
status-addr = ":8289"

[mydumper]
### Specify the path for Dumpling to export data. If Dumpling performs
    ↪ several times and the data belongs to different directories, you can
    ↪ place all the exported data in the same parent directory and specify
    ↪ this parent directory here.
data-source-dir = "/path/to/source-dir"

[tikv-importer]
### Whether to allow importing data into tables that already have data. The
    ↪ default value is `false`.
### When using parallel import, because multiple TiDB Lightning instances
    ↪ import a table at the same time, this configuration item must be set
    ↪ to `true`.
parallel-import = true
### "local": The default mode. It applies to large dataset import, for
    ↪ example, greater than 1 TiB. However, during the import, downstream
    ↪ TiDB is not available to provide services.
### "tidb": You can use this mode for small dataset import, for example,
    ↪ smaller than 1 TiB. During the import, downstream TiDB is available
    ↪ to provide services.
backend = "local"

### Specify the path for local sorting data.
sorted-kv-dir = "/path/to/sorted-dir"
```

If the data source is stored in external storage such as Amazon S3 or GCS, you need to configure additional parameters for connection. You can specify parameters for such configuration. For example, the following example assumes that data is stored in Amazon S3:

```
tiup tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
    ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
    -d 's3://my-bucket/sql-backup'
```

For more parameter descriptions, see URI Formats of External Storage Services.

13.7.13.2.3 Step 3: Start TiDB Lightning to import data

During parallel import, the server configuration requirements for each TiDB Lightning node are the same as the non-parallel import mode. Each TiDB Lightning node needs to consume the same resources. It is recommended to deploy them on different servers. For detailed deployment steps, see Deploy TiDB Lightning.

Start TiDB Lightning on each server in turn. If you use `nohup` to directly start it from the command line, it might exit due to the SIGHUP signal. So it is recommended to put `nohup` in the script, for example:

```
### !/bin/bash
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out &
```

During parallel import, TiDB Lightning automatically performs the following checks after starting the task.

- Check whether there is enough space on the local disk (controlled by the `sort-kv-dir` configuration) and on the TiKV cluster for importing data. To learn the required disk space, see Downstream storage space requirements and Resource requirements. TiDB Lightning samples the data sources and estimates the percentage of the index size from the sample result. Because indexes are included in the estimation, there might be cases where the size of the source data is less than the available space on the local disk, but still the check fails.
- Check whether the regions in the TiKV cluster are distributed evenly and whether there are too many empty regions. If the number of empty regions exceeds max(1000, number of tables * 3), i.e. greater than the bigger one of "1000" or "3 times the number of tables", then the import cannot be executed.
- Check whether the data is imported in order from the data sources. The size of `mydumper.batch-size` is automatically adjusted based on the result of the check. Therefore, the `mydumper.batch-size` configuration is no longer available.

You can also turn off the check and perform a forced import with the `lightning.check-requirements` configuration. For more detailed checks, see TiDB Lightning prechecks

13.7.13.2.4 Step 4: Check the import progress

After starting the import, you can check the progress in either of the following ways:

- Check the progress through the `grep` log keyword `progress`. It is updated every 5 minutes by default.

- Check the progress through the monitoring console. For details, see TiDB Lightning Monitoring.

Wait for all TiDB Lightning instances to finish, then the entire import is completed.

13.7.13.3 Example 2: Import single tables in parallel

TiDB Lightning also supports parallel import of single tables. For example, import multiple single tables stored in Amazon S3 by different TiDB Lightning instances into the downstream TiDB cluster in parallel. This method can speed up the overall import speed. When remote storages such as Amazon S3 is used, the configuration parameters of TiDB Lightning are the same as those of BR. For more details, see URI Formats of External Storage Services.

> **Note:**
>
> In the local environment, you can use the `--filesize` or `--where` parameter of Dumpling to divide the data of a single table into different parts and export it to the local disks of multiple servers in advance. This way, you can still perform parallel import. The configuration is the same as Example 1.

Assuming that the source files are stored in Amazon S3, the table files are `my_db.my_table.00001.sql` ~ `my_db.my_table.10000.sql`, a total of 10,000 SQL files. If you want to use 2 TiDB Lightning instances to speed up the import, you need to add the following settings in the configuration file:

```
[[mydumper.files]]
### the db schema file
pattern = '(?i)^(?:[^/]*/)*my_db-schema-create\.sql'
schema = "my_db"
type = "schema-schema"

[[mydumper.files]]
### the table schema file
pattern = '(?i)^(?:[^/]*/)*my_db\.my_table-schema\.sql'
schema = "my_db"
table = "my_table"
type = "table-schema"

[[mydumper.files]]
### Only import 00001~05000 and ignore other files
pattern = '(?i)^(?:[^/]*/)*my_db\.my_table\.(0[0-4][0-9][0-9][0-9]|05000)\.
    ↪ sql'
```

```
schema = "my_db"
table = "my_table"
type = "sql"

[tikv-importer]
### Whether to allow importing data into tables that already have data. The
    ↪ default value is `false`.
### When using parallel import, because multiple TiDB Lightning instances
    ↪ import a table at the same time, this configuration item must be set
    ↪ to `true`.
parallel-import = true
```

You can modify the configuration of the other instance to only import the `05001 ~ 10000` data files.

For other steps, see the relevant steps in Example 1.

13.7.13.4 Handle errors

13.7.13.4.1 Some TiDB Lightning nodes exit abnormally

If one or more TiDB Lightning nodes exit abnormally during a parallel import, identify the cause based on the logged error, and handle the error according to the error type:

- If the error shows normal exit (for example, exit in response to a kill command) or termination by the operating system due to OOM, adjust the configuration and then restart the TiDB Lightning nodes.
- If the error has no impact on data accuracy, for example, network timeout, perform the following steps:
    1. Run the `checkpoint-error-ignore` command with the setting `--checkpoint-error-ignore=all` on all failed nodes to clean errors in the checkpoint source data.
    2. Restart these nodes to continue importing data from checkpoints.
- If you see errors in the log that result in data inaccuracies, such as a checksum mismatch indicating invalid data in the source file, you can perform the following steps to resolve this issue:
    1. Run the `checkpoint-error-destroy` command on all Lightning nodes, including successful nodes. This command removes the imported data from failed tables and resets the checkpoint status of these tables to "not yet started".

2. Reconfigure and import the data of failed tables by using the `filter` parameter on all TiDB Lightning nodes, including normally exiting nodes.

   When you reconfigure the Lightning parallel import task, do not include the `checkpoint-error-destroy` command in the startup script of each Lightning node. Otherwise, this command deletes shared metadata used by multiple parallel import tasks, which might cause issues during data import. For example, if a second Lightning import task is started, it will delete the metadata written by the first task, leading to abnormal data import.

13.7.13.4.2 During an import, an error "Target table is calculating checksum. Please wait until the checksum is finished and try again" is reported

Some parallel imports involve a large number of tables or tables with a small volume of data. In this case, it is possible that before one or more tasks start processing a table, other tasks of this table have finished and data checksum is in progress. At this time, an error `Target table is calculating checksum. Please wait until the checksum is finished and try again` is reported. In this case, you can wait for the completion of checksum and then restart the failed tasks. The error disappears and data accuracy is not affected.

13.7.14 TiDB Lightning Error Resolution

Starting from v5.4.0, you can configure TiDB Lightning to skip errors like invalid type conversion and unique key conflicts, and to continue the data processing as if those wrong row data does not exist. A report will be generated for you to read and manually fix errors afterward. This is ideal for importing from a slightly dirty data source, where locating the errors manually is difficult and restarting TiDB Lightning on every encounter is costly.

This document introduces TiDB Lightning error types, how to query the errors, and provides an example. The following configuration items are involved:

- `lightning.max-error`: the tolerance threshold of type error
- `conflict.strategy`, `conflict.threshold`, and `conflict.max-record-rows`: configurations related to conflicting data
- `tikv-importer.duplicate-resolution` (deprecated in v8.0.0 and will be removed in a future release): the conflict handling configuration that can only be used in the physical import mode
- `lightning.task-info-schema-name`: the database where conflicting data is stored when TiDB Lightning detects conflicts

For more information, see TiDB Lightning (Task).

13.7.14.1 Type error

You can use the `lightning.max-error` configuration to increase the tolerance of errors related to data types. If this configuration is set to *N*, TiDB Lightning allows and skips up to *N* type errors from the data source before it exists. The default value `0` means that no error is allowed.

These errors are recorded in a database. After the import is completed, you can view the errors in the database and process them manually. For more information, see Error Report.

```
[lightning]
max-error = 0
```

The above configuration covers the following errors:

- Invalid values (example: set `'Text'` to an INT column).
- Numeric overflow (example: set `500` to a TINYINT column)
- String overflow (example: set `'Very Long Text'` to a VARCHAR(5) column).
- Zero date-time (namely `'0000-00-00'` and `'2021-12-00'`).
- Set NULL to a NOT NULL column.
- Failed to evaluate a generated column expression.
- Column count mismatch. The number of values in the row does not match the number of columns of the table.
- Any other SQL errors.

The following errors are always fatal, and cannot be skipped by changing `lightning.max-error`:

- Syntax error (such as unclosed quotation marks) in the original CSV, SQL or Parquet file.
- I/O, network or system permission errors.

13.7.14.2 Conflict errors

You can use the `conflict.threshold` configuration item to increase the tolerance of errors related to data conflict. If this configuration item is set to *N*, TiDB Lightning allows and skips up to *N* conflict errors from the data source before it exits. The default value is `10000`, which means that 10000 errors are tolerant.

These errors are recorded in a table. After the import is completed, you can view the errors in the database and process them manually. For more information, see Error Report

13.7.14.3 Error report

If TiDB Lightning encounters errors during the import, it outputs a statistics summary about these errors in both your terminal and the log file when it exits.

- The error report in the terminal is similar to the following table:

#	ERROR TYPE	ERROR COUNT	ERROR DATA TABLE
1	Data Type	1000	`lightning_task_info.type_error_v1`

- The error report in the TiDB Lightning log file is as follows:

```
[2022/03/13 05:33:57.736 +08:00] [WARN] [errormanager.go:459] ["Detect
    ↪ 1000 data type errors in total, please refer to table `lightning_
    ↪ task_info`.`type_error_v1` for more details"]
```

All errors are written to tables in the `lightning_task_info` database in the downstream TiDB cluster. After the import is completed, if the error data is collected, you can view the errors in the database and process them manually.

You can change the database name by configuring `lightning.task-info-schema-name`.

```
[lightning]
task-info-schema-name = 'lightning_task_info'
```

TiDB Lightning creates three tables and one view in this database:

```
CREATE TABLE type_error_v1 (
    task_id    bigint NOT NULL,
    create_time datetime(6) NOT NULL DEFAULT now(6),
    table_name varchar(261) NOT NULL,
    path       varchar(2048) NOT NULL,
    offset     bigint NOT NULL,
    error      text NOT NULL,
    row_data   text NOT NULL
);
CREATE TABLE conflict_error_v3 (
    task_id    bigint NOT NULL,
    create_time datetime(6) NOT NULL DEFAULT now(6),
    table_name varchar(261) NOT NULL,
    index_name varchar(128) NOT NULL,
    key_data   text NOT NULL,
    row_data   text NOT NULL,
    raw_key    mediumblob NOT NULL,
    raw_value  mediumblob NOT NULL,
    raw_handle mediumblob NOT NULL,
    raw_row    mediumblob NOT NULL,
    kv_type    tinyint(1) NOT NULL,
    INDEX (task_id, table_name),
    INDEX (index_name),
    INDEX (table_name, index_name),
    INDEX (kv_type)
```

```
);
CREATE TABLE conflict_records (
    task_id    bigint NOT NULL,
    create_time datetime(6) NOT NULL DEFAULT now(6),
    table_name varchar(261) NOT NULL,
    path       varchar(2048) NOT NULL,
    offset     bigint NOT NULL,
    error      text NOT NULL,
    row_id     bigint NOT NULL COMMENT 'the row id of the conflicted row',
    row_data   text NOT NULL COMMENT 'the row data of the conflicted row',
    KEY (task_id, table_name)
);
CREATE VIEW conflict_view AS
    SELECT 0 AS is_precheck_conflict, task_id, create_time, table_name,
        ↪ index_name, key_data, row_data, raw_key, raw_value, raw_handle,
        ↪ raw_row, kv_type, NULL AS path, NULL AS offset, NULL AS error,
        ↪ NULL AS row_id
    FROM conflict_error_v3
    UNION ALL
    SELECT 1 AS is_precheck_conflict, task_id, create_time, table_name,
        ↪ NULL AS index_name, NULL AS key_data, row_data, NULL AS raw_key,
        ↪ NULL AS raw_value, NULL AS raw_handle, NULL AS raw_row, NULL AS
        ↪ kv_type, path, offset, error, row_id
    FROM conflict_records;
```

The `type_error_v1` table records all type errors managed by `lightning.max-error`. Each error corresponds to one row.

The `conflict_error_v3` table records conflicts detected during postprocess conflict detection, managed by the `conflict` configuration group in the physical import mode. Each pair of conflicts corresponds to two rows.

The `conflict_records` table records conflicts detected during pre-import conflict detection, managed by the `conflict` configuration group in both logical and physical import modes. Each error corresponds to one row.

The `conflict_view` view records conflicts that are detected by both pre-import and postprocess conflict detection, managed by the `conflict` configuration group in both logical and physical import modes. This view is created by performing a `UNION` operation on the `conflict_error_v3` and `conflict_records` tables.

Column	SyntaxType Conflict	Description
task_id		The TiDB Lightning task ID that generates this error
create_time		The time at which the error is recorded
table_name		The name of the table that contains the error, in the form of '`db`.`tbl`'

Column SyntaxType Conflict	Description
path	The path of the file that contains the error
offset	The byte position in the file where the error is found
error	The error message
context	The text that surrounds the error
index_name	The name of the unique key in conflict. It is `'PRIMARY'` for primary key conflicts.
key_data	The formatted key handle of the row that causes the error. The content is for human reference only, and not intended to be machine-readable.
row_data	The formatted row data that causes the error. The content is for human reference only, and not intended to be machine-readable
raw_key	The key of the conflicted KV pair
raw_value	The value of the conflicted KV pair
raw_handle	The row handle of the conflicted row
raw_row	The encoded value of the conflicted row

Note:

The error report records the file offset, not line/column number which is inefficient to obtain. You can quickly jump near a byte position (using 183 as example) using the following commands:

- shell, printing the first several lines.

```
head -c 183 file.csv | tail
```

- shell, printing the next several lines:

```
tail -c +183 file.csv | head
```

- vim — `:goto 183` or `183go`

13.7.14.4 Example

In this example, a data source is prepared with some known errors.

1. Prepare the database and table schema.

```
mkdir example && cd example

echo 'CREATE SCHEMA example;' > example-schema-create.sql
```

```
echo 'CREATE TABLE t(a TINYINT PRIMARY KEY, b VARCHAR(12) NOT NULL
    ↪ UNIQUE);' > example.t-schema.sql
```

2. Prepare the data.

```
cat <<EOF > example.t.1.sql

    INSERT INTO t (a, b) VALUES
    (0, NULL),           -- column is NOT NULL
    (1, 'one'),
    (2, 'two'),
    (40, 'forty'),       -- conflicts with the other 40 below
    (54, 'fifty-four'),  -- conflicts with the other 'fifty-four' below
    (77, 'seventy-seven'), -- the string is longer than 12 characters
    (600, 'six hundred'), -- the number overflows TINYINT
    (40, 'forty'),      -- conflicts with the other 40 above
    (42, 'fifty-four');  -- conflicts with the other 'fifty-four' above

EOF
```

3. Configure TiDB Lightning to enable strict SQL mode, use the Local-backend to import data, replace duplicates, and skip up to 10 errors.

```
cat <<EOF > config.toml

    [lightning]
    max-error = 10

    [tikv-importer]
    backend = 'local'
    sorted-kv-dir = '/tmp/lightning-tmp/'

    [conflict]
    strategy = 'replace'
    [mydumper]
    data-source-dir = '.'
    [tidb]
    host = '127.0.0.1'
    port = 4000
    user = 'root'
    password = ''
    sql-mode = 'STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE'

EOF
```

4. Run TiDB Lightning. This command will exit successfully because all errors are skipped.

```
tiup tidb-lightning -c config.toml
```

5. Verify that the imported table only contains the two normal rows:

```
$ mysql -u root -h 127.0.0.1 -P 4000 -e 'select * from example.t'
+---+-----+
| a | b   |
+---+-----+
| 1 | one |
| 2 | two |
+---+-----+
```

6. Check whether the `type_error_v1` table has caught the three rows involving type conversion:

```
$ mysql -u root -h 127.0.0.1 -P 4000 -e 'select * from lightning_task_
   ↪ info.type_error_v1;' -E

*************************** 1. row ***************************
   task_id: 1635888701843303564
create_time: 2021-11-02 21:31:42.620090
 table_name: `example`.`t`
      path: example.t.1.sql
    offset: 46
     error: failed to cast value as varchar(12) CHARACTER SET utf8mb4
        ↪ COLLATE utf8mb4_bin for column `b` (#2): [table:1048]Column
        ↪  'b' cannot be null
  row_data: (0,NULL)

*************************** 2. row ***************************
   task_id: 1635888701843303564
create_time: 2021-11-02 21:31:42.627496
 table_name: `example`.`t`
      path: example.t.1.sql
    offset: 183
     error: failed to cast value as varchar(12) CHARACTER SET utf8mb4
        ↪ COLLATE utf8mb4_bin for column `b` (#2): [types:1406]Data
        ↪ Too Long, field len 12, data len 13
  row_data: (77,'seventy-seven')

*************************** 3. row ***************************
   task_id: 1635888701843303564
create_time: 2021-11-02 21:31:42.629929
```

```
 table_name: `example`.`t`
      path: example.t.1.sql
    offset: 253
     error: failed to cast value as tinyint(4) for column `a` (#1): [
        ↪ types:1690]constant 600 overflows tinyint
  row_data: (600,'six hundred')
```

7. Check whether the `conflict_error_v3` table has caught the four rows that have unique/primary key conflicts:

```
$ mysql -u root -h 127.0.0.1 -P 4000 -e 'select * from lightning_task_
   ↪ info.conflict_error_v3;' --binary-as-hex -E

*************************** 1. row ***************************
   task_id: 1635888701843303564
create_time: 2021-11-02 21:31:42.669601
 table_name: `example`.`t`
 index_name: PRIMARY
   key_data: 40
   row_data: (40, "forty")
    raw_key: 0x7480000000000000C15F728000000000000028
  raw_value: 0x800001000000020500666F727479

```

13.7.15 Troubleshoot TiDB Lightning

This document summarizes the common problems you might encounter when you use TiDB Lightning and their solutions.

13.7.15.1 Import speed is too slow

Normally it takes 2 minutes per thread for TiDB Lightning to import a 256 MB data file. If the speed is much slower than this, there is an error. You can check the time taken for each data file from the log mentioning `restore chunk ⋯ takes`. This can also be observed from metrics on Grafana.

There are several reasons why TiDB Lightning becomes slow:

Cause 1: `region-concurrency` is set too high, which causes thread contention and reduces performance.

1. The setting can be found from the start of the log by searching `region-concurrency`.
2. If TiDB Lightning shares the same machine with other services (for example, TiKV Importer), `region-concurrency` must be **manually** set to 75% of the total number of CPU cores.
3. If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning may not be able to read this out. In this case, `region-concurrency` must also be **manually** reduced.

Cause 2: The table schema is too complex.

Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Dumpling output. If the indices are negligible, you may first remove them from the schema, and add them back using `CREATE INDEX` after the import is complete.

Cause 3: Each file is too large.

TiDB Lightning works the best when the data source is broken down into multiple files of size around 256 MB so that the data can be processed in parallel. If each file is too large, TiDB Lightning might not respond.

If the data source is CSV, and all CSV files have no fields containing newline control characters (U+000A and U+000D), you can turn on "strict format" to let TiDB Lightning automatically split the large files.

```
[mydumper]
strict-format = true
```

Cause 4: TiDB Lightning is too old.

Try the latest version. Maybe there is new speed improvement.

13.7.15.2 The `tidb-lightning` process suddenly quits while running in background

It is potentially caused by starting `tidb-lightning` incorrectly, which causes the system to send a SIGHUP signal to stop the `tidb-lightning` process. In this situation, `tidb-lightning.log` usually outputs the following log:

```
[2018/08/10 07:29:08.310 +08:00] [INFO] [main.go:41] ["got signal to exit"]
    ↪ [signal=hangup]
```

It is not recommended to directly use `nohup` in the command line to start `tidb-lightning`. You can start `tidb-lightning` by executing a script.

In addition, if the last log of TiDB Lightning shows that the error is "Context canceled", you need to search for the first "ERROR" level log. This "ERROR" level log is usually followed by "got signal to exit", which indicates that TiDB Lightning received an interrupt signal and then exited.

13.7.15.3 The TiDB cluster uses lots of CPU resources and runs very slowly after using TiDB Lightning

If `tidb-lightning` abnormally exited, the cluster might be stuck in the "import mode", which is not suitable for production. The current mode can be retrieved using the following command:

```
tidb-lightning-ctl --config tidb-lightning.toml --fetch-mode
```

You can force the cluster back to "normal mode" using the following command:

```
tidb-lightning-ctl --config tidb-lightning.toml --fetch-mode
```

13.7.15.4 TiDB Lightning reports an error

13.7.15.4.1 `could not find first pair, this shouldn't happen`

This error occurs possibly because the number of files opened by TiDB Lightning exceeds the system limit when TiDB Lightning reads the sorted local files. In the Linux system, you can use the `ulimit -n` command to confirm whether the value of this system limit is too small. It is recommended that you adjust this value to `1000000` (`ulimit -n 1000000`) during the import.

13.7.15.4.2 `checksum failed: checksum mismatched remote vs local`

Cause: The checksum of a table in the local data source and the remote imported database differ. This error has several deeper reasons. You can further locate the reason by checking the log that contains `checksum mismatched`.

The lines that contain `checksum mismatched` provide the information `total_kvs: x vs y`, where `x` indicates the number of key-value pairs (KV pairs) calculated by the target cluster after the import is completed, and `y` indicates the number of key-value pairs generated by the local data source.

- If `x` is greater, it means that there are more KV pairs in the target cluster.
    - It is possible that this table is not empty before the import and therefore affects the data checksum. It is also possible that TiDB Lightning has previously failed and shut down, but did not restart correctly.
- If `y` is greater, it means that there are more KV pairs in the local data source.
    - If the checksum of the target database is all 0, it means that no import has occurred. It is possible that the cluster is too busy to receive any data.
    - It is possible that the exported data contains duplicate data, such as the UNIQUE and PRIMARY KEYs with duplicate values, or that the downstream table structure is case-insensitive while the data is case-sensitive.
- Other possible reasons
    - If the data source is machine-generated and not backed up by Dumpling, make sure the data conforms to the table limits. For example, the AUTO_INCREMENT column needs to be positive and not 0.

Solutions:

1. Delete the corrupted data using `tidb-lightning-ctl`, check the table structure and the data, and restart TiDB Lightning to import the affected tables again.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error
    ↪ -destroy=all
```

2. Consider using an external database to store the checkpoints (change `[checkpoint] ↪ dsn`) to reduce the target database's load.

3. If TiDB Lightning was improperly restarted, see also the "How to properly restart TiDB Lightning" section in the FAQ.

13.7.15.4.3 `Checkpoint for … has invalid status:` (error code)

Cause: Checkpoint is enabled, and TiDB Lightning or TiKV Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed.

The error code is an integer smaller than 25, with possible values of 0, 3, 6, 9, 12, 14, 15, 17, 18, 20, and 21. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later step the exit occurs at.

Solutions:

If the error was caused by invalid data source, delete the imported data using `tidb- ↪ lightning-ctl` and start Lightning again.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error-
    ↪ destroy=all
```

See the Checkpoints control section for other options.

13.7.15.4.4 `cannot guess encoding for input file, please convert to UTF-8 manually`

Cause: TiDB Lightning only recognizes the UTF-8 and GB-18030 encodings for the table schemas. This error is emitted if the file isn't in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical `ALTER TABLE` executions.

Solutions:

1. Fix the schema so that the file is entirely in either UTF-8 or GB-18030.

2. Manually `CREATE` the affected tables in the target database.

3. Set `[mydumper] character-set = "binary"` to skip the check. Note that this might introduce mojibake into the target database.

13.7.15.4.5 [sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 …}'

Cause: A table contains a column with the `timestamp` type, but the time value itself does not exist. This is either because of DST changes or the time value has exceeded the supported range (Jan 1, 1970 to Jan 19, 2038).

Solutions:

1. Ensure TiDB Lightning and the source database are using the same time zone.

   When executing TiDB Lightning directly, the time zone can be forced using the `$TZ` environment variable.

   ```
   # Manual deployment, and force Asia/Shanghai.
   TZ='Asia/Shanghai' bin/tidb-lightning -config tidb-lightning.toml
   ```

2. Ensure the entire cluster is using the same and latest version of `tzdata` (version 2018i or above).

   On CentOS, run `yum info tzdata` to check the installed version and whether there is an update. Run `yum upgrade tzdata` to upgrade the package.

13.7.15.4.6 [Error 8025: entry too large, the max entry size is 6291456]

Cause: A single row of key-value pairs generated by TiDB Lightning exceeds the limit set by TiDB.

Solution:

- Use the `tidb_txn_entry_size_limit` system variable to dynamically increase the limit.
- Note that TiKV has a similar limit. If the data size of a single write request exceeds `raft-entry-max-size` (`8MiB` by default), TiKV refuses to process this request. When a table has a row of a large size, you need to modify both configurations.

13.7.15.4.7 Encounter rpc error: code = Unimplemented ... when TiDB Lightning switches the mode

Cause: Some node(s) in the cluster does not support `switch-mode`. For example, if the TiFlash version is earlier than `v4.0.0-rc.2`, `switch-mode` is not supported.

Solutions:

- If there are TiFlash nodes in the cluster, you can update the cluster to `v4.0.0-rc.2` or higher versions.
- Temporarily disable TiFlash if you do not want to upgrade the cluster.

13.7.15.4.8 `tidb lightning encountered error: TiDB version too old, expected '>=4.0.0', found '3.0.18'`

TiDB Lightning Local-backend only supports importing data to TiDB clusters of v4.0.0 and later versions. If you try to use Local-backend to import data to a v2.x or v3.x cluster, the above error is reported. At this time, you can modify the configuration to use Importer-backend or TiDB-backend for data import.

Some `nightly` versions might be similar to v4.0.0-beta.2. These `nightly` versions of TiDB Lightning actually support Local-backend. If you encounter this error when using a `nightly` version, you can skip the version check by setting the configuration `check-requirements = false`. Before setting this parameter, make sure that the configuration of TiDB Lightning supports the corresponding version; otherwise, the import might fail.

13.7.15.4.9 `restore table test.district failed: unknown columns in header [...]`

This error occurs usually because the CSV data file does not contain a header (the first row is not column names but data). Therefore, you need to add the following configuration to the TiDB Lightning configuration file:

```
[mydumper.csv]
header = false
```

13.7.15.4.10 `Unknown character set`

TiDB does not support all MySQL character sets. Therefore, TiDB Lightning reports this error if an unsupported character set is used when creating the table schema during an import. To bypass this error, you can create the table schema in the downstream in advance using the character sets supported by TiDB according to the specific data.

13.7.15.4.11 `invalid compression type ...`

- TiDB Lightning v6.4.0 and later versions only support the following compressed data files: `gzip`, `snappy`, and `zstd`. Other types of compressed files cause errors. If an unsupported compressed file exists in the directory where the source data file is stored, this will cause the task to report an error. You can move those unsupported files out of the import data directory to avoid such errors. For more details, see Compressed files.

> **Note:**
>
> The Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.

13.7.15.5 TiDB Lightning Configuration

This document provides samples for global configuration and task configuration, and describes the usage of command-line parameters.

13.7.15.5.1 Configuration files

TiDB Lightning has two configuration classes: "global" and "task", and they have compatible structures. Their distinction arises only when the server mode is enabled. When server mode is disabled (the default), TiDB Lightning will only execute one task, and the same configuration file is used for both global and task configurations.

TiDB Lightning (Global)

```
###### tidb-lightning global configuration

[lightning]
#### The HTTP port for displaying the web interface, pulling Prometheus
   ↪ metrics, exposing debug data,
#### and submitting import tasks (in server mode). Setting it to 0 disables
   ↪ the port.
status-addr = ':8289'

#### Server mode. Defaults to false, which means an import task starts
   ↪ immediately after you execute the command.
#### If this value is set to true, after you execute the command,
#### TiDB Lightning waits until you submit an import task in the web
   ↪ interface.
#### See the "TiDB Lightning Web Interface" section for details.
server-mode = false

#### Logging
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14

#### Controls whether to enable the diagnostic logs. The default value is
   ↪ false, that is, only the logs related to the import are output, and
   ↪ the logs of other dependent components are not output.
#### When you set it to true, logs from both the import process and other
   ↪ dependent components are output, and GRPC debugging is enabled, which
   ↪  can be used for diagnosis.
#### This parameter is introduced in v7.3.0.
enable-diagnose-logs = false
```

TiDB Lightning (Task)

```
###### tidb-lightning task configuration

[lightning]
#### Checks whether the cluster satisfies the minimum requirement before
   ↪ starting the task, and check whether TiKV has more than 10% free
   ↪ space left during running time.
#check-requirements = true

#### The maximum number of engines to be opened concurrently.
#### Each table is split into one "index engine" to store indices, and
   ↪ multiple
#### "data engines" to store row data. These settings control the maximum
#### concurrent number for each type of engines. Generally, you can use the
   ↪ following two default values.
index-concurrency = 2
table-concurrency = 6

#### The concurrency number of data. It is set to the number of logical CPU
#### cores by default. When deploying together with other components, you
   ↪ can
#### set it to 75% of the size of logical CPU cores to limit the CPU usage.
#### region-concurrency =

#### The maximum I/O concurrency. Excessive I/O concurrency causes an
   ↪ increase in
#### I/O latency because the disk's internal buffer is frequently refreshed,
#### which causes the cache miss and slows down the read speed. Depending on
   ↪  the storage
#### medium, this value might need to be adjusted for optimal performance.
io-concurrency = 5

#### The maximum number of non-fatal errors to tolerate before stopping TiDB
   ↪  Lightning.
#### Non-fatal errors are localized to a few rows, and ignoring those rows
   ↪ allows the import process to continue.
#### Setting this to N means that TiDB Lightning will stop as soon as
   ↪ possible when the (N+1)-th error is encountered.
#### The skipped rows will be inserted into tables inside the "task info"
   ↪ schema on the target TiDB, which can be configured below.
#### The default value is `MaxInt64` bytes, that is, 9223372036854775807
   ↪ bytes.
max-error = 0
#### task-info-schema-name is the name of the schema or database that stores
```

```
   ↪  TiDB Lightning execution results.
#### To disable error recording, set this to an empty string.
#### task-info-schema-name = 'lightning_task_info'

#### In parallel import mode, the schema name that stores the meta
   ↪ information for each TiDB Lightning instance in the target cluster.
#### By default, the value is "lightning_metadata".
#### Configure this parameter only if parallel import is enabled.
#### **Note:**
#### - The value set for this parameter must be the same for each TiDB
   ↪ Lightning instance
####  that participates in the same parallel import; otherwise, the
   ↪ correctness of the imported data cannot be ensured.
#### - If parallel import mode is enabled, make sure that the user used for
   ↪ import (for the tidb.user configuration)
####  has permissions to create and access the databases corresponding to
   ↪ this configuration.
#### - TiDB Lightning removes this schema after the import is completed.
####  So do not use any existing schema name to configure this parameter.
meta-schema-name = "lightning_metadata"

[security]
#### Specifies certificates and keys for TLS connections within the cluster.
#### Public certificate of the CA. Leave empty to disable TLS.
#### ca-path = "/path/to/ca.pem"
#### Public certificate of this service.
#### cert-path = "/path/to/lightning.pem"
#### Private key of this service.
#### key-path = "/path/to/lightning.key"

[checkpoint]
#### Whether to enable checkpoints.
#### While importing data, TiDB Lightning records which tables have been
   ↪ imported, so
#### even if TiDB Lightning or another component crashes, you can start from
   ↪  a known
#### good state instead of restarting from scratch.
enable = true
#### The schema name (database name) to store the checkpoints.
schema = "tidb_lightning_checkpoint"
#### Where to store the checkpoints.
#### - file: store as a local file.
#### - mysql: store into a remote MySQL-compatible database
driver = "file"
#### The data source name (DSN) indicating the location of the checkpoint
```

```
   ↪ storage.
#### For the "file" driver, the DSN is a path. If the path is not specified,
   ↪  TiDB Lightning would
#### default to "/tmp/CHECKPOINT_SCHEMA.pb".
#### For the "mysql" driver, the DSN is a URL in the form of "USER:PASS@tcp(
   ↪ HOST:PORT)/".
#### If the URL is not specified, the TiDB server from the [tidb] section is
   ↪  used to
#### store the checkpoints. You should specify a different MySQL-compatible
#### database server to reduce the load of the target TiDB cluster.
#### dsn = "/tmp/tidb_lightning_checkpoint.pb"
#### Whether to keep the checkpoints after all data are imported. If false,
   ↪ the
#### checkpoints will be deleted. Keeping the checkpoints can aid debugging
   ↪ but
#### will leak metadata about the data source.
#### keep-after-success = false

[conflict]
#### Starting from v7.3.0, a new version of strategy is introduced to handle
   ↪  conflicting data. The default value is "". Starting from v8.0.0,
   ↪ TiDB Lightning optimizes the conflict strategy for both physical and
   ↪ logical import modes.
#### - "": in the physical import mode, TiDB Lightning does not detect or
   ↪ handle conflicting data. If the source file contains conflicting
   ↪ primary or unique key records, the subsequent step reports an error.
   ↪ In the logical import mode, TiDB Lightning converts the "" strategy
   ↪ to the "error" strategy for processing.
#### - "error": when detecting conflicting primary or unique key records in
   ↪ the imported data, TiDB Lightning terminates the import and reports
   ↪ an error.
#### - "replace": when encountering conflicting primary or unique key
   ↪ records, TiDB Lightning retains the latest data and overwrites the
   ↪ old data.
####           When you use the physical import mode, the conflicting data
   ↪ are recorded in the `lightning_task_info.conflict_view` view of the
   ↪ target TiDB cluster.
####           In the `lightning_task_info.conflict_view` view, if the `is_
   ↪ precheck_conflict` field for a row is `0`, it means that the
   ↪ conflicting data recorded in that row is detected by postprocess
   ↪ conflict detection; if the `is_precheck_conflict` field for a row is
   ↪ `1`, it means that conflicting data recorded in that row is detected
   ↪ by pre-import conflict detection.
####           You can manually insert the correct records into the target
   ↪ table based on your application requirements. Note that the target
```

```
   ↪ TiKV must be v5.2.0 or later versions.
#### - "ignore": when encountering conflicting primary or unique key records
   ↪ , TiDB Lightning retains the old data and ignores the new data. This
   ↪ option can only be used in the logical import mode.
strategy = ""
#### Controls whether to enable pre-import conflict detection, which checks
   ↪ conflicts in data before importing it to TiDB. The default value is
   ↪ false, indicating that TiDB Lightning only checks conflicts after the
   ↪  import. If you set it to true, TiDB Lightning checks conflicts both
   ↪ before and after the import. This parameter can be used only in the
   ↪ physical import mode. In scenarios where the number of conflict
   ↪ records is greater than 1,000,000, it is recommended to set `precheck
   ↪ -conflict-before-import = true` for better performance in conflict
   ↪ detection. In other scenarios, it is recommended to disable it.
#### precheck-conflict-before-import = false
#### Controls the maximum number of conflict errors that can be handled when
   ↪  strategy is "replace" or "ignore". You can set it only when the
   ↪ strategy is "replace" or "ignore". The default value is 10000. If you
   ↪  set a value larger than 10000, the import process might experience
   ↪ performance degradation.
#### threshold = 10000
#### Controls the maximum number of records in the `conflict_records` table.
   ↪  The default value is 10000.
#### Starting from v8.1.0, there is no need to configure `max-record-rows`
   ↪ manually, because TiDB Lightning automatically assigns the value of `
   ↪ max-record-rows` with the value of `threshold`, regardless of the
   ↪ user input. `max-record-rows` will be deprecated in a future release.
#### In the physical import mode, if the strategy is "replace", the conflict
   ↪  records that are overwritten are recorded.
#### In the logical import mode, if the strategy is "ignore", the conflict
   ↪ records that are ignored are recorded; if the strategy is "replace",
   ↪ the conflict records are not recorded.
#### max-record-rows = 10000

[tikv-importer]
#### "local": Physical import mode, used by default. It applies to large
   ↪ dataset import,
#### for example, greater than 1 TiB. However, during the import, downstream
   ↪  TiDB is not available to provide services.
#### "tidb": Logical import mode. You can use this mode for small dataset
   ↪ import,
#### for example, smaller than 1 TiB. During the import, downstream TiDB is
   ↪ available to provide services.
#### backend = "local"
#### Whether to enable multiple TiDB Lightning instances (in physical import
```

```
    ↪  mode) to import data to one or more target tables in parallel.
#### The default value is `false`.
#### When you use parallel import mode, you must set the parameter to `true
    ↪ `,
#### but the premise is that no data exists in the target table, that is,
    ↪ all data can only be imported by TiDB Lightning.
#### Note that this parameter is only used in scenarios where the target
    ↪ table is empty.
#### parallel-import = false

#### The `duplicate-resolution` parameter is deprecated starting from v8.0.0
    ↪  and will be removed in a future release. For more information, see <
    ↪ https://docs.pingcap.com/tidb/stable/tidb-lightning-physical-import-
    ↪ mode-usage#the-old-version-of-conflict-detection-deprecated-in-v800>.
#### Whether to detect and resolve duplicate records (unique key conflict)
    ↪ in the physical import mode.
#### The following resolution algorithms are supported:
#### - 'none': does not detect duplicate records.
####       If there are duplicate records in the data source, it might lead
    ↪  to inconsistent data in the target TiDB.
####       If you set `duplicate-resolution = 'none'` and do not set `
    ↪ conflict.strategy`, TiDB Lightning will automatically assign `""` to
    ↪ `conflict.strategy`.
#### - 'remove': If you set `duplicate-resolution = 'remove'` and do not set
    ↪  `conflict.strategy`, TiDB Lightning will automatically assign "
    ↪ replace" to `conflict.strategy` and enable the new version of
    ↪ conflict detection.
#### The default value is 'none'.
#### duplicate-resolution = 'none'
#### The maximum number of KV pairs in one request when sending data to TiKV
    ↪  in physical import mode.
#### Starting from v7.2.0, this parameter is deprecated and no longer takes
    ↪ effect after it is set.
#### If you want to adjust the amount of data sent to TiKV in one request,
    ↪ use the `send-kv-size` parameter instead.
#### send-kv-pairs = 32768
#### The maximum size of one request when sending data to TiKV in physical
    ↪ import mode.
#### The default value is "16K". It is not recommended to adjust this
    ↪ parameter.
#### This parameter is introduced in v7.2.0.
#### send-kv-size = "16K"
#### Whether to enable compression when sending KV pairs to TiKV in the
    ↪ physical import mode.
#### Currently, only the Gzip compression algorithm is supported.
```

```
#### To use this algorithm, you can fill in either "gzip" or "gz" for this
   ↪ parameter.
#### By default, the compression is not enabled.
#### compress-kv-pairs = ""
#### The directory of local KV sorting in the physical import mode. If the
   ↪ disk
#### performance is low (such as in HDD), it is recommended to set the
   ↪ directory
#### on a different disk from `data-source-dir` to improve import speed.
#### sorted-kv-dir = ""
#### The concurrency that TiKV writes KV data in the physical import mode.
#### When the network transmission speed between TiDB Lightning and TiKV
#### exceeds 10 Gigabit, you can increase this value accordingly.
#### range-concurrency = 16
#### Limits the bandwidth in which TiDB Lightning writes data into each TiKV
#### node in the physical import mode. 0 by default, which means no limit.
#### store-write-bwlimit = "128MiB"

#### Specifies the disk quota for local temporary files when physical import
   ↪  mode is used.
#### When the disk quota is insufficient, TiDB Lightning stops reading
   ↪ source data and writing temporary files,
#### but prioritizes writing the already sorted key-value pairs to TiKV.
#### After TiDB Lightning deletes the local temporary files, the import
   ↪ process continues.
#### This option takes effect only when you set the `backend` option to `
   ↪ local`.
#### The default value is `MaxInt64` bytes, that is, 9223372036854775807
   ↪ bytes.
#### disk-quota = "10GB"

#### Specifies whether Physical Import Mode adds indexes via SQL.
#### The default value is `false`, which means that TiDB Lightning will
   ↪ encode both row data and index data
#### into KV pairs and import them into TiKV together.
#### This mechanism is consistent with that of the historical versions.
#### If you set it to `true`, it means that TiDB Lightning adds indexes via
   ↪ SQL after importing the row data.
#### The benefit of adding indexes via SQL is that you can separately import
   ↪  data and import indexes,
#### and import data more quickly. After the data is imported, even if the
   ↪ indexes fail to be added,
#### it does not affect the consistency of the imported data.
#### add-index-by-sql = false
```

```
#### When you use TiDB Lightning to import a multi-tenant TiDB cluster, use
   ↪ this parameter to specify the corresponding key space name.
#### The default value is an empty string, which means TiDB Lightning will
   ↪ automatically get the key space name of the corresponding tenant to
   ↪ import data.
#### If you specify a value, the specified key space name will be used to
   ↪ import data.
#### keyspace-name = ""

#### In Physical Import Mode, this parameter controls the scope in which
   ↪ TiDB Lightning stops PD scheduling.
#### The value options are as follows:
#### - "table": pause scheduling only for the Region that stores the target
   ↪ table data. The default value is "table".
#### - "global": pause global scheduling. When importing data to a cluster
   ↪ without any business traffic,
####  it is recommended to set this parameter to "global" to avoid
   ↪ interference from other scheduling.
#### pause-pd-scheduler-scope = "table"

#### In Physical Import Mode, this parameter controls the number of Regions
   ↪ when splitting Regions in a batch.
#### The maximum number of Regions that can be split at the same time per
   ↪ TiDB Lightning instance is:
#### region-split-batch-size * region-split-concurrency * table-concurrency
#### This parameter is introduced in v7.1.0. The default value is `4096`.
#### region-split-batch-size = 4096

#### In Physical Import Mode, this parameter controls the concurrency when
   ↪ splitting Regions.
#### The default value is the number of CPU cores.
#### This parameter is introduced in v7.1.0.
#### region-split-concurrency =

#### In Physical Import Mode, this parameter controls the number of retries
   ↪ to wait for the Region to come online
#### after the split and scatter operations.
#### The default value is `1800` and the maximum retry interval is two
   ↪ seconds.
#### The number of retries will not be increased if any Region becomes
   ↪ online between retries.
#### This parameter is introduced in v7.1.0.
#### region-check-backoff-limit = 1800

#### In Physical Import Mode, this parameter controls the I/O block size for
```

```
   ↪  sorting local files. When the disk IOPS is a bottleneck, you can
   ↪ increase this value to improve data import performance.
#### This parameter is introduced in v7.6.0. The default value is "16KiB".
   ↪ The value must be greater than or equal to `1B`. Note that if you
   ↪ only specify a number (for example, `16`), the unit is Byte instead
   ↪ of KiB.
#### block-size = "16KiB"

#### In Logical Import Mode, this parameter controls the size of each SQL
   ↪ statement executed on the downstream TiDB server.
#### This parameter is introduced in v8.0.0.
#### It specifies the expected size of the VALUES part of each INSERT or
   ↪ REPLACE statement in a single transaction.
#### This parameter is not a hard limit. The actual SQL executed might be
   ↪ longer or shorter, depending on the actual content imported.
#### The default value is "96KiB", which is optimized for import speed when
   ↪ TiDB Lightning is the only client of the cluster.
#### Due to the implementation details of TiDB Lightning, the value is
   ↪ capped at 96 KiB. Setting a larger value will not take effect.
#### You can decrease this value to reduce the stress on the cluster due to
   ↪ large transactions.
#### logical-import-batch-size = "96KiB"

#### In Logical Import Mode, this parameter controls the maximum number of
   ↪ rows inserted per transaction.
#### This parameter is introduced in v8.0.0. The default value is `65536`
   ↪ rows.
#### When both `logical-import-batch-size` and `logical-import-batch-rows`
   ↪ are specified, the parameter whose value reaches its threshold first
   ↪ will take effect.
#### You can decrease this value to reduce the stress on the cluster due to
   ↪ large transactions.
#### logical-import-batch-rows = 65536

#### In Logical Import Mode, this parameter controls whether to use prepared
   ↪  statements and statement cache to improve performance. The default
   ↪ value is `false`.
logical-import-prep-stmt = false

[mydumper]
#### Block size for file reading. Keep it longer than the longest string of
   ↪ the data source.
read-block-size = "64KiB" # default value

#### The engine file needs to be imported sequentially. Due to parallel
```

```
    ↪ processing,
#### multiple data engines will be imported at nearly the same time, and
    ↪ this
#### creates a queue and wastes resources. Therefore, TiDB Lightning
    ↪ slightly
#### increases the size of the first few batches to properly distribute
#### resources. The scale up factor is controlled by this parameter, which
#### expresses the ratio of duration between the "import" and "write" steps
#### with full concurrency. This can be calculated by using the ratio
#### (import duration/write duration) of a single table of size around 1 GiB
    ↪ .
#### The exact timing can be found in the log. If "import" is faster, the
    ↪ batch
#### size variance is smaller, and a ratio of zero means a uniform batch
    ↪ size.
#### This value should be in the range (0 <= batch-import-ratio < 1).
batch-import-ratio = 0.75

#### Local source data directory or the URI of the external storage.
#### For more information about the URI of the external storage, see https
    ↪ ://docs.pingcap.com/tidb/v6.6/backup-and-restore-storages#uri-format.
data-source-dir = "/data/my_database"

#### The character set of the schema files, containing CREATE TABLE
    ↪ statements;
#### only supports one of:
#### - utf8mb4: the schema files must be encoded as UTF-8; otherwise, an
    ↪ error is reported.
#### - gb18030: the schema files must be encoded as GB-18030; otherwise,
####           an error is reported
#### - auto:   (default) automatically detects whether the schema is UTF-8
    ↪ or
####           GB-18030. An error is reported if the encoding is neither.
#### - latin1: the schema files use MySQL latin1 encoding, also known as
    ↪ Code Page 1252.
#### - binary: do not try to decode the schema files
character-set = "auto"

#### Specifies the character set of the source data file.
#### Lightning converts the source file from the specified character set to
    ↪ UTF-8 encoding when importing.
#### Currently, this configuration only specifies the character set of the
    ↪ CSV files with the following options supported:
#### - utf8mb4: Indicates that the source data file uses UTF-8 encoding.
#### - GB18030: Indicates that the source data file uses the GB-18030
```

```
    ↪ encoding.
#### - GBK: The source data file uses GBK encoding (GBK encoding is an
    ↪ extension of the GB-2312 character set, also known as Code Page 936).
#### - latin1: The source data file uses MySQL latin1 encoding, also known
    ↪ as Code Page 1252.
#### - binary: Indicates that Lightning does not convert the encoding (by
    ↪ default).
#### If left blank, the default value "binary" is used, that is to say,
    ↪ Lightning does not convert the encoding.
#### Note that Lightning does not predict about the character set of the
    ↪ source data file
#### and only converts the source file and import the data based on this
    ↪ configuration.
#### If the value of this configuration is not the same as the actual
    ↪ encoding of the source data file,
#### a failed import, data loss or data disorder might appear.
data-character-set = "binary"
#### Specifies the replacement character in case of incompatible characters
    ↪ during the character set conversion of the source data file.
#### This configuration must not be duplicated with field separators, quote
    ↪ definers, and line breaks.
#### The default value is "\uFFFD", which is the "error" Rune or Unicode
    ↪ replacement character in UTF-8 encoding.
#### Changing the default value might result in potential degradation of
    ↪ parsing performance for the source data file.
data-invalid-char-replace = "\uFFFD"

#### the input data in a "strict" format speeds up processing.
#### "strict-format = true" requires that:
#### in CSV, every value cannot contain literal new lines (U+000A and U+000D
    ↪ , or \r and \n) even
#### when quoted, which means new lines are strictly used to separate rows.
#### "Strict" format allows TiDB Lightning to quickly locate split positions
    ↪  of a large file for parallel processing.
#### However, if the input data is not "strict", it may split a valid data
    ↪ in half and
#### corrupt the result.
#### The default value is false for safety instead of speed.
strict-format = false

#### If strict-format is true, TiDB Lightning splits large CSV files into
    ↪ multiple chunks to process in
#### parallel. max-region-size is the maximum size of each chunk after
    ↪ splitting.
#### max-region-size = "256MiB" # default value
```

```
#### Only import tables if these wildcard rules are matched. See the
   ↪ corresponding section for details.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
   ↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA.*']

#### Configures how CSV files are parsed.
[mydumper.csv]
#### Separator between fields. Must not be empty.
separator = ','
#### Quoting delimiter. Empty value means no quoting.
delimiter = '"'
#### Line terminator. Empty value means both "\n" (LF) and "\r\n" (CRLF) are
   ↪  line terminators.
terminator = ''
#### Whether the CSV files contain a header.
#### If `header` is true, TiDB Lightning treats the first row as a table
   ↪ header and does not import it as data.
#### If `header` is false, the first row is also imported as CSV data.
header = true
#### Whether the column names in the CSV file header are matched to those
   ↪ defined in the target table.
#### The default value is `true`, which means that you have confirmed that
   ↪ the column names in the CSV header
#### are consistent with those in the target table, so that even if the
   ↪ order of the columns is different between the two,
#### TiDB Lightning can still import the data successfully by mapping the
   ↪ column names.
#### If the column names between the CSV table header and the target table
   ↪ do not match
#### (for example, some column names in the CSV table header cannot be found
   ↪  in the target table)
#### but the column order is the same, set this configuration to `false`.
#### In this scenario, TiDB Lightning will ignore the CSV header to avoid
   ↪ errors and import the data
#### directly in the order of the columns in the target table.
#### Therefore, if the columns are not in the same order,
#### you need to manually adjust the order of the columns in the CSV file to
   ↪  be consistent with that
#### in the target table before importing;
#### otherwise data discrepancies might occur.
#### It is important to note that this parameter only applies if the `header
   ↪ ` parameter is set to `true`.
#### If `header` is set to `false`, it means that the CSV file does not
   ↪ contain a header,
```

```
#### so this parameter is not relevant.
header-schema-match = true
#### Whether the CSV contains any NULL value.
#### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
#### When `not-null` is false (that is, CSV can contain NULL),
#### fields equal to this value will be treated as NULL.
null = '\N'
#### Whether to interpret backslash escapes inside fields.
backslash-escape = true
#### If a line ends with a separator, remove it.
trim-last-separator = false

#### [[mydumper.files]]
#### Expression used for parsing AWS Aurora parquet files
#### pattern = '(?i)^(?:[^/]*/)*([a-z0-9_]+)\.([a-z0-9_]+)/(?:[^/]*/)*(?:[a-
    ↪ z0-9\-_.]+\.(parquet))$'
#### schema = '$1'
#### table = '$2'
#### type = '$3'

[tidb]
#### Configuration of any TiDB server from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
#### Configure the password to connect to TiDB. The password can either be
    ↪ plaintext or Base64 encoded.
password = ""
#### Table schema information is fetched from TiDB via this status-port.
status-port = 10080
#### Address of any PD server from the cluster. Starting from v7.6.0, TiDB
    ↪ supports setting multiple PD addresses.
pd-addr = "172.16.31.4:2379,56.78.90.12:3456"
#### tidb-lightning imports TiDB as a library and generates some logs itself
    ↪ .
#### This setting controls the log level of the TiDB library.
log-level = "error"

#### Sets the TiDB session variable to speed up the Checksum and Analyze
    ↪ operations. Note that if checksum-via-sql is set to "true", TiDB
    ↪ Lightning will execute the ADMIN CHECKSUM TABLE <table> SQL statement
    ↪  to perform the Checksum operation on TiDB. In this case, the
    ↪ following parameters `distsql-scan-concurrency` and `checksum-table-
    ↪ concurrency` will not take effect.
```

```
#### See https://docs.pingcap.com/tidb/stable/statistics#control-analyze-
   ↪ concurrency
#### for the meaning of each setting
build-stats-concurrency = 20
distsql-scan-concurrency = 15
index-serial-scan-concurrency = 20
checksum-table-concurrency = 2

#### The default SQL mode used to parse and execute the SQL statements.
sql-mode = "ONLY_FULL_GROUP_BY,NO_AUTO_CREATE_USER"
#### Sets maximum packet size allowed for SQL connections.
#### Set this to 0 to automatically fetch the `max_allowed_packet` variable
   ↪ from server on every connection.
max-allowed-packet = 67_108_864

#### Whether to use TLS for SQL connections. Valid values are:
#### * ""          - force TLS (same as "cluster") if [tidb.security]
   ↪ section is populated, otherwise same as "false"
#### * "false"     - disable TLS
#### * "cluster"   - force TLS and verify the server's certificate with the
   ↪  CA specified in the [tidb.security] section
#### * "skip-verify" - force TLS but do not verify the server's certificate
   ↪  (insecure!)
#### * "preferred" - same as "skip-verify", but if the server does not
   ↪ support TLS, fallback to unencrypted connection
#### tls = ""

#### Specifies certificates and keys for TLS-enabled MySQL connections.
#### Defaults to a copy of the [security] section.
#### [tidb.security]
#### Public certificate of the CA. Set to empty string to disable TLS for
   ↪ SQL.
#### ca-path = "/path/to/ca.pem"
#### Public certificate of this service. Default to copy of `security.cert-
   ↪ path`
#### cert-path = "/path/to/lightning.pem"
#### Private key of this service. Default to copy of `security.key-path`
#### key-path = "/path/to/lightning.key"

#### Sets other TiDB session variables
#### [tidb.session-vars]
#### tidb_enable_clustered_index = "OFF"

#### In the physical import mode, when data importing is complete, TiDB
   ↪ Lightning can
```

```
#### automatically perform the Checksum and Analyze operations. It is
   ↪ recommended
#### to leave these as true in the production environment.
#### The execution order: Checksum -> Analyze.
#### Note that in the logical import mode, Checksum and Analyze is not
   ↪ needed, and they are always
#### skipped in the actual operation.
[post-restore]
#### Specifies whether to perform `ADMIN CHECKSUM TABLE <table>` for each
   ↪ table to verify data integrity after importing.
#### The following options are available:
#### - "required" (default value): Perform admin checksum. If checksum fails
   ↪ , TiDB Lightning will exit with failure.
#### - "optional": Perform admin checksum. If checksum fails, TiDB Lightning
   ↪  will report a WARN log but ignore any error.
#### - "off": Do not perform checksum.
#### Note that since v4.0.8, the default value has changed from "true" to "
   ↪ required".
#### Note:
#### 1. Checksum failure usually means import exception (data loss or
   ↪ inconsistency). It is recommended to always enable checksum.
#### 2. For backward compatibility, bool values "true" and "false" are also
   ↪ allowed for this field.
#### "true" is equivalent to "required" and "false" is equivalent to "off".
checksum = "required"
#### Specifies whether the ADMIN CHECKSUM TABLE <table> operation is
   ↪ executed via TiDB.
#### The default value is "false", which means that the ADMIN CHECKSUM TABLE
   ↪  <table> command is sent to TiKV for execution via TiDB Lightning.
#### It is recommended that you set this value to "true" to make it easier
   ↪ to locate the problem if checksum fails.
#### Meanwhile, if you want to adjust concurrency when this value is "true",
   ↪  you need to set the `tidb_checksum_table_concurrency` variable in
   ↪ TiDB (https://docs.pingcap.com/tidb/stable/system-variables#tidb_
   ↪ checksum_table_concurrency).
checksum-via-sql = "false"
#### Specifies whether to perform `ANALYZE TABLE <table>` for each table
   ↪ after checksum is done.
#### Options available for this field are the same as `checksum`. However,
   ↪ the default value for this field is "optional".
analyze = "optional"

#### Configures the background periodic actions.
#### Supported units: h (hour), m (minute), s (second).
[cron]
```

```
#### Duration between which TiDB Lightning automatically refreshes the
    ↪ import mode
#### status. Should be shorter than the corresponding TiKV setting.
switch-mode = "5m"
#### Duration between which an import progress is printed to the log.
log-progress = "5m"
#### The time interval for checking the local disk quota when you use the
    ↪ physical import mode.
#### The default value is 60 seconds.
#### check-disk-quota = "60s"
```

13.7.15.6 TiDB Lightning Command Line Flags

You can configure TiDB Lightning either using the configuration file or in command line. This document describes the command line flags of TiDB Lightning.

13.7.15.6.1 Command line flags

`tidb-lightning`

You can configure the following parameters using `tidb-lightning`:

Parameter	Description	Corresponding configuration item
`--config <file>`	Read the global configuration from the file. If this parameter is not specified, TiDB Lightning uses the default configuration.	
`-V`	Print the program version.	

Parameter	Description	Corresponding configuration item
`-d <directory>`	Local directory or external storage URI of data files.	`mydumper.data-source-dir`
`-L <level>`	Log level: `debug`, `info`, `warn`, `error`, or `fatal`. `info` by default.	`lightning.level`
`-f <rule>`	Table filter rules. Can be specified multiple times.	`mydumper.filter`

Parameter	Description	Corresponding configuration item
`--backend <backend>`	Select an import mode. `local` refers to physical import mode; `tidb` refers to logical import mode.	`tikv-importer.backend`

Parameter	Description	Corresponding configuration item
`--log` ↪ `-` ↪ `file` ↪ `<` ↪ `file` ↪ `>`	Log file path. By default, it is `/tmp/` ↪ `lightning` ↪ `.` ↪ `log` ↪ `.{` ↪ `timestamp` ↪ `}.` If set to '-', it means that the log files will be output to stdout.	`lightning` ↪ `.` ↪ `log` ↪ `-` ↪ `file` ↪
`--` ↪ `status` ↪ `-` ↪ `addr` ↪ `<` ↪ `ip` ↪ `:` ↪ `port` ↪ `>`	Listening address of the TiDB Lightning server	`lightning` ↪ `.` ↪ `status` ↪ `-` ↪ `port` ↪

Parameter	Description	Corresponding configuration item
--pd- ↪ urls ↪ < ↪ host1 ↪ : ↪ port1 ↪ , ↪ host2 ↪ : ↪ port2 ↪ ,..., ↪ hostn ↪ : ↪ portn ↪ >	PD endpoint address. Starting from v7.6.0, TiDB supports setting multiple PD addresses.	tidb. ↪ pd ↪ - ↪ addr ↪
-- ↪ tidb ↪ - ↪ host ↪ < ↪ host ↪ >	TiDB server host	tidb. ↪ host ↪
-- ↪ tidb ↪ - ↪ port ↪ < ↪ port ↪ >	TiDB server port (default = 4000)	tidb. ↪ port ↪

Parameter	Description	Corresponding configuration item
-- ↪ tidb ↪ - ↪ status ↪ < ↪ port ↪ >	TiDB status port (default = 10080)	tidb. ↪ status ↪ - ↪ port ↪
-- ↪ tidb ↪ - ↪ user ↪ < ↪ user ↪ >	User name to connect to TiDB	tidb. ↪ user ↪
-- ↪ tidb ↪ - ↪ password ↪ < ↪ password ↪ >	Password to connect to TiDB. The password can either be plaintext or Base64 encoded.	tidb. ↪ password ↪

Parameter	Description	Corresponding configuration item
`--enable-checkpoint <bool>`	Whether to enable checkpoints (default = true)	`checkpoint.enable`
`--analyze <level>`	Analyze tables after importing. Available values are "required", "optional" (default value), and "off".	`post-restore.analyze`

Parameter	Description	Corresponding configuration item
`--checksum <level>`	Compare checksum after importing. Available values are "required" (default value), "optional", and "off".	`post-restore.checksum`

Parameter	Description	Corresponding configuration item
`--check-requirements bool`	Check cluster version compatibility before starting the task, and check whether TiKV has more than 10% free space left during running time. (default = true)	`lightning.check-requirements`

Parameter	Description	Corresponding configuration item
`--ca` ↪ `<` ↪ `file` ↪ `>`	CA certificate path for TLS connection	`security` ↪ `.` ↪ `ca` ↪ `-` ↪ `path` ↪
`--` ↪ `cert` ↪ `<` ↪ `file` ↪ `>`	Certificate path for TLS connection	`security` ↪ `.` ↪ `cert` ↪ `-` ↪ `path` ↪
`--key` ↪ `<` ↪ `file` ↪ `>`	Private key path for TLS connection	`security` ↪ `.` ↪ `key` ↪ `-` ↪ `path` ↪
`--` ↪ `server` ↪ `-` ↪ `mode` ↪	Start TiDB Lightning in server mode	`lightning` ↪ `.` ↪ `server` ↪ `-` ↪ `mode` ↪

If you specify both a command line parameter and the corresponding setting in the configuration file, the command line parameter takes precedence. For example, running `tiup tidb ↪ -lightning -L debug --config cfg.toml` would always set the log level to "debug" regardless of the content of `cfg.toml`.

13.7.15.6.2 `tidb-lightning-ctl`

All parameters of `tidb-lightning` apply to `tidb-lightning-ctl`. In addition, you can also configure the following parameters using `tidb-lightning-ctl`:

Parameter	Description
`--compact`	Perform a full compaction.
`--switch-mode <mode>`	Switch every TiKV store to the given mode: normal or import.
`--fetch-mode`	Print the current mode of every TiKV store.
`--import-engine <uuid>`	Import the closed engine file from TiKV Importer into the TiKV cluster.

Parameter	Description
-- ↪ cleanup ↪ - ↪ engine ↪ < ↪ uuid ↪ >	Delete the engine file from TiKV Importer.
-- ↪ checkpoint ↪ - ↪ dump ↪ < ↪ folder ↪ >	Dump current checkpoint as CSVs into the folder.
-- ↪ checkpoint ↪ - ↪ error ↪ - ↪ destroy ↪ < ↪ table ↪ _ ↪ name ↪ >	Remove the checkpoint. If it causes an error, drop the table.
-- ↪ checkpoint ↪ - ↪ error ↪ - ↪ ignore ↪ < ↪ table ↪ _ ↪ name ↪ >	Ignore any error recorded in the checkpoint involving the given table.

Parameter	Description
`--checkpoint-remove <table_name>`	Unconditionally remove the checkpoint of the table.

The `<table_name>` must either be a qualified table name in the form `` `db`.`tbl` `` (including the backquotes), or the keyword `all`.

13.7.15.7 TiDB Lightning Monitoring

`tidb-lightning` supports metrics collection via Prometheus. This document introduces the monitor configuration and monitoring metrics of TiDB Lightning.

13.7.15.7.1 Monitor configuration

If TiDB Lightning is manually installed, follow the instructions below.

The metrics of `tidb-lightning` can be gathered directly by Prometheus as long as it is discovered. You can set the metrics port in `tidb-lightning.toml`:

```
[lightning]
#### HTTP port for debugging and Prometheus metrics pulling (0 to disable)
pprof-port = 8289

...
```

You need to configure Prometheus to make it discover the servers. For instance, you can directly add the server address to the `scrape_configs` section:

```
...
scrape_configs:
  - job_name: 'tidb-lightning'
    static_configs:
      - targets: ['192.168.20.10:8289']
```

13.7.15.7.2 Grafana dashboard

Grafana is a web interface to visualize Prometheus metrics as dashboards.

Row 1: Speed

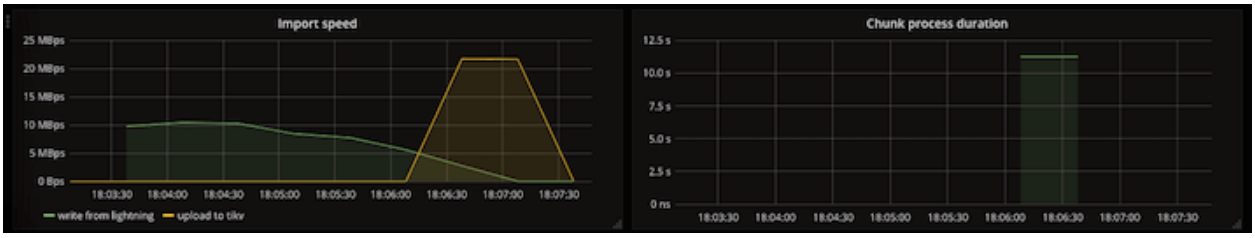

Figure 485: Panels in first row

Panel	Series	Description
Import speed	write from TiDB Lightning	Speed of sending KVs from TiDB Lightning to TiKV Importer, which depends on each table's complexity
Import speed	upload to tikv	Total upload speed from TiKV Importer to all TiKV replicas

Panel	Series	Description
Chunk process duration		Average time needed to completely encode one single data file

Sometimes the import speed will drop to zero allowing other parts to catch up. This is normal.

Row 2: Progress

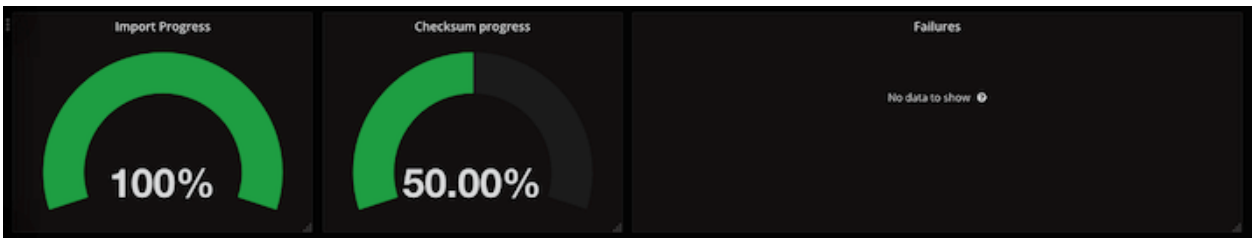

Figure 486: Panels in second row

Panel	Description
Import progress	Percentage of data files encoded so far
Checksum progress	Percentage of tables are verified to be imported successfully
Failures	Number of failed tables and their point of failure, normally empty

Row 3: Resource

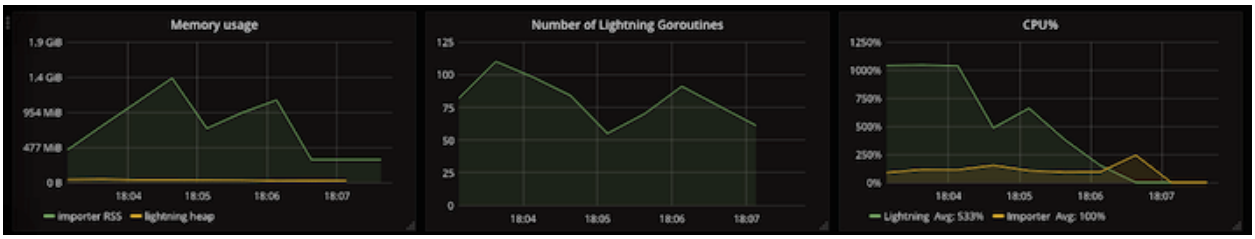

Figure 487: Panels in third row

Panel	Description
Memory usage	Amount of memory occupied by each service
Number of TiDB Lightning Goroutines	Number of running goroutines used by TiDB Lightning
CPU%	Number of logical CPU cores utilized by each service

Row 4: Quota

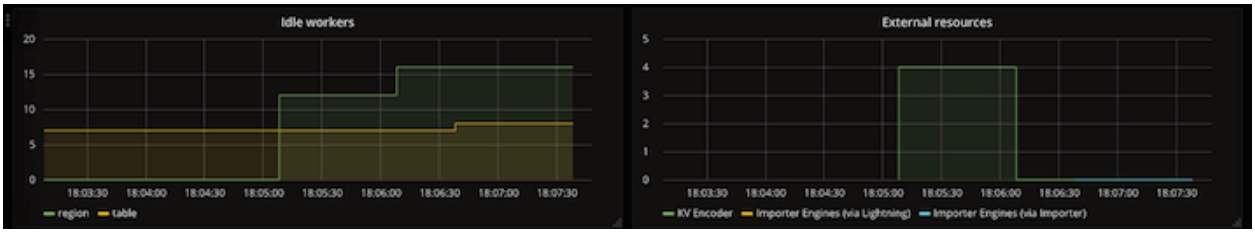

Figure 488: Panels in fourth row

Panel	Series	Description
Idle workers	io	Number of unused `io-concurrency`, normally close to configured value (default 5), and close to 0 means the disk is too slow

Panel	Series	Description
Idle workers	closed-engine	Number of engines which is closed but not yet cleaned up, normally close to index + table-concurrency (default 8), and close to 0 means TiDB Lightning is faster than TiKV Importer, which will cause TiDB Lightning to stall

Panel	Series	Description
Idle workers	table	Number of unused `table-concurrency`, normally 0 until the end of process
Idle workers	index	Number of unused `index-concurrency`, normally 0 until the end of process
Idle workers	region	Number of unused `region-concurrency`, normally 0 until the end of process

Panel	Series	Description
External resources	KV Encoder	Counts active KV encoders, normally the same as `region` ↪ - ↪ `concurrency` ↪ until the end of process
External resources	Importer Engines	Counts opened engine files, should never exceed the `max-` ↪ `open` ↪ - ↪ `engines` ↪ setting

Row 5: Read speed

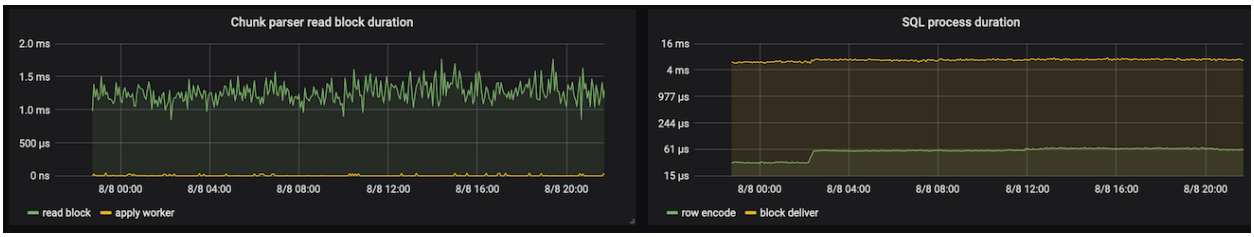

Figure 489: Panels in fifth row

Panel	Series	Description
Chunk parser read block duration	read block	Time taken to read one block of bytes to prepare for parsing
Chunk parser read block duration	apply worker	Time elapsed to wait for an idle io-concurrency
SQL process duration	row encode	Time taken to parse and encode a single row
SQL process duration	block deliver	Time taken to send a block of KV pairs to TiKV Importer

If any of the duration is too high, it indicates that the disk used by TiDB Lightning is too slow or busy with I/O.

Row 6: Storage

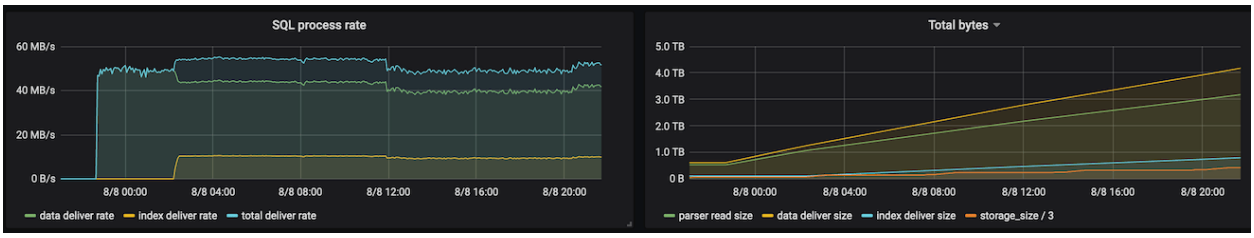

Figure 490: Panels in sixth row

Panel	Series	Description
SQL process rate	data deliver rate	Speed of delivery of data KV pairs to TiKV Importer
SQL process rate	index deliver rate	Speed of delivery of index KV pairs to TiKV Importer
SQL process rate	total deliver rate	The sum of two rates above

Panel	Series	Description
Total bytes	parser read size	Number of bytes being read by TiDB Lightning
Total bytes	data deliver size	Number of bytes of data KV pairs already delivered to TiKV Importer
Total bytes	index deliver size	Number of bytes of index KV pairs already delivered to TiKV Importer

Panel	Series	Description
Total bytes	storage_size / 3	Total size occupied by the TiKV cluster, divided by 3 (the default number of replicas)

Row 7: Import speed

Figure 491: Panels in seventh row

Panel	Series	Description
Delivery duration	Range delivery	Time taken to upload a range of KV pairs to the TiKV cluster

Panel	Series	Description
Delivery duration	SST delivery	Time taken to upload an SST file to the TiKV cluster
SST process duration	Split SST	Time taken to split the stream of KV pairs into SST files
SST process duration	SST upload	Time taken to upload an SST file
SST process duration	SST ingest	Time taken to ingest an uploaded SST file
SST process duration	SST size	File size of an SST file

13.7.15.7.3 Monitoring metrics

This section explains the monitoring metrics of `tidb-lightning`.

Metrics provided by `tidb-lightning` are listed under the namespace `lightning_*`.

- **`lightning_importer_engine`** (Counter)

  Counts open and closed engine files. Labels:

  - **type**:
    - `open`
    - `closed`

- **`lightning_idle_workers`** (Gauge)

  Counts idle workers. Labels:

  - **name**:
    - `table`: the remainder of `table-concurrency`, normally 0 until the end of the process
    - `index`: the remainder of `index-concurrency`, normally 0 until the end of the process
    - `region`: the remainder of `region-concurrency`, normally 0 until the end of the process
    - `io`: the remainder of `io-concurrency`, normally close to configured value (default 5), and close to 0 means the disk is too slow
    - `closed-engine`: number of engines which have been closed but not yet cleaned up, normally close to index + table-concurrency (default 8). A value close to 0 means TiDB Lightning is faster than TiKV Importer, which might cause TiDB Lightning to stall

- **`lightning_kv_encoder`** (Counter)

  Counts open and closed KV encoders. KV encoders are in-memory TiDB instances that convert SQL `INSERT` statements into KV pairs. The net values need to be bounded in a healthy situation. Labels:

  - **type**:
    - `open`
    - `closed`

- **`lightning_tables`** (Counter)

  Counts processed tables and their statuses. Labels:

  - **state**: the status of the table, indicating which phase should be completed
    - `pending`: not yet processed
    - `written`: all data encoded and sent
    - `closed`: all corresponding engine files closed
    - `imported`: all engine files have been imported into the target cluster
    - `altered_auto_inc`: AUTO_INCREMENT ID altered
    - `checksum`: checksum performed

    - `analyzed`: statistics analysis performed
    - `completed`: the table has been fully imported and verified
  - **result**: the result of the current phase
    - `success`: the phase completed successfully
    - `failure`: the phase failed (did not complete)

- **`lightning_engines`** (Counter)

  Counts number of engine files processed and their status. Labels:

  - **state**: the status of the engine, indicating which phase should be completed
    - `pending`: not yet processed
    - `written`: all data encoded and sent
    - `closed`: engine file closed
    - `imported`: the engine file has been imported into the target cluster
    - `completed`: the engine has been fully imported
  - **result**: the result of the current phase
    - `success`: the phase completed successfully
    - `failure`: the phase failed (did not complete)

- **`lightning_chunks`** (Counter)

  Counts number of chunks processed and their status. Labels:

  - **state**: a chunk's status, indicating which phase the chunk is in
    - `estimated`: (not a state) this value gives total number of chunks in current task
    - `pending`: loaded but not yet processed
    - `running`: data are being encoded and sent
    - `finished`: the entire chunk has been processed
    - `failed`: errors happened during processing

- **`lightning_import_seconds`** (Histogram)

  Bucketed histogram for the time needed to import a table.

- **`lightning_row_read_bytes`** (Histogram)

  Bucketed histogram for the size of a single SQL row.

- **`lightning_row_encode_seconds`** (Histogram)

  Bucketed histogram for the time needed to encode a single SQL row into KV pairs.

- **`lightning_row_kv_deliver_seconds`** (Histogram)

  Bucketed histogram for the time needed to deliver a set of KV pairs corresponding to one single SQL row.

- **`lightning_block_deliver_seconds`** (Histogram)

  Bucketed histogram for the time needed to deliver a block of KV pairs to Importer.

- **`lightning_block_deliver_bytes`** (Histogram)

  Bucketed histogram for the uncompressed size of a block of KV pairs delivered to Importer.

- **`lightning_chunk_parser_read_block_seconds`** (Histogram)

  Bucketed histogram for the time needed by the data file parser to read a block.

- **`lightning_checksum_seconds`** (Histogram)

  Bucketed histogram for the time needed to compute the checksum of a table.

- **`lightning_apply_worker_seconds`** (Histogram)

  Bucketed histogram for the time needed to acquire an idle worker (see also the `lightning_idle_workers` gauge). Labels:

  - **name**:
    - `table`
    - `index`
    - `region`
    - `io`
    - `closed-engine`

13.7.15.8 TiDB Lightning Web Interface

TiDB Lightning provides a webpage for viewing the import progress and performing some simple task management. This is called the *server mode*.

To enable server mode, either start `tidb-lightning` with the `--server-mode` flag

```
tiup tidb-lightning --server-mode --status-addr :8289
```

or set the `lightning.server-mode` setting in the configuration file.

```
[lightning]
server-mode = true
status-addr = ':8289'
```

After TiDB Lightning is launched, visit `http://127.0.0.1:8289` to control the program (the actual URL depends on the `status-addr` setting).

In server mode, TiDB Lightning does not start running immediately. Rather, users submit (multiple) *tasks* via the web interface to import data.

13.7.15.8.1 Front page

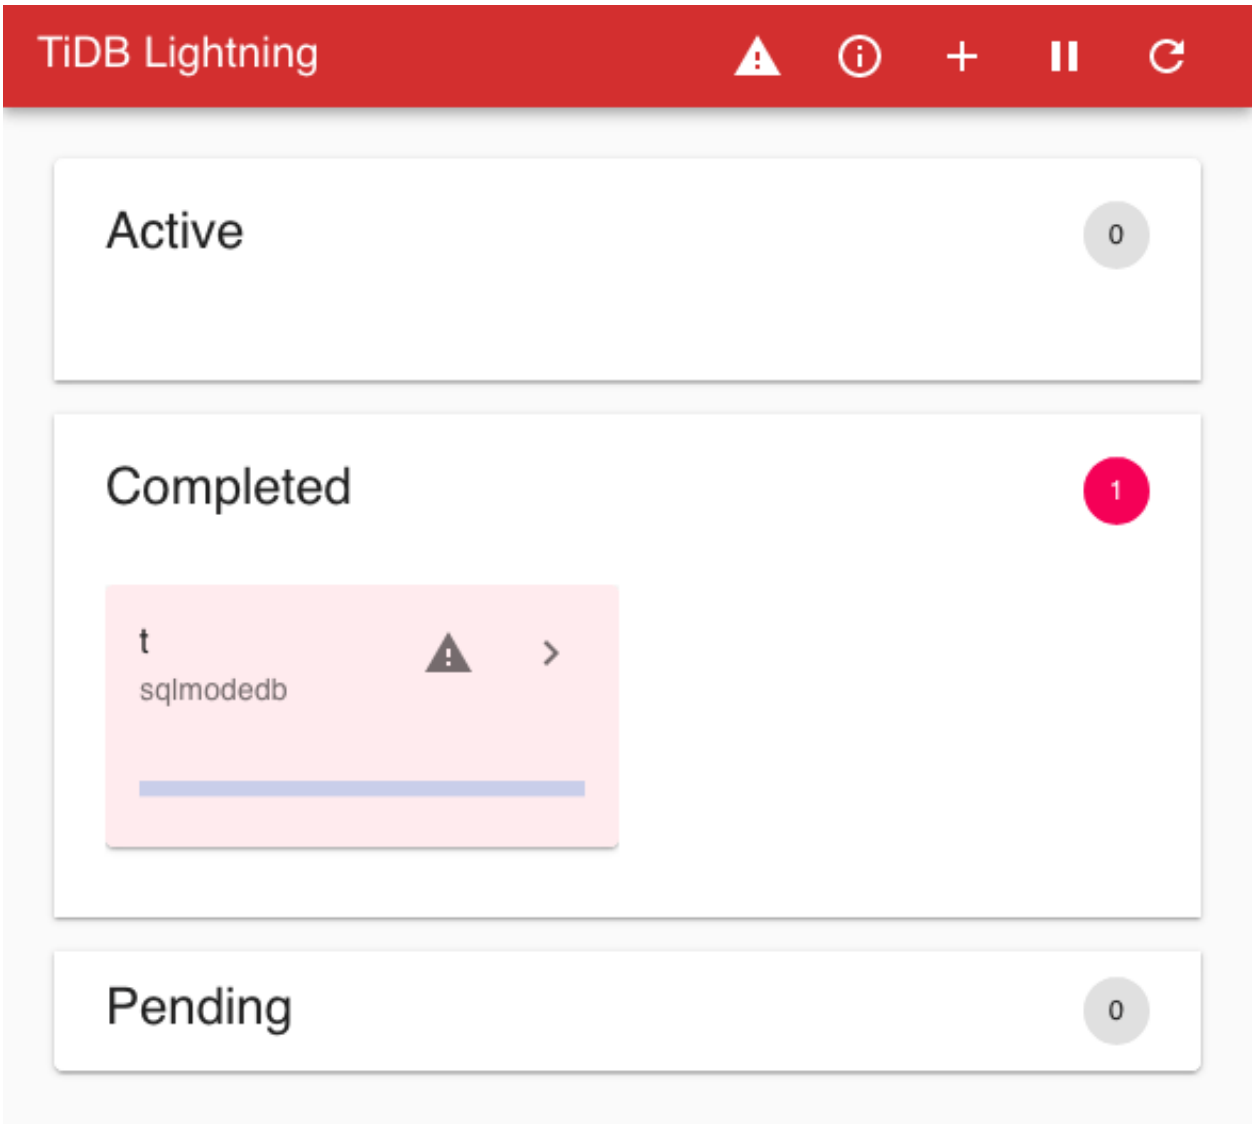

Figure 492: Front page of the web interface

Functions of the title bar, from left to right:

Icon	Function
"TiDB Lightning"	Click to go back to the front page

Icon	Function
	Display any error message from *previous* task
	List current and queued tasks; a badge may appear here to indicate number of queued tasks
+	Submit a task
/	Pause/resume current execution
	Configure auto-refresh of the web page

Three panels below the title bar show all tables in different states:

- Active: these tables are currently being imported
- Completed: these tables have been imported successfully or failed
- Pending: these tables are not yet processed

Each panel contains cards describing the status of the table.

13.7.15.8.2 Submit task

Click the + button on the title bar to submit a task.

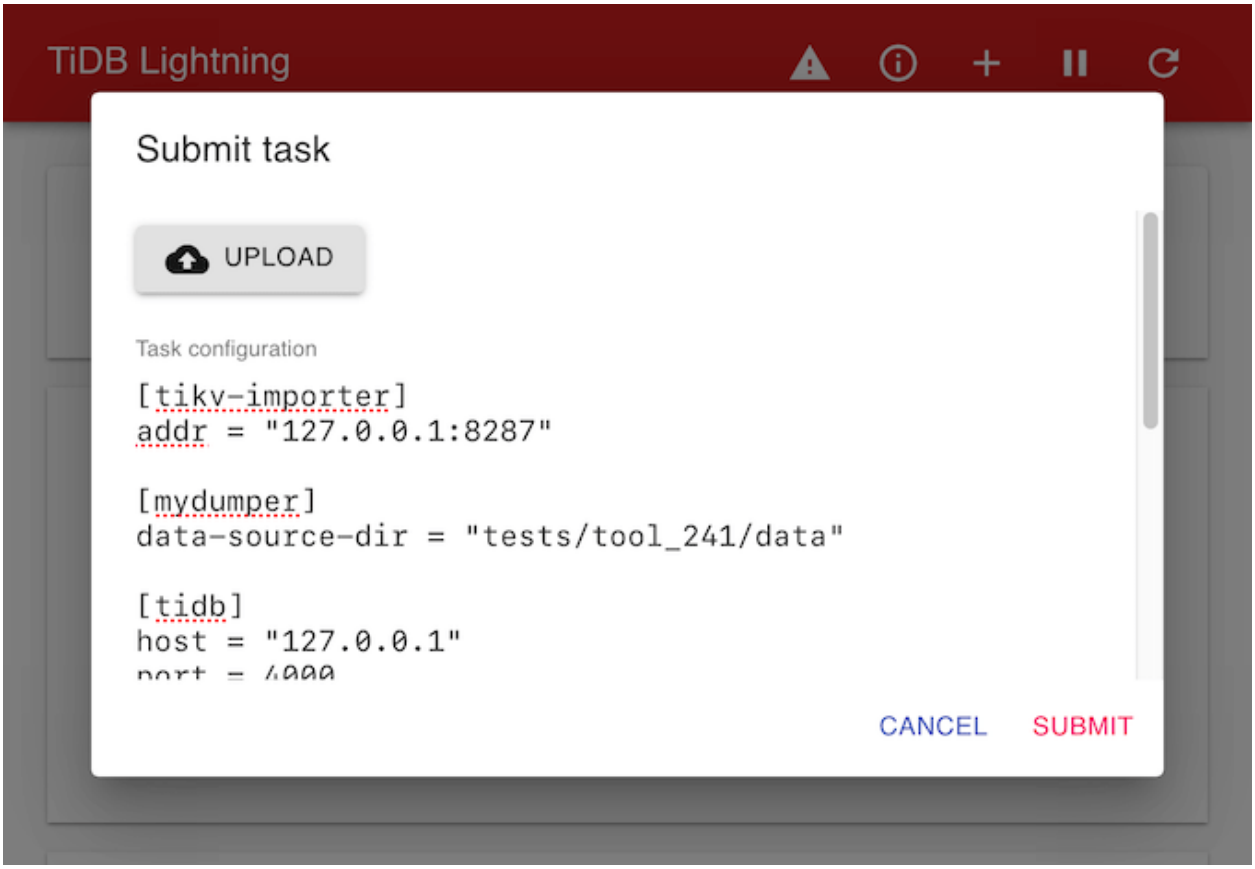

Figure 493: Submit task dialog

Tasks are TOML files described as task configurations. One could also open a local TOML file by clicking **UPLOAD**.

Click **SUBMIT** to run the task. If a task is already running, the new task will be queued and executed after the current task succeeds.

13.7.15.8.3 Table progress

Click the > button of a table card on the front page to view the detailed progress of a table.

Figure 494: Table progress

The page shows the import progress of every engine and data files associated with the table.

Click **TiDB Lightning** on the title bar to go back to the front page.

13.7.15.8.4 Task management

Click the button on the title bar to manage the current and queued tasks.

Figure 495: Task management page

Each task is labeled by the time it was submitted. Clicking the task would show the configuration formatted as JSON.

Manage tasks by clicking the button next to a task. You can stop a task immediately, or reorder queued tasks.

13.7.15.9 TiDB Lightning FAQs

This document lists the frequently asked questions (FAQs) and answers about TiDB Lightning.

13.7.15.9.1 What is the minimum TiDB/TiKV/PD cluster version supported by TiDB Lightning?

The version of TiDB Lightning should be the same as the cluster. If you use the Local-backend mode, the earliest available version is 4.0.0. If you use the Importer-backend mode or the TiDB-backend mode, the earliest available version is 2.0.9, but it is recommended to use the 3.0 stable version.

13.7.15.9.2 Does TiDB Lightning support importing multiple schemas (databases)?

Yes.

13.7.15.9.3 What are the privilege requirements for the target database?

For details about the permissions, see Prerequisites for using TiDB Lightning.

13.7.15.9.4 TiDB Lightning encountered an error when importing one table. Will it affect other tables? Will the process be terminated?

If only one table has an error encountered, the rest will still be processed normally.

13.7.15.9.5 How to properly restart TiDB Lightning?

1. Stop the `tidb-lightning` process.
2. Start a new `tidb-lightning` task: execute the previous start command, such as `nohup tiup tidb-lightning -config tidb-lightning.toml`.

13.7.15.9.6 How to ensure the integrity of the imported data?

TiDB Lightning by default performs checksum on the local data source and the imported tables. If there is checksum mismatch, the process would be aborted. These checksum information can be read from the log.

You could also execute the `ADMIN CHECKSUM TABLE` SQL command on the target table to recompute the checksum of the imported data.

```
ADMIN CHECKSUM TABLE `schema`.`table`;
```

```
+---------+------------+--------------------+-----------+-------------+
| Db_name | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+---------+------------+--------------------+-----------+-------------+
| schema | table     | 5505282386844578743 |     3 |         96 |
+---------+------------+--------------------+-----------+-------------+
1 row in set (0.01 sec)
```

13.7.15.9.7 What kinds of data source formats are supported by TiDB Lightning?

TiDB Lightning supports:

- Importing files exported by Dumpling, CSV files, and Apache Parquet files generated by Amazon Aurora, Apache Hive, and Snowflake.
- Reading data from a local disk or from the Amazon S3 storage.

13.7.15.9.8 Could TiDB Lightning skip creating schema and tables?

Starting from v5.1, TiDB Lightning can automatically recognize the schema and tables in the downstream. If you use TiDB Lightning earlier than v5.1, you need to set `no-schema = true` in the `[mydumper]` section in `tidb-lightning.toml`. This makes TiDB Lightning skip the `CREATE TABLE` invocations and fetch the metadata directly from the target database. TiDB Lightning will exit with error if a table is actually missing.

13.7.15.9.9 How to prohibit importing invalid data?

You can prohibit importing invalid data by enabling Strict SQL Mode.

By default, the `sql_mode` used by TiDB Lightning is `"ONLY_FULL_GROUP_BY,NO_AUTO_CREATE_USER"`, which allows invalid data such as the date `1970-00-00`.

To prohibit importing invalid data, you need to change the `sql-mode` setting to `"STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION"` in the `[tidb]` section in `tidb-lightning.toml`.

```
...
[tidb]
sql-mode = "STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION"
...
```

13.7.15.9.10 How to stop the `tidb-lightning` process?

To stop the `tidb-lightning` process, you can choose the corresponding operation according to your deployment method.

- For manual deployment: if `tidb-lightning` is running in foreground, press Ctrl+C to exit. Otherwise, obtain the process ID using the `ps aux | grep tidb-lightning` command and then terminate the process using the `kill -2 ${PID}` command.

13.7.15.9.11 Can TiDB Lightning be used with 1-Gigabit network card?

TiDB Lightning is best used with a 10-Gigabit network card.

1-Gigabit network cards can only provide a total bandwidth of 120 MB/s, which has to be shared among all target TiKV stores. TiDB Lightning can easily saturate all bandwidth of the 1-Gigabit network in physical import mode and bring down the cluster because PD is unable to be contacted anymore.

13.7.15.9.12 Why TiDB Lightning requires so much free space in the target TiKV cluster?

With the default settings of 3 replicas, the space requirement of the target TiKV cluster is 6 times the size of data source. The extra multiple of "2" is a conservative estimation because the following factors are not reflected in the data source:

- The space occupied by indices
- Space amplification in RocksDB

13.7.15.9.13 How to completely destroy all intermediate data associated with TiDB Lightning?

1. Delete the checkpoint file.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-
    ↪ remove=all
```

   If, for some reason, you cannot run this command, try manually deleting the file `/tmp ↪ /tidb_lightning_checkpoint.pb`.

2. If you are using Local-backend, delete the `sorted-kv-dir` directory in the configuration.

3. Delete all tables and databases created on the TiDB cluster, if needed.

4. Clean up the residual metadata. You need to clean up the metadata schema manually if either of the following conditions exist.

   - For TiDB Lightning v5.1.x and v5.2.x versions, the `tidb-lightning-ctl` command does not clean up the metadata schema in the target cluster. You need to clean it up manually.
   - If you have deleted the checkpoint files manually, you need to clean up the downstream metadata schema manually; otherwise, the correctness of subsequent imports might be affected.

   Use the following command to clean up the metadata:

```
DROP DATABASE IF EXISTS `lightning_metadata`;
```

13.7.15.9.14 How to get the runtime goroutine information of TiDB Lightning

1. If `status-port` has been specified in the configuration file of TiDB Lightning, skip this step. Otherwise, you need to send the USR1 signal to TiDB Lightning to enable `status-port`.

   Get the process ID (PID) of TiDB Lightning using commands like `ps`, and then run the following command:

```
kill -USR1 <lightning-pid>
```

   Check the log of TiDB Lightning. The log of `starting HTTP server` / `start HTTP ↪ server` / `started HTTP server` shows the newly enabled `status-port`.

2. Access `http://<lightning-ip>:<status-port>/debug/pprof/goroutine?debug=2` to get the goroutine information.

13.7.15.9.15 Why is TiDB Lightning not compatible with Placement Rules in SQL?

TiDB Lightning is not compatible with Placement Rules in SQL. When TiDB Lightning imports data that contains placement policies, TiDB Lightning reports an error.

The reason is explained as follows:

The purpose of placement rule in SQL is to control the data location of certain TiKV nodes at the table or partition level. TiDB Lightning imports data in text files into the target TiDB cluster. If the data files is exported with the definition of placement rules, during the import process, TiDB Lightning must create the corresponding placement rule policy in the target cluster based on the definition. When the source cluster and the target cluster have different topology, this might cause problems.

Suppose the source cluster has the following topology:

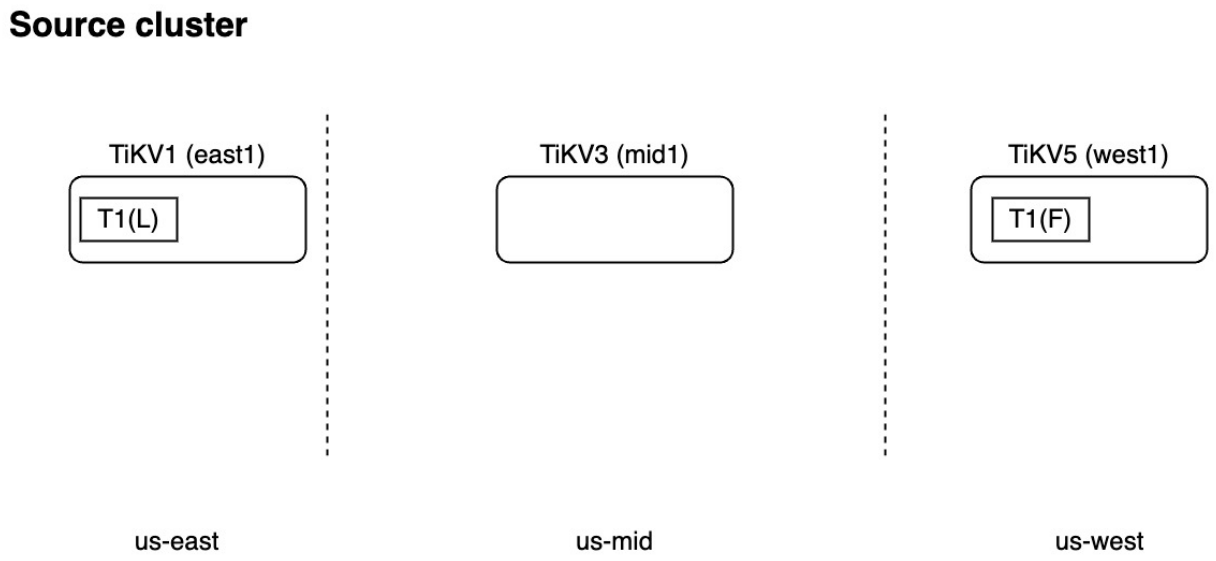

Figure 496: TiDB Lightning FAQ - source cluster topology

The source cluster has the following placement policy:

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east" REGIONS="us-east,us-
    ↪ west";
```

Situation 1: The target cluster has 3 replicas, and the topology is different from the source cluster. In such cases, when TiDB Lightning creates the placement policy in the target cluster, it will not report an error. However, the semantics in the target cluster is wrong.

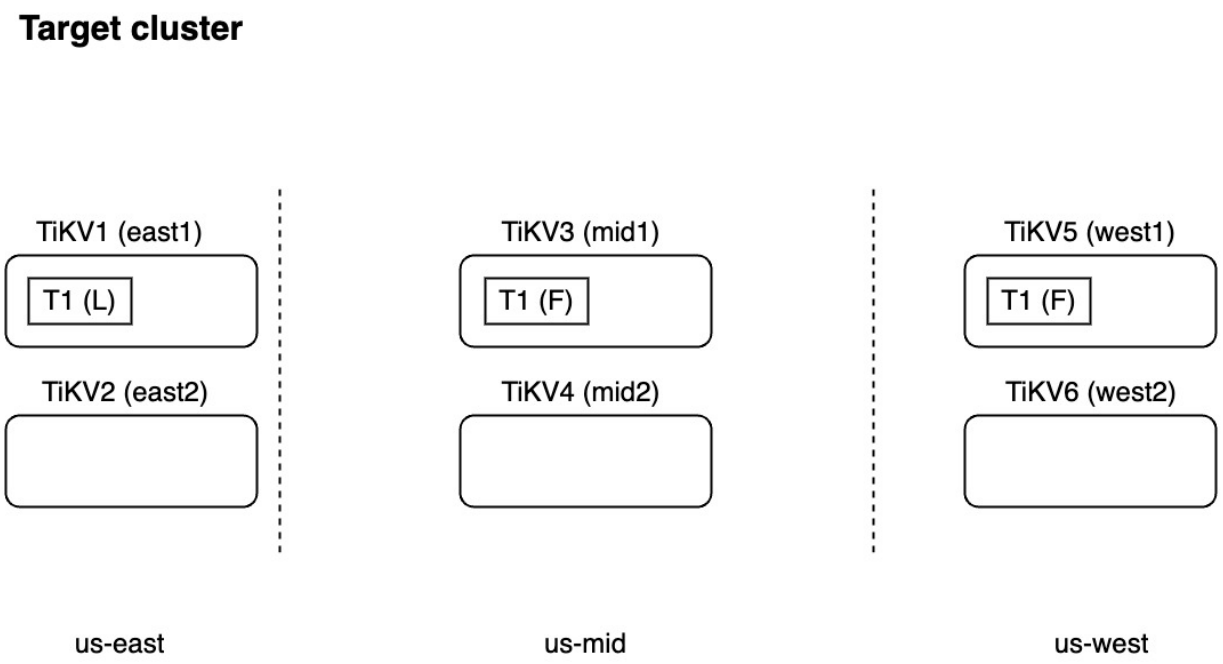

Figure 497: TiDB Lightning FAQ - situation 1

Situation 2: The target cluster locates the follower replica in another TiKV node in region "us-mid" and does not have the region "us-west" in the topology. In such cases, when creating the placement policy in the target cluster, TiDB Lightning will report an error.

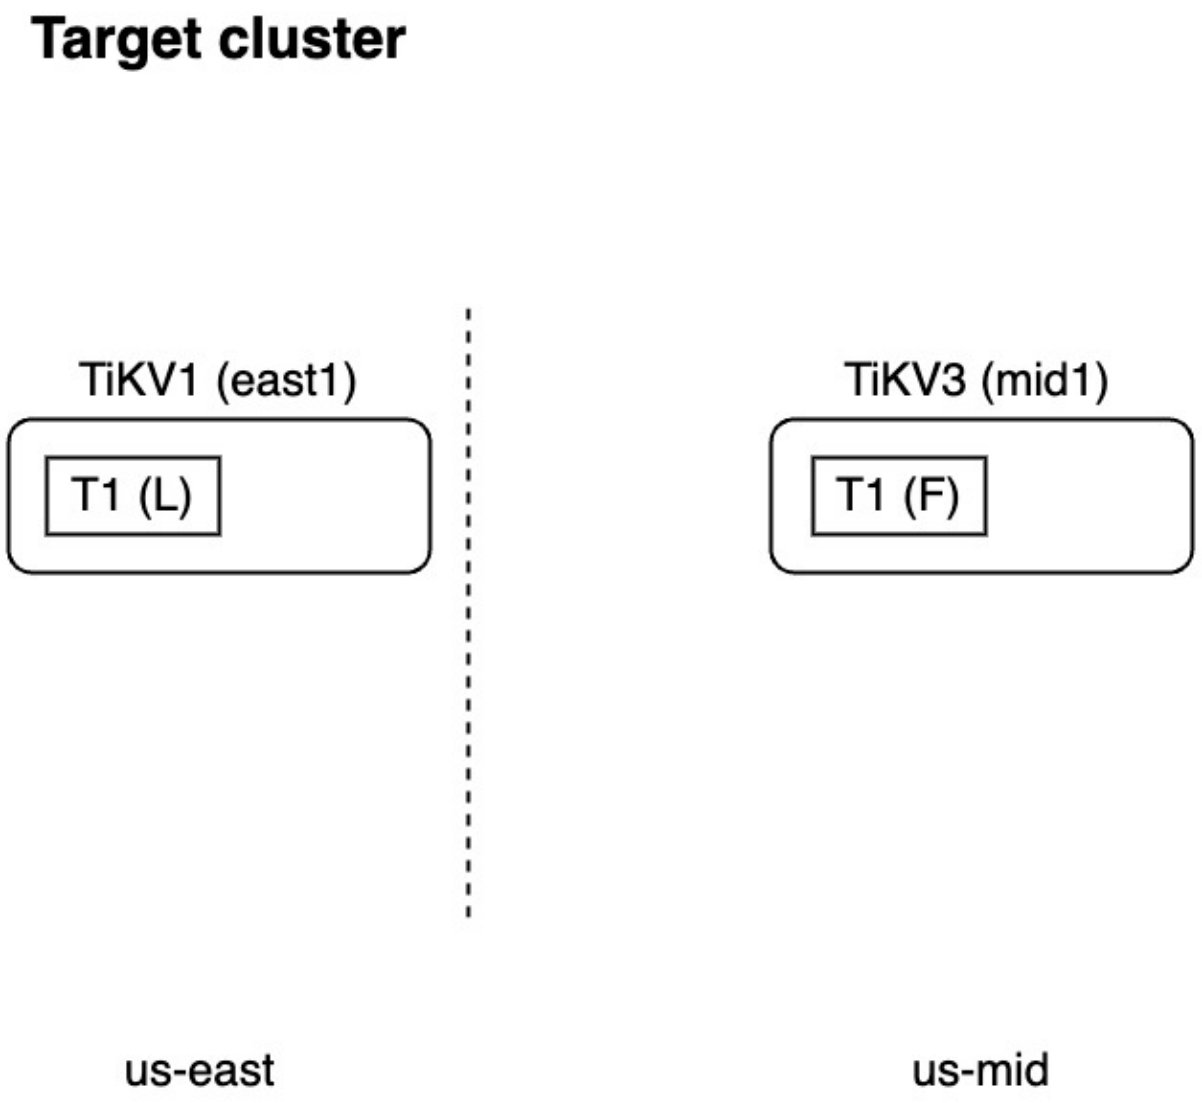

Figure 498: TiDB Lightning FAQ - situation 2

Workaround:

To use placement rules in SQL with TiDB Lightning, you need to make sure that the related labels and objects have been created in the target TiDB cluster **before** you import data into the target table. Because the placement rules in SQL acts at the PD and TiKV layer, TiDB Lightning can get the necessary information to find out which TiKV should be used to store the imported data. In this way, this placement rule in SQL is transparent to TiDB Lightning.

The steps are as follows:

1. Plan the data distribution topology.

2. Configure the required labels for TiKV and PD.
3. Create the placement rule policy and apply the created policy to the target table.
4. Use TiDB Lightning to import data into the target table.

13.7.15.9.16 How can I use TiDB Lightning and Dumpling to copy a schema?

If you want to copy both the schema definition and table data from one schema to a new schema, follow the steps in this section. In this example, you'll learn how to make a copy of the `test` schema into a new schema called `test2`.

1. Create a backup of the original schema with `-B test` to select only the schema that you need.

```
tiup dumpling -B test -o /tmp/bck1
```

2. Create a `/tmp/tidb-lightning.toml` file with the following content:

```
[tidb]
host = "127.0.0.1"
port = 4000
user = "root"

[tikv-importer]
backend = "tidb"

[mydumper]
data-source-dir = "/tmp/bck1"

[[mydumper.files]]
pattern = '^[a-z]*\.(.*)\.[0-9]*\.sql$'
schema = 'test2'
table = '$1'
type = 'sql'

[[mydumper.files]]
pattern = '^[a-z]*\.(.*)\-schema\.sql$'
schema = 'test2'
table = '$1'
type = 'table-schema'
```

   In this configuration file, set `schema = 'test2'` as you want to use a different schema name than the one used in the original dump. The filename is used to determine the name of the table.

3. Use this configuration file to run the import.

```
tiup tidb-lightning -config /tmp/tidb-lightning.toml
```

13.7.15.10 TiDB Lightning Glossary

This page explains the special terms used in TiDB Lightning's logs, monitoring, configurations, and documentation.

13.7.15.10.1 A

Analyze

An operation to rebuild the statistics information of a TiDB table, which is running the `ANALYZE TABLE` statement.

Because TiDB Lightning imports data without going through TiDB, the statistics information is not automatically updated. Therefore, TiDB Lightning explicitly analyzes every table after importing. This step can be omitted by setting the `post-restore.analyze` configuration to `false`.

`AUTO_INCREMENT_ID`

Every table has an associated `AUTO_INCREMENT_ID` counter to provide the default value of an auto-incrementing column. In TiDB, this counter is additionally used to assign row IDs.

Because TiDB Lightning imports data without going through TiDB, the `AUTO_INCREMENT_ID` counter is not automatically updated. Therefore, TiDB Lightning explicitly alters `AUTO_INCREMENT_ID` to a valid value. This step is always performed, even if the table has no `AUTO_INCREMENT` columns.

13.7.15.10.2 B

Back end

Back end is the destination where TiDB Lightning sends the parsed result. Also spelled as "backend".

See TiDB Lightning architecture for details.

13.7.15.10.3 C

Checkpoint

TiDB Lightning continuously saves its progress into a local file or a remote database while importing. This allows it to resume from an intermediate state should it crashes in the process. See the Checkpoints section for details.

Checksum

In TiDB Lightning, the checksum of a table is a set of 3 numbers calculated from the content of each KV pair in that table. These numbers are respectively:

- the number of KV pairs,
- total length of all KV pairs, and
- the bitwise-XOR of CRC-64-ECMA value each pair.

TiDB Lightning validates the imported data by comparing the local and remote checksums of every table. The program would stop if any pair does not match. You can skip this check by setting the `post-restore.checksum` configuration to `false`.

See also the FAQs for how to properly handle checksum mismatch.

Chunk

A continuous range of source data, normally equivalent to a single file in the data source.

When a file is too large, TiDB Lightning might split a file into multiple chunks.

Compaction

An operation that merges multiple small SST files into one large SST file, and cleans up the deleted entries. TiKV automatically compacts data in background while TiDB Lightning is importing.

> **Note:**
>
> For legacy reasons, you can still configure TiDB Lightning to explicitly trigger a compaction every time a table is imported. However, this is not recommended and the corresponding settings are disabled by default.

See RocksDB's wiki page on Compaction for its technical details.

13.7.15.10.4 D

Data engine

An engine for sorting actual row data.

When a table is very large, its data is placed into multiple data engines to improve task pipelining and save space of TiKV Importer. By default, a new data engine is opened for every 100 GB of SQL data, which can be configured through the `mydumper.batch-size` setting.

TiDB Lightning processes multiple data engines concurrently. This is controlled by the `lightning.table-concurrency` setting.

13.7.15.10.5 E

Engine

In TiKV Importer, an engine is a RocksDB instance for sorting KV pairs.

TiDB Lightning transfers data to TiKV Importer through engines. It first opens an engine, sends KV pairs to it (with no particular order), and finally closes the engine. The engine sorts the received KV pairs after it is closed. These closed engines can then be further uploaded to the TiKV stores for ingestion.

Engines use TiKV Importer's `import-dir` as temporary storage, which are sometimes referred to as "engine files".

See also data engine and index engine.

13.7.15.10.6 F

Filter

A configuration list that specifies which tables to be imported or excluded.

See Table Filter for details.

13.7.15.10.7 I

Import mode

A configuration that optimizes TiKV for writing at the cost of degraded read speed and space usage.

TiDB Lightning automatically switches to and off the import mode while running. However, if TiKV gets stuck in import mode, you can use `tidb-lightning-ctl` to force revert to normal mode.

Index engine

An engine for sorting indices.

Regardless of number of indices, every table is associated with exactly one index engine.

TiDB Lightning processes multiple index engines concurrently. This is controlled by the `lightning.index-concurrency` setting. Since every table has exactly one index engine, this also configures the maximum number of tables to process at the same time.

Ingest

An operation which inserts the entire content of an SST file into the RocksDB (TiKV) store.

Ingestion is a very fast operation compared with inserting KV pairs one by one. This operation is the determinant factor for the performance of TiDB Lightning.

See RocksDB's wiki page on Creating and Ingesting SST files for its technical details.

13.7.15.10.8 K

KV pair

Abbreviation of "key-value pair".

KV encoder

A routine which parses SQL or CSV rows to KV pairs. Multiple KV encoders run in parallel to speed up processing.

13.7.15.10.9 L

Local checksum

The checksum of a table calculated by TiDB Lightning itself before sending the KV pairs to TiKV Importer.

13.7.15.10.10 N

Normal mode

The mode where import mode is disabled.

13.7.15.10.11 P

Post-processing

The period of time after the entire data source is parsed and sent to TiKV Importer. TiDB Lightning is waiting for TiKV Importer to upload and ingest the SST files.

13.7.15.10.12 R

Remote checksum

The checksum of a table calculated by TiDB after it has been imported.

13.7.15.10.13 S

Scattering

An operation that randomly reassigns the leader and the peers of a Region. Scattering ensures that the imported data are distributed evenly among TiKV stores. This reduces stress on PD.

Splitting

An engine is typically very large (around 100 GB), which is not friendly to TiKV if treated as a single region. TiKV Importer splits an engine into multiple small SST files (configurable by TiKV Importer's `import.region-split-size` setting) before uploading.

SST file

SST is the abbreviation of "sorted string table". An SST file is RocksDB's (and thus TiKV's) native storage format of a collection of KV pairs.

TiKV Importer produces SST files from a closed engine. These SST files are uploaded and then ingested into TiKV stores.

13.8 Use Dumpling to Export Data

This document introduces the data export tool - Dumpling. Dumpling exports data stored in TiDB/MySQL as SQL or CSV data files and can be used to make a logical full backup or export. Dumpling also supports exporting data to Amazon S3.

You can get Dumpling using TiUP by running `tiup install dumpling`. Afterwards, you can use `tiup dumpling ...` to run Dumpling.

The Dumpling installation package is included in the TiDB Toolkit. To download the TiDB Toolkit, see Download TiDB Tools.

For detailed usage of Dumpling, use the `--help` option or refer to Option list of Dumpling.

When using Dumpling, you need to execute the export command on a running cluster.

TiDB also provides other tools that you can choose to use as needed.

- For backups of SST files (key-value pairs) or backups of incremental data that are not sensitive to latency, refer to BR.
- For real-time backups of incremental data, refer to TiCDC.
- All exported data can be imported back to TiDB using TiDB Lightning.

> **Note:**
>
> PingCAP previously maintained a fork of the mydumper project with enhancements specific to TiDB. Starting from v7.5.0, Mydumper is deprecated and most of its features have been replaced by Dumpling. It is strongly recommended that you use Dumpling instead of mydumper.

Dumpling has the following advantages:

- Support exporting data in multiple formats, including SQL and CSV.
- Support the table-filter feature, which makes it easier to filter data.
- Support exporting data to Amazon S3 cloud storage.
- More optimizations are made for TiDB:
    - Support configuring the memory limit of a single TiDB SQL statement.

- If Dumpling can access the PD address and the `INFORMATION_SCHEMA.CLUSTER_INFO` table of the TiDB cluster, Dumpling supports automatically adjusting the GC safe point time to block GC for TiDB v4.0.0 and later versions.
- Use TiDB's hidden column `_tidb_rowid` to optimize the performance of concurrent data export from a single table.
- For TiDB, you can set the value of `tidb_snapshot` to specify the time point of the data backup. This ensures the consistency of the backup, instead of using `FLUSH TABLES WITH READ LOCK` to ensure the consistency.

Note:

Dumpling cannot connect to PD in the following scenarios:

- The TiDB cluster is running on Kubernetes (unless Dumpling itself is run inside the Kubernetes environment).
- The TiDB cluster is running on TiDB Cloud.

In such cases, you need to manually adjust the TiDB GC time to avoid export failure.

13.8.1 Export data from TiDB or MySQL

13.8.1.1 Required privileges

- PROCESS: Required to query the cluster information to obtain the PD address and then control GC via the PD.
- SELECT: Required when exporting tables.
- RELOAD: Required when using `consistency flush`. Note that only TiDB supports this privilege. When the upstream is an RDS database or a managed service, you can ignore this privilege.
- LOCK TABLES: Required when using `consistency lock`. This privilege must be granted for all the databases and tables to be exported.
- REPLICATION CLIENT: Required when exporting metadata to record data snapshot. This privilege is optional and you can ignore it if you do not need to export metadata.

13.8.1.2 Export to SQL files

This document assumes that there is a TiDB instance on the 127.0.0.1:4000 host and that this TiDB instance has a root user without a password.

Dumpling exports data to SQL files by default. You can also export data to SQL files by adding the `--filetype sql` flag:

```
tiup dumpling -u root -P 4000 -h 127.0.0.1 --filetype sql -t 8 -o /tmp/test
    ↪ -r 200000 -F 256MiB
```

In the command above:

- The `-h`, `-P`, and `-u` option respectively mean the address, the port, and the user. If a password is required for authentication, you can use `-p $YOUR_SECRET_PASSWORD` to pass the password to Dumpling.
- The `-o` (or `--output`) option specifies the export directory of the storage, which supports an absolute local file path or an external storage URI.
- The `-t` option specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and also increases the database's memory consumption. Therefore, it is not recommended to set the number too large. Usually, it's less than 64.
- The `-r` option enables the in-table concurrency to speed up the export. The default value is `0`, which means disabled. A value greater than 0 means it is enabled, and the value is of `INT` type. When the source database is TiDB, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting, and reduces the memory usage. The specific `-r` value does not affect the split algorithm. When the source database is MySQL and the primary key or the first column of the composite primary key is of the `INT` type, specifying `-r` can also enable the in-table concurrency.
- The `-F` option is used to specify the maximum size of a single file (the unit here is `MiB`; inputs like `5GiB` or `8KB` are also acceptable). It is recommended to keep its value to 256 MiB or less if you plan to use TiDB Lightning to load this file into a TiDB instance.

> **Note:**
>
> If the size of a single exported table exceeds 10 GB, it is **strongly recommended to use** the `-r` and `-F` options.

13.8.1.2.1 URI formats of the storage services

This section describes the URI formats of the storage services, including Amazon S3, GCS, and Azure Blob Storage. The URI format is as follows:

```
[scheme]://[host]/[path]?[parameters]
```

For more information, see URI Formats of External Storage Services.

13.8.1.3 Export to CSV files

You can export data to CSV files by adding the `--filetype csv` argument.

When you export data to CSV files, you can use `--sql <SQL>` to filter the records with the SQL statements. For example, you can export all records that match `id < 100` in `test.sbtest1` using the following command:

```
tiup dumpling -u root -P 4000 -h 127.0.0.1 -o /tmp/test --filetype csv --sql
    ↪  'select * from `test`.`sbtest1` where id < 100' -F 100MiB --output-
    ↪ filename-template 'test.sbtest1.{{.Index}}'
```

In the command above:

- The `--sql` option can be used only for exporting to CSV files. The command above executes the `SELECT * FROM <table-name> WHERE id <100` statement on all tables to be exported. If a table does not have the specified field, the export fails.

- When you use the `--sql` option, Dumpling cannot obtain the exported table and schema information. You can specify the file name format of the CSV files using the `--output-filename-template` option, which facilitates the subsequent use of TiDB Lightning to import the data file. For example, `--output-filename-template='
  ↪ test.sbtest1.{{.Index}}'` specifies that the exported CSV files are named as `test.sbtest1.000000000` or `test.sbtest1.000000001`.

- You can use options like `--csv-separator` and `--csv-delimiter` to configure the CSV file format. For details, refer to the Dumpling option list.

> **Note:**
>
> *Strings* and *keywords* are not distinguished by Dumpling. If the imported data is the Boolean type, the value of `true` is converted to `1` and the value of `false` is converted to `0`.

13.8.1.4 Compress the exported data files

You can use the `--compress <format>` option to compress the CSV and SQL data and table structure files exported by Dumpling. This parameter supports the following compression algorithms: `gzip`, `snappy`, and `zstd`. The compression is disabled by default.

- This option only compresses individual data and table structure files. It cannot compress the entire folder and generate a single compressed package.
- This option can save disk space, but it also slows down the export speed and increases CPU consumption. Use this option with caution in scenarios where the export speed is critical.

- For TiDB Lightning v6.5.0 and later versions, you can use compressed files exported by Dumpling as the data source without additional configuration.

> **Note:**
>
> The Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.

13.8.1.5 Format of exported files

- `metadata`: The start time of the exported files and the position of the master binary log.

```
cat metadata
```

```
Started dump at: 2020-11-10 10:40:19
SHOW MASTER STATUS:
       Log: tidb-binlog
       Pos: 420747102018863124
Finished dump at: 2020-11-10 10:40:20
```

- `{schema}-schema-create.sql`: The SQL file used to create the schema

```
cat test-schema-create.sql
```

```
CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 */;
```

- `{schema}.{table}-schema.sql`: The SQL file used to create the table

```
cat test.t1-schema.sql
```

```
CREATE TABLE `t1` (
  `id` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

- `{schema}.{table}.{0001}.{sql|csv}`: The date source file

```
cat test.t1.0.sql
```

```
/*!40101 SET NAMES binary*/;
INSERT INTO `t1` VALUES
(1);
```

- `*-schema-view.sql`, `*-schema-trigger.sql`, `*-schema-post.sql`: Other exported files

13.8.1.6 Export data to Amazon S3 cloud storage

Starting from v4.0.8, Dumpling supports exporting data to cloud storages. If you need to back up data to Amazon S3, you need to specify the Amazon S3 storage path in the `-o` parameter.

You need to create an Amazon S3 bucket in the specified region (see the Amazon documentation - How do I create an S3 Bucket). If you also need to create a folder in the bucket, see the Amazon documentation - Creating a folder.

Pass `SecretKey` and `AccessKey` of the account with the permission to access the Amazon S3 backend storage to the Dumpling node as environment variables.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

Dumpling also supports reading credential files from `~/.aws/credentials`. For more information about URI parameter descriptions, see URI Formats of External Storage Services.

```
tiup dumpling -u root -P 4000 -h 127.0.0.1 -r 200000 -o "s3://${Bucket}/${
    ↪ Folder}"
```

13.8.1.7 Filter the exported data

13.8.1.7.1 Use the `--where` option to filter data

By default, Dumpling exports all databases except system databases (including `mysql` ↪ , `sys`, `INFORMATION_SCHEMA`, `PERFORMANCE_SCHEMA`, `METRICS_SCHEMA`, and `INSPECTION` ↪ `_SCHEMA`). You can use `--where <SQL where expression>` to select the records to be exported.

```
tiup dumpling -u root -P 4000 -h 127.0.0.1 -o /tmp/test --where "id < 100"
```

The above command exports the data that matches `id < 100` from each table. Note that you cannot use the `--where` parameter together with `--sql`.

13.8.1.7.2 Use the `--filter` option to filter data

Dumpling can filter specific databases or tables by specifying the table filter with the `--filter` option. The syntax of table filters is similar to that of `.gitignore`. For details, see Table Filter.

```
tiup dumpling -u root -P 4000 -h 127.0.0.1 -o /tmp/test -r 200000 --filter "
    ↪ employees.*" --filter "*.WorkOrder"
```

The above command exports all the tables in the `employees` database and the `WorkOrder` tables in all databases.

13.8.1.7.3 Use the `-B` or `-T` option to filter data

Dumpling can also export specific databases with the `-B` option or specific tables with the `-T` option.

> **Note:**
>
> - The `--filter` option and the `-T` option cannot be used at the same time.
> - The `-T` option can only accept a complete form of inputs like `database -name.table-name`, and inputs with only the table name are not accepted. Example: Dumpling cannot recognize `-T WorkOrder`.

Examples:

- `-B employees` exports the `employees` database.
- `-T employees.WorkOrder` exports the `employees.WorkOrder` table.

13.8.1.8 Improve export efficiency through concurrency

The exported file is stored in the `./export-<current local time>` directory by default. Commonly used options are as follows:

- The `-t` option specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and also increases the database's memory consumption. Therefore, it is not recommended to set the number too large.
- The `-r` option enables the in-table concurrency to speed up the export. The default value is `0`, which means disabled. A value greater than 0 means it is enabled, and the value is of `INT` type. When the source database is TiDB, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting, and reduces the memory usage. The specific `-r` value does not affect the split algorithm. When the source database is MySQL and the primary key or the first column of the composite primary key is of the `INT` type, specifying `-r` can also enable the in-table concurrency.
- The `--compress <format>` option specifies the compression format of the dump. It supports the following compression algorithms: `gzip`, `snappy`, and `zstd`. This option can speed up dumping of data if storage is the bottleneck or if storage capacity is a concern. The drawback is an increase in CPU usage. Each file is compressed individually.

With the above options specified, Dumpling can have a quicker speed of data export.

13.8.1.9 Adjust Dumpling's data consistency options

> **Note:**
>
> The default value is `auto` for the data consistency option. In most scenarios, you do not need to adjust the default data consistency options of Dumpling.

Dumpling uses the `--consistency <consistency level>` option to control the way in which data is exported for "consistency assurance". When using snapshot for consistency, you can use the `--snapshot` option to specify the timestamp to be backed up. You can also use the following levels of consistency:

- `flush`: Use `FLUSH TABLES WITH READ LOCK` to temporarily interrupt the DML and DDL operations of the replica database, to ensure the global consistency of the backup connection, and to record the binlog position (POS) information. The lock is released after all backup connections start transactions. It is recommended to perform full backups during off-peak hours or on the MySQL replica database.
- `snapshot`: Get a consistent snapshot of the specified timestamp and export it.
- `lock`: Add read locks on all tables to be exported.
- `none`: No guarantee for consistency.
- `auto`: Use `flush` for MySQL and `snapshot` for TiDB.

After everything is done, you can see the exported file in `/tmp/test`:

```
ls -lh /tmp/test | awk '{print $5 "\t" $9}'
```

```
140B metadata
66B  test-schema-create.sql
300B test.sbtest1-schema.sql
190K test.sbtest1.0.sql
300B test.sbtest2-schema.sql
190K test.sbtest2.0.sql
300B test.sbtest3-schema.sql
190K test.sbtest3.0.sql
```

13.8.1.10 Export historical data snapshots of TiDB

Dumpling can export the data of a certain tidb_snapshot with the `--snapshot` option specified.

The `--snapshot` option can be set to a TSO (the `Position` field output by the `SHOW MASTER STATUS` command) or a valid time of the `datetime` data type (in the form of `YYYY-MM-DD hh:mm:ss`), for example:

```
tiup dumpling --snapshot 417773951312461825
tiup dumpling --snapshot "2020-07-02 17:12:45"
```

The TiDB historical data snapshots when the TSO is `417773951312461825` and the time is `2020-07-02 17:12:45` are exported.

13.8.1.11 Control the memory usage of exporting large tables

When Dumpling is exporting a large single table from TiDB, Out of Memory (OOM) might occur because the exported data size is too large, which causes connection abort and export failure. You can use the following parameters to reduce the memory usage of TiDB:

- Setting `-r` to split the data to be exported into chunks. This reduces the memory overhead of TiDB's data scan and enables concurrent table data dump to improve export efficiency. When the upstream database is TiDB v3.0 or later versions, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting and the specific `-r` value does not affect the split algorithm.
- Reduce the value of `--tidb-mem-quota-query` to `8589934592` (8 GB) or lower. `--tidb-mem-quota-query` controls the memory usage of a single query statement in TiDB.
- Adjust the `--params "tidb_distsql_scan_concurrency=5"` parameter. `tidb_distsql_scan_concurrency` is a session variable which controls the concurrency of the scan operations in TiDB.

13.8.1.12 Manually set the TiDB GC time

When exporting data from TiDB (less than 1 TB), if the TiDB version is v4.0.0 or later and Dumpling can access the PD address and the `INFORMATION_SCHEMA.CLUSTER_INFO` table of the TiDB cluster, Dumpling automatically adjusts the GC safe point to block GC without affecting the original cluster.

However, in either of the following scenarios, Dumpling cannot automatically adjust the GC time:

- The data size is very large (more than 1 TB).
- Dumpling cannot connect directly to PD, for example, if the TiDB cluster is on TiDB Cloud or on Kubernetes that is separated from Dumpling.

In such scenarios, you must manually extend the GC time in advance to avoid export failure due to GC during the export process.

To manually adjust the GC time, use the following SQL statement:

```
SET GLOBAL tidb_gc_life_time = '720h';
```

After Dumpling exits, regardless of whether the export is successful or not, you must set the GC time back to its original value (the default value is `10m`).

```
SET GLOBAL tidb_gc_life_time = '10m';
```

13.8.2 Option list of Dumpling

Options	Usage	Default value
`-V` or `--version`	Output the Dumpling version and exit directly	
`-B` or `--database`	Export specified databases	
`-T` or `--tables-list`	Export specified tables	

Options	Usage	Default value
`-f` or `--` `filter`	Export tables that match the filter pattern. For the filter syntax, see table-filter.	`[\*.\*,!/^(mysql|sys|INFORMATION_SCHEMA|PERFORMANCE_SCHEMA|METRICS_SCHEMA|INSPECTION_SCHEMA)$/.\*]` (export all databases or tables excluding system schemas)
`--` `case-sensitive`	whether table-filter is case-sensitive	false (case-insensitive)
`-h` or `--` `host`	The IP address of the connected database host	“127.0.0.1”

Options	Usage	Default value
`-t` or `--threads`	The number of concurrent backup threads	4
`-r` or `--rows`	Enable the in-table concurrency to speed up the export. The default value is `0`, which means disabled. A value greater than 0 means it is enabled, and the value is of `INT` type. When the source database is TiDB, a `-r` value greater than 0 indicates that the TiDB region information is used for splitting, and reduces the memory usage. The specific `-r` value does not affect the split algorithm. When the source database is MySQL and the primary key or the first column of the composite primary key is of the `INT` type, specifying `-r` can also enable the in-table concurrency.	
`-L` or `--logfile`	Log output address. If it is empty, the log will be output to the console	“”
`--loglevel`	Log level {debug,info,warn,error,dpanic,panic,fatal}	“info”
`--logfmt`	Log output format {text,json}	“text”
`-d` or `--no-data`	Do not export data (suitable for scenarios where only the schema is exported)	
`--no-header`	Export CSV files of the tables without generating header	
`-W` or `--no-views`	Do not export the views	true
`-m` or `--no-schemas`	Do not export the schema with only the data exported	

Options	Usage	Default value
`-s` or `--statement-size`	Control the size of the `INSERT` statements; the unit is bytes	
`-F` or `--filesize`	The file size of the divided tables. The unit must be specified such as `128B`, `64KiB`, `32MiB`, and `1.5GiB`.	
`--filetype`	Exported file type (csv/sql)	"sql"
`-o` or `--output`	Specify the absolute local file path or external storage URI for exporting the data.	"./export-${time}"
`-S` or `--sql`	Export data according to the specified SQL statement. This command does not support concurrent export.	
`--consistency`	flush: use FTWRL before the dump snapshot: dump the TiDB data at a specific snapshot of a TSO lock: execute `lock tables read` on all tables to be dumped none: dump without adding locks, which cannot guarantee consistency auto: use –consistency flush for MySQL; use –consistency snapshot for TiDB	"auto"
`--snapshot`	Snapshot TSO; valid only when `consistency=snapshot`	
`--where`	Specify the scope of the table backup through the `where` condition	
`-p` or `--password`	The password of the connected database host	
`-P` or `--port`	The port of the connected database host	4000
`-u` or `--user`	The username of the connected database host	"root"

Options	Usage	Default value
`--dump-empty-database`	Export the `CREATE DATABASE` statements of the empty databases	true
`--ca`	The address of the certificate authority file for TLS connection	
`--cert`	The address of the client certificate file for TLS connection	
`--key`	The address of the client private key file for TLS connection	
`--csv-delimiter`	Delimiter of character type variables in CSV files	'"'
`--csv-separator`	Separator of each value in CSV files. It is not recommended to use the default ','. It is recommended to use '|+|' or other uncommon character combinations	','
`--csv-null-value`	Representation of null values in CSV files	"\N"
`--csv-line-terminator`	The terminator at the end of a line for CSV files. When exporting data to a CSV file, you can specify the desired terminator with this option. This option supports "\r\n" and "\n". The default value is "\r\n", which is consistent with the earlier versions. Because quotes in bash have different escaping rules, if you want to specify LF (linefeed) as a terminator, you can use a syntax similar to `--csv-line-terminator $'\n'`.	"\r\n"

Options	Usage	Default value
`--csv`	Indicates that the source data can be exported to a CSV file in a specific required format for the database. The option value can be `""`, `"snowflake"`, `"redshift"`, or `"bigquery"`. The default value is `""`, which means to encode and export the source data according to UTF-8. If you set the option to `"snowflake"` or `"redshift"`, the binary data type in the source data will be converted to hexadecimal, but the `0x` prefix will be removed. For example, `0x61` will be represented as `61`. If you set the option to `"bigquery"`, the binary data type will be encoded using base64. In some cases, the binary strings might contain garbled characters.	`""`
`--escape-backslash`	Use backslash (\) to escape special characters in the export file	true
`--output-filename-template`	The filename templates represented in the format of golang template Support the `{{.DB}}`, `{{.Table}}`, and `{{.Index}}` arguments The three arguments represent the database name, table name, and chunk ID of the data file	`{{.DB}}.{{.Table}}.{{.Index}}`
`--status-addr`	Dumpling's service address, including the address for Prometheus to pull metrics and pprof debugging	":8281"
`--tidb-mem-quota-query`	The memory limit of exporting SQL statements by a single line of Dumpling command, and the unit is byte. For v4.0.10 or later versions, if you do not set this parameter, TiDB uses the value of the `mem-quota-query` configuration item as the memory limit value by default. For versions earlier than v4.0.10, the parameter value defaults to 32 GB.	34359738368
`--params`	Specifies the session variable for the connection of the database to be exported. The required format is `"character_set_client=latin1,character_set_connection=latin1"`	

Options	Usage	Default value
`-c` or `--compress`	Compresses the CSV and SQL data and table structure files exported by Dumpling. It supports the following compression algorithms: `gzip`, `snappy`, and `zstd`.	""

13.9 TiCDC

13.9.1 TiCDC Overview

TiCDC is a tool used to replicate incremental data from TiDB. Specifically, TiCDC pulls TiKV change logs, sorts captured data, and exports row-based incremental data to downstream databases.

13.9.1.1 Usage scenarios

TiCDC has multiple usage scenarios, including:

- Providing high availability and disaster recovery solutions for multiple TiDB clusters. TiCDC ensures eventual data consistency between primary and secondary clusters in case of a disaster.
- Replicating real-time data changes to homogeneous systems. This provides data sources for various scenarios, such as monitoring, caching, global indexing, data analysis, and primary-secondary replication between heterogeneous databases.

13.9.1.2 Major features

13.9.1.2.1 Key capabilities

TiCDC has the following key capabilities:

- Replicating incremental data between TiDB clusters with second-level RPO and minute-level RTO.
- Bidirectional replication between TiDB clusters, allowing the creation of a multi-active TiDB solution using TiCDC.
- Replicating incremental data from a TiDB cluster to a MySQL database or other MySQL-compatible databases with low latency.
- Replicating incremental data from a TiDB cluster to a Kafka cluster. The recommended data format includes Canal-JSON, Avro, and Debezium.
- Replicating incremental data from a TiDB cluster to storage services, such as Amazon S3, GCS, Azure Blob Storage, and NFS.
- Replicating tables with the ability to filter databases, tables, DMLs, and DDLs.

- High availability with no single point of failure, supporting dynamically adding and deleting TiCDC nodes.
- Cluster management through Open API, including querying task status, dynamically modifying task configuration, and creating or deleting tasks.

13.9.1.2.2 Replication order

- For all DDL or DML statements, TiCDC outputs them **at least once**.
- When the TiKV or TiCDC cluster encounters a failure, TiCDC might send the same DDL/DML statement repeatedly. For duplicated DDL/DML statements:
    - The MySQL sink can execute DDL statements repeatedly. For DDL statements that can be executed repeatedly in the downstream, such as `TRUNCATE TABLE` ↪ , the statement is executed successfully. For those that cannot be executed repeatedly, such as `CREATE TABLE`, the execution fails, and TiCDC ignores the error and continues with the replication process.
    - The Kafka sink provides different strategies for data distribution.
        - You can distribute data to different Kafka partitions based on the table, primary key, or timestamp. This ensures that the updated data of a row is sent to the same partition in order.
        - All these distribution strategies send `Resolved TS` messages to all topics and partitions periodically. This indicates that all messages earlier than the `Resolved TS` have already been sent to the topics and partitions. The Kafka consumer can use the `Resolved TS` to sort the messages received.
        - The Kafka sink sometimes sends duplicated messages, but these duplicated messages do not affect the constraints of `Resolved Ts`. For example, if a changefeed is paused and then resumed, the Kafka sink might send `msg1` ↪ , `msg2`, `msg3`, `msg2`, and `msg3` in order. You can filter out the duplicated messages from Kafka consumers.

13.9.1.2.3 Replication consistency

- MySQL sink
    - TiCDC enables the redo log to ensure eventual consistency of data replication.
    - TiCDC ensures that the order of single-row updates is consistent with the upstream.
    - TiCDC does not ensure that the downstream transactions are executed in the same order as the upstream transactions.

> **Note:**
> Since v6.2, you can use the sink URI parameter `transaction-atomicity` to control whether to split single-table transactions. Splitting single-table transactions can greatly reduce the latency and memory consumption of replicating large transactions.

13.9.1.3 TiCDC architecture

TiCDC is an incremental data replication tool for TiDB, which is highly available through PD's etcd. The replication process consists of the following steps:

1. Multiple TiCDC processes pull data changes from TiKV nodes.
2. TiCDC sorts and merges the data changes.
3. TiCDC replicates the data changes to multiple downstream systems through multiple replication tasks (changefeeds).

The architecture of TiCDC is illustrated in the following figure:

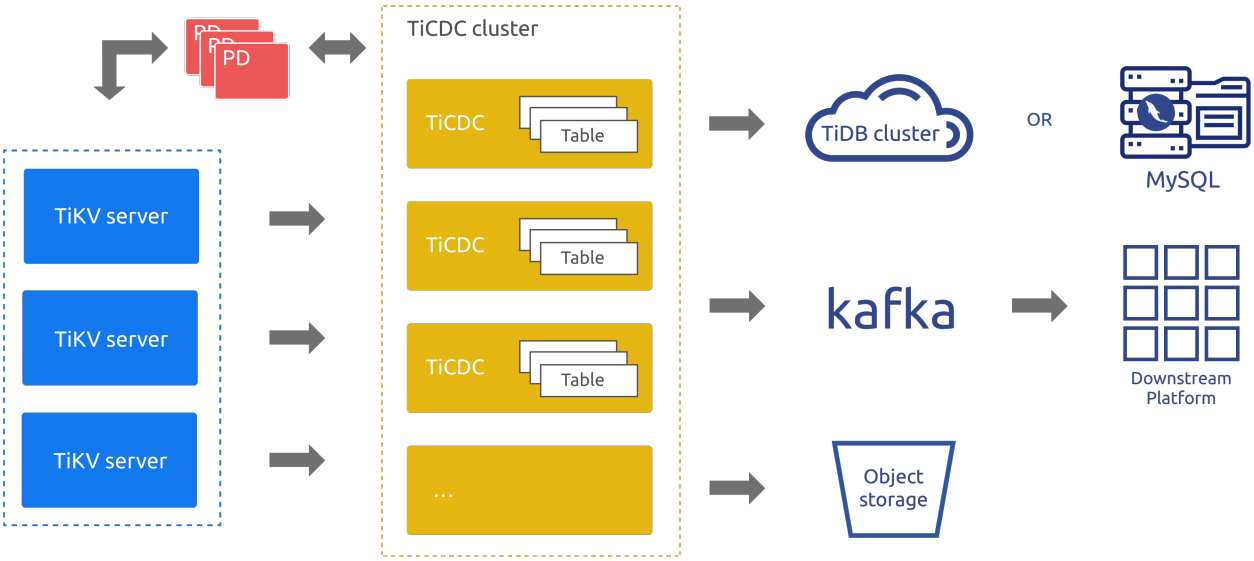

Figure 499: TiCDC architecture

The components in the architecture diagram are described as follows:

- TiKV Server: TiKV nodes in a TiDB cluster. When data changes occur, TiKV nodes send the changes as change logs (KV change logs) to TiCDC nodes. If TiCDC nodes detect that the change logs are not continuous, they will actively request the TiKV nodes to provide change logs.

- TiCDC: TiCDC nodes where TiCDC processes run. Each node runs a TiCDC process. Each process pulls data changes from one or more tables in TiKV nodes and replicates the changes to the downstream system through the sink component.
- PD: The scheduling module in a TiDB cluster. This module is responsible for scheduling cluster data and usually consists of three PD nodes. PD provides high availability through the etcd cluster. In the etcd cluster, TiCDC stores its metadata, such as node status information and changefeed configurations.

As shown in the architecture diagram, TiCDC supports replicating data to TiDB, MySQL, Kafka, and storage services.

13.9.1.4 Best practices

- When you use TiCDC to replicate data between two TiDB clusters, if the network latency between the two clusters is higher than 100 ms:
    - For TiCDC versions earlier than v6.5.2, it is recommended to deploy TiCDC in the region (IDC) where the downstream TiDB cluster is located.
    - With a series of improvements introduced starting from TiCDC v6.5.2, it is recommended to deploy TiCDC in the region (IDC) where the upstream TiDB cluster is located.
- TiCDC only replicates tables that have at least one valid index. A valid index is defined as follows:
    - A primary key (`PRIMARY KEY`) is a valid index.
    - A unique index (`UNIQUE INDEX`) is valid if every column of the index is explicitly defined as non-nullable (`NOT NULL`) and the index does not have a virtual generated column (`VIRTUAL GENERATED COLUMNS`).
- To ensure eventual consistency when using TiCDC for disaster recovery, you need to configure redo log and ensure that the storage system where the redo log is written can be read normally when a disaster occurs in the upstream.

13.9.1.5 Implementation of processing data changes

This section mainly describes how TiCDC processes data changes generated by upstream DML operations.

For data changes generated by upstream DDL operations, TiCDC obtains the complete DDL SQL statement, converts it into the corresponding format based on the sink type of the downstream, and sends it to the downstream. This section does not elaborate on this.

Note:

The logic of how TiCDC processes data changes might be adjusted in subsequent versions.

MySQL binlog directly records all DML SQL statements executed in the upstream. Unlike MySQL, TiCDC listens to the real-time information of each Region Raft Log in the upstream TiKV, and generates data change information based on the difference between the data before and after each transaction, which corresponds to multiple SQL statements. TiCDC only guarantees that the output change events are equivalent to the changes in the upstream TiDB, and does not guarantee that it can accurately restore the SQL statements that caused the data changes in the upstream TiDB.

Data change information includes the data change types and the data values before and after the change. The difference between the data before and after the transaction can result in three types of events:

1. The `DELETE` event: corresponds to a `DELETE` type data change message, which contains the data before the change.
2. The `INSERT` event: corresponds to a `PUT` type data change message, which contains the data after the change.
3. The `UPDATE` event: corresponds to a `PUT` type data change message, which contains the data both before and after the change.

Based on the data change information, TiCDC generates data in the appropriate formats for different downstream types, and sends the data to the downstream. For example, it generates data in formats such as Canal-JSON and Avro, and writes the data to Kafka, or converts the data back into SQL statements and sends them to the downstream MySQL or TiDB.

Currently, when TiCDC adapts data change information for the corresponding protocol, for specific `UPDATE` events, it might split them into one `DELETE` event and one `INSERT` event. For more information, see Split `UPDATE` events for MySQL sinks and Split primary or unique key `UPDATE` events for non-MySQL sinks.

When the downstream is MySQL or TiDB, TiCDC cannot guarantee that the SQL statements written to the downstream are exactly the same as the SQL statements executed in the upstream. This is because TiCDC does not directly obtain the original DML statements executed in the upstream, but generates SQL statements based on the data change information. However, TiCDC ensures the consistency of the final results.

For example, the following SQL statement is executed in the upstream:

```
Create Table t1 (A int Primary Key, B int);

BEGIN;
Insert Into t1 values(1,2);
Insert Into t1 values(2,2);
Insert Into t1 values(3,3);
Commit;

Update t1 set b = 4 where b = 2;
```

TiCDC generates the following two SQL statements based on the data change information, and writes them to the downstream:

```
INSERT INTO `test.t1` (`A`,`B`) VALUES (1,2),(2,2),(3,3);
UPDATE `test`.`t1`
SET `A` = CASE
       WHEN `A` = 1 THEN 1
       WHEN `A` = 2 THEN 2
END, `B` = CASE
       WHEN `A` = 1 THEN 4
       WHEN `A` = 2 THEN 4
END
WHERE `A` = 1 OR `A` = 2;
```

13.9.1.6 Unsupported scenarios

Currently, the following scenarios are not supported:

- A TiKV cluster that uses RawKV alone.
- The `CREATE SEQUENCE` DDL operation and the `SEQUENCE` function in TiDB. When the upstream TiDB uses `SEQUENCE`, TiCDC ignores `SEQUENCE` DDL operations/functions performed upstream. However, DML operations using `SEQUENCE` functions can be correctly replicated.
- Currently, performing TiDB Lightning physical import on tables and databases that are being replicated by TiCDC is not supported. For more information, see Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning and BR from upstream.
- Before v8.2.0, BR does not support restoring data for a cluster with TiCDC replication tasks. For more information, see Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning and BR from upstream.
- Starting from v8.2.0, BR relaxes the restrictions on data restoration for TiCDC: if the `BackupTS` (the backup time) of the data to be restored is earlier than the changefeed `CheckpointTS` (the timestamp that indicates the current replication progress), BR can proceed with the data restoration normally. Considering that the `BackupTS` is usually

much earlier, it can be assumed that in most scenarios, BR supports restoring data for a cluster with TiCDC replication tasks.

TiCDC only partially supports scenarios involving large transactions in the upstream. For details, refer to the TiCDC FAQ, where you can find details on whether TiCDC supports replicating large transactions and any associated risks.

13.9.2 Deploy and Maintain TiCDC

This document describes how to deploy and maintain a TiCDC cluster, including the hardware and software recommendations. You can either deploy TiCDC along with a new TiDB cluster or add the TiCDC component to an existing TiDB cluster.

13.9.2.1 Software and hardware recommendations

In production environments, the recommendations of hardware for TiCDC are as follows:

CPU	Memory	Disk	Network	Number of TiCDC cluster instances (minimum requirements for production environment)
16 core+	64 GB+	500 GB+ SSD	10 Gigabit network card (2 preferred)	2

For more information, see Software and Hardware Recommendations.

13.9.2.2 Deploy a new TiDB cluster that includes TiCDC using TiUP

When you deploy a new TiDB cluster using TiUP, you can also deploy TiCDC at the same time. You only need to add the `cdc_servers` section in the configuration file that TiUP uses to start the TiDB cluster. The following is an example:

```
cdc_servers:
  - host: 10.0.1.20
    gc-ttl: 86400
    data_dir: "/cdc-data"
  - host: 10.0.1.21
```

```
gc-ttl: 86400
data_dir: "/cdc-data"
```

More references:

- For detailed operations, see Edit the initialization configuration file.
- For detailed configurable fields, see Configure `cdc_servers` using TiUP.
- For detailed steps to deploy a TiDB cluster, see Deploy a TiDB Cluster Using TiUP.

> **Note:**
>
> Before installing TiCDC, ensure that you have manually configured the SSH mutual trust and sudo without password between the TiUP control machine and the TiCDC host.

13.9.2.3 Add or scale out TiCDC to an existing TiDB cluster using TiUP

The method of scaling out a TiCDC cluster is similar to that of deploying one. It is recommended to use TiUP to perform the scale-out.

1. Create a `scale-out.yml` file to add the TiCDC node information. The following is an example:

```
cdc_servers:
  - host: 10.1.1.1
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
  - host: 10.1.1.2
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
  - host: 10.0.1.4
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
```

2. Run the scale-out command on the TiUP control machine:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

For more use cases, see Scale out a TiCDC cluster.

13.9.2.4 Delete or scale in TiCDC from an existing TiDB cluster using TiUP

It is recommended that you use TiUP to scale in TiCDC nodes. The following is the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

For more use cases, see Scale in a TiCDC cluster.

13.9.2.5 Upgrade TiCDC using TiUP

You can upgrade TiDB clusters using TiUP, during which TiCDC is upgraded as well. After you execute the upgrade command, TiUP automatically upgrades the TiCDC component. The following is an example:

```
tiup update --self && \
tiup update --all && \
tiup cluster upgrade <cluster-name> <version> --transfer-timeout 600
```

> **Note:**
>
> In the preceding command, you need to replace `<cluster-name>` and `<version>` with the actual cluster name and cluster version. For example, the version can be v8.4.0.

13.9.2.5.1 Upgrade cautions

When you upgrade a TiCDC cluster, you need to pay attention to the following:

- TiCDC v4.0.2 reconfigured `changefeed`. For details, see Configuration file compatibility notes.
- If you encounter any problem during the upgrade, you can refer to upgrade FAQs for solutions.
- Since v6.3.0, TiCDC supports rolling upgrade. During the upgrade, the replication latency is stable and does not fluctuate significantly. Rolling upgrade takes effect automatically if the following conditions are met:
- TiCDC is v6.3.0 or later.
    - TiUP is v1.11.3 or later.
    - At least two TiCDC instances are running in the cluster.

13.9.2.6 Modify TiCDC cluster configurations using TiUP

This section describes how to use the `tiup cluster edit-config` command to modify the configurations of TiCDC. In the following example, it is assumed that you need to change the default value of `gc-ttl` from `86400` to `172800` (48 hours).

1. Run the `tiup cluster edit-config` command. Replace `<cluster-name>` with the actual cluster name:

```
tiup cluster edit-config <cluster-name>
```

2. In the vi editor, modify the `cdc server-configs`:

```
server_configs:
  tidb: {}
  tikv: {}
  pd: {}
  tiflash: {}
  tiflash-learner: {}
  cdc:
    gc-ttl: 172800
```

   In the preceding command, `gc-ttl` is set to 48 hours.

3. Run the `tiup cluster reload -R cdc` command to reload the configuration.

13.9.2.7 Stop and start TiCDC using TiUP

You can use TiUP to easily stop and start TiCDC nodes. The commands are as follows:

- Stop TiCDC: `tiup cluster stop -R cdc`
- Start TiCDC: `tiup cluster start -R cdc`
- Restart TiCDC: `tiup cluster restart -R cdc`

13.9.2.8 Enable TLS for TiCDC

See Enable TLS Between TiDB Components.

13.9.2.9 View TiCDC status using the command-line tool

Run the following command to view the TiCDC cluster status. Note that you need to replace `v<CLUSTER_VERSION>` with the TiCDC cluster version, such as `v8.4.0`:

```
tiup cdc:v<CLUSTER_VERSION> cli capture list --server=http://10.0.10.25:8300
```

```
[
  {
    "id": "806e3a1b-0e31-477f-9dd6-f3f2c570abdd",
    "is-owner": true,
    "address": "127.0.0.1:8300",
    "cluster-id": "default"
  },
  {
    "id": "ea2a4203-56fe-43a6-b442-7b295f458ebc",
    "is-owner": false,
    "address": "127.0.0.1:8301",
    "cluster-id": "default"
  }
]
```

- `id`: Indicates the ID of the service process.
- `is-owner`: Indicates whether the service process is the owner node.
- `address`: Indicates the address via which the service process provides interface to the outside.
- `cluster-id`: Indicates the ID of the TiCDC cluster. The default value is `default`.

13.9.3 Changefeed

13.9.3.1 Changefeed Overview

A changefeed is a replication task in TiCDC, which replicates the data change logs of specified tables in a TiDB cluster to the designated downstream. You can run and manage multiple changefeeds in a TiCDC cluster.

13.9.3.1.1 Changefeed state transfer

The state of a replication task represents the running status of the replication task. During the running of TiCDC, replication tasks might fail with errors, be manually paused, resumed, or reach the specified `TargetTs`. These behaviors can lead to the change of the replication task state. This section describes the states of TiCDC replication tasks and the transfer relationships between states.

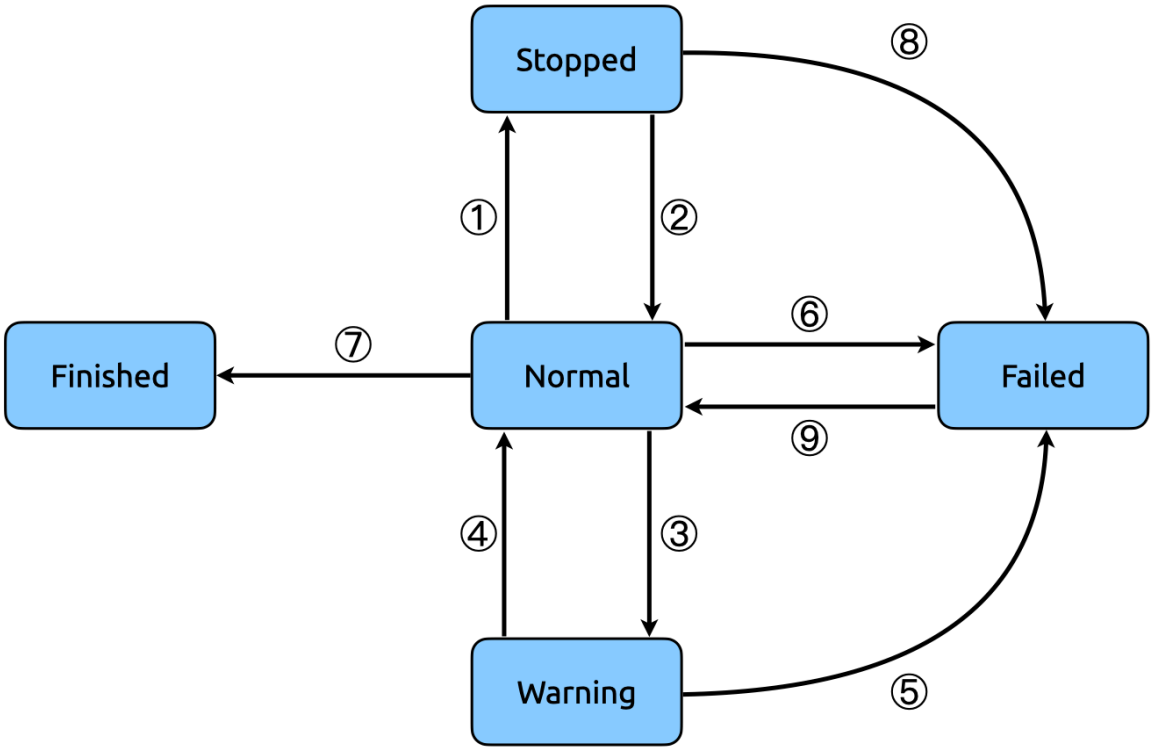

Figure 500: TiCDC state transfer

The states in the preceding state transfer diagram are described as follows:

- `Normal`: The replication task runs normally and the checkpoint-ts proceeds normally. A changefeed in this state blocks GC to advance.
- `Stopped`: The replication task is stopped, because the user manually pauses the changefeed. The changefeed in this state blocks GC operations.
- `Warning`: The replication task returns an error. The replication cannot continue due to some recoverable errors. The changefeed in this state keeps trying to resume until the state transfers to `Normal`. The default retry time is 30 minutes (which can be adjusted by `changefeed-error-stuck-duration`). If it exceeds this time, the changefeed enters a failed state. The changefeed in this state blocks GC operations.
- `Finished`: The replication task is finished and has reached the preset `TargetTs`. The changefeed in this state does not block GC operations.
- `Failed`: The replication task fails. The changefeed in this state does not keep trying to resume. To give you enough time to handle the failure, the changefeed in this state blocks GC operations. The duration of the blockage is specified by the `gc-ttl` parameter, with a default value of 24 hours. If the underlying issue is resolved within this duration, you can manually resume the changefeed. Otherwise, if the changefeed remains in this state beyond the `gc-ttl` duration, the replication task cannot resume and cannot be recovered.

Note:

- If GC is blocked by a changefeed, the changefeed will block GC advancement for up to the time specified by `gc-ttl`. After that, the changefeed will be set to the `failed` state, with an error type of `ErrGCTTLExceeded`, and will no longer block GC advancement.
- If the changefeed encounters errors with error codes `ErrGCTTLExceeded`, `ErrSnapshotLostByGC`, or `ErrStartTsBeforeGC`, it does not block GC operations.

The numbers in the preceding state transfer diagram are described as follows.

- Run the `changefeed pause` command.
- Run the `changefeed resume` command to resume the replication task.
- Recoverable errors occur during the `changefeed` operation, and the operation is retried automatically.
- The changefeed automatic retry succeeds, and `checkpoint-ts` continues to advance.
- The changefeed automatic retry exceeds 30 minutes and fails. The changefeed enters the failed state. At this time, the changefeed continues to block upstream GC for a duration specified by `gc-ttl`.
- The changefeed encounters an unrecoverable error and directly enters the failed state. At this time, the changefeed continues to block upstream GC for a duration specified by `gc-ttl`.
- The replication progress of the changefeed reaches the value set by `target-ts`, and the replication is completed.
- The changefeed has been suspended for a duration longer than the value specified by `gc-ttl`, thus encountering GC advancement errors, and cannot be resumed.
- If the cause of the failure has been resolved, and the changefeed was suspended for a duration shorter than the value specified by `gc-ttl`, run the `changefeed resume` command to resume the replication task.

13.9.3.1.2 Operate changefeeds

You can manage a TiCDC cluster and its replication tasks using the command-line tool `cdc cli`. For details, see Manage TiCDC changefeeds.

You can also use the HTTP interface (the TiCDC OpenAPI feature) to manage a TiCDC cluster and its replication tasks. For details, see TiCDC OpenAPI.

If your TiCDC is deployed using TiUP, you can start `cdc cli` by running the `tiup cdc :v<CLUSTER_VERSION> cli` command. Replace `v<CLUSTER_VERSION>` with the TiCDC cluster version, such as `v8.4.0`. You can also run `cdc cli` directly.

13.9.3.2 Create Changefeeds

13.9.3.2.1 Replicate Data to MySQL-compatible Databases

This document describes how to replicate incremental data to the downstream TiDB database or other MySQL-compatible databases using TiCDC. It also introduces how to use the eventually consistent replication feature in disaster scenarios.

Create a replication task

Create a replication task by running the following command:

```
cdc cli changefeed create \
    --server=http://10.0.10.25:8300 \
    --sink-uri="mysql://root:123456@127.0.0.1:3306/" \
    --changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"mysql://root:123456@127.0.0.1:3306/","opts":{},"create-
    ↪ time":"2023-11-28T22:04:08.103600025+08:00","start-ts
    ↪ ":415241823337054209,"target-ts":0,"admin-job-type":0,"sort-engine":"
    ↪ unified","sort-dir":".","config":{"case-sensitive":false,"filter":{"
    ↪ rules":["*.*"],"ignore-txn-start-ts":null,"ddl-allow-list":null},"
    ↪ mounter":{"worker-num":16},"sink":{"dispatchers":null},"scheduler":{"
    ↪ type":"table-number","polling-time":-1}},"state":"normal","history":
    ↪ null,"error":null}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the replication task. The format must match the `^[ ↪ a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. For details, see Configure sink URI with `mysql/tidb`.
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the changefeed configuration file. For details, see TiCDC Changefeed Configuration Parameters.

Note:

- TiCDC only replicates incremental data. To initialize full data, use Dumpling/TiDB Lightning or BR.
- After the full data is initialized, you need to specify the `start-ts` as the TSO when the upstream backup is performed. For example, the `pos` value in the metadata file under the Dumpling directory, or the `backupTS` value in the log output after BR completes the backup.

Configure sink URI for MySQL or TiDB

Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
```

Note:

`/path` is not used for the MySQL sink.

Sample configuration for MySQL:

```
--sink-uri="mysql://root:123456@127.0.0.1:3306"
```

The following are descriptions of sink URI parameters and parameter values that can be configured for MySQL or TiDB:

Parameter/Parameter value	Description
`root`	The username of the downstream database. To replicate data to TiDB or other MySQL-compatible databases, make sure that the downstream database user has certain permissions.
`123456`	The password of the downstream database (can be encoded using Base64).
`127.0.0.1`	The IP address of the downstream database.
`3306`	The port for the downstream data.
`worker-count`	The number of SQL statements that can be concurrently executed to the downstream (optional, `16` by default).
`cache-prep-stmts`	Controls whether to use prepared statements when executing SQL in the downstream and enable prepared statement cache on the client side (optional, `true` by default).

Parameter/Parameter value	Description
`max-txn-row`	The size of a transaction batch that can be executed to the downstream (optional, `256` by default).
`ssl-ca`	The path of the CA certificate file needed to connect to the downstream MySQL instance (optional).
`ssl-cert`	The path of the certificate file needed to connect to the downstream MySQL instance (optional).
`ssl-key`	The path of the certificate key file needed to connect to the downstream MySQL instance (optional).
`time-zone`	The time zone used when connecting to the downstream MySQL instance, which is effective since v4.0.8. This is an optional parameter. If this parameter is not specified, the time zone of TiCDC service processes is used. If this parameter is set to an empty value, such as `time-zone=""`, no time zone is specified when TiCDC connects to the downstream MySQL instance and the default time zone of the downstream is used.
`transaction-atomicity`	The atomicity level of a transaction. This is an optional parameter, with the default value of `none`. When the value is `table`, TiCDC ensures the atomicity of a single-table transaction. When the value is `none`, TiCDC splits the single-table transaction.

To encode the database password in the sink URI using Base64, use the following command:

```
echo -n '123456' | base64 # '123456' is the password to be encoded.
```

The encoded password is `MTIzNDU2`:

```
MTIzNDU2
```

> **Note:**
>
> When the sink URI contains special characters such as `! * ' ( ) ; : @ & = + $ , / ? % # [ ]`, you need to escape the special characters, for example, in URI Encoder.

Permissions required for the downstream database user

To replicate data to TiDB or other MySQL-compatible databases, the downstream database user needs the following permissions:

- `Select`
- `Index`
- `Insert`
- `Update`
- `Delete`
- `Create`
- `Drop`
- `Alter`
- `Create View`

To replicate `RECOVER TABLE` to the downstream TiDB, the downstream database user also needs the `Super` permission.

If the downstream TiDB cluster has read-only mode enabled, the downstream database user also needs the `RESTRICTED_REPLICA_WRITER_ADMIN` permission.

Eventually consistent replication in disaster scenarios

Starting from v6.1.1, this feature becomes GA. Starting from v5.3.0, TiCDC supports backing up incremental data from an upstream TiDB cluster to an object storage or an NFS of the downstream cluster. When the upstream cluster encounters a disaster and becomes unavailable, TiCDC can restore the downstream data to the recent eventually consistent state. This is the eventually consistent replication capability provided by TiCDC. With this capability, you can switch applications to the downstream cluster quickly, avoiding long-time downtime and improving service continuity.

Currently, TiCDC can replicate incremental data from a TiDB cluster to another TiDB cluster or a MySQL-compatible database system (including Aurora, MySQL, and MariaDB). In case the upstream cluster crashes, TiCDC can restore data in the downstream cluster within 5 minutes, given the conditions that TiCDC replicates data normally before the crash, and the replication lag is small. It allows data loss of 10s at most, that is, RTO <= 5 min, and P95 RPO <= 10s.

TiCDC replication lag increases in the following scenarios:

- The TPS increases significantly in a short time.
- Large or long transactions occur in the upstream.
- The TiKV or TiCDC cluster in the upstream is reloaded or upgraded.
- Time-consuming DDL statements, such as `add index`, are executed in the upstream.
- The PD is configured with aggressive scheduling strategies, resulting in frequent transfer of Region leaders, or frequent Region merge or Region split.

Note:

Starting from v6.1.1, the eventually consistent replication feature of TiCDC supports Amazon S3-compatible object storage. Starting from v6.1.4, this feature supports GCS- and Azure-compatible object storage.

Prerequisites

- Prepare a highly available object storage or NFS for storing TiCDC's real-time incremental data backup files. These files can be accessed in case of a disaster in the upstream.
- Enable this feature for changefeeds that need to have eventual consistency in disaster scenarios. To enable it, you can add the following configuration to the changefeed configuration file.

```
[consistent]
##### Consistency level. Options include:
##### - none: the default value. In a non-disaster scenario, eventual
    ↪ consistency is only guaranteed if and only if finished-ts is
    ↪ specified.
##### - eventual: Uses redo log to guarantee eventual consistency in case of
    ↪  the primary cluster disasters.
level = "eventual"

##### Individual redo log file size, in MiB. By default, it's 64. It is
    ↪ recommended to be no more than 128.
max-log-size = 64

##### The interval for flushing or uploading redo logs to Amazon S3, in
    ↪ milliseconds. It is recommended that this configuration be equal to
    ↪ or greater than 2000.
flush-interval = 2000

##### The path under which redo log backup is stored. The scheme can be nfs
    ↪ (NFS directory), or Amazon S3, GCS, and Azure (uploaded to object
    ↪ storage).
storage = "$SCHEME://logbucket/test-changefeed?endpoint=http://$ENDPOINT/"
```

Disaster recovery

When a disaster happens in the primary cluster, you need to recover manually in the secondary cluster by running the `cdc redo` command. The recovery process is as follows.

1. Ensure that all the TiCDC processes have exited. This is to prevent the primary cluster from resuming service during data recovery and prevent TiCDC from restarting data synchronization.
2. Use cdc binary for data recovery. Run the following command:

```
cdc redo apply --tmp-dir="/tmp/cdc/redo/apply" \
    --storage="s3://logbucket/test-changefeed?endpoint=http
        ↪ ://10.0.10.25:24927/" \
    --sink-uri="mysql://normal:123456@10.0.10.55:3306/"
```

In this command:

- `tmp-dir`: Specifies the temporary directory for downloading TiCDC incremental data backup files.
- `storage`: Specifies the address for storing the TiCDC incremental data backup files, either an URI of object storage or an NFS directory.
- `sink-uri`: Specifies the secondary cluster address to restore the data to. Scheme can only be `mysql`.

13.9.3.2.2 Replicate Data to Kafka

This document describes how to create a changefeed that replicates incremental data to Apache Kafka using TiCDC.

Create a replication task

Create a replication task by running the following command:

```
cdc cli changefeed create \
    --server=http://10.0.10.25:8300 \
    --sink-uri="kafka://127.0.0.1:9092,127.0.0.1:9093,127.0.0.1:9094/topic-
        ↪ name?protocol=canal-json&kafka-version=2.4.0&partition-num=6&max-
        ↪ message-bytes=67108864&replication-factor=1" \
    --changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"kafka://127.0.0.1:9092,127.0.0.1:9093,127.0.0.1:9094/
    ↪ topic-name?protocol=canal-json&kafka-version=2.4.0&partition-num=6&
    ↪ max-message-bytes=67108864&replication-factor=1","opts":{},"create-
    ↪ time":"2023-11-28T22:04:08.103600025+08:00","start-ts
    ↪ ":415241823337054209,"target-ts":0,"admin-job-type":0,"sort-engine":"
    ↪ unified","sort-dir":".","config":{"case-sensitive":false,"filter":{"
    ↪ rules":["*.*"],"ignore-txn-start-ts":null,"ddl-allow-list":null},"
    ↪ mounter":{"worker-num":16},"sink":{"dispatchers":null},"scheduler":{"
    ↪ type":"table-number","polling-time":-1}},"state":"normal","history":
    ↪ null,"error":null}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the replication task. The format must match the `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. For details, see Configure sink URI with `kafka`.
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the changefeed configuration file. For details, see TiCDC Changefeed Configuration Parameters.

Supported Kafka versions

The following table shows the minimum supported Kafka versions for each TiCDC version:

TiCDC version	Minimum supported Kafka version
TiCDC >= v8.1.0	2.1.0
v7.6.0 <= TiCDC < v8.1.0	2.4.0
v7.5.2 <= TiCDC < v8.0.0	2.1.0
v7.5.0 <= TiCDC < v7.5.2	2.4.0
v6.5.0 <= TiCDC < v7.5.0	2.1.0
v6.1.0 <= TiCDC < v6.5.0	2.0.0

Configure sink URI for Kafka

Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[host]:[port][/path]?[query_parameters]
```

Tip:

If there are multiple hosts or ports for the downstream Kafka, you can configure multiple `[host]:[port]` in the sink URI. For example:

```
[scheme]://[host]:[port],[host]:[port],[host]:[port][/path]?[
    ↪ query_parameters]
```

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=canal-json&kafka-
    ↪ version=2.4.0&partition-num=6&max-message-bytes=67108864&replication-
    ↪ factor=1"
```

The following are descriptions of sink URI parameters and values that can be configured for Kafka:

Parameter/Parameter value	Description
`host`	The IP address of the downstream Kafka services.
`port`	The port for the downstream Kafka.
`topic-name`	Variable. The name of the Kafka topic.
`protocol`	The protocol with which messages are output to Kafka. The value options are `canal-json`、`open-protocol`、`avro`、`debezium` and `simple`.
`kafka-version`	The version of the downstream Kafka. This value needs to be consistent with the actual version of the downstream Kafka.
`kafka-client-id`	Specifies the Kafka client ID of the replication task (optional. `TiCDC_sarama_producer_replication ID` by default).
`partition-num`	The number of the downstream Kafka partitions (optional. The value must be **no greater than** the actual number of partitions; otherwise, the replication task cannot be created successfully. `3` by default).
`max-message-bytes`	The maximum size of data that is sent to Kafka broker each time (optional, `10MB` by default). From v5.0.6 and v4.0.6, the default value has changed from `64MB` and `256MB` to `10MB`.
`replication-factor`	The number of Kafka message replicas that can be saved (optional, `1` by default). This value must be greater than or equal to the value of `min.insync.replicas` in Kafka.
`required-acks`	A parameter used in the `Produce` request, which notifies the broker of the number of replica acknowledgements it needs to receive before responding. Value options are `0` (`NoResponse`: no response, only `TCP ACK` is provided), `1` (`WaitForLocal`: responds only after local commits are submitted successfully), and `-1` (`WaitForAll`: responds after all replicated replicas are committed successfully. You can configure the minimum number of replicated replicas using the `min.insync.replicas` configuration item of the broker). (Optional, the default value is `-1`).
`compression`	The compression algorithm used when sending messages (value options are `none`, `lz4`, `gzip`, `snappy`, and `zstd`; `none` by default). Note that the Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.

Parameter/Parameter value	Description
`auto-create-topic`	Determines whether TiCDC creates the topic automatically when the `topic-name` passed in does not exist in the Kafka cluster (optional, `true` by default).
`enable-tidb-extension`	Optional. `false` by default. When the output protocol is `canal-json`, if the value is `true`, TiCDC sends WATERMARK events and adds the TiDB extension field to Kafka messages. From v6.1.0, this parameter is also applicable to the `avro` protocol. If the value is `true`, TiCDC adds three TiDB extension fields to the Kafka message.
`max-batch-size`	New in v4.0.9. If the message protocol supports outputting multiple data changes to one Kafka message, this parameter specifies the maximum number of data changes in one Kafka message. It currently takes effect only when Kafka's `protocol` is `open-protocol` (optional, `16` by default).
`enable-tls`	Whether to use TLS to connect to the downstream Kafka instance (optional, `false` by default).
`ca`	The path of the CA certificate file needed to connect to the downstream Kafka instance (optional).
`cert`	The path of the certificate file needed to connect to the downstream Kafka instance (optional).
`key`	The path of the certificate key file needed to connect to the downstream Kafka instance (optional).
`insecure-skip-verify`	Whether to skip certificate verification when connecting to the downstream Kafka instance (optional, `false` by default).
`sasl-user`	The identity (authcid) of SASL/PLAIN or SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional).
`sasl-password`	The password of SASL/PLAIN or SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional). If it contains special characters, they need to be URL encoded.
`sasl-mechanism`	The name of SASL authentication needed to connect to the downstream Kafka instance. The value can be `plain`, `scram-sha-256`, `scram-sha-512`, or `gssapi`.
`sasl-gssapi-auth-type`	The gssapi authentication type. Values can be `user` or `keytab` (optional).
`sasl-gssapi-keytab-path`	The gssapi keytab path (optional).
`sasl-gssapi-kerberos-config-path`	The gssapi kerberos configuration path (optional).
`sasl-gssapi-service-name`	The gssapi service name (optional).

Parameter/Parameter value	Description
`sasl-gssapi-user`	The user name of gssapi authentication (optional).
`sasl-gssapi-password`	The password of gssapi authentication (optional). If it contains special characters, they need to be URL encoded.
`sasl-gssapi-realm`	The gssapi realm name (optional).
`sasl-gssapi-disable-pafxfast`	Whether to disable the gssapi PA-FX-FAST (optional).
`dial-timeout`	The timeout in establishing a connection with the downstream Kafka. The default value is `10s`.
`read-timeout`	The timeout in getting a response returned by the downstream Kafka. The default value is `10s`.
`write-timeout`	The timeout in sending a request to the downstream Kafka. The default value is `10s`.
`avro-decimal-handling-mode`	Only effective with the `avro` protocol. Determines how Avro handles the DECIMAL field. The value can be `string` or `precise`, indicating either mapping the DECIMAL field to a string or a precise floating number.
`avro-bigint-unsigned-handling-mode`	Only effective with the `avro` protocol. Determines how Avro handles the BIGINT UNSIGNED field. The value can be `string` or `long`, indicating either mapping the BIGINT UNSIGNED field to a 64-bit signed number or a string.

Best practices

- It is recommended that you create your own Kafka Topic. At a minimum, you need to set the maximum amount of data of each message that the Topic can send to the Kafka broker, and the number of downstream Kafka partitions. When you create a changefeed, these two settings correspond to `max-message-bytes` and `partition-num`, respectively.
- If you create a changefeed with a Topic that does not yet exist, TiCDC will try to create the Topic using the `partition-num` and `replication-factor` parameters. It is recommended that you specify these parameters explicitly.
- In most cases, it is recommended to use the `canal-json` protocol.

Note:

When `protocol` is `open-protocol`, TiCDC encodes multiple events into one Kafka message and avoids generating messages that exceed the length specified by `max-message-bytes`. If the encoded result of a single row change event exceeds the value of `max-message-bytes`, the changefeed reports an error and prints logs.

TiCDC uses the authentication and authorization of Kafka

The following are examples when using Kafka SASL authentication:

- SASL/PLAIN

```
shell  --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-user=alice-user&sasl-password=alice-secret&sasl-mechanism=plain"
```

- SASL/SCRAM

SCRAM-SHA-256 and SCRAM-SHA-512 are similar to the PLAIN method. You just need to specify `sasl-mechanism` as the corresponding authentication method.

- SASL/GSSAPI

SASL/GSSAPI `user` authentication:

```
shell  --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-mechanism=gssapi&sasl-gssapi-auth-type=user&sasl-gssapi-kerberos-
↪ config-path=/etc/krb5.conf&sasl-gssapi-service-name=kafka&sasl-gssapi-
↪ user=alice/for-kafka&sasl-gssapi-password=alice-secret&sasl-gssapi-realm
↪ =example.com"
```

Values of `sasl-gssapi-user` and `sasl-gssapi-realm` are related to the principle specified in kerberos. For example, if the principle is set as `alice/for-kafka@example.com`, then `sasl-gssapi-user` and `sasl-gssapi-realm` are specified as `alice/for-kafka` and `example.com` respectively.

SASL/GSSAPI `keytab` authentication:

```
shell  --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-mechanism=gssapi&sasl-gssapi-auth-type=keytab&sasl-gssapi-kerberos
↪ -config-path=/etc/krb5.conf&sasl-gssapi-service-name=kafka&sasl-gssapi-
↪ user=alice/for-kafka&sasl-gssapi-keytab-path=/var/lib/secret/alice.key&
↪ sasl-gssapi-realm=example.com"
```

For more information about SASL/GSSAPI authentication methods, see Configuring GSSAPI.

- TLS/SSL encryption

  If the Kafka broker has TLS/SSL encryption enabled, you need to add the `-enable ↪ -tls=true` parameter to `--sink-uri`. If you want to use self-signed certificates, you also need to specify `ca`, `cert` and `key` in `--sink-uri`.

- ACL authorization

  The minimum set of permissions required for TiCDC to function properly is as follows.

  - The `Create`, `Write`, and `Describe` permissions for the Topic resource type.
  - The `DescribeConfig` permission for the Cluster resource type.

The usage scenarios for each permission are as follows:

```
| Resource type | Type of operation | Scenario                                |
| :-------------| :------------- | :-------------------------------|
| Cluster     | `DescribeConfig`| Gets the cluster metadata while the
   ↪ changefeed is running |
| Topic       | `Describe`    | Tries to create a topic when the changefeed
   ↪ starts |
| Topic       | `Create`      | Tries to create a topic when the changefeed
   ↪ starts |
| Topic       | `Write`       | Sends data to the topic              |

When creating or starting a changefeed, you can disable the `Describe` and `
   ↪ Create` permissions if the specified Kafka topic already exists.
```

Integrate TiCDC with Kafka Connect (Confluent Platform)

To use the data connectors provided by Confluent to stream data to relational or non-relational databases, you need to use the `avro` protocol and provide a URL for Confluent Schema Registry in `schema-registry`.

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?&protocol=avro&replication-
   ↪ factor=3" --schema-registry="http://127.0.0.1:8081" --config
   ↪ changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

For detailed integration guide, see Quick Start Guide on Integrating TiDB with Confluent Platform.

Integrate TiCDC with AWS Glue Schema Registry

Starting from v7.4.0, TiCDC supports using the AWS Glue Schema Registry as the Schema Registry when users choose the Avro protocol for data replication. The configuration example is as follows:

```
./cdc cli changefeed create --server=127.0.0.1:8300 --changefeed-id="kafka-
    ↪ glue-test" --sink-uri="kafka://127.0.0.1:9092/topic-name?&protocol=
    ↪ avro&replication-factor=3" --config changefeed_glue.toml
```

```
[sink]
[sink.kafka-config.glue-schema-registry-config]
region="us-west-1"
registry-name="ticdc-test"
access-key="xxxx"
secret-access-key="xxxx"
token="xxxx"
```

In the above configuration, `region` and `registry-name` are required fields, while `access-key`, `secret-access-key`, and `token` are optional fields. The best practice is to set the AWS credentials as environment variables or store them in the `~/.aws/credentials` file instead of setting them in the changefeed configuration file.

For more information, refer to the official AWS SDK for Go V2 documentation.

Customize the rules for Topic and Partition dispatchers of Kafka Sink

Matcher rules

Take the following configuration of `dispatchers` as an example:

```
[sink]
dispatchers = [
  {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1", partition
     ↪  = "ts" },
  {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2", partition
     ↪  = "index-value" },
  {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3", partition
     ↪  = "table"},
  {matcher = ['test6.*'], partition = "ts"}
]
```

- For the tables that match the matcher rule, they are dispatched according to the policy specified by the corresponding topic expression. For example, the `test3.aa` table is dispatched according to "Topic expression 2"; the `test5.aa` table is dispatched according to "Topic expression 3".
- For a table that matches multiple matcher rules, it is dispatched according to the first matching topic expression. For example, the `test1.aa` table is distributed according to "Topic expression 1".
- For tables that do not match any matcher rule, the corresponding data change events are sent to the default topic specified in `--sink-uri`. For example, the `test10.aa` table is sent to the default topic.

- For tables that match the matcher rule but do not specify a topic dispatcher, the corresponding data changes are sent to the default topic specified in `--sink-uri`. For example, the `test6.aa` table is sent to the default topic.

Topic dispatchers

You can use topic = "xxx" to specify a Topic dispatcher and use topic expressions to implement flexible topic dispatching policies. It is recommended that the total number of topics be less than 1000.

The format of the Topic expression is `[prefix]{schema}[middle][{table}][suffix]`.

- `prefix`: optional. Indicates the prefix of the Topic Name.
- `{schema}`: required. Used to match the schema name. Starting from v7.1.4, this parameter is optional.
- `middle`: optional. Indicates the delimiter between schema name and table name.
- `{table}`: optional. Used to match the table name.
- `suffix`: optional. Indicates the suffix of the Topic Name.

`prefix`, `middle` and `suffix` can only include the following characters: `a-z`, `A-Z`, `0-9`, `.`, `_` and `-`. `{schema}` and `{table}` are both lowercase. Placeholders such as `{Schema}` and `{TABLE}` are invalid.

Some examples:

- `matcher = ['test1.table1', 'test2.table2'], topic = "hello_{schema}_{table}"`
  - The data change events corresponding to `test1.table1` are sent to the topic named `hello_test1_table1`.
  - The data change events corresponding to `test2.table2` are sent to the topic named `hello_test2_table2`.
- `matcher = ['test3.*', 'test4.*'], topic = "hello_{schema}_world"`
  - The data change events corresponding to all tables in `test3` are sent to the topic named `hello_test3_world`.
  - The data change events corresponding to all tables in `test4` are sent to the topic named `hello_test4_world`.
- `matcher = ['test5.*, 'test6.*'], topic = "hard_code_topic_name"`
  - The data change events corresponding to all tables in `test5` and `test6` are sent to the topic named `hard_code_topic_name`. You can specify the topic name directly.
- `matcher = ['*.*'], topic = "{schema}_{table}"`

- All tables listened by TiCDC are dispatched to separate topics according to the "schema_table" rule. For example, for the `test.account` table, TiCDC dispatches its data change log to a Topic named `test_account`.

Dispatch DDL events

Schema-level DDLs

DDLs that are not related to a specific table are called schema-level DDLs, such as `create database` and `drop database`. The events corresponding to schema-level DDLs are sent to the default topic specified in `--sink-uri`.

Table-level DDLs

DDLs that are related to a specific table are called table-level DDLs, such as `alter table` and `create table`. The events corresponding to table-level DDLs are sent to the corresponding topic according to dispatcher configurations.

For example, for a dispatcher like `matcher = ['test.*'], topic = {schema}_{table}`, DDL events are dispatched as follows:

- If a single table is involved in the DDL event, the DDL event is sent to the corresponding topic as is. For example, for the DDL event `drop table test.table1`, the event is sent to the topic named `test_table1`.
- If multiple tables are involved in the DDL event (`rename table` / `drop table` / `drop view` may involve multiple tables), the DDL event is split into multiple events and sent to the corresponding topics. For example, for the DDL event `rename table test.table1 to test.table10, test.table2 to test.table20`, the event `rename table test.table1 to test.table10` is sent to the topic named `test_table1` and the event `rename table test.table2 to test.table20` is sent to the topic named `test.table2`.

Partition dispatchers

You can use `partition = "xxx"` to specify a partition dispatcher. It supports five dispatchers: `default`, `index-value`, `columns`, `table`, and `ts`. The dispatcher rules are as follows:

- `default`: uses the `table` dispatcher rule by default. It calculates the partition number using the schema name and table name, ensuring data from a table is sent to the same partition. As a result, the data from a single table only exists in one partition and is guaranteed to be ordered. However, this dispatcher rule limits the send throughput, and the consumption speed cannot be improved by adding consumers.
- `index-value`: calculates the partition number using either the primary key, a unique index, or an index explicitly specified by `index`, distributing table data across multiple partitions. The data from a single table is sent to multiple partitions, and the data in each partition is ordered. You can improve the consumption speed by adding consumers.

- `columns`: calculates the partition number using the values of explicitly specified columns, distributing table data across multiple partitions. The data from a single table is sent to multiple partitions, and the data in each partition is ordered. You can improve the consumption speed by adding consumers.
- `table`: calculates the partition number using the schema name and table name.
- `ts`: calculates the partition number using the commitTs of the row change, distributing table data across multiple partitions. The data from a single table is sent to multiple partitions, and the data in each partition is ordered. You can improve the consumption speed by adding consumers. However, multiple changes of a data item might be sent to different partitions and the consumer progress of different consumers might be different, which might cause data inconsistency. Therefore, the consumer needs to sort the data from multiple partitions by commitTs before consuming.

Take the following configuration of `dispatchers` as an example:

```
[sink]
dispatchers = [
    {matcher = ['test.*'], partition = "index-value"},
    {matcher = ['test1.*'], partition = "index-value", index = "index1"},
    {matcher = ['test2.*'], partition = "columns", columns = ["id", "a"]},
    {matcher = ['test3.*'], partition = "table"},
]
```

- Tables in the `test` database use the `index-value` dispatcher, which calculates the partition number using the value of the primary key or unique index. If a primary key exists, the primary key is used; otherwise, the shortest unique index is used.
- Tables in the `test1` table use the `index-value` dispatcher and calculate the partition number using values of all columns in the index named `index1`. If the specified index does not exist, an error is reported. Note that the index specified by `index` must be a unique index.
- Tables in the `test2` database use the `columns` dispatcher and calculate the partition number using the values of columns `id` and `a`. If any of the columns does not exist, an error is reported.
- Tables in the `test3` database use the `table` dispatcher.
- Tables in the `test4` database use the `default` dispatcher, that is the `table` dispatcher, as they do not match any of the preceding rules.

If a table matches multiple dispatcher rules, the first matching rule takes precedence.

Note:

Since v6.1.0, to clarify the meaning of the configuration, the configuration used to specify the partition dispatcher has been changed from `dispatcher`

to `partition`, with `partition` being an alias for `dispatcher`. For example, the following two rules are exactly equivalent.

```
[sink]
dispatchers = [
   {matcher = ['*.*'], dispatcher = "index-value"},
   {matcher = ['*.*'], partition = "index-value"},
]
```

However, `dispatcher` and `partition` cannot appear in the same rule. For example, the following rule is invalid.

```
{matcher = ['*.*'], dispatcher = "index-value", partition = "
   ↪ table"},
```

Column selectors

The column selector feature supports selecting columns from events and sending only the data changes related to those columns to the downstream.

Take the following configuration of `column-selectors` as an example:

```
[sink]
column-selectors = [
    {matcher = ['test.t1'], columns = ['a', 'b']},
    {matcher = ['test.*'], columns = ["*", "!b"]},
    {matcher = ['test1.t1'], columns = ['column*', '!column1']},
    {matcher = ['test3.t'], columns = ["column?", "!column1"]},
]
```

- For table `test.t1`, only columns `a` and `b` are sent.
- For tables in the `test` database (excluding the `t1` table), all columns except `b` are sent.
- For table `test1.t1`, any column starting with `column` is sent, except for `column1`.
- For table `test3.t`, any 7-character column starting with `column` is sent, except for `column1`.
- For tables that do not match any rule, all columns are sent.

Note:

After being filtered by the `column-selectors` rules, the data in the table must have a primary key or unique key to be replicated. Otherwise, the changefeed reports an error when it is created or running.

Scale out the load of a single large table to multiple TiCDC nodes

This feature splits the data replication range of a single large table into multiple ranges, according to the data volume and the number of modified rows per minute, and it makes the data volume and the number of modified rows replicated in each range approximately the same. This feature distributes these ranges to multiple TiCDC nodes for replication, so that multiple TiCDC nodes can replicate a large single table at the same time. This feature can solve the following two problems:

- A single TiCDC node cannot replicate a large single table in time.
- The resources (such as CPU and memory) consumed by TiCDC nodes are not evenly distributed.

> **Warning:**
>
> TiCDC v7.0.0 only supports scaling out the load of a large single table on Kafka changefeeds.

Sample configuration:

```
[scheduler]
##### The default value is "false". You can set it to "true" to enable this
    ↪ feature.
enable-table-across-nodes = true
##### When you enable this feature, it only takes effect for tables with the
    ↪  number of regions greater than the `region-threshold` value.
region-threshold = 100000
##### When you enable this feature, it takes effect for tables with the
    ↪ number of rows modified per minute greater than the `write-key-
    ↪ threshold` value.
##### Note:
##### * The default value of `write-key-threshold` is 0, which means that
    ↪ the feature does not split the table replication range according to
    ↪ the number of rows modified in a table by default.
##### * You can configure this parameter according to your cluster workload.
    ↪  For example, if it is configured as 30000, it means that the feature
    ↪  will split the replication range of a table when the number of
    ↪ modified rows per minute in the table exceeds 30000.
##### * When `region-threshold` and `write-key-threshold` are configured at
    ↪ the same time:
#####  TiCDC will check whether the number of modified rows is greater than
    ↪ `write-key-threshold` first.
```

```
#####  If not, next check whether the number of Regions is greater than `
    ↪ region-threshold`.
write-key-threshold = 30000
```

You can query the number of Regions a table contains by the following SQL statement:

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.TIKV_REGION_STATUS WHERE DB_NAME="
    ↪ database1" AND TABLE_NAME="table1" AND IS_INDEX=0;
```

Handle messages that exceed the Kafka topic limit

Kafka topic sets a limit on the size of messages it can receive. This limit is controlled by the `max.message.bytes` parameter. If TiCDC Kafka sink sends data that exceeds this limit, the changefeed reports an error and cannot proceed to replicate data. To solve this problem, TiCDC adds a new configuration `large-message-handle-option` and provides the following solution.

Currently, this feature supports two encoding protocols: Canal-JSON and Open Protocol. When using the Canal-JSON protocol, you must specify `enable-tidb-extension=true` in `sink-uri`.

TiCDC data compression

Starting from v7.4.0, TiCDC Kafka sink supports compressing data immediately after encoding and comparing the compressed data size with the message size limit. This feature can effectively reduce the occurrence of messages exceeding the size limit.

An example configuration is as follows:

```
[sink.kafka-config.large-message-handle]
##### This configuration is introduced in v7.4.0.
##### "none" by default, which means that the compression feature is
    ↪ disabled.
##### Possible values are "none", "lz4", and "snappy". The default value is
    ↪ "none".
large-message-handle-compression = "none"
```

When `large-message-handle-compression` is enabled, the message received by the consumer is encoded using a specific compression protocol, and the consumer application needs to use the specified compression protocol to decode the data.

This feature is different from the compression feature of the Kafka producer:

- The compression algorithm specified in `large-message-handle-compression` compresses a single Kafka message. The compression is performed before comparing with the message size limit.
- At the same time, you can also configure the compression algorithm by using the `compression` parameter in `sink-uri`. This compression algorithm is applied to the entire data sending request, which contains multiple Kafka messages.

If you set `large-message-handle-compression`, when TiCDC receives a message, it first compares it to the value of the message size limit parameter, and messages larger than the size limit are compressed. If you also set `compression` in `sink-uri`, TiCDC compresses the entire sending data request again at the sink level based on the `sink-uri` setting.

The compression ratio for the two preceding compression methods is calculated as follows: `compression ratio = size before compression / size after compression * 100`.

Send handle keys only

Starting from v7.3.0, TiCDC Kafka sink supports sending only the handle keys when the message size exceeds the limit. This can significantly reduce the message size and avoid changefeed errors and task failures caused by the message size exceeding the Kafka topic limit. Handle Key refers to the following:

- If the table to be replicated has primary key, the primary key is the handle key.
- If the table does not have primary key but has NOT NULL Unique Key, the NOT NULL Unique Key is the handle key.

The sample configuration is as follows:

```
[sink.kafka-config.large-message-handle]
##### large-message-handle-option is introduced in v7.3.0.
##### Defaults to "none". When the message size exceeds the limit, the
    ↪ changefeed fails.
##### When set to "handle-key-only", if the message size exceeds the limit,
    ↪ only the handle key is sent in the data field. If the message size
    ↪ still exceeds the limit, the changefeed fails.
large-message-handle-option = "claim-check"
```

Consume messages with handle keys only

The message format with handle keys only is as follows:

```
{
    "id": 0,
    "database": "test",
    "table": "tp_int",
    "pkNames": [
        "id"
    ],
    "isDdl": false,
    "type": "INSERT",
    "es": 1639633141221,
    "ts": 1639633142960,
    "sql": "",
    "sqlType": {
        "id": 4
```

```
    },
    "mysqlType": {
        "id": "int"
    },
    "data": [
        {
          "id": "2"
        }
    ],
    "old": null,
    "_tidb": {   // TiDB extension fields
        "commitTs": 429918007904436226, // A TiDB TSO timestamp
        "onlyHandleKey": true
    }
}
```

When a Kafka consumer receives a message, it first checks the `onlyHandleKey` field. If this field exists and is `true`, it means that the message only contains the handle key of the complete data. In this case, to get the complete data, you need to query the upstream TiDB and use `tidb_snapshot` to read historical data.

> **Warning:**
>
> When the Kafka consumer processes data and queries TiDB, the data might have been deleted by GC. You need to modify the GC Lifetime of the TiDB cluster to a larger value to avoid this situation.

Send large messages to external storage

Starting from v7.4.0, TiCDC Kafka sink supports sending large messages to external storage when the message size exceeds the limit. Meanwhile, TiCDC sends a message to Kafka that contains the address of the large message in the external storage. This can avoid changefeed failures caused by the message size exceeding the Kafka topic limit.

An example configuration is as follows:

```
[sink.kafka-config.large-message-handle]
##### large-message-handle-option is introduced in v7.3.0.
##### Defaults to "none". When the message size exceeds the limit, the
    ↪ changefeed fails.
##### When set to "handle-key-only", if the message size exceeds the limit,
    ↪ only the handle key is sent in the data field. If the message size
    ↪ still exceeds the limit, the changefeed fails.
```

```
##### When set to "claim-check", if the message size exceeds the limit, the
    ↪ message is sent to external storage.
large-message-handle-option = "claim-check"
claim-check-storage-uri = "s3://claim-check-bucket"
```

When `large-message-handle-option` is set to `"claim-check"`, `claim-check-storage ↪ -uri` must be set to a valid external storage address. Otherwise, creating the changefeed will fail.

> **Tip**
>
> For more information about the URI parameters of Amazon S3, GCS, and Azure Blob Storage in TiCDC, see URI Formats of External Storage Services.

TiCDC does not clean up messages on external storage services. Data consumers need to manage external storage services on their own.

Consume large messages from external storage

The Kafka consumer receives a message that contains the address of the large message in the external storage. The message format is as follows:

```
{
    "id": 0,
    "database": "test",
    "table": "tp_int",
    "pkNames": [
        "id"
    ],
    "isDdl": false,
    "type": "INSERT",
    "es": 1639633141221,
    "ts": 1639633142960,
    "sql": "",
    "sqlType": {
        "id": 4
    },
    "mysqlType": {
        "id": "int"
    },
    "data": [
        {
          "id": "2"
        }
```

```
    ],
    "old": null,
    "_tidb": {   // TiDB extension fields
        "commitTs": 429918007904436226, // A TiDB TSO timestamp
        "claimCheckLocation": "s3:/claim-check-bucket/${uuid}.json"
    }
}
```

If the message contains the `claimCheckLocation` field, the Kafka consumer reads the large message data stored in JSON format according to the address provided by the field. The message format is as follows:

```
{
  key: "xxx",
  value: "xxx",
}
```

The `key` and `value` fields correspond to the same-named fields in the Kafka message. Consumers can get the original large message by parsing the data in these two fields. Only Kafka messages encoded with the Open Protocol contain valid content in the `key` field. TiCDC encodes both `key` and `value` into a single JSON object to deliver the complete message at once. For other protocols, the `key` field is always empty.

Send the `value` field to external storage only

Starting from v8.4.0, TiCDC supports sending only the `value` field of Kafka messages to external storage. This feature is only applicable to non-Open Protocol scenarios. You can control this feature by setting the `claim-check-raw-value` parameter, which defaults to `false`.

> **Note:**
>
> When using the Open Protocol, if you set `claim-check-raw-value` to `true`, an error will occur.

When `claim-check-raw-value` is set to `true`, the changefeed sends the `value` field of Kafka messages directly to external storage without additional JSON serialization of `key` and `value`. This reduces CPU overhead. Additionally, consumers can read directly consumable data from external storage, reducing deserialization overhead.

An example configuration is as follows:

```
protocol = "simple"

[sink.kafka-config.large-message-handle]
```

```
large-message-handle-option = "claim-check"
claim-check-storage-uri = "s3://claim-check-bucket"
claim-check-raw-value = true
```

13.9.3.2.3 Replicate Data to Pulsar

This document describes how to create a changefeed that replicates incremental data to Pulsar using TiCDC.

Create a replication task to replicate incremental data to Pulsar

Create a replication task by running the following command:

```
cdc cli changefeed create \
    --server=http://127.0.0.1:8300 \
--sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
    ↪ protocol=canal-json" \
--config=./t_changefeed.toml \
--changefeed-id="simple-replication-task"
```

```

Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7277814241002263370,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"pulsar://127.0.0.1:6650/consumer-test?
    ↪ protocol=canal-json","create_time":"2024-11-11T14
    ↪ :42:32.000904+08:00","start_ts":444203257406423044,"config":{"memory_
    ↪ quota":1073741824,"case_sensitive":false,"force_replicate":false,"
    ↪ ignore_ineligible_table":false,"check_gc_safe_point":true,"enable_
    ↪ sync_point":false,"bdr_mode":false,"sync_point_interval
    ↪ ":600000000000,"sync_point_retention":86400000000000,"filter":{"rules
    ↪ ":["pulsar_test.*"]},"mounter":{"worker_num":16},"sink":{"protocol":"
    ↪ canal-json","csv":{"delimiter":",","quote":"\"","null":"\\N","include
    ↪ _commit_ts":false,"binary_encoding_method":"base64"},"dispatchers
    ↪ ":[{"matcher":["pulsar_test.*"],"partition":"","topic":"test_{schema}
    ↪ _{table}"}],"encoder_concurrency":16,"terminator":"\r\n","date_
    ↪ separator":"day","enable_partition_separator":true,"only_output_
    ↪ updated_columns":false,"delete_only_output_handle_key_columns":false
    ↪ ,"pulsar_config":{"connection-timeout":30,"operation-timeout":30,"
    ↪ batching-max-messages":1000,"batching-max-publish-delay":10,"send-
    ↪ timeout":30},"advance_timeout":150},"consistent":{"level":"none","max
    ↪ _log_size":64,"flush_interval":2000,"use_file_backend":false},"
    ↪ scheduler":{"enable_table_across_nodes":false,"region_threshold
    ↪ ":100000,"write_key_threshold":0},"integrity":{"integrity_check_level
    ↪ ":"none","corruption_handle_level":"warn"}},"state":"normal","creator
    ↪ _version":"v8.4.0","resolved_ts":444203257406423044,"checkpoint_ts
    ↪ ":444203257406423044,"checkpoint_time":"2024-11-11 14:42:31.410"}
```

The meaning of each parameter is as follows:

- `--server`: the address of a TiCDC server in the TiCDC cluster.
- `--changefeed-id`: the ID of the replication task. The format must match the regular expression `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$`. If the ID is not specified, TiCDC automatically generates a UUID (in the version 4 format) as the ID.
- `--sink-uri`: the downstream address of the replication task. See Use Sink URI to configure Pulsar.
- `--start-ts`: the start TSO of the changefeed. The TiCDC cluster starts pulling data from this TSO. The default value is the current time.
- `--target-ts`: the target TSO of the changefeed. The TiCDC cluster stops pulling data at this TSO. It is empty by default, which means that TiCDC does not automatically stop pulling data.
- `--config`: the changefeed configuration file. See TiCDC changefeed configuration parameters.

Use Sink URI and changefeed config to configure Pulsar

You can use Sink URI to specify the connection information for the TiCDC target system, and use changefeed config to configure parameters related to Pulsar.

Sink URI

A Sink URI follows the following format:

```
[scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
```

Configuration example 1:

```
--sink-uri="pulsar://127.0.0.1:6650/persistent://abc/def/yktest?protocol=
    ↪ canal-json"
```

Configuration example 2:

```
--sink-uri="pulsar://127.0.0.1:6650/yktest?protocol=canal-json"
```

The configurable parameters in a URI are as follows:

Parameter	Description
`pulsar`	The scheme for the downstream Pulsar. The value can be `pulsar`, `pulsar+ssl`, `pulsar+http`, or `pulsar+https`, in which `pulsar+http` and `pulsar+https` are supported starting from v8.2.0.
`127.0.0.1`	The IP address by which the downstream Pulsar provides service.

Parameter	Description
`6650`	The connection port for the downstream Pulsar.
`persistent://abc/def/yktest`	As shown in the preceding configuration example 1, this parameter is used to specify the tenant, namespace, and topic of Pulsar.
`yktest`	As shown in the preceding configuration example 2, if the topic you want to specify is in the default namespace `default` of the default tenant `public` in Pulsar, you can configure the URI with just the topic name, for example, `yktest`. This is equivalent to specifying the topic as `persistent://public/default/yktest`.

Changefeed config parameters

The following are examples of changefeed config parameters:

```
[sink]
##### `dispatchers` is used to specify matching rules.
##### Note: When the downstream MQ is Pulsar, if the routing rule for `
    ↪ partition` is not specified as any of `ts`, `index-value`, `table`,
    ↪ or `default`, each Pulsar message will be routed using the string you
    ↪  set as the key.
##### For example, if you specify the routing rule for a matcher as the
    ↪ string `code`, then all Pulsar messages that match that matcher will
    ↪ be routed with `code` as the key.
##### dispatchers = [
#####   {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1",
    ↪ partition = "ts" },
#####   {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2",
    ↪ partition = "index-value" },
#####   {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3",
    ↪ partition = "table"},
#####   {matcher = ['test6.*'], partition = "default"},
#####   {matcher = ['test7.*'], partition = "test123"}
##### ]

##### `protocol` is used to specify the protocol format for encoding
    ↪ messages.
##### When the downstream is Pulsar, the protocol can only be canal-json.
##### protocol = "canal-json"

##### The following parameters only take effect when the downstream is
    ↪ Pulsar.
[sink.pulsar-config]
##### Authentication on the Pulsar server is done using a token. Specify the
    ↪  value of the token.
```

```
authentication-token = "xxxxxxxxxxxxx"
##### When you use a token for Pulsar server authentication, specify the
    ↪ path to the file where the token is located.
token-from-file="/data/pulsar/token-file.txt"
##### Pulsar uses the basic account and password to authenticate the
    ↪ identity. Specify the account.
basic-user-name="root"
##### Pulsar uses the basic account and password to authenticate the
    ↪ identity. Specify the password.
basic-password="password"
##### The certificate path on the client, which is required when Pulsar
    ↪ enables the mTLS authentication.
auth-tls-certificate-path="/data/pulsar/certificate"
##### The private key path on the client, which is required when Pulsar
    ↪ enables the mTLS authentication.
auth-tls-private-key-path="/data/pulsar/certificate.key"
##### The path to the trusted certificate file of the Pulsar TLS
    ↪ authentication, which is required when Pulsar enables the mTLS
    ↪ authentication or TLS encrypted transmission.
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
##### The path to the encrypted private key on the client, which is required
    ↪  when Pulsar enables TLS encrypted transmission.
tls-key-file-path="/data/pulsar/tls-key-file"
##### The path to the encrypted certificate file on the client, which is
    ↪ required when Pulsar enables TLS encrypted transmission.
tls-certificate-file="/data/pulsar/tls-certificate-file"
##### Pulsar oauth2 issuer-url. For more information, see the Pulsar website
    ↪ : https://pulsar.apache.org/docs/2.10.x/client-libraries-go/#tls-
    ↪ encryption-and-authentication
oauth2.oauth2-issuer-url="https://xxxx.auth0.com"
##### Pulsar oauth2 audience
oauth2.oauth2-audience="https://xxxx.auth0.com/api/v2/"
##### Pulsar oauth2 private-key
oauth2.oauth2-private-key="/data/pulsar/privateKey"
##### Pulsar oauth2 client-id
oauth2.oauth2-client-id="0Xx...Yyxeny"
##### Pulsar oauth2 oauth2-scope
oauth2.oauth2-scope="xxxx"
##### The number of cached Pulsar producers in TiCDC. The value is 10240 by
    ↪ default. Each Pulsar producer corresponds to one topic. If the number
    ↪  of topics you need to replicate is larger than the default value,
    ↪ you need to increase the number.
pulsar-producer-cache-size=10240
##### Pulsar data compression method. No compression is used by default.
    ↪ Optional values are "lz4", "zlib", and "zstd".
```

```
compression-type=""
##### The timeout for the Pulsar client to establish a TCP connection with
    ↪ the server. The value is 5 seconds by default.
connection-timeout=5
##### The timeout for Pulsar clients to initiate operations such as creating
    ↪  and subscribing to a topic. The value is 30 seconds by default.
operation-timeout=30
##### The maximum number of messages in a single batch for a Pulsar producer
    ↪  to send. The value is 1000 by default.
batching-max-messages=1000
##### The interval at which Pulsar producer messages are saved for batching.
    ↪  The value is 10 milliseconds by default.
batching-max-publish-delay=10
##### The timeout for a Pulsar producer to send a message. The value is 30
    ↪ seconds by default.
send-timeout=30
```

Best practice

- You need to specify the `protocol` parameter when creating a changefeed. Currently, only the `canal-json` protocol is supported for replicating data to Pulsar.
- The `pulsar-producer-cache-size` parameter indicates the number of producers cached in the Pulsar client. Because each producer in Pulsar can only correspond to one topic, TiCDC adopts the LRU method to cache producers, and the default limit is 10240. If the number of topics you need to replicate is larger than the default value, you need to increase the number.

TLS encrypted transmission

Starting from v7.5.1 and v8.0.0, TiCDC supports TLS encrypted transmission for Pulsar. The configuration example is as follows:

Sink URI:

```
--sink-uri="pulsar+ssl://127.0.0.1:6651/persistent://public/default/yktest?
    ↪ protocol=canal-json"
```

Configuration:

```
[sink.pulsar-config]
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
```

If the `tlsRequireTrustedClientCertOnConnect=true` parameter is configured for your Pulsar server, you also need to configure the `tls-key-file-path` and `tls-certificate-file` parameters in the changefeed configuration file. For example:

```
[sink.pulsar-config]
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
tls-certificate-file="/data/pulsar/tls-certificate-file"
tls-key-file-path="/data/pulsar/tls-key-file"
```

TiCDC authentication and authorization for Pulsar

The following is a sample configuration when you use token authentication with Pulsar:

- Token

  Sink URI:

  ```
  --sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
      ↪ protocol=canal-json"
  ```

  Config parameter:

  ```
  [sink.pulsar-config]
  authentication-token = "xxxxxxxxxxxx"
  ```

- Token from file

  Sink URI:

  ```
  --sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
      ↪ protocol=canal-json"
  ```

  Config parameter:

  ```
  [sink.pulsar-config]
  # Pulsar uses tokens for authentication on the Pulsar server. Specify
      ↪ the path to the token file, which will be read from the TiCDC
      ↪ server.
  token-from-file="/data/pulsar/token-file.txt"
  ```

- mTLS authentication

  Sink URI:

  ```
  --sink-uri="pulsar+ssl://127.0.0.1:6651/persistent://public/default/
      ↪ yktest?protocol=canal-json"
  ```

  Config parameters:

  ```
  [sink.pulsar-config]
  # Certificate path of the Pulsar mTLS authentication
  auth-tls-certificate-path="/data/pulsar/certificate"
  # Private key path of the Pulsar mTLS authentication
  ```

```
auth-tls-private-key-path="/data/pulsar/certificate.key"
# Path to the trusted certificate file of the Pulsar mTLS
    ↪ authentication
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
```

- OAuth2 authentication

  Starting from v7.5.1 and v8.0.0, TiCDC supports the OAuth2 authentication for Pulsar.

  Sink URI:

```
--sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
    ↪ protocol=canal-json"
```

  Config parameters:

```
[sink.pulsar-config]
# Pulsar oauth2 issuer-url. For more information, see the Pulsar
    ↪ website: https://pulsar.apache.org/docs/2.10.x/client-libraries-
    ↪ go/#oauth2-authentication
oauth2.oauth2-issuer-url="https://xxxx.auth0.com"
# Pulsar oauth2 audience
oauth2.oauth2-audience="https://xxxx.auth0.com/api/v2/"
# Pulsar oauth2 private-key
oauth2.oauth2-private-key="/data/pulsar/privateKey"
# Pulsar oauth2 client-id
oauth2.oauth2-client-id="0Xx...Yyxeny"
# Pulsar oauth2 oauth2-scope
oauth2.oauth2-scope="xxxx"
```

Customize the dispatching rules for topics and partitions in Pulsar Sink

Matching rules for Matcher

Take the `dispatchers` configuration item in the following sample configuration file as an example:

```
[sink]
dispatchers = [
  {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1", partition
     ↪  = "ts" },
  {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2", partition
     ↪  = "index-value" },
  {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3", partition
     ↪  = "table"},
  {matcher = ['test6.*'], partition = "default"},
  {matcher = ['test7.*'], partition = "test123"}
]
```

- The tables that match a matcher rule are dispatched according to the policy specified by the corresponding topic expression. For example, the table `test3.aa` is dispatched according to `Topic expression 2`, and the table `test5.aa` is dispatched according to `Topic expression 3`.
- For a table that matches more than one matcher rule, it is dispatched according to the first matching topic expression. For example, the table `test1.aa` is dispatched according to `Topic expression 1`.
- For tables that do not match any matcher, the corresponding data change events are sent to the default topic specified in `-sink-uri`. For example, the table `test10.aa` is sent to the default topic.
- For tables that match the matcher rule but do not have a topic dispatcher specified, the corresponding data changes are sent to the default topic specified in `-sink-uri`. For example, the table `test6.abc` is sent to the default topic.

Topic dispatcher

You can use `topic = "xxx"` to specify a topic dispatcher and use topic expressions to implement flexible topic dispatching policies. It is recommended that the total number of topics be less than 1000.

The format of a topic expression is `[tenant_and_namespace][prefix]{schema}[middle][{table}][suffix]`. The following are the meanings of each part:

- `tenant_and_namespace`: Optional. Represents the tenant and namespace of the topic, such as `persistent://abc/def/`. If not configured, it means that the topic is in the default namespace `default` under the default tenant `public` of Pulsar.
- `prefix`: Optional. Represents the prefix of the topic name.
- `{schema}`: Optional. Represents the database name.
- `middle`: Optional. Represents the separator between a database name and a table name.
- `{table}`: Optional. Represents the table name.
- `suffix`: Optional. Represents the suffix of the topic name.

`prefix`, `middle`, and `suffix` only support uppercase and lowercase letters (`a-z`, `A-Z`), numbers (`0-9`), dots (`.`), underscores (`_`), and hyphens (`-`). `{schema}` and `{table}` must be lowercase. Placeholders such as `{Schema}` and `{TABLE}` that contain uppercase letters are invalid.

The following are some examples:

- `matcher = ['test1.table1', 'test2.table2'], topic = "hello_{schema}_{table}"`
  - Data change events corresponding to the table `test1.table1` are despatched to a topic named `hello_test1_table1`.
  - Data change events corresponding to the table `test2.table2` are despatched to a topic named `hello_test2_table2`.

- `matcher = ['test3.*', 'test4.*'], topic = "hello_{schema}_world"`
  - Data change events for all tables under `test3` are despatched to a topic named `hello_test3_world`.
  - Data change events for all tables under `test4` are despatched to a topic named `hello_test4_world`.
- `matcher = ['*.*'], topic = "{schema}_{table}"`
  - For all tables that TiCDC listens on, they are despatched to separate topics according to the `databaseName_tableName` rule. For example, for the table `test.account`, TiCDC despatches its data change log to a topic named `test_account`.

Dispatch DDL events

Database-level DDL events

DDL statements such as `CREATE DATABASE` and `DROP DATABASE` that are not related to a specific table are called database-level DDL statements. Events corresponding to database-level DDL statements are dispatched to the default topic specified in `--sink-uri`.

Table-level DDL events

DDL statements such as `ALTER TABLE` and `CREATE TABLE` that are related to a specific table are called table-level DDL statements. Events corresponding to table-level DDL statements are dispatched to an appropriate topic according to the configuration of `dispatchers`.

For example, for a `dispatchers` configuration like `matcher = ['test.*'], topic = {schema}_{table}`, the DDL events are despatched as follows:

- If a DDL event only involves a single table, the DDL event is dispatched to the appropriate topic as it is. For example, for the DDL event `DROP TABLE test.table1`, the event is dispatched to the topic named `test_table1`.
- If a DDL event involves more than one table (`RENAME TABLE`, `DROP TABLE`, and `DROP VIEW` might all involve more than one table), the single DDL event is split into multiple ones and dispatched to appropriate topics. For example, for the DDL event `RENAME TABLE test.table1 TO test.table10, test.table2 TO test.table20`, the processing is as follows:
  - Dispatch the DDL event for `RENAME TABLE test.table1 TO test.table10` to a topic named `test_table1`.
  - Dispatch the DDL event for `RENAME TABLE test.table2 TO test.table20` to a topic named `test_table2`.

Partition dispatcher

Currently, TiCDC only supports consumers to consume messages using the exclusive subscription model, that is, each consumer can consume messages from all partitions in a topic.

You can specify a partition dispatcher with `partition = "xxx"`. The following partition dispatches are supported: `default`, `ts`, `index-value`, and `table`. If you fill in any other string, TiCDC will pass that string as the `key` of the message in the messages sent to the Pulsar server.

The dispatching rules are as follows:

- `default`: By default, events are dispatched by the schema name and table name, which is the same as when `table` is specified.
- `ts`: Use commitTs of row changes to perform hash calculation and dispatch events.
- `index-value`: Use the value of the table primary key or unique index to perform hash calculation and dispatch events.
- `table`: Use the schema name and table name to perform hash calculation and dispatch events.
- Other self-defined string: The self-defined string is used directly as the key for the Pulsar message, and the Pulsar producer uses this key value for dispatching.

13.9.3.2.4 Replicate Data to Storage Services

Starting from TiDB v6.5.0, TiCDC supports saving row change events to storage services, including Amazon S3, GCS, Azure Blob Storage, and NFS. This document describes how to create a changefeed that replicates incremental data to such storage services using TiCDC, and how data is stored. The organization of this document is as follows:

- How to replicate data to storage services.
- How data is stored in storage services.

Replicate change data to storage services

Run the following command to create a changefeed task:

```
cdc cli changefeed create \
    --server=http://10.0.10.25:8300 \
    --sink-uri="s3://logbucket/storage_test?protocol=canal-json" \
    --changefeed-id="simple-replication-task"
```

The output is as follows:

```
Info: {"upstream_id":7171388873935111376,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"s3://logbucket/storage_test?protocol=
    ↪ canal-json","create_time":"2024-11-11T18:52:05.566016967+08:00","
    ↪ start_ts":437706850431664129,"engine":"unified","config":{"case_
    ↪ sensitive":false,"enable_old_value":true,"force_replicate":false,"
```

```
↪ ignore_ineligible_table":false,"check_gc_safe_point":true,"enable_
↪ sync_point":false,"sync_point_interval":600000000000,"sync_point_
↪ retention":86400000000000,"filter":{"rules":["*.*"],"event_filters":
↪ null},"mounter":{"worker_num":16},"sink":{"protocol":"canal-json","
↪ schema_registry":"","csv":{"delimiter":",","quote":"\"","null":"\\N
↪ ","include_commit_ts":false},"column_selectors":null,"transaction_
↪ atomicity":"none","encoder_concurrency":16,"terminator":"\r\n","date_
↪ separator":"none","enable_partition_separator":false},"consistent":{"
↪ level":"none","max_log_size":64,"flush_interval":2000,"storage
↪ ":""}},"state":"normal","creator_version":"v8.4.0"}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the changefeed. The format must match the `^[a-zA-Z0 ↪ -9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the changefeed. For details, see Configure sink URI.
- `--start-ts`: The starting TSO of the changefeed. TiCDC starts pulling data from this TSO. The default value is the current time.
- `--target-ts`: The ending TSO of the changefeed. TiCDC stops pulling data until this TSO. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: The configuration file of the changefeed. For details, see TiCDC changefeed configuration parameters.

Configure sink URI

This section describes how to configure Sink URI for storage services, including Amazon S3, GCS, Azure Blob Storage, and NFS. Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[host]/[path]?[query_parameters]
```

For `[query_parameters]` in the URI, the following parameters can be configured:

Parameter	Description	Default value	Value range
`worker- ↪ count`	Concurrency for saving data changes to cloud storage in the downstream.	`16`	`[1, 512]`

Parameter	Description	Default value	Value range
`flush-interval`	Interval for saving data changes to cloud storage in the downstream.	`5s`	`[2s, 10m]`
`file-size`	A data change file is stored to cloud storage if the number of bytes exceeds the value of this parameter.	`67108864`	`[1048576, 536870912]`
`protocol`	The protocol format of the messages sent to the downstream.	N/A	`canal-json` and `csv`

Parameter	Description	Default value	Value range
`enable-tidb-extension`	When `protocol` is set to `canal-json` and `enable-tidb-extension` is set to `true`, TiCDC sends WATERMARK events and adds the TiDB extension field to Canal-JSON messages.	`false`	`false` and `true`

Note:

Data change files are saved to the downstream when either `flush-interval` or `file-size` meets the requirements. The `protocol` parameter is mandatory. If TiCDC does not receive this parameter when creating a changefeed, the `CDC:ErrSinkUnknownProtocol` error is returned.

Configure sink URI for external storage

When storing data in a cloud storage system, you need to set different authentication parameters depending on the cloud service provider. This section describes the authentication methods when using Amazon S3, Google Cloud Storage (GCS), and Azure Blob Storage, and how to configure accounts to access the corresponding storage services.

The following is an example configuration for Amazon S3:

```
--sink-uri="s3://bucket/prefix?protocol=canal-json"
```

Before replicating data, you need to set appropriate access permissions for the directory in Amazon S3:

- Minimum permissions required by TiCDC: `s3:ListBucket`, `s3:PutObject`, and `s3:GetObject`.
- If the changefeed configuration item `sink.cloud-storage-config.flush-concurrency` is greater than 1, which means parallel uploading of single files is enabled, you need to additionally add permissions related to ListParts:
    - `s3:AbortMultipartUpload`
    - `s3:ListMultipartUploadParts`
    - `s3:ListBucketMultipartUploads`

If you have not created a replication data storage directory, refer to Create a bucket to create an S3 bucket in the specified region. If necessary, you can also create a folder in the bucket by referring to Organize objects in the Amazon S3 console by using folders.

You can configure an account to access Amazon S3 in the following ways:

- Method 1: Specify the access key

  If you specify an access key and a secret access key, authentication is performed according to them. In addition to specifying the key in the URI, the following methods are supported:

    - TiCDC reads the `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables.
    - TiCDC reads the `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY` environment variables.
    - TiCDC reads the shared credentials file in the path specified by the `$AWS_SHARED_CREDENTIALS_FILE` environment variable.
    - TiCDC reads the shared credentials file in the `~/.aws/credentials` path.

- Method 2: Access based on an IAM role

  Associate an IAM role with configured permissions to access Amazon S3 to the EC2 instance running the TiCDC server. After successful setup, TiCDC can directly access the corresponding directories in Amazon S3 without additional settings.

The following is an example configuration for GCS:

```
--sink-uri="gcs://bucket/prefix?protocol=canal-json"
```

You can configure the account used to access GCS by specifying an access key. Authentication is performed according to the specified `credentials-file`. In addition to specifying the key in the URI, the following methods are supported:

- TiCDC reads the file in the path specified by the `$GOOGLE_APPLICATION_CREDENTIALS` environment variable.
- TiCDC reads the file `~/.config/gcloud/application_default_credentials.json`.

- TiCDC obtains credentials from the metadata server when the cluster is running in GCE or GAE.

The following is an example configuration for Azure Blob Storage:

```
--sink-uri="azure://bucket/prefix?protocol=canal-json"
```

You can configure an account to access Azure Blob Storage in the following ways:

- Method 1: Specify a shared access signature

  If you configure `account-name` and `sas-token` in the URI, the storage account name and shared access signature token specified by this parameter are used. Because the shared access signature token has the `&` character, you need to encode it as `%26` before adding it to the URI. You can also directly encode the entire `sas-token` using percent-encoding.

- Method 2: Specify the access key

  If you configure `account-name` and `account-key` in the URI, the storage account name and key specified by this parameter are used. In addition to specifying the key file in the URI, TiCDC can also read the key from the environment variable `$AZURE_STORAGE_KEY`.

- Method 3: Use Azure AD to restore the backup

  Configure the environment variables `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET`.

> **Tip:**
>
> For more information about the URI parameters of Amazon S3, GCS, and Azure Blob Storage in TiCDC, see URI Formats of External Storage Services.

Configure sink URI for NFS

The following is an example configuration for NFS:

```
--sink-uri="file:///my-directory/prefix?protocol=canal-json"
```

Storage path structure

This section describes the storage path structure of data change records, metadata, and DDL events.

Data change records

Data change records are saved to the following path:

```
{scheme}://{prefix}/{schema}/{table}/{table-version-separator}/{partition-
    ↪ separator}/{date-separator}/CDC{num}.{extension}
```

- `scheme`: specifies the storage type, for example, `s3`, `gcs`, `azure`, or `file`.
- `prefix`: specifies the user-defined parent directory, for example, s3://**bucket/bbb/ccc**.
- `schema`: specifies the schema name, for example, s3://bucket/bbb/ccc/**test**.
- `table`: specifies the table name, for example, s3://bucket/bbb/ccc/test/**table1**.
- `table-version-separator`: specifies the separator that separates the path by the table version, for example, s3://bucket/bbb/ccc/test/table1/**9999**.
- `partition-separator`: specifies the separator that separates the path by the table partition, for example, s3://bucket/bbb/ccc/test/table1/9999/**20**.
- `date-separator`: classifies the files by the transaction commit date. The default value is `day`. Value options are:
    - `none`: no `date-separator`. For example, all files with `test.table1` version being `9999` are saved to `s3://bucket/bbb/ccc/test/table1/9999`.
    - `year`: the separator is the year of the transaction commit date, for example, s3://bucket/bbb/ccc/test/table1/9999/**2022**.
    - `month`: the separator is the year and month of the transaction commit date, for example, s3://bucket/bbb/ccc/test/table1/9999/**2022-01**.
    - `day`: the separator is the year, month, and day of the transaction commit date, for example, s3://bucket/bbb/ccc/test/table1/9999/**2022-01-02**.
- `num`: saves the serial number of the file that records the data change, for example, s3://bucket/bbb/ccc/test/table1/9999/2022-01-02/CDC**000005**.csv.
- `extension`: specifies the extension of the file. TiDB v6.5.0 supports the CSV and Canal-JSON formats.

> **Note:**
>
> The table version changes in the following scenarios:
>
> - The upstream TiDB performs a DDL operation on the table.
> - TiCDC schedules the table across nodes.
> - The changefeed to which the table belongs restarts.
>
> Note that the change of the table version does not mean the change of the table schema. For example, adding a comment to a column does not cause the schema file content to change.

Index files

An index file is used to prevent written data from being overwritten by mistake. It is stored in the same path as the data change records.

```
{scheme}://{prefix}/{schema}/{table}/{table-version-separator}/{partition-
    ↪ separator}/{date-separator}/meta/CDC.index
```

The index file records the largest file name used in the current directory. For example:

```
CDC000005.csv
```

In this example, the files `CDC000001.csv` through `CDC000004.csv` in this directory are occupied. When a table scheduling or node restart occurs in the TiCDC cluster, the new node reads the index file and determines if `CDC000005.csv` is occupied. If it is not occupied, the new node writes the file starting from `CDC000005.csv`. If it is occupied, it starts writing from `CDC000006.csv`, which prevents overwriting data written by other nodes.

Metadata

Metadata is saved in the following path:

```
{protocol}://{prefix}/metadata
```

Metadata is a JSON-formatted file, for example:

```
{
    "checkpoint-ts":433305438660591626
}
```

- `checkpoint-ts`: Transactions with `commit-ts` smaller than `checkpoint-ts` are written to the target storage in the downstream.

DDL events

DDL events at the table level

When a DDL event of an upstream table causes a table version change, TiCDC automatically does the following:

- Switches to a new path to write data change records. For example, when the version of `test.table1` changes to `441349361156227074`, TiCDC changes to the `s3://bucket/bbb/ccc/test/table1/441349361156227074/2022-01-02/` path to write data change records.
- Generates a schema file in the following path to store the table schema information:

```
{scheme}://{prefix}/{schema}/{table}/meta/schema_{table-version}_{hash
    ↪ }.json
```

Taking the `schema_441349361156227074_3131721815.json` schema file as an example, the table schema information in this file is as follows:

```
{
    "Table":"table1",
    "Schema":"test",
    "Version":1,
    "TableVersion":441349361156227074,
    "Query":"ALTER TABLE test.table1 ADD OfficeLocation blob(20)",
    "Type":5,
    "TableColumns":[
        {
            "ColumnName":"Id",
            "ColumnType":"INT",
            "ColumnNullable":"false",
            "ColumnIsPk":"true"
        },
        {
            "ColumnName":"LastName",
            "ColumnType":"CHAR",
            "ColumnLength":"20"
        },
        {
            "ColumnName":"FirstName",
            "ColumnType":"VARCHAR",
            "ColumnLength":"30"
        },
        {
            "ColumnName":"HireDate",
            "ColumnType":"DATETIME"
        },
        {
            "ColumnName":"OfficeLocation",
            "ColumnType":"BLOB",
            "ColumnLength":"20"
        }
    ],
    "TableColumnsTotal":"5"
}
```

- `Table`: Table name.
- `Schema`: Schema name.
- `Version`: Protocol version of the storage sink.
- `TableVersion`: Table version.
- `Query`: DDL statement.

- `Type`: DDL type.
- `TableColumns`: An array of one or more maps, each of which describes a column in the source table.
    - `ColumnName`: Column name.
    - `ColumnType`: Column type. For details, see Data type.
    - `ColumnLength`: Column length. For details, see Data type.
    - `ColumnPrecision`: Column precision. For details, see Data type.
    - `ColumnScale`: The number of digits following the decimal point (the scale). For details, see Data type.
    - `ColumnNullable`: The column can be NULL when the value of this option is `true`.
    - `ColumnIsPk`: The column is part of the primary key when the value of this option is `true`.
- `TableColumnsTotal`: The size of the `TableColumns` array.

DDL events at the database level

When a database-level DDL event is performed in the upstream database, TiCDC automatically generates a schema file in the following path to store the database schema information:

```
{scheme}://{prefix}/{schema}/meta/schema_{table-version}_{hash}.json
```

Taking the `schema_441349361156227000_3131721815.json` schema file as an example, the database schema information in this file is as follows:

```
{
  "Table": "",
  "Schema": "schema1",
  "Version": 1,
  "TableVersion": 441349361156227000,
  "Query": "CREATE DATABASE `schema1`",
  "Type": 1,
  "TableColumns": null,
  "TableColumnsTotal": 0
}
```

Data type

This section describes the data types used in the `schema_{table-version}_{hash}.json` file (hereafter referred to as "schema file" in the following sections). The data types are defined as `T(M[, D])`. For details, see Data Types.

Integer types

Integer types in TiDB are defined as `IT[(M)] [UNSIGNED]`, where

- `IT` is the integer type, which can be `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, `BIGINT`, or `BIT`.
- `M` is the display width of the type.

Integer types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{IT} [UNSIGNED]",
    "ColumnPrecision":"{M}"
}
```

Decimal types

Decimal types in TiDB are defined as `DT[(M,D)][UNSIGNED]`, where

- `DT` is the floating-point type, which can be `FLOAT`, `DOUBLE`, `DECIMAL`, or `NUMERIC`.
- `M` is the precision of the data type, or the total number of digits.
- `D` is the number of digits following the decimal point.

Decimal types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{DT} [UNSIGNED]",
    "ColumnPrecision":"{M}",
    "ColumnScale":"{D}"
}
```

Date and time types

Date types in TiDB are defined as `DT`, where

- `DT` is the date type, which can be `DATE` or `YEAR`.

The date types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{DT}"
}
```

The time types in TiDB are defined as `TT[(M)]`, where

- `TT` is the time type, which can be `TIME`, `DATETIME`, or `TIMESTAMP`.
- `M` is the precision of seconds in the range from 0 to 6.

The time types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{TT}",
    "ColumnScale":"{M}"
}
```

String types

The string types in TiDB are defined as `ST[(M)]`, where

- `ST` is the string type, which can be `CHAR`, `VARCHAR`, `TEXT`, `BINARY`, `BLOB`, or `JSON`.
- `M` is the maximum length of the string.

The string types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{ST}",
    "ColumnLength":"{M}"
}
```

Enum and Set types

The Enum and Set types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{ENUM/SET}",
}
```

13.9.3.3 Manage Changefeeds

This document describes how to create and manage TiCDC changefeeds by using the TiCDC command-line tool `cdc cli`. You can also manage changefeeds via the HTTP interface of TiCDC. For details, see TiCDC OpenAPI.

13.9.3.3.1 Create a replication task

Run the following command to create a replication task:

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7178706266519722477,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"mysql://root:xxxxx@127.0.0.1:4000/?time
    ↪ -zone=","create_time":"2024-11-11T15:05:46.679218+08:00","start_ts
    ↪ ":438156275634929669,"engine":"unified","config":{"case_sensitive":
    ↪ false,"enable_old_value":true,"force_replicate":false,"ignore_
    ↪ ineligible_table":false,"check_gc_safe_point":true,"enable_sync_point
    ↪ ":true,"bdr_mode":false,"sync_point_interval":30000000000,"sync_point
    ↪ _retention":3600000000000,"filter":{"rules":["test.*"],"event_filters
    ↪ ":null},"mounter":{"worker_num":16},"sink":{"protocol":"","schema_
    ↪ registry":"","csv":{"delimiter":",","quote":"\"","null":"\\N","
    ↪ include_commit_ts":false},"column_selectors":null,"transaction_
    ↪ atomicity":"none","encoder_concurrency":16,"terminator":"\r\n","date_
    ↪ separator":"none","enable_partition_separator":false},"consistent":{"
    ↪ level":"none","max_log_size":64,"flush_interval":2000,"storage
    ↪ ":""}},"state":"normal","creator_version":"v8.4.0"}
```

13.9.3.3.2 Query the replication task list

Run the following command to query the replication task list:

```
cdc cli changefeed list --server=http://10.0.10.25:8300
```

```
[{
    "id": "simple-replication-task",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "2020-07-07 16:07:44.881",
      "error": null
    }
}]
```

- `checkpoint` indicates that TiCDC has already replicated data before this time point to the downstream.
- `state` indicates the state of the replication task.
    - `normal`: The replication task runs normally.
    - `stopped`: The replication task is stopped (manually paused).
    - `error`: The replication task is stopped (by an error).
    - `removed`: The replication task is removed. Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, run the `changefeed query` command.

- `finished`: The replication task is finished (data is replicated to the `target-ts`). Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, run the `changefeed query` command.

13.9.3.3.3 Query a specific replication task

To query a specific replication task, run the `changefeed query` command. The query result includes the task information and the task state. You can specify the `--simple` or `-s` argument to simplify the query result that will only include the basic replication state and the checkpoint information. If you do not specify this argument, detailed task configuration, replication states, and replication table information are output.

```
cdc cli changefeed query -s --server=http://10.0.10.25:8300 --changefeed-id=
    ↪ simple-replication-task
```

```
{
 "state": "normal",
 "tso": 419035700154597378,
 "checkpoint": "2020-08-27 10:12:19.579",
 "error": null
}
```

In the preceding command and result:

- `state` is the replication state of the current changefeed. Each state must be consistent with the state in `changefeed list`.
- `tso` represents the largest transaction TSO in the current changefeed that has been successfully replicated to the downstream.
- `checkpoint` represents the corresponding time of the largest transaction TSO in the current changefeed that has been successfully replicated to the downstream.
- `error` records whether an error has occurred in the current changefeed.

```
cdc cli changefeed query --server=http://10.0.10.25:8300 --changefeed-id=
    ↪ simple-replication-task
```

```
{
  "info": {
    "sink-uri": "mysql://127.0.0.1:3306/?max-txn-row=20\u0026worker-count
        ↪ =4",
    "opts": {},
    "create-time": "2020-08-27T10:33:41.687983832+08:00",
    "start-ts": 419036036249681921,
    "target-ts": 0,
    "admin-job-type": 0,
```

```
    "sort-engine": "unified",
    "sort-dir": ".",
    "config": {
      "case-sensitive": false,
      "filter": {
        "rules": [
          "*.*"
        ],
        "ignore-txn-start-ts": null,
        "ddl-allow-list": null
      },
      "mounter": {
        "worker-num": 16
      },
      "sink": {
        "dispatchers": null,
      },
      "scheduler": {
        "type": "table-number",
        "polling-time": -1
      }
    },
    "state": "normal",
    "history": null,
    "error": null
  },
  "status": {
    "resolved-ts": 419036036249681921,
    "checkpoint-ts": 419036036249681921,
    "admin-job-type": 0
  },
  "count": 0,
  "task-status": [
    {
      "capture-id": "97173367-75dc-490c-ae2d-4e990f90da0f",
      "status": {
        "tables": {
          "47": {
            "start-ts": 419036036249681921
          }
        },
        "operation": null,
        "admin-job-type": 0
      }
    }
```

```
  ]
}
```

In the preceding command and result:

- `info` is the replication configuration of the queried changefeed.
- `status` is the replication state of the queried changefeed.
    - `resolved-ts`: The largest transaction `TS` in the current changefeed. Note that this `TS` has been successfully sent from TiKV to TiCDC.
    - `checkpoint-ts`: The largest transaction `TS` in the current `changefeed`. Note that this `TS` has been successfully written to the downstream.
    - `admin-job-type`: The status of a changefeed:
        - `0`: The state is normal.
        - `1`: The task is paused. When the task is paused, all replicated `processors` exit. The configuration and the replication status of the task are retained, so you can resume the task from `checkpoint-ts`.
        - `2`: The task is resumed. The replication task resumes from `checkpoint-ts`.
        - `3`: The task is removed. When the task is removed, all replicated `processors` are ended, and the configuration information of the replication task is cleared up. Only the replication status is retained for later queries.
- `task-status` indicates the state of each replication sub-task in the queried changefeed.

13.9.3.3.4 Pause a replication task

Run the following command to pause a replication task:

```
cdc cli changefeed pause --server=http://10.0.10.25:8300 --changefeed-id
    ↪ simple-replication-task
```

In the preceding command:

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to pause.

13.9.3.3.5 Resume a replication task

Run the following command to resume a paused replication task:

```
cdc cli changefeed resume --server=http://10.0.10.25:8300 --changefeed-id
    ↪ simple-replication-task
```

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to resume.

- `--overwrite-checkpoint-ts`: starting from v6.2.0, you can specify the starting TSO of resuming the replication task. TiCDC starts pulling data from the specified TSO. The argument accepts `now` or a specific TSO (such as 434873584621453313). The specified TSO must be in the range of (GC safe point, CurrentTSO]. If this argument is not specified, TiCDC replicates data from the current `checkpoint-ts` by default. You can use the `cdc cli changefeed list` command to check the current value of `checkpoint-ts`.
- `--no-confirm`: when the replication is resumed, you do not need to confirm the related information. Defaults to `false`.

Note:

- If the TSO specified in `--overwrite-checkpoint-ts` (`t2`) is larger than the current checkpoint TSO in the changefeed (`t1`), data between `t1` and `t2` will not be replicated to the downstream. This causes data loss. You can obtain `t1` by running `cdc cli changefeed query`.
- If the TSO specified in `--overwrite-checkpoint-ts` (`t2`) is smaller than the current checkpoint TSO in the changefeed (`t1`), TiCDC pulls data from an old time point (`t2`), which might cause data duplication (for example, if the downstream is MQ sink).

13.9.3.3.6 Remove a replication task

Run the following command to remove a replication task:

```
cdc cli changefeed remove --server=http://10.0.10.25:8300 --changefeed-id
    ↪ simple-replication-task
```

In the preceding command:

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to remove.

13.9.3.3.7 Update task configuration

TiCDC supports modifying the configuration of the replication task (not dynamically). To modify the changefeed configuration, pause the task, modify the configuration, and then resume the task.

```
cdc cli changefeed pause -c test-cf --server=http://10.0.10.25:8300
cdc cli changefeed update -c test-cf --server=http://10.0.10.25:8300 --sink-
    ↪ uri="mysql://127.0.0.1:3306/?max-txn-row=20&worker-count=8" --config=
    ↪ changefeed.toml
```

```
cdc cli changefeed resume -c test-cf --server=http://10.0.10.25:8300
```

Currently, you can modify the following configuration items:

- `sink-uri` of the changefeed.
- The changefeed configuration file and all configuration items in the file.
- The `target-ts` of the changefeed.

13.9.3.3.8 Manage processing units of replication sub-tasks (`processor`)

- Query the `processor` list:

```
cdc cli processor list --server=http://10.0.10.25:8300
```

```
[
        {
                "id": "9f84ff74-abf9-407f-a6e2-56aa35b33888",
                "capture-id": "b293999a-4168-4988-a4f4-35d9589b226b",
                "changefeed-id": "simple-replication-task"
        }
]
```

- Query a specific changefeed which corresponds to the status of a specific replication task:

```
cdc cli processor query --server=http://10.0.10.25:8300 --changefeed-id
    ↪ =simple-replication-task --capture-id=b293999a-4168-4988-a4f4-35
    ↪ d9589b226b
```

```
{
  "status": {
    "tables": {
      "56": {   # 56 ID of the replication table, corresponding to tidb_
          ↪ table_id of a table in TiDB
        "start-ts": 417474117955485702
      }
    },
    "operation": null,
    "admin-job-type": 0
  },
  "position": {
    "checkpoint-ts": 417474143881789441,
    "resolved-ts": 417474143881789441,
    "count": 0
  }
}
```

In the preceding command:

- `status.tables`: Each key number represents the ID of the replication table, corresponding to `tidb_table_id` of a table in TiDB.
- `resolved-ts`: The largest TSO among the sorted data in the current processor.
- `checkpoint-ts`: The largest TSO that has been successfully written to the downstream in the current processor.

13.9.3.3.9 Replicate tables with the new framework for collations enabled

Starting from v4.0.15, v5.0.4, v5.1.1 and v5.2.0, TiCDC supports tables that have enabled new framework for collations.

13.9.3.3.10 Replicate tables without a valid index

Since v4.0.8, TiCDC supports replicating tables that have no valid index by modifying the task configuration. To enable this feature, configure in the changefeed configuration file as follows:

```
force-replicate = true
```

> **Warning:**
>
> When `force-replicate` is set to `true`, data consistency is not guaranteed. For tables without a valid index, operations such as `INSERT` and `REPLACE` are not reentrant, so there is a risk of data redundancy. TiCDC guarantees that data is distributed only at least once during the replication process. Therefore, enabling this feature to replicate tables without a valid index will definitely cause data redundancy. If you do not accept data redundancy, it is recommended to add an effective index, such as adding a primary key column with the `AUTO RANDOM` attribute.

13.9.3.3.11 Unified Sorter

> **Note:**
>
> Starting from v6.0.0, TiCDC uses the DB Sorter engine by default, and no longer uses the Unified Sorter. It is recommended that you do not configure the `sort engine` item.

Unified sorter is the sorting engine in TiCDC. It can mitigate OOM problems caused by the following scenarios:

- The data replication task in TiCDC is paused for a long time, during which a large amount of incremental data is accumulated and needs to be replicated.
- The data replication task is started from an early timestamp so it becomes necessary to replicate a large amount of incremental data.

For the changefeeds created using `cdc cli` after v4.0.13, Unified Sorter is enabled by default; for the changefeeds that have existed before v4.0.13, the previous configuration is used.

To check whether or not the Unified Sorter feature is enabled on a changefeed, you can run the following example command (assuming the IP address of the PD instance is `http://10.0.10.25:2379`):

```
cdc cli --server="http://10.0.10.25:8300" changefeed query --changefeed-id=
    ↪ simple-replication-task | grep 'sort-engine'
```

In the output of the above command, if the value of `sort-engine` is "unified", it means that Unified Sorter is enabled on the changefeed.

Note:

- If your servers use mechanical hard drives or other storage devices that have high latency or limited bandwidth, the performance of Unified Sorter will be affected significantly.
- By default, Unified Sorter uses `data_dir` to store temporary files. It is recommended to ensure that the free disk space is greater than or equal to 500 GiB. For production environments, it is recommended to ensure that the free disk space on each node is greater than (the maximum `checkpoint-ts` delay allowed by the business) * (upstream write traffic at business peak hours). In addition, if you plan to replicate a large amount of historical data after `changefeed` is created, make sure that the free space on each node is greater than the amount of the replicated data.

13.9.3.4 TiCDC Client Authentication

Starting from v8.1.0, TiCDC supports client authentication using Mutual Transport Layer Security (mTLS) or TiDB username and password.

- mTLS authentication provides security control at the transport layer, enabling TiCDC to verify the client identity.
- TiDB username and password authentication provides security control at the application layer, ensuring that only authorized users can log in through the TiCDC node.

These two authentication methods can be used either independently or in combination to meet different scenarios and security requirements.

> **Note:**
>
> To ensure the security of network access, it is strongly recommended to use TiCDC client authentication only when TLS is enabled. If TLS is not enabled, the username and password are transmitted as plaintext over the network, which can lead to serious credential leaks.

13.9.3.4.1 Use mTLS for client authentication

1. In the TiCDC server, configure the `security.mtls` parameter as `true` to enable mTLS authentication:

```
[security]
# This parameter controls whether to enable the TLS client
    ↪ authentication. The default value is false.
mtls = true
```

2. Configure the client certificate.

   When using the TiCDC command-line tool, you can specify the client certificate using the following methods. TiCDC will attempt to read the client certificate in the following order:

   1. Specify the certificate and private key using the command-line parameters `--cert` and `--key`. If the server uses a self-signed certificate, you also need to specify the trusted CA certificate using the `--ca` parameter.

```
cdc cli changefeed list --cert client.crt --key client.key --ca ca.
    ↪ crt
```

   2. Specify the paths to the certificate, private key, and CA certificate using the environment variables `TICDC_CERT_PATH`, `TICDC_KEY_PATH`, and `TICDC_CA_PATH`.

```
export TICDC_CERT_PATH=client.crt
export TICDC_KEY_PATH=client.key
export TICDC_CA_PATH=ca.crt
```

3. Specify the certificate using the shared credential file `~/.ticdc/credentials`. You can modify the configuration using the `cdc cli configure-credentials` command.

When using TiCDC OpenAPI, you can specify the client certificate and private key using `--cert` and `--key`. If the server uses a self-signed certificate, you also need to specify the trusted CA certificate using the `--cacert` parameter. For example:

```
curl -X GET http://127.0.0.1:8300/api/v2/status --cert client.crt --key
    ↪  client.key --cacert ca.crt
```

13.9.3.4.2 Use TiDB username and password for client authentication

1. Create a user in TiDB and grant the user permission to log in from the TiCDC node.

```
CREATE USER 'test'@'ticdc_ip_address' IDENTIFIED BY 'password';
```

2. In the TiCDC server, configure `security.client-user-required` and `security.client-allowed-user` to enable username and password authentication:

```
[security]
# This parameter controls whether to use username and password for
    ↪ client authentication. The default value is false.
client-user-required = true
# This parameter lists the usernames that are allowed for client
    ↪ authentication. Authentication requests with usernames not in
    ↪ this list will be rejected. The default value is null.
client-allowed-user = ["test"]
```

3. Specify the username and password of the user created in step 1.

   When using the TiCDC command-line tool, you can specify the username and password using the following methods. TiCDC will attempt to read the client certificate in the following order:

   1. Specify the username and password using the command-line parameters `--user` and `--password`:

      ```
      cdc cli changefeed list --user test --password password
      ```

   2. Specify the username using the command-line parameter `--user`. Then, enter the password in the terminal:

      ```
      cdc cli changefeed list --user test
      ```

   3. Specify the username and password using the environment variables `TICDC_USER` and `TICDC_PASSWORD`:

```
export TICDC_USER=test
export TICDC_PASSWORD=password
```

4. Specify the username and password using the shared credential file `~/.ticdc/credentials`. You can modify the configuration using the `cdc cli configure-credentials` command.

When using TiCDC OpenAPI, you can specify the username and password using `--user <user>:<password>`. For example:

```
curl -X GET http://127.0.0.1:8300/api/v2/status --user test:password
```

13.9.3.5 Changefeed Log Filters

TiCDC supports filtering data by tables and events. This document introduces how to use the two types of filters.

13.9.3.5.1 Table filter

Table filter is a feature that allows you to keep or filter out specific databases and tables by specifying the following configurations:

```
[filter]
#### Filter rules
rules = ['*.*', '!test.*']
```

Common filter rules:

- `rules = ['*.*']`
  - Replicate all tables (not including system tables)
- `rules = ['test1.*']`
  - Replicate all tables in the `test1` database
- `rules = ['*.*', '!scm1.tbl2']`
  - Replicate all tables except for the `scm1.tbl2` table
- `rules = ['scm1.tbl2', 'scm1.tbl3']`
  - Only replicate tables `scm1.tbl2` and `scm1.tbl3`
- `rules = ['scm1.tidb_*']`
  - Replicate all tables in the `scm1` database whose names start with `tidb_`

For more information, see Table filter syntax.

13.9.3.5.2 Event filter rules

Starting in v6.2.0, TiCDC supports event filter. You can configure event filter rules to filter out the DML and DDL events that meet the specified conditions.

The following is an example of event filter rules:

```
[filter]
#### The event filter rules must be under the `[filter]` configuration. You
    ↪ can configure multiple event filters at the same time.

[[filter.event-filters]]
matcher = ["test.worker"] # matcher is an allow list, which means this rule
    ↪ only applies to the worker table in the test database.
ignore-event = ["insert"] # Ignore insert events.
ignore-sql = ["^drop", "add column"] # Ignore DDLs that start with "drop" or
    ↪  contain "add column".
ignore-delete-value-expr = "name = 'john'" # Ignore delete DMLs that contain
    ↪  the condition "name = 'john'".
ignore-insert-value-expr = "id >= 100" # Ignore insert DMLs that contain the
    ↪  condition "id >= 100".
ignore-update-old-value-expr = "age < 18 or name = 'lili'" # Ignore update
    ↪ DMLs whose old value contains "age < 18" or "name = 'lili'".
ignore-update-new-value-expr = "gender = 'male' and age > 18" # Ignore
    ↪ update DMLs whose new value contains "gender = 'male'" and "age >
    ↪ 18".
```

Description of configuration parameters:

- `matcher`: the database and table that this event filter rule applies to. The syntax is the same as table filter.
- `ignore-event`: the event type to be ignored. This parameter accepts an array of strings. You can configure multiple event types. Currently, the following event types are supported:

Event	Type	Alias	Description
all dml			Matches all DML events
all ddl			Matches all DDL events
insert	DML		Matches `insert` DML event
update	DML		Matches `update` DML event
delete	DML		Matches `delete` DML event
create schema	DDL	create database	Matches `create database` event

Event	Type	Alias	Description
drop schema	DDL	drop database	Matches `drop database` event
create table	DDL		Matches `create table` event
drop table	DDL		Matches `drop table` event
rename table	DDL		Matches `rename table` event
truncate table	DDL		Matches `truncate table` event
alter table	DDL		Matches `alter table` event, including all clauses of `alter table`, `create index` and `drop index`
add table partition	DDL		Matches `add table partition` event
drop table partition	DDL		Matches `drop table partition` event
truncate table partition	DDL		Matches `truncate table` ↪ `partition` event
create view	DDL		Matches `create view`event
drop view	DDL		Matches `drop view` event
modify schema charset and collate	DDL		Matches `modify schema` ↪ `charset and collate` event
recover table	DDL		Matches `recover table` event
rebase auto id	DDL		Matches `rebase auto id` event
modify table comment	DDL		Matches `modify table comment` event
modify table charset and collate	DDL		Matches `modify table` ↪ `charset and collate` event
exchange table partition	DDL		Matches `exchange table` ↪ `partition` event

Event	Type	Alias	Description
reorganize table partition	DDL		Matches `reorganize table partition` event
alter table partitioning	DDL		Matches `alter table partitioning` event
remove table partitioning	DDL		Matches `remove table partitioning` event
add column	DDL		Matches `add column` event
drop column	DDL		Matches `drop column` event
modify column	DDL		Matches `modify column` event
set default value	DDL		Matches `set default value` event
add primary key	DDL		Matches `add primary key` event
drop primary key	DDL		Matches `drop primary key` event
rename index	DDL		Matches `rename index` event
alter index visibility	DDL		Matches `alter index visibility` event
alter ttl info	DDL		Matches `alter ttl info` event
alter ttl remove	DDL		Matches DDL events that remove all TTL attributes of a table
multi schema change	DDL		Matches DDL events that change multiple attributes of a table within the same DDL statement

Note:

TiDB's DDL statements support changing multiple attributes of a single table at the same time, such as `ALTER TABLE t MODIFY COLUMN a INT , ADD COLUMN b INT, DROP COLUMN c;`. This operation is defined as MultiSchemaChange. If you want to filter out this type of DDL, you need to configure `"multi schema change"` in `ignore-event`.

- `ignore-sql`: the regular expressions of the DDL statements to be filtered out. This parameter accepts an array of strings, in which you can configure multiple regular expressions. This configuration only applies to DDL events.
- `ignore-delete-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `DELETE` type of DML events with a specified value.
- `ignore-insert-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `INSERT` type of DML events with a specified value.
- `ignore-update-old-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `UPDATE` type of DML events with a specified old value.
- `ignore-update-new-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `UPDATE` DML events with a specified new value.

Note:

- When TiDB updates a value in the column of the clustered index, TiDB splits an `UPDATE` event into a `DELETE` event and an `INSERT` event. TiCDC does not identify such events as an `UPDATE` event and thus cannot correctly filter out such events.
- When you configure a SQL expression, make sure all tables that matches `matcher` contain all the columns specified in the SQL expression. Otherwise, the replication task cannot be created. In addition, if the table schema changes during the replication, which results in a table no longer containing a required column, the replication task fails and cannot be resumed automatically. In such a situation, you must manually modify the configuration and resume the task.

13.9.3.6 Changefeed DDL Replication

This document describes the rules and special cases of DDL replication in TiCDC.

13.9.3.6.1 DDL allow list

Currently, TiCDC uses an allow list to determine whether to replicate a DDL statement. Only the DDL statements in the allow list are replicated to the downstream. The DDL statements not in the allow list are not replicated.

The allow list of DDL statements supported by TiCDC is as follows:

- create database
- drop database
- create table
- drop table
- add column
- drop column
- create index / add index
- drop index
- truncate table
- modify column
- rename table
- alter column default value
- alter table comment
- rename index
- add partition
- drop partition
- truncate partition
- create view
- drop view
- alter table character set
- alter database character set
- recover table
- add primary key
- drop primary key
- rebase auto id
- alter table index visibility
- exchange partition
- reorganize partition
- alter table ttl
- alter table remove ttl

13.9.3.6.2 DDL replication considerations

Asynchronous execution of `ADD INDEX` and `CREATE INDEX` DDLs

When the downstream is TiDB, TiCDC executes `ADD INDEX` and `CREATE INDEX` DDL operations asynchronously to minimize the impact on changefeed replication latency. This means that, after replicating `ADD INDEX` and `CREATE INDEX` DDLs to the downstream TiDB for execution, TiCDC returns immediately without waiting for the completion of the DDL execution. This avoids blocking subsequent DML executions.

During the execution of the `ADD INDEX` or `CREATE INDEX` DDL operation in the downstream, when TiCDC executes the next DDL operation of the same table, this DDL operation

might be blocked in the `queueing` state for a long time. This can cause TiCDC to repeatedly execute this DDL operation, and if retries take too long, it might lead to replication task failure. Starting from v8.4.0, if TiCDC has the `SUPER` permission of the downstream database, it periodically runs `ADMIN SHOW DDL JOBS` to check the status of asynchronously executed DDL tasks. TiCDC will wait for index creation to complete before proceeding with replication. Although this might increase replication latency, it avoids replication task failure.

Note:

- If the execution of certain downstream DMLs relies on indexes that have not completed replication, these DMLs might be executed slowly, thereby affecting TiCDC replication latency.
- Before replicating DDLs to the downstream, if a TiCDC node crashes or if the downstream is performing other write operations, the DDL replication has an extremely low probability of failure. You can check the downstream to see whether that occurs.

DDL replication considerations for renaming tables

Due to the lack of some context during the replication process, TiCDC has some constraints on the replication of `RENAME TABLE` DDLs.

Rename a single table in a DDL statement

If a DDL statement renames a single table, TiCDC only replicates the DDL statement when the old table name matches the filter rule. The following is an example.

Assume that the configuration file of your changefeed is as follows:

```
[filter]
rules = ['test.t*']
```

TiCDC processes this type of DDL as follows:

DDL	Whether to replicate	Reason for the handling
`RENAME TABLE test.t1 TO test.t2`	Replicate	`test.t1` matches the filter rule
`RENAME TABLE test.t1 TO ignore.t1`	Replicate	`test.t1` matches the filter rule

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `ignore` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `ignore` ↪ `.` ↪ `t2` ↪	Ignore	`ignore` ↪ `.` ↪ `t1` ↪ ↪ does not match the filter rule

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `n1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪	Report an error and exit the replication	The old table name `test` ↪ `.` ↪ `n1` ↪ ↪ does not match the filter rule, but the new table name `test` ↪ `.` ↪ `t1` ↪ ↪ matches the filter rule. This operation is illegal. In this case, refer to the

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `ignore` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪	Report an error and exit the replication	Same reason as above.

Rename multiple tables in a DDL statement

If a DDL statement renames multiple tables, TiCDC replicates the DDL statement only when the **old database name**, **old table names**, and **new database name** all match the filter rule.

In addition, TiCDC does not support the `RENAME TABLE` DDL that swaps the table names. The following is an example.

Assume that the configuration file of your changefeed is as follows:

```
[filter]
rules = ['test.t*']
```

TiCDC processes this type of DDL as follows:

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ `,` ↪ ↪ `test` ↪ `.` ↪ `t3` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t4` ↪	Replicate	All database names and table names match the filter rule.

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `ignore1` ↪ `,` ↪ ↪ `test` ↪ `.` ↪ `t3` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `ignore2` ↪	Replicate	The old database name, the old table names, and the new database name match the filter rule.

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `ignore` ↪ `.` ↪ `t1` ↪ `,` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t22` ↪ `;` ↪	Report an error	The new database name `ignore` ↪ does not match the filter rule.

DDL	Whether to replicate	Reason for the handling
`RENAME TABLE test.t1 TO test.t4, test.t3 TO test.t1, test.t4 TO test.t3;`	Report an error	The `RENAME TABLE` DDL swaps the names of `test.t1` and `test.t3` in one DDL statement, which TiCDC cannot handle correctly. In this case, refer to the error message for handling

DDL	Whether to replicate	Reason for the handling

DDL statement considerations

When executing cross-database DDL statements (such as `CREATE TABLE db1.t1 LIKE t2`) in the upstream, it is recommended that you explicitly specify all relevant database names in DDL statements (such as `CREATE TABLE db1.t1 LIKE db2.t2`). Otherwise, cross-database DDL statements might not be executed correctly in the downstream due to the lack of database name information.

Notes on using event filter rules to filter DDL events

If a filtered DDL statement involves table creation or deletion, TiCDC only filters out the DDL statement without affecting the replication behavior of DML statements. The following is an example.

Assume that the configuration file of your changefeed is as follows:

```
[filter]
rules = ['test.t*']

matcher = ["test.t1"] # This filter rule applies only to the t1 table in the test database.
ignore-event = ["create table", "drop table", "truncate table", "rename table"]
```

DDL	DDL behavior	DML behavior	Explanation
`CREATE` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `(` ↪ `id` ↪ ↪ `INT` ↪ `,` ↪ ↪ `name` ↪ ↪ `VARCHAR` ↪ `(50)` ↪ `)` ↪ `;` ↪	Ignore	Replicate	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `CREATE` ↪ ↪ `TABLE` ↪ ↪ event is ignored. The replication of DML events remains unaffected.

DDL	DDL behavior	DML behavior	Explanation
`CREATE` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ ↪ `(` ↪ `id` ↪ ↪ `INT` ↪ `,` ↪ ↪ `name` ↪ ↪ `VARCHAR` ↪ `(50)` ↪ `)` ↪ `;` ↪	Replicate	Replicate	`test` ↪ `.` ↪ `t2` ↪ ↪ does not match the event filter rule.

DDL	DDL behavior	DML behavior	Explanation
`CREATE` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `ignore` ↪ ↪ `(` ↪ `id` ↪ ↪ `INT` ↪ `,` ↪ ↪ `name` ↪ ↪ `VARCHAR` ↪ `(50)` ↪ `)` ↪ `;` ↪	Ignore	Ignore	`test` ↪ `.` ↪ `ignore` ↪ ↪ matches the event filter rule, so both DDL and DML events are ignored.

DDL	DDL behavior	DML behavior	Explanation
`DROP` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ `;` ↪	Ignore	-	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `DROP` ↪ ↪ `TABLE` ↪ ↪ event is ignored. Because the table is deleted, TiCDC no longer replicates DML events for `t1`.

DDL	DDL behavior	DML behavior	Explanation
`TRUNCATE TABLE test . t1 ;`	Ignore	Replicate	`test . t1` matches the event filter rule, so the `TRUNCATE TABLE` event is ignored. The replication of DML events remains unaffected.

DDL	DDL behavior	DML behavior	Explanation
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ `;` ↪	Ignore	Replicate	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `RENAME` ↪ ↪ `TABLE` ↪ ↪ event is ignored. The replication of DML events remains unaffected.

DDL	DDL behavior	DML behavior	Explanation
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `ignore` ↪ `;` ↪	Ignore	Ignore	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `RENAME` ↪ ↪ `TABLE` ↪ ↪ event is ignored. `test` ↪ `.` ↪ `ignore` ↪ ↪ matches the event filter rule, so both DDL and DML events are ignored.

Note:

- When replicating data to a database, use the event filter to filter DDL events with caution. Ensure that the upstream and downstream database schemas remain consistent during replication. Otherwise, TiCDC might report errors or cause undefined replication behavior.
- For versions earlier than v6.5.8, v7.1.4, and v7.5.1, using the event filter to filter DDL events involving table creation or deletion affects DML replication. It is not recommended to use this feature in these versions.

13.9.3.7 Bidirectional Replication

TiCDC supports bi-directional replication (BDR) among two TiDB clusters. Based on this feature, you can create a multi-active TiDB solution using TiCDC.

This section describes how to use bi-directional replication taking two TiDB clusters as an example.

13.9.3.7.1 Deploy bi-directional replication

TiCDC only replicates incremental data changes that occur after a specified timestamp to the downstream cluster. Before starting the bi-directional replication, you need to take the following steps:

1. (Optional) According to your needs, import the data of the two TiDB clusters into each other using the data export tool Dumpling and data import tool TiDB Lightning.
2. Deploy two TiCDC clusters between the two TiDB clusters. The cluster topology is as follows. The arrows in the diagram indicate the directions of data flow.

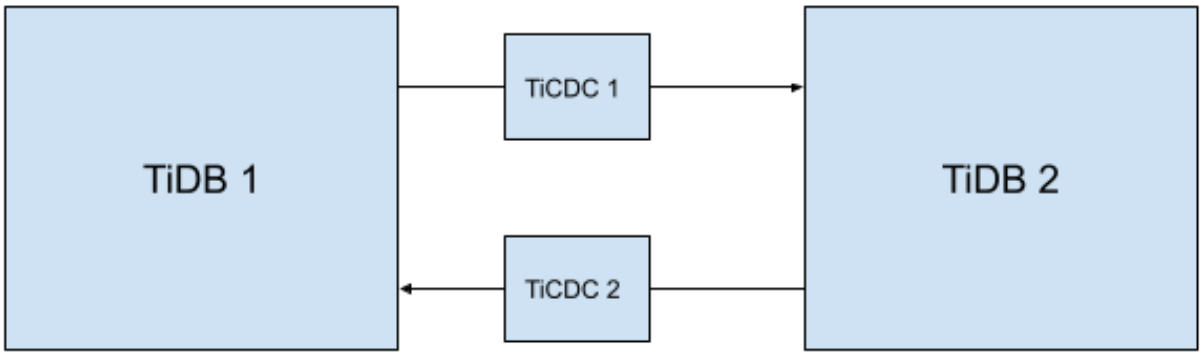

Figure 501: TiCDC bidirectional replication

3. Specify the starting time point of data replication for the upstream and downstream clusters.

    1. Check the time point of the upstream and downstream clusters. In the case of two TiDB clusters, make sure that data in the two clusters are consistent at certain time points. For example, the data of TiDB A at `ts=1` and the data of TiDB B at `ts=2` are consistent.
    2. When you create the changefeed, set the `--start-ts` of the changefeed for the upstream cluster to the corresponding `tso`. That is, if the upstream cluster is TiDB A, set `--start-ts=1`; if the upstream cluster is TiDB B, set `--start-ts =2`.

4. In the configuration file specified by the `--config` parameter, add the following configuration:

```
# Whether to enable the bi-directional replication mode
bdr-mode = true
```

After the configuration takes effect, the clusters can perform bi-directional replication.

13.9.3.7.2 DDL types

Starting from v7.6.0, to support DDL replication as much as possible in bi-directional replication, TiDB divides the DDLs that TiCDC originally supports into two types: replicable DDLs and non-replicable DDLs, according to the impact of DDLs on the business.

Replicable DDLs

Replicable DDLs are the DDLs that can be directly executed and replicated to other TiDB clusters in bi-directional replication.

Replicable DDLs include:

- `CREATE DATABASE`
- `CREATE TABLE`
- `ADD COLUMN`: the column can be `null`, or has `not null` and `default value` at the same time
- `ADD NON-UNIQUE INDEX`
- `DROP INDEX`
- `MODIFY COLUMN`: you can only modify the `default value` and `comment` of the column
- `ALTER COLUMN DEFAULT VALUE`
- `MODIFY TABLE COMMENT`
- `RENAME INDEX`
- `ADD TABLE PARTITION`
- `DROP PRIMARY KEY`
- `ALTER TABLE INDEX VISIBILITY`
- `ALTER TABLE TTL`
- `ALTER TABLE REMOVE TTL`
- `CREATE VIEW`
- `DROP VIEW`

Non-replicable DDLs

Non-replicable DDLs are the DDLs that have a great impact on the business, and might cause data inconsistency between clusters. Non-replicable DDLs cannot be directly replicated to other TiDB clusters in bi-directional replication through TiCDC. Non-replicable DDLs must be executed through specific operations.

Non-replicable DDLs include:

- `DROP DATABASE`
- `DROP TABLE`
- `ADD COLUMN`: the column is `not null` and does not have a `default value`
- `DROP COLUMN`
- `ADD UNIQUE INDEX`
- `TRUNCATE TABLE`
- `MODIFY COLUMN`: you can modify the attributes of the column except `default value` and `comment`
- `RENAME TABLE`
- `DROP PARTITION`
- `TRUNCATE PARTITION`
- `ALTER TABLE CHARACTER SET`
- `ALTER DATABASE CHARACTER SET`
- `RECOVER TABLE`
- `ADD PRIMARY KEY`
- `REBASE AUTO ID`
- `EXCHANGE PARTITION`
- `REORGANIZE PARTITION`

13.9.3.7.3 DDL replication

To solve the problem of replicable DDLs and non-replicable DDLs, TiDB introduces the following BDR roles:

- `PRIMARY`: You can execute replicable DDLs, but not non-replicable DDLs. Replicable DDLs executed in a PRIMARY cluster will be replicated to the downstream by TiCDC.
- `SECONDARY`: You cannot execute replicable DDLs or non-replicable DDLs. However, DDLs executed in a PRIMARY cluster can be replicated to a SECONDARY cluster by TiCDC.

When no BDR role is set, you can execute any DDL. However, the changefeed in BDR mode does not replicate any DDL on that cluster.

In short, in BDR mode, TiCDC only replicates replicable DDLs in the PRIMARY cluster to the downstream.

Replication scenarios of replicable DDLs

1. Choose a TiDB cluster and execute `ADMIN SET BDR ROLE PRIMARY` to set it as the primary cluster.

```
ADMIN SET BDR ROLE PRIMARY;
Query OK, 0 rows affected
Time: 0.003s

ADMIN SHOW BDR ROLE;
+----------+
| BDR_ROLE |
+----------+
| primary  |
+----------+
```

2. On other TiDB clusters, execute `ADMIN SET BDR ROLE SECONDARY` to set them as the secondary clusters.
3. Execute **replicable DDLs** on the primary cluster. The successfully executed DDLs will be replicated to the secondary clusters by TiCDC.

> **Note:**
>
> To prevent misuse:
>
> - If you try to execute **non-replicable DDLs** on the primary cluster, you will get the Error 8263.
> - If you try to execute **replicable DDLs** or **non-replicable DDLs** on the secondary clusters, you will get the Error 8263.

Replication scenarios of non-replicable DDLs

1. Execute `ADMIN UNSET BDR ROLE` on all TiDB clusters to unset the BDR role.
2. Stop writing data to the tables that need to execute DDLs in all clusters.
3. Wait until all writes to the corresponding tables in all clusters are replicated to other clusters, and then manually execute all DDLs on each TiDB cluster.
4. Wait until the DDLs are completed, and then resume writing data.
5. Follow the steps in Replication scenarios of replicable DDLs to switch back to the replication scenario of replicable DDLs.

> **Warning:**
>
> After you execute `ADMIN UNSET BDR ROLE` on all TiDB clusters, none of the DDLs are replicated by TiCDC. You need to manually execute the DDLs on each cluster separately.

13.9.3.7.4 Stop bi-directional replication

After the application has stopped writing data, you can insert a special record into each cluster. By checking the two special records, you can make sure that data in two clusters are consistent.

After the check is completed, you can stop the changefeed to stop bi-directional replication, and execute `ADMIN UNSET BDR ROLE` on all TiDB clusters.

13.9.3.7.5 Limitations

- Use BDR role only in the following scenarios:
  - 1 `PRIMARY` cluster and n `SECONDARY` clusters (replication scenarios of replicable DDLs)
  - n clusters that have no BDR roles (replication scenarios in which you can manually execute non-replicable DDLs on each cluster)

> **Note:**
>
> Do not set the BDR role in other scenarios, for example, setting `PRIMARY` ↪ , `SECONDARY`, and no BDR roles at the same time. If you set the BDR role incorrectly, TiDB cannot guarantee data correctness and consistency during data replication.

- Usually do not use `AUTO_INCREMENT` or `AUTO_RANDOM` to avoid data conflicts in the replicated tables. If you need to use `AUTO_INCREMENT` or `AUTO_RANDOM`, you can set different `auto_increment_increment` and `auto_increment_offset` for different clusters to ensure that different clusters can be assigned different primary keys. For example, if there are three TiDB clusters (A, B, and C) in bi-directional replication, you can set them as follows:

    - In Cluster A, set `auto_increment_increment=3` and `auto_increment_offset` ↪ `=2000`
    - In Cluster B, set `auto_increment_increment=3` and `auto_increment_offset` ↪ `=2001`
    - In Cluster C, set `auto_increment_increment=3` and `auto_increment_offset` ↪ `=2002`

    This way, A, B, and C will not conflict with each other in the implicitly assigned `AUTO_` ↪ `INCREMENT` ID and `AUTO_RANDOM` ID. If you need to add a cluster in BDR mode, you need to temporarily stop writing data of the related application, set the appropriate values for `auto_increment_increment` and `auto_increment_offset` on all clusters, and then resume writing data of the related application.

- Bi-directional replication clusters cannot detect write conflicts, which might cause undefined behaviors. Therefore, you must ensure that there are no write conflicts from the application side.

- Bi-directional replication supports more than two clusters, but does not support multiple clusters in cascading mode, that is, a cyclic replication like TiDB A -> TiDB B -> TiDB C -> TiDB A. In such a topology, if one cluster fails, the whole data replication will be affected. Therefore, to enable bi-directional replication among multiple clusters, you need to connect each cluster with every other clusters, for example, `TiDB A <-> TiDB B`, `TiDB B <-> TiDB C`, `TiDB C <-> TiDB A`.

13.9.3.8 TiCDC Data Integrity Validation for Single-Row Data

Starting from v7.1.0, TiCDC introduces the data integrity validation feature, which uses a checksum algorithm to validate the integrity of single-row data. This feature helps verify whether any error occurs in the process of writing data from TiDB, replicating it through TiCDC, and then writing it to a Kafka cluster. Currently, only changefeeds using Kafka as the downstream and Simple or Avro as the protocol support this feature. For more information about the checksum algorithm, see Algorithm for checksum calculation.

13.9.3.8.1 Enable the feature

TiCDC disables data integrity validation by default. To enable it, perform the following steps:

1. Enable the checksum integrity validation feature for single-row data in the upstream TiDB cluster by setting the `tidb_enable_row_level_checksum` system variable:

```
SET GLOBAL tidb_enable_row_level_checksum = ON;
```

This configuration only takes effect for newly created sessions, so you need to reconnect to TiDB.

2. In the configuration file specified by the `--config` parameter when you create a changefeed, add the following configurations:

```
[integrity]
integrity-check-level = "correctness"
corruption-handle-level = "warn"
```

3. When using Avro as the data encoding format, you need to set `enable-tidb-extension=true` in the `sink-uri`. To prevent numerical precision loss during network transmission, which can cause checksum validation failures, you also need to set `avro-decimal-handling-mode=string` and `avro-bigint-unsigned-handling-mode=string`. The following is an example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="kafka-avro-checksum" --sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=avro&enable-tidb-extension=true&avro-decimal-handling-mode=string&avro-bigint-unsigned-handling-mode=string" --schema-registry=http://127.0.0.1:8081 --config changefeed_config.toml
```

With the preceding configuration, each message written to Kafka by the changefeed will include the corresponding data's checksum. You can verify data consistency based on these checksum values.

> **Note:**
>
> For existing changefeeds, if `avro-decimal-handling-mode` and `avro-bigint-unsigned-handling-mode` are not set, enabling the checksum validation feature might cause schema compatibility issues. To resolve this issue, you can modify the compatibility type of the Schema Registry to `NONE`. For more details, see Schema Registry.

13.9.3.8.2 Disable the feature

TiCDC disables data integrity validation by default. To disable this feature after enabling it, perform the following steps:

1. Follow the `Pause Task -> Modify Configuration -> Resume Task` process described in Update task configuration and remove all `[integrity]` configurations in the configuration file specified by the `--config` parameter of the changefeed.

```
[integrity]
integrity-check-level = "none"
corruption-handle-level = "warn"
```

2. Execute the following SQL statement in the upstream TiDB to disable the checksum integrity validation feature (tidb_enable_row_level_checksum):

```
SET GLOBAL tidb_enable_row_level_checksum = OFF;
```

The preceding configuration only takes effect for newly created sessions. After all clients writing to TiDB have reconnected, the messages written by changefeed to Kafka will no longer include the checksum for the corresponding data.

13.9.3.8.3 Checksum algorithms

Checksum V1

Before v8.4.0, TiDB and TiCDC use Checksum V1 for checksum calculation and verification.

After you enable the checksum integrity validation feature for single-row data, TiDB uses the CRC32 algorithm to calculate the checksum of each row and writes it to TiKV along with the data. TiCDC reads the data from TiKV and recalculates the checksum using the same algorithm. If the two checksums are equal, it indicates that the data is consistent during the transmission from TiDB to TiCDC.

TiCDC then encodes the data into a specific format and sends it to Kafka. After the Kafka consumer reads the data, it calculates a new checksum using the same CRC32 algorithm as TiDB. If the new checksum is equal to the checksum in the data, it indicates that the data is consistent during the transmission from TiCDC to the Kafka consumer.

Checksum V2

Starting from v8.4.0, TiDB and TiCDC introduce Checksum V2 to address issues of Checksum V1 in verifying old values in Update or Delete events after `ADD COLUMN` or `DROP COLUMN` operations.

For clusters created in v8.4.0 or later, or clusters upgraded to v8.4.0, TiDB uses Checksum V2 by default when single-row data checksum verification is enabled. TiCDC supports handling both Checksum V1 and V2. This change only affects TiDB and TiCDC internal implementation and does not affect checksum calculation methods for downstream Kafka consumers.

13.9.3.8.4 Algorithm for checksum calculation

The pseudocode for the checksum calculation algorithm is as follows:

```
fn checksum(columns) {
    let result = 0
```

```
    for column in sort_by_schema_order(columns) {
        result = crc32.update(result, encode(column))
    }
    return result
}
```

- `columns` should be sorted by column ID. In the Avro schema, fields are already sorted by column ID, so you can directly use the order in `columns`.
- The `encode(column)` function encodes the column value into bytes. Encoding rules vary based on the data type of the column. The specific rules are as follows:
    - TINYINT, SMALLINT, INT, BIGINT, MEDIUMINT, and YEAR types are converted to UINT64 and encoded in little-endian. For example, the number `0x0123456789abcdef` is encoded as `hex'0x0123456789abcdef'`.
    - FLOAT and DOUBLE types are converted to DOUBLE and then encoded as UINT64 in IEEE754 format.
    - BIT, ENUM, and SET types are converted to UINT64.
        - BIT type is converted to UINT64 in binary format.
        - ENUM and SET types are converted to their corresponding INT values in UINT64. For example, if the data value of a `SET('a','b','c')` type column is `'a,c'`, the value is encoded as `0b101`, which is `5` in decimal.
    - TIMESTAMP, DATE, DURATION, DATETIME, JSON, and DECIMAL types are first converted to STRING and then converted to bytes.
    - CHAR, VARCHAR, VARSTRING, STRING, TEXT, and BLOB types (including TINY, MEDIUM, and LONG) are directly converted to bytes.
    - NULL and GEOMETRY types are excluded from the checksum calculation and this function returns empty bytes.

For more information about the implementation of data consumption and checksum verification using Golang, see TiCDC row data checksum verification.

Note:

- After enabling the checksum validation feature, DECIMAL and UNSIGNED BIGINT types data will be converted to STRING types. Therefore, in the downstream consumer code, you need to convert them back to their corresponding numerical types before calculating checksum values.
- The checksum verification process does not include DELETE events. This is because DELETE events only contain the handle key column, while the checksum is calculated based on all columns.

13.9.3.9 Upstream and Downstream Clusters Data Validation and Snapshot Read

When you use TiCDC to build upstream and downstream clusters of TiDB, you might need to perform consistent snapshot read or data consistency validation on the upstream and downstream without stopping the replication. In the regular replication mode, TiCDC only guarantees that the data is eventually consistent, but cannot guarantee that the data is consistent during the replication process. Therefore, it is difficult to perform consistent read of dynamically changing data. To meet such a need, TiCDC provides the Syncpoint feature.

Syncpoint uses the snapshot feature provided by TiDB and enables TiCDC to maintain a `ts-map` that has consistency between upstream and downstream snapshots during the replication process. In this way, the issue of verifying the consistency of dynamic data is converted to the issue of verifying the consistency of static snapshot data, which achieves the effect of nearly real-time verification.

13.9.3.9.1 Enable Syncpoint

After enabling the Syncpoint feature, you can use Consistent snapshot read and Data consistency validation.

To enable the Syncpoint feature, set the value of the TiCDC configuration item `enable-sync-point` to `true` when creating a replication task. After enabling Syncpoint, TiCDC writes the following information to the downstream TiDB cluster:

1. During the replication, TiCDC periodically (configured by `sync-point-interval`) aligns snapshots between the upstream and downstream and saves the upstream and downstream TSO correspondences in the downstream `tidb_cdc.syncpoint_v1` table.
2. During the replication, TiCDC also periodically (configured by `sync-point-interval`) executes `SET GLOBAL tidb_external_ts = @@tidb_current_ts`, which sets a consistent snapshot point that has been replicated in backup clusters.

The following TiCDC configuration example enables Syncpoint when creating a replication task:

```
#### Enables SyncPoint.
enable-sync-point = true

#### Aligns the upstream and downstream snapshots every 5 minutes
sync-point-interval = "5m"

#### Cleans up the ts-map data in the downstream tidb_cdc.syncpoint_v1 table every hour
sync-point-retention = "1h"
```

13.9.3.9.2 Consistent snapshot read

> **Note:**
>
> Before you perform consistent snapshot read, make sure that you have enabled the Syncpoint feature. If multiple replication tasks use the same downstream TiDB cluster and have Syncpoint enabled, each of these tasks updates `tidb_external_ts` and `ts-map` based on their respective replication progress. In this case, you need to set up consistent snapshot read at the replication task level by reading records from the `ts-map` table. Meanwhile, you need to avoid downstream applications reading data using `tidb_enable_external_ts_read`, because multiple replication tasks might interfere with each other and result in inconsistent results.

When you need to query the data from the backup cluster, you can set `SET GLOBAL|SESSION tidb_enable_external_ts_read = ON;` for the application to obtain transactionally consistent data on the backup cluster.

In addition, you can also select a previous point in time for snapshot read by querying `ts-map`.

13.9.3.9.3 Data consistency validation

> **Note:**
>
> Before you perform data consistency validation, make sure that you have enabled the Syncpoint feature.

To validate the data of upstream and downstream clusters, you only need to configure `snapshot` in sync-diff-inspector.

Step 1: obtain `ts-map`

You can execute the following SQL statement in the downstream TiDB cluster to obtain the upstream TSO (`primary_ts`) and downstream TSO (`secondary_ts`):

```
select * from tidb_cdc.syncpoint_v1;
+--
   ↪ ---------------+---------------+--------------------+--------------------+----
   ↪
| ticdc_cluster_id | changefeed | primary_ts      | secondary_ts     |
   ↪ created_at        |
```

```
+--
    ↪ ---------------+---------------+-------------------+--------------------+----
    ↪
| default         | test-2 | 435953225454059520 | 435953235516456963 |
    ↪ 2022-09-13 08:40:15 |
+--
    ↪ ---------------+---------------+-------------------+--------------------+----
    ↪
```

The fields in the preceding `syncpoint_v1` table are described as follows:

- `ticdc_cluster_id`: The ID of the TiCDC cluster in this record.
- `changefeed`: The ID of the changefeed in this record. Because different TiCDC clusters might have changefeeds with the same name, you need to confirm the `ts-map` inserted by a changefeed with the TiCDC cluster ID and changefeed ID.
- `primary_ts`: The timestamp of the upstream database snapshot.
- `secondary_ts`: The timestamp of the downstream database snapshot.
- `created_at`: The time when this record is inserted.

Step 2: configure snapshot

Then configure the snapshot information of the upstream and downstream databases by using the `ts-map` information obtained in Step 1.

Here is a configuration example of the `Datasource config` section:

```
############################ Datasource config ########################
[data-sources.uptidb]
    host = "172.16.0.1"
    port = 4000
    user = "root"
    password = ""
    snapshot = "435953225454059520"

[data-sources.downtidb]
    host = "172.16.0.2"
    port = 4000
    user = "root"
    snapshot = "435953235516456963"
```

13.9.3.9.4 Notes

- Before TiCDC creates a changefeed, make sure that the value of the TiCDC configuration item `enable-sync-point` is set to `true`. Only in this way, Syncpoint is enabled and the `ts-map` is saved in the downstream. The default format of the configuration

item `sync-point-interval` is `"h m s"`, for example `"1h30m30s"`, and the minimum value is `"30s"`. For the complete configuration information, see TiCDC task configuration file.

- When you perform data validation using Syncpoint, you need to modify the Garbage Collection (GC) time of TiKV to ensure that the historical data corresponding to snapshot is not collected by GC during the data check. It is recommended that you modify the GC time to 1 hour and recover the setting after the check.
- The above example only shows the section of `Datasource config`. For complete configuration, refer to sync-diff-inspector User Guide.
- Starting from v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.
- Starting from v8.2.0, TiCDC makes the following adjustments to the generation rules of `primary_ts` values:
    - Whenever TiCDC generates a new `primary_ts`, its value must be an integer multiple of `sync-point-interval`.
    - For each new changefeed, TiCDC calculates an initial `primary_ts`. This initial value is greater than or equal to the changefeed start time (`startTs`), and is the smallest integer multiple of `sync-point-interval`.

This setting is used to align the Syncpoints of different changefeeds during data replication. For example, multiple downstream clusters can restore to the `secondary_ts` of a Syncpoint with the same `primary_ts` by executing the `FLASHBACK TABLE` statement, achieving data consistency across downstream clusters.

13.9.3.10 TiCDC Behavior in Splitting UPDATE Events

13.9.3.10.1 Split `UPDATE` events for MySQL sinks

Starting from v6.5.10, v7.5.2, v8.1.1, and v8.2.0, when using the MySQL sink, any TiCDC node that receives a request for replicating a table will fetch the current timestamp `thresholdTS` from PD before starting the replication to the downstream. Based on the value of this timestamp, TiCDC decides whether to split `UPDATE` events:

- For transactions containing one or multiple `UPDATE` changes, if the transaction `commitTS` is less than `thresholdTS`, TiCDC splits the `UPDATE` event into a `DELETE` event and an `INSERT` event before writing them to the Sorter module.
- For `UPDATE` events with the transaction `commitTS` greater than or equal to `thresholdTS` ↪ , TiCDC does not split them. For more information, see GitHub issue #10918.

Note:

> In v8.1.0, when using MySQL Sink, TiCDC also decides whether to split `UPDATE` events based on the value of `thresholdTS`, but `thresholdTS` is obtained differently. Specifically, in v8.1.0, `thresholdTS` is the current timestamp fetched from PD at TiCDC startup, but this way might cause data inconsistency issues in multi-node scenarios. For more information, see GitHub issue #11219.

This behavior change (that is, deciding whether to split `UPDATE` events based on `thresholdTS`) addresses the issue of downstream data inconsistencies caused by the potentially incorrect order of `UPDATE` events received by TiCDC, which can lead to an incorrect order of split `DELETE` and `INSERT` events.

Take the following SQL statements as an example:

```
CREATE TABLE t (a INT PRIMARY KEY, b INT);
INSERT INTO t VALUES (1, 1);
INSERT INTO t VALUES (2, 2);

BEGIN;
UPDATE t SET a = 3 WHERE a = 2;
UPDATE t SET a = 2 WHERE a = 1;
COMMIT;
```

In this example, the two `UPDATE` statements within the transaction have a sequential dependency on execution. The primary key `a` is changed from `2` to `3`, and then the primary key `a` is changed from `1` to `2`. After this transaction is executed, the records in the upstream database are `(2, 1)` and `(3, 2)`.

However, the order of `UPDATE` events received by TiCDC might differ from the actual execution order of the upstream transaction. For example:

```
UPDATE t SET a = 2 WHERE a = 1;
UPDATE t SET a = 3 WHERE a = 2;
```

- Before this behavior change, TiCDC writes these `UPDATE` events to the Sorter module and then splits them into `DELETE` and `INSERT` events. After the split, the actual execution order of these events in the downstream is as follows:

  ```
  BEGIN;
  DELETE FROM t WHERE a = 1;
  REPLACE INTO t VALUES (2, 1);
  DELETE FROM t WHERE a = 2;
  REPLACE INTO t VALUES (3, 2);
  COMMIT;
  ```

After the downstream executes the transaction, the records in the database are `(3, 2)`, which are different from the records in the upstream database (`(2, 1)` and `(3, 2)`), indicating a data inconsistency issue.

- After this behavior change, if the transaction `commitTS` is less than the `thresholdTS` ↪ fetched from PD when TiCDC starts replicating the corresponding table to the downstream, TiCDC splits these `UPDATE` events into `DELETE` and `INSERT` events before writing them to the Sorter module. After the sorting by the Sorter module, the actual execution order of these events in the downstream is as follows:

```
BEGIN;
DELETE FROM t WHERE a = 1;
DELETE FROM t WHERE a = 2;
REPLACE INTO t VALUES (2, 1);
REPLACE INTO t VALUES (3, 2);
COMMIT;
```

After the downstream executes the transaction, the records in the downstream database are the same as those in the upstream database, which are `(2, 1)` and `(3, 2)`, ensuring data consistency.

As you can see from the preceding example, splitting the `UPDATE` event into `DELETE` and `INSERT` events before writing them to the Sorter module ensures that all `DELETE` events are executed before `INSERT` events after the split, thereby maintaining data consistency regardless of the order of `UPDATE` events received by TiCDC.

Note:

After this behavior change, when using the MySQL sink, TiCDC does not split the `UPDATE` event in most cases. Consequently, there might be primary key or unique key conflicts during changefeed runtime, causing the changefeed to restart automatically. After the restart, TiCDC will split the conflicting `UPDATE` events into `DELETE` and `INSERT` events before writing them to the Sorter module. This ensures that all events within the same transaction are correctly ordered, with all `DELETE` events preceding `INSERT` events, thus correctly completing data replication.

13.9.3.10.2 Split primary or unique key `UPDATE` events for non-MySQL sinks

Transactions containing a single `UPDATE` change

Starting from v6.5.3, v7.1.1, and v7.2.0, when using a non-MySQL sink, for transactions that only contain a single update change, if the primary key or non-null unique index value

is modified in an `UPDATE` event, TiCDC splits this event into `DELETE` and `INSERT` events. For more information, see GitHub issue #9086.

This change primarily addresses the issue that TiCDC only outputs the new value without the old value by default when using the CSV and AVRO protocols. Due to this issue, when the primary key or non-null unique index value changes, the consumer can only receive the new value, making it impossible to process the value before the change (for example, delete the old value). Take the following SQL as an example:

```
CREATE TABLE t (a INT PRIMARY KEY, b INT);
INSERT INTO t VALUES (1, 1);
UPDATE t SET a = 2 WHERE a = 1;
```

In this example, the primary key `a` is updated from `1` to `2`. If the `UPDATE` event is not split, the consumer can only obtain the new value `a = 2` and cannot obtain the old value `a = 1` when using the CSV and AVRO protocols. This might cause the downstream consumer to only insert the new value `2` without deleting the old value `1`.

Transactions containing multiple `UPDATE` changes

Starting from v6.5.4, v7.1.2, and v7.4.0, for transactions containing multiple changes, if the primary key or non-null unique index value is modified in the `UPDATE` event, TiCDC splits the event into `DELETE` and `INSERT` events and ensures that all events follow the sequence of `DELETE` events preceding `INSERT` events. For more information, see GitHub issue #9430.

This change primarily addresses the potential issue of primary key or unique key conflicts that consumers might encounter when writing data changes from the Kafka sink or other sinks to a relational database or performing a similar operation. This issue is caused by the potentially incorrect order of `UPDATE` events received by TiCDC.

Take the following SQL as an example:

```
CREATE TABLE t (a INT PRIMARY KEY, b INT);
INSERT INTO t VALUES (1, 1);
INSERT INTO t VALUES (2, 2);

BEGIN;
UPDATE t SET a = 3 WHERE a = 1;
UPDATE t SET a = 1 WHERE a = 2;
UPDATE t SET a = 2 WHERE a = 3;
COMMIT;
```

In this example, by executing three SQL statements to swap the primary keys of two rows, TiCDC only receives two update change events, that is, changing the primary key `a` from `1` to `2` and changing the primary key `a` from `2` to `1`. If consumers directly write these two `UPDATE` events to the downstream, a primary key conflict will occur, leading to changefeed errors.

Therefore, TiCDC splits these two events into four events, that is, deleting records `(1, 1)` and `(2, 2)` and writing records `(2, 1)` and `(1, 2)`.

Control whether to split primary or unique key `UPDATE` events

Starting from v6.5.10, v7.1.6, v7.5.3, and v8.1.1, when using a non-MySQL sink, TiCDC supports controlling whether to split primary or unique key `UPDATE` events via the `output-raw-change-event` parameter, as described in the GitHub issue #11211. The specific behavior of this parameter is as follows:

- When you set `output-raw-change-event = false`, if the primary key or non-null unique index value is modified in an `UPDATE` event, TiCDC splits the event into `DELETE` and `INSERT` events and ensures that all events follow the sequence of `DELETE` events preceding `INSERT` events.
- When you set `output-raw-change-event = true`, TiCDC does not split `UPDATE` events, and the consumer side is responsible for dealing with the problems described in Split primary or unique key `UPDATE` events for non-MySQL sinks. Otherwise there might be a risk of data inconsistency. Note that when the primary key of a table is a clustered index, updates to the primary key are still split into `DELETE` and `INSERT` events in TiDB, and such behavior is not affected by the `output-raw-change-event` parameter.

> **Note**
>
> In the following tables, UK/PK stands for primary key or unique key.

Release 6.5 compatibility

Version	Protocol	Split UK/PK `UPDATE` events	Not split UK/PK `UPDATE` events	Comments
<= v6.5.2	ALL			
v6.5.3 / v6.5.4	Canal/Open			
v6.5.3	CSV/Avro			Split but does not sort. See #9086

13.9.4 Monitor and Alert

13.9.4.1 TiCDC Monitoring Metrics Summary

Starting from v7.0.0, when you deploy Grafana using TiUP, the TiCDC Summary Dashboard is automatically added to the Grafana monitoring page. Through this dashboard, you can quickly understand the status of TiCDC servers and changefeeds.

The following image shows the monitoring panels of the TiCDC Summary Dashboard:

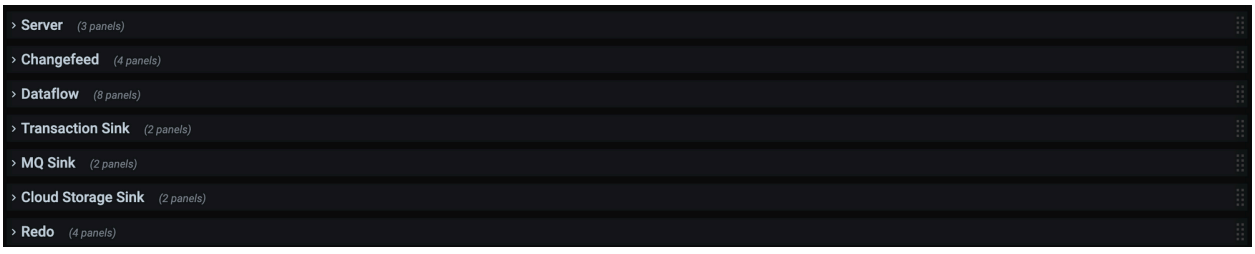

Figure 502: TiCDC Summary Dashboard - Overview

Each monitoring panel is described as follows:

- Server: summary of TiCDC nodes in the cluster.

- Changefeed: the latency and status information of TiCDC changefeeds.
- Dataflow: statistics of data changes processed by TiCDC internal modules.
- Transaction Sink: the write latency of the downstream MySQL or TiDB.
- MQ Sink: the write latency of the downstream MQ system.
- Cloud Storage Sink: the write speed of the downstream cloud storage.
- Redo: the write latency when the redo feature is enabled.

13.9.4.1.1 Server panel

The **Server** panel is as follows:

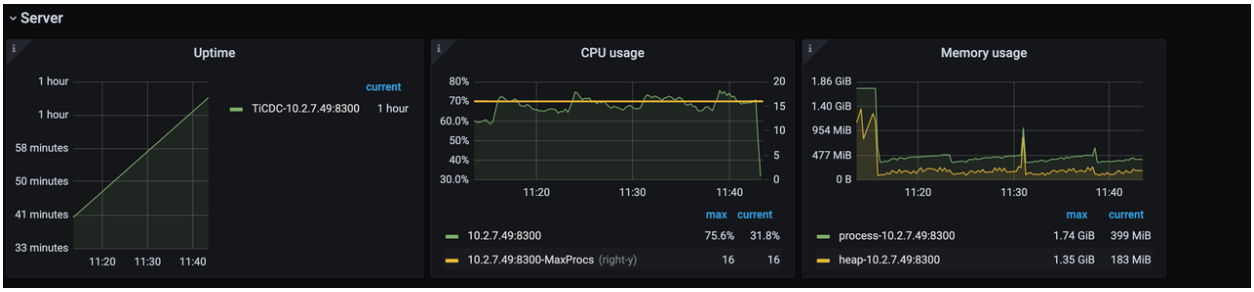

Figure 503: TiCDC Summary Dashboard - Server metrics

- **Uptime**: the time that TiCDC nodes have been running.
- **CPU usage**: the CPU usage of TiCDC nodes.
- **Memory usage**: the memory usage of TiCDC nodes.

13.9.4.1.2 Changefeed panel

The **Changefeed** panel is as follows:

Figure 504: TiCDC Summary Dashboard - Changefeed metrics

- **Changefeed checkpoint lag**: indicates the data replication latency between the upstream TiDB cluster and the downstream system, measured in time. In general, this metric reflects the overall health of the data replication task. Usually, the smaller the lag, the better the status of the replication task. When the lag increases, it usually indicates that the replication ability of the changefeed or the consumption ability of the downstream system cannot keep up with the write speed of the upstream.
- **Changefeed resolved ts lag**: indicates the data latency between the upstream TiDB cluster and the TiCDC node, measured in time. This metric reflects the ability of the changefeed to pull the data changes from the upstream. When the lag increases, it means that the changefeed cannot pull the data changes generated by the upstream in time.

13.9.4.1.3 Dataflow panel

Figure 505: TiCDC Summary Dashboard - Puller metrics

- **Puller output events/s**: the number of data changes output by the Puller module to the Sorter module per second in the TiCDC node. This metric reflects the speed at which TiCDC pulls the data changes from the upstream.
- **Puller output events**: the total number of data changes output by the Puller module to the Sorter module in the TiCDC node.

Figure 506: TiCDC Summary Dashboard - Sorter metrics

- **Sorter output events/s**: the number of data changes output by the Sorter module per second to the Sink module in the TiCDC node. Note that the data output rate of Sorter is affected by the Sink module. Therefore, when you find that the output rate of the Sorter module is lower than that of the Puller module, it does not necessarily mean that the sorting speed of the Sorter module is too slow. You need to first observe the metrics related to the Sink module to confirm whether the Sink module takes a long time to flush data, resulting in a decrease in Sorter module output.
- **Sorter output event**: the total number of data changes output by the Sorter module to the Sink module in the TiCDC node.

Figure 507: TiCDC Summary Dashboard - Mounter metrics

- **Mounter output events/s**: the number of data changes decoded by the Mounter module per second in the TiCDC node. When the upstream data changes involve a large number of fields, the decoding speed of the Mounter module might be affected.
- **Mounter output event**: the total number of data changes decoded by the Mounter module in the TiCDC node.

Figure 508: TiCDC Summary Dashboard - Sink metrics

- **Sink flush rows/s**: the number of data changes output by the Sink module to the downstream per second in the TiCDC node. This metric reflects the speed at which the data changes are replicated to the downstream. When **Sink flush rows/s** is lower than **Puller output events/s**, the replication latency might increase.

- **Sink flush rows**: the total number of data changes output by the Sink module to the downstream in the TiCDC node.

13.9.4.1.4 Transaction Sink panel

The **Transaction Sink** panel displays data only when the downstream is MySQL or TiDB.

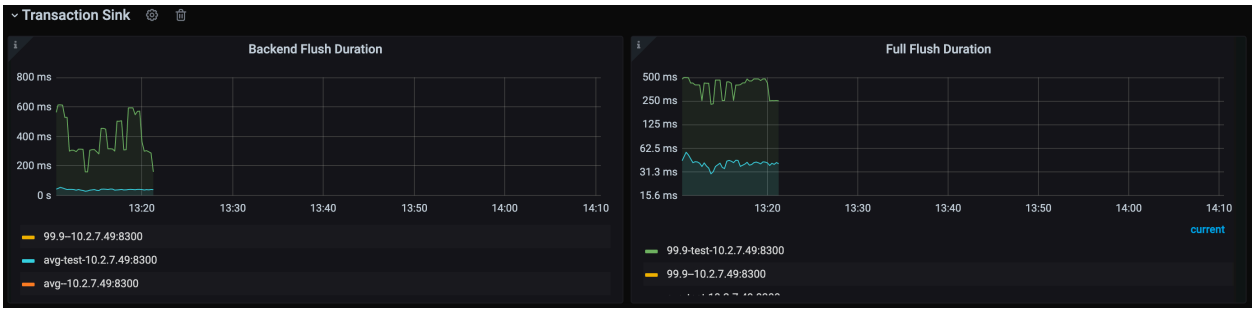

Figure 509: TiCDC Summary Dashboard - Transaction Sink metrics

- **Backend Flush Duration**: the duration that the TiCDC Transaction Sink module takes to execute a SQL statement on the downstream. By observing this metric, you can determine whether the performance of the downstream is the bottleneck of the replication speed. Generally, the p999 value should be below 500 ms. When the value exceeds this limit, the replication speed might be affected, resulting in an increase in the Changefeed checkpoint lag.
- **Full Flush Duration**: the total duration consumed by each transaction in TiCDC from sorting by Sorter to sending downstream. By subtracting the **Backend Flush Duration** value from this value, you can get the total queueing time of a transaction before it is executed on the downstream. If the queueing time is too long, you can consider allocating more memory quota to the replication task.

13.9.4.1.5 MQ Sink panel

The **MQ Sink** panel displays data only when the downstream is Kafka.

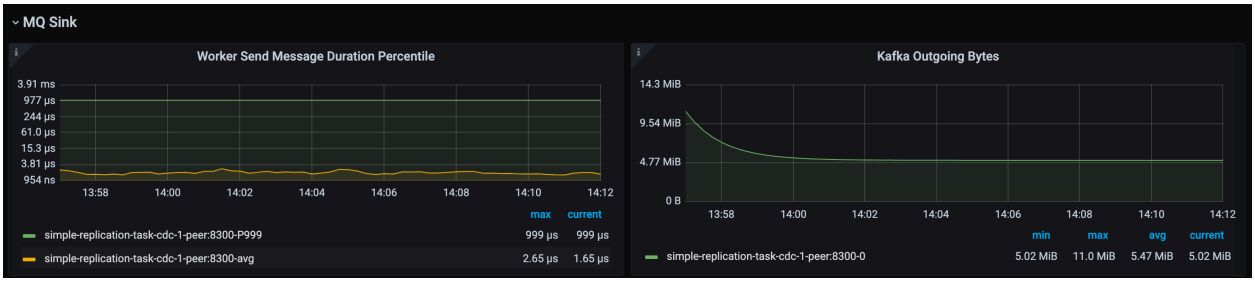

Figure 510: TiCDC Summary Dashboard - Transaction Sink metrics

- **Worker Send Message Duration Percentile**: The latency of TiCDC MQ Sink worker sending data to the downstream.
- **Kafka Ongoing Bytes**: The speed at which TiCDC MQ Sink sends data to the downstream.

13.9.4.1.6 Cloud Storage Sink panel

The **Cloud Storage Sink** panel displays data only when the downstream is Cloud Storage.

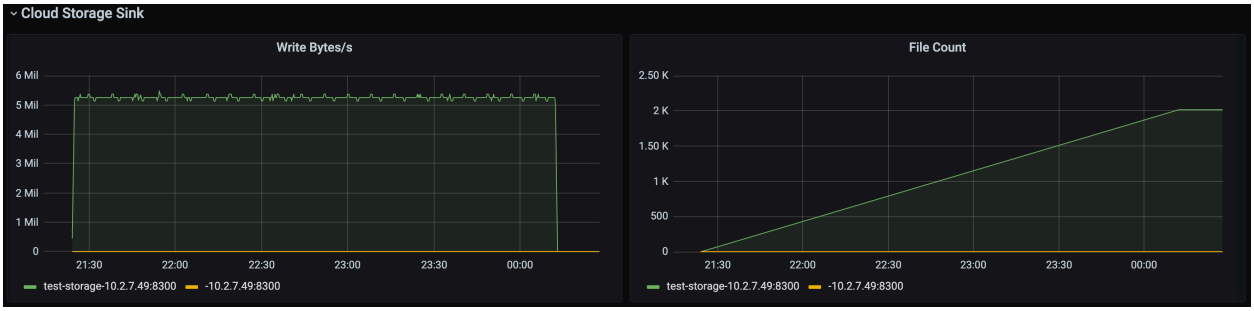

Figure 511: TiCDC Summary Dashboard - Transaction Sink metrics

- **Write Bytes/s**: The speed at which the Cloud Storage Sink module writes data to the downstream.
- **File Count**: the total number of files written by the Cloud Storage Sink module.

13.9.4.1.7 Redo panel

The **Redo** panel displays data only when the Redo Log feature is enabled.

Figure 512: TiCDC Summary Dashboard - Transaction Sink metrics

- **Redo Write rows/s**: the number of rows written per second by the Redo module. When the Redo feature is enabled, if the latency of a replication task increases, you can observe whether there is a significant difference between this metric and the value of Puller Output event/s. If so, the increase in latency might be due to the insufficient writing capacity of the Redo module.
- **Redo Write byte/s**: the speed at which data is written per second by the Redo module.
- **Redo flush log duration**: the time taken for the Redo module to flush data to the downstream. If this metric value is high, this operation might affect the replication speed.
- **Redo flushall duration**: the total time that data changes stay in the Redo module.

13.9.4.2 TiCDC Monitoring Metrics Details

If you use TiUP to deploy the TiDB cluster, you can see a sub-dashboard for TiCDC in the monitoring system which is deployed at the same time. You can get an overview of TiCDC's current status from the TiCDC dashboard, where the key metrics are displayed. This document provides a detailed description of these key metrics.

The metric description in this document is based on the following replication task example, which replicates data to MySQL using the default configuration.

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
    ↪ ://root:1234560127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task"
```

The TiCDC dashboard contains four monitoring panels. See the following screenshot:

Figure 513: TiCDC Dashboard - Overview

The description of each panel is as follows:

- **Server**: The summary information of TiKV nodes and TiCDC nodes in the TiDB cluster
- **Changefeed**: The detailed information of TiCDC replication tasks
- **Events**: The detail information about the data flow within the TiCDC cluster
- **TiKV**: TiKV information related to TiCDC

13.9.4.2.1 Server

The following is an example of the **Server** panel:

Figure 514: TiCDC Dashboard - Server metrics

The description of each metric in the **Server** panel is as follows:

- Uptime: The time for which TiKV nodes and TiCDC nodes have been running
- Goroutine count: The number of goroutines of a TiCDC node
- Open FD count: The number of file handles opened by TiCDC nodes
- Ownership: The current status of nodes in the TiCDC cluster
- Ownership history: The ownership history of the TiCDC cluster
- CPU usage: The CPU usage of TiCDC nodes
- Memory usage: The memory usage of TiCDC nodes

13.9.4.2.2 Changefeed

The following is an example of the **Changefeed** panel:

Figure 515: TiCDC Dashboard - Changefeed metrics 1

- Changefeed table count: The number of tables that each TiCDC node needs to replicate in the replication task
- Processor resolved ts: The timestamps that have been resolved in the TiCDC cluster
- Table resolved ts: The replication progress of each table in the replication task
- Changefeed checkpoint: The progress of replicating data to the downstream. Normally, the green bars are connected to the yellow line
- PD etcd requests/s: The number of requests that a TiCDC node sends to PD per second
- Exit error count/m: The number of errors that interrupt the replication task per minute
- Changefeed checkpoint lag: The progress lag of data replication (the unit is second) between the upstream and the downstream
- Processor resolved ts lag: The progress lag of data replication (the unit is second) between the upstream and TiCDC nodes

Figure 516: TiCDC Dashboard - Changefeed metrics 2

- Sink write duration: The histogram of the time spent by TiCDC writing a transaction change to the downstream
- Sink write duration percentile: The time (P95, P99, and P999) spent by TiCDC writing a transaction change to the downstream within one second
- Flush sink duration: The histogram of the time spent by TiCDC asynchronously flushing data to the downstream
- Flush sink duration percentile: The time (P95, P99, and P999) spent by TiCDC asynchronously flushing data to the downstream within one second

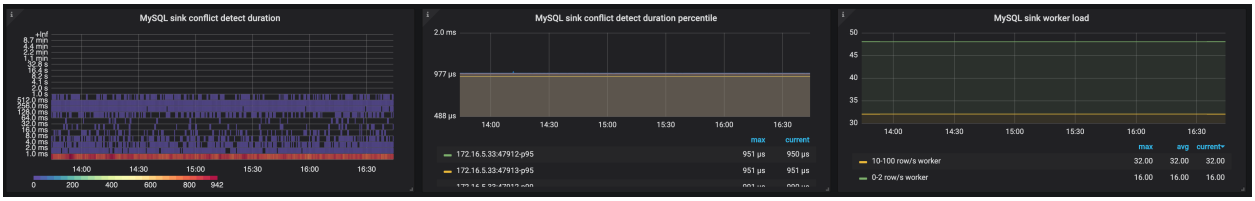

Figure 517: TiCDC Dashboard - Changefeed metrics 3

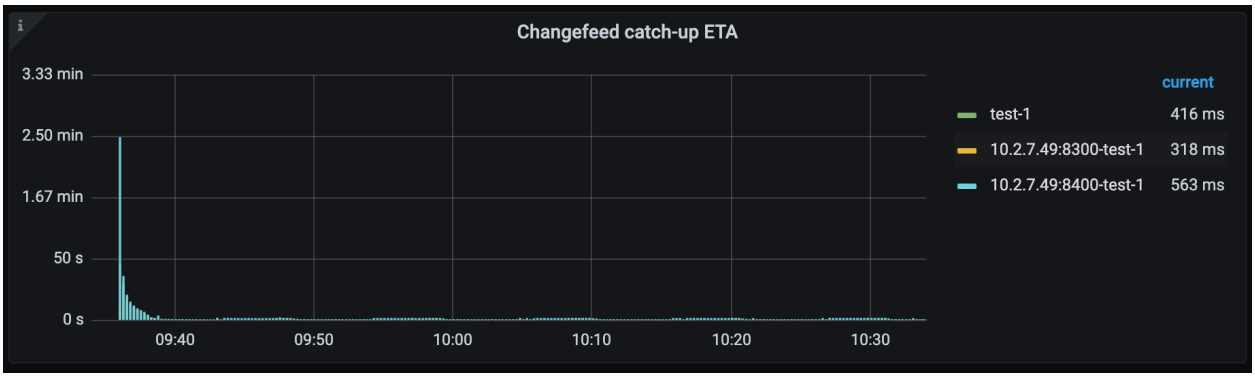
- MySQL sink conflict detect duration: The histogram of the time spent on detecting MySQL sink conflicts
- MySQL sink conflict detect duration percentile: The time (P95, P99, and P999) spent on detecting MySQL sink conflicts within one second
- MySQL sink worker load: The workload of MySQL sink workers of TiCDC nodes



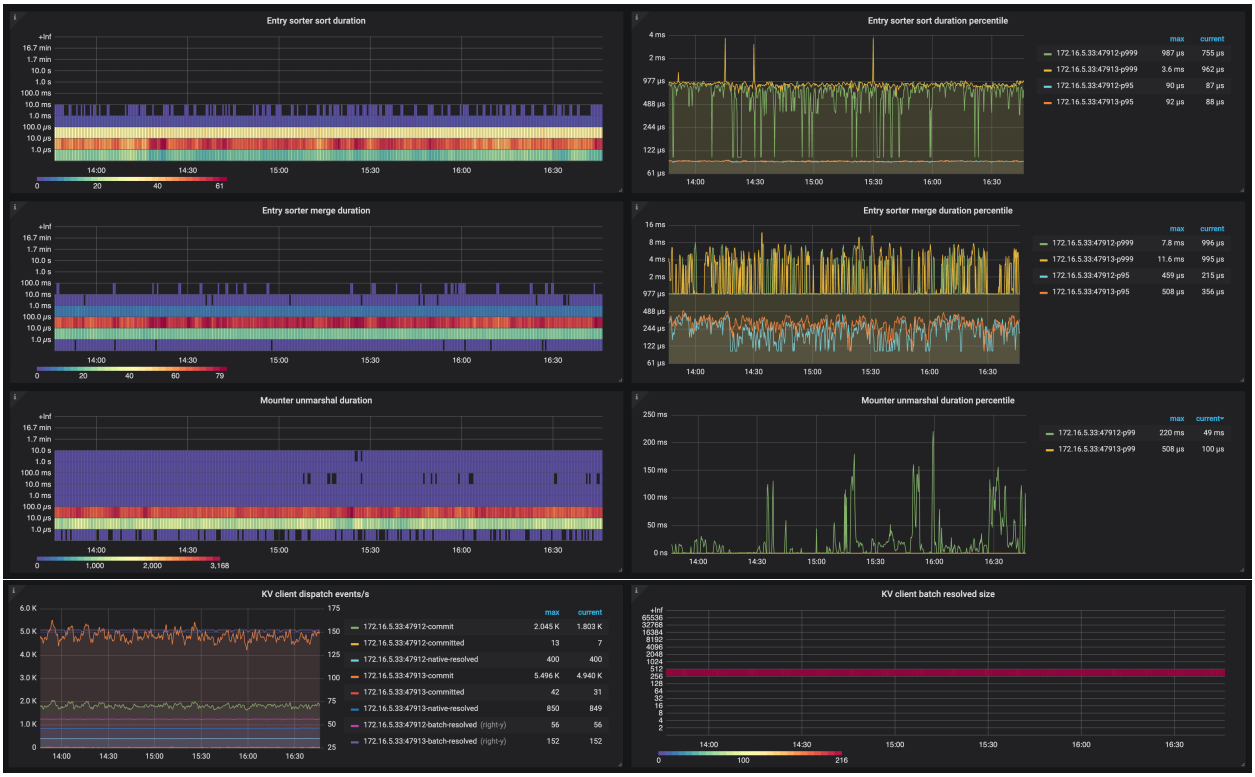


Figure 518: TiCDC Dashboard - Changefeed metrics 4

- Changefeed catch-up ETA: The estimated time needed for the replication task to catch up with the upstream cluster data. When the upstream write speed is faster than the TiCDC replication speed, the metric might be extremely large. Because TiCDC replication speed is subject to many factors, this metric is for reference only and might not be the actual replication time.

13.9.4.2.3 Events

The following is an example of the **Events** panel:

The description of each metric in the **Events** panel is as follows:

- Eventfeed count: The number of Eventfeed RPC requests of TiCDC nodes
- Event size percentile: The event size (P95, P99, and P999) which TiCDC receives from TiKV within one second
- Eventfeed error/m: The number of errors reported by Eventfeed RPC requests of TiCDC nodes per minute
- KV client receive events/s: The number of events that the KV client module of TiCDC nodes receives from TiKV per second
- Puller receive events/s: The number of events that the Puller module of TiCDC nodes receives from the KV client per second
- Puller output events/s: The number of events that the Puller module of TiCDC nodes sends to the Sorter module per second
- Sink flush rows/s: The number of events that TiCDC nodes write to the downstream per second
- Puller buffer size: The number of events that TiCDC nodes cache in the Puller module
- Entry sorter buffer size: The number of events that TiCDC nodes cache in the Sorter module
- Processor/Mounter buffer size: The number of events that TiCDC nodes cache in the Processor module and the Mounter module
- Sink row buffer size: The number of events that TiCDC nodes cache in the Sink module
- Entry sorter sort duration: The histogram of the time spent by TiCDC nodes sorting events
- Entry sorter sort duration percentile: The time (P95, P99, and P999) spent by TiCDC

sorting events within one second

- Entry sorter merge duration: The histogram of the time spent by TiCDC nodes merging sorted events
- Entry sorter merge duration percentile: The time (P95, P99, and P999) spent by TiCDC merging sorted events within one second
- Mounter unmarshal duration: The histogram of the time spent by TiCDC nodes unmarshalling events
- Mounter unmarshal duration percentile: The time (P95, P99, and P999) spent by TiCDC unmarshalling events within one second
- KV client dispatch events/s: The number of events that the KV client module dispatches among the TiCDC nodes
- KV client batch resolved size: The batch size of resolved timestamp messages that TiKV sends to TiCDC

13.9.4.2.4 TiKV

The following is an example of the **TiKV** panel:

The description of each metric in the **TiKV** panel is as follows:

- CDC endpoint CPU: The CPU usage of the CDC endpoint threads on TiKV nodes
- CDC worker CPU: The CPU usage of the CDC worker threads on TiKV nodes
- Min resolved ts: The minimum resolved timestamp on TiKV nodes
- Min resolved region: The Region ID of the minimum resolved timestamp on TiKV nodes
- Resolved ts lag duration percentile: The lag between the minimum resolved timestamp on TiKV nodes and the current time
- Initial scan duration: The histogram of the time spent on incremental scan when TiKV nodes connect to TiCDC nodes
- Initial scan duration percentile: The time (P95, P99, and P999) spent on the incremental scan of TiKV nodes within one second
- Memory without block cache: The memory usage of TiKV nodes excluding the RocksDB block cache
- CDC pending bytes in memory: The memory usage of CDC module on TiKV nodes
- Captured region count: The number of event-capturing Regions on TiKV nodes

13.9.4.3 TiCDC Alert Rules

This document describes the TiCDC alert rules and the corresponding solutions. In descending order, the severity levels are: **Critical**, **Warning**.

13.9.4.3.1 Critical alerts

This section introduces critical alerts and solutions.

`cdc_checkpoint_high_delay`

For critical alerts, you need to pay close attention to abnormal monitoring metrics.

- Alert rule:

  `ticdc_owner_checkpoint_ts_lag > 600`

- Description:

  A replication task is delayed more than 10 minutes.

- Solution:

  See TiCDC Handles Replication Interruption.

`cdc_resolvedts_high_delay`

- Alert rule:

  `ticdc_owner_resolved_ts_lag > 300`

- Description:

  The Resolved TS of a replication task is delayed more than 5 minutes.

- Solution:

  See TiCDC Handles Replication Interruption.

`ticdc_changefeed_failed`

- Alert rule:

  `(max_over_time(ticdc_owner_status[1m])== 2)> 0`

- Description:

  A replication task encounters an unrecoverable error and enters the failed state.

- Solution:

  This alert is similar to replication interruption. See TiCDC Handles Replication Interruption.

`ticdc_processor_exit_with_error_count`

- Alert rule:

  `changes(ticdc_processor_exit_with_error_count[1m])> 0`

- Description:

  A replication task reports an error and exits.

- Solution:

  See TiCDC Handles Replication Interruption.

13.9.4.3.2 Warning alerts

Warning alerts are a reminder for an issue or error.

`cdc_multiple_owners`

- Alert rule:

  `sum(rate(ticdc_owner_ownership_counter[30s]))>= 2`

- Description:

  There are multiple owners in the TiCDC cluster.

- Solution:

  Collect TiCDC logs to locate the root cause.

`cdc_sink_flush_duration_time_more_than_10s`

- Alert rule:

  ```
  histogram_quantile(0.9, rate(ticdc_sink_txn_worker_flush_duration[1m]))
  ↪ > 10
  ```

- Description:

  It takes a replication task more than 10 seconds to write data to the downstream database.

- Solution:

  Check whether there are problems in the downstream database.

`cdc_processor_checkpoint_tso_no_change_for_1m`

- Alert rule:

  ```
  changes(ticdc_processor_checkpoint_ts[1m])< 1
  ```

- Description:

  A replication task has not advanced for more than 1 minute.

- Solution:

  See TiCDC Handles Replication Interruption.

`ticdc_puller_entry_sorter_sort_bucket`

- Alert rule:

  ```
  histogram_quantile(0.9, rate(ticdc_puller_entry_sorter_sort_bucket{}[1m
  ↪ ]))> 1
  ```

- Description:

  The delay of TiCDC puller entry sorter is too high.

- Solution:

  Collect TiCDC logs to locate the root cause.

`ticdc_puller_entry_sorter_merge_bucket`

- Alert rule:

  ```
  histogram_quantile(0.9, rate(ticdc_puller_entry_sorter_merge_bucket{}[1
  ↪ m]))> 1
  ```

- Description:

  The delay of TiCDC puller entry sorter merge is too high.

- Solution:

  Collect TiCDC logs to locate the root cause.

`tikv_cdc_min_resolved_ts_no_change_for_1m`

- Alert rule:

```
changes(tikv_cdc_min_resolved_ts[1m])< 1 and ON (instance)tikv_cdc_
↪ region_resolve_status{status="resolved"} > 0 and ON (instance)tikv_
↪ cdc_captured_region_total > 0
```

- Description:

  The minimum Resolved TS 1 of TiKV CDC has not advanced for 1 minute.

- Solution:

  Collect TiKV logs to locate the root cause.

`tikv_cdc_scan_duration_seconds_more_than_10min`

- Alert rule:

```
histogram_quantile(0.9, rate(tikv_cdc_scan_duration_seconds_bucket{}[1m
↪ ]))> 600
```

- Description:

  The TiKV CDC module has scanned for incremental replication for more than 10 minutes.

- Solution:

  Collect TiCDC monitoring metrics and TiKV logs to locate the root cause.

`ticdc_sink_mysql_execution_error`

- Alert rule:

```
changes(ticdc_sink_mysql_execution_error[1m])> 0
```

- Description:

  An error occurs when a replication task writes data to the downstream MySQL.

- Solution:

  There are many possible root causes. See Troubleshoot TiCDC.

`ticdc_memory_abnormal`

- Alert rule:

  ```
  go_memstats_heap_alloc_bytes{job="ticdc"} > 1e+10
  ```

- Description:

  The TiCDC heap memory usage exceeds 10 GiB.

- Solution:

  Collect TiCDC logs to locate the root cause.

13.9.4.4 Architecture and Principles of TiCDC

13.9.4.4.1 TiCDC architecture

Consisting of multiple TiCDC nodes, a TiCDC cluster uses a distributed and stateless architecture. The design of TiCDC and its components is as follows:

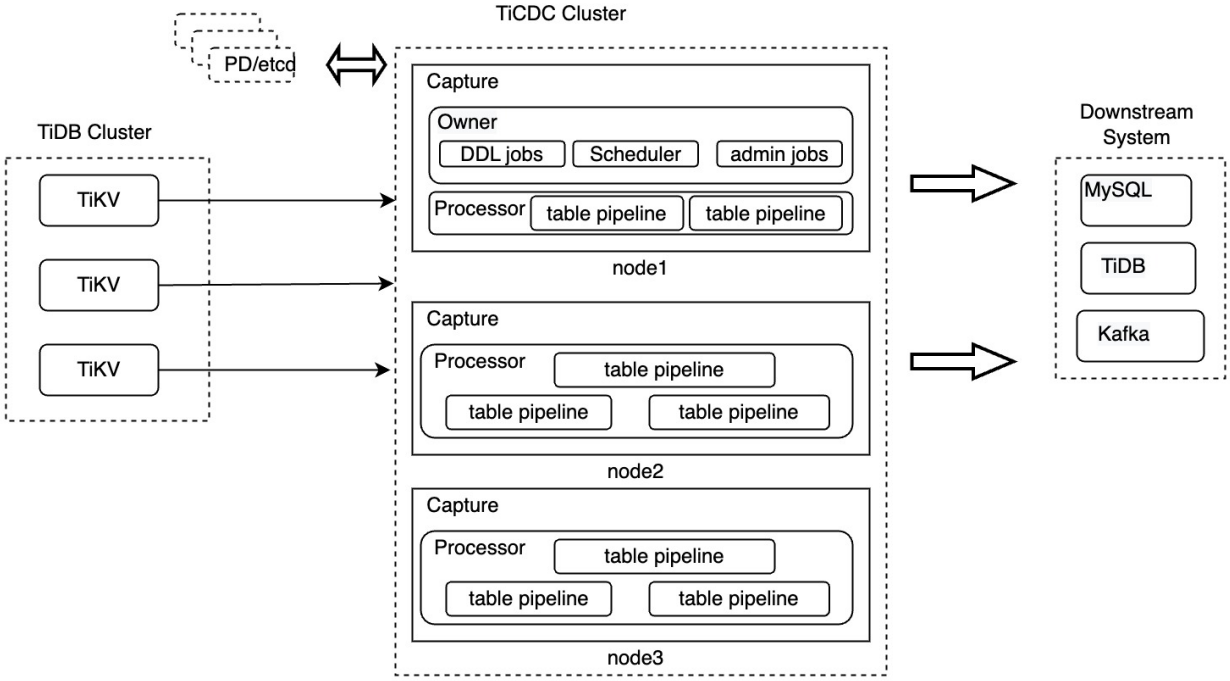

Figure 519: TiCDC architecture

13.9.4.4.2 TiCDC components

In the preceding diagram, a TiCDC cluster consists of multiple nodes running TiCDC instances. Each TiCDC instance carries a Capture process. One of the Capture processes is elected as the owner Capture, which is responsible for scheduling workload, replicating DDL statements, and performing management tasks.

Each Capture process contains one or multiple Processor threads for replicating data from tables in the upstream TiDB. Because table is the minimum unit of data replication in TiCDC, a Processor is composed of multiple table pipelines.

Each pipeline contains the following components: Puller, Sorter, Mounter, and Sink.

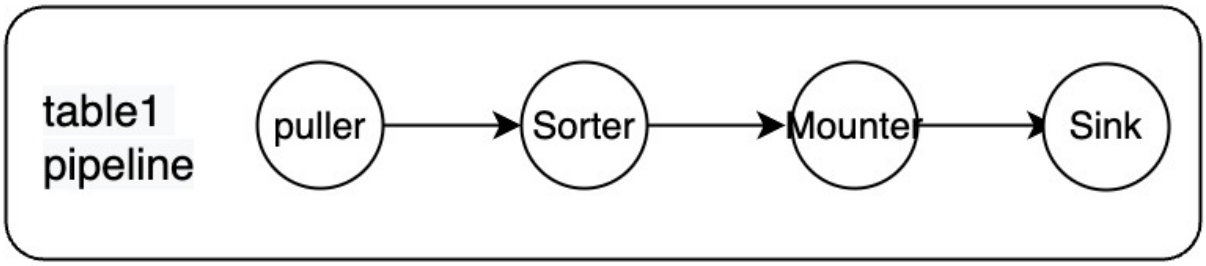

Figure 520: TiCDC architecture

These components work in serial with each other to complete the replication process, including pulling data, sorting data, loading data, and replicating data from the upstream to the downstream. The components are described as follows:

- Puller: pulls DDL and row changes from TiKV nodes.
- Sorter: sorts the changes received from TiKV nodes in ascending order of timestamps.
- Mounter: converts the changes into a format that TiCDC sink can process based on the schema information.
- Sink: replicates the changes to the downstream system.

To realize high availability, each TiCDC cluster runs multiple TiCDC nodes. These nodes regularly report their status to the etcd cluster in PD, and elect one of the nodes as the owner of the TiCDC cluster. The owner node schedules data based on the status stored in etcd and writes the scheduling results to etcd. The Processor completes tasks according to the status in etcd. If the node running the Processor fails, the cluster schedules tables to other nodes. If the owner node fails, the Capture processes in other nodes will elect a new owner. See the following figure:

TiCDC architecture

13.9.4.4.3 Changefeeds and tasks

Changefeed and Task in TiCDC are two logical concepts. The specific description is as follows:

- Changefeed: Represents a replication task. It carries the information about the tables to be replicated and the downstream.

- Task: After TiCDC receives a replication task, it splits this task into several subtasks. Such a subtask is called Task. These Tasks are assigned to the Capture processes of the TiCDC nodes for processing.

For example:

```
cdc cli changefeed create --server="http://127.0.0.1:8300" --sink-uri="kafka
    ↪ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&partition-num=6&max-
    ↪ message-bytes=67108864&replication-factor=1"
cat changefeed.toml
......
[sink]
dispatchers = [
    {matcher = ['test1.tab1', 'test2.tab2'], topic = "{schema}_{table}"},
    {matcher = ['test3.tab3', 'test4.tab4'], topic = "{schema}_{table}"},
]
```

For a detailed description of the parameters in the preceding `cdc cli changefeed create` command, see TiCDC Changefeed Configuration Parameters.

The preceding `cdc cli changefeed create` command creates a changefeed task that replicates `test1.tab1`, `test1.tab2`, `test3.tab3`, and `test4.tab4` to the Kafka cluster. The processing flow after TiCDC receives this command is as follows:

1. TiCDC sends this task to the owner Capture process.
2. The owner Capture process saves information about this changefeed task in etcd in PD.
3. The owner Capture process splits the changefeed task into several Tasks and notifies other Capture processes of the Tasks to be completed.
4. The Capture processes start pulling data from TiKV nodes, process the data, and complete replication.

The following is the TiCDC architecture diagram with Changefeed and Task included:

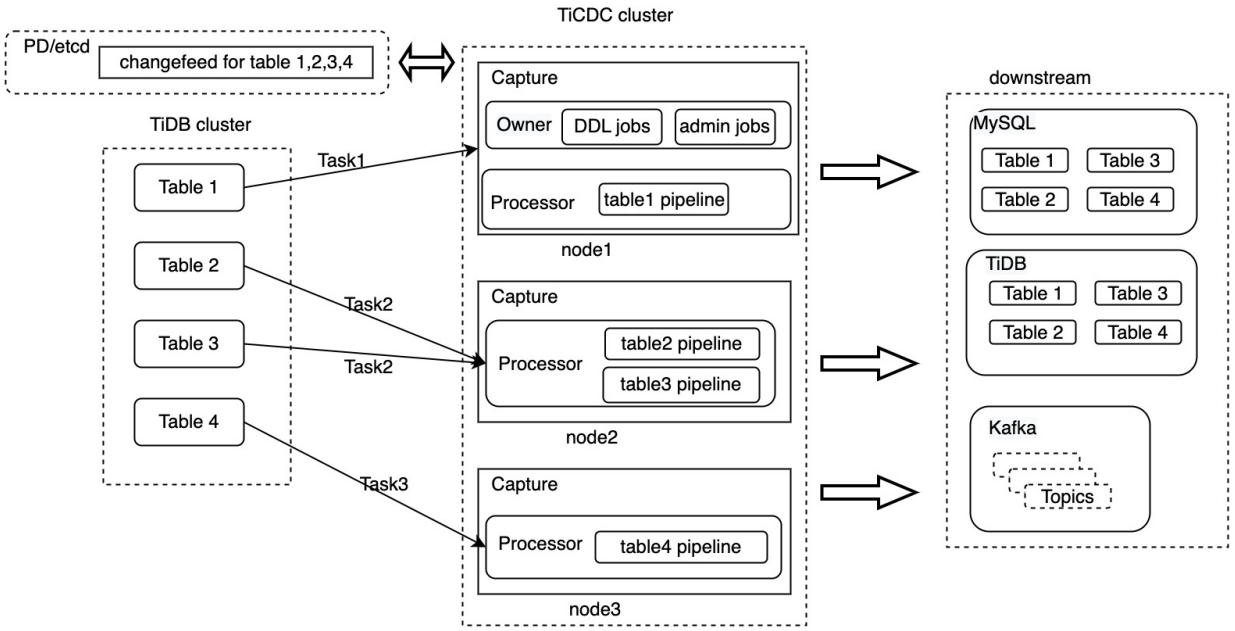

Figure 521: TiCDC architecture

In the preceding diagram, a changefeed is created to replicate four tables to downstream. This changefeed is split into three Tasks, which are sent to the three Capture processes respectively in the TiCDC cluster. After TiCDC processes the data, the data is replicated to the downstream system.

TiCDC supports replicating data to MySQL, TiDB, and Kafka databases. The preceding diagram only illustrates the process of data transfer at the changefeed level. The following sections describe in detail how TiCDC processes data, using Task1 that replicates table `table1` as an example.

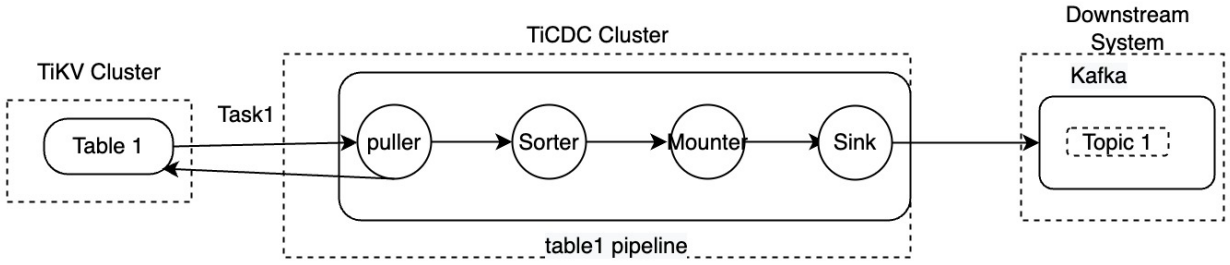

Figure 522: TiCDC architecture

1. Push data: When a data change occurs, TiKV pushes data to the Puller module.
2. Scan incremental data: The Puller module pulls data from TiKV when it finds the data changes received not continuous.

3. Sort data: The Sorter module sorts the data received from TiKV based on the timestamps and sends the sorted data to the Mounter module.
4. Mount data: After receiving the data changes, the Mounter module loads the data in a format that TiCDC sink can understand.
5. Replicate data: The Sink module replicates the data changes to the downstream.

The upstream of TiCDC is the distributed relational database TiDB that supports transactions. When TiCDC replicates data, it should ensure the consistency of data and that of transactions when replicating multiple tables, which is a great challenge. The following sections introduce the key technologies and concepts used by TiCDC to address this challenge.

13.9.4.4.4 Key concepts of TiCDC

For the downstream relational databases, TiCDC ensures the consistency of transactions in a single table and eventual transaction consistency in multiple tables. In addition, TiCDC ensures that any data change that has occurred in the upstream TiDB cluster can be replicated to the downstream at least once.

Architecture-related concepts

- Capture: The process that runs the TiCDC node. Multiple Capture processes constitute a TiCDC cluster. Each Capture process is responsible for replicating data changes in TiKV, including receiving and actively pulling data changes, and replicating the data to the downstream.
- Capture Owner: The owner Capture among multiple Capture processes. Only one owner role exists in a TiCDC cluster at a time. The Capture Owner is responsible for scheduling data within the cluster.
- Processor: The logical thread inside Capture. Each Processor is responsible for processing the data of one or more tables in the same replication stream. A Capture node can run multiple Processors.
- Changefeed: A task that replicates data from an upstream TiDB cluster to a downstream system. A changefeed contains multiple Tasks, and each Task is processed by a Capture node.

Timestamp-related concepts

TiCDC introduces a series of timestamps (TS) to indicate the status of data replication. These timestamps are used to ensure that data is replicated to the downstream at least once and that the consistency of data is guaranteed.

ResolvedTS

This timestamp exists in both TiKV and TiCDC.

- ResolvedTS in TiKV: Represents the start time of the earliest transaction in a Region leader, that is, `ResolvedTS` = max(`ResolvedTS`, min(`StartTS`)). Because a TiDB

cluster contains multiple TiKV nodes, the minimum ResolvedTS of the Region leader on all TiKV nodes is called the global ResolvedTS. The TiDB cluster ensures that all transactions before the global ResolvedTS are committed. Alternatively, you can assume that there are no uncommitted transactions before this timestamp.

- ResolvedTS in TiCDC:
  - table ResolvedTS: Each table has a table-level ResolvedTS, which indicates all data changes in the table that are smaller than the Resolved TS have been received. To make it simple, this timestamp is the same as the minimum value of the ResolvedTS of all Regions corresponding to this table on the TiKV node.
  - global ResolvedTS: The minimum ResolvedTS of all Processors on all TiCDC nodes. Because each TiCDC node has one or more Processors, each Processor corresponds to multiple table pipelines.

  For TiCDC, the ResolvedTS sent by TiKV is a special event in the format of `<resolvedTS: timestamp>`. In general, the ResolvedTS satisfies the following constraints:

```
table ResolvedTS >= global ResolvedTS
```

CheckpointTS

This timestamp exists only in TiCDC. It means that the data changes that occur before this timestamp have been replicated to the downstream system.

- table CheckpointTS: Because TiCDC replicates data in tables, the table checkpointTS indicates all data changes that occur before CheckpointTS have been replicated at the table level.
- processor CheckpointTS: Indicates the minimum table CheckpointTS on a Processor.
- global CheckpointTS: Indicates the minimum CheckpointTS among all Processors.

Generally, a checkpointTS satisfies the following constraint:

```
table CheckpointTS >= global CheckpointTS
```

Because TiCDC only replicates data smaller than the global ResolvedTS to the downstream, the complete constraint is as follows:

```
table ResolvedTS >= global ResolvedTS >= table CheckpointTS >= global
    ↪ CheckpointTS
```

After data changes and transactions are committed, the ResolvedTS on the TiKV node will continue to advance, and the Puller module on the TiCDC node keeps receiving data pushed by TiKV. The Puller module also decides whether to scan incremental data based on

the data changes it has received, which ensures that all data changes are sent to the TiCDC node.

The Sorter module sorts data received by the Puller module in ascending order according to the timestamp. This process ensures data consistency at the table level. Next, the Mounter module assembles the data changes from the upstream into a format that the Sink module can consume, and sends it to the Sink module. The Sink module replicates the data changes between the CheckpointTS and the ResolvedTS to the downstream in the order of the timestamp, and advances the checkpointTS after the downstream receives the data changes.

The preceding sections only cover data changes of DML statements and do not include DDL statements. The following sections introduce the timestamp related to DDL statements.

Barrier TS

Barrier TS is generated when there are DDL change events or a Syncpoint is used.

- DDL change events: Barrier TS ensures that all changes before the DDL statement are replicated to the downstream. After this DDL statement is executed and replicated, TiCDC starts replicating other data changes. Because DDL statements are processed by the Capture Owner, the Barrier TS corresponding to a DDL statement is only generated by the owner node.
- Syncpoint: When you enable the Syncpoint feature of TiCDC, a Barrier TS is generated by TiCDC according to the `sync-point-interval` you specified. When all table changes before this Barrier TS are replicated, TiCDC inserts the current global CheckpointTS as the primary TS to the table recording tsMap in downstream. Then TiCDC continues data replication.

After a Barrier TS is generated, TiCDC ensures that only data changes that occur before this Barrier TS are replicated to downstream. Before these data changes are replicated to downstream, the replication task does not proceed. The owner TiCDC checks whether all target data has been replicated by continuously comparing the global CheckpointTS and the Barrier TS. If the global CheckpointTS equals to the Barrier TS, TiCDC continues replication after performing a designated operation (such as executing a DDL statement or recording the global CheckpointTS downstream). Otherwise, TiCDC waits for all data changes that occur before the Barrier TS to be replicated to the downstream.

13.9.4.4.5 Major processes

This section describes the major processes of TiCDC to help you better understand its working principles.

Note that the following processes occur only within TiCDC and are transparent to users. Therefore, you do not need to care about which TiCDC node you are starting.

Start TiCDC

- For a TiCDC node that is not an owner, it works as follows:

    1. Starts the Capture process.
    2. Starts the Processor.
    3. Receives the Task scheduling command executed by the Owner.
    4. Starts or stops tablePipeline according to the scheduling command.

- For an owner TiCDC node, it works as follows:

    1. Starts the Capture process.
    2. The node is elected as the Owner and the corresponding thread is started.
    3. Reads the changefeed information.
    4. Starts the changefeed management process.
    5. Reads the schema information in TiKV according to the changefeed configuration and the latest CheckpointTS to determine the tables to be replicated.
    6. Reads the list of tables currently replicated by each Processor and distributes the tables to be added.
    7. Updates the replication progress.

Stop TiCDC

Usually, you stop a TiCDC node when you need to upgrade it or perform some planned maintenance operations. The process of stopping a TiCDC node is as follows:

1. The node receives the command to stop itself.
2. The node sets its service status to unavailable.
3. The node stops receiving new replication tasks.
4. The node notifies the Owner node to transfer its data replication tasks to other nodes.
5. The node stops after the replication tasks are transferred to other nodes.

13.9.4.5 TiCDC Server Configurations

This document describes the CLI and configuration file parameters used in TiCDC.

13.9.4.5.1 `cdc server` CLI parameters

The following are descriptions of options available in a `cdc server` command:

- `addr`: The listening address of TiCDC, the HTTP API address, and the Prometheus address of the TiCDC service. The default value is `127.0.0.1:8300`.
- `advertise-addr`: The advertised address via which clients access TiCDC. If unspecified, the value is the same as that of `addr`.
- `pd`: A comma-separated list of PD endpoints.
- `config`: The address of the configuration file that TiCDC uses (optional). This option is supported since TiCDC v5.0.0. This option can be used in the TiCDC deployment since TiUP v1.4.0. For detailed configuration description, see TiCDC Changefeed Configurations

- `data-dir`: Specifies the directory that TiCDC uses when it needs to use disks to store files. The sort engine used by TiCDC and redo logs use this directory to store temporary files. It is recommended to ensure that the free disk space for this directory is greater than or equal to 500 GiB. If you are using TiUP, you can configure `data_dir` in the `cdc_servers` section, or directly use the default `data_dir` path in `global`.
- `gc-ttl`: The TTL (Time To Live) of the service level `GC safepoint` in PD set by TiCDC, and the duration that the replication task can suspend, in seconds. The default value is `86400`, which means 24 hours. Note: Suspending of the TiCDC replication task affects the progress of TiCDC GC safepoint, which means that it affects the progress of upstream TiDB GC, as detailed in Complete Behavior of TiCDC GC safepoint.
- `log-file`: The path to which logs are output when the TiCDC process is running. If this parameter is not specified, logs are written to the standard output (stdout).
- `log-level`: The log level when the TiCDC process is running. The default value is `"info"`.
- `ca`: Specifies the path of the CA certificate file in PEM format for TLS connection (optional).
- `cert`: Specifies the path of the certificate file in PEM format for TLS connection (optional).
- `cert-allowed-cn`: Specifies the path of the common name in PEM format for TLS connection (optional).
- `key`: Specifies the path of the private key file in PEM format for TLS connection (optional).
- `tz`: Time zone used by the TiCDC service. TiCDC uses this time zone when it internally converts time data types such as `TIMESTAMP` or when it replicates data to the downstream. The default is the local time zone in which the process runs. If you specify `time-zone` (in `sink-uri`) and `tz` at the same time, the internal TiCDC processes use the time zone specified by `tz`, and the sink uses the time zone specified by `time-zone` for replicating data to the downstream. Make sure that the time zone specified by `tz` is the same as that specified by `time-zone` (in `sink-uri`).
- `cluster-id`: (optional) The ID of the TiCDC cluster. The default value is `default`. `cluster-id` is the unique identifier of a TiCDC cluster. TiCDC nodes with the same `cluster-id` belong to the same cluster. The length of a `cluster-id` is 128 characters at most. `cluster-id` must follow the pattern of `^[a-zA-Z0-9]+(-[a-zA-Z0-9]+)*$` and cannot be one of the following: `owner`, `capture`, `task`, `changefeed`, `job`, and `meta`.

13.9.4.5.2 `cdc server` configuration file parameters

The following describes the configuration file specified by the `config` option in the `cdc server` command:

```
#### The configuration method of the following parameters is the same as
    ↪ that of CLI parameters, but the CLI parameters have higher priorities
    ↪ .
addr = "127.0.0.1:8300"
advertise-addr = ""
```

```
log-file = ""
log-level = "info"
data-dir = ""
gc-ttl = 86400 # 24 h
tz = "System"
cluster-id = "default"
#### This parameter specifies the maximum memory threshold (in bytes) for
   ↪ tuning GOGC: Setting a smaller threshold increases the GC frequency.
   ↪ Setting a larger threshold reduces GC frequency and consumes more
   ↪ memory resources for the TiCDC process. Once the memory usage exceeds
   ↪  this threshold, GOGC Tuner stops working. The default value is 0,
   ↪ indicating that GOGC Tuner is disabled.
gc-tuner-memory-threshold = 0

[security]
  ca-path = ""
  cert-path = ""
  key-path = ""
  # This parameter controls whether to enable the TLS client authentication.
     ↪  The default value is false.
  mtls = false
  # This parameter controls whether to use username and password for client
     ↪ authentication. The default value is false.
  client-user-required = false
  # This parameter lists the usernames that are allowed for client
     ↪ authentication. Authentication requests with usernames not in this
     ↪ list will be rejected. The default value is null.
  client-allowed-user = ["username_1", "username_2"]

#### The session duration between TiCDC and etcd services, measured in
   ↪ seconds. This parameter is optional and its default value is 10.
capture-session-ttl = 10 # 10s

#### The interval at which the Owner module in the TiCDC cluster attempts to
   ↪  push the replication progress. This parameter is optional and its
   ↪ default value is `50000000` nanoseconds (that is, 50 milliseconds).
   ↪ You can configure this parameter in two ways: specifying only the
   ↪ number (for example, configuring it as `40000000` represents 40000000
   ↪  nanoseconds, which is 40 milliseconds), or specifying both the
   ↪ number and unit (for example, directly configuring it as `40ms`).
owner-flush-interval = 50000000 # 50 ms

#### The interval at which the Processor module in the TiCDC cluster
   ↪ attempts to push the replication progress. This parameter is optional
   ↪  and its default value is `50000000` nanoseconds (that is, 50
```

```
   ↪ milliseconds). The configuration method of this parameter is the same
   ↪  as that of `owner-flush-interval`.
processor-flush-interval = 50000000 # 50 ms

#### [log]
#### # The output location for internal error logs of the zap log module.
   ↪ This parameter is optional and its default value is "stderr".
####  error-output = "stderr"
####  [log.file]
####    # The maximum size of a single log file, measured in MiB. This
   ↪ parameter is optional and its default value is 300.
####    max-size = 300 # 300 MiB
####    # The maximum number of days to retain log files. This parameter is
   ↪ optional and its default value is `0`, indicating never to delete.
####    max-days = 0
####    # The number of log files to retain. This parameter is optional and
   ↪ its default value is `0`, indicating to keep all log files.
####    max-backups = 0

#[sorter]
#### The size of the shared pebble block cache in the Sorter module for the
   ↪ 8 pebble DBs started by default, measured in MiB. The default value
   ↪ is 128.
#### cache-size-in-mb = 128
#### The directory where sorter files are stored relative to the data
   ↪ directory (`data-dir`). This parameter is optional and its default
   ↪ value is "/tmp/sorter".
#### sorter-dir = "/tmp/sorter"

#### [kv-client]
####  The number of threads that can be used in a single Region worker.
   ↪ This parameter is optional and its default value is 8.
####  worker-concurrent = 8
####  The number of threads in the shared thread pool of TiCDC, mainly used
   ↪  for processing KV events. This parameter is optional and its default
   ↪  value is 0, indicating that the default pool size is twice the
   ↪ number of CPU cores.
####  worker-pool-size = 0
####  The retry duration of Region connections. This parameter is optional
   ↪ and its default value is `60000000000` nanoseconds (that is, 1 minute
   ↪ ). You can configure this parameter in two ways: specifying only the
   ↪ number (for example, configuring it as `50000000` represents 50000000
   ↪  nanoseconds, which is 50 milliseconds), or specifying both the
   ↪ number and unit (for example, directly configuring it as `50ms`).
####  region-retry-duration = 60000000000
```

13.9.4.6 CLI and Configuration Parameters of TiCDC Changefeeds

13.9.4.6.1 Changefeed CLI parameters

This section introduces the command-line parameters of TiCDC changefeeds by illustrating how to create a replication (changefeed) task:

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7178706266519722477,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"mysql://root:xxxxx@127.0.0.1:4000/?time
    ↪ -zone=","create_time":"2024-11-11T15:05:46.679218+08:00","start_ts
    ↪ ":438156275634929669,"engine":"unified","config":{"case_sensitive":
    ↪ false,"enable_old_value":true,"force_replicate":false,"ignore_
    ↪ ineligible_table":false,"check_gc_safe_point":true,"enable_sync_point
    ↪ ":true,"bdr_mode":false,"sync_point_interval":30000000000,"sync_point
    ↪ _retention":3600000000000,"filter":{"rules":["test.*"],"event_filters
    ↪ ":null},"mounter":{"worker_num":16},"sink":{"protocol":"","schema_
    ↪ registry":"","csv":{"delimiter":",","quote":"\"","null":"\\N","
    ↪ include_commit_ts":false},"column_selectors":null,"transaction_
    ↪ atomicity":"none","encoder_concurrency":16,"terminator":"\r\n","date_
    ↪ separator":"none","enable_partition_separator":false},"consistent":{"
    ↪ level":"none","max_log_size":64,"flush_interval":2000,"storage
    ↪ ":""}},"state":"normal","creator_version":"v8.4.0"}
```

- `--changefeed-id`: The ID of the replication task. The format must match the `^[ ↪ a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. Configure `--sink-uri` according to the following format. Currently, the scheme supports `mysql`, `tidb`, and `kafka`.

  ```
  [scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
  ```

  When the sink URI contains special characters such as `! * ' ( ) ; : @ & = + $ ↪ , / ? % # [ ]`, you need to escape the special characters, for example, in URI Encoder.

- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the configuration file of the changefeed.

13.9.4.6.2 Changefeed configuration parameters

This section introduces the configuration of a replication task.

```
#### Specifies the memory quota (in bytes) that can be used in the capture
    ↪ server by the sink manager.
#### If the value is exceeded, the overused part will be recycled by the go
    ↪ runtime.
#### The default value is `1073741824` (1 GB).
#### memory-quota = 1073741824

#### Specifies whether the database names and tables in the configuration
    ↪ file are case-sensitive.
#### Starting from v6.5.6, v7.1.3, and v7.5.0, the default value changes
    ↪ from true to false.
#### This configuration item affects configurations related to filter and
    ↪ sink.
case-sensitive = false

#### Specifies whether to enable the Syncpoint feature, which is supported
    ↪ since v6.3.0 and is disabled by default.
#### Since v6.4.0, only the changefeed with the SYSTEM_VARIABLES_ADMIN or
    ↪ SUPER privilege can use the TiCDC Syncpoint feature.
#### Note: This configuration item only takes effect if the downstream is
    ↪ TiDB.
#### enable-sync-point = false

#### Specifies the interval at which Syncpoint aligns the upstream and
    ↪ downstream snapshots.
#### The format is in h m s. For example, "1h30m30s".
#### The default value is "10m" and the minimum value is "30s".
#### Note: This configuration item only takes effect if the downstream is
    ↪ TiDB.
#### sync-point-interval = "5m"

#### Specifies how long the data is retained by Syncpoint in the downstream
    ↪ table. When this duration is exceeded, the data is cleaned up.
```

```
#### The format is in h m s. For example, "24h30m30s".
#### The default value is "24h".
#### Note: This configuration item only takes effect if the downstream is
    ↪ TiDB.
#### sync-point-retention = "1h"

#### Starting from v6.5.6, v7.1.3, and v7.5.0, this configuration item
    ↪ specifies the SQL mode used when parsing DDL statements. Multiple
    ↪ modes are separated by commas.
#### The default value is the same as the default SQL mode of TiDB.
#### sql-mode = "ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_
    ↪ ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_
    ↪ SUBSTITUTION"

#### The duration for which the changefeed is allowed to automatically retry
    ↪  when internal errors or exceptions occur. The default value is 30
    ↪ minutes.
#### The changefeed enters the failed state if internal errors or exceptions
    ↪  occur in the changefeed and persist longer than the duration set by
    ↪ this parameter.
#### When the changefeed is in the failed state, you need to restart the
    ↪ changefeed manually for recovery.
#### The format of this parameter is "h m s", for example, "1h30m30s".
changefeed-error-stuck-duration = "30m"

#### The default value is false, indicating that bi-directional replication
    ↪ (BDR) mode is not enabled.
#### To set up BDR clusters using TiCDC, modify this parameter to `true` and
    ↪  set the TiDB clusters to BDR mode.
#### For more information, see https://docs.pingcap.com/tidb/stable/ticdc-
    ↪ bidirectional-replication.
#### bdr-mode = false

[mounter]
#### The number of threads with which the mounter decodes KV data. The
    ↪ default value is 16.
#### worker-num = 16

[filter]
#### Ignores the transaction of specified start_ts.
#### ignore-txn-start-ts = [1, 2]

#### Filter rules.
#### Filter syntax: <https://docs.pingcap.com/tidb/stable/table-filter#
    ↪ syntax>.
```

```
rules = ['*.*', '!test.*']

#### Event filter rules.
#### The detailed syntax is described in <https://docs.pingcap.com/tidb/
    ↪ stable/ticdc-filter>
#### The first event filter rule.
#### [[filter.event-filters]]
#### matcher = ["test.worker"] # matcher is an allow list, which means this
    ↪ rule only applies to the worker table in the test database.
#### ignore-event = ["insert"] # Ignore insert events.
#### ignore-sql = ["^drop", "add column"] # Ignore DDLs that start with "
    ↪ drop" or contain "add column".
#### ignore-delete-value-expr = "name = 'john'" # Ignore delete DMLs that
    ↪ contain the condition "name = 'john'".
#### ignore-insert-value-expr = "id >= 100" # Ignore insert DMLs that
    ↪ contain the condition "id >= 100".
#### ignore-update-old-value-expr = "age < 18" # Ignore update DMLs whose
    ↪ old value contains "age < 18".
#### ignore-update-new-value-expr = "gender = 'male'" # Ignore update DMLs
    ↪ whose new value contains "gender = 'male'".

#### The second event filter rule.
#### matcher = ["test.fruit"] # matcher is an allow list, which means this
    ↪ rule only applies to the fruit table in the test database.
#### ignore-event = ["drop table", "delete"] # Ignore the `drop table` DDL
    ↪ events and the `delete` DML events. Note that when a value in the
    ↪ clustered index column is updated in TiDB, TiCDC splits an `UPDATE`
    ↪ event into `DELETE` and `INSERT` events. TiCDC cannot identify such
    ↪ events as `UPDATE` events and thus cannot correctly filter out such
    ↪ events.
#### ignore-sql = ["^drop table", "alter table"] # Ignore DDL statements
    ↪ that start with `drop table` or contain `alter table`.
#### ignore-insert-value-expr = "price > 1000 and origin = 'no where'" #
    ↪ Ignore insert DMLs that contain the conditions "price > 1000" and "
    ↪ origin = 'no where'".

[scheduler]
#### Allocate tables to multiple TiCDC nodes for replication on a per-Region
    ↪  basis.
#### Note: This configuration item only takes effect on Kafka changefeeds
    ↪ and is not supported on MySQL changefeeds.
#### The value is "false" by default. Set it to "true" to enable this
    ↪ feature.
enable-table-across-nodes = false
#### When `enable-table-across-nodes` is enabled, there are two allocation
```

```
   ↪ modes:
#### 1. Allocate tables based on the number of Regions, so that each TiCDC
   ↪ node handles roughly the same number of Regions. If the number of
   ↪ Regions for a table exceeds the value of `region-threshold`, the
   ↪ table will be allocated to multiple nodes for replication. The
   ↪ default value of `region-threshold` is 10000.
#### region-threshold = 10000
#### 2. Allocate tables based on the write traffic, so that each TiCDC node
   ↪ handles roughly the same number of modified rows. Only when the
   ↪ number of modified rows per minute in a table exceeds the value of `
   ↪ write-key-threshold`, will this allocation take effect.
#### write-key-threshold = 30000
#### Note:
#### * The default value of `write-key-threshold` is 0, which means that the
   ↪  traffic allocation mode is not used by default.
#### * You only need to configure one of the two modes. If both `region-
   ↪ threshold` and `write-key-threshold` are configured, TiCDC
   ↪ prioritizes the traffic allocation mode, namely `write-key-threshold
   ↪ `.

[sink]
############### MQ sink configuration items ############
#### For the sink of MQ type, you can use dispatchers to configure the event
   ↪  dispatcher.
#### Since v6.1.0, TiDB supports two types of event dispatchers: partition
   ↪ and topic. For more information, see <partition and topic link>.
#### The matching syntax of matcher is the same as the filter rule syntax.
   ↪ For details about the matcher rules, see <>.
#### Note: This configuration item only takes effect if the downstream is MQ
   ↪ .
#### Note: When the downstream MQ is Pulsar, if the routing rule for `
   ↪ partition` is not specified as any of `ts`, `index-value`, `table`,
   ↪ or `default`, each Pulsar message will be routed using the string you
   ↪  set as the key.
#### For example, if you specify the routing rule for a matcher as the
   ↪ string `code`, then all Pulsar messages that match that matcher will
   ↪ be routed with `code` as the key.
#### dispatchers = [
####   {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1",
   ↪ partition = "index-value"},
####   {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2",
   ↪ partition = "index-value", index = "index1"},
####   {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3",
   ↪ partition = "table"},
####   {matcher = ['test6.*'], partition = "columns", columns = "['a', 'b
```

```
    ↪ ']"}
####   {matcher = ['test7.*'], partition = "ts"}
#### ]

#### column-selectors is introduced in v7.5.0 and only takes effect when the
    ↪  downstream is Kafka.
#### column-selectors is used to select specific columns for replication.
#### column-selectors = [
####    {matcher = ['test.t1'], columns = ['a', 'b']},
####    {matcher = ['test.*'], columns = ["*", "!b"]},
####    {matcher = ['test1.t1'], columns = ['column*', '!column1']},
####    {matcher = ['test3.t'], columns = ["column?", "!column1"]},
#### ]

#### The protocol configuration item specifies the protocol format used for
    ↪ encoding messages.
#### When the downstream is Kafka, the protocol can be canal-json, avro,
    ↪ debezium, open-protocol, or simple.
#### When the downstream is Pulsar, the protocol can only be canal-json.
#### When the downstream is a storage service, the protocol can only be
    ↪ canal-json or csv.
#### Note: This configuration item only takes effect if the downstream is
    ↪ Kafka, Pulsar, or a storage service.
#### protocol = "canal-json"

#### Starting from v7.2.0, the `delete-only-output-handle-key-columns`
    ↪ parameter specifies the output of DELETE events. This parameter is
    ↪ valid only for canal-json and open-protocol protocols.
#### This parameter is incompatible with `force-replicate`. If both this
    ↪ parameter and `force-replicate` is set to `true`, TiCDC reports an
    ↪ error when creating a changefeed.
#### The default value is false, which means outputting all columns. When
    ↪ you set it to true, only primary key columns or unique index columns
    ↪ are output.
#### The Avro protocol is not controlled by this parameter and always
    ↪ outputs only the primary key columns or unique index columns.
#### The CSV protocol is not controlled by this parameter and always outputs
    ↪  all columns.
delete-only-output-handle-key-columns = false

#### Schema registry URL.
#### Note: This configuration item only takes effect if the downstream is MQ
    ↪ .
#### schema-registry = "http://localhost:80801/subjects/{subject-name}/
    ↪ versions/{version-number}/schema"
```

```
#### Specifies the number of encoder threads used when encoding data.
#### Note: This configuration item only takes effect if the downstream is MQ
   ↪ .
#### The default value is 32.
#### encoder-concurrency = 32

#### Specifies whether to enable kafka-sink-v2 that uses the kafka-go sink
   ↪ library.
#### Note: This configuration item is experimental, and only takes effect if
   ↪  the downstream is MQ.
#### The default value is false.
#### enable-kafka-sink-v2 = false

#### Starting from v7.1.0, this configuration item specifies whether to only
   ↪  output the updated columns.
#### Note: This configuration item only applies to the MQ downstream using
   ↪ the open-protocol and canal-json.
#### The default value is false.
#### only-output-updated-columns = false

############### Storage sink configuration items ############
#### The following three configuration items are only used when you
   ↪ replicate data to storage sinks and can be ignored when replicating
   ↪ data to MQ or MySQL sinks.
#### Row terminator, used for separating two data change events. The default
   ↪  value is an empty string, which means "\r\n" is used.
#### terminator = ''
#### Date separator type used in the file directory. Value options are `none
   ↪ `, `year`, `month`, and `day`. `day` is the default value and means
   ↪ separating files by day. For more information, see <https://docs.
   ↪ pingcap.com/tidb/stable/ticdc-sink-to-cloud-storage#data-change-
   ↪ records>.
#### Note: This configuration item only takes effect if the downstream is a
   ↪ storage service.
date-separator = 'day'
#### Whether to use partitions as the separation string. The default value
   ↪ is true, which means that partitions in a table are stored in
   ↪ separate directories. It is recommended that you keep the value as `
   ↪ true` to avoid potential data loss in downstream partitioned tables <
   ↪ https://github.com/pingcap/tiflow/issues/8724>. For usage examples,
   ↪ see <https://docs.pingcap.com/tidb/dev/ticdc-sink-to-cloud-storage#
   ↪ data-change-records)>.
#### Note: This configuration item only takes effect if the downstream is a
   ↪ storage service.
```

```
enable-partition-separator = true

#### Controls whether to disable the output of schema information. The
    ↪ default value is false, which means enabling the output of schema
    ↪ information.
#### Note: This parameter only takes effect when the sink type is MQ and the
    ↪  output protocol is Debezium.
debezium-disable-schema = false

#### Since v6.5.0, TiCDC supports saving data changes to storage services in
    ↪  CSV format. Ignore the following configurations if you replicate
    ↪ data to MQ or MySQL sinks.
#### [sink.csv]
#### The character used to separate fields in the CSV file. The value must
    ↪ be an ASCII character and defaults to `,`.
#### delimiter = ','
#### The quotation character used to surround fields in the CSV file. The
    ↪ default value is `"`. If the value is empty, no quotation is used.
#### quote = '"'
#### The character displayed when a CSV column is null. The default value is
    ↪  `\N`.
#### null = '\N'
#### Whether to include commit-ts in CSV rows. The default value is false.
#### include-commit-ts = false
#### The encoding method of binary data, which can be 'base64' or 'hex'. The
    ↪  default value is 'base64'.
#### binary-encoding-method = 'base64'
#### Whether to output handle key information. The default value is false.
#### This configuration parameter is for internal implementation only, so it
    ↪  is not recommended to set it.
#### output-handle-key = false
#### Whether to output the value before the row data changes. The default
    ↪ value is false.
#### When it is enabled, the UPDATE event will output two rows of data: the
    ↪ first row is a DELETE event that outputs the data before the change;
    ↪ the second row is an INSERT event that outputs the changed data.
#### When it is enabled (setting it to true), the "is-update" column will be
    ↪  added before the column with data changes. This added column is used
    ↪  to identify whether the data change of the current row comes from
    ↪ the UPDATE event or the original INSERT/DELETE event.
#### If the data change of the current row comes from the UPDATE event, the
    ↪ value of the "is-update" column is true. Otherwise it is false.
#### output-old-value = false

#### Starting from v8.0.0, TiCDC supports the Simple message encoding
```

```
    ↪ protocol. The following are the configuration parameters for the
    ↪ Simple protocol.
#### For more information about the protocol, see <https://docs.pingcap.com/
    ↪ tidb/stable/ticdc-simple-protocol>.
#### The following configuration parameters control the sending behavior of
    ↪ bootstrap messages.
#### send-bootstrap-interval-in-sec controls the time interval for sending
    ↪ bootstrap messages, in seconds.
#### The default value is 120 seconds, which means that a bootstrap message
    ↪ is sent every 120 seconds for each table.
#### send-bootstrap-interval-in-sec = 120

#### send-bootstrap-in-msg-count controls the message interval for sending
    ↪ bootstrap, in message count.
#### The default value is 10000, which means that a bootstrap message is
    ↪ sent every 10000 row changed messages for each table.
#### send-bootstrap-in-msg-count = 10000
#### Note: If you want to disable the sending of bootstrap messages, set
    ↪ both send-bootstrap-interval-in-sec and send-bootstrap-in-msg-count
    ↪ to 0.

#### send-bootstrap-to-all-partition controls whether to send bootstrap
    ↪ messages to all partitions.
#### The default value is true, which means that bootstrap messages are sent
    ↪  to all partitions of the corresponding table topic.
#### Setting it to false means bootstrap messages are sent to only the first
    ↪  partition of the corresponding table topic.
#### send-bootstrap-to-all-partition = true

[sink.kafka-config.codec-config]
#### encoding-format controls the encoding format of the Simple protocol
    ↪ messages. Currently, the Simple protocol message supports "json" and
    ↪ "avro" encoding formats.
#### The default value is "json".
#### encoding-format = "json"

[sink.open]

    ↪ events.
output-raw-change-event = false
```

13.9.4.7 Output Protocols

13.9.4.7.1 TiCDC Avro Protocol

TiCDC Avro protocol is a third-party implementation of the Confluent Avro data exchange protocol defined by Confluent Platform. Avro is a data format defined by Apache Avro™

This document describes how TiCDC implements the Confluent Avro protocol, and the interaction between Avro and Confluent Schema Registry.

> **Warning:**
>
> Starting from v7.3.0, if you enable TiCDC to replicate tables without a valid index, TiCDC will report an error when you create a changefeed that uses the Avro protocol.

Use Avro

The following is a configuration example using Avro:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-avro" --sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=
    ↪ avro" --schema-registry=http://127.0.0.1:8081 --config changefeed_
    ↪ config.toml
```

The value of `--schema-registry` supports the `https` protocol and `username:password` authentication. The username and password must be URL-encoded. For example, `--schema ↪ -registry=https://username:password@schema-registry-uri.com`.

> **Note:**
>
> When using the Avro protocol, one Kafka topic can only contain data for one table. You need to configure the Topic dispatcher in the configuration file.

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

Definition of the data format

TiCDC converts a DML event into a Kafka event, and the Key and Value of an event are encoded according to the Avro protocol.

Key data format

```
{
    "name":"{{TableName}}",
    "namespace":"{{Namespace}}",
    "type":"record",
    "fields":[
        {{ColumnValueBlock}},
        {{ColumnValueBlock}},
    ]
}
```

- `{{TableName}}` indicates the name of the table where the event occurs.
- `{{Namespace}}` is the namespace of Avro.
- `{{ColumnValueBlock}}` defines the format of each column of data.

The `fields` in the key contains only primary key columns or unique index columns.

Value data format

```
{
    "name":"{{TableName}}",
    "namespace":"{{Namespace}}",
    "type":"record",
    "fields":[
        {{ColumnValueBlock}},
        {{ColumnValueBlock}},
    ]
}
```

The data format of Value is the same as that of Key, by default. However, `fields` in the Value contains all columns.

> **Note:**
>
> The Avro protocol encodes DML events as follows:
>
> - For Delete events, Avro only encodes the Key part. The Value part is empty.
> - For Insert events, Avro encodes all column data to the Value part.
> - For Update events, Avro encodes only all column data that is updated to the Value part.
>
> The Avro protocol does not encode the old values for Update and Delete events. Additionally, to be compatible with most Confluent sink connectors that rely on `null` records to identify deletions (`delete.on.null`), Delete events do not include extension information, such as `_tidb_commit_ts`, even when `enable-tidb-extension` is enabled. If you need these features, consider using other protocols such as Canal-JSON or Debezium.

TiDB extension fields

By default, Avro only collects data of changed rows in DML events and does not collect the type of data changes or TiDB-specific CommitTS (the unique identifiers of transactions). To address this issue, TiCDC introduces the following three TiDB extension fields to the Avro protocol message. When `enable-tidb-extension` is set to `true` (`false` by default) in `sink-uri`, TiCDC adds these three fields to the Avro messages during message generation.

- `_tidb_op`: The DML type. "c" indicates insert and "u" indicates updates.
- `_tidb_commit_ts`: The unique identifier of a transaction.
- `_tidb_commit_physical_time`: The physical timestamp in a transaction identifier.

The following is a configuration example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-avro-enable-extension" --sink-uri="kafka://127.0.0.1:9092/topic
    ↪ -name?protocol=avro&enable-tidb-extension=true" --schema-registry=
    ↪ http://127.0.0.1:8081 --config changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

After you enable `enable-tidb-extension`, the data format of the Value will be as follows:

```
{
    "name":"{{TableName}}",
    "namespace":"{{Namespace}}",
    "type":"record",
    "fields":[
        {{ColumnValueBlock}},
        {{ColumnValueBlock}},
        {
            "name":"_tidb_op",
            "type":"string"
        },
        {
            "name":"_tidb_commit_ts",
            "type":"long"
        },
        {
            "name":"_tidb_commit_physical_time",
            "type":"long"
        }
    ]
}
```

Compared with the Value data format with `enable-tidb-extension` disabled, three new fields are added: `_tidb_op`, `_tidb_commit_ts`, and `_tidb_commit_physical_time`.

Column data format

The Column data is the `{{ColumnValueBlock}}` part of the Key/Value data format. TiCDC generates the Column data format based on the SQL Type. The basic Column data format is as follows:

```
{
    "name":"{{ColumnName}}",
```

```
    "type":{
        "connect.parameters":{
            "tidb_type":"{{TIDB_TYPE}}"
        },
        "type":"{{AVRO_TYPE}}"
    }
}
```

If one column can be NULL, the Column data format can be:

```
{
    "default":null,
    "name":"{{ColumnName}}",
    "type":[
        "null",
        {
            "connect.parameters":{
                "tidb_type":"{{TIDB_TYPE}}"
            },
            "type":"{{AVRO_TYPE}}"
        }
    ]
}
```

- `{{ColumnName}}` indicates the column name.
- `{{TIDB_TYPE}}` indicates the type in TiDB, which is not a one-to-one mapping with the SQL type.
- `{{AVRO_TYPE}}` indicates the type in the Avro Specification.

SQL TYPE	TIDB_TYPE	AVRO_TYPE	Description
BOOL	INT	int	
TINYINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
SMALLINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
MEDIUMINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
INT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED and AVRO_TYPE is long.
BIGINT	BIGINT	long	When it is unsigned, TIDB_TYPE is BIGINT UNSIGNED. If `avro-bigint-unsigned-handling-mode` is string, AVRO_TYPE is string.
TINYBLOB	BLOB	bytes	-
BLOB	BLOB	bytes	-
MEDIUMBLOB	BLOB	bytes	-

SQL TYPE	TIDB_TYPE	AVRO_TYPE	Description
LONGBLOB	BLOB	bytes	-
BINARY	BLOB	bytes	-
VARBINARY	BLOB	bytes	-
TINYTEXT	TEXT	string	-
TEXT	TEXT	string	-
MEDIUMTEXT	TEXT	string	-
LONGTEXT	TEXT	string	-
CHAR	TEXT	string	-
VARCHAR	TEXT	string	-
FLOAT	FLOAT	double	-
DOUBLE	DOUBLE	double	-
DATE	DATE	string	-
DATETIME	DATETIME	string	-
TIMESTAMP	TIMESTAMP	string	-
TIME	TIME	string	-
YEAR	YEAR	int	-
BIT	BIT	bytes	-
JSON	JSON	string	-
ENUM	ENUM	string	-
SET	SET	string	-
DECIMAL	DECIMAL	bytes	When `avro-decimal-handling-mode` is string, AVRO_TYPE is string.

In the Avro protocol, two other `sink-uri` parameters might affect the Column data format as well: `avro-decimal-handling-mode` and `avro-bigint-unsigned-handling-mode`.

- `avro-decimal-handling-mode` controls how Avro handles decimal fields, including:
  - string: Avro handles decimal fields as strings.
  - precise: Avro handles decimal fields as bytes.
- `avro-bigint-unsigned-handling-mode` controls how Avro handles BIGINT UNSIGNED fields, including:
  - string: Avro handles BIGINT UNSIGNED fields as strings.
  - long: Avro handles BIGINT UNSIGNED fields as 64-bit signed integers. When the value is greater than `9223372036854775807`, overflow will occur.

The following is a configuration example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-avro-string-option" --sink-uri="kafka://127.0.0.1:9092/topic-
    ↪ name?protocol=avro&avro-decimal-handling-mode=string&avro-bigint-
    ↪ unsigned-handling-mode=string" --schema-registry=http
    ↪ ://127.0.0.1:8081 --config changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

Most SQL types are mapped to the base Column data format. Some other SQL types extend the base data format to provide more information.

BIT(64)

```
{
    "name":"{{ColumnName}}",
    "type":{
        "connect.parameters":{
            "tidb_type":"BIT",
            "length":"64"
        },
        "type":"bytes"
    }
}
```

ENUM/SET(a,b,c)

```
{
    "name":"{{ColumnName}}",
    "type":{
        "connect.parameters":{
            "tidb_type":"ENUM/SET",
            "allowed":"a,b,c"
        },
        "type":"string"
    }
}
```

DECIMAL(10, 4)

```
{
    "name":"{{ColumnName}}",
    "type":{
        "connect.parameters":{
```

```
            "tidb_type":"DECIMAL",
        },
        "logicalType":"decimal",
        "precision":10,
        "scale":4,
        "type":"bytes"
    }
}
```

DDL events and schema changes

Avro does not send DDL events and Watermark events to downstream. It checks whether a schema changes each time a DML event occurs. If a schema changes, Avro generates a new schema and registers it with the Schema Registry. If the schema change does not pass the compatibility check, the registration fails. TiCDC does not resolve any schema compatibility issues.

For example, the default compatibility policy of Confluent Schema Registry is `BACKWARD`, and you add a non-empty column to the source table. In this situation, Avro generates a new schema but fails to register it with Schema Registry due to compatibility issues. At this time, the changefeed enters an error state.

Note that, even if a schema change passes the compatibility check and a new version is registered, the data producers and consumers still need to acquire the new schema for data encoding and decoding.

For more information about schemas, refer to Schema Registry related documents.

Consumer implementation

The TiCDC Avro protocol can be deserialized by `io.confluent.kafka.serializers.KafkaAvroDeserializer`.

The consumer program can acquire the latest schema via Schema Registry API, and then use the schema to deserialize the data encoded by the TiCDC Avro protocol.

Distinguish event types

The consumer program can distinguish DML event types by the following rules:

- If there is only the Key part, it is a Delete event.
- If there are both Key and Value parts, it is either an Insert or an Update event. If the TiDB extension fields are enabled, you can use the `_tidb_op` field to identify if it is an Insert or Update event. If the TiDB extension fields are not enabled, you cannot distinguish them.

Topic distribution

Schema Registry supports three Subject Name Strategies: TopicNameStrategy, RecordNameStrategy, and TopicRecordNameStrategy. Currently, TiCDC Avro only supports TopicNameStrategy, which means that a Kafka topic can only receive data in one data format.

Therefore, TiCDC Avro prohibits mapping multiple tables to the same topic. When you create a changefeed, an error will be reported if the topic rule does not include the `{schema}` and `{table}` placeholders in the configured distribution rule.

Compatibility

When upgrading the TiCDC cluster to v7.0.0, if a table replicated using Avro contains the `FLOAT` data type, you need to manually adjust the compatibility policy of Confluent Schema Registry to `None` before upgrading so that the changefeed can successfully update the schema. Otherwise, after upgrading, the changefeed will be unable to update the schema and enter an error state. For more information, see #8490.

13.9.4.7.2 TiCDC Canal-JSON Protocol

Canal-JSON is a data exchange format protocol defined by Alibaba Canal. In this document, you can learn how Canal-JSON data formats are implemented in TiCDC, including the TiDB extension field, the definitions of the Canal-JSON data formats, and comparison with the official Canal.

Use Canal-JSON

When using Message Queue (MQ) as the downstream Sink, you can specify Canal-JSON in `sink-uri`. TiCDC wraps and constructs Canal-JSON messages with Event as the basic unit, and sends TiDB data change Events to the downstream.

There are three types of Events:

- DDL Event: Represents a DDL change record. It is sent after an upstream DDL statement is successfully executed. The DDL Event is sent to the MQ Partition with the index being 0.
- DML Event: Represents a row data change record. This type of Event is sent when a row change occurs. It contains the information about the row after the change occurs.
- WATERMARK Event: Represents a special time point. It indicates that the Events received before this point is complete. It applies only to the TiDB extension field and takes effect when you set `enable-tidb-extension` to `true` in `sink-uri`.

The following is an example of using `Canal-JSON`:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-canal-json" --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka
    ↪ -version=2.4.0&protocol=canal-json"
```

TiDB extension field

The Canal-JSON protocol is originally designed for MySQL. It does not contain important fields such as the TiDB-specific unique identifier for the CommitTS transaction. To solve this problem, TiCDC appends a TiDB extension field to the Canal-JSON protocol format. After you set `enable-tidb-extension` to `true` (`false` by default) in `sink-uri`, TiCDC behaves as follows when generating Canal-JSON messages:

- TiCDC sends DML Event and DDL Event messages that contain a field named `_tidb`.
- TiCDC sends WATERMARK Event messages.

The following is an example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-canal-json-enable-tidb-extension" --sink-uri="kafka
    ↪ ://127.0.0.1:9092/topic-name?kafka-version=2.4.0&protocol=canal-json&
    ↪ enable-tidb-extension=true"
```

Definitions of message formats

This section describes the formats of DDL Event, DML Event and WATERMARK Event, and how the data is parsed on the consumer side.

DDL Event

TiCDC encodes a DDL Event into the following Canal-JSON format.

```
{
    "id": 0,
    "database": "test",
    "table": "",
    "pkNames": null,
    "isDdl": true,
    "type": "QUERY",
    "es": 1639633094670,
    "ts": 1639633095489,
    "sql": "drop database if exists test",
    "sqlType": null,
    "mysqlType": null,
    "data": null,
    "old": null,
    "_tidb": {   // TiDB extension field
        "commitTs": 429918007904436226 // A TiDB TSO timestamp
    }
}
```

The fields are explained as follows.

Field	Type	Description
id	Number	The default value is 0 in TiCDC.
database	String	The name of the database where the row is located
table	String	The name of the table where the row is located
pkNames	Array	The names of all the columns that make up the primary key
isDdl	Bool	Whether the message is a DDL event
type	String	Event types defined by Canal-JSON

Field	Type	Description
es	Number	13-bit (millisecond) timestamp when the event that generated the message happened
ts	Number	13-bit (millisecond) timestamp when TiCDC generated the message
sql	String	When isDdl is `true`, records the corresponding DDL statement
sqlType	Object	When isDdl is `false`, records how the data type of each column is represented in Java
mysqlType	object	When isDdl is `false`, records how the data type of each column is represented in MySQL
data	Object	When isDdl is `false`, records the name of each column and its data value
old	Object	Only if the message is generated by an update Event, records the name of each column and the data value before the update
_tidb	Object	TiDB extension field. It exists only if you set `enable-tidb-extension` to `true`. The value of `commitTs` is the TSO of the transaction that caused the row to change.

DML Event

TiCDC encodes a row of DML data change event as follows:

```
{
    "id": 0,
    "database": "test",
    "table": "tp_int",
    "pkNames": [
        "id"
    ],
    "isDdl": false,
    "type": "INSERT",
    "es": 1639633141221,
    "ts": 1639633142960,
    "sql": "",
    "sqlType": {
        "c_bigint": -5,
        "c_int": 4,
        "c_mediumint": 4,
        "c_smallint": 5,
        "c_tinyint": -6,
        "id": 4
    },
    "mysqlType": {
        "c_bigint": "bigint",
        "c_int": "int",
```

```
        "c_mediumint": "mediumint",
        "c_smallint": "smallint",
        "c_tinyint": "tinyint",
        "id": "int"
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "2147483647",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "127",
            "id": "2"
        }
    ],
    "old": null,
    "_tidb": {   // TiDB extension field
        "commitTs": 429918007904436226 // A TiDB TSO timestamp
    }
}
```

WATERMARK Event

TiCDC sends a WATERMARK Event only when you set `enable-tidb-extension` to `true`. The value of the `type` field is `TIDB_WATERMARK`. The Event contains the `_tidb` field, and the field contains only one parameter `watermarkTs`. The value of `watermarkTs` is the TSO recorded when the Event is sent.

When you receive an Event of this type, all Events with `commitTs` less than `watermarkTs` have been sent. Because TiCDC provides the "At Least Once" semantics, data might be sent repeatedly. If a subsequent Event with `commitTs` less than `watermarkTs` is received, you can safely ignore this Event.

The following is an example of the WATERMARK Event.

```
{
    "id": 0,
    "database": "",
    "table": "",
    "pkNames": null,
    "isDdl": false,
    "type": "TIDB_WATERMARK",
    "es": 1640007049196,
    "ts": 1640007050284,
    "sql": "",
    "sqlType": null,
    "mysqlType": null,
```

```
    "data": null,
    "old": null,
    "_tidb": {   // TiDB extension field
        "watermarkTs": 429918007904436226 // A TiDB TSO timestamp
    }
}
```

Data parsing on the consumer side

As you can see from the example above, Canal-JSON has a unified data format, with different field filling rules for different Event types. Consumers can parse data in this JSON format using a unified method, and then determine the Event type by checking the field values:

- When `isDdl` is `true`, the message contains a DDL Event.
- When `isDdl` is `false`, you need to further check the `type` field. If `type` is `TIDB_WATERMARK`, it is a WATERMARK Event; otherwise, it is a DML Event.

Field descriptions

The Canal-JSON format records the corresponding data type in the `mysqlType` field and the `sqlType` field.

MySQL Type field

In the `mysqlType` field, the Canal-JSON format records the string of MySQL Type in each column. For more information, see TiDB Data Types.

SQL Type field

In the `sqlType` field, the Canal-JSON format records Java SQL Type of each column, which is the data type corresponding to the data in JDBC. Its value can be calculated by MySQL Type and the specific data value. The mapping is as follows:

MySQL Type	Java SQL Type Code
Boolean	-6
Float	7
Double	8
Decimal	3
Char	1
Varchar	12
Binary	2004
Varbinary	2004
Tinytext	2005
Text	2005
Mediumtext	2005
Longtext	2005
Tinyblob	2004

MySQL Type	Java SQL Type Code
Blob	2004
Mediumblob	2004
Longblob	2004
Date	91
Datetime	93
Timestamp	93
Time	92
Year	12
Enum	4
Set	-7
Bit	-7
JSON	12

Integer types

You need to consider whether integer types have the `Unsigned` constraint and the value size, which corresponds to different Java SQL Type Codes respectively, as shown in the following table.

MySQL Type String	Value Range	Java SQL Type Code
tinyint	[-128, 127]	-6
tinyint unsigned	[0, 127]	-6
tinyint unsigned	[128, 255]	5
smallint	[-32768, 32767]	5
smallint unsigned	[0, 32767]	5
smallint unsigned	[32768, 65535]	4
mediumint	[-8388608, 8388607]	4
mediumint unsigned	[0, 8388607]	4
mediumint unsigned	[8388608, 16777215]	4
int	[-2147483648, 2147483647]	4
int unsigned	[0, 2147483647]	4
int unsigned	[2147483648, 4294967295]	-5
bigint	[-9223372036854775808, 9223372036854775807]	-5
bigint unsigned	[0, 9223372036854775807]	-5
bigint unsigned	[9223372036854775808, 18446744073709551615]	3

The following table shows the mapping relationships between Java SQL Types in TiCDC and their codes.

Java SQL Type	Java SQL Type Code
CHAR	1
DECIMAL	3

Java SQL Type	Java SQL Type Code
INTEGER	4
SMALLINT	5
REAL	7
DOUBLE	8
VARCHAR	12
DATE	91
TIME	92
TIMESTAMP	93
BLOB	2004
CLOB	2005
BIGINT	-5
TINYINT	-6
Bit	-7

For more information about Java SQL Types, see Java SQL Class Types.

Binary and Blob types

TiCDC encodes binary types in the Canal-JSON format by converting each byte to its character representation as follows:

- Printable characters are represented using the ISO/IEC 8859-1 character encodings.
- Non-printable characters and certain characters with special meaning in HTML are represented using their UTF-8 escape sequence.

The following table shows the detailed representation information.

Character type	Value range	Character representation
Control characters	[0, 31]	UTF-8 escape (such as `\u0000` through `\u001F`)
Horizontal tab	[9]	`\t`
Line feed	[10]	`\n`
Carriage return	[13]	`\r`
Printable characters	[32, 127]	Literal character (such as `A`)
Ampersand	[38]	`\u0026`
Less-than sign	[60]	`\u0038`
Greater-than sign	[62]	`\u003E`
Extended control characters	[128, 159]	Literal character
ISO 8859-1 (Latin-1)	[160, 255]	Literal character

Example of the encoding

For example, the following 16 bytes `[5 7 10 15 36 50 43 99 120 60 38 255 254 45 55 70]` stored in a `VARBINARY` column called `c_varbinary` are encoded in a Canal-JSON

Update event as follows:

```
{
    ...
    "data": [
        {
            ...
            "c_varbinary": "\u0005\u0007\n\u000f$2+cx\u003c\u0026ÿþ-7F"
        }
    ]
    ...
}
```

Comparison of TiCDC Canal-JSON and the official Canal

The way that TiCDC implements the Canal-JSON data format, including the Update Event and the mysqlType field, differs from the official Canal. The following table shows the main differences.

Item	TiCDC Canal-JSON	Canal
Event of Update Type	By default, the old field contains all the column data. When only_output_updated_columns is true, the old field contains only the modified column data.	The old field contains only the modified column data
mysqlType ↪ field	For types with parameters, it does not contain the information of the type parameter	For types with parameters, it contains the full information of the type parameter

Compatibility with the official Canal

Starting from v6.5.6, v7.1.3, and v7.6.0, TiCDC Canal-JSON supports compatibility with the data format of the official Canal. When creating a changefeed, you can set content ↪ -compatible=true in sink-uri to enable this feature. In this mode, TiCDC outputs Canal-JSON format data that is compatible with the official Canal. The specific changes are as follows:

- The mysqlType field contains the full information of the type parameter for each type.
- An Event of Update Type only outputs the modified column data.

Event of Update Type

For an Event of Update Type:

- In TiCDC, the `old` field contains all the column data
- In the official Canal, the `old` field contains only the modified column data

Assume that the following SQL statements are executed sequentially in the upstream TiDB:

```
create table tp_int
(
    id         int auto_increment,
    c_tinyint  tinyint  null,
    c_smallint smallint null,
    c_mediumint mediumint null,
    c_int      int      null,
    c_bigint   bigint   null,
    constraint pk
        primary key (id)
);

insert into tp_int(c_tinyint, c_smallint, c_mediumint, c_int, c_bigint)
values (127, 32767, 8388607, 2147483647, 9223372036854775807);

update tp_int set c_int = 0, c_tinyint = 0 where c_smallint = 32767;
```

For the `update` statement, TiCDC outputs an Event message with `type` as `UPDATE`, as shown below. The `update` statement only modifies the `c_int` and `c_tinyint` columns. The `old` field in the output event message contains all the column data.

```
{
    "id": 0,
    ...
    "type": "UPDATE",
    ...
    "sqlType": {
        ...
    },
    "mysqlType": {
        ...
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
```

```
        }
    ],
    "old": [                          // In TiCDC, this field contains all
        ↪ the column data.
        {
            "c_bigint": "9223372036854775807",
            "c_int": "2147483647",    // Modified column
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "127",       // Modified column
            "id": "2"
        }
    ]
}
```

For the official Canal, the `old` field in the output event message contains only the modified column data, as shown below.

```
{
    "id": 0,
    ...
    "type": "UPDATE",
    ...
    "sqlType": {
        ...
    },
    "mysqlType": {
        ...
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
    ],
    "old": [                          // In Canal, this field contains only
        ↪ the modified column data.
        {
            "c_int": "2147483647",    // Modified column
            "c_tinyint": "127",       // Modified column
        }
```

```
    ]
}
```

`mysqlType` field

For the `mysqlType` field, if a type contains parameters, the official Canal contains the full information of the type parameter. TiCDC does not contain such information.

In the following example, the table-defining SQL statement contains a parameter for each column, such as the ones for `decimal`, `char`, `varchar` and `enum`. By comparing the Canal-JSON formats generated by TiCDC and the official Canal, you can see that TiCDC only contains the basic MySQL information in the `mysqlType` field. If you need the full information of the type parameter, you need to implement it by other means.

Assume that the following SQL statements are executed sequentially in the upstream TiDB:

```
create table t (
    id    int auto_increment,
    c_decimal  decimal(10, 4) null,
    c_char     char(16)    null,
    c_varchar  varchar(16) null,
    c_binary   binary(16)  null,
    c_varbinary varbinary(16) null,
    c_enum enum('a','b','c') null,
    c_set set('a','b','c') null,
    c_bit bit(64)          null,
    constraint pk
        primary key (id)
);

insert into t (c_decimal, c_char, c_varchar, c_binary, c_varbinary, c_enum,
    ↪ c_set, c_bit)
values (123.456, "abc", "abc", "abc", "abc", 'a', 'a,b', b'1000001');
```

The output of TiCDC is as follows:

```
{
    "id": 0,
    ...
    "isDdl": false,
    "sqlType": {
        ...
    },
    "mysqlType": {
        "c_binary": "binary",
        "c_bit": "bit",
        "c_char": "char",
```

```
        "c_decimal": "decimal",
        "c_enum": "enum",
        "c_set": "set",
        "c_varbinary": "varbinary",
        "c_varchar": "varchar",
        "id": "int"
    },
    "data": [
        {
            ...
        }
    ],
    "old": null,
}
```

The output of the official Canal is as follows:

```
{
    "id": 0,
    ...
    "isDdl": false,
    "sqlType": {
        ...
    },
    "mysqlType": {
        "c_binary": "binary(16)",
        "c_bit": "bit(64)",
        "c_char": "char(16)",
        "c_decimal": "decimal(10, 4)",
        "c_enum": "enum('a','b','c')",
        "c_set": "set('a','b','c')",
        "c_varbinary": "varbinary(16)",
        "c_varchar": "varchar(16)",
        "id": "int"
    },
    "data": [
        {
            ...
        }
    ],
    "old": null,
}
```

Changes in TiCDC Canal-JSON

Changes in the `Old` field of the `Delete` events

From v5.4.0, the `old` field of the `Delete` events has changed.

The following is a `Delete` event message. Before v5.4.0, the `old` field contains the same content as the "data" field. In v5.4.0 and later versions, the `old` field is set to null. You can get the deleted data by using the "data" field.

```
{
    "id": 0,
    "database": "test",
    ...
    "type": "DELETE",
    ...
    "sqlType": {
        ...
    },
    "mysqlType": {
        ...
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
    ],
    "old": null,
    // The following is an example before v5.4.0. The `old` field contains
        ↪ the same content as the "data" field.
    "old": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
    ]
}
```

13.9.4.7.3 TiCDC CSV Protocol

When using a cloud storage service as the downstream sink, you can send DML events

to the cloud storage service in CSV format.

Use CSV

The following is an example of the configuration when using the CSV protocol:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ csv-test" --sink-uri="s3://bucket/prefix" --config changefeed.toml
```

The configuration in the `changefeed.toml` file is as follows:

```
[sink]
protocol = "csv"
terminator = "\n"

[sink.csv]
delimiter = ',' # Before v7.6.0, you can only set the delimiter to a single
    ↪ character. Starting from v7.6.0, you can set it to 1-3 characters.
    ↪ For example, `$^` or `|@|`.
quote = '"'
null = '\N'
include-commit-ts = true
output-old-value = false
```

Transactional constraints

- In a single CSV file, the `commit-ts` of a row is equal to or smaller than that of the subsequent row.
- The same transactions of a single table are stored in the same CSV file.
- Multiple tables of the same transaction can be stored in different CSV files.

Data storage path structure

For more information about the storage path structure of the data, see Storage path structure.

Definition of the data format

In the CSV file, each column is defined as follows:

- Column 1: The operation-type indicator, including `I`, `U`, and `D`. `I` means `INSERT`, `U` means `UPDATE`, and `D` means `DELETE`.
- Column 2: Table name.
- Column 3: Schema name.
- Column 4: The `commit-ts` of the source transaction. This column is optional.
- Column 5: The `is-update` column only exists when the value of `output-old-value` is true, which is used to identify whether the row data change comes from the UPDATE event (the value of the column is true) or the INSERT/DELETE event (the value is false).

- Column 6 to the last column: One or more columns with data changes.

Assume that table `hr.employee` is defined as follows:

```
CREATE TABLE `employee` (
  `Id` int NOT NULL,
  `LastName` varchar(20) DEFAULT NULL,
  `FirstName` varchar(30) DEFAULT NULL,
  `HireDate` date DEFAULT NULL,
  `OfficeLocation` varchar(20) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

When `include-commit-ts = true` and `output-old-value = false`, the DML events of this table are stored in the CSV format as follows:

```
"I","employee","hr",433305438660591626,101,"Smith","Bob","2014-06-04","New
    ↪ York"
"U","employee","hr",433305438660591627,101,"Smith","Bob","2015-10-08","Los
    ↪ Angeles"
"D","employee","hr",433305438660591629,101,"Smith","Bob","2017-03-13","
    ↪ Dallas"
"I","employee","hr",433305438660591630,102,"Alex","Alice","2017-03-14","
    ↪ Shanghai"
"U","employee","hr",433305438660591630,102,"Alex","Alice","2018-06-15","
    ↪ Beijing"
```

When `include-commit-ts = true` and `output-old-value = true`, the DML events of this table are stored in the CSV format as follows:

```
"I","employee","hr",433305438660591626,false,101,"Smith","Bob
    ↪ ","2014-06-04","New York"
"D","employee","hr",433305438660591627,true,101,"Smith","Bob","2015-10-08","
    ↪ Shanghai"
"I","employee","hr",433305438660591627,true,101,"Smith","Bob","2015-10-08","
    ↪ Los Angeles"
"D","employee","hr",433305438660591629,false,101,"Smith","Bob
    ↪ ","2017-03-13","Dallas"
"I","employee","hr",433305438660591630,false,102,"Alex","Alice
    ↪ ","2017-03-14","Shanghai"
"D","employee","hr",433305438660591630,true,102,"Alex","Alice
    ↪ ","2017-03-14","Beijing"
"I","employee","hr",433305438660591630,true,102,"Alex","Alice
    ↪ ","2018-06-15","Beijing"
```

Data type mapping

MySQL type	CSV type	Example	Description
`BOOLEAN/TINYINT/SMALLINT/INT/MEDIUMINT/BIGINT`	Integer	`123`	-
`FLOAT/DOUBLE`	Float	`153.123`	-
`NULL`	Null	`\N`	-
`TIMESTAMP/DATETIME`	String	`"1973-12-30 15:30:00.123456"`	Format: `yyyy-MM-dd HH:mm:ss.%06d`
`DATE`	String	`"2000-01-01"`	Format: `yyyy-MM-dd`
`TIME`	String	`"23:59:59"`	Format: `yyyy-MM-dd`
`YEAR`	Integer	`1970`	-
`VARCHAR/JSON/TINYTEXT/MEDIUMTEXT/LONGTEXT/TEXT/CHAR`	String	`"test"`	UTF-8 encoded
`VARBINARY/TINYBLOB/MEDIUMBLOB/LONGBLOB/BLOB/BINARY`	String	`"6Zi/5pav"` or `"e998bfe696af"`	Base64 or hex encoded
`BIT`	Integer	`81`	-
`DECIMAL`	String	`"129012.1230000"`	-
`ENUM`	String	`"a"`	-
`SET`	String	`"a,b"`	-

13.9.4.7.4 TiCDC Debezium Protocol

Debezium is a tool for capturing database changes. It converts each captured database change into a message called an "event" and sends these events to Kafka. Starting from v8.0.0, TiCDC supports sending TiDB changes to Kafka using a Debezium style output format, simplifying migration from MySQL databases for users who had previously been using Debezium's MySQL integration.

Use the Debezium message format

When you use Kafka as the downstream sink, specify the `protocol` field as `debezium` in `sink-uri` configuration. Then TiCDC encapsulates the Debezium messages based on the events and sends TiDB data change events to the downstream.

Currently, the Debezium protocol only supports Row Changed events and directly ignores DDL events and WATERMARK events. A Row changed event represents a data change in a row. When a row changes, the Row Changed event is sent, including relevant information about the row both before and after the change. A WATERMARK event marks the replication progress of a table, indicating that all events earlier than the watermark have been sent to the downstream.

The configuration example for using the Debezium message format is as follows:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-debezium" --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-
    ↪ version=2.4.0&protocol=debezium"
```

The Debezium output format contains the schema information of the current row so that downstream consumers can better understand the data structure of the current row. For scenarios where schema information is unnecessary, you can also disable the schema output by setting the `debezium-disable-schema` parameter to `true` in the changefeed configuration file or `sink-uri`.

In addition, the original Debezium format does not include important fields such as the unique transaction identifier of the `CommitTS` in TiDB. To ensure data integrity, TiCDC adds two fields, `CommitTs` and `ClusterID`, to the Debezium format to identify the relevant information of TiDB data changes.

Message format definition

This section describes the format definition of the DML event output in the Debezium format.

DML event

TiCDC encodes a DML event in the following format:

```
{
    "payload":{
        "ts_ms":1707103832957,
        "transaction":null,
        "op":"c",
        "before":null,
        "after":{
            "a":4,
            "b":2
        },
        "source":{
            "version":"2.4.0.Final",
            "connector":"TiCDC",
            "name":"default",
            "ts_ms":1707103832263,
            "snapshot":"false",
            "db":"test",
            "table":"t2",
            "server_id":0,
            "gtid":null,
            "file":"",
            "pos":0,
            "row":0,
            "thread":0,
```

```
        "query":null,
        "commit_ts":447507027004751877,
        "cluster_id":"default"
    }
},
"schema":{
    "type":"struct",
    "optional":false,
    "name":"default.test.t2.Envelope",
    "version":1,
    "fields":{
        {
            "type":"struct",
            "optional":true,
            "name":"default.test.t2.Value",
            "field":"before",
            "fields":[
                {
                    "type":"int32",
                    "optional":false,
                    "field":"a"
                },
                {
                    "type":"int32",
                    "optional":true,
                    "field":"b"
                }
            ]
        },
        {
            "type":"struct",
            "optional":true,
            "name":"default.test.t2.Value",
            "field":"after",
            "fields":[
                {
                    "type":"int32",
                    "optional":false,
                    "field":"a"
                },
                {
                    "type":"int32",
                    "optional":true,
                    "field":"b"
                }
```

```
                ]
            },
            {
                "type":"string",
                "optional":false,
                "field":"op"
            },
            ...
        }
    }
}
```

The key fields of the preceding JSON data are explained as follows:

Field	Type	Description
payload.op	String	The type of the change event. `"c"` indicates an `INSERT` event, `"u"` indicates an `UPDATE` event, and `"d"` indicates a `DELETE` event.
payload.ts_ms	Number	The timestamp (in milliseconds) when TiCDC generates this message.
payload.before	JSON	The data value before the change event of a statement. For `"c"` events, the value of the `before` field is `null`.
payload.after	JSON	The data value after the change event of a statement. For `"d"` events, the value of the `after` field is `null`.
payload.source.commit_ts	Number	The `CommitTs` identifier when TiCDC generates this message.
payload.source.db	String	The name of the database where the event occurs.
payload.source.table	String	The name of the table where the event occurs.
schema.fields	JSON	The type information of each field in the payload, including the schema information of the row data before and after the change.

Data type mapping

The data format mapping in the TiCDC Debezium message basically follows the Debezium data type mapping rules, which is generally consistent with the native message of the Debezium Connector for MySQL. However, for some data types, the following differences exist between TiCDC Debezium and Debezium Connector messages:

- Currently, TiDB does not support spatial data types, including GEOMETRY, LINESTRING, POLYGON, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, and GEOMETRYCOLLECTION.
- For string-like data types, including Varchar, String, VarString, TinyBlob, MediumBlob, BLOB, and LongBlob, when the column has the BINARY flag, TiCDC encodes

it as a String type after encoding it in Base64; when the column does not have the BINARY flag, TiCDC encodes it directly as a String type. The native Debezium Connector encodes it in different ways according to `binary.handling.mode`.

- For the Decimal data type, including `DECIMAL` and `NUMERIC`, TiCDC uses the float64 type to represent it. The native Debezium Connector encodes it in float32 or float64 according to the different precision of the data type.

13.9.4.7.5 TiCDC Open Protocol

TiCDC Open Protocol is a row-level data change notification protocol that provides data sources for monitoring, caching, full-text indexing, analysis engines, and primary-secondary replication between different databases. TiCDC complies with TiCDC Open Protocol and replicates data changes of TiDB to third-party data medium such as MQ (Message Queue).

TiCDC Open Protocol uses Event as the basic unit to replicate data change events to the downstream. The Event is divided into three categories:

- Row Changed Event: Represents the data change in a row. When a row is changed, this Event is sent and contains information about the changed row.
- DDL Event: Represents the DDL change. This Event is sent after a DDL statement is successfully executed in the upstream. The DDL Event is broadcasted to every MQ Partition.
- Resolved Event: Represents a special time point before which the Event received is complete.

Restrictions

- In most cases, the Row Changed Event of a version is sent only once, but in special situations such as node failure and network partition, the Row Changed Event of the same version might be sent multiple times.
- On the same table, the Row Changed Events of each version which is first sent are incremented in the order of timestamps (TS) in the Event stream.
- Resolved Events are periodically broadcasted to each MQ Partition. The Resolved Event means that any Event with a TS earlier than Resolved Event TS has been sent to the downstream.
- DDL Events are broadcasted to each MQ Partition.
- Multiple Row Changed Events of a row are sent to the same MQ Partition.

Message format

A Message contains one or more Events, arranged in the following format:

Key:

Offset(Byte)	0~7	8~15	16~(15+length1)	...	...
Parameter	Protocol version	Length1	Event Key1	LengthN	Event KeyN

Value:

Offset(Byte)	0~7	8~(7+length1)	...	...
Parameter	Length1	Event Value1	LengthN	Event ValueN

- `LengthN` represents the length of the `N`th key/value.
- The length and protocol version are the big-endian `int64` type.
- The version of the current protocol is `1`.

Event format

This section introduces the formats of Row Changed Event, DDL Event, and Resolved Event.

Row Changed Event

- **Key:**

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":1
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that causes the row change.
Schema Name	String	The name of the schema where the row is in.
Table Name	String	The name of the table where the row is in.

- **Value:**

`Insert` event. The newly added row data is output.

```
{
    "u":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
```

```
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

`Update` event. The newly added row data ("u") and the row data before the update ("p") are output.

```
{
    "u":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    },
    "p":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

`Delete` event. The deleted row data is output.

```
{
    "d":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

Parameter	Type	Description
Column Name	String	The column name.
Column Type	Number	The column type. For details, see Column Type Code.
Where Handle	Boolean	Determines whether this column can be the filter condition of the `Where` clause. When this column is unique on the table, `Where Handle` is `true`.
Flag	Number	The bit flags of columns. For details, see Bit flags of columns.
Column Value	Any	The Column value.

DDL Event

- **Key:**

```
{
    "ts":<TS>,
```

```
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":2
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that performs the DDL change.
Schema Name	String	The schema name of the DDL change, which might be an empty string.
Table Name	String	The table name of the DDL change, which might be am empty string.

- **Value:**

```
{
    "q":<DDL Query>,
    "t":<DDL Type>
}
```

Parameter	Type	Description
DDL Query	String	DDL Query SQL
DDL Type	String	The DDL type. For details, see DDL Type Code.

Resolved Event

- **Key:**

```
{
    "ts":<TS>,
    "t":3
}
```

Parameter	Type	Description
TS	Number	The Resolved timestamp. Any TS earlier than this Event has been sent.

- **Value:** None

Examples of the Event stream output

This section shows and displays the output logs of the Event stream.

Suppose that you execute the following SQL statement in the upstream and the MQ Partition number is 2:

```
CREATE TABLE test.t1(id int primary key, val varchar(16));
```

From the following Log 1 and Log 3, you can see that the DDL Event is broadcasted to all MQ Partitions, and that the Resolved Event is periodically broadcasted to each MQ Partition.

```
1. [partition=0] [key="{\"ts\":415508856908021766,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":2}"] [value="{\"q\":\"CREATE TABLE test.t1(id int
   ↪ primary key, val varchar(16))\",\"t\":3}"]
2. [partition=0] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
3. [partition=1] [key="{\"ts\":415508856908021766,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":2}"] [value="{\"q\":\"CREATE TABLE test.t1(id int
   ↪ primary key, val varchar(16))\",\"t\":3}"]
4. [partition=1] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
INSERT INTO test.t1(id, val) VALUES (1, 'aa');
INSERT INTO test.t1(id, val) VALUES (2, 'aa');
UPDATE test.t1 SET val = 'bb' WHERE id = 2;
INSERT INTO test.t1(id, val) VALUES (3, 'cc');
COMMIT;
```

- From the following Log 5 and Log 6, you can see that Row Changed Events on the same table might be sent to different partitions based on the primary key, but changes to the same row are sent to the same partition so that the downstream can easily process the Event concurrently.
- From Log 6, multiple changes to the same row in a transaction are only sent in one Row Changed Event.
- Log 8 is a repeated event of Log 7. Row Changed Event might be repeated, but the first Event of each version is sent orderly.

```
5. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":1},\"val\":{\"t\":15,\"v\":\"aa\"}}}"]
6. [partition=1] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":2},\"val\":{\"t\":15,\"v\":\"bb\"}}}"]
7. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"cc\"}}}"]
```

```
8. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"cc\"}}}"]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
DELETE FROM test.t1 WHERE id = 1;
UPDATE test.t1 SET val = 'dd' WHERE id = 3;
UPDATE test.t1 SET id = 4, val = 'ee' WHERE id = 2;
COMMIT;
```

- Log 9 is the Row Changed Event of the `Delete` type. This type of Event only contains primary key columns or unique index columns.
- Log 13 and Log 14 are Resolved Events. The Resolved Event means that in this Partition, any events smaller than the Resolved TS (including Row Changed Event and DDL Event) have been sent.

```
9. [partition=0] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"d\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":1}}}"]
10. [partition=1] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"d\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":2}}}"]
11. [partition=0] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"ZGQ=\"}}}"]
12. [partition=0] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":4},\"val\":{\"t\":15,\"v\":\"ZWU=\"}}}"]
13. [partition=0] [key="{\"ts\":415508881038376963,\"t\":3}"] [value=]
14. [partition=1] [key="{\"ts\":415508881038376963,\"t\":3}"] [value=]
```

Protocol parsing for consumers

Currently, TiCDC does not provide the standard parsing library for TiCDC Open Protocol, but the Golang version and Java version of parsing examples are provided. You can refer to the data format provided in this document and the following examples to implement the protocol parsing for consumers.

- Golang examples
- Java examples

Column type code

`Column Type Code` represents the column data type of the Row Changed Event.

Type	Code	Output Example	Description
TINYINT/BOOLEAN	1	{“t”:1,“v”:1}	
SMALLINT	2	{“t”:2,“v”:1}	
INT	3	{“t”:3,“v”:123}	
FLOAT	4	{“t”:4,“v”:153.123}	
DOUBLE	5	{“t”:5,“v”:153.123}	
NULL	6	{“t”:6,“v”:null}	
TIMESTAMP	7	{“t”:7,“v”:“1973-12-30 15:30:00”}	
BIGINT	8	{“t”:8,“v”:123}	
MEDIUMINT	9	{“t”:9,“v”:123}	
DATE	10/14	{“t”:10,“v”:“2000-01-01”}	
TIME	11	{“t”:11,“v”:“23:59:59”}	
DATETIME	12	{“t”:12,“v”:“2015-12-20 23:58:58”}	
YEAR	13	{“t”:13,“v”:1970}	

Type	Code	Output Example	Description
VARCHAR/VARBINARY	15/253	{“t”:15,“v”:“test”} / {“t”:15,“v”:“\\x89PNG\\r\\n\\x1a\\n”}	The value is encoded in UTF-8. When the upstream type is VARBINARY, invisible characters are escaped.
BIT	16	{“t”:16,“v”:81}	
JSON	245	{“t”:245,“v”:“{\”key1\“:\”value1\“}”}	
DECIMAL	246	{“t”:246,“v”:“129012.1230000”}

Create Sequence	34
Alter Sequence	35
Drop Sequence	36

Bit flags of columns

The bit flags represent specific attributes of columns.

Bit	Value	Name	Description
1	0x01	BinaryFlag	Whether the column is a binary-encoded column.
2	0x02	HandleKeyFlag	Whether the column is a Handle index column.
3	0x04	GeneratedColumnFlag	Whether the column is a generated column.
4	0x08	PrimaryKeyFlag	Whether the column is a primary key column.
5	0x10	UniqueKeyFlag	Whether the column is a unique index column.
6	0x20	MultipleKeyFlag	Whether the column is a composite index column.
7	0x40	NullableFlag	Whether the column is a nullable column.
8	0x80	UnsignedFlag	Whether the column is an unsigned column.

Example:

If the value of a column flag is `85`, the column is a nullable column, a unique index column, a generated column, and a binary-encoded column.

```
85 == 0b_101_0101
   == NullableFlag | UniqueKeyFlag | GeneratedColumnFlag | BinaryFlag
```

If the value of a column is `46`, the column is a composite index column, a primary key column, a generated column, and a Handle key column.

```
46 == 0b_010_1110
   == MultipleKeyFlag | PrimaryKeyFlag | GeneratedColumnFlag | HandleKeyFlag
```

Note:

- `BinaryFlag` is meaningful only when the column type is BLOB/TEXT (including TINYBLOB/TINYTEXT and BINARY/CHAR). When the upstream column is the BLOB type, the `BinaryFlag` value is set to `1`. When the upstream column is the TEXT type, the `BinaryFlag` value is set to `0`.
- To replicate a table from the upstream, TiCDC selects a valid index as the Handle index. The `HandleKeyFlag` value of the Handle index column is set to `1`.

13.9.4.7.6 TiCDC Simple Protocol

Starting from v8.0.0, TiCDC supports the Simple protocol. This document describes how to use the TiCDC Simple protocol and the data format implementation.

Use the TiCDC Simple protocol

When you use Kafka as the downstream, specify `protocol` as `"simple"` in the changefeed configuration. Then TiCDC encodes each row change or DDL event as a message, and sends the data change event to the downstream.

The configuration example for using the Simple protocol is as follows:

`sink-uri` configuration:

```
--sink-uri = "kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0"
```

Changefeed configuration:

```
[sink]
protocol = "simple"
```

```
##### The following configuration parameters control the sending behavior of
    ↪  bootstrap messages.
##### send-bootstrap-interval-in-sec controls the time interval for sending
    ↪ bootstrap messages, in seconds.
##### The default value is 120 seconds, which means that a bootstrap message
    ↪  is sent every 120 seconds for each table.
send-bootstrap-interval-in-sec = 120

##### send-bootstrap-in-msg-count controls the message interval for sending
    ↪ bootstrap, in message count.
##### The default value is 10000, which means that a bootstrap message is
    ↪ sent every 10000 row changed messages for each table.
send-bootstrap-in-msg-count = 10000
##### Note: If you want to disable the sending of bootstrap messages, set
    ↪ both send-bootstrap-interval-in-sec and send-bootstrap-in-msg-count
    ↪ to 0.

##### send-bootstrap-to-all-partition controls whether to send bootstrap
    ↪ messages to all partitions.
##### The default value is true, which means that bootstrap messages are
    ↪ sent to all partitions of the corresponding table topic.
##### Setting it to false means bootstrap messages are sent to only the
    ↪ first partition of the corresponding table topic.
send-bootstrap-to-all-partition = true

[sink.kafka-config.codec-config]
##### encoding-format controls the encoding format of the Simple protocol
    ↪ messages. Currently, the Simple protocol message supports "json" and
    ↪ "avro" encoding formats.
##### The default value is "json".
encoding-format = "json"
```

Message types

The TiCDC Simple protocol has the following message types.

DDL:

- `CREATE`: the creating table event.
- `RENAME`: the renaming table event.
- `CINDEX`: the creating index event.
- `DINDEX`: the deleting index event.
- `ERASE`: the deleting table event.
- `TRUNCATE`: the truncating table event.

- `ALTER`: the altering table event, including adding columns, dropping columns, modifying column types, and other `ALTER TABLE` statements supported by TiCDC.
- `QUERY`: other DDL events.

DML:

- `INSERT`: the inserting event.
- `UPDATE`: the updating event.
- `DELETE`: the deleting event.

Other:

- `WATERMARK`: containing a TSO (that is, a 64-bit timestamp) of the upstream TiDB cluster, which marks the table replication progress. All events earlier than the watermark have been sent to the downstream.
- `BOOTSTRAP`: containing the schema information of a table, used to build the table schema for the downstream.

Message format

In the Simple protocol, each message contains only one event. The Simple protocol supports encoding messages in JSON and Avro formats. This document uses JSON format as an example. For Avro format messages, their fields and meanings are the same as those in JSON format messages, but the encoding format is different. For details about the Avro format, see Simple Protocol Avro Schema.

DDL

TiCDC encodes a DDL event in the following JSON format:

```
{
   "version":1,
   "type":"ALTER",
   "sql":"ALTER TABLE `user` ADD COLUMN `createTime` TIMESTAMP",
   "commitTs":447987408682614795,
   "buildTs":1708936343598,
   "tableSchema":{
      "schema":"simple",
      "table":"user",
      "tableID":148,
      "version":447987408682614791,
      "columns":[
         {
            "name":"id",
            "dataType":{
               "mysqlType":"int",
```

```
            "charset":"binary",
            "collate":"binary",
            "length":11
         },
         "nullable":false,
         "default":null
      },
      {
         "name":"name",
         "dataType":{
            "mysqlType":"varchar",
            "charset":"utf8mb4",
            "collate":"utf8mb4_bin",
            "length":255
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"age",
         "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"score",
         "dataType":{
            "mysqlType":"float",
            "charset":"binary",
            "collate":"binary",
            "length":12
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"createTime",
         "dataType":{
            "mysqlType":"timestamp",
            "charset":"binary",
```

```
            "collate":"binary",
            "length":19
         },
         "nullable":true,
         "default":null
      }
   ],
   "indexes":[
      {
         "name":"primary",

               "length":12
            },
            "nullable":true,
            "default":null
         }
      ],
      "indexes":[
         {
            "name":"primary",
            "unique":true,
            "primary":true,
            "nullable":false,
            "columns":[
               "id"
            ]
         }
      ]
   }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`type`	String	The DDL event type, including `CREATE`, `RENAME`, `CINDEX`, `DINDEX`, `ERASE`, `TRUNCATE`, `ALTER`, and `QUERY`.

Field	Type	Description
`sql`	String	The DDL statement.
`commitTs`	Number	The commit timestamp when the DDL statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`tableSchema`	Object	The current schema information of the table. For more information, see TableSchema definition.
`preTableSchema` ↪	Object	The schema information of the table before the DDL statement is executed. All DDL events, except the `CREATE` type of DDL event, have this field.

DML

INSERT

TiCDC encodes an `INSERT` event in the following JSON format:

```
{
  "version":1,
  "database":"simple",
  "table":"user",
  "tableID":148,
  "type":"INSERT",
  "commitTs":447984084414103554,
  "buildTs":1708923662983,
  "schemaVersion":447984074911121426,
  "data":{
    "age":"25",
    "id":"1",
    "name":"John Doe",
    "score":"90.5"
  }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`database`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`type`	String	The DML event type, including `INSERT`, `UPDATE`, and `DELETE`.
`commitTs`	Number	The commit timestamp when the DML statement execution is completed in the upstream.

Field	Type	Description
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`schemaVersion` ↪	Number	The schema version number of the table when the DML message is encoded.
`data`	Object	The inserted data, where the field name is the column name and the field value is the column value.

The `INSERT` event contains the `data` field, and does not contain the `old` field.

UPDATE

TiCDC encodes an `UPDATE` event in the following JSON format:

```
{
   "version":1,
   "database":"simple",
   "table":"user",
   "tableID":148,
   "type":"UPDATE",
   "commitTs":447984099186180098,
   "buildTs":1708923719184,
   "schemaVersion":447984074911121426,
   "data":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"95"
   },
   "old":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"90.5"
   }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`database`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`type`	String	The DML event type, including `INSERT`, `UPDATE`, and `DELETE`.

Field	Type	Description
`commitTs`	Number	The commit timestamp when the DML statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`schemaVersion` ↪	Number	The schema version number of the table when the DML message is encoded.
`data`	Object	The data after updating, where the field name is the column name and the field value is the column value.
`old`	Object	The data before updating, where the field name is the column name and the field value is the column value.

The `UPDATE` event contains both the `data` and `old` fields, which represent the data after and before updating respectively.

DELETE

TiCDC encodes a `DELETE` event in the following JSON format:

```
{
   "version":1,
   "database":"simple",
   "table":"user",
   "tableID":148,
   "type":"DELETE",
   "commitTs":447984114259722243,
   "buildTs":1708923776484,
   "schemaVersion":447984074911121426,
   "old":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"95"
   }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`database`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`type`	String	The DML event type, including `INSERT`, `UPDATE`, and `DELETE`.

Field	Type	Description
`commitTs`	Number	The commit timestamp when the DML statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`schemaVersion` ↪	Number	The schema version number of the table when the DML message is encoded.
`old`	Object	The deleted data, where the field name is the column name and the field value is the column value.

The `DELETE` event contains the `old` field, and does not contain the `data` field.

WATERMARK

TiCDC encodes a `WATERMARK` event in the following JSON format:

```
{
   "version":1,
   "type":"WATERMARK",
   "commitTs":447984124732375041,
   "buildTs":1708923816911
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`type`	String	The `WATERMARK` event type.
`commitTs`	Number	The commit timestamp of the `WATERMARK`.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.

BOOTSTRAP

TiCDC encodes a `BOOTSTRAP` event in the following JSON format:

```
{
   "version":1,
   "type":"BOOTSTRAP",
   "commitTs":0,
   "buildTs":1708924603278,
   "tableSchema":{
      "schema":"simple",
      "table":"new_user",
      "tableID":148,
      "version":447984074911121426,
```

```
"columns":[
   {
      "name":"id",
      "dataType":{
         "mysqlType":"int",
         "charset":"binary",
         "collate":"binary",
         "length":11
      },
      "nullable":false,
      "default":null
   },
   {
      "name":"name",
      "dataType":{
         "mysqlType":"varchar",
         "charset":"utf8mb4",
         "collate":"utf8mb4_bin",
         "length":255
      },
      "nullable":true,
      "default":null
   },
   {
      "name":"age",
      "dataType":{
         "mysqlType":"int",
         "charset":"binary",
         "collate":"binary",
         "length":11
      },
      "nullable":true,
      "default":null
   },
   {
      "name":"score",
      "dataType":{
         "mysqlType":"float",
         "charset":"binary",
         "collate":"binary",
         "length":12
      },
      "nullable":true,
      "default":null
   }
```

```
    ],
    "indexes":[
      {
        "name":"primary",
        "unique":true,
        "primary":true,
        "nullable":false,
        "columns":[
          "id"
        ]
      }
    ]
  }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`type`	String	The `BOOTSTRAP` event type.
`commitTs`	Number	The `commitTs` of the `BOOTSTRAP` is `0`. Because it is generated internally by TiCDC, its `commitTs` is meaningless.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`tableSchema`	Object	The schema information of the table. For more information, see TableSchema definition.

Message generation and sending rules

DDL

- Generation time: TiCDC sends a DDL event after all transactions before this DDL event have been sent.
- Destination: TiCDC sends DDL events to all partitions of the corresponding topic.

DML

- Generation time: TiCDC sends DML events in the order of the `commitTs` of the transaction.
- Destination: TiCDC sends DDL events to the corresponding partition of the corresponding topic according to the user-configured dispatch rules.

WATERMARK

- Generation time: TiCDC sends `WATERMARK` events periodically to mark the replication progress of a changefeed. The current interval is 1 second.
- Destination: TiCDC sends `WATERMARK` events to all partitions of the corresponding topic.

BOOTSTRAP

- Generation time:
  - After creating a new changefeed, before the first DML event of a table is sent, TiCDC sends a `BOOTSTRAP` event to the downstream to build the table schema.
  - Additionally, TiCDC sends `BOOTSTRAP` events periodically to allow newly joined consumers to build the table schema. The default interval is 120 seconds or every 10000 messages. You can adjust the sending interval by configuring the `send-bootstrap-interval-in-sec` and `send-bootstrap-in-msg-count` parameters in the `sink` configuration.
  - If a table does not receive any new DML messages within 30 minutes, the table is considered inactive. TiCDC stops sending `BOOTSTRAP` events for the table until new DML events are received.
- Destination: By default, TiCDC sends `BOOTSTRAP` events to all partitions of the corresponding topic. You can adjust the sending strategy by configuring the `send-bootstrap-to-all-partition` parameter in the sink configuration.

Message consumption methods

Because the TiCDC Simple protocol does not include the schema information of the table when sending a DML message, the downstream needs to receive the DDL or BOOTSTRAP message and cache the schema information of the table before consuming a DML message. When receiving a DML message, the downstream obtains the corresponding table schema information from the cache by searching the `table` name and `schemaVersion` fields of the DML message, and then correctly consumes the DML message.

The following describes how the downstream consumes DML messages based on DDL or BOOTSTRAP messages. According to preceding descriptions, the following information is known:

- Each DML message contains a `schemaVersion` field to mark the schema version number of the table corresponding to the DML message.
- Each DDL message contains a `tableSchema` and `preTableSchema` field to mark the schema information of the table before and after the DDL event.
- Each BOOTSTRAP message contains a `tableSchema` field to mark the schema information of the table corresponding to the BOOTSTRAP message.

The consumption methods are introduced in the following two scenarios.

Scenario 1: The consumer starts consuming from the beginning

In this scenario, the consumer starts consuming from the creation of a table, so the consumer can receive all DDL and BOOTSTRAP messages of the table. In this case, the consumer can obtain the schema information of the table through the `table` name and `schemaVersion` field of the DML message. The detailed process is as follows:

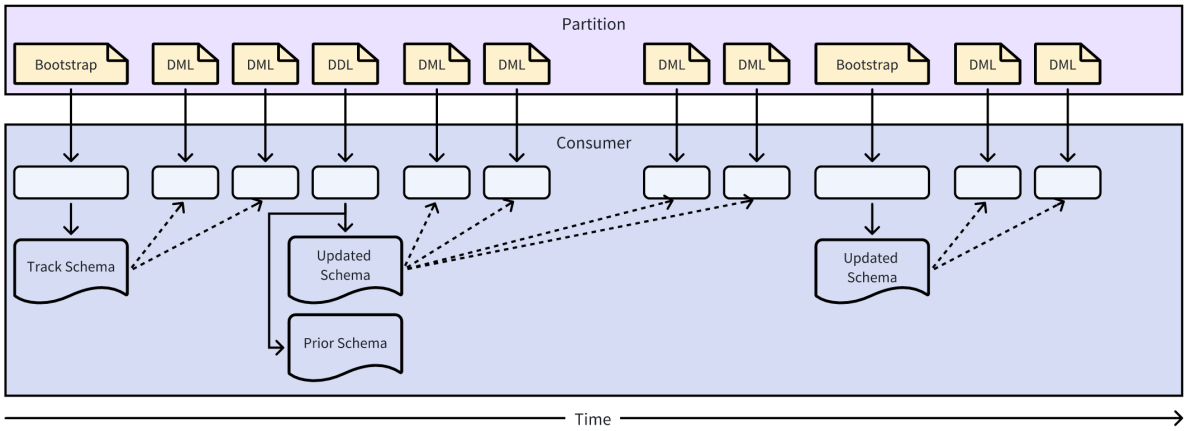

Figure 523: TiCDC Simple Protocol consumer scene 1

Scenario 2: The consumer starts consuming from the middle

When a new consumer joins the consumer group, it might start consuming from the middle, so it might miss earlier DDL and BOOTSTRAP messages of the table. In this case, the consumer might receive some DML messages before obtaining the schema information of the table. Therefore, the consumer needs to wait for a period of time until it receives the DDL or BOOTSTRAP message to obtain the schema information of the table. Because TiCDC sends BOOTSTRAP messages periodically, the consumer can always obtain the schema information of the table within a period of time. The detailed process is as follows:

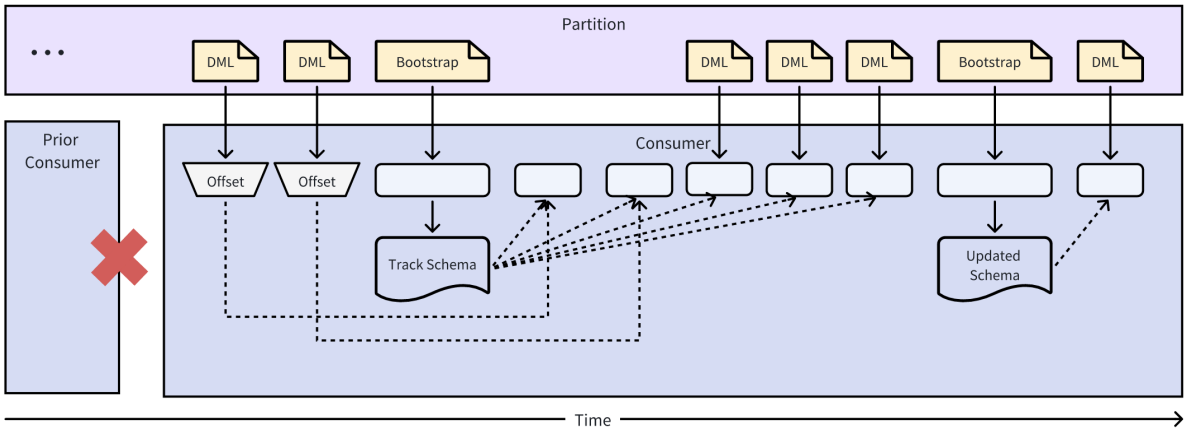

Figure 524: TiCDC Simple Protocol consumer scene 2

Reference

TableSchema definition

TableSchema is a JSON object that contains the schema information of the table, including the table name, table ID, table version number, column information, and index information. The JSON message format is as follows:

```
{
    "schema":"simple",
    "table":"user",
    "tableID":148,
    "version":447984074911121426,
    "columns":[
        {
        "name":"id",
        "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
        },
        "nullable":false,
        "default":null
        },
        {
        "name":"name",
        "dataType":{
            "mysqlType":"varchar",
            "charset":"utf8mb4",
```

```
            "collate":"utf8mb4_bin",
            "length":255
        },
        "nullable":true,
        "default":null
        },
        {
        "name":"age",
        "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
        },
        "nullable":true,
        "default":null
        },
        {
        "name":"score",
        "dataType":{
            "mysqlType":"float",
            "charset":"binary",
            "collate":"binary",
            "length":12
        },
        "nullable":true,
        "default":null
        }
    ],
    "indexes":[
        {
        "name":"primary",
        "unique":true,
        "primary":true,
        "nullable":false,
        "columns":[
            "id"
        ]
        }
    ]
}
```

The preceding JSON data is explained as follows:

Field	Type	Description
`schema`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`version`	Number	The schema version number of the table.
`columns`	Array	The column information, including the column name, data type, whether it can be null, and the default value.
`indexes`	Array	The index information, including the index name, whether it is unique, whether it is a primary key, and the index columns.

You can uniquely identify the schema information of a table by the table name and the schema version number.

> **Note:**
>
> Due to the implementation limitations of TiDB, the schema version number of a table does not change when the `RENAME TABLE` DDL operation is executed.

Column definition

Column is a JSON object that contains the schema information of the column, including the column name, data type, whether it can be null, and the default value.

```
{
        "name":"id",
        "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
        },
        "nullable":false,
        "default":null
}
```

The preceding JSON data is explained as follows:

Field	Type	Description
`name`	String	The name of the column.
`dataType`	Object	The data type information, including the MySQL data type, character set, collation, and field length.
`nullable`	Boolean	Whether the column can be null.
`default`	String	The default value of the column.

Index definition

Index is a JSON object that contains the schema information of the index, including the index name, whether it is unique, whether it is a primary key, and the index column.

```
{
        "name":"primary",
        "unique":true,
        "primary":true,
        "nullable":false,
        "columns":[
            "id"
        ]
}
```

The preceding JSON data is explained as follows:

Field	Type	Description
`name`	String	The name of the index.
`unique`	Boolean	Whether the index is unique.
`primary`	Boolean	Whether the index is a primary key.
`nullable`	Boolean	Whether the index can be null.
`columns`	Array	The column names included in the index.

mysqlType reference table

The following table describes the value range of the `mysqlType` field in the TiCDC Simple protocol and its type in TiDB (Golang) and Avro (Java). When you need to parse DML messages, you can correctly parse the data according to this table and the `mysqlType` field in the DML message, depending on the protocol and language you use.

TiDB type (Golang) represents the type of the corresponding `mysqlType` when it is processed in TiDB and TiCDC (Golang). **Avro type (Java)** represents the type of the corresponding `mysqlType` when it is encoded into Avro format messages.

mysqlType	Value range	TiDB type (Golang)	Avro type
tinyint	[-128, 127]	int64	long
tinyint unsigned	[0, 255]	uint64	long
smallint	[-32768, 32767]	int64	long
smallint unsigned	[0, 65535]	uint64	long
mediumint	[-8388608, 8388607]	int64	long
mediumint unsigned	[0, 16777215]	uint64	long
int	[-2147483648, 2147483647]	int64	long
int unsigned	[0, 4294967295]	uint64	long
bigint	[-9223372036854775808, 9223372036854775807]	int64	long
bigint unsigned	[0, 9223372036854775807]	uint64	long

mysqlType	Value range	TiDB type (Golang)	Avro type
bigint unsigned	[9223372036854775808, 18446744073709551615]	uint64	string
float	/	float32	float
double	/	float64	double
decimal	/	string	string
varchar	/	[]uint8	string
char	/	[]uint8	string
varbinary	/	[]uint8	bytes
binary	/	[]uint8	bytes
tinytext	/	[]uint8	string
text	/	[]uint8	string
mediumtext	/	[]uint8	string
longtext	/	[]uint8	string
tinyblob	/	[]uint8	bytes
blob	/	[]uint8	bytes
mediumblob	/	[]uint8	bytes
longblob	/	[]uint8	bytes
date	/	string	string
datetime	/	string	string
timestamp	/	string	string
time	/	string	string
year	/	int64	long
enum	/	uint64	long
set	/	uint64	long
bit	/	uint64	long
json	/	string	string
bool	/	int64	long

Avro schema definition

The Simple protocol supports outputting messages in Avro format. For details about the Avro format, see Simple Protocol Avro Schema.

13.9.4.8 TiCDC OpenAPI v2

TiCDC provides the OpenAPI feature for querying and operating the TiCDC cluster. The OpenAPI feature is a subset of the `cdc cli` tool.

> **Note:**
>
> TiCDC OpenAPI v1 will be removed in the future. It is recommended to use TiCDC OpenAPI v2.

You can use the APIs to perform the following maintenance operations on the TiCDC cluster:

- Get the status information of a TiCDC node
- Check the health status of a TiCDC cluster
- Create a replication task
- Remove a replication task
- Update the replication configuration
- Query the replication task list
- Query a specific replication task
- Pause a replication task
- Resume a replication task
- Query the replication subtask list
- Query a specific replication subtask
- Query the TiCDC service process list
- Evict an owner node
- Dynamically adjust the log level of the TiCDC server

The request body and returned values of all APIs are in JSON format. A successful request returns a `200 OK` message. The following sections describe the specific usage of the APIs.

In the following examples, the listening IP address of the TiCDC server is `127.0.0.1` ↪ and the port is `8300`. You can specify the IP address and port bound to TiCDC via `--addr=ip:port` when starting the TiCDC server.

13.9.4.8.1 API error message template

After an API request is sent, if an error occurs, the returned error message is in the following format:

```
{
    "error_msg": "",
    "error_code": ""
}
```

In the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

13.9.4.8.2 Return format of the API List interface

If an API request returns a list of resources (for example, a list of all `Captures`), the TiCDC return format is as follows:

```
{
  "total": 2,
```

```
  "items": [
    {
      "id": "d2912e63-3349-447c-90ba-wwww",
      "is_owner": true,
      "address": "127.0.0.1:8300"
    },
    {
      "id": "d2912e63-3349-447c-90ba-xxxx",
      "is_owner": false,
      "address": "127.0.0.1:8302"
    }
  ]
}
```

In the above example:

- `total`: indicates the total number of resources.
- `items`: an array that contains all the resources returned by this request. All elements of the array are of the same resource.

13.9.4.8.3 Get the status information of a TiCDC node

This API is a synchronous interface. If the request is successful, the status information of the corresponding node is returned.

Request URI

`GET /api/v2/status`

Example

The following request gets the status information of the TiCDC node whose IP address is `127.0.0.1` and port number is `8300`.

```
curl -X GET http://127.0.0.1:8300/api/v2/status
```

```
{
  "version": "v8.4.0",
  "git_hash": "10413bded1bdb2850aa6d7b94eb375102e9c44dc",
  "id": "d2912e63-3349-447c-90ba-72a4e04b5e9e",
  "pid": 1447,
  "is_owner": true,
  "liveness": 0
}
```

The parameters of the above output are described as follows:

- `version`: the current version number of TiCDC.

- `git_hash`: the Git hash value.
- `id`: the capture ID of the node.
- `pid`: the capture process ID (PID) of the node.
- `is_owner`: indicates whether the node is an owner.
- `liveness`: whether this node is live. `0` means normal. `1` means that the node is in the `graceful shutdown` state.

13.9.4.8.4 Check the health status of a TiCDC cluster

This API is a synchronous interface. If the cluster is healthy, `200 OK` is returned.

Request URI

`GET /api/v2/health`

Example

```
curl -X GET http://127.0.0.1:8300/api/v2/health
```

If the cluster is healthy, the response is `200 OK` and an empty JSON object:

```
{}
```

If the cluster is not healthy, the response is a JSON object containing the error message.

13.9.4.8.5 Create a replication task

This interface is used to submit a replication task to TiCDC. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v2/changefeeds`

Parameter descriptions

```
{
  "changefeed_id": "string",
  "replica_config": {
    "bdr_mode": true,
    "case_sensitive": false,
    "check_gc_safe_point": true,
    "consistent": {
      "flush_interval": 0,
      "level": "string",
      "max_log_size": 0,
      "storage": "string"
    },
    "enable_old_value": true,
```

```
"enable_sync_point": true,
"filter": {
  "event_filters": [
    {
      "ignore_delete_value_expr": "string",
      "ignore_event": [
        "string"
      ],
      "ignore_insert_value_expr": "string",
      "ignore_sql": [
        "string"
      ],
      "ignore_update_new_value_expr": "string",
      "ignore_update_old_value_expr": "string",
      "matcher": [
        "string"
      ]
    }
  ],
  "ignore_txn_start_ts": [
    0
  ],
  "rules": [
    "string"
  ]
},
"force_replicate": true,
"ignore_ineligible_table": true,
"memory_quota": 0,
"mounter": {
  "worker_num": 0
},
"sink": {
  "column_selectors": [
    {
      "columns": [
        "string"
      ],
      "matcher": [
        "string"
      ]
    }
  ],
  "csv": {
    "delimiter": "string",
```

```
      "include_commit_ts": true,
      "null": "string",
      "quote": "string"
    },
    "date_separator": "string",
    "dispatchers": [
      {
        "matcher": [
          "string"
        ],
        "partition": "string",
        "topic": "string"
      }
    ],
    "enable_partition_separator": true,
    "encoder_concurrency": 0,
    "protocol": "string",
    "schema_registry": "string",
    "terminator": "string",
    "transaction_atomicity": "string"
  },
  "sync_point_interval": "string",
  "sync_point_retention": "string"
 },
 "sink_uri": "string",
 "start_ts": 0,
 "target_ts": 0
}
```

The parameters are described as follows:

Parameter name	Description
`changefeed_id`	`STRING` type. The ID of the replication task. (Optional)
`replica_config`	Configuration parameters for the replication task. (Optional)
`sink_uri`	`STRING` type. The downstream address of the replication task. (**Required**)
`start_ts`	`UINT64` type. Specifies the start TSO of the changefeed. The TiCDC cluster will start pulling data from this TSO. The default value is the current time. (Optional)
`target_ts`	`UINT64` type. Specifies the target TSO of the changefeed. The TiCDC cluster stops pulling data when reaching this TSO. The default value is empty, meaning TiCDC does not stop automatically. (Optional)

The meaning and format of `changefeed_id`, `start_ts`, `target_ts`, and `sink_uri` are the same as those described in the Use `cdc cli` to create a replication task document. For the detailed description of these parameters, see that document. Note that when you specify the certificate path in `sink_uri`, make sure you have uploaded the corresponding certificate to the corresponding TiCDC server.

The descriptions of the `replica_config` parameters are as follows.

Parameter name	Description
`bdr_mode`	`BOOLEAN` type. Determines whether to enable bidirectional replication. The default value is `false`. (Optional)
`case_sensitive`	`BOOLEAN` type. Determines whether to be case-sensitive when filtering table names. Starting from v6.5.6, v7.1.3, and v7.5.0, the default value changes from `true` to `false`. (Optional)
`check_gc_safe_point`	`BOOLEAN` type. Determines whether to check that the start time of the replication task is earlier than the GC time. The default value is `true`. (Optional)
`consistent`	The configuration parameters of redo log. (Optional)
`enable_sync_point`	`BOOLEAN` type. Determines whether to enable `sync point`. (Optional)
`filter`	The configuration parameters of `filter`. (Optional)
`force_replicate`	`BOOLEAN` type. The default value is `false`. When you set it to `true`, the replication task forcibly replicates the tables without unique indexes. (Optional)
`ignore_ineligible_table`	`BOOLEAN` type. The default value is `false`. When you set it to `true`, the replication task ignores the tables that cannot be replicated. (Optional)

Parameter name	Description
`memory_quota`	`UINT64` type. The memory quota for the replication task. (Optional)
`mounter`	The configuration parameters of `mounter`. (Optional)
`sink`	The configuration parameters of `sink`. (Optional)
`sync_point_interval`	`STRING` type. Note that the returned value is a time in nanosecond of the `UINT64` type. When the `sync point` feature is enabled, this parameter specifies the interval at which Syncpoint aligns the upstream and downstream snapshots. The default value is `10m` and the minimum value is `30s`. (Optional)
`sync_point_retention`	`STRING` type. Note that the returned value is a time in nanosecond of the `UINT64` type. When the `sync point` feature is enabled, this parameter specifies how long the data is retained by Syncpoint in the downstream table. When this duration is exceeded, the data is cleaned up. The default value is `24h`. (Optional)

The `consistent` parameters are described as follows:

Parameter name	Description
`flush_interval`	`UINT64` type. The interval to flush redo log files. (Optional)
`level`	`STRING` type. The consistency level of the replicated data. (Optional)
`max_log_size`	`UINT64` type. The maximum value of redo log. (Optional)
`storage`	`STRING` type. The destination address of the storage. (Optional)
`use_file_backend`	`BOOL` type. Specifies whether to store the redo log in a local file. (Optional)
`encoding_worker_num`	`INT` type. The number of encoding and decoding workers in the redo module. (Optional)
`flush_worker_num`	`INT` type. The number of flushing workers in the redo module. (Optional)
`compression`	`STRING` type. The behavior to compress redo log files. Available options are `""` and `"lz4"`. The default value is `""`, which means no compression. (Optional)

Parameter name	Description
`flush_concurrency`	`INT` type. The concurrency for uploading a single file. The default value is `1`, which means concurrency is disabled. (Optional)

The `filter` parameters are described as follows:

Parameter name	Description
`event_filters`	The configuration to filter events. (Optional)
`ignore_txn_start_ts`	`UINT64 ARRAY` type. Specifying this will ignore transactions that specify `start_ts`, such as `[1, 2]`. (Optional)
`rules`	`STRING ARRAY` type. The rules for table schema filtering, such as `['foo*.*', 'bar*.*']`. For more information, see Table Filter. (Optional)

The `filter.event_filters` parameters are described as follows. For more information, see Changefeed Log Filters.

Parameter name	Description
`ignore_delete_value_expr`	`STRING ARRAY` type. For example, `"name = 'john'"` means to filter out DELETE DML statements containing the `name = 'john'` condition. (Optional)
`ignore_event`	`STRING ARRAY` type. For example, `["insert"]` indicates that the INSERT events are filtered out. (Optional)
`ignore_insert_value_expr`	`STRING ARRAY` type. For example, `"id >= 100"` means to filter out INSERT DML statements that match the `id >= 100` condition. (Optional)
`ignore_sql`	`STRING ARRAY` type. For example, `["^drop", "add column"]` means to filter out DDL statements that start with `DROP` or contain `ADD COLUMN`. (Optional)
`ignore_update_new_value_expr`	`STRING ARRAY` type. For example, `"gender = 'male'"` means to filter out the UPDATE DML statements with the new value `gender = 'male'`. (Optional)

Parameter name	Description
`ignore_update_old_value_expr`	`STRING ARRAY` type. For example, `"age < 18"` means to filter out the UPDATE DML statements with the old value `age < 18`. (Optional)
`matcher`	`STRING ARRAY` type. It works as an allowlist. For example, `["test.worker"]` means that the filter rule applies only to the `worker` table in the `test` database. (Optional)

The `mounter` parameter is described as follows:

Parameter name	Description
`worker_num`	`INT` type. The number of Mounter threads. Mounter is used to decode the data output from TiKV. The default value is `16`. (Optional)

The `sink` parameters are described as follows:

Parameter name	Description
`column_selectors`	The column selector configuration. (Optional)
`csv`	The CSV configuration. (Optional)
`date_separator`	`STRING` type. Indicates the date separator type of the file directory. Value options are `none`, `year`, `month`, and `day`. `none` is the default value and means that the date is not separated. (Optional)
`dispatchers`	An configuration array for event dispatching. (Optional)
`encoder_concurrency`	`INT` type. The number of encoder threads in the MQ sink. The default value is `16`. (Optional)
`protocol`	`STRING` type. For MQ sinks, you can specify the protocol format of the message. The following protocols are currently supported: `canal-json`, `open-protocol`, `avro`, `debezium`, and `simple`.

Parameter name	Description
`schema_registry`	`STRING` type. The schema registry address. (Optional)
`terminator`	`STRING` type. The terminator is used to separate two data change events. The default value is null, which means `"\r\n"` is used as the terminator. (Optional)
`transaction_atomicity`	`STRING` type. The atomicity level of the transaction. (Optional)
`only_output_updated_columns`	`BOOLEAN` type. For MQ sinks using the `canal-json` or `open-protocol` protocol, you can specify whether only output the modified columns. The default value is `false`. (Optional)
`cloud_storage_config`	The storage sink configuration. (Optional)
`open`	The Open Protocol configuration. (Optional)
`debezium`	The Debezium Protocol configuration. (Optional)

`sink.column_selectors` is an array. The parameters are described as follows:

Parameter name	Description
`columns`	`STRING ARRAY` type. The column array.
`matcher`	`STRING ARRAY` type. The matcher configuration. It has the same matching syntax as the filter rule does.

The `sink.csv` parameters are described as follows:

Parameter name	Description
`delimiter`	`STRING` type. The character used to separate fields in the CSV file. The value must be an ASCII character and defaults to `,`.
`include_commit_ts`	`BOOLEAN` type. Whether to include commit-ts in CSV rows. The default value is `false`.
`null`	`STRING` type. The character that is displayed when a CSV column is null. The default value is `\N`.
`quote`	`STRING` type. The quotation character used to surround fields in the CSV file. If the value is empty, no quotation is used. The default value is `"`.
`binary_encoding_method`	`STRING` type. The encoding method of binary data, which can be `"base64"` or `"hex"`. The default value is `"base64"`.

`sink.dispatchers`: for the sink of MQ type, you can use this parameter to configure the event dispatcher. The following dispatchers are supported: `default`, `ts`, `index-value`, and `table`. The dispatcher rules are as follows:

- `default`: dispatches events in the `table` mode.
- `ts`: uses the commitTs of the row change to create the hash value and dispatch events.
- `index-value`: uses the name and value of the selected HandleKey column to create the hash value and dispatch events.
- `table`: uses the schema name of the table and the table name to create the hash value and dispatch events.

`sink.dispatchers` is an array. The parameters are described as follows:

Parameter name	Description
`matcher`	`STRING ARRAY` type. It has the same matching syntax as the filter rule does.
`partition`	`STRING` type. The target partition for dispatching events.
`topic`	`STRING` type. The target topic for dispatching events.

`sink.cloud_storage_config` parameters are described as follows:

Parameter name	Description
`worker_count`	`INT` type. The concurrency for saving data changes to the downstream cloud storage.
`flush_interval`	`STRING` type. The interval for saving data changes to the downstream cloud storage.
`file_size`	`INT` type. A data change file is saved to the cloud storage when the number of bytes in this file exceeds the value of this parameter.
`file_expiration_days`	`INT` type. The duration to retain files, which takes effect only when `date-separator` is configured as `day`.
`file_cleanup_cron_spec`	`STRING` type. The running cycle of the scheduled cleanup task, compatible with the crontab configuration, with a format of `<Second> <Minute> <Hour> <Day of the month> <Month> <Day of the week (Optional)>`.
`flush_concurrency`	`INT` type. The concurrency for uploading a single file.
`output_raw_change_event`	`BOOLEAN` type. Controls whether to output the original data change event for a non-MySQL sink.

`sink.open` parameters are described as follows:

Parameter name	Description
`output_old_value`	`BOOLEAN` type. It controls whether to output the value before the row data changes. The default value is `true`. When it is disabled, the UPDATE event does not output the “p” field.

`sink.debezium` parameters are described as follows:

Parameter name	Description
`output_old_value`	`BOOLEAN` type. It controls whether to output the value before the row data changes. The default value is true. When it is disabled, the UPDATE event does not output the “before” field.

Example

The following request creates a replication task with an ID of `test5` and `sink_uri` of `blackhome://`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v2/changefeeds -d '{"changefeed_id":"test5","sink_uri":"blackhole
    ↪ ://"}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

Response body format

```
{
  "admin_job_type": 0,
  "checkpoint_time": "string",
  "checkpoint_ts": 0,
  "config": {
    "bdr_mode": true,
    "case_sensitive": false,
    "check_gc_safe_point": true,

    "terminator": "string",
    "transaction_atomicity": "string"
```

```
    },
    "sync_point_interval": "string",
    "sync_point_retention": "string"
  },
  "create_time": "string",
  "creator_version": "string",
  "error": {
    "addr": "string",
    "code": "string",
    "message": "string"
  },
  "id": "string",
  "resolved_ts": 0,
  "sink_uri": "string",
  "start_ts": 0,
  "state": "string",
  "target_ts": 0,
  "task_status": [
    {
      "capture_id": "string",
      "table_ids": [
        0
      ]
    }
  ]
}
```

The parameters are described as follows:

Parameter name	Description
`admin_job_type`	`INTEGER` type. The admin job type.
`checkpoint_time`	`STRING` type. The formatted time of the current checkpoint for the replication task.
`checkpoint_ts`	`STRING` type. The TSO of the current checkpoint for the replication task.
`config`	The replication task configuration. The structure and meaning are the same as that of the `replica_config` configuration in creating the replication task.
`create_time`	`STRING` type. The time when the replication task is created.
`creator_version`	`STRING` type. The TiCDC version when the replication task is created.
`error`	The replication task error.
`id`	`STRING` type. The replication task ID.

Parameter name	Description
`resolved_ts`	`UINT64` type. The replication task resolved ts.
`sink_uri`	`STRING` type. The replication task sink URI.
`start_ts`	`UINT64` type. The replication task start ts.
`state`	`STRING` type. The replication task status. It can be `normal`, `stopped`, `error`, `failed`, or `finished`.
`target_ts`	`UINT64` type. The replication task target ts.
`task_status`	The detailed status of dispatching the replication task.

The `task_status` parameters are described as follows:

Parameter name	Description
`capture_id`	`STRING` type. The capture ID.
`table_ids`	`UINT64 ARRAY` type. The ID of the table being replicated on this capture.

The `error` parameters are described as follows:

Parameter name	Description
`addr`	`STRING` type. The capture address.
`code`	`STRING` type. The error code.
`message`	`STRING` type. The details of the error.

13.9.4.8.6 Remove a replication task

This API is an idempotent interface (that is, it can be applied multiple times without changing the result beyond the initial application) for removing a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

```
DELETE /api/v2/changefeeds/{changefeed_id}
```

Parameter descriptions

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be removed.

Example

The following request removes the replication task with the ID `test1`.

```
curl -X DELETE http://127.0.0.1:8300/api/v2/changefeeds/test1
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

13.9.4.8.7 Update the replication configuration

This API is used for updating a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

To modify the changefeed configuration, follow the steps of `pause the replication task -> modify the configuration -> resume the replication task`.

Request URI

`PUT /api/v2/changefeeds/{changefeed_id}`

Parameter descriptions

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be updated.

Parameters for the request body

```
{
  "replica_config": {
    "bdr_mode": true,
    "case_sensitive": false,
    "check_gc_safe_point": true,
    "consistent": {
      "flush_interval": 0,
      "level": "string",
      "max_log_size": 0,
      "storage": "string"
    },
    "enable_old_value": true,
    "enable_sync_point": true,
    "filter": {
      "event_filters": [
        {
          "ignore_delete_value_expr": "string",
          "ignore_event": [
```

```
          "string"
        ],
        "ignore_insert_value_expr": "string",
        "ignore_sql": [
          "string"
        ],
        "ignore_update_new_value_expr": "string",
        "ignore_update_old_value_expr": "string",
        "matcher": [
          "string"
        ]
      }
    ],
    "ignore_txn_start_ts": [
      0
    ],
    "rules": [
      "string"
    ]
  },
  "force_replicate": true,
  "ignore_ineligible_table": true,
  "memory_quota": 0,
  "mounter": {
    "worker_num": 0
  },
  "sink": {
    "column_selectors": [
      {
        "columns": [
          "string"
        ],
        "matcher": [
          "string"
        ]
      }
    ],
    "csv": {
      "delimiter": "string",
      "include_commit_ts": true,
      "null": "string",
      "quote": "string"
    },
    "date_separator": "string",
    "dispatchers": [
```

```
      {
        "matcher": [
          "string"
        ],
        "partition": "string",
        "topic": "string"
      }
    ],
    "enable_partition_separator": true,
    "encoder_concurrency": 0,
    "protocol": "string",
    "schema_registry": "string",
    "terminator": "string",
    "transaction_atomicity": "string"
  },
  "sync_point_interval": "string",
  "sync_point_retention": "string"
 },
 "sink_uri": "string",
 "target_ts": 0
}
```

Currently, only the following configurations can be modified via the API.

Parameter name	Description
`target_ts`	`UINT64` type. Specifies the target TSO of the changefeed. (Optional)
`sink_uri`	`STRING` type. The downstream address of the replication task. (Optional)
`replica_config`	The configuration parameters of sink. It must be complete. (Optional)

The meanings of the above parameters are the same as those in the Create a replication task section. See that section for details.

Example

The following request updates the `target_ts` of the replication task with the ID `test1` to 32.

```
curl -X PUT -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v2/changefeeds/test1 -d '{"target_ts":32}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned. The meanings of the JSON response body are the same as those in the Create a replication task section. See that section for details.

13.9.4.8.8 Query the replication task list

This API is a synchronous interface. If the request is successful, the basic information of all replication tasks (changefeed) in the TiCDC cluster is returned.

Request URI

`GET /api/v2/changefeeds`

Parameter descriptions

Query parameter

Parameter name	Description
`state`	When this parameter is specified, the information of replication tasks in this specified state is returned. (Optional)

The value options for `state` are `all`, `normal`, `stopped`, `error`, `failed`, and `finished`.

If this parameter is not specified, the basic information of replication tasks in the `normal`, `stopped`, or `failed` state is returned by default.

Example

The following request queries the basic information of all replication tasks in the `normal` state.

```
curl -X GET http://127.0.0.1:8300/api/v2/changefeeds?state=normal
```

```
{
  "total": 2,
  "items": [
    {
      "id": "test",
      "state": "normal",
      "checkpoint_tso": 439749918821711874,
      "checkpoint_time": "2023-02-27 23:46:52.888",
      "error": null
    },
    {
      "id": "test2",
      "state": "normal",
      "checkpoint_tso": 439749918821711874,
      "checkpoint_time": "2023-02-27 23:46:52.888",
      "error": null
    }
  ]
```

```
}
```

The parameters in the returned result above are described as follows:

- `id`: the ID of the replication task.
- `state`: the current state of the replication task.
- `checkpoint_tso`: the TSO of the current checkpoint of the replication task.
- `checkpoint_time`: the formatted time of the current checkpoint of the replication task.
- `error`: the error information of the replication task.

13.9.4.8.9 Query a specific replication task

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication task (changefeed) is returned.

Request URI

`GET /api/v2/changefeeds/{changefeed_id}`

Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be queried.

Example

The following request queries the detailed information of the replication task with the ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v2/changefeeds/test1
```

The meanings of the JSON response body are the same as those in the Create a replication task section. See that section for details.

13.9.4.8.10 Query whether a specific replication task is completed

This API is a synchronous interface. If the request is successful, it returns the synchronization status of the specified replication task (changefeed), including whether the task is completed and additional details.

Request URI

`GET /api/v2/changefeed/{changefeed_id}/synced`

Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be queried.

Examples

The following request queries the synchronization status of the replication task with the ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v2/changefeed/test1/synced
```

Example 1: The synchronization is completed

```
{
  "synced": true,
  "sink_checkpoint_ts": "2023-11-30 15:14:11.015",
  "puller_resolved_ts": "2023-11-30 15:14:12.215",
  "last_synced_ts": "2023-11-30 15:08:35.510",
  "now_ts": "2023-11-30 15:14:11.511",
  "info": "Data syncing is finished"
}
```

The response includes the following fields:

- `synced`: whether this replication task is completed. `true` means the task is completed, and `false` means potential incompleteness. If it is `false`, you need to check both the `info` field and other fields for the specific status.
- `sink_checkpoint_ts`: the checkpoint-ts value of the sink module, in PD time.
- `puller_resolved_ts`: the resolved-ts value of the puller module, in PD time.
- `last_synced_ts`: the commit-ts value of the latest data processed by TiCDC, in PD time.
- `now_ts`: current PD time.
- `info`: supplementary information to assist in determining the synchronization status, especially when `synced` is `false`.

Example 2: The synchronization is not completed

```
{
  "synced": false,
  "sink_checkpoint_ts": "2023-11-30 15:26:31.519",
  "puller_resolved_ts": "2023-11-30 15:26:23.525",
  "last_synced_ts": "2023-11-30 15:24:30.115",
  "now_ts": "2023-11-30 15:26:31.511",
  "info": "The data syncing is not finished, please wait"
}
```

This example shows the response of an ongoing replication task. By checking both `synced` and `info` fields, you can learn that the replication task is not completed yet and further waiting is expected.

Example 3: The synchronization status needs further check

```
{
  "synced":false,
  "sink_checkpoint_ts":"2023-12-13 11:45:13.515",
  "puller_resolved_ts":"2023-12-13 11:45:13.525",
  "last_synced_ts":"2023-12-13 11:45:07.575",
  "now_ts":"2023-12-13 11:50:24.875",
  "info":"Please check whether PD is online and TiKV Regions are all
     ↪ available. If PD is offline or some TiKV regions are not available,
     ↪ it means that the data syncing process is complete. To check whether
     ↪  TiKV regions are all available, you can view 'TiKV-Details' > '
     ↪ Resolved-Ts' > 'Max Leader Resolved TS gap' on Grafana. If the gap
     ↪ is large, such as a few minutes, it means that some regions in TiKV
     ↪ are unavailable. Otherwise, if the gap is small and PD is online, it
     ↪  means the data syncing is incomplete, so please wait"
}
```

This API enables you to query the synchronization status even when the upstream cluster encounters disasters. In certain situations, you might not be able to directly determine whether the current data replication task of TiCDC is completed or not. In such cases, you can request this API, and then check both the `info` field in the response and the current status of the upstream cluster to determine the specific status.

In this example, `sink_checkpoint_ts` is behind `now_ts` in time, either because TiCDC is still catching up with data replication, or because the PD or TiKV has failed. If this is due to TiCDC still catching up with data replication, it means that the replication task is not completed yet. If this is due to a PD or TiKV failure, it means that the replication task is completed. Therefore, you need to check the `info` field to assist in determining the cluster status.

Example 4: Query error

```
{
  "error_msg": "[CDC:ErrPDEtcdAPIError]etcd api call error: context deadline
     ↪  exceeded",
  "error_code": "CDC:ErrPDEtcdAPIError"
}
```

In cases where PD in the upstream cluster fails for a long period of time, querying this API might return an error similar to the preceding one, which provides no information for further check. Because PD failures directly affect TiCDC data replication, when getting such errors, you can assume that TiCDC has completed the data replication as much as possible, but data loss might still occur in the downstream cluster due to PD failures.

13.9.4.8.11 Pause a replication task

This API pauses a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v2/changefeeds/{changefeed_id}/pause`

Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be paused.

Example

The following request pauses the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v2/changefeeds/test1/pause
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

13.9.4.8.12 Resume a replication task

This API resumes a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v2/changefeeds/{changefeed_id}/resume`

Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be resumed.

Parameters for the request body

```
{
  "overwrite_checkpoint_ts": 0
}
```

Parameter name	Description
`overwrite_checkpoint_ts`	`UINT64` type. Reassign a checkpoint TSO when resuming a replication task (changefeed).

Example

The following request resumes the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v2/changefeeds/test1/resume -d '{}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

13.9.4.8.13 Query the replication subtask list

This API is a synchronous interface. If the request is successful, the basic information of all replication subtasks (`processor`) is returned.

Request URI

`GET /api/v2/processors`

Example

```
curl -X GET http://127.0.0.1:8300/api/v2/processors
```

```
{
  "total": 3,
  "items": [
    {
      "changefeed_id": "test2",
      "capture_id": "d2912e63-3349-447c-90ba-72a4e04b5e9e"
    },
    {
      "changefeed_id": "test1",
      "capture_id": "d2912e63-3349-447c-90ba-72a4e04b5e9e"
    },
    {
      "changefeed_id": "test",
      "capture_id": "d2912e63-3349-447c-90ba-72a4e04b5e9e"
    }
  ]
}
```

The parameters are described as follows:

- `changefeed_id`: the changefeed ID.
- `capture_id`: the capture ID.

13.9.4.8.14 Query a specific replication subtask

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication subtask (`processor`) is returned.

Request URI

`GET /api/v2/processors/{changefeed_id}/{capture_id}`

Parameter descriptions

Path parameters

Parameter name	Description
`changefeed_id`	The changefeed ID of the replication subtask to be queried.
`capture_id`	The capture ID of the replication subtask to be queried.

Example

The following request queries the detailed information of a subtask whose `changefeed_id` is `test` and `capture_id` is `561c3784-77f0-4863-ad52-65a3436db6af`. A subtask can be identified by `changefeed_id` and `capture_id`.

```
curl -X GET http://127.0.0.1:8300/api/v2/processors/test/561c3784-77f0-4863-ad52-65a3436db6af
```

```
{
  "table_ids": [
    80
  ]
}
```

The parameter is described as follows:

- `table_ids`: The table ID to be replicated on this capture.

13.9.4.8.15 Query the TiCDC service process list

This API is a synchronous interface. If the request is successful, the basic information of all replication processes (`capture`) is returned.

Request URI

`GET /api/v2/captures`

Example

```
curl -X GET http://127.0.0.1:8300/api/v2/captures
```

```
{
  "total": 1,
  "items": [
    {
      "id": "d2912e63-3349-447c-90ba-72a4e04b5e9e",
      "is_owner": true,
      "address": "127.0.0.1:8300"
    }
  ]
}
```

The parameters are described as follows:

- `id`: the capture ID.
- `is_owner`: whether the capture is the owner.
- `address`: the address of the capture.

13.9.4.8.16 Evict an owner node

This API is an asynchronous interface. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v2/owner/resign`

Example

The following request evicts the current owner node of TiCDC and triggers a new round of elections to generate a new owner node.

```
curl -X POST http://127.0.0.1:8300/api/v2/owner/resign
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

13.9.4.8.17 Dynamically adjust the log level of the TiCDC server

This API is a synchronous interface. If the request is successful, `200 OK` is returned.

Request URI

`POST /api/v2/log`

Request parameter

Parameter for the request body

Parameter name	Description
`log_level`	The log level you want to set.

`log_level` supports the log levels provided by zap: "debug", "info", "warn", "error", "dpanic" , "panic", and "fatal".

Example

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v2/log -d '{"log_level":"debug"}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

13.9.4.9 TiCDC OpenAPI v1

> **Note**
>
> TiCDC OpenAPI v1 is deprecated and will be deleted in the future. It is recommended to use TiCDC OpenAPI v2.

TiCDC provides the OpenAPI feature for querying and operating the TiCDC cluster, which is similar to the feature of `cdc cli` tool.

You can use the APIs to perform the following maintenance operations on the TiCDC cluster:

- Get the status information of a TiCDC node
- Check the health status of a TiCDC cluster
- Create a replication task
- Remove a replication task
- Update the replication configuration
- Query the replication task list
- Query a specific replication task
- Pause a replication task
- Resume a replication task
- Query the replication subtask list
- Query a specific replication subtask
- Query the TiCDC service process list
- Evict an owner node
- Manually trigger the load balancing of all tables in a replication task
- Manually schedule a table to another node

- Dynamically adjust the log level of the TiCDC server

The request body and returned value of all APIs are in JSON format. The following sections describe the specific usage of the APIs.

In the following examples, the listening IP address of the TiCDC server is `127.0.0.1` and the port is `8300`. You can bind a specified IP and port via `--addr=ip:port` when starting the TiCDC server.

13.9.4.9.1 API error message template

After sending an API request, if an error occurs, the returned error message is in the following format:

```
{
    "error_msg": "",
    "error_code": ""
}
```

From the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

13.9.4.9.2 Get the status information of a TiCDC node

This API is a synchronous interface. If the request is successful, the status information of the corresponding node is returned.

Request URI

`GET /api/v1/status`

Example

The following request gets the status information of the TiCDC node whose IP address is `127.0.0.1` and port number is `8300`.

```
curl -X GET http://127.0.0.1:8300/api/v1/status
```

```
{
    "version": "v5.2.0-master-dirty",
    "git_hash": "f191cd00c53fdf7a2b1c9308a355092f9bf8824e",
    "id": "c6a43c16-0717-45af-afd6-8b3e01e44f5d",
    "pid": 25432,
    "is_owner": true
}
```

The fields of the above output are described as follows:

- version: The current TiCDC version number.

- git_hash: The Git hash value.
- id: The capture ID of the node.
- pid: The capture process PID of the node.
- is_owner: Indicates whether the node is an owner.

13.9.4.9.3 Check the health status of a TiCDC cluster

This API is a synchronous interface. If the cluster is healthy, `200 OK` is returned.

Request URI

`GET /api/v1/health`

Example

```
curl -X GET http://127.0.0.1:8300/api/v1/health
```

13.9.4.9.4 Create a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v1/changefeeds`

Parameter description

Compared to the optional parameters for creating a replication task using the `cli` command, the optional parameters for creating such task using the API are not as complete. This API supports the following parameters.

Parameters for the request body

Parameter name | Description |
:———————— | :———————- ——————————- |
`changefeed_id` | `STRING` type. The ID of the replication task. (Optional) |
`start_ts` | `UINT64` type. Specifies the start TSO of the changefeed. (Optional) |
`target_ts` | `UINT64` type. Specifies the target TSO of the changefeed. (Optional) |
`sink_uri` | `STRING` type. The downstream address of the replication task. (**Required**) |
`force_replicate` | `BOOLEAN` type. Determines whether to forcibly replicate the tables without unique indexes. (Optional) |
`ignore_ineligible_table` | `BOOLEAN` type. Determines whether to ignore the tables that cannot be replicated. (Optional) |
`filter_rules` | `STRING` type array. The rules for table schema filtering. (Optional) |
`ignore_txn_start_ts` | `UINT64` type array. Ignores the transaction of a specified start_ts. (Optional) |
`mounter_worker_num` | `INT` type. The mounter thread number. (Optional) |
`sink_config` | The configuration parameters of sink. (Optional) |

The meaning and format of `changefeed_id`, `start_ts`, `target_ts`, and `sink_uri` are the same as those described in the Use `cdc cli` to create a replication task document. For the detailed description of these parameters, see this document. Note that when you specify the certificate path in `sink_uri`, make sure you have uploaded the corresponding certificate to the corresponding TiCDC server.

Some other parameters in the above table are described further as follows.

`force_replicate`: This parameter defaults to `false`. When it is specified as `true`, TiCDC tries to forcibly replicate tables that do not have a unique index.

`ignore_ineligible_table`: This parameter defaults to `false`. When it is specified as `true`, TiCDC ignores tables that cannot be replicated.

`filter_rules`: The rules for table schema filtering, such as `filter_rules = ['foo *.*','bar*.*']`. For details, see the Table Filter document.

`ignore_txn_start_ts`: When this parameter is specified, the specified start_ts is ignored. For example, `ignore-txn-start-ts = [1, 2]`.

`mounter_worker_num`: The thread number of mounter. Mounter is used to decode the data output from TiKV. The default value is `16`.

The configuration parameters of sink are as follows:

```
{
  "dispatchers":[
    {"matcher":["test1.*", "test2.*"], "dispatcher":"ts"},
    {"matcher":["test3.*", "test4.*"], "dispatcher":"index-value"}
  ],
  "protocol":"canal-json"
}
```

`dispatchers`: For the sink of MQ type, you can use dispatchers to configure the event dispatcher. Four dispatchers are supported: `default`, `ts`, `index-value`, and `table`. The dispatcher rules are as follows:

- `default`: dispatches events in the `table` mode.
- `ts`: uses the commitTs of the row change to create the hash value and dispatch events.
- `index-value`: uses the name and value of the selected HandleKey column to create the hash value and dispatch events.
- `table`: uses the schema name of the table and the table name to create the hash value and dispatch events.

`matcher`: The matching syntax of matcher is the same as the filter rule syntax.

`protocol`: For the sink of MQ type, you can specify the protocol format of the message. Currently the following protocols are supported: `canal-json`, `open-protocol`, `avro`, `debezium`, and `simple`.

Example

The following request creates a replication task with an ID of `test5` and a `sink_uri` of `blackhole://`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/changefeeds -d '{"changefeed_id":"test5","sink_uri":"blackhole
    ↪ ://"}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.5 Remove a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`DELETE /api/v1/changefeeds/{changefeed_id}`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be removed.

Example

The following request removes the replication task with the ID `test1`.

```
curl -X DELETE http://127.0.0.1:8300/api/v1/changefeeds/test1
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.6 Update the replication configuration

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

To modify the changefeed configuration, follow the steps of `pause the replication task -> modify the configuration -> resume the replication task`.

Request URI

`PUT /api/v1/changefeeds/{changefeed_id}`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be updated.

Parameters for the request body

Currently, only the following configuration can be modified via the API.

Parameter name | Description |
:——————— | :————————— ——————————— |
`target_ts` | `UINT64` type. Specifies the target TSO of the changefeed. (Optional) |
`sink_uri` | `STRING` type. The downstream address of the replication task. (Optional) |
`filter_rules` | `STRING` type array. The rules for table schema filtering. (Optional) |
`ignore_txn_start_ts` | `UINT64` type array. Ignores the transaction of a specified start_ts. (Optional) |
`mounter_worker_num` | `INT` type. The mounter thread number. (Optional) |
`sink_config` | The configuration parameters of sink. (Optional) |

The meanings of the above parameters are the same as those in the Create a replication task section. See that section for details.

Example

The following request updates the `mounter_worker_num` of the replication task with the ID `test1` to 32.

```
curl -X PUT -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/changefeeds/test1 -d '{"mounter_worker_num":32}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.7 Query the replication task list

This API is a synchronous interface. If the request is successful, the basic information of all nodes in the TiCDC cluster is returned.

Request URI

`GET /api/v1/changefeeds`

Parameter description

Query parameters

Parameter name | Description |
:—— | :————————————- —— |

`state` | When this parameter is specified, the replication status information only of this state is returned.(Optional) |

The value options for `state` are `all`, `normal`, `stopped`, `error`, `failed`, and `finished`.

If this parameter is not specified, the basic information of replication tasks whose state is normal, stopped, or failed is returned by default.

Example

The following request queries the basic information of all replication tasks whose state is `normal`.

```
curl -X GET http://127.0.0.1:8300/api/v1/changefeeds?state=normal
```

```
[
    {
        "id": "test1",
        "state": "normal",
        "checkpoint_tso": 426921294362574849,
        "checkpoint_time": "2021-08-10 14:04:54.242",
        "error": null
    },
    {
        "id": "test2",
        "state": "normal",
        "checkpoint_tso": 426921294362574849,
        "checkpoint_time": "2021-08-10 14:04:54.242",
        "error": null
    }
]
```

The fields in the returned result above are described as follows:

- id: The ID of the replication task.
- state: The current state of the replication task.
- checkpoint_tso: The TSO representation of the current checkpoint of the replication task.
- checkpoint_time: The formatted time representation of the current checkpoint of the replication task.
- error: The error information of the replication task.

13.9.4.9.8 Query a specific replication task

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication task is returned.

Request URI

`GET /api/v1/changefeeds/{changefeed_id}`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be queried.

Example

The following request queries the detailed information of the replication task with the ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v1/changefeeds/test1
```

```
{
    "id": "test1",
    "sink_uri": "blackhole://",
    "create_time": "2021-08-10 11:41:30.642",
    "start_ts": 426919038970232833,
    "target_ts": 0,
    "checkpoint_tso": 426921014615867393,
    "checkpoint_time": "2021-08-10 13:47:07.093",
    "sort_engine": "unified",
    "state": "normal",
    "error": null,
    "error_history": null,
    "creator_version": "",
    "task_status": [
        {
            "capture_id": "d8924259-f52f-4dfb-97a9-c48d26395945",
            "table_ids": [
                63,
                65
            ],
            "table_operations": {}
        }
    ]
}
```

13.9.4.9.9 Pause a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v1/changefeeds/{changefeed_id}/pause`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be paused.

Example

The following request pauses the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/pause
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.10 Resume a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v1/changefeeds/{changefeed_id}/resume`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be resumed.

Example

The following request resumes the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/resume
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.11 Query the replication subtask list

This API is a synchronous interface. If the request is successful, the basic information of all replication subtasks (`processor`) is returned.

Request URI

`GET /api/v1/processors`

Example

```
curl -X GET http://127.0.0.1:8300/api/v1/processors
```

```
[
    {
        "changefeed_id": "test1",
        "capture_id": "561c3784-77f0-4863-ad52-65a3436db6af"
    }
]
```

13.9.4.9.12 Query a specific replication subtask

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication subtask (`processor`) is returned.

Request URI

`GET /api/v1/processors/{changefeed_id}/{capture_id}`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The changefeed ID of the replication subtask to be queried.
`capture_id`	The capture ID of the replication subtask to be queried.

Example

The following request queries the detailed information of a subtask whose `changefeed_id` is `test` and `capture_id` is `561c3784-77f0-4863-ad52-65a3436db6af`. A subtask can be indentifed by `changefeed_id` and `capture_id`.

```
curl -X GET http://127.0.0.1:8300/api/v1/processors/test1/561c3784-77f0
    ↪ -4863-ad52-65a3436db6af
```

```
{
    "checkpoint_ts": 426919123303006208,
    "resolved_ts": 426919123369066496,
    "table_ids": [
        63,
        65
    ],
```

```
    "error": null
}
```

13.9.4.9.13 Query the TiCDC service process list

This API is a synchronous interface. If the request is successful, the basic information of all replication processes (`capture`) is returned.

Request URI

`GET /api/v1/captures`

Example

```
curl -X GET http://127.0.0.1:8300/api/v1/captures
```

```
[
    {
        "id": "561c3784-77f0-4863-ad52-65a3436db6af",
        "is_owner": true,
        "address": "127.0.0.1:8300"
    }
]
```

13.9.4.9.14 Evict an owner node

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v1/owner/resign`

Example

The following request evicts the current owner node of TiCDC and triggers a new round of elections to generate a new owner node.

```
curl -X POST http://127.0.0.1:8300/api/v1/owner/resign
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.15 Manually trigger the load balancing of all tables in a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v1/changefeeds/{changefeed_id}/tables/rebalance_table`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be scheduled.

Example

The following request triggers the load balancing of all tables in the changefeed with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/tables/
    ↪ rebalance_table
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.16 Manually schedule a table to another node

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

Request URI

`POST /api/v1/changefeeds/{changefeed_id}/tables/move_table`

Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be scheduled.

Parameters for the request body

Parameter name	Description
`target_capture_id`	The ID of the target capture.
`table_id`	The ID of the table to be scheduled.

Example

The following request schedules the table with the ID `49` in the changefeed with the ID

`test1` to the capture with the ID `6f19a6d9-0f8c-4dc9-b299-3ba7c0f216f5`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/changefeeds/changefeed-test1/tables/move_table -d '{"capture_
    ↪ id":"6f19a6d9-0f8c-4dc9-b299-3ba7c0f216f5","table_id":49}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

13.9.4.9.17 Dynamically adjust the log level of the TiCDC server

This API is a synchronous interface. If the request is successful, `202 OK` is returned.

Request URI

`POST /api/v1/log`

Request parameters

Parameters for the request body

Parameter name	Description
`log_level`	The log level you want to set.

`log_level` supports the log levels provided by zap: "debug", "info", "warn", "error", "dpanic" , "panic", and "fatal".

Example

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/log -d '{"log_level":"debug"}'
```

If the request is successful, `202 OK` is returned. If the request fails, an error message and error code are returned.

13.9.4.10 TiCDC Data Consumption

13.9.4.10.1 TiCDC Row Data Checksum Verification Based on Avro

This document introduces how to consume data sent to Kafka by TiCDC and encoded by Avro protocol using Golang, and how to perform data verification using the Single-row data checksum feature.

The source code of this example is available in the `avro-checksum-verification` directory.

The example in this document uses kafka-go to create a simple Kafka consumer program. This program continuously reads data from a specified topic, calculates the checksum, and verifies its value.

```
package main

import (
    "context"
    "encoding/binary"
    "encoding/json"
    "hash/crc32"
    "io"
    "math"
    "net/http"
    "strconv"
    "strings"

    "github.com/linkedin/goavro/v2"
    "github.com/pingcap/log"
    "github.com/pingcap/tidb/parser/mysql"
    "github.com/pingcap/tidb/types"
    "github.com/pingcap/tiflow/pkg/errors"
    "github.com/segmentio/kafka-go"
    "go.uber.org/zap"
)

const (
    // The first byte of the Confluent Avro wire format is always 0.
    // For more details, see https://docs.confluent.io/platform/current/
        ↪ schema-registry/fundamentals/serdes-develop/index.html#wire-format
        ↪ .
    magicByte = uint8(0)
)

func main() {
    var (
        kafkaAddr       = "127.0.0.1:9092"
        schemaRegistryURL = "http://127.0.0.1:8081"

        topic         = "avro-checksum-test"
        consumerGroupID = "avro-checksum-test"
    )

    consumer := kafka.NewReader(kafka.ReaderConfig{
        Brokers: []string{kafkaAddr},
        GroupID: consumerGroupID,
        Topic:   topic,
        MaxBytes: 10e6, // 10MB
```

```
    })
    defer consumer.Close()

    ctx := context.Background()
    log.Info("start consuming ...", zap.String("kafka", kafkaAddr), zap.
        ↪ String("topic", topic), zap.String("groupID", consumerGroupID))
    for {
        // 1. Fetch the kafka message.
        message, err := consumer.FetchMessage(ctx)
        if err != nil {
            log.Error("read kafka message failed", zap.Error(err))
        }

        value := message.Value
        if len(value) == 0 {
            log.Info("delete event does not have value, skip checksum
                ↪ verification", zap.String("topic", topic))
        }

        // 2. Decode the value to get the corresponding value map and schema
            ↪ map.
        valueMap, valueSchema, err := getValueMapAndSchema(value,
            ↪ schemaRegistryURL)
        if err != nil {
            log.Panic("decode kafka value failed", zap.String("topic", topic)
                ↪ , zap.ByteString("value", value), zap.Error(err))
        }

        // 3. Calculate and verify checksum value using the value map and
            ↪ schema map obtained in the previous step.
        err = CalculateAndVerifyChecksum(valueMap, valueSchema)
        if err != nil {
            log.Panic("calculate checksum failed", zap.String("topic", topic)
                ↪ , zap.ByteString("value", value), zap.Error(err))
        }

        // 4. Commit offset after the data is successfully consumed.
        if err := consumer.CommitMessages(ctx, message); err != nil {
            log.Error("commit kafka message failed", zap.Error(err))
            break
        }
    }
}
```

The key steps for calculating the checksum value are `getValueMapAndSchema()` and

`CalculateAndVerifyChecksum()`. The following sections describe the implementation of these two functions.

Decode data and get the corresponding schema

The `getValueMapAndSchema()` method decodes data and gets the corresponding schema. This method returns both the data and schema as a `map[string]interface{}` type.

```
// data is the key or value of the received kafka message, and url is the
    ↪ schema registry url.
// This function returns the decoded value and corresponding schema as map.
func getValueMapAndSchema(data []byte, url string) (map[string]interface{},
    ↪ map[string]interface{}, error) {
    schemaID, binary, err := extractSchemaIDAndBinaryData(data)
    if err != nil {
        return nil, nil, err
    }

    codec, err := GetSchema(url, schemaID)
    if err != nil {
        return nil, nil, err
    }

    native, _, err := codec.NativeFromBinary(binary)
    if err != nil {
        return nil, nil, err
    }

    result, ok := native.(map[string]interface{})
    if !ok {
        return nil, nil, errors.New("raw avro message is not a map")
    }

    schema := make(map[string]interface{})
    if err := json.Unmarshal([]byte(codec.Schema()), &schema); err != nil {
        return nil, nil, errors.Trace(err)
    }

    return result, schema, nil
}

// extractSchemaIDAndBinaryData
func extractSchemaIDAndBinaryData(data []byte) (int, []byte, error) {
    if len(data) < 5 {
        return 0, nil, errors.ErrAvroInvalidMessage.FastGenByArgs()
    }
    if data[0] != magicByte {
```

```
        return 0, nil, errors.ErrAvroInvalidMessage.FastGenByArgs()
    }
    return int(binary.BigEndian.Uint32(data[1:5])), data[5:], nil
}

// GetSchema fetches the schema from the schema registry by the schema ID.
// This function returns a goavro.Codec that can be used to encode and
    ↪ decode the data.
func GetSchema(url string, schemaID int) (*goavro.Codec, error) {
    requestURI := url + "/schemas/ids/" + strconv.Itoa(schemaID)

    req, err := http.NewRequest("GET", requestURI, nil)
    if err != nil {
        log.Error("Cannot create the request to look up the schema", zap.
            ↪ Error(err))
        return nil, errors.WrapError(errors.ErrAvroSchemaAPIError, err)
    }
    req.Header.Add(
        "Accept",
        "application/vnd.schemaregistry.v1+json, application/vnd.
            ↪ schemaregistry+json, "+
            "application/json",
    )

    httpClient := &http.Client{}
    resp, err := httpClient.Do(req)
    if err != nil {
        return nil, err
    }
    defer resp.Body.Close()

    body, err := io.ReadAll(resp.Body)

```

Calculate and verify the checksum value

The `valueMap` and `valueSchema` obtained in the previous step contain all the elements used for checksum calculation and verification.

The checksum calculation and verification process on the consumer side includes the following steps:

1. Get the expected checksum value.
2. Iterate over each column, generate a byte slice according to the column value and the corresponding MySQL type, and update the checksum value continuously.
3. Compare the checksum value calculated in the previous step with the checksum value obtained from the received message. If they are not the same, the checksum verification fails and the data might be corrupted.

The sample code is as follows:

```
func CalculateAndVerifyChecksum(valueMap, valueSchema map[string]interface
    ↪ {}) error {
```

```
// The fields variable stores the column type information for each data
    ↪ change event. The column IDs are used to sort the fields, which is
    ↪  the same as the order in which the checksum is calculated.
fields, ok := valueSchema["fields"].([]interface{})
if !ok {
    return errors.New("schema fields should be a map")
}

// 1. Get the expected checksum value from valueMap, which is encoded as
    ↪  a string.
// If the expected checksum value is not found, it means that the
    ↪ checksum feature is not enabled when TiCDC sends the data. In this
    ↪  case, this function returns directly.
o, ok := valueMap["_tidb_row_level_checksum"]
if !ok {
    return nil
}
expected := o.(string)
if expected == "" {
    return nil
}

// expectedChecksum is the expected checksum value passed from TiCDC.
expectedChecksum, err := strconv.ParseUint(expected, 10, 64)
if err != nil {
    return errors.Trace(err)
}

// 2. Iterate over each field and calculate the checksum value.
var actualChecksum uint32
// buf stores the byte slice used to update the checksum value each time
    ↪ .
buf := make([]byte, 0)
for _, item := range fields {
    field, ok := item.(map[string]interface{})
    if !ok {
        return errors.New("schema field should be a map")
    }

    // The tidbOp and subsequent columns are not involved in the checksum
        ↪  calculation, because they are used to assist data consumption
        ↪  and not real TiDB column data.
    colName := field["name"].(string)
    if colName == "_tidb_op" {
        break
```

```
}

// The holder variable stores the type information of each column.
var holder map[string]interface{}

13.9.4.10.2 Guide for Developing a Storage Sink Consumer

This document describes how to design and implement a TiDB data change consumer.

> **Note:**
>
> The storage sink cannot handle the `DROP DATABASE` DDL. Therefore, avoid executing this DDL. If you do need to execute this DDL, execute it manually in the downstream MySQL.

TiCDC does not provide any standard way for implementing a consumer. This document provides a consumer example program written in Golang. This program can read data from the storage service and write the data to a MySQL-compatible database. You can refer to the data format and instructions provided in this example to implement a consumer on your own.

Consumer program written in Golang

Design a consumer

The following diagram shows the overall consumption process of the consumer:

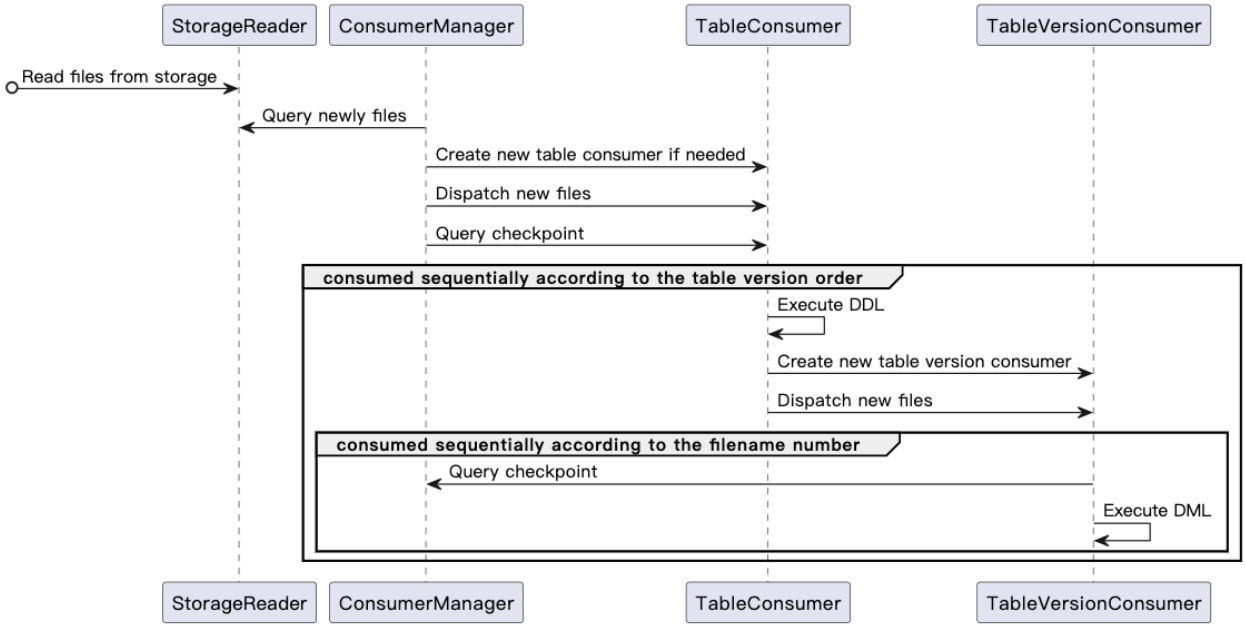

Figure 525: TiCDC storage consumer overview

The components of the consumer and their features are described as follows:

```
type StorageReader struct {
}
// Read the files from storage.
// Add new files and delete files that do not exist in storage.
func (c *StorageReader) ReadFiles() {}

// Query newly added files and the latest checkpoint from storage. One file
    ↪ can only be returned once.
func (c *StorageReader) ExposeNewFiles() (int64, []string) {}

// ConsumerManager is responsible for assigning tasks to TableConsumer.
// Different consumers can consume data concurrently,
// but data of one table must be processed by the same TableConsumer.
type ConsumerManager struct {
  // StorageCheckpoint is recorded in the metadata file, and it can be
      ↪ fetched by calling `StorageReader.ExposeNewFiles()`.
  // This checkpoint indicates that the data whose transaction commit time
      ↪ is less than this checkpoint has been stored in storage.
  StorageCheckpoint int64
  // This checkpoint indicates where the consumer has consumed.
  // ConsumerManager periodically collects TableConsumer.Checkpoint,
  // then Checkpoint is updated to the minimum value of all TableConsumer.
      ↪ Checkpoint.
```

```
  Checkpoint int64

  tableFiles[schema][table]*TableConsumer
}

// Query newly added files from StorageReader.
// For a newly created table, create a TableConsumer for it.
// If any, send new files to the corresponding TableConsumer.
func (c *ConsumerManager) Dispatch() {}
type TableConsumer struct {
  // This checkpoint indicates where this TableConsumer has consumed.
  // Its initial value is ConsumerManager.Checkpoint.
  // TableConsumer.Checkpoint is equal to TableVersionConsumer.Checkpoint.
  Checkpoint int64

  schema,table string
  // Must be consumed sequentially according to the order of table versions.
  verConsumers map[version int64]*TableVersionConsumer
  currentVer, previousVer int64
}

// Send newly added files to the corresponding TableVersionConsumer.
// For any DDL, assign a TableVersionConsumer for the new table version.
func (tc *TableConsumer) Dispatch() {}

// If DDL query is empty or its tableVersion is less than TableConsumer.
   ↪ Checkpoint,
// - ignore this DDL, and consume the data under the table version.
// Otherwise,
// - execute the DDL first, and then consume the data under the table
   ↪ version.
// - For tables that are dropped, auto-recycling is performed after the drop
   ↪  table DDL is executed.
func (tc *TableConsumer) ExecuteDDL() {}

type TableVersionConsumer struct {
  // This checkpoint indicates where the TableVersionConsumer has consumed.
  // Its initial value is TableConsumer.Checkpoint.
  Checkpoint int64

  schema,table,version string
  // For the same table version, data in different partitions can be
     ↪ consumed concurrently.
  # partitionNum int64
  // Must be consumed sequentially according to the data file number.
```

```
  fileSet map[filename string]*TableVersionConsumer
  currentVersion
}
// If data commit ts is less than TableConsumer.Checkpoint
// or bigger than ConsumerManager.StorageCheckpoint,
// - ignore this data.
// Otherwise,
// - process this data and write it to MySQL.
func (tc *TableVersionConsumer) ExecuteDML() {}
```

Process DDL events

The consumer traverses the directory for the first time. The following is an example:

```
├── metadata
├── test
    ├── tbl_1
        ├── 437752935075545091
            ├── CDC000001.json
            ├── schema.json
```

The consumer parses the table schema of the `schema.json` file and obtains the DDL Query statements:

- If no Query statement is found or `TableVersion` is less than the consumer checkpoint, the consumer skips this statement.
- If Query statements exist or `TableVersion` is equal to or greater than the consumer checkpoint, the consumer executes the DDL statements in the downstream MySQL.

Then the consumer starts replicating the `CDC000001.json` file.

In the following example, the DDL Query statement in the `test/tbl_1/437752935075545091/schema.json` file is not empty:

```
{
    "Table":"test",
    "Schema":"tbl_1",
    "Version": 1,
    "TableVersion":437752935075545091,
    "Query": "create table tbl_1 (Id int primary key, LastName char(20),
        ↪ FirstName varchar(30), HireDate datetime, OfficeLocation Blob(20))
        ↪ ",
    "TableColumns":[
        {
            "ColumnName":"Id",
            "ColumnType":"INT",
            "ColumnNullable":"false",
```

```
            "ColumnIsPk":"true"
        },
        {
            "ColumnName":"LastName",
            "ColumnType":"CHAR",
            "ColumnLength":"20"
        },
        {
            "ColumnName":"FirstName",
            "ColumnType":"VARCHAR",
            "ColumnLength":"30"
        },
        {
            "ColumnName":"HireDate",
            "ColumnType":"DATETIME"
        },
        {
            "ColumnName":"OfficeLocation",
            "ColumnType":"BLOB",
            "ColumnLength":"20"
        }
    ],
    "TableColumnsTotal":"5"
}
```

When the consumer traverses the directory again, it finds a new version directory of the table. Note that the consumer can consume data in the new directory only after all files in the `test/tbl_1/437752935075545091` directory have been consumed.

```
├── metadata
├── test
    ├── tbl_1
        ├── 437752935075545091
            ├── CDC000001.json
            ├── schema.json
        ├── 437752935075546092
            ├── CDC000001.json
            ├── schema.json
```

The consumption logic is consistent. Specifically, the consumer parses the table schema of the `schema.json` file and obtains and processes DDL Query statements accordingly. Then the consumer starts replicating the `CDC000001.json` file.

Process DML events

After DDL events are properly processed, you can process DML events in the `{schema}/{table}/{table-version-separator}/` directory based on the specific file format

(CSV or Canal-JSON) and file number.

TiCDC ensures that data is replicated at least once. Therefore, there might be duplicate data. You need to compare the commit ts of the change data with the consumer checkpoint. If the commit ts is less than the consumer checkpoint, you need to perform deduplication.

13.9.4.11 TiCDC Compatibility

This section describes compatibility issues related to TiCDC and how to handle them.

13.9.4.11.1 Compatibility with TiDB Lightning

TiDB Lightning provides two data import modes: logical import mode and physical import mode. This section describes the compatibility of these modes with TiCDC and the steps to use TiDB Lightning and TiCDC together in a cluster.

In the logical import mode, TiDB Lightning imports data by executing SQL statements. This mode is compatible with TiCDC. To use TiDB Lightning's logical import mode with TiCDC for data replication, perform the following steps:

1. Create a changefeed. For more information, see Create a replication task.
2. Start TiDB Lightning and import data using the logical import mode. For more information, see Use logical import mode.

In the physical import mode, TiDB Lightning imports data by inserting SST files into TiKV. TiCDC is not compatible with this mode and does not support replicating data imported through physical import mode. If you need to use both TiDB Lightning's physical import mode and TiCDC, choose one of the following solutions based on your downstream system:

- If the downstream is a TiDB cluster, perform the following steps:

    1. Use TiDB Lightning to import data into both the upstream and downstream TiDB clusters to ensure data consistency.
    2. Create a changefeed to replicate subsequent incremental data written through SQL. For more information, see Create a replication task.

- If the downstream is not a TiDB cluster, perform the following steps:

    1. Use the offline import tool provided by your downstream system to import TiDB Lightning's input files.
    2. Create a changefeed to replicate subsequent incremental data written through SQL. For more information, see Create a replication task.

13.9.4.11.2 CLI and configuration file compatibility

- In TiCDC v4.0.0, `ignore-txn-commit-ts` is removed and `ignore-txn-start-ts` is added, which uses start_ts to filter transactions.
- In TiCDC v4.0.2, `db-dbs/db-tables/ignore-dbs/ignore-tables` are removed and `rules` is added, which uses new filter rules for databases and tables. For detailed filter syntax, see Table Filter.
- Starting from TiCDC v6.2.0, `cdc cli` can directly interact with TiCDC server via TiCDC Open API. You can specify the address of the TiCDC server using the `--server` parameter. `--pd` is deprecated.
- Since v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.

13.9.4.11.3 Handle compatibility issues

This section describes compatibility issues related to TiCDC and how to handle them.

Incompatibility issue caused by using the TiCDC v5.0.0-rc `cdc cli` tool to operate a v4.0.x cluster

When using the `cdc cli` tool of TiCDC v5.0.0-rc to operate a v4.0.x TiCDC cluster, you might encounter the following abnormal situations:

- If the TiCDC cluster is v4.0.8 or an earlier version, using the v5.0.0-rc `cdc cli` tool to create a replication task might cause cluster anomalies and get the replication task stuck.
- If the TiCDC cluster is v4.0.9 or a later version, using the v5.0.0-rc `cdc cli` tool to create a replication task will cause the old value and unified sorter features to be unexpectedly enabled by default.

Solutions:

Use the `cdc` executable file corresponding to the TiCDC cluster version to perform the following operations:

1. Delete the changefeed created using the v5.0.0-rc `cdc cli` tool. For example, run the `tiup cdc:v4.0.9 cli changefeed remove -c xxxx --pd=xxxxx --force` command.
2. If the replication task is stuck, restart the TiCDC cluster. For example, run the `tiup cluster restart <cluster_name> -R cdc` command.
3. Re-create the changefeed. For example, run the `tiup cdc:v4.0.9 cli changefeed create --sink-uri=xxxx --pd=xxx` command.

Note:

This issue exists only when `cdc cli` is v5.0.0-rc. `cdc cli` tool of other v5.0.x versions is compatible with v4.0.x clusters.

Compatibility notes for `sort-dir` and `data-dir`

The `sort-dir` configuration is used to specify the temporary file directory for the TiCDC sorter. Its functionalities might vary in different versions. The following table lists `sort-dir`'s compatibility changes across versions.

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v4.0.11 or earlier v4.0 version, v5.0.0-rc	It is a changefeed configuration item and specifies temporary file directory for the file sorter and unified ↪ sorter.	In these versions, file ↪ sorter and unified ↪ sorter are **experimental features** and **NOT** recommended for the production environment. If mul-	It is not recommended to use unified ↪ sorter in the production environment.

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v4.0.12, v4.0.13, v5.0.0, and v5.0.1	It is a configuration item of changefeed or of cdc ↪ server ↪ .	By default, the sort ↪ - ↪ dir ↪ configuration of a changefeed does not take effect, and the sort ↪ - ↪ dir ↪ configuration of cdc ↪ ↪ server ↪ defaults to /	You need to configure sort ↪ - ↪ dir ↪ using the cdc ↪ ↪ server ↪ command-line parameter (or TiUP).

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v4.0.14 and later v4.0 versions, v5.0.3 and later v5.0 versions, later TiDB versions	sort ↪ - ↪ dir ↪ is deprecated. It is recommended to configure data ↪ - ↪ dir ↪ .	You can configure data ↪ - ↪ dir ↪ using the latest version of TiUP. In these TiDB versions, unified ↪ sorter is enabled by default. Make sure that data ↪ - ↪ dir ↪ has been con-	You need to configure data ↪ - ↪ dir ↪ using the cdc ↪ ↪ server ↪ command-line parameter (or TiUP).

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v6.0.0 and later versions	data ↪ - ↪ dir ↪ is used for saving the temporary files generated by TiCDC.	Starting from v6.0.0, TiCDC uses db ↪ sorter ↪ as the sort engine by default. data ↪ - ↪ dir ↪ is the disk directory for this engine.	You need to configure data ↪ - ↪ dir ↪ using the cdc ↪ ↪ server ↪ command-line parameter (or TiUP).

Compatibility with temporary tables

Since v5.3.0, TiCDC supports global temporary tables. Replicating global temporary tables to the downstream using TiCDC of a version earlier than v5.3.0 causes table definition error.

If the upstream cluster contains a global temporary table, the downstream TiDB cluster

is expected to be v5.3.0 or a later version. Otherwise, an error occurs during the replication process.

Compatibility with vector data types

Starting from v8.4.0, TiCDC supports replicating tables with vector data types to downstream (experimental).

When the downstream is Kafka or a storage service (such as Amazon S3, GCS, Azure Blob Storage, or NFS), TiCDC converts vector data types into string types before writing to the downstream.

When the downstream is a MySQL-compatible database that does not support vector data types, TiCDC fails to write DDL events involving vector types to the downstream. In this case, add the `has-vector-type=true` parameter to `sink-url`, which allows TiCDC to convert vector data types into the `LONGTEXT` type before writing.

13.9.5 Troubleshoot TiCDC

This document introduces the common errors you might encounter when using TiCDC, and the corresponding maintenance and troubleshooting methods.

> **Note:**
>
> In this document, the server address specified in `cdc cli` commands is `server =http://127.0.0.1:8300`. When you use the command, replace the address with your actual TiCDC Server address.

13.9.5.1 TiCDC replication interruptions

13.9.5.1.1 How do I know whether a TiCDC replication task is interrupted?

- Check the `changefeed checkpoint` monitoring metric of the replication task (choose the right `changefeed id`) in the Grafana dashboard. If the metric value stays unchanged, or the `checkpoint lag` metric keeps increasing, the replication task might be interrupted.
- Check the `exit error count` monitoring metric. If the metric value is greater than `0`, an error has occurred in the replication task.
- Execute `cdc cli changefeed list` and `cdc cli changefeed query` to check the status of the replication task. `stopped` means the task has stopped, and the `error` item provides the detailed error message. After the error occurs, you can search `error on running processor` in the TiCDC server log to see the error stack for troubleshooting.

- In some extreme cases, the TiCDC service is restarted. You can search the `FATAL` level log in the TiCDC server log for troubleshooting.

13.9.5.1.2 How do I know whether the replication task is stopped manually?

You can know whether the replication task is stopped manually by executing `cdc cli`. For example:

```
cdc cli changefeed query --server=http://127.0.0.1:8300 --changefeed-id 28
    ↪ c43ffc-2316-4f4f-a70b-d1a7c59ba79f
```

In the output of the above command, `admin-job-type` shows the state of this replication task. For more information about each state and its meaning, see Changefeed states.

13.9.5.1.3 How do I handle replication interruptions?

A replication task might be interrupted in the following known scenarios:

- The downstream continues to be abnormal, and TiCDC still fails after many retries.
    - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
    - Handling method: You can resume the replication task by executing `cdc cli changefeed resume` after the downstream is back to normal.
- Replication cannot continue because of incompatible SQL statement(s) in the downstream.
    - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
    - Handling procedures:
        1. Query the status information of the replication task using the `cdc cli changefeed query` command and record the value of `checkpoint-ts`.
        2. Use the new task configuration file and add the `ignore-txn-start-ts` parameter to skip the transaction corresponding to the specified `start-ts`.
        3. Pause the replication task by executing `cdc cli changefeed pause -c <changefeed-id>`.
        4. Specify the new task configuration file by executing `cdc cli changefeed update -c <changefeed-id> --config <config-file-path>`.
        5. Resume the replication task by executing `cdc cli changefeed resume -c <changefeed-id>`.

13.9.5.1.4 What should I do to handle the OOM that occurs after TiCDC is restarted after a task interruption?

- Update your TiDB cluster and TiCDC cluster to the latest versions. The OOM problem has already been resolved in **v4.0.14 and later v4.0 versions, v5.0.2 and later v5.0 versions, and the latest versions**.

13.9.5.2 How do I handle the `Error 1298: Unknown or incorrect time zone: 'UTC'` error when creating the replication task or replicating data to MySQL?

This error is returned when the downstream MySQL does not load the time zone. You can load the time zone by running `mysql_tzinfo_to_sql`. After loading the time zone, you can create tasks and replicate data normally.

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql -p
```

If the output of the command above is similar to the following one, the import is successful:

```
Enter password:
Warning: Unable to load '/usr/share/zoneinfo/iso3166.tab' as time zone.
    ↪ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/leap-seconds.list' as time zone
    ↪ . Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone.tab' as time zone.
    ↪ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone1970.tab' as time zone.
    ↪ Skipping it.
```

If the downstream is a special MySQL environment (a public cloud RDS or some MySQL derivative versions) and importing the time zone using the preceding method fails, you can use the default time zone of the downstream by setting `time-zone` to an empty value, such as `time-zone=""`.

When using time zones in TiCDC, it is recommended to explicitly specify the time zone, such as `time-zone="Asia/Shanghai"`. Also, make sure that the `tz` specified in TiCDC server configurations and the `time-zone` specified in Sink URI are consistent with the time zone configuration of the downstream database. This prevents data inconsistency caused by inconsistent time zones.

13.9.5.3 How do I handle the incompatibility issue of configuration files caused by TiCDC upgrade?

Refer to Notes for compatibility.

13.9.5.4 The `start-ts` timestamp of the TiCDC task is quite different from the current time. During the execution of this task, replication is interrupted and an error `[CDC:ErrBufferReachLimit]` occurs. What should I do?

Since v4.0.9, you can try to enable the unified sorter feature in your replication task, or use the BR tool for an incremental backup and restore, and then start the TiCDC replication task from a new time.

13.9.5.5 When the downstream of a changefeed is a database similar to MySQL and TiCDC executes a time-consuming DDL statement, all other changefeeds are blocked. What should I do?

1. Pause the execution of the changefeed that contains the time-consuming DDL statement. Then you can see that other changefeeds are no longer blocked.
2. Search for the `apply job` field in the TiCDC log and confirm the `start-ts` of the time-consuming DDL statement.
3. Manually execute the DDL statement in the downstream. After the execution finishes, go on performing the following operations.
4. Modify the changefeed configuration and add the above `start-ts` to the `ignore-txn-start-ts` configuration item.
5. Resume the paused changefeed.

13.9.5.6 The `[tikv:9006]GC life time is shorter than transaction duration, transaction starts at xx, GC safe point is yy` error is reported when I use TiCDC to create a changefeed. What should I do?

You need to run the `pd-ctl service-gc-safepoint --pd <pd-addrs>` command to query the current GC safepoint and service GC safepoint. If the GC safepoint is smaller than the `start-ts` of the TiCDC replication task (changefeed), you can directly add the `--disable-gc-check` option to the `cdc cli create changefeed` command to create a changefeed.

If the result of `pd-ctl service-gc-safepoint --pd <pd-addrs>` does not have `gc_worker service_id`:

- If your PD version is v4.0.8 or earlier, refer to PD issue #3128 for details.
- If your PD is upgraded from v4.0.8 or an earlier version to a later version, refer to PD issue #3366 for details.

13.9.5.7 When I use TiCDC to replicate messages to Kafka, Kafka returns the `Message was too large` error. Why?

For TiCDC v4.0.8 or earlier versions, you cannot effectively control the size of the message output to Kafka only by configuring the `max-message-bytes` setting for Kafka in the Sink URI. To control the message size, you also need to increase the limit on the bytes of messages to be received by Kafka. To add such a limit, add the following configuration to the Kafka server configuration.

```
### The maximum byte number of a message that the broker receives
message.max.bytes=2147483648
### The maximum byte number of a message that the broker copies
replica.fetch.max.bytes=2147483648
### The maximum message byte number that the consumer side reads
fetch.message.max.bytes=2147483648
```

13.9.5.8 How can I find out whether a DDL statement fails to execute in downstream during TiCDC replication? How to resume the replication?

If a DDL statement fails to execute, the replication task (changefeed) automatically stops. The checkpoint-ts is the DDL statement's finish-ts. If you want TiCDC to retry executing this statement in the downstream, use `cdc cli changefeed resume` to resume the replication task. For example:

```
cdc cli changefeed resume -c test-cf --server=http://127.0.0.1:8300
```

If you want to skip this DDL statement that goes wrong, set the start-ts of the changefeed to the checkpoint-ts (the timestamp at which the DDL statement goes wrong) plus one, and then run the `cdc cli changefeed create` command to create a new changefeed task. For example, if the checkpoint-ts at which the DDL statement goes wrong is `415241823337054209`, run the following commands to skip this DDL statement:

To skip this DDL statement that goes wrong, you can configure the `ignore-txn-start-ts` parameter to skip the transactions corresponding to the specified `start-ts`. For example:

1. Search the TiCDC log for the `apply job` field, and identify the `start-ts` of the DDLs that are taking a long time.
2. Modify the changefeed configuration. Add the above `start-ts` to the `ignore-txn-start-ts` configuration item.
3. Resume the suspended changefeed.

> **Note:**
>
> Although setting the changefeed `start-ts` to the value of `checkpoint-ts` (at the time of the error) plus one and then recreating the task can skip the DDL statement, it can also cause TiCDC to lose the DML data change at the time of `checkpointTs+1`. Therefore, this operation is strictly prohibited in production environments.

```
cdc cli changefeed remove --server=http://127.0.0.1:8300 --changefeed-id
    ↪ simple-replication-task
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task" --sort-engine="unified" --start-ts 415241823337054210
```

13.9.5.9 The `Kafka: client has run out of available brokers to talk to: EOF` error is reported when I use TiCDC to replicate messages to Kafka. What should I do?

This error is typically caused by the connection failure between TiCDC and the Kafka cluster. To troubleshoot, you can check the Kafka logs and network status. One possible reason is that you did not specify the correct `kafka-version` parameter when creating the replication task, causing the Kafka client inside TiCDC to use the wrong Kafka API version when accessing the Kafka server. You can fix this issue by specifying the correct `kafka-version` parameter in the `--sink-uri` configuration. For example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri "kafka
    ↪ ://127.0.0.1:9092/test?topic=test&protocol=open-protocol&kafka-
    ↪ version=2.4.0"
```

13.9.6 TiCDC FAQs

This document introduces the common questions that you might encounter when using TiCDC.

> **Note:**
>
> In this document, the server address specified in `cdc cli` commands is `--server=http://127.0.0.1:8300`. When you use the command, replace the address with your actual PD address.

13.9.6.1 How do I choose `start-ts` when creating a task in TiCDC?

The `start-ts` of a replication task corresponds to a Timestamp Oracle (TSO) in the upstream TiDB cluster. TiCDC requests data from this TSO in a replication task. Therefore, the `start-ts` of the replication task must meet the following requirements:

- The value of `start-ts` is larger than the `tikv_gc_safe_point` value of the current TiDB cluster. Otherwise, an error occurs when you create a task.

- Before starting a task, ensure that the downstream has all data before `start-ts`. For scenarios such as replicating data to message queues, if the data consistency between upstream and downstream is not required, you can relax this requirement according to your application need.

If you do not specify `start-ts`, or specify `start-ts` as `0`, when a replication task is started, TiCDC gets a current TSO and starts the task from this TSO.

13.9.6.2 Why can't some tables be replicated when I create a task in TiCDC?

When you execute `cdc cli changefeed create` to create a replication task, TiCDC checks whether the upstream tables meet the replication requirements. If some tables do not meet the requirements, `some tables are not eligible to replicate` is returned with a list of ineligible tables. You can choose `Y` or `y` to continue creating the task, and all updates on these tables are automatically ignored during the replication. If you choose an input other than `Y` or `y`, the replication task is not created.

13.9.6.3 How do I view the state of TiCDC replication tasks?

To view the status of TiCDC replication tasks, use `cdc cli`. For example:

```
cdc cli changefeed list --server=http://127.0.0.1:8300
```

The expected output is as follows:

```
[{
    "id": "4e24dde6-53c1-40b6-badf-63620e4940dc",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "2020-07-07 16:07:44.881",
      "error": null
    }
}]
```

- `checkpoint`: TiCDC has replicated all data before this timestamp to downstream.
- `state`: The state of this replication task. For more information about each state and its meaning, see Changefeed states.

> **Note:**
>
> This feature is introduced in TiCDC 4.0.3.

13.9.6.4 How to verify if TiCDC has replicated all updates after upstream stops updating?

After the upstream TiDB cluster stops updating, you can verify if replication is complete by comparing the latest TSO timestamp of the upstream TiDB cluster with the replication progress in TiCDC. If the TiCDC replication progress timestamp is greater than or equal to the upstream TiDB cluster's TSO, then all updates have been replicated. To verify replication completeness, perform the following steps:

1. Get the latest TSO timestamp from the upstream TiDB cluster.

> **Note:**
> Use the `TIDB_CURRENT_TSO()` function to get the current TSO, instead of using functions like `NOW()` that return the current time.

The following example uses `TIDB_PARSE_TSO()` to convert the TSO to a readable time format for further comparison:

```
BEGIN;
SELECT TIDB_PARSE_TSO(TIDB_CURRENT_TSO());
ROLLBACK;
```

The output is as follows:

```
+-----------------------------------+
| TIDB_PARSE_TSO(TIDB_CURRENT_TSO()) |
+-----------------------------------+
| 2024-11-12 20:35:34.848000     |
+-----------------------------------+
```

2. Get the replication progress in TiCDC.

   You can check the replication progress in TiCDC using one of the following methods:

   - **Method 1**: query the checkpoint of the changefeed (recommended).

     Use the TiCDC command-line tool `cdc cli` to view the checkpoint for all replication tasks:

     ```
     cdc cli changefeed list --server=http://127.0.0.1:8300
     ```

     The output is as follows:

     ```
     [
       {
         "id": "syncpoint",
         "namespace": "default",
     ```

```
    "summary": {
      "state": "normal",
      "tso": 453880043653562372,
      "checkpoint": "2024-11-12 20:36:01.447",
      "error": null
    }
  }
]
```

In the output, `"checkpoint": "2024-11-12 20:36:01.447"` indicates that TiCDC has replicated all upstream TiDB changes before this time. If this timestamp is greater than or equal to the upstream TiDB cluster's TSO obtained in step 1, then all updates have been replicated downstream.

- **Method 2**: query Syncpoint from the downstream TiDB.

  If the downstream is a TiDB cluster and the TiCDC Syncpoint feature is enabled, you can get the replication progress by querying the Syncpoint in the downstream TiDB.

> **Note:**
> The Syncpoint update interval is controlled by the `sync-point-interval` configuration item. For the most up-to-date replication progress, use method 1.

Execute the following SQL statement in the downstream TiDB to get the upstream TSO (`primary_ts`) and downstream TSO (`secondary_ts`):

```
SELECT * FROM tidb_cdc.syncpoint_v1;
```

The output is as follows:

```
+--
   ↪ ---------------+------------+--------------------+--------------------
   ↪
| ticdc_cluster_id | changefeed | primary_ts   | secondary_ts     |
   ↪ created_at        |
+--
   ↪ ---------------+------------+--------------------+--------------------
   ↪
| default          | syncpoint | 453879870259200000 |
   ↪ 453879870545461257 | 2024-11-12 20:25:01 |
| default          | syncpoint | 453879948902400000 |
   ↪ 453879949214351361 | 2024-11-12 20:30:01 |
| default          | syncpoint | 453880027545600000 |
   ↪ 453880027751907329 | 2024-11-12 20:35:00 |
```

```
+--
    ↪ ----------------+------------+--------------------+--------------------
    ↪
```

In the output, each row shows the upstream TiDB snapshot at `primary_ts` matches the downstream TiDB snapshot at `secondary_ts`.

To view the replication progress, convert the latest `primary_ts` to a readable time format:

```
SELECT TIDB_PARSE_TSO(453880027545600000);
```

The output is as follows:

```
+-----------------------------------+
| TIDB_PARSE_TSO(453880027545600000) |
+-----------------------------------+
| 2024-11-12 20:35:00               |
+-----------------------------------+
```

If the time corresponding to the latest `primary_ts` is greater than or equal to the upstream TiDB cluster's TSO obtained in step 1, then TiCDC has replicated all updates downstream.

13.9.6.5 What is `gc-ttl` in TiCDC?

Since v4.0.0-rc.1, PD supports external services in setting the service-level GC safepoint. Any service can register and update its GC safepoint. PD ensures that the key-value data later than this GC safepoint is not cleaned by GC.

When the replication task is unavailable or interrupted, this feature ensures that the data to be consumed by TiCDC is retained in TiKV without being cleaned by GC.

When starting the TiCDC server, you can specify the Time To Live (TTL) duration of GC safepoint by configuring `gc-ttl`. You can also use TiUP to modify `gc-ttl`. The default value is 24 hours. In TiCDC, this value means:

- The maximum time the GC safepoint is retained at the PD after the TiCDC service is stopped.
- When TiKV's GC is blocked by TiCDC's GC safepoint, `gc-ttl` indicates the maximum replication delay of a TiCDC replication task. If the delay of the replication task exceeds the value set by `gc-ttl`, the replication task enters into the `failed` state and reports the `ErrGCTTLExceeded` error. It cannot be recovered, and no longer blocks GC safepoint to advance.

The second behavior above is introduced in TiCDC v4.0.13 and later versions. The purpose is to prevent a replication task in TiCDC from suspending for too long, causing the GC safepoint of the upstream TiKV cluster not to continue for a long time and retaining too many outdated data versions, thus affecting the performance of the upstream cluster.

Note:

In some scenarios, for example, when you use TiCDC for incremental replication after full replication with Dumpling/BR, the default 24 hours of `gc-ttl` may not be sufficient. You need to specify an appropriate value for `gc-ttl` when you start the TiCDC server.

13.9.6.6 What is the complete behavior of TiCDC garbage collection (GC) safepoint?

If a replication task starts after the TiCDC service starts, the TiCDC owner updates the PD service GC safepoint with the smallest value of `checkpoint-ts` among all replication tasks. The service GC safepoint ensures that TiCDC does not delete data generated at that time and after that time. If the replication task is interrupted, or manually stopped, the `checkpoint-ts` of this task does not change. Meanwhile, PD's corresponding service GC safepoint is not updated either.

If the replication task is suspended longer than the time specified by `gc-ttl`, the replication task enters the `failed` status and cannot be resumed. The PD corresponding service GC safepoint will continue.

The default Time-To-Live (TTL) that TiCDC sets for a service GC safepoint is 24 hours, which means that the GC mechanism does not delete the data required by TiCDC for continuing replication if the TiCDC service can be recovered within 24 hours after it is interrupted.

13.9.6.7 How to recover a replication task after it fails?

1. Use `cdc cli changefeed query` to query the error information of the replication task and fix the error as soon as possible.
2. Increase the value of `gc-ttl` to allow more time to fix the error, ensuring that the replication task does not enter the `failed` status due to the replication delay exceeding `gc-ttl` after the error is fixed.
3. After evaluating the impact on the system, increase the value of `tidb_gc_life_time` in TiDB to block GC and retain data, ensuring that the replication task does not enter the `failed` status due to GC cleaning data after the error is fixed.

13.9.6.8 How to understand the relationship between the TiCDC time zone and the time zones of the upstream/downstream databases?

	Upstream time zone	TiCDC time zone	Downstream time zone
Configuration method	See Time Zone Support	Configured using the `--tz` parameter when you start the TiCDC server	Configured using the `time-zone` parameter in `sink-uri`

	Upstream time zone	TiCDC time zone	Downstream time zone
Description	The time zone of the upstream TiDB, which affects DML operations of the timestamp type and DDL operations related to timestamp type columns.	TiCDC assumes that the upstream TiDB's time zone is the same as the TiCDC time zone configuration, and performs related operations on the timestamp column.	The downstream MySQL processes the timestamp in the DML and DDL operations according to the downstream time zone setting.

Note:

Be careful when you set the time zone of the TiCDC server, because this time zone is used for converting the time type. Keep the upstream time zone, TiCDC time zone, and the downstream time zone consistent. The TiCDC server chooses its time zone in the following priority:

- TiCDC first uses the time zone specified using `--tz`.
- When `--tz` is not available, TiCDC tries to read the time zone set using the `TZ` environment variable.
- When the `TZ` environment variable is not available, TiCDC uses the default time zone of the machine.

13.9.6.9 What is the default behavior of TiCDC if I create a replication task without specifying the configuration file in `--config`?

If you use the `cdc cli changefeed create` command without specifying the `-config` parameter, TiCDC creates the replication task in the following default behaviors:

- Replicates all tables except system tables
- Only replicates tables that contain valid indexes

13.9.6.10 Does TiCDC support outputting data changes in the Canal protocol?

Yes. Note that for the Canal protocol, TiCDC only supports the JSON output format, while the protobuf format is not officially supported yet. To enable Canal output, specify `protocol` as `canal-json` in the `--sink-uri` configuration. For example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri="kafka
    ↪ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&protocol=canal-json"
    ↪ --config changefeed.toml
```

Note:

- This feature is introduced in TiCDC 4.0.2.
- TiCDC currently supports outputting data changes in the Canal-JSON format only to MQ sinks such as Kafka.

For more information, refer to TiCDC changefeed configurations.

13.9.6.11 Why does the latency from TiCDC to Kafka become higher and higher?

- Check how do I view the state of TiCDC replication tasks.
- Adjust the following parameters of Kafka:
    - Increase the `message.max.bytes` value in `server.properties` to `1073741824` (1 GB).
    - Increase the `replica.fetch.max.bytes` value in `server.properties` to `1073741824` (1 GB).
    - Increase the `fetch.message.max.bytes` value in `consumer.properties` to make it larger than the `message.max.bytes` value.

13.9.6.12 When TiCDC replicates data to Kafka, can I control the maximum size of a single message in TiDB?

When `protocol` is set to `avro` or `canal-json`, messages are sent per row change. A single Kafka message contains only one row change and is generally no larger than Kafka's limit. Therefore, there is no need to limit the size of a single message. If the size of a single Kafka message does exceed Kafka's limit, refer to Why does the latency from TiCDC to Kafka become higher and higher?.

When `protocol` is set to `open-protocol`, messages are sent in batches. Therefore, one Kafka message might be excessively large. To avoid this situation, you can configure the `max-message-bytes` parameter to control the maximum size of data sent to the Kafka broker each time (optional, `10MB` by default). You can also configure the `max-batch-size` parameter (optional, `16` by default) to specify the maximum number of change records in each Kafka message.

13.9.6.13 If I modify a row multiple times in a transaction, will TiCDC output multiple row change events?

No. When you modify the same row in one transaction multiple times, TiDB only sends the latest modification to TiKV. Therefore, TiCDC can only obtain the result of the latest modification.

13.9.6.14 When TiCDC replicates data to Kafka, does a message contain multiple types of data changes?

Yes. A single message might contain multiple `update`s or `delete`s, and `update` and `delete` might co-exist.

13.9.6.15 When TiCDC replicates data to Kafka, how do I view the timestamp, table name, and schema name in the output of TiCDC Open Protocol?

The information is included in the key of Kafka messages. For example:

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":1
}
```

For more information, refer to TiCDC Open Protocol event format.

13.9.6.16 When TiCDC replicates data to Kafka, how do I know the timestamp of the data changes in a message?

You can get the unix timestamp by moving `ts` in the key of the Kafka message by 18 bits to the right.

13.9.6.17 How does TiCDC Open Protocol represent `null`?

In TiCDC Open Protocol, the type code `6` represents `null`.

Type	Code	Output Example	Note
Null	6	`{"t":6,"v":null}`	

For more information, refer to TiCDC Open Protocol column type code.

13.9.6.18 How can I tell if a Row Changed Event of TiCDC Open Protocol is an `INSERT` event or an `UPDATE` event?

- `UPDATE` event contains both `"p"` and `"u"` fields
- `INSERT` event only contains the `"u"` field
- `DELETE` event only contains the `"d"` field

For more information, refer to Open protocol Row Changed Event format.

13.9.6.19 How much PD storage does TiCDC use?

When using TiCDC, you might encounter the `etcdserver: mvcc: database space exceeded` error, which is primarily related to the mechanism that TiCDC uses etcd in PD to store metadata.

etcd uses Multi-Version Concurrency Control (MVCC) to store data, and the default compaction interval in PD is 1 hour. This means that etcd retains multiple versions of all data for 1 hour before compaction.

Before v6.0.0, TiCDC uses etcd in PD to store and update metadata for all tables in a changefeed. Therefore, the PD storage space used by TiCDC is proportional to the number of tables being replicated by the changefeed. When TiCDC is replicating a large number of tables, the etcd storage space could fill up quickly, increasing the probability of the `etcdserver: mvcc: database space exceeded` error.

If you encounter this error, refer to etcd maintenance space-quota to clean up the etcd storage space.

Starting from v6.0.0, TiCDC optimizes its metadata storage mechanism, effectively avoiding the etcd storage space issues caused by the preceding reasons. If your TiCDC version is earlier than v6.0.0, it is recommended to upgrade to v6.0.0 or later versions.

13.9.6.20 Does TiCDC support replicating large transactions? Is there any risk?

TiCDC provides partial support for large transactions (more than 5 GB in size). Depending on different scenarios, the following risks might exist:

- The latency of primary-secondary replication might greatly increase.
- When TiCDC's internal processing capacity is insufficient, the replication task error `ErrBufferReachLimit` might occur.
- When TiCDC's internal processing capacity is insufficient or the throughput capacity of TiCDC's downstream is insufficient, out of memory (OOM) might occur.

Since v6.2, TiCDC supports splitting a single-table transaction into multiple transactions. This can greatly reduce the latency and memory consumption of replicating large transactions. Therefore, if your application does not have a high requirement on transaction atomicity, it is recommended to enable the splitting of large transactions to avoid possible replication latency and OOM. To enable the splitting, set the value of the sink uri parameter `transaction-atomicity` to `none`.

If you still encounter an error above, it is recommended to use BR to restore the incremental data of large transactions. The detailed operations are as follows:

1. Record the `checkpoint-ts` of the changefeed that is terminated due to large transactions, use this TSO as the `--lastbackupts` of the BR incremental backup, and execute incremental data backup.
2. After backing up the incremental data, you can find a log record similar to `["Full backup Failed summary : total backup ranges: 0, total success: 0, total failed: 0"] [BackupTS=421758868510212097]` in the BR log output. Record the `BackupTS` in this log.
3. Restore the incremental data.

4. Create a new changefeed and start the replication task from `BackupTS`.
5. Delete the old changefeed.

13.9.6.21 Does TiCDC replicate data changes caused by lossy DDL operations to the downstream?

Lossy DDL refers to DDL that might cause data changes when executed in TiDB. Some common lossy DDL operations include:

- Modifying the type of a column, for example, INT -> VARCHAR
- Modifying the length of a column, for example, VARCHAR(20) -> VARCHAR(10)
- Modifying the precision of a column, for example, DECIMAL(10, 3) -> DECIMAL(10, 2)
- Modifying the UNSIGNED or SIGNED attribute of a column, for example, INT UNSIGNED -> INT SIGNED

Before TiDB v7.1.0, TiCDC replicates DML events with identical old and new data to the downstream. When the downstream is MySQL, these DML events do not cause any data changes until the downstream receives and executes the DDL statement. However, when the downstream is Kafka or a cloud storage service, TiCDC writes a row of redundant data to the downstream.

Starting from TiDB v7.1.0, TiCDC eliminates these redundant DML events and no longer replicates them to downstream.

13.9.6.22 The default value of the time type field is inconsistent when replicating a DDL statement to the downstream MySQL 5.7. What can I do?

Suppose that the `create table test (id int primary key, ts timestamp)` statement is executed in the upstream TiDB. When TiCDC replicates this statement to the downstream MySQL 5.7, MySQL uses the default configuration. The table schema after the replication is as follows. The default value of the `timestamp` field becomes `CURRENT_TIMESTAMP`:

```
mysql root@127.0.0.1:test> show create table test;
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
| Table | Create Table
   ↪                                                                    |
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
| test | CREATE TABLE `test` (
   ↪                                                          |
```

```
|       |   `id` int(11) NOT NULL,
   ↪                                                    |
|       |   `ts` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
   ↪ CURRENT_TIMESTAMP, |
|       |   PRIMARY KEY (`id`)
   ↪                                                   |
|       | ) ENGINE=InnoDB DEFAULT CHARSET=latin1
   ↪                                    |
+--
   ↪ -----+-------------------------------------------------------------------------
   ↪
1 row in set
```

From the result, you can see that the table schema before and after the replication is inconsistent. This is because the default value of `explicit_defaults_for_timestamp` in TiDB is different from that in MySQL. See MySQL Compatibility for details.

Since v5.0.1 or v4.0.13, for each replication to MySQL, TiCDC automatically sets `explicit_defaults_for_timestamp = ON` to ensure that the time type is consistent between the upstream and downstream. For versions earlier than v5.0.1 or v4.0.13, pay attention to the compatibility issue caused by the inconsistent `explicit_defaults_for_timestamp` value when using TiCDC to replicate the time type data.

13.9.6.23 Why do `INSERT`/`UPDATE` statements from the upstream become `REPLACE INTO` after being replicated to the downstream if I set `safe-mode` to `true` when I create a TiCDC replication task?

TiCDC guarantees that all data is replicated at least once. When there is duplicate data in the downstream, write conflicts occur. To avoid this problem, TiCDC converts `INSERT` and `UPDATE` statements into `REPLACE INTO` statements. This behavior is controlled by the `safe-mode` parameter.

In versions earlier than v6.1.3, the default value of `safe-mode` is `true`, which means all `INSERT` and `UPDATE` statements are converted into `REPLACE INTO` statements.

In v6.1.3 and later versions, the default value of `safe-mode` changes to `false`, and TiCDC can automatically determine whether the downstream has duplicate data. If no duplicate data is detected, TiCDC directly replicates `INSERT` and `UPDATE` statements without conversion; otherwise, TiCDC converts `INSERT` and `UPDATE` statements into `REPLACE INTO` statements and then replicates them.

13.9.6.24 Why does TiCDC use disks? When does TiCDC write to disks? Does TiCDC use memory buffer to improve replication performance?

When upstream write traffic is at peak hours, the downstream may fail to consume all data in a timely manner, resulting in data pile-up. TiCDC uses disks to process the data that is piled up. TiCDC needs to write data to disks during normal operation. However,

this is not usually the bottleneck for replication throughput and replication latency, given that writing to disks only results in latency within a hundred milliseconds. TiCDC also uses memory to accelerate reading data from disks to improve replication performance.

13.9.6.25 Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning physical import mode and BR from upstream?

Currently, TiCDC is not yet fully compatible with TiDB Lightning physical import mode and BR. Therefore, avoid using TiDB Lightning physical import mode and BR on tables that are replicated by TiCDC. Otherwise, unknown errors might occur, such as TiCDC replication getting stuck, a significant spike in replication latency, or data loss.

If you need to use TiDB Lightning physical import mode or BR to restore data for some tables replicated by TiCDC, take these steps:

1. Remove the TiCDC replication task related to these tables.
2. Use TiDB Lightning physical import mode or BR to restore data separately in the upstream and downstream clusters of TiCDC.
3. After the restoration is complete and data consistency between the upstream and downstream clusters is verified, create a new TiCDC replication task for incremental replication, with the timestamp (TSO) from the upstream backup as the `start-ts` for the task. For example, assuming the snapshot timestamp of the BR backup in the upstream cluster is `431434047157698561`, you can create a new TiCDC replication task using the following command:

```
cdc cli changefeed create -c "upstream-to-downstream-some-tables" --
    ↪ start-ts=431434047157698561 --sink-uri="mysql://root@127
    ↪ .0.0.1:4000? time-zone="
```

13.9.6.26 After a changefeed resumes from pause, its replication latency gets higher and higher and returns to normal only after a few minutes. Why?

When a changefeed is resumed, TiCDC needs to scan the historical versions of data in TiKV to catch up with the incremental data logs generated during the pause. The replication process proceeds only after the scan is completed. The scan process might take several to tens of minutes.

13.9.6.27 How should I deploy TiCDC to replicate data between two TiDB cluster located in different regions?

For TiCDC versions earlier than v6.5.2, it is recommended that you deploy TiCDC in the downstream TiDB cluster. If the network latency between the upstream and downstream is high, for example, more than 100 ms, the latency produced when TiCDC executes SQL statements to the downstream might increase dramatically due to the MySQL transmission

protocol issues. This results in a decrease in system throughput. However, deploying TiCDC in the downstream can greatly ease this problem. After optimization, starting from TiCDC v6.5.2, it is recommended that you deploy TiCDC in the upstream TiDB cluster.

13.9.6.28 What is the order of executing DML and DDL statements?

Currently, TiCDC adopts the following order:

1. TiCDC blocks the replication progress of the tables affected by DDL statements until the DDL `commitTS`. This ensures that DML statements executed before DDL `commitTS` can be successfully replicated to the downstream first.
2. TiCDC continues with the replication of DDL statements. If there are multiple DDL statements, TiCDC replicates them in a serial manner.
3. After the DDL statements are executed in the downstream, TiCDC will continue with the replication of DML statements executed after DDL `commitTS`.

13.9.6.29 How should I check whether the upstream and downstream data is consistent?

If the downstream is a TiDB cluster or MySQL instance, it is recommended that you compare the data using sync-diff-inspector.

13.9.6.30 Replication of a single table can only be run on a single TiCDC node. Will it be possible to use multiple TiCDC nodes to replicate data of multiple tables?

Starting from v7.1.0, TiCDC supports the MQ sink to replicate data change logs at the granularity of TiKV Regions, which achieves scalable processing capability and allows TiCDC to replicate a single table with a large number of Regions. To enable this feature, you can configure the following parameter in the TiCDC configuration file:

```
[scheduler]
enable-table-across-nodes = true
```

13.9.6.31 Does TiCDC replication get stuck if the upstream has long-running uncommitted transactions?

TiDB has a transaction timeout mechanism. When a transaction runs for a period longer than `max-txn-ttl`, TiDB forcibly rolls it back. TiCDC waits for the transaction to be committed before proceeding with the replication, which causes replication delay.

13.9.6.32 Why can't I use the `cdc cli` command to operate a TiCDC cluster deployed by TiDB Operator?

This is because the default port number of the TiCDC cluster deployed by TiDB Operator is `8301`, while the default port number of the `cdc cli` command to connect to the TiCDC

server is 8300. When using the `cdc cli` command to operate the TiCDC cluster deployed by TiDB Operator, you need to explicitly specify the `--server` parameter, as follows:

```
./cdc cli changefeed list --server "127.0.0.1:8301"
[
  {
    "id": "4k-table",
    "namespace": "default",
    "summary": {
      "state": "stopped",
      "tso": 441832628003799353,
      "checkpoint": "2023-05-30 22:41:57.910",
      "error": null
    }
  },
  {
    "id": "big-table",
    "namespace": "default",
    "summary": {
      "state": "normal",
      "tso": 441872834546892882,
      "checkpoint": "2023-06-01 17:18:13.700",
      "error": null
    }
  }
]
```

13.9.6.33 Does TiCDC replicate generated columns of DML operations?

Generated columns include virtual generated columns and stored generated columns. TiCDC ignores virtual generated columns and only replicates stored generated columns to the downstream. However, stored generated columns are also ignored when the downstream is MySQL or another MySQL-compatible database (rather than Kafka or other storage services).

> **Note:**
>
> When replicating stored generated columns to Kafka or a storage service and then writing them back to MySQL, `Error 3105 (HY000): The value ↪ specified for generated column 'xx' in table 'xxx' is not ↪ allowed` might occur. To avoid this error, you can use Open Protocol for replication. The output of this protocol includes bit flags of columns, which can distinguish whether a column is a generated column.

13.9.6.34 How do I resolve frequent `CDC:ErrMySQLDuplicateEntryCDC` errors?

When using TiCDC to replicate data to TiDB or MySQL, you might encounter the following error if SQL statements in the upstream are executed in a specific pattern:

```
CDC:ErrMySQLDuplicateEntryCDC
```

The cause of the error: TiDB combines `DELETE + INSERT` operations on the same row within the same transaction into a single `UPDATE` row change. When TiCDC replicates these changes as updates to the downstream, the `UPDATE` operations attempting to swap unique key values might result in conflicts.

Taking the following table as an example:

```
CREATE TABLE data_table (
    id BIGINT(20) NOT NULL PRIMARY KEY,
    value BINARY(16) NOT NULL,
    UNIQUE KEY value_index (value)
) CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

If the upstream attempts to swap the `value` field of the two rows in the table:

```
DELETE FROM data_table WHERE id = 1;
DELETE FROM data_table WHERE id = 2;
INSERT INTO data_table (id, value) VALUES (1, 'v3');
INSERT INTO data_table (id, value) VALUES (2, 'v1');
```

TiDB generates two `UPDATE` row changes, so TiCDC converts them into two `UPDATE` statements for replication to the downstream:

```
UPDATE data_table SET value = 'v3' WHERE id = 1;
UPDATE data_table SET value = 'v1' WHERE id = 2;
```

If the downstream table still contains `v1` when executing the second `UPDATE` statement, it violates the unique key constraint on the `value` column, resulting in the `CDC:ErrMySQLDuplicateEntryCDC` error.

If the `CDC:ErrMySQLDuplicateEntryCDC` error occurs frequently, you can enable TiCDC safe mode by setting the `safe-mode=true` parameter in the `sink-uri` configuration:

```
mysql://user:password@host:port/?safe-mode=true
```

In safe mode, TiCDC splits the `UPDATE` operation into `DELETE + REPLACE INTO` for execution, thus avoiding the unique key conflict error.

13.9.7 TiCDC Glossary

This glossary provides TiCDC-related terms and definitions. These terms appears in TiCDC logs, monitoring metrics, configurations, and documents.

For TiDB-related terms and definitions, refer to TiDB glossary.

13.9.7.1 C

13.9.7.1.1 Capture

A single TiCDC instance on which the replication task of the cluster runs. Multiple captures form a TiCDC cluster.

13.9.7.1.2 Changed data

The data to be written to TiCDC from the upstream TiDB cluster, including the DML-caused data changes and the DDL-caused table schema changes.

13.9.7.1.3 Changefeed

An incremental replication task in TiCDC, which outputs the data change logs of several tables in a TiDB cluster to the designated downstream.

13.9.7.2 O

13.9.7.2.1 Owner

A capture of a special role that manages the TiCDC cluster and schedules replication tasks of the cluster. An owner is elected by captures and there is at most one owner at any time.

13.9.7.3 P

13.9.7.3.1 Processor

TiCDC replication tasks allocate data tables on TiCDC instances, and the processor refers to the replication processing unit of these tables. Processor tasks include pulling, sorting, restoring, and distributing changed data.

13.10 PingCAP Clinic Diagnostic Service

13.10.1 PingCAP Clinic Overview

PingCAP Clinic Diagnostic Service (PingCAP Clinic) is a diagnostic service provided by PingCAP for TiDB clusters that are deployed using either TiUP or TiDB Operator. This service helps to troubleshoot cluster problems remotely and provides a quick check of cluster status locally. With PingCAP Clinic, you can ensure the stable operation of your TiDB cluster for its full life-cycle, predict potential problems, reduce the probability of problems, troubleshoot cluster problems quickly, and fix cluster problems.

PingCAP Clinic provides the following two components to diagnose cluster problems:

- Diag client:

  Diag client (Diag) is an open-source diagnostic tool deployed on the cluster side. Diag is used to collect cluster diagnostic data, upload diagnostic data to the Clinic Server, and perform a quick health check locally on your cluster. For a full list of diagnostic data that can be collected by Diag, see PingCAP Clinic Diagnostic Data.

> **Note:**
>
> Diag supports TiDB v4.0 and later versions, but **does not support** collecting data from clusters deployed using TiDB Ansible.

- Clinic Server:

  Clinic Server is a cloud service deployed in the cloud. By providing diagnostic services in the SaaS model, the Clinic Server can not only receive uploaded diagnostic data but also work as an online diagnostic environment to store data, view data, and provide cluster diagnostic reports. Clinic Server provides two independent services depending on the storage location:

  - Clinic Server for international users: Data is stored in AWS in US.
  - Clinic Server for users in the Chinese mainland: Data is stored in AWS in China (Beijing) regions.

13.10.1.1 User scenarios

- Troubleshoot cluster problems remotely

  When your cluster has some problems that cannot be fixed quickly, you can get support from PingCAP or the community. When contacting technical support for remote assistance, you need to save various diagnostic data from the cluster and forward the data to the support staff. In this case, you can use Diag to collect diagnostic data with one click. Diag helps you to collect complete diagnostic data quickly, which can avoid complex manual data collection operations. After collecting data, you can upload the data to the Clinic Server for PingCAP technical support staff to troubleshoot cluster problems. The Clinic Server provides secure storage for uploaded diagnostic data and supports the online diagnosis, which greatly improves the troubleshooting efficiency.

- Quickly check cluster status

  Even if your cluster is running stably for now, it is necessary to periodically check the cluster to detect potential stability risks. You can identify potential health risks of a cluster using the local and server-side quick check feature provided by PingCAP Clinic.

13.10.1.2 Implementation principles

This section introduces the implementation principles about how Diag collects diagnostic data from a cluster.

First, Diag gets cluster topology information from the deployment tool TiUP (tiup-cluster) or TiDB Operator (tidb-operator). Then, Diag collects different types of diagnostic data through various data collection methods as follows:

- Transfer server files through SCP

  For clusters deployed using TiUP, Diag can collect log files and configuration files directly from the nodes of the target component through the Secure copy protocol (SCP).

- Collect data by running commands remotely through SSH

  For clusters deployed using TiUP, Diag can connect to the target component system through SSH (Secure Shell) and run commands (such as Insight) to obtain system information, including kernel logs, kernel parameters, and basic information of the system and hardware.

- Collect data through HTTP call

  - By calling the HTTP interface of TiDB components, Diag can get the real-time configuration sampling information and the real-time performance sampling information of TiDB, TiKV, PD, and other components.
  - By calling the HTTP interface of Prometheus, Diag can get alert information and monitoring metrics data.

- Query database parameters through SQL statements

  Using SQL statements, Diag can query system variables and other information of TiDB. To use this method, you need to **additionally provide** the username and password to access TiDB when collecting data.

13.10.1.3 The limitations of Clinic Server

Note:

- Clinic Server is free from July 15, 2022 to April 15, 2025. You will be notified through email before April 15, 2025 if the service starts charging fee afterwards.
- If you want to adjust the usage limitations, get support from PingCAP.

Service Type	Limitation
Number of clusters	10/organization
Storage capacity	50 GB/cluster
Storage duration	180 days
Data size	3 GB/package
Saving duration of the data rebuild environment	3 days

13.10.1.4 Next step

- Use PingCAP Clinic in an on-premise environment
  - Quick Start with PingCAP Clinic
  - Troubleshoot Clusters using PingCAP Clinic
  - PingCAP Clinic Diagnostic Data
- Use PingCAP Clinic on Kubernetes
  - Troubleshoot TiDB Cluster using PingCAP Clinic
  - PingCAP Clinic Diagnostic Data

13.10.2 Quick Start Guide for PingCAP Clinic

This document describes how to use PingCAP Clinic diagnosis service (PingCAP Clinic) to collect, upload, and view cluster diagnosis data quickly.

PingCAP Clinic consists of two components: Diag client (shorten as Diag) and Clinic Server cloud service (shorten as Clinic Server). For details of these two components, refer to PingCAP Clinic Overview.

13.10.2.1 User scenarios

- To accurately identify and quickly resolve problems in your cluster when seeking help remotely from PingCAP technical support, you can collect diagnostic data with Diag, upload the collected data to the Clinic Server, and provide the data access link to the technical support.
- When the cluster is running properly and you need to check the status of the cluster, you can use Diag to collect diagnostic data, upload the data to Clinic Server, and view the results of Health Report.

Note:

- The following methods to collect and upload data are **only** applicable to clusters deployed using TiUP. For clusters deployed using TiDB Operator on Kubernetes, see PingCAP Clinic for TiDB Operator environments.
- The diagnostic data collected by PingCAP Clinic is **only** used for troubleshooting cluster problems.

13.10.2.2 Prerequisites

Before using PingCAP Clinic, you need to install Diag and prepare an environment for uploading data.

1. On your control machine with TiUP installed, run the following command to install Diag:

```
tiup install diag
```

2. Log in to Clinic Server.

   Go to the Clinic Server for international users and select **Continue with TiDB Account** to enter the TiDB Cloud login page. If you do not have a TiDB Cloud account, create one on that page.

> **Note:**
> A TiDB Cloud account is only used for logging in to Clinic Server in SSO mode and is not mandatory for accessing the TiDB Cloud service.

   Go to the Clinic Server for users in the Chinese mainland and select **Continue with AskTUG** to enter the AskTUG community login page. If you do not have an AskTUG account, create one on that page

3. Create an organization on the Clinic Server. Organization is a collection of TiDB clusters. You can upload diagnostic data on the created organization.

4. Get an access token to upload data. When uploading collected data through Diag, you need a token for user authentication to ensure the data is isolated securely. If you already get a token from the Clinic Server, you can reuse the token.

   To get a token, click the icon in the lower-right corner of the Cluster page, select **Get Access Token For Diag Tool**, and click + in the pop-up window. Make sure that you have copied and saved the token that is displayed.

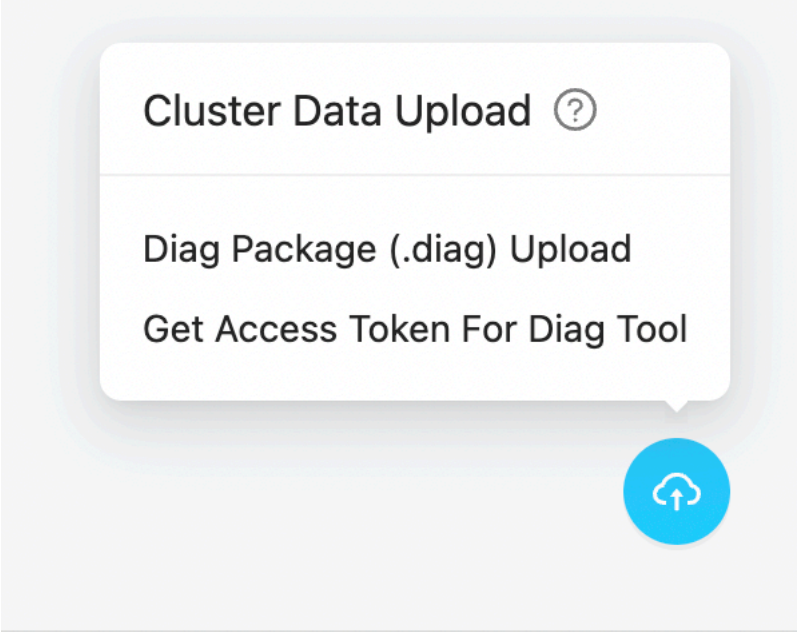

Figure 526: An example of a token

Note:

- For data security, TiDB only displays the token information when it is created. If you lost the information, you can delete the old token and create a new one.
- A token is only used for uploading data.

5. Set the token and `region` in Diag.

    - Run the following command to set the `clinic.token`:

    ```
    tiup diag config clinic.token ${token-value}
    ```

    - Run the following command to set the `clinic.region`:

    `region` determines the encryption certificate used for packing data and the target service when uploading the data. For example:

Note:

- Diag v0.9.0 and later versions support setting `region`.
- For versions earlier than Diag v0.9.0, data is uploaded to Clinic Server in the Chinese region by default. To set `region` in these versions, run the `tiup update diag` command to upgrade Diag to the latest version and then set `region` in Diag.

When using Clinic Server for international users, set `region` to `US` using the following command:

```
tiup diag config clinic.region US
```

When using Clinic Server for users in the Chinese mainland, set `region` to `CN` using the following command:

```
tiup diag config clinic.region CN
```

6. (Optional) Enable log redaction.

   When TiDB provides detailed log information, it might print sensitive information (for example, user data) in the log. If you want to avoid leaking sensitive information in the local log and Clinic Server, you can enable log redaction in the TiDB side. For more information, see log redaction.

13.10.2.3 Steps

1. Run Diag to collect diagnostic data.

   For example, to collect the diagnostic data from 4 hours ago to 2 hours ago based on the current time, run the following command:

   ```
   tiup diag collect ${cluster-name} -f="-4h" -t="-2h"
   ```

   After you run the command, Diag does not start collecting data immediately. Instead, Diag provides the estimated data size and the target data storage path in the output for you to confirm whether to continue. To confirm that you want to start collecting data, enter `Y`.

   After the collection is complete, Diag provides the folder path where the collected data is located.

2. Upload the collected data to Clinic Server.

> **Note:**
> The size of data (the compressed file with collected data) to be uploaded should be **no larger than** 3 GB. Otherwise, the data upload fails.

- If the network where your cluster is located can access the internet, you can directly upload the folder with collected data using the following command:

  ```
  tiup diag upload ${filepath}
  ```

  After the upload is completed, the `Download URL` is displayed in the output.

> **Note:**
> When uploading data using this method, you need to use Diag v0.9.0 or a later version. You can get the Diag version when you run it. If the Diag version is earlier than 0.9.0, you can use the `tiup update diag` command to upgrade Diag to the latest version.

- If the network where your cluster is located cannot access the internet, you need to pack the collected data and upload the package. For details, see Method 2. Pack and upload data.

3. After the upload is complete, get the data access link from `Download URL` in the command output.

   By default, the diagnostic data includes the cluster name, cluster topology information, log content in the collected diagnostic data, and Grafana Dashboard information reorganized based on the metrics in the collected data.

   You can use the data to troubleshoot cluster problems by yourself, or you can provide the data access link to PingCAP technical support staff to facilitate the remote troubleshooting.

4. View the results of Health Report

   After data is uploaded, Clinic Server processes the data automatically in the background. The Health Report is generated in approximately 5 to 15 minutes. You can view the report by opening the diagnostic data link and click the "Health Report".

13.10.2.4 What's next

- PingCAP Clinic Overview
- Troubleshoot Clusters Using PingCAP Clinic
- PingCAP Clinic Diagnostic Data

13.10.3 Troubleshoot Clusters Using PingCAP Clinic

For TiDB clusters and DM clusters deployed using TiUP, you can use PingCAP Clinic Diagnostic Service (PingCAP Clinic) to troubleshoot cluster problems remotely and perform a quick check on cluster status locally using Diag client (Diag) and Clinic Server.

> **Note:**
>
> - This document **only** applies to clusters deployed using TiUP in a self-hosted environment. For clusters deployed using TiDB Operator on Kubernetes, see PingCAP Clinic for TiDB Operator environments.

- PingCAP Clinic **does not support** collecting data from clusters deployed using TiDB Ansible.

13.10.3.1 User scenarios

- Troubleshoot cluster problems remotely
  - When your cluster has some problems, if you need to get support from PingCAP, you can perform the following operations to facilitate the remote troubleshooting: collect diagnostic data with Diag, upload the collected data to the Clinic Server, and provide the data access link to the technical support staff.
  - When your cluster has some problems, if you cannot analyze the problems immediately, you can use Diag to collect and save the data for later analysis.
- Perform a quick check on the cluster status locally

  Even if your cluster is running stably for now, it is necessary to periodically check the cluster to detect potential stability risks. You can identify potential health risks of a cluster using the local quick check feature provided by PingCAP Clinic. The local check only checks configuration. To check more items, such as metrics and logs, it is recommended to upload the diagnostic data to the Clinic Server and use the Health Report feature.

13.10.3.2 Prerequisites

Before using PingCAP Clinic, you need to install Diag (a component to collect data provided by PingCAP Clinic) and prepare the environment to upload data.

1. Install Diag.
   - If you have installed TiUP on your control machine, run the following command to install Diag:

     ```
     tiup install diag
     ```

   - If you have installed Diag, you can use the following command to upgrade Diag to the latest version:

     ```
     tiup update diag
     ```

Note:

- For clusters without an internet connection, you need to deploy Diag offline. For details, refer to Deploy TiUP offline: Method 2.
- Diag is **only** provided in the TiDB Server offline mirror package of v5.4.0 or later.

2. Get and set an access token (token) to upload data.

   When uploading collected data through Diag, you need a token for user authentication. If you already set a token Diag, you can reuse the token and skip this step.

   To get a token, perform the following steps:

   - Log in to the Clinic Server.
     Clinic Server for international users: Data is stored in AWS in US regions.
     Clinic Server for users in the Chinese mainland: Data is stored in AWS in China (Beijing) regions.
   - Click the icon in the lower-right corner of the Cluster page, select **Get Access Token For Diag Tool**, and click + in the pop-up window. Make sure that you have copied and saved the token that is displayed.

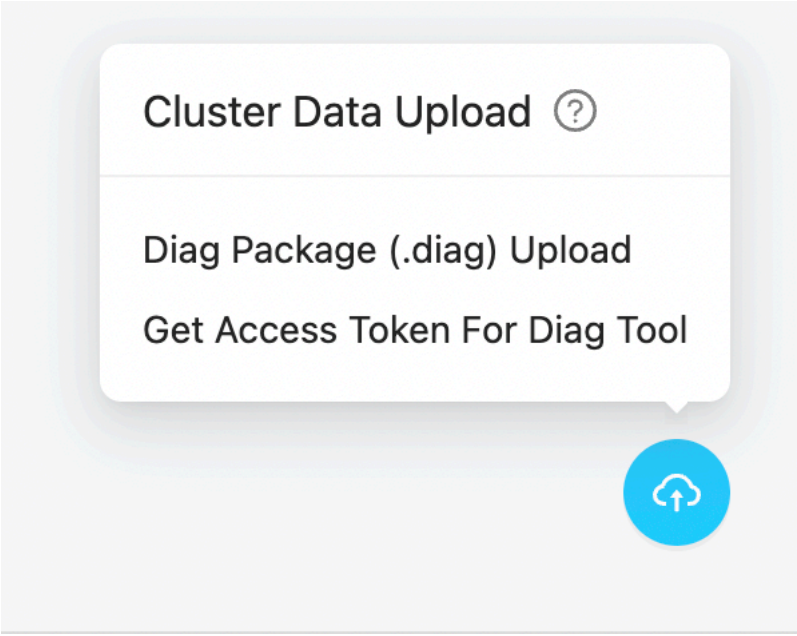

Figure 527: Get the Token

Note:

- When accessing Clinic Server for the first time, before getting a token, you need to prepare the environment by referring to Quick Start with PingCAP Clinic.

- For data security, TiDB only displays the token upon the token creation. If you have lost the token, delete the old token and create a new one.
- A token is only used for uploading data.

- Then, set the token in Diag. For example:

```
tiup diag config clinic.token ${token-value}
```

3. Set the `region` in Diag.

   `region` determines the encryption certificate used for packing data and the target service when uploading the data. For example:

Note:

- Diag v0.9.0 and later versions support setting `region`.
- For versions earlier than Diag v0.9.0, data is uploaded to Clinic Server in the Chinese region by default. To set `region` in these versions, run the `tiup update diag` command to upgrade Diag to the latest version and then set `region` in Diag.

   When using Clinic Server for international users, set `region` to `US` using the following command:

```
tiup diag config clinic.region US
```

   When using Clinic Server for users in the Chinese mainland, set `region` to `CN` using the following command:

```
tiup diag config clinic.region CN
```

4. (Optional) Enable log redaction.

   When TiDB provides detailed log information, it might print sensitive information (for example, user data) in the log. If you want to avoid leaking sensitive information in the local log and Clinic Server, you can enable log redaction in the TiDB side. For more information, see log redaction.

13.10.3.3 Troubleshoot cluster problems remotely

You can use Diag to quickly collect diagnostic data from TiDB clusters and DM clusters, including monitoring data and configuration information.

13.10.3.3.1 Step 1. Check the data to be collected

For a full list of data that can be collected by Diag, see PingCAP Clinic Diagnostic Data.

To improve the efficiency of the later diagnosis, you are recommended to collect full diagnostic data including monitoring data and configuration information. For details, see Collect data from clusters.

13.10.3.3.2 Step 2. Collect data

With Diag, you can collect data from the TiDB clusters and the DM clusters deployed using TiUP.

1. Run the data collection command of Diag.

   For example, to collect the diagnostic data from 4 hours ago to 2 hours ago based on the current time, run the following command:

   ```
   tiup diag collect ${cluster-name} -f="-4h" -t="-2h"
   ```

   ```
   tiup diag collectdm ${dm-cluster-name} -f="-4h" -t="-2h"
   ```

   Descriptions of the parameters for data collection:

   - `-f/--from`: specifies the start time of the data collection. If you do not specify this parameter, the default start time is 2 hours before the current time. To modify the time zone, use the `-f="12:30 +0800"` syntax. If you do not specify the time zone information in this parameter, such as `+0800`, the time zone is UTC by default.
   - `-t/--to`: specifies the end time of the data collection. If you do not specify this parameter, the default end time is the current moment. To modify the time zone, use the `-f="12:30 +0800"` syntax. If you do not specify the time zone information in this parameter, such as `+0800`, the time zone is UTC by default.

   Parameter usage tips:

   In addition to specifying the data collection time, you can use Diag to specify more parameters. To get all parameters, run the `tiup diag collect -h` or `tiup diag collectdm -h` command.

Note:

- Diag does not collect system variables data (db_vars) by default. To collect this data, you need to additionally provide a username and password that can access the database. Note that the reading access to system variables should be enabled in this database.
- Diag does not collect performance data (`perf`) and debug data (`debug`) by default.

- To collect full diagnostic data including system variables, use the command `tiup diag collect <cluster-name> --include="system,monitor,log,config,db_vars,perf,debug"`.

- `-l`: the bandwidth limit for transferring files, the unit is Kbit/s, and the default value is `100000` (the `-l` parameter of scp).
- `-N/--node`: only collects data from a specified node. The format is `ip:port`.
- `--include`: only collects specific types of data. The optional values are `system`, `monitor`, `log`, `config`, and `db_vars`. To include two or more types, you can use `,` as a separator between the types.
- `--exclude`: does not collect specific types of data. The optional values are `system`, `monitor`, `log`, `config`, and `db_vars`. To exclude two or more types, you can use `,` as a separator between the types.
- `--metricsfilter`: only collects specified Prometheus metrics. You can specify metrics using a comma-separated list of metric prefixes. For example, `--metricsfilter=tidb,pd` collects metrics that start with `tidb` and metrics that start with `pd`.

Tip:
To get available metric prefixes, you can query the TiDB monitoring API using the following command:

```
curl -s 'http://${prometheus-host}:${prometheus-port}/api/v1/label/__name__/values' | jq -r '.data[]' | cut -d\_ -f1 | uniq -c | sort -rn
```

After you run the command, Diag does not start collecting data immediately. Instead, Diag provides the estimated data size and the target data storage path in the output for you to confirm whether to continue. For example:

```
Estimated size of data to collect:
Host              Size      Target
----              ----      ------
172.16.7.129:9090 43.57 MB 1775 metrics, compressed
172.16.7.87       0 B       /tidb-deploy/tidb-4000/log/tidb_stderr.log
... ...
172.16.7.179      325 B     /tidb-deploy/tikv-20160/conf/tikv.toml
Total             2.01 GB   (inaccurate)
These data will be stored in /home/user/diag-fNTnz5MGhr6
Do you want to continue? [y/N]: (default=N)
```

2. Enter `Y` to confirm that you want to start collecting data.

   Collecting data takes a certain amount of time. The time varies according to the volume of data to be collected. For example, in a test environment, collecting 1 GB of data takes about 10 minutes.

   After the collection is complete, Diag provides the folder path where the collected data is located. For example:

```
Collected data are stored in /home/user/diag-fNTnz5MGhr6
```

13.10.3.3.3 Step 3. View data locally (optional)

The collected data is stored in separate subdirectories based on its data source. These subdirectories are named after machine names and port numbers. The storage locations of the configuration, logs, and other files of each node are the same as their relative storage paths in the real server of your TiDB cluster:

- Basic information of the system and hardware: in `insight.json`
- Contents in the system `/etc/security/limits.conf`: in `limits.conf`
- List of kernel parameters: in `sysctl.conf`
- Kernel logs: in `dmesg.log`
- Network connection during data collection: in `ss.txt`
- Configuration data: in the `config.json` directory of each node
- Meta-information for the cluster itself: in `meta.yaml` (this file is located at the top level of the directory that stores collected data)
- Monitoring data: in the `/monitor` file directory. The monitoring data is compressed by default and cannot be viewed directly. To directly view the JSON files with monitoring data, disable compression with the `--compress-metrics=false` parameter when collecting data.

13.10.3.3.4 Step 4. Upload data

To provide cluster diagnostic data to PingCAP technical support staff, you need to upload the data to the Clinic Server first, and then send the obtained data access link to the staff. The Clinic Server is a cloud service that stores and shares diagnostic data securely.

Depending on the network connection of the cluster, you can choose one of the following methods to upload data:

- Methods 1: if the network where the cluster is located can access the internet, you can directly upload data using the upload command.
- Methods 2: if the network where the cluster is located cannot access the internet, you need to pack the data and then upload it.

> **Note:**
>
> If you did not set a token or `region` in Diag before uploading data, Diag reports the upload failure and reminds you to set a token or `region`. To set a token, see the second step in Prerequisites.

Method 1. Upload directly

If the network where the cluster is located can access the internet, you can directly upload the folder with collected data obtained in Step 2: Collect data using the following command:

```
tiup diag upload
```

After the upload is completed, the `Download URL` is displayed in the output. You can open the link of `Download URL` to see the uploaded data or send the link to the PingCAP technical support staff you contacted before.

Method 2. Pack and upload data

If the network where your cluster is located cannot access the internet, you need to pack the data on your intranet and upload the data package to the Clinic Server using a device with internet access. The detailed operations are as follows:

1. Pack the collected data obtained in Step 2. Collect data by running the following command:

   ```
   tiup diag package ${filepath}
   ```

   During packaging, Diag encrypts and compresses the data at the same time. In the test environment, 800 MB of data was compressed to 57 MB. The following is an example output:

   ```
   Starting component `diag`: /root/.tiup/components/diag/v0.7.0/diag
       ↪ package diag-fNTnz5MGhr6
   packaged data set saved to /home/user/diag-fNTnz5MGhr6.diag
   ```

   After the packaging is complete, the data is packaged to the `.diag` format. The `.diag` file can only be decrypted and viewed after being uploaded to the Clinic Server. If you want to directly forward the collected data instead of uploading it to the Clinic Server, you can compress the data by your own method and forward it.

2. From a machine with internet access, upload the compressed data package:

   ```
   tiup diag upload ${filepath}
   ```

The following is an example output:

```
[root@Copy-of-VM-EE-CentOS76-v1 user]# tiup diag upload /home/user/
    ↪ diag-fNTnz5MGhr6
Starting component `diag`: /root/.tiup/components/diag/v0.7.0/diag
    ↪ upload /home/user/diag-fNTnz5MGhr6
>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>>><<<<<<<<<
Completed!
Download URL: "https://clinic.pingcap.com.cn/portal/#/orgs/4/clusters/
    ↪ XXXX"
```

3. After the upload is complete, you can open the link of `Download URL` to see the uploaded data or send the link to the PingCAP technical support staff you contacted before.

13.10.3.4 Perform a quick check on the cluster status locally

You can have a quick check on the cluster status locally using Diag. Even if your cluster is running stably for now, it is necessary to periodically check the cluster to detect potential stability risks. You can identify potential health risks of a cluster using the local quick check feature provided by PingCAP Clinic. The local check only checks configuration. To check more items, such as metrics and logs, it is recommended to upload the diagnostic data to the Clinic Server and use the Health Report feature.

1. Collect configuration data:

```
tiup diag collect ${cluster-name} --include="config"
```

The data of configuration files are relatively small. After the collection, the collected data is stored in the current path by default. In the test environment, for a cluster with 18 nodes, the data size of configuration files is less than 10 KB.

2. Diagnose configuration data:

```
tiup diag check ${subdir-in-output-data}
```

`${subdir-in-output-data}` in the above command is the path that stores the collected data, and this path has the `meta.yaml` file.

3. View the diagnostic result:

The diagnostic result is returned on the command line. For example:

```
Starting component `diag`: /root/.tiup/components/diag/v0.7.0/diag
    ↪ check diag-fNTnz5MGhr6

# Diagnostic result
lili 2022-01-24T09:33:57+08:00
```

```
## 1. Cluster basic information
- Cluster ID: 7047403704292855808
- Cluster Name: lili
- Cluster Version: v5.3.0

## 2. Sampling information
- Sample ID: fNTnz5MGhr6
- Sampling Date: 2022-01-24T09:33:57+08:00
- Sample Content:: [system monitor log config]

## 3. Diagnostic result, including potential configuration problems
In this inspection, 22 rules were executed.

The results of **1** rules were abnormal and needed to be further
    ↪ discussed with support team.

The following is the details of the abnormalities.

### Diagnostic result summary
The configuration rules are all derived from PingCAP's OnCall Service.

If the results of the configuration rules are found to be abnormal,
    ↪ they may cause the cluster to fail.

There were **1** abnormal results.

#### Path to save the diagnostic result file

Rule Name: tidb-max-days
- RuleID: 100
- Variation: TidbConfig.log.file.max-days
- For more information, please visit: https://s.tidb.io/msmo6awg
- Check Result:
  TidbConfig_172.16.7.87:4000 TidbConfig.log.file.max-days:0 warning
  TidbConfig_172.16.7.86:4000 TidbConfig.log.file.max-days:0 warning
  TidbConfig_172.16.7.179:4000 TidbConfig.log.file.max-days:0 warning

Result report and record are saved at diag-fNTnz5MGhr6/report
    ↪ -220125153215
```

In the last section of the diagnostic result (under `#### Path to save the ↪ diagnostic result file` in the above example output), for each configuration potential risk found, Diag provides a corresponding knowledge base link with detailed configuration suggestions. In the example above, the relevant link is `https://s.tidb`

↪ .io/msmo6awg.

13.10.3.5 FAQ

1. If the data upload fails, can I re-upload it?

   Yes. Data upload supports breakpoint upload. If the upload fails, you can upload it again directly.

2. After uploading data, I cannot open the returned data access link. What should I do?

   Log in to Clinic Server first. If you still cannot open the link after login success, check whether you have access to data. If not, contact the data owner for permission. After getting the permission, log in to Clinic Server and open the link again.

3. How long will the uploaded data be kept on the Clinic Server?

   The longest time is 180 days. You can delete the data you uploaded on the Clinic Server page at any time.

13.10.4 PingCAP Clinic Diagnostic Data

This document provides the types of diagnostic data that can be collected by PingCAP Clinic Diagnostic Service (PingCAP Clinic) from the TiDB and DM clusters deployed using TiUP. Also, the document lists the parameters for data collection corresponding to each data type. When running a command to collect data using Diag client (Diag), you can add the required parameters to the command according to the types of the data to be collected.

The diagnostic data collected by PingCAP Clinic is **only** used for troubleshooting cluster problems.

A diagnostic service deployed in the cloud, Clinic Server provides two independent services depending on the data storage location:

- Clinic Server for international users: If you upload the collected data to Clinic Server for international users, the data will be stored in the Amazon S3 service deployed by PingCAP in AWS US regions. PingCAP uses strict data access policies and only authorized technical support can access the data.
- Clinic Server for users in the Chinese mainland: If you upload the collected data to Clinic Server for users in the Chinese mainland, the data will be stored in the Amazon S3 service deployed by PingCAP in China (Beijing) regions. PingCAP uses strict data access policies and only authorized technical support can access the data.

13.10.4.1 TiDB clusters

This section lists the types of diagnostic data that can be collected by Diag from the TiDB clusters deployed using TiUP.

13.10.4.1.1 TiDB cluster information

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Basic information of the cluster, including the cluster ID	`cluster ↪ . ↪ json ↪`	The data is collected per run by default.
Detailed information of the cluster	`meta. ↪ yaml ↪`	The data is collected per run by default.

13.10.4.1.2 TiDB diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`tidb.log`	`--include=log`
Error log	`tidb_stderr.log`	`--include=log`
Slow log	`tidb_slow_query.log`	`--include=log`
Configuration file	`tidb.toml`	`--include=config`
Real-time configuration	`config.json`	`--include=config`

13.10.4.1.3 TiKV diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`tikv.log`	`--include=log`
Error log	`tikv_stderr.log`	`--include=log`
Configuration file	`tikv.toml`	`--include=config`
Real-time configuration	`config.json`	`--include=config`

13.10.4.1.4 PD diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`pd.log`	`--include=log`
Error log	`pd_stderr.log`	`--include=log`
Configuration file	`pd.toml`	`--include=config`
Real-time configuration	`config.json`	`--include=config`

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Outputs of the command `tiup ctl :v< CLUSTER _ VERSION > pd -u http ://${pd IP}:${PORT} store`	`store.json`	`--include=config`

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Outputs of the command `tiup ↪ ctl ↪ :v< ↪ CLUSTER ↪ _ ↪ VERSION ↪ > ↪ pd ↪ -u ↪ http ↪ :// ↪ ${ ↪ pd ↪ IP ↪ }:$ ↪ { ↪ PORT ↪ } ↪ config ↪ ↪ placement ↪ - ↪ rules ↪ ↪ show ↪`	`placement ↪ - ↪ rule ↪ . ↪ json ↪`	`-- ↪ include ↪ = ↪ config ↪`

13.10.4.1.5 TiFlash diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`tiflash` ↪ `.` ↪ `log`	`--` ↪ `include` ↪ `=log`
Error log	`tiflash` ↪ `_` ↪ `stderr` ↪ `.` ↪ `log`	`--` ↪ `include` ↪ `=log`
Configuration file	`tiflash` ↪ `-` ↪ `learner` ↪ `.` ↪ `toml` ↪ `,` `tiflash` ↪ `-` ↪ `preprocessed` ↪ `.` ↪ `toml` ↪ `,` `tiflash` ↪ `.` ↪ `toml` ↪	`--` ↪ `include` ↪ `=` ↪ `config` ↪
Real-time configuration	`config` ↪ `.` ↪ `json` ↪	`--` ↪ `include` ↪ `=` ↪ `config` ↪

13.10.4.1.6 TiCDC diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`ticdc.` ↪ `log`	`--` ↪ `include` ↪ `=log`
Error log	`ticdc_` ↪ `stderr` ↪ `.` ↪ `log`	`--` ↪ `include` ↪ `=log`
Configuration file	`ticdc.` ↪ `toml` ↪	`--` ↪ `include` ↪ `=` ↪ `config` ↪
Debug data	`info.` ↪ `txt`, `status` ↪ `.` ↪ `txt`, `changefeeds` ↪ `.` ↪ `txt`, `captures` ↪ `.` ↪ `txt`, `processors` ↪ `.` ↪ `txt`	`--` ↪ `include` ↪ `=` ↪ `debug` (Diag does not collect this data type by default)

13.10.4.1.7 Prometheus monitoring data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
All metrics data	`{metric_name}.json`	`--include=monitor`
All alerts data	`alerts.json`	`--include=monitor`

13.10.4.1.8 TiDB system variables

Data type	Exported file	Parameter for data collection by PingCAP Clinic
TiDB system variables	`mysql.` ↪ `tidb` ↪ `.` ↪ `csv`	`--` ↪ `include` ↪ `=db_` ↪ `vars` (Diag does not collect this data type by default; if you need to collect this data type, database credential is required)
	`global` ↪ `_` ↪ `variables` ↪ `.` ↪ `csv`	`--` ↪ `include` ↪ `=db_` ↪ `vars` (Diag does not collect this data type by default)

13.10.4.1.9 System information of the cluster node

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Kernel log	`dmesg.` ↪ `log`	`--` ↪ `include` ↪ `=` ↪ `system` ↪
Basic information of the system and hardware	`insight` ↪ `.` ↪ `json` ↪	`--` ↪ `include` ↪ `=` ↪ `system` ↪
Contents in the `/etc/` ↪ `security` ↪ `/` ↪ `limits` ↪ `.` ↪ `conf` ↪	`limits` ↪ `.` ↪ `conf` ↪	`--` ↪ `include` ↪ `=` ↪ `system` ↪
List of kernel parameters	`sysctl` ↪ `.` ↪ `conf` ↪	`--` ↪ `include` ↪ `=` ↪ `system` ↪
Socket system information, which is the output of the `ss` command	`ss.txt`	`--` ↪ `include` ↪ `=` ↪ `system` ↪

13.10.4.2 DM clusters

This section lists the types of diagnostic data that can be collected by Diag from the DM clusters deployed using TiUP.

13.10.4.2.1 DM cluster information

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Basic information of the cluster, including the cluster ID	`cluster` ↪ `.` ↪ `json` ↪	The data is collected per run by default.
Detailed information of the cluster	`meta.` ↪ `yaml` ↪	The data is collected per run by default.

13.10.4.2.2 dm-master diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`dm-master.log`	`--include=log`
Error log	`dm-master_stderr.log`	`--include=log`
Configuration file	`dm-master.toml`	`--include=config`

13.10.4.2.3 dm-worker diagnostic data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Log	`dm-worker.log`	`--include=log`
Error log	`dm-worker_stderr.log`	`--include=log`
Configuration file	`dm-work.toml`	`--include=config`

13.10.4.2.4 Prometheus monitoring data

Data type	Exported file	Parameter for data collection by PingCAP Clinic
All metrics data	`{metric_name}.json`	`--include=monitor`
All alerts data	`alerts.json`	`--include=monitor`

13.10.4.2.5 System information of the cluster node

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Kernel log	`dmesg.log`	`--include=system`
Basic information of the system and hardware	`insight.json`	`--include=system`
Contents in the `/etc/security/limits.conf` system	`limits.conf`	`--include=system`
List of kernel parameters	`sysctl.conf`	`--include=system`

Data type	Exported file	Parameter for data collection by PingCAP Clinic
Socket system information, which is the output of the `ss` command	`ss.txt`	`--include=system`

13.11 TiSpark

13.11.1 TiSpark User Guide

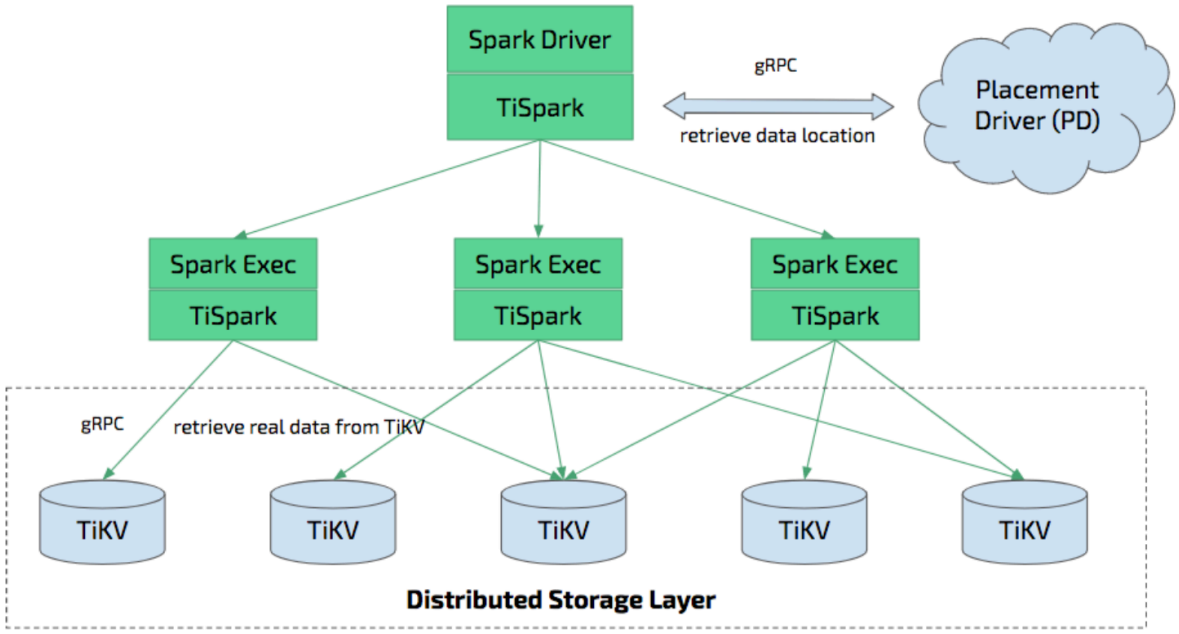

Figure 528: TiSpark architecture

13.11.1.1 TiSpark vs TiFlash

TiSpark is a thin layer built for running Apache Spark on top of TiDB/TiKV to answer the complex OLAP queries. It takes advantages of both the Spark platform and the distributed TiKV cluster and seamlessly glues to TiDB, the distributed OLTP database, to provide a Hybrid Transactional/Analytical Processing (HTAP) solution to serve as a one-stop solution for both online transactions and analysis.

TiFlash is another tool that enables HTAP. Both TiFlash and TiSpark allow the use of multiple hosts to execute OLAP queries on OLTP data. TiFlash stores data in a columnar format, which allows more efficient analytical queries. TiFlash and TiSpark can be used together.

13.11.1.2 What is TiSpark

TiSpark depends on the TiKV cluster and the PD cluster. You also need to set up a Spark cluster. This document provides a brief introduction to how to setup and use TiSpark. It requires some basic knowledge of Apache Spark. For more information, see Apache Spark website.

Deeply integrating with Spark Catalyst Engine, TiSpark provides precise control on computing. This allows Spark to read data from TiKV efficiently. TiSpark also supports index seek, which enables high-speed point query. TiSpark accelerates data queries by pushing computing to TiKV so as to reduce the volume of data to be processed by Spark SQL. Meanwhile, TiSpark can use TiDB built-in statistics to select the best query plan.

With TiSpark and TiDB, you can run both transaction and analysis tasks on the same platform without building and maintaining ETLs. This simplifies the system architecture and reduces the cost of maintenance.

You can use tools of the Spark ecosystem for data processing on TiDB:

- TiSpark: Data analysis and ETLs
- TiKV: Data retrieval
- Scheduling system: Report generation

Also, TiSpark supports distributed writes to TiKV. Compared with writes to TiDB by using Spark and JDBC, distributed writes to TiKV can implement transactions (either all data are written successfully or all writes fail), and the writes are faster.

> **Warning:**
>
> Because TiSpark accesses TiKV directly, the access control mechanisms used by TiDB Server are not applicable to TiSpark. Since TiSpark v2.5.0, TiSpark supports user authentication and authorization, for more information, see Security.

13.11.1.3 Requirements

- TiSpark supports Spark >= 2.3.
- TiSpark requires JDK 1.8 and Scala 2.11/2.12.
- TiSpark runs in any Spark mode such as `YARN`, `Mesos`, and `Standalone`.

13.11.1.4 Recommended deployment configurations of Spark

> **Warning:**
>
> Deploying TiSpark using TiUP as described in this doc has been deprecated.

Since TiSpark is a TiDB connector of Spark, to use it, a running Spark cluster is required.

This document provides basic advice on deploying Spark. Please turn to the Spark official website for detailed hardware recommendations.

For independent deployment of Spark cluster:

- It is recommended to allocate 32 GB memory for Spark. Reserve at least 25% of the memory for the operating system and the buffer cache.
- It is recommended to provision at least 8 to 16 cores per machine for Spark. First, you must assign all the CPU cores to Spark.

The following is an example based on the `spark-env.sh` configuration:

```
SPARK_EXECUTOR_MEMORY = 32g
SPARK_WORKER_MEMORY = 32g
SPARK_WORKER_CORES = 8
```

13.11.1.5 Get TiSpark

TiSpark is a third-party jar package for Spark that provides the ability to read and write TiKV.

13.11.1.5.1 Get mysql-connector-j

The `mysql-connector-java` dependency is no longer provided because of the limit of the GPL license.

The following versions of TiSpark's jar will no longer include `mysql-connector-java`.

- TiSpark > 3.0.1

- TiSpark > 2.5.1 for TiSpark 2.5.x
- TiSpark > 2.4.3 for TiSpark 2.4.x

However, TiSpark needs `mysql-connector-java` for writing and authentication. In such cases, you need to import `mysql-connector-java` manually using either of the following methods:

- Put `mysql-connector-java` into spark jars file.
- Import `mysql-connector-java` when you submit a spark job. See the following example:

```
spark-submit --jars tispark-assembly-3.0_2.12-3.1.0-SNAPSHOT.jar,mysql-
    ↪ connector-java-8.0.29.jar
```

13.11.1.5.2 Choose TiSpark version

You can choose TiSpark version according to your TiDB and Spark version.

TiSpark version	TiDB, TiKV, PD version	Spark version	Scala version
2.4.x-scala_2.11	5.x, 4.x	2.3.x, 2.4.x	2.11
2.4.x-scala_2.12	5.x, 4.x	2.4.x	2.12
2.5.x	5.x, 4.x	3.0.x, 3.1.x	2.12
3.0.x	5.x, 4.x	3.0.x, 3.1.x, 3.2.x	2.12
3.1.x	6.x, 5.x, 4.x	3.0.x, 3.1.x, 3.2.x, 3.3.x	2.12
3.2.x	6.x, 5.x, 4.x	3.0.x, 3.1.x, 3.2.x, 3.3.x	2.12

TiSpark 2.4.4, 2.5.2, 3.0.2, 3.1.1, and 3.2.3 are the latest stable versions and are highly recommended.

> **Note:**
>
> TiSpark does not guarantee compatibility with TiDB v7.0.0 and later versions.

13.11.1.5.3 Get TiSpark jar

You can get the TiSpark jar using one of the following methods:

- Get from maven central and search for `pingcap`

- Get from TiSpark releases
- Build from source with the steps below

> **Note:**
>
> Currently, java8 is the only choice to build TiSpark, run mvn -version to check.

```
git clone https://github.com/pingcap/tispark.git
```

Run the following command under the TiSpark root directory.

```
// add -Dmaven.test.skip=true to skip the tests
mvn clean install -Dmaven.test.skip=true
// or you can add properties to specify spark version
mvn clean install -Dmaven.test.skip=true -Pspark3.2.1
```

13.11.1.5.4 TiSpark jar's artifact ID

The Artifact ID of TiSpark varies with TiSpark versions.

TiSpark version	Artifact ID
2.4.x-${scala_version}, 2.5.0	tispark-assembly
2.5.1	tispark-assembly-${spark_version}
3.0.x, 3.1.x, 3.2.x	tispark-assembly-${spark_version}-${scala_version}

13.11.1.6 Getting started

This document describes how to use TiSpark in spark-shell.

13.11.1.6.1 Start spark-shell

To use TiSpark in spark-shell:

Add the following configuration in `spark-defaults.conf`:

```
spark.sql.extensions org.apache.spark.sql.TiExtensions
spark.tispark.pd.addresses ${your_pd_address}
spark.sql.catalog.tidb_catalog org.apache.spark.sql.catalyst.catalog.
    ↪ TiCatalog
spark.sql.catalog.tidb_catalog.pd.addresses ${your_pd_address}
```

Start spark-shell with the `--jars` option.

```
spark-shell --jars tispark-assembly-{version}.jar
```

13.11.1.6.2 Get TiSpark version

You can get TiSpark version information by running the following command in spark-shell:

```
spark.sql("select ti_version()").collect
```

13.11.1.6.3 Read data using TiSpark

You can use Spark SQL to read data from TiKV.

```
spark.sql("use tidb_catalog")
spark.sql("select count(*) from ${database}.${table}").show
```

13.11.1.6.4 Write data using TiSpark

You can use the Spark DataSource API to write data to TiKV, for which ACID is guaranteed.

```
val tidbOptions: Map[String, String] = Map(
  "tidb.addr" -> "127.0.0.1",
  "tidb.password" -> "",
  "tidb.port" -> "4000",
  "tidb.user" -> "root"
)

val customerDF = spark.sql("select * from customer limit 100000")

customerDF.write
.format("tidb")
.option("database", "tpch_test")
.option("table", "cust_test_select")
.options(tidbOptions)
.mode("append")
.save()
```

See Data Source API User Guide for more details.

Starting from TiSpark 3.1, you can write data to TiKV using Spark SQL. For more information, see insert SQL.

13.11.1.6.5 Write data using JDBC DataSource

You can also use Spark JDBC to write to TiDB without the use of TiSpark.

This is beyond the scope of TiSpark. This document only provides an example here. For detailed information, see JDBC To Other Databases.

```
import org.apache.spark.sql.execution.datasources.jdbc.JDBCOptions

val customer = spark.sql("select * from customer limit 100000")
// you might need to repartition the source to make it balanced across
   ↪ nodes
// and increase concurrency
val df = customer.repartition(32)
df.write
.mode(saveMode = "append")
.format("jdbc")
.option("driver", "com.mysql.jdbc.Driver")
 // replace the host and port with yours and be sure to use rewrite batch
.option("url", "jdbc:mysql://127.0.0.1:4000/test?rewriteBatchedStatements=
   ↪ true")
.option("useSSL", "false")
// as tested, setting to `150` is a good practice
.option(JDBCOptions.JDBC_BATCH_INSERT_SIZE, 150)
.option("dbtable", s"cust_test_select") // database name and table name
   ↪ here
.option("isolationLevel", "NONE") // set isolationLevel to NONE
.option("user", "root") // TiDB user here
.save()
```

Set `isolationLevel` to `NONE` to avoid large single transactions which might lead to TiDB OOM and also avoid the `ISOLATION LEVEL does not support` error (TiDB currently only supports `REPEATABLE-READ`).

13.11.1.6.6 Delete data using TiSpark

You can use Spark SQL to delete data from TiKV.

```
spark.sql("use tidb_catalog")
spark.sql("delete from ${database}.${table} where xxx")
```

See delete feature for more details.

13.11.1.6.7 Work with other data sources

You can use multiple catalogs to read data from different data sources as follows:

```
// Read from Hive
spark.sql("select * from spark_catalog.default.t").show

// Join Hive tables and TiDB tables
spark.sql("select t1.id,t2.id from spark_catalog.default.t t1 left join tidb
   ↪ _catalog.test.t t2").show
```

13.11.1.7 TiSpark configurations

The configurations in the following table can be put together with `spark-defaults.conf` or passed in the same way as other Spark configuration properties.

Key	Default value	Description
`spark.↪ tispark↪ .pd↪ .↪ addresses↪`	`127.0.0.1:2379`	The addresses of PD clusters, which are split by commas.
`spark.↪ tispark↪ .↪ grpc↪ .↪ framesize↪`	`2147483647`	The maximum frame size of gRPC response in bytes (default to 2G).
`spark.↪ tispark↪ .↪ grpc↪ .↪ timeout↪ _in↪ _↪ sec`	`10`	The gRPC timeout time in seconds.

Key	Default value	Description
spark.tispark.plan.allow_agg_pushdown	true	Whether aggregations are allowed to push down to TiKV (in case of busy TiKV nodes).
spark.tispark.plan.allow_index_read	true	Whether index is enabled in planning (which might cause heavy pressure on TiKV).
spark.tispark.index.scan_batch_size	20000	The number of row keys in a batch for the concurrent index scan.
spark.tispark.index.scan_concurrency	5	The maximum number of threads for index scan that retrieves row keys (shared among tasks inside each JVM).

Key	Default value	Description
spark.tispark.table.scan_concurrency	512	The maximum number of threads for table scan (shared among tasks inside each JVM).
spark.tispark.request.command.priority	Low	The value options are `Low`, `Normal`, `High`. This setting impacts the resources allocated in TiKV. `Low` is recommended because the OLTP workload is not disturbed.
spark.tispark.coprocess.codec_format	chblock	Retain the default codec format for coprocessor. Available options are `default`, `chblock` and `chunk`.
spark.tispark.coprocess.streaming	false	Whether to use streaming for response fetching (experimental).

Key	Default value	Description
spark.tispark.plan.unsupported_pushdown_exprs		A comma-separated list of expressions. In case you have a very old version of TiKV, you might disable the push down of some expressions if they are not supported.
spark.tispark.plan.downgrade.index_threshold	1000000000	If the range of index scan on one Region exceeds this limit in the original request, downgrade this Region's request to table scan rather than the planned index scan. By default, the downgrade is disabled.
spark.tispark.show.rowid	false	Whether to show row ID if the ID exists.
spark.tispark.db_prefix		The string that indicates the extra prefix for all databases in TiDB. This string distinguishes the databases in TiDB from the Hive databases with the same name.

Key	Default value	Description
spark.tispark.request.isolation.level	SI	Whether to resolve locks for the underlying TiDB clusters. When you use the "RC", you get the latest version of the record smaller than your tso and ignore the locks. When you use "SI", you resolve the locks and get the records depending on whether the resolved lock is committed or aborted.
spark.tispark.coprocessor.chunk_batch_size	1024	Rows fetched from coprocessor.
spark.tispark.isolation_read_engines	tikv,tiflash	List of readable engines of TiSpark, comma separated. Storage engines not listed will not be read.
spark.tispark.stale_read	optional	The stale read timestamp(ms). See here for more details.

Key	Default value	Description
spark.↪ tispark↪ .↪ tikv↪ .↪ tls↪ _↪ enable↪	false	Whether to enable TiSpark TLS.
spark.↪ tispark↪ .↪ tikv↪ .↪ trust↪ _↪ cert↪ _↪ collection↪		The trusted certificate for TiKV Client, used for verifying the remote PD's certificate, for example, /home/tispark/config/root.pem The file should contain an X.509 certificate collection.
spark.↪ tispark↪ .↪ tikv↪ .↪ key↪ _↪ cert↪ _↪ chain↪		An X.509 certificate chain file for TiKV Client, for example, /home/tispark/config/client.pem.
spark.↪ tispark↪ .↪ tikv↪ .↪ key↪ _↪ file↪		A PKCS#8 private key file for TiKV Client, for example, /home/tispark/client_pkcs8.key.

Key	Default value	Description
spark.tispark.tikv.jks_enable	false	Whether to use the JAVA key store instead of the X.509 certificate.
spark.tispark.tikv.jks_trust_path		A JKS format certificate for TiKV Client, generated by keytool, for example, /home/tispark/config/tikv-truststore.
spark.tispark.tikv.jks_trust_password		The password of spark.tispark.tikv.jks_trust_path.
spark.tispark.tikv.jks_key_path		A JKS format key for TiKV Client, generated by keytool, for example, /home/tispark/config/tikv-clientstore.

Key	Default value	Description
spark. ↪ tispark ↪ . ↪ tikv ↪ . ↪ jks ↪ _ ↪ key ↪ _ ↪ password ↪		The password of `spark.tispark.tikv.jks_key_path`.
spark. ↪ tispark↪ ↪ . ↪ jdbc ↪ . ↪ tls ↪ _ ↪ enable ↪	`false`	Whether to enable TLS when using the JDBC connector.
spark. ↪ tispark ↪ . ↪ jdbc ↪ . ↪ server ↪ _ ↪ cert ↪ _ ↪ store ↪		The trusted certificate for JDBC. It is a Java keystore (JKS) format certificate generated by `keytool`, for example, `/home/tispark/config/jdbc-truststore`. The default value is “”, which means TiSpark does not verify the TiDB server.
spark. ↪ tispark ↪ . ↪ jdbc ↪ . ↪ server ↪ _ ↪ cert ↪ _ ↪ password ↪		The password of `spark.tispark.jdbc.server_cert_store`.

Key	Default value	Description
`spark.tispark.jdbc.client_cert_store`		A PKCS#12 certificate for JDBC. It is a JKS format certificate generated by `keytool`, for example, `/home/tispark/config/jdbc-clientstore`. Default is "", which means TiDB server doesn't verify TiSpark.
`spark.tispark.jdbc.client_cert_store_password`		The password of `spark.tispark.jdbc.client_cert_store`.
`spark.tispark.tikv.tls_reload_interval`	`10s`	The interval for checking if there is any reloading certificates. The default value is `10s` (10 seconds).

Key	Default value	Description
spark.tispark.tikv.conn.recycle_time	60s	The interval for cleaning expired connections with TiKV. It takes effect only when certificate reloading is enabled. The default value is 60s (60 seconds).
spark.tispark.host_mapping		The route map used to configure the mapping between public IP addresses and intranet IP addresses. When the TiDB cluster is running on the intranet, you can map a set of intranet IP addresses to public IP addresses for an outside Spark cluster to access. The format is {Intranet IP1}:{Public IP1};{Intranet IP2}:{Public IP2}, for example, 192.168.0.2:8.8.8.8;192.168.0.3:9.9.9.9.
spark.tispark.new_collation_enable		When new collation is enabled on TiDB, this configuration can be set to true. If new collation is not enabled on TiDB, this configuration can be set to false. If this item is not configured, TiSpark configures new collation automatically based on the TiDB version. The configuration rule is as follows: If the TiDB version is greater than or equal to v6.0.0, it is true; otherwise, it is false.
spark.tispark.replica_read	leader	The type of the replica to read. Value options are leader, follower, and learner. Multiple types can be specified at the same time and TiSpark selects the type according to the order.

Key	Default value	Description
spark.tispark.replica_read.label		The label of the target TiKV node. The format is label_x=value_x,label_y=value_y, and the items are connected by logical conjunction.

13.11.1.7.1 TLS configurations

TiSpark TLS has two parts: TiKV Client TLS and JDBC connector TLS. To enable TLS in TiSpark, you need to configure both. `spark.tispark.tikv.xxx` is used for TiKV Client to create a TLS connection with PD and TiKV server. `spark.tispark.jdbc.xxx` is used for JDBC to connect with TiDB server in TLS connection.

When TiSpark TLS is enabled, you must configure either the X.509 certificate with `tikv.trust_cert_collection`, `tikv.key_cert_chain` and `tikv.key_file` configurations, or the JKS certificate with `tikv.jks_enable`, `tikv.jks_trust_path` and `tikv.jks_key_path`. `jdbc.server_cert_store` and `jdbc.client_cert_store` are optional.

TiSpark only supports TLSv1.2 and TLSv1.3.

- The following is an example of opening TLS configuration with the X.509 certificate in TiKV Client.

```
spark.tispark.tikv.tls_enable                                true
spark.tispark.tikv.trust_cert_collection                     /home/tispark/root.
   ↪ pem
spark.tispark.tikv.key_cert_chain                            /home/tispark/client
   ↪ .pem
spark.tispark.tikv.key_file                                  /home/tispark/client
   ↪ .key
```

- The following is an example of enabling TLS with JKS configurations in TiKV Client.

```
spark.tispark.tikv.tls_enable                                true
spark.tispark.tikv.jks_enable                                true
spark.tispark.tikv.jks_key_path                              /home/tispark/config
   ↪ /tikv-truststore
```

```
spark.tispark.tikv.jks_key_password                    tikv_trustore_
    ↪ password
spark.tispark.tikv.jks_trust_path                      /home/tispark/config
    ↪ /tikv-clientstore
spark.tispark.tikv.jks_trust_password                  tikv_clientstore_
    ↪ password
```

When both JKS and X.509 certificates are configured, JKS would have a higher priority. That means TLS builder will use JKS certificate first. Therefore, do not set `spark.tispark ↪ .tikv.jks_enable=true` when you just want to use a common PEM certificate.

- The following is an example of enabling TLS in JDBC connector.

```
spark.tispark.jdbc.tls_enable                          true
spark.tispark.jdbc.server_cert_store                   /home/tispark/jdbc-
    ↪ truststore
spark.tispark.jdbc.server_cert_password                jdbc_truststore_
    ↪ password
spark.tispark.jdbc.client_cert_store                   /home/tispark/jdbc-
    ↪ clientstore
spark.tispark.jdbc.client_cert_password                jdbc_clientstore_
    ↪ password
```

- For details about how to open TiDB TLS, see Enable TLS between TiDB Clients and Servers.
- For details about how to generate a JAVA key store, see Connecting Securely Using SSL.

13.11.1.7.2 Log4j configuration

When you start `spark-shell` or `spark-sql` and run query, you might see the following warnings:

```
Failed to get database ****, returning NoSuchObjectException
Failed to get database ****, returning NoSuchObjectException
```

where `****` is the database name.

The warnings are benign and occurs because Spark cannot find `****` in its own catalog. You can just ignore these warnings.

To mute them, append the following text to `${SPARK_HOME}/conf/log4j.properties`.

```
### tispark disable "WARN ObjectStore:568 - Failed to get database"
log4j.logger.org.apache.hadoop.hive.metastore.ObjectStore=ERROR
```

13.11.1.7.3 Time zone configuration

Set time zone by using the `-Duser.timezone` system property (for example, `-Duser.timezone=GMT-7`), which affects the `Timestamp` type.

Do not use `spark.sql.session.timeZone`.

13.11.1.8 Features

The major features of TiSpark are as follows:

Feature support	TiSpark 2.4.x	TiSpark 2.5.x	TiSpark 3.0.x	TiSpark 3.1.x
SQL select without tidb_catalog				
SQL select with tidb_catalog				
DataFrame append				
DataFrame reads				
SQL show databases				
SQL show tables				
SQL auth				
SQL delete				
SQL insert				
TLS				
DataFrame auth				

13.11.1.8.1 Support for expression index

TiDB v5.0 supports expression index.

TiSpark currently supports retrieving data from tables with `expression index`, but the `expression index` will not be used by the planner of TiSpark.

13.11.1.8.2 Work with TiFlash

TiSpark can read data from TiFlash via the configuration `spark.tispark.isolation_read_engines`.

13.11.1.8.3 Support for partitioned tables

Read partitioned tables from TiDB

TiSpark can read the range and hash partitioned tables from TiDB.

Currently, TiSpark does not support a MySQL/TiDB partition table syntax `select col_name from table_name partition(partition_name)`. However, you can still use the `where` condition to filter the partitions.

TiSpark decides whether to apply partition pruning according to the partition type and the partition expression associated with the table.

TiSpark applies partition pruning on range partitioning only when the partition expression is one of the following:

- column expression
- `YEAR($argument)` where the argument is a column and its type is datetime or string literal that can be parsed as datetime.

If partition pruning is not applicable, TiSpark's reading is equivalent to doing a table scan over all partitions.

Write into partitioned tables

Currently, TiSpark only supports writing data into the range and hash partitioned tables under the following conditions:

- The partition expression is a column expression.
- The partition expression is `YEAR($argument)` where the argument is a column and its type is datetime or string literal that can be parsed as datetime.

There are two ways to write into partitioned tables:

- Use datasource API to write into partition table which supports replace and append semantics.
- Use delete statement with Spark SQL.

> **Note:**
>
> Currently, TiSpark only supports writing into partitioned tables with utf8mb4_bin collation enabled.

13.11.1.8.4 Security

If you are using TiSpark v2.5.0 or a later version, you can authenticate and authorize TiSpark users by using TiDB.

The authentication and authorization feature is disabled by default. To enable it, add the following configurations to the Spark configuration file `spark-defaults.conf`.

```
// Enable authentication and authorization
spark.sql.auth.enable true

// Configure TiDB information
spark.sql.tidb.addr $your_tidb_server_address
spark.sql.tidb.port $your_tidb_server_port
spark.sql.tidb.user $your_tidb_server_user
spark.sql.tidb.password $your_tidb_server_password
```

For more information, see Authorization and authentication through TiDB server.

13.11.1.8.5 Other features

- Push down
- Delete with TiSpark
- Stale read
- TiSpark with multiple catalogs
- TiSpark TLS
- TiSpark plan

13.11.1.9 Statistics information

TiSpark uses the statistic information for:

- Determining which index to use in your query plan with the minimum estimated cost.
- Small table broadcasting, which enables efficient broadcast join.

To allow TiSpark to access statistic information, make sure that relevant tables have been analyzed.

See Introduction to Statistics for more details about how to analyze tables.

Since TiSpark 2.0, statistics information is automatically loaded by default.

13.11.1.10 FAQ

See TiSpark FAQ.

13.12 sync-diff-inspector

13.12.1 sync-diff-inspector User Guide

sync-diff-inspector is a tool used to compare data stored in the databases with the MySQL protocol. For example, it can compare the data in MySQL with that in TiDB, the data in MySQL with that in MySQL, or the data in TiDB with that in TiDB. In addition, you can also use this tool to repair data in the scenario where a small amount of data is inconsistent.

This guide introduces the key features of sync-diff-inspector and describes how to configure and use this tool. To download sync-diff-inspector, use one of the following methods:

- Binary package. The sync-diff-inspector binary package is included in the TiDB Toolkit. To download the TiDB Toolkit, see Download TiDB Tools.
- Docker image. Execute the following command to download:

```
docker pull pingcap/tidb-tools:latest
```

13.12.1.1 Key features

- Compare the table schema and data
- Generate the SQL statements used to repair data if the data inconsistency exists
- Support data check for tables with different schema or table names
- Support data check in the sharding scenario
- Support data check for TiDB upstream-downstream clusters
- Support data check in the DM replication scenario

13.12.1.2 Restrictions of sync-diff-inspector

- Online check is not supported for data migration between MySQL and TiDB. Ensure that no data is written into the upstream-downstream checklist, and that data in a certain range is not changed. You can check data in this range by setting `range`.
- In TiDB and MySQL, `FLOAT`, `DOUBLE` and other floating-point types are implemented differently. `FLOAT` and `DOUBLE` respectively take 6 and 15 significant digits for calculating checksum. If you do not want to use this feature, set `ignore-columns` to skip checking these columns.
- Support checking tables that do not contain the primary key or the unique index. However, if data is inconsistent, the generated SQL statements might not be able to repair the data correctly.

13.12.1.3 Database privileges for sync-diff-inspector

To access table schemas and query data, sync-diff-inspector requires specific database privileges. Grant the following privileges on both the upstream and downstream databases:

- `SELECT`: required to compare data.
- `RELOAD`: required to view table schemas.

> **Note**:
>
> - **DO NOT** grant the `SHOW DATABASES` privilege on all databases (`*.*` ↪). Otherwise, sync-diff-inspector will attempt to access inaccessible databases, which causes errors.
> - For MySQL data sources, ensure that the `skip_show_database` system variable is set to `OFF`. If this variable is set to `ON`, the check might fail.

13.12.1.4 Configuration file description

The configuration of sync-diff-inspector consists of the following parts:

- `Global config`: General configurations, such as number of threads to check, whether to export SQL statement to fix inconsistent tables, whether to compare the data, and whether to skip checking tables that do not exist in the upstream or downstream.
- `Databases config`: Configures the instances of the upstream and downstream databases.
- `Routes`: Rules for upstream multiple schema names to match downstream single schema names **(optional)**.
- `Task config`: Configures the tables for checking. If some tables have a certain mapping relationship between the upstream and downstream databases or have some special requirements, you must configure these tables.
- `Table config`: Special configurations for specific tables, such as specified ranges and columns to be ignored **(optional)**.

Below is the description of a complete configuration file:

- Note: configurations with `s` after their name can have multiple values, so you need to use square brackets `[]` to contain the configuration values.

```
### Diff Configuration.

########################### Global config ###########################
### The number of goroutines created to check data. The number of
   ↪ connections between sync-diff-inspector and upstream/downstream
   ↪ databases is slightly greater than this value.
check-thread-count = 4

### If enabled, SQL statements is exported to fix inconsistent tables.
export-fix-sql = true

### Only compares the data instead of the table structure. This
   ↪ configuration item is an experimental feature. It is not recommended
   ↪ that you use it in the production environment.
check-data-only = false

### Only compares the table structure instead of the data.
check-struct-only = false

### If enabled, sync-diff-inspector skips checking tables that do not exist
   ↪ in the upstream or downstream.
skip-non-existing-table = false
```

```
########################### Datasource config ###########################
[data-sources]
[data-sources.mysql1] # mysql1 is the only custom ID for the database
    ↪ instance. It is used for the following `task.source-instances/task.
    ↪ target-instance` configuration.
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = "" # The password for connecting to the upstream database. It
        ↪  can be plain text or Base64-encoded.

    # (optional) Use mapping rules to match multiple upstream sharded tables
        ↪ . Rule1 and rule2 are configured in the following Routes section.
    route-rules = ["rule1", "rule2"]

[data-sources.tidb0]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = "" # The password for connecting to the downstream database.
        ↪ It can be plain text or Base64-encoded.

    # (optional) Use TLS to connect TiDB.
    # security.ca-path = ".../ca.crt"
    # security.cert-path = ".../cert.crt"
    # security.key-path = ".../key.crt"

    # (optional) Use the snapshot feature. If enabled, historical data is
        ↪ used for comparison.
    # snapshot = "386902609362944000"
    # When "snapshot" is set to "auto", the last syncpoints generated by
        ↪ TiCDC in the upstream and downstream are used for comparison. For
        ↪ details, see <https://github.com/pingcap/tidb-tools/issues/663>.
    # snapshot = "auto"

############################### Routes ###############################
### To compare the data of a large number of tables with different schema
    ↪ names or table names, or check the data of multiple upstream sharded
    ↪ tables and downstream table family, use the table-rule to configure
    ↪ the mapping relationship. You can configure the mapping rule only for
    ↪  the schema or table. Also, you can configure the mapping rules for
    ↪ both the schema and the table.
[routes]
[routes.rule1] # rule1 is the only custom ID for the configuration. It is
```

```
    ↪ used for the above `data-sources.route-rules` configuration.
schema-pattern = "test_*"  # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "t_*"      # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test"     # The name of the schema in the target database
target-table = "t"         # The name of the target table
[routes.rule2]
schema-pattern = "test2_*"  # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "t2_*"      # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test2"     # The name of the schema in the target database
target-table = "t2"         # The name of the target table

############################ task config ##########################
### Configures the tables of the target database that need to be compared.
[task]
    # output-dir saves the following information:
    # 1 sql: The SQL file to fix tables that is generated after error is
        ↪ detected. One chunk corresponds to one SQL file.
    # 2 log: sync-diff.log
    # 3 summary: summary.txt
    # 4 checkpoint: a dir
    output-dir = "./output"
    # The upstream database. The value is the unique ID declared by data-
        ↪ sources.
    source-instances = ["mysql1"]
    # The downstream database. The value is the unique ID declared by data-
        ↪ sources.
    target-instance = "tidb0"
    # The tables of downstream databases to be compared. Each table needs to
        ↪  contain the schema name and the table name, separated by '.'
    # Use "?" to match any character and "*" to match characters of any
        ↪ length.
    # For detailed match rules, refer to golang regexp pkg: https://github.
        ↪ com/google/re2/wiki/Syntax.
    target-check-tables = ["schema*.table*", "!c.*", "test2.t2"]
    # (optional) Extra configurations for some tables, Config1 is defined in
        ↪  the following table config example.
    target-configs = ["config1"]

########################### Table config ########################
### Special configurations for specific tables. The tables to be configured
    ↪ must be in `task.target-check-tables`.
```

```
[table-configs.config1] # config1 is the only custom ID for this
    ↪ configuration. It is used for the above `task.target-configs`
    ↪ configuration.
### The name of the target table, you can use regular expressions to match
    ↪ multiple tables, but one table is not allowed to be matched by
    ↪ multiple special configurations at the same time.
target-tables = ["schema*.test*", "test2.t2"]
### (optional) Specifies the range of the data to be checked
### It needs to comply with the syntax of the WHERE clause in SQL.
range = "age > 10 AND age < 20"
### (optional) Specifies the column used to divide data into chunks. If you
    ↪ do not configure it,
### sync-diff-inspector chooses an appropriate column (primary key, unique
    ↪ key, or a field with index).
index-fields = ["col1","col2"]
### (optional) Ignores checking some columns such as some types (json, bit,
    ↪ blob, etc.)
### that sync-diff-inspector does not currently support.
### The floating-point data type behaves differently in TiDB and MySQL. You
    ↪ can use
### `ignore-columns` to skip checking these columns.
ignore-columns = ["",""]
### (optional) Specifies the size of the chunk for dividing the table. If
    ↪ not specified, this configuration can be deleted or be set as 0.
chunk-size = 0
### (optional) Specifies the "collation" for the table. If not specified,
    ↪ this configuration can be deleted or be set as an empty string.
collation = ""
```

13.12.1.5 Run sync-diff-inspector

Run the following command:

```
./sync_diff_inspector --config=./config.toml
```

This command outputs a check report `summary.txt` in the `output-dir` of `config.toml` and the log `sync_diff.log`. In the `output-dir`, a folder named by the hash value of the `config. toml` file is also generated. This folder includes the checkpoint node information of breakpoints and the SQL file generated when the data is inconsistent.

13.12.1.5.1 Progress information

sync-diff-inspector sends progress information to `stdout` when running. Progress information includes the comparison results of table structures, comparison results of table data and the progress bar.

> **Note:**
>
> To ensure the display effect, keep the display window width above 80 characters.

```
A total of 2 tables need to be compared

Comparing the table structure of ``sbtest`.`sbtest96`` ... equivalent
Comparing the table structure of ``sbtest`.`sbtest99`` ... equivalent

Comparing the table data of ``sbtest`.`sbtest99`` ...

--------------------------------------------------------------------------------
    ↪ _
Progress [=============================================================>--] 98%
    ↪  193/200
```

```
A total of 2 tables need to be compared

Comparing the table structure of ``sbtest`.`sbtest96`` ... equivalent
Comparing the table structure of ``sbtest`.`sbtest99`` ... equivalent
Comparing the table data of ``sbtest`.`sbtest96`` ... failure
Comparing the table data of ``sbtest`.`sbtest99`` ... failure

--------------------------------------------------------------------------------
    ↪ _
Progress [============================================================>]
    ↪ 100% 0/0
The data of `sbtest`.`sbtest99` is not equal
The data of `sbtest`.`sbtest96` is not equal

The rest of tables are all equal.

A total of 2 tables have been compared, 0 tables finished, 2 tables failed,
    ↪ 0 tables skipped.
The patch file has been generated in
       'output/fix-on-tidb2/'
You can view the comparison details through 'output/sync_diff.log'
```

13.12.1.5.2 Output file

The directory structure of the output file is as follows:

```
output/
```

```
|-- checkpoint # Saves the breakpoint information
| |-- bbfec8cc8d1f58a5800e63aa73e5 # Config hash. The placeholder file which
   ↪  identifies the configuration file corresponding to the output
   ↪ directory (output/)
  |-- DO_NOT_EDIT_THIS_DIR
  -- sync_diff_checkpoints.pb # The breakpoint information
|
|-- fix-on-target # Saves SQL files to fix data inconsistency
| |-- xxx.sql
| |-- xxx.sql
|  -- xxx.sql
|
|-- summary.txt # Saves the summary of the check results
-- sync_diff.log # Saves the output log information when sync-diff-
   ↪ inspector is running
```

13.12.1.5.3 Log

The log of sync-diff-inspector is saved in `${output}/sync_diff.log`, among which `${output}` is the value of `output-dir` in the `config.toml` file.

13.12.1.5.4 Progress

The running sync-diff-inspector periodically (every 10 seconds) prints the progress in checkpoint, which is located at `${output}/checkpoint/sync_diff_checkpoints.pb`, among which `${output}` is the value of `output-dir` in the `config.toml` file.

13.12.1.5.5 Result

After the check is finished, sync-diff-inspector outputs a report. It is located at `${output}/summary.txt`, and `${output}` is the value of `output-dir` in the `config.toml` file.

```
+--------------------+-------------------+---------------+---------+-----------+
   ↪
|       TABLE        | STRUCTURE EQUALITY | DATA DIFF ROWS | UPCOUNT |
   ↪ DOWNCOUNT |
+--------------------+-------------------+---------------+---------+-----------+

| `sbtest`.`sbtest96` | true          | +0/-101      |  999999 |  1000100 |
+--------------------+-------------------+---------------+---------+-----------+
   ↪
Time Cost: 16.75370462s
Average Speed: 113.277149MB/s
```

- `TABLE`: The corresponding database and table names
- `RESULT`: Whether the check is completed. If you have configured `skip-non-existing = true`, the value of this column is `skipped` for tables that do not exist in the upstream or downstream
- `STRUCTURE EQUALITY`: Checks whether the table structure is the same
- `DATA DIFF ROWS`: `rowAdd/rowDelete`. Indicates the number of rows that need to be added/deleted to fix the table
- `UPCOUNT`: The number of rows in this table in the upstream data source
- `DOWNCOUNT`: The number of rows in this table in the downstream data source

13.12.1.5.6 SQL statements to fix inconsistent data

If different rows exist during the data checking process, the SQL statements will be generated to fix them. If the data inconsistency exists in a chunk, a SQL file named by `chunk.Index` will be generated. The SQL file is located at `${output}/fix-on-${instance}`, and `${instance}` is the value of `task.target-instance` in the `config.toml` file.

A SQL file contains the tale to which the chunk belong and the range information. For the SQL files, you should consider the following three situations:

- If the rows in the downstream database are missing, REPLACE statements will be applied
- If the rows in the downstream database are redundant, DELETE statements will be applied
- If some data of the rows in the downstream database is inconsistent, REPLACE statements will be applied and inconsistent columns will be marked with annotation in the SQL file

```
-- table: sbtest.sbtest99
-- range in sequence: (3690708) < (id) <= (3720581)
/*
  DIFF COLUMNS   `K`                  `C`                                  `PAD`

    ↪
  source data   2501808   'hello'                          'world'

    ↪
  target data   5003616   '0709824117-9809973320-4456050422'
     ↪ '1714066100-7057807621-1425865505'

    ↪
*/
REPLACE INTO `sbtest`.`sbtest99`(`id`,`k`,`c`,`pad`) VALUES
    ↪ (3700000,2501808,'hello','world');
```

13.12.1.6 Note

- sync-diff-inspector consumes a certain amount of server resources when checking data. Avoid using sync-diff-inspector to check data during peak business hours.
- Before comparing the data in MySQL with that in TiDB, check the character set and `collation` configuration of the tables. This is especially important when the primary key or unique key of a table is the `varchar` type. If collation rules differ between upstream and downstream databases, sorting issues might occur, leading to inaccurate verification results. For example, MySQL's default collation is case-insensitive, while TiDB's default collation is case-sensitive. This inconsistency might cause identical delete and insert records in the repair SQL. To avoid this issue, use the `index-fields` configuration to specify index columns that are not affected by case sensitivity. If you configure `collation` in the sync-diff-inspector configuration file and explicitly use the same collation for both upstream and downstream during chunk-based comparison, note that the order of index fields depends on the table's collation configuration. If the collations differ, one side might be unable to use the index. Additionally, if the character sets differ between upstream and downstream (for example, MySQL uses UTF-8 while TiDB uses UTF-8MB4), it is not possible to unify the collation configuration.
- If the primary key differs between upstream and downstream tables, sync-diff-inspector does not use the original primary key column to divide chunks. For example, when sharded tables in MySQL are merged into TiDB using a composite primary key that includes the original primary key and a shard key. In this case, configure the original primary key column using `index-fields` and set `check-data-only` to `true`.
- sync-diff-inspector divides data into chunks first according to TiDB statistics and you need to guarantee the accuracy of the statistics. You can manually run the `analyze table {table_name}` command when the TiDB server's *workload is light*.
- Pay special attention to `table-rules`. If you configure `schema-pattern="test1"`, `table-pattern = "t_1"`, `target-schema="test2"` and `target-table = "t_2"`, the `test1.t_1` schema in the source database and the `test2.t_2` schema in the target database are compared. Sharding is enabled by default in sync-diff-inspector, so if the source database has a `test2.t_2` table, the `test1.t_1` table and `test2.t_2` table in the source database serving as sharding are compared with the `test2.t_2` table in the target database.
- The generated SQL file is only used as a reference for repairing data, and you need to confirm it before executing these SQL statements to repair data.

13.12.2 Data Check for Tables with Different Schema or Table Names

When using replication tools such as TiDB Data Migration, you can set `route-rules` to replicate data to a specified table in the downstream. sync-diff-inspector enables you to verify tables with different schema names or table names by setting `rules`.

The following is a simple configuration example. To learn the complete configuration, refer to sync-diff-inspector User Guide.

```
########################### Datasource config ############################
[data-sources.mysql1]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = ""
    route-rules = ["rule1"]

[data-sources.tidb0]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = ""
############################## Routes ############################
[routes.rule1]
schema-pattern = "test_1"  # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "t_1"      # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test_2"   # The name of the schema in the target database
target-table = "t_2"       # The name of the target table
```

This configuration can be used to check `test_2.t_2` in the downstream and `test_1.t_1` in the `mysql1` instance.

To check a large number of tables with different schema names or table names, you can simplify the configuration by setting the mapping relationship by using `rules`. You can configure the mapping relationship of either schema or table, or of both. For example, all the tables in the upstream `test_1` database are replicated to the downstream `test_2` database, which can be checked through the following configuration:

```
########################### Datasource config ############################
[data-sources.mysql1]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = ""
    route-rules = ["rule1"]

[data-sources.tidb0]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = ""
############################## Routes ############################
[routes.rule1]
```

```
schema-pattern = "test_1"  # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "*"        # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test_2"   # The name of the schema in the target database
target-table = "t_2"       # The name of the target table
```

13.12.2.1 The initialization of table routers and some examples

13.12.2.1.1 The initialization of table routers

- If a `target-schema/target-table` table named `schema.table` exists in the rules, the behavior of sync-diff-inspector is as follows:
    - If there is a rule that matches `schema.table` to `schema.table`, sync-diff-inspector does nothing.
    - If there is no rule that matches `schema.table` to `schema.table`, sync-diff-inspector will add a new rule `schema.table -> _no__exists__db_._no__exists__table_` to the table router. After that, sync-diff-inspector will treat the table `schema.table` as the table `_no__exists__db_._no__exists__table_`.
- If `target-schema` exists only in the rules as follows:

```
[routes.rule1]
schema-pattern = "schema_2" # the schema to match. Support wildcard
    ↪ characters * and ?
target-schema = "schema" # the target schema
```

    - If there is no schema `schema` in the upstream, sync-diff-inspector does nothing.
    - If there is a schema `schema` in the upstream, and a rule matches the schema, sync-diff-inspector does nothing.
    - If there is a schema `schema` in the upstream, but no rule matches the schema, sync-diff-inspector will add a new rule `schema -> _no__exists__db_` to the table router. After that, sync-diff-inspector will treat the table `schema` as the table `_no__exists__db_`.
- If `target-schema.target-table` does not exist in the rules, sync-diff-inspector will add a rule to match `target-schema.target-table` to `target-schema.target-table` to make it case-insensitive, because the table router is case-insensitive.

13.12.2.1.2 Examples

Suppose there are seven tables in the upstream cluster:

- `inspector_mysql_0.tb_emp1`
- `Inspector_mysql_0.tb_emp1`
- `inspector_mysql_0.Tb_emp1`
- `inspector_mysql_1.tb_emp1`
- `Inspector_mysql_1.tb_emp1`
- `inspector_mysql_1.Tb_emp1`
- `Inspector_mysql_1.Tb_emp1`

In the configuration example, the upstream cluster has a rule `Source.rule1`, and the target table is `inspector_mysql_1.tb_emp1`.

Example 1

If the configuration is as follows:

```
[Source.rule1]
schema-pattern = "inspector_mysql_0"
table-pattern = "tb_emp1"
target-schema = "inspector_mysql_1"
target-table = "tb_emp1"
```

The routing results will be as follows:

- `inspector_mysql_0.tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `Inspector_mysql_0.tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `inspector_mysql_0.Tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `inspector_mysql_1.tb_emp1` is routed to `_no__exists__db_._no__exists__table_`
- `Inspector_mysql_1.tb_emp1` is routed to `_no__exists__db_._no__exists__table_`
- `inspector_mysql_1.Tb_emp1` is routed to `_no__exists__db_._no__exists__table_`
- `Inspector_mysql_1.Tb_emp1` is routed to `_no__exists__db_._no__exists__table_`

Example 2

If the configuration is as follows:

```
[Source.rule1]
schema-pattern = "inspector_mysql_0"
target-schema = "inspector_mysql_1"
```

The routing results will be as follows:

- `inspector_mysql_0.tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `Inspector_mysql_0.tb_emp1` is routed to `inspector_mysql_1.tb_emp1`

- inspector_mysql_0.Tb_emp1 is routed to inspector_mysql_1.Tb_emp1
- inspector_mysql_1.tb_emp1 is routed to _no__exists__db_._no__exists__table_
- Inspector_mysql_1.tb_emp1 is routed to _no__exists__db_._no__exists__table_
- inspector_mysql_1.Tb_emp1 is routed to _no__exists__db_._no__exists__table_
- Inspector_mysql_1.Tb_emp1 is routed to _no__exists__db_._no__exists__table_

Example 3

If the configuration is as follows:

```
[Source.rule1]
schema-pattern = "other_schema"
target-schema = "other_schema"
```

The routing results will be as follows:

- inspector_mysql_0.tb_emp1 is routed to inspector_mysql_0.tb_emp1
- Inspector_mysql_0.tb_emp1 is routed to Inspector_mysql_0.tb_emp1
- inspector_mysql_0.Tb_emp1 is routed to inspector_mysql_0.Tb_emp1
- inspector_mysql_1.tb_emp1 is routed to inspector_mysql_1.tb_emp1
- Inspector_mysql_1.tb_emp1 is routed to inspector_mysql_1.tb_emp1
- inspector_mysql_1.Tb_emp1 is routed to inspector_mysql_1.tb_emp1
- Inspector_mysql_1.Tb_emp1 is routed to inspector_mysql_1.tb_emp1

Example 4

If the configuration is as follows:

```
[Source.rule1]
schema-pattern = "inspector_mysql_?"
table-pattern = "tb_emp1"
target-schema = "inspector_mysql_1"
target-table = "tb_emp1"
```

The routing results will be as follows:

- inspector_mysql_0.tb_emp1 is routed to inspector_mysql_1.tb_emp1
- Inspector_mysql_0.tb_emp1 is routed to inspector_mysql_1.tb_emp1
- inspector_mysql_0.Tb_emp1 is routed to inspector_mysql_1.tb_emp1
- inspector_mysql_1.tb_emp1 is routed to inspector_mysql_1.tb_emp1
- Inspector_mysql_1.tb_emp1 is routed to inspector_mysql_1.tb_emp1
- inspector_mysql_1.Tb_emp1 is routed to inspector_mysql_1.tb_emp1
- Inspector_mysql_1.Tb_emp1 is routed to inspector_mysql_1.tb_emp1

Example 5

If you do not set any rules, the routing results will be as follows:

- `inspector_mysql_0.tb_emp1` is routed to `inspector_mysql_0.tb_emp1`
- `Inspector_mysql_0.tb_emp1` is routed to `Inspector_mysql_0.tb_emp1`
- `inspector_mysql_0.Tb_emp1` is routed to `inspector_mysql_0.Tb_emp1`
- `inspector_mysql_1.tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `Inspector_mysql_1.tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `inspector_mysql_1.Tb_emp1` is routed to `inspector_mysql_1.tb_emp1`
- `Inspector_mysql_1.Tb_emp1` is routed to `inspector_mysql_1.tb_emp1`

13.12.3 Data Check in the Sharding Scenario

sync-diff-inspector supports data check in the sharding scenario. Assume that you use the TiDB Data Migration tool to replicate data from multiple MySQL instances into TiDB, you can use sync-diff-inspector to check upstream and downstream data.

For scenarios where the number of upstream sharded tables is small and the naming rules of sharded tables do not have a pattern as shown below, you can use `Datasource config` to configure `table-0`, set corresponding `rules` and configure the tables that have the mapping relationship between the upstream and downstream databases. This configuration method requires setting all sharded tables.

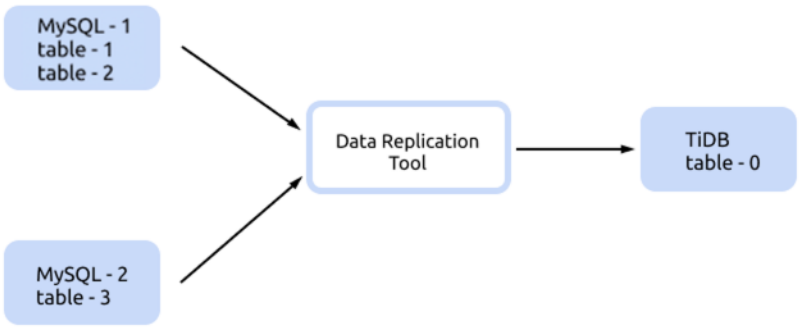

Figure 529: shard-table-replica-1

Below is a complete example of the sync-diff-inspector configuration.

```
### Diff Configuration.

############################ Global config ############################

### The number of goroutines created to check data. The number of
    ↪ connections between upstream and downstream databases are slightly
    ↪ greater than this value
check-thread-count = 4

### If enabled, SQL statements is exported to fix inconsistent tables
```

```
export-fix-sql = true

### Only compares the table structure instead of the data
check-struct-only = false

########################### Datasource config ###########################
[data-sources.mysql1]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = ""

    route-rules = ["rule1"]

[data-sources.mysql2]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = ""

    route-rules = ["rule2"]

[data-sources.tidb0]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = ""

############################## Routes ##############################
[routes.rule1]
schema-pattern = "test"    # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "table-[1-2]" # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test"     # The name of the schema in the target database
target-table = "table-0"   # The name of the target table

[routes.rule2]
schema-pattern = "test"  # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "table-3" # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test"    # The name of the schema in the target database
target-table = "table-0" # The name of the target table
```

```
########################### Task config ###########################
[task]
    output-dir = "./output"

    source-instances = ["mysql1", "mysql2"]

    target-instance = "tidb0"

    # The tables of downstream databases to be compared. Each table needs to
       ↪  contain the schema name and the table name, separated by '.'
    target-check-tables = ["test.table-0"]
```

You can use `table-rules` for configuration when there are a large number of upstream sharded tables and the naming rules of all sharded tables have a pattern, as shown below:

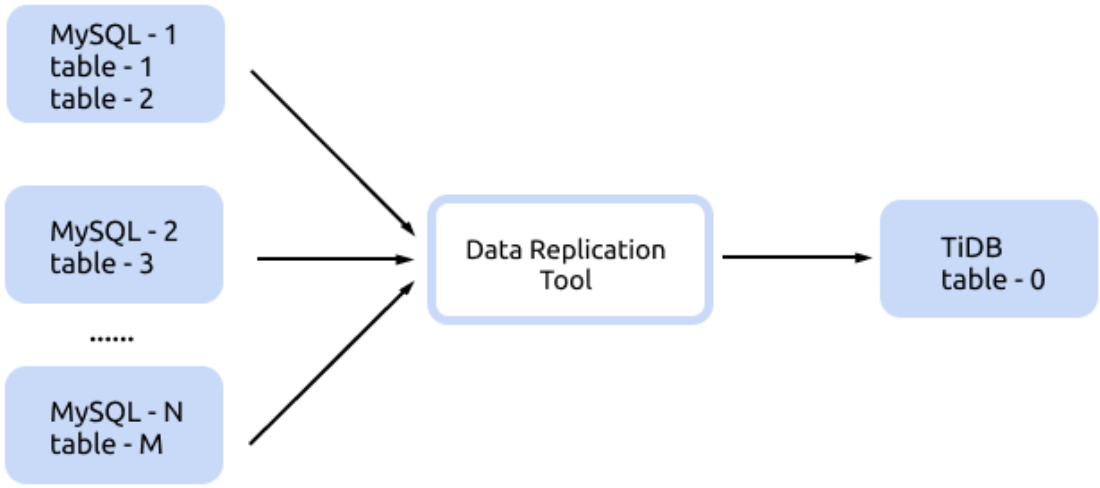

Figure 530: shard-table-replica-2

Below is a complete example of the sync-diff-inspector configuration.

```
### Diff Configuration.
########################### Global config ###########################

### The number of goroutines created to check data. The number of
   ↪ connections between upstream and downstream databases are slightly
   ↪ greater than this value.
check-thread-count = 4

### If enabled, SQL statements is exported to fix inconsistent tables.
export-fix-sql = true
```

```
### Only compares the table structure instead of the data.
check-struct-only = false

############################ Datasource config ############################
[data-sources.mysql1]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = ""

[data-sources.mysql2]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = ""

[data-sources.tidb0]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = ""

############################## Routes ##############################
[routes.rule1]
schema-pattern = "test"   # Matches the schema name of the data source.
    ↪ Supports the wildcards "*" and "?"
table-pattern = "table-*" # Matches the table name of the data source.
    ↪ Supports the wildcards "*" and "?"
target-schema = "test"    # The name of the schema in the target database
target-table = "table-0"  # The name of the target table

############################ Task config ############################
[task]
    output-dir = "./output"
    source-instances = ["mysql1", "mysql2"]

    target-instance = "tidb0"

    # The tables of downstream databases to be compared. Each table needs to
       ↪  contain the schema name and the table name, separated by '.'
    target-check-tables = ["test.table-0"]
```

13.12.3.1 Note

If `test.table-0` exists in the upstream database, the downstream database also compares this table.

13.12.4 Data Check in the DM Replication Scenario

When using replication tools such as TiDB Data Migration, you need to check the data consistency before and after the replication process. You can set a specific `task-name` configuration from `DM-master` to perform a data check.

The following is a simple configuration example. To learn the complete configuration, refer to Sync-diff-inspector User Guide.

```
### Diff Configuration.

############################# Global config ############################

### The number of goroutines created to check data. The number of
    ↪ connections between upstream and downstream databases are slightly
    ↪ greater than this value.
check-thread-count = 4

### If enabled, SQL statements is exported to fix inconsistent tables.
export-fix-sql = true

### Only compares the table structure instead of the data.
check-struct-only = false

### The IP address of dm-master and the format is "http://127.0.0.1:8261".
dm-addr = "http://127.0.0.1:8261"

### Specifies the `task-name` of DM.
dm-task = "test"

############################# Task config ##############################
[task]
    output-dir = "./output"

    # The tables of downstream databases to be compared. Each table needs to
        ↪  contain the schema name and the table name, separated by '.'
    target-check-tables = ["hb_test.*"]
```

This example is configured in dm-task = “test”, which checks all the tables of hb_test schema under the “test” task. It automatically gets the regular matching of the schemas between upstream and downstream databases to verify the data consistency after DM replication.

13.13 TiProxy

13.13.1 TiProxy Overview

TiProxy is the official proxy component of PingCAP. It is placed between the client and the TiDB server to provide load balancing, connection persistence, service discovery, and other features for TiDB.

TiProxy is an optional component. You can also use a third-party proxy component or connect directly to the TiDB server without using a proxy.

The following figure shows the architecture of TiProxy:

13.13.1.1 Main features

TiProxy provides connection migration, failover, service discovery, and quick deployment.

13.13.1.1.1 Connection migration

TiProxy can migrate connections from one TiDB server to another without breaking the client connection.

As shown in the following figure, the client originally connects to TiDB 1 through TiProxy. After the connection migration, the client actually connects to TiDB 2. When TiDB 1 is about to be offline or the ratio of connections on TiDB 1 to connections on TiDB 2 exceeds the set threshold, the connection migration is triggered. The client is unaware of the connection migration.

Connection migration usually occurs in the following scenarios:

- When a TiDB server performs scaling in, rolling upgrade, or rolling restart, TiProxy can migrate connections from the TiDB server that is about to be offline to other TiDB servers to keep the client connection alive.
- When a TiDB server performs scaling out, TiProxy can migrate existing connections to the new TiDB server to achieve real-time load balancing without resetting the client connection pool.

13.13.1.1.2 Failover

When a TiDB server is at risk of running out of memory (OOM) or fails to connect to PD or TiKV, TiProxy detects the issue automatically and migrates the connections to another TiDB server, thus ensuring continuous client connectivity.

13.13.1.1.3 Service discovery

When a TiDB server performs scaling in or scaling out, if you use a common load balancer, you need to manually update the TiDB server list. However, TiProxy can automatically discover the TiDB server list without manual intervention.

13.13.1.1.4 Quick deployment

TiProxy is integrated into TiUP, TiDB Operator, TiDB Dashboard, and Grafana, and supports built-in virtual IP management, reducing the deployment, operation, and management costs.

13.13.1.2 User scenarios

TiProxy is suitable for the following scenarios:

- Connection persistence: When a TiDB server performs scaling in, rolling upgrade, or rolling restart, the client connection is broken, resulting in an error. If the client does not have an idempotent error retry mechanism, you need to manually check and fix the error, which greatly increases the labor cost. TiProxy can keep the client connection, so that the client does not report an error.
- Frequent scaling in and scaling out: The workload of an application might change periodically. To save costs, you can deploy TiDB on the cloud and automatically scale in and scale out TiDB servers according to the workload. However, scaling in might cause the client to disconnect, and scaling out might result in unbalanced load. TiProxy can keep the client connection and achieve load balancing.
- CPU load imbalance: When background tasks consume a significant amount of CPU resources or workloads across connections vary significantly, leading to an imbalanced CPU load, TiProxy can migrate connections based on CPU usage to achieve load balancing. For more details, see CPU-based load balancing.
- TiDB server OOM: When a runaway query causes a TiDB server to run out of memory, TiProxy can proactively detect the OOM risk and migrate other healthy connections to a different TiDB server, thus ensuring continuous client connectivity. For more details, see Memory-based load balancing.

TiProxy is not suitable for the following scenarios:

- Sensitive to performance: The performance of TiProxy is lower than that of HAProxy and other load balancers, so using TiProxy will reduce the QPS. For details, refer to TiProxy Performance Test Report.
- Sensitive to cost: If the TiDB cluster uses hardware load balancers, virtual IP, or the load balancer provided by Kubernetes, adding TiProxy will increase the cost. In addition, if you deploy the TiDB cluster across availability zones on the cloud, adding TiProxy will also increase the traffic cost across availability zones.
- Failover for unexpected TiDB server downtime: TiProxy can keep the client connection only when the TiDB server is offline or restarted as planned. If the TiDB server is offline unexpectedly, the connection is still broken.

It is recommended that you use TiProxy for the scenarios that TiProxy is suitable for and use HAProxy or other proxies when your application is sensitive to performance.

13.13.1.3 Installation and usage

This section describes how to deploy and change TiProxy using TiUP. For how to deploy TiProxy using TiDB Operator in Kubernetes, see TiDB Operator documentation.

13.13.1.3.1 Deploy TiProxy

1. Before TiUP v1.15.0, you need to manually generate a self-signed certificate.

   Generate a self-signed certificate for the TiDB instance and place the certificate on all TiDB instances to ensure that all TiDB instances have the same certificate. For detailed steps, see Generate self-signed certificates.

2. Configure the TiDB instances.

   When using TiProxy, you also need to configure the following items for the TiDB instances:

   - Before TiUP v1.15.0, configure the `security.session-token-signing-cert` and `security.session-token-signing-key` of TiDB instances to the path of the certificate. Otherwise, the connection cannot be migrated.
   - Configure the `graceful-wait-before-shutdown` of TiDB instances to a value greater than the longest transaction duration of the application. Otherwise, the client might disconnect when the TiDB server is offline. You can view the transaction duration through the Transaction metrics on the TiDB monitoring dashboard. For details, see TiProxy usage limitations.

   A configuration example is as follows:

```
server_configs:
  tidb:
    security.session-token-signing-cert: "/var/sess/cert.pem"
    security.session-token-signing-key: "/var/sess/key.pem"
    security.ssl-ca: "/var/ssl/ca.pem"
    security.ssl-cert: "/var/ssl/cert.pem"
    security.ssl-key: "/var/ssl/key.pem"
    graceful-wait-before-shutdown: 15
```

3. Configure the TiProxy instances.

   To ensure the high availability of TiProxy, it is recommended to deploy at least two TiProxy instances and configure a virtual IP by setting `ha.virtual-ip` and `ha.interface` to route the traffic to the available TiProxy instance.

   When selecting the model and number of TiProxy instances, consider the following factors:

   - For the workload type and maximum QPS, see TiProxy Performance Test Report.

- Because the number of TiProxy instances is less than that of TiDB servers, the network bandwidth of TiProxy is more likely to become a bottleneck than that of TiDB servers. Therefore, you also need to consider the network bandwidth. For example, in AWS, the baseline network bandwidth of the same series of EC2 is not proportional to the number of CPU cores. For details, see Network performance. In such cases, when the network bandwidth becomes a bottleneck, splitting the TiProxy instance into more and smaller instances can improve QPS.

It is recommended to specify the version number of TiProxy in the topology configuration so that TiProxy will not be upgraded when you upgrade the TiDB cluster through `tiup cluster upgrade`. Otherwise, the client connection might be disconnected during TiProxy upgrade.

To configure TiProxy configuration items, see TiProxy configuration.

A configuration example is as follows:

```
component_versions:
  tiproxy: "v1.2.0"
server_configs:
  tiproxy:
    security.server-tls.ca: "/var/ssl/ca.pem"
    security.server-tls.cert: "/var/ssl/cert.pem"
    security.server-tls.key: "/var/ssl/key.pem"
    ha.virtual-ip: "10.0.1.10/24"
    ha.interface: "eth0"
```

4. Start the cluster.

   To start the cluster using TiUP, see TiUP documentation.

5. Connect to TiProxy.

   After the cluster is deployed, the cluster exposes the ports of TiDB server and TiProxy at the same time. The client should connect to the port of TiProxy instead of the port of TiDB server.

13.13.1.3.2 Modify TiProxy configuration

To ensure that TiProxy keeps the client connection, do not restart TiProxy unless necessary. Therefore, most of the TiProxy configuration items can be modified online. For the list of configuration items that support online change, see TiProxy configuration.

When using TiUP to change the TiProxy configuration, if the configuration item to be changed supports online change, you can use the `--skip-restart` option to avoid restarting TiProxy.

13.13.1.3.3 Upgrade TiProxy

When you deploy TiProxy, it is recommended to specify the version of TiProxy so that TiProxy will not be upgraded when you upgrade the TiDB cluster.

If you need to upgrade TiProxy, add `--tiproxy-version` in the upgrade command to specify the version of TiProxy:

```
tiup cluster upgrade <cluster-name> <version> --tiproxy-version <tiproxy-
    ↪ version>
```

13.13.1.3.4 Restart the TiDB cluster

When you restart the TiDB cluster using `tiup cluster restart`, TiDB servers are not rolling restarted, which causes the client connection to be disconnected. Therefore, avoid using this command.

Instead, when you upgrade the cluster using `tiup cluster upgrade` or reload the configuration using `tiup cluster reload`, TiDB servers are rolling restarted, so the client connection is not affected.

13.13.1.4 Compatibility with other components

- TiProxy only supports TiDB v6.5.0 and later versions.
- TiProxy's TLS connection has incompatible features with TiDB. For details, see Security.
- TiDB Dashboard and Grafana support TiProxy from v7.6.0.
- TiUP supports TiProxy from v1.14.1, and TiDB Operator supports TiProxy from v1.5.1.
- Because the interface provided by the status port of TiProxy is different from that of TiDB server, when you use TiDB Lightning to import data, the target database should be the address of TiDB server, not the address of TiProxy.

13.13.1.5 Security

TiProxy provides TLS connections. The TLS connection between the client and TiProxy is enabled according to the following rules:

- If the `security.server-tls` configuration of TiProxy is set to not use TLS connection, the TLS connection between the client and TiProxy is not enabled regardless of whether the client enables TLS connection.
- If the `security.server-tls` configuration of TiProxy is set to use TLS connection, the TLS connection between the client and TiProxy is enabled only when the client enables TLS connection.

The TLS connection between TiProxy and TiDB server is enabled according to the following rules:

- If TiProxy's `security.require-backend-tls` is set to `true`, TiProxy and TiDB server always enable TLS connection regardless of whether the client enables TLS connection. If TiProxy's `security.sql-tls` is set to not use TLS or TiDB server does not configure TLS certificate, the client reports an error.
- If TiProxy's `security.require-backend-tls` is set to `false`, TiProxy's `security.sql-tls` is configured with TLS and TiDB server is configured with a TLS certificate, TiProxy and TiDB server only enable TLS connection when the client enables TLS connection.
- If TiProxy's `security.require-backend-tls` is set to `false`, TiProxy's `security.sql-tls` is set to not use TLS or TiDB server does not configure a TLS certificate, TiProxy and TiDB server do not enable TLS connection.

TiProxy has the following behaviors incompatible with TiDB:

- The `STATUS` and `SHOW STATUS` statements might return different TLS information. The `STATUS` statement returns the TLS information between the client and TiProxy, while the `SHOW STATUS` statement returns the TLS information between TiProxy and TiDB server.
- TiProxy does not support certificate-based authentication. Otherwise, the client might fail to log in because the TLS certificate between the client and TiProxy is different from that between TiProxy and TiDB server, and TiDB server verifies the TLS certificate based on the TLS certificate on TiProxy.

13.13.1.6 Limitations

TiProxy cannot keep the client connection in the following scenarios:

- TiDB is offline unexpectedly. TiProxy only keeps the client connection when the TiDB server is offline or restarted as planned, and does not support failover of the TiDB server.
- TiProxy performs scaling in, upgrade, or restart. Once TiProxy is offline, the client connection is broken.
- TiDB actively disconnects the connection. For example, when a session does not send a request for a period of time longer than `wait_timeout`, TiDB actively disconnects the connection, and TiProxy also disconnects the client connection.

TiProxy cannot migrate connections in the following scenarios, and thus cannot keep the client connection or achieve load balancing:

- The duration of a single statement or a single transaction exceeds the `graceful-wait-before-shutdown` configured on the TiDB server.
- The session uses the cursor to read data, and the cursor is not closed or the data is not read within the `graceful-wait-before-shutdown` configured on the TiDB server.
- The session creates a local temporary table.

- The session holds a user-level lock.
- The session holds a table lock.
- The session creates a prepared statement, and the prepared statement is invalid. For example, the table related to the prepared statement is dropped after the prepared statement is created.
- The session creates a session-level execution plan binding, and the binding is invalid. For example, the table related to the binding is dropped after the binding is created.
- After the session is created, the user used by the session is deleted or the username is changed.

13.13.1.7 Supported connectors

TiProxy requires that the connector used by the client supports authentication plugins. Otherwise, the connection might fail.

The following table lists some supported connectors:

Language	Connector	The minimum supported version
Java	MySQL Connector/J	5.1.19
C	libmysqlclient	5.5.7
Go	Go SQL Driver	1.4.0
JavaScript	MySQL Connector/Node.js	1.0.2
JavaScript	mysqljs/mysql	2.15.0
JavaScript	node-mysql2	1.0.0-rc-6
PHP	mysqlnd	5.4
Python	MySQL Connector/Python	1.0.7
Python	PyMySQL	0.7

Note that some connectors call the common library to connect to the database, and these connectors are not listed in the table. You can refer to the above table for the required version of the corresponding library. For example, MySQL/Ruby uses libmysqlclient to connect to the database, so it requires that the libmysqlclient used by MySQL/Ruby is version 5.5.7 or later.

13.13.1.8 TiProxy resources

- TiProxy Release Notes
- TiProxy Issues: Lists TiProxy GitHub issues

13.13.2 TiProxy Load Balancing Policies

TiProxy v1.0.0 only supports status-based and connection count-based load balancing policies for TiDB servers. Starting from v1.1.0, TiProxy introduces five additional load balancing policies: label-based, health-based, memory-based, CPU-based, and location-based.

By default, TiProxy applies these policies with the following priorities:

1. Status-based load balancing: when a TiDB server is shutting down, TiProxy migrates connections from that TiDB server to an online TiDB server.
2. Label-based load balancing: TiProxy prioritizes routing requests to TiDB servers that share the same label as the TiProxy instance, enabling resource isolation at the computing layer.
3. Health-based load balancing: when the health of a TiDB server is abnormal, TiProxy migrates connections from that TiDB server to a healthy TiDB server.
4. Memory-based load balancing: when a TiDB server is at risk of running out of memory (OOM), TiProxy migrates connections from that TiDB server to a TiDB server with lower memory usage.
5. CPU-based load balancing: when the CPU usage of a TiDB server is much higher than that of other TiDB servers, TiProxy migrates connections from that TiDB server to a TiDB server with lower CPU usage.
6. Location-based load balancing: TiProxy prioritizes routing requests to the TiDB server geographically closest to TiProxy.
7. Connection count-based load balancing: when the connection count of a TiDB server is much higher than that of other TiDB servers, TiProxy migrates connections from that TiDB server to a TiDB server with fewer connections.

To adjust the priorities of load balancing policies, see Configure load balancing policies.

13.13.2.1 Status-based load balancing

TiProxy periodically checks whether a TiDB server is offline or shutting down using the SQL port and status port.

13.13.2.2 Label-based load balancing

Label-based load balancing prioritizes routing connections to TiDB servers that share the same label as TiProxy, enabling resource isolation at the computing layer. This policy is disabled by default and should only be enabled when your workload requires computing resource isolation.

To enable label-based load balancing, you need to:

- Specify the matching label name through `balance.label-name`.
- Configure the `labels` configuration item in TiProxy.
- Configure the `labels` configuration item in TiDB servers.

After configuration, TiProxy uses the label name specified in `balance.label-name` to route connections to TiDB servers with matching label values.

Consider an application that handles both transaction and BI workloads. To prevent these workloads from interfering with each other, configure your cluster as follows:

1. Set `balance.label-name` to `"app"` in TiProxy, indicating that TiDB servers will be matched by the label name `"app"`, and connections will be routed to TiDB servers with matching label values.
2. Configure two TiProxy instances, adding `"app"="Order"` and `"app"="BI"` to their respective `labels` configuration items.
3. Divide TiDB instances into two groups, adding `"app"="Order"` and `"app"="BI"` to their respective `labels` configuration items.
4. Optional: For storage layer isolation, configure Placement Rules or Resource Control.
5. Direct transaction and BI clients to connect to their respective TiProxy instance addresses.

Example configuration for this topology:

```
component_versions:
  tiproxy: "v1.1.0"
server_configs:
  tiproxy:
    balance.label-name: "app"
  tidb:
    graceful-wait-before-shutdown: 15
tiproxy_servers:
  - host: tiproxy-host-1
    config:
      labels: {app: "Order"}
  - host: tiproxy-host-2
    config:
      labels: {app: "BI"}
tidb_servers:
  - host: tidb-host-1
    config:
      labels: {app: "Order"}
  - host: tidb-host-2
    config:
      labels: {app: "Order"}
  - host: tidb-host-3
    config:
      labels: {app: "BI"}
  - host: tidb-host-4
    config:
      labels: {app: "BI"}
tikv_servers:
  - host: tikv-host-1
  - host: tikv-host-2
  - host: tikv-host-3
pd_servers:
```

```
  - host: pd-host-1
  - host: pd-host-2
  - host: pd-host-3
```

13.13.2.3 Health-based load balancing

TiProxy determines the health of a TiDB server by querying its error count. When the health of a TiDB server is abnormal while others are normal, TiProxy migrates connections from that server to a healthy TiDB server, achieving automatic failover.

This policy is suitable for the following scenarios:

- A TiDB server frequently fails to send requests to TiKV, causing frequent SQL execution failures.
- A TiDB server frequently fails to send requests to PD, causing frequent SQL execution failures.

13.13.2.4 Memory-based load balancing

TiProxy queries the memory usage of TiDB servers. When the memory usage of a TiDB server is rapidly increasing or reaching a high level, TiProxy migrates connections from that server to a TiDB server with lower memory usage, preventing unnecessary connection termination due to OOM. TiProxy does not guarantee identical memory usage across TiDB servers. This policy only takes effect when a TiDB server is at risk of OOM.

When a TiDB server is at risk of OOM, TiProxy attempts to migrate all connections from it. Usually, if OOM is caused by runaway queries, ongoing runaway queries will not be migrated to another TiDB server for re-execution, because these connections can only be migrated after the transaction is complete.

This policy has the following limitations:

- If the memory usage of a TiDB server grows too quickly and reaches OOM within 30 seconds, TiProxy might not be able to detect the OOM risk in time, potentially leading to connection termination.
- TiProxy aims to maintain client connections without termination, not to reduce the memory usage of TiDB servers to avoid OOM. Therefore, TiDB servers might still encounter OOM.
- This policy applies only to TiDB server v8.0.0 and later versions. For earlier versions of TiDB servers, this policy does not take effect.

13.13.2.5 CPU-based load balancing

TiProxy queries the CPU usage of TiDB servers and migrates connections from a TiDB server with high CPU usage to a server with lower usage, reducing overall query latency.

TiProxy does not guarantee identical CPU usage across TiDB servers but ensures that the CPU usage differences are minimized.

This policy is suitable for the following scenarios:

- When background tasks (such as `ANALYZE`) consume a significant amount of CPU resources, the TiDB servers executing these tasks have higher CPU usage.
- When workloads on different connections vary greatly, even if the connection count on each TiDB server is similar, the CPU usage might differ significantly.
- When TiDB servers in the cluster have different CPU resource configurations, even with balanced connection counts, the actual CPU usage might be imbalanced.

13.13.2.6 Location-based load balancing

TiProxy prioritizes routing connections to geographically closer TiDB servers based on the locations of TiProxy and TiDB servers.

This policy is suitable for the following scenarios:

- When a TiDB cluster is deployed across availability zones in the cloud, to reduce cross-availability zone traffic costs between TiProxy and TiDB servers, TiProxy prioritizes routing requests to TiDB servers in the same availability zone.
- When a TiDB cluster is deployed across data centers, to reduce network latency between TiProxy and TiDB servers, TiProxy prioritizes routing requests to TiDB servers in the same data center.

By default, this policy has a lower priority than health-based, memory-based, and CPU-based load balancing policies. You can increase its priority by setting `policy` to `location`. To maintain availability and performance, it is recommended to ensure that at least three TiDB servers are in the same location.

TiProxy determines the locations of itself and TiDB servers based on the `zone` label. You need to set the following configuration items:

- In the `labels` configuration item of the TiDB server, set `zone` to the current availability zone. For configuration details, see Configure labels for TiDB.
- In the `labels` configuration item of TiProxy, set `zone` to the current availability zone.

For clusters deployed using TiDB Operator, see High availability of data.

The following is an example of a cluster configuration:

```
component_versions:
  tiproxy: "v1.1.0"
server_configs:
  tidb:
    graceful-wait-before-shutdown: 15
```

```
tiproxy_servers:
  - host: tiproxy-host-1
    config:
      labels:
        zone: east
  - host: tiproxy-host-2
    config:
      labels:
        zone: west
tidb_servers:
  - host: tidb-host-1
    config:
      labels:
        zone: east
  - host: tidb-host-2
    config:
      labels:
        zone: west
tikv_servers:
  - host: tikv-host-1
  - host: tikv-host-2
  - host: tikv-host-3
pd_servers:
  - host: pd-host-1
  - host: pd-host-2
  - host: pd-host-3
```

In the preceding configuration, the TiProxy instance on `tiproxy-host-1` prioritizes routing requests to the TiDB server on `tidb-host-1` because `tiproxy-host-1` has the same `zone` configuration as `tidb-host-1`. Similarly, the TiProxy instance on `tiproxy-host-2` prioritizes routing requests to the TiDB server on `tidb-host-2`.

13.13.2.7 Connection count-based load balancing

TiProxy migrates connections from a TiDB server with more connections to a server with fewer connections. This policy is not configurable and has the lowest priority.

Typically, TiProxy identifies the load on TiDB servers based on CPU usage. This policy usually takes effect in the following scenarios:

- When the TiDB cluster is just starting up, the CPU usage of all TiDB servers is close to 0. In this case, this policy prevents imbalanced load during startup.
- When the CPU-based load balancing is not enabled, this policy ensures load balancing.

13.13.2.8 Configure load balancing policies

TiProxy lets you configure the combination and priority of load balancing policies through the `policy` configuration item.

- `resource`: the resource priority policy performs load balancing based on the following priority order: status, label, health, memory, CPU, location, and connection count.
- `location`: the location priority policy performs load balancing based on the following priority order: status, label, location, health, memory, CPU, and connection count.
- `connection`: the minimum connection count policy performs load balancing based on the following priority order: status, label, and connection count.

13.13.2.9 More resources

For more information about the load balancing policies of TiProxy, see the design document.

13.13.3 TiProxy Traffic Replay

> **Warning:**
>
> Currently, the TiProxy traffic replay feature is experimental. It is not recommended that you use it in production environments. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

Starting from TiProxy v1.3.0, you can use TiProxy to capture access traffic in a TiDB production cluster and replay it in a test cluster at a specified rate. This feature enables you to reproduce actual workloads from the production cluster in a test environment, verifying SQL statement execution results and performance.

13.13.3.1 Use cases

Traffic replay is suitable for the following scenarios:

- **Verify TiDB version upgrades**: Replay production traffic on a test cluster with a new TiDB version to verify that the new TiDB version can successfully execute all SQL statements.
- **Assess change impact**: Simulate production traffic on a test cluster to verify the impact of changes on the cluster. For example, verify the effects before modifying configuration items or system variables, altering table schemas, or enabling new TiDB features.

- **Validate performance before TiDB scaling**: Replay traffic at corresponding rates on a test cluster with a new scale to validate whether the performance meets requirements. For example, to plan a 50% cluster downscale for cost savings, replay traffic at half speed to validate if SQL latency meets requirements after scaling.
- **Test performance limits**: Replay traffic multiple times on a test cluster of the same scale, increasing the replay rate each time to test the throughput limit of that scale and assess whether performance meets future business growth needs.

Traffic replay is not suitable for the following scenarios:

- Verify SQL compatibility between TiDB and MySQL: TiProxy only supports reading traffic files it generates and cannot capture traffic from MySQL for replay on TiDB.
- Compare SQL execution results between TiDB versions: TiProxy only verifies if SQL statements execute successfully but does not compare results.

13.13.3.2 Usage

1. Prepare the test environment:
    1. Create a test cluster. For more information, see Deploy a TiDB Cluster Using TiUP.
    2. Install `tiproxyctl` and ensure the host with `tiproxyctl` can connect to TiProxy instances in both production and test clusters. For more information, see Install TiProxy Control.
    3. Replicate data from the production cluster to the test cluster. For more information, see Data Migration Overview.
    4. Run the `ANALYZE` statement in the test cluster to update statistics.
2. Use the `tiproxyctl traffic capture` command to connect to the production cluster's TiProxy instance and start capturing traffic.

> **Note:**
>
> - TiProxy captures traffic on all connections, including existing and newly created ones.
> - In TiProxy primary-secondary mode, connect to the primary TiProxy instance.
> - If TiProxy is configured with a virtual IP, it is recommended to connect to the virtual IP address.
> - The higher the CPU usage of TiProxy, the greater the impact of traffic capture on QPS. To reduce the impact on the production cluster, it is recommended to reserve at least 30% of CPU capacity, which results in an approximately 3% decrease in average QPS. For detailed performance data, see Traffic capture test.

- TiProxy does not automatically delete previous capture files when capturing traffic again. You need to manually delete them.

For example, the following command connects to the TiProxy instance at `10.0.1.10:3080`, captures traffic for one hour, and saves it to the `/tmp/traffic` directory on the TiProxy instance:

```
tiproxyctl traffic capture --host 10.0.1.10 --port 3080 --output="/tmp/
    ↪ traffic" --duration=1h
```

Traffic files are automatically rotated and compressed. Example files in the `/tmp/traffic` directory:

```
ls /tmp/traffic
# meta   traffic-2024-08-29T17-37-12.477.log.gz traffic-2024-08-29T17
    ↪ -43-11.166.log.gz traffic.log
```

For more information, see `tiproxyctl traffic capture`.

3. Copy the traffic file directory to the test cluster's TiProxy instance.

4. Use `tiproxyctl traffic replay` to connect to the test cluster's TiProxy instance and start replaying traffic.

   By default, SQL statements are executed at the same rate as in the production cluster, and each database connection corresponds to a connection in the production cluster to simulate the production load and ensure consistent transaction execution order.

   For example, the following command connects to the TiProxy instance at `10.0.1.10:3080` using username `u1` and password `123456`, reads traffic files from the `/tmp/traffic` directory on the TiProxy instance, and replays the traffic:

   ```
   tiproxyctl traffic replay --host 10.0.1.10 --port 3080 --username="u1"
       ↪ --password="123456" --input="/tmp/traffic"
   ```

   Because all traffic runs under user `u1`, ensure `u1` can access all databases and tables. If no such user exists, create one.

   For more information, see `tiproxyctl traffic replay`.

5. View the replay report.

   After replay completion, the report is stored in the `tiproxy_traffic_replay` database on the test cluster. This database contains two tables: `fail` and `other_errors`.

   The `fail` table stores failed SQL statements, with the following fields:

   - `cmd_type`: the type of a failed command, such as `Query` (execute an ordinary statement), `Prepare` (prepare a statement), and `Execute` (execute a prepared statement).

- `digest`: the digest of the failed SQL statement.
- `sample_stmt`: the SQL text when the statement first failed.
- `sample_err_msg`: the error message when the SQL statement failed.
- `sample_conn_id`: the connection ID recorded in the traffic file for the SQL statement. You can use this to view the execution context in the traffic file.
- `sample_capture_time`: the execution time recorded in the traffic file for the SQL statement. You can use this to view the execution context in the traffic file.
- `sample_replay_time`: the time when the SQL statement failed during replay. You can use this to view error information in the TiDB log file.
- `count`: the number of times the SQL statement failed.

The following is an example output of the `fail` table:

```
SELECT * FROM tiproxy_traffic_replay.fail LIMIT 1\G
```

```
*************************** 1. row ***************************
         cmd_type: StmtExecute
           digest: 89
                ↪ c5c505772b8b7e8d5d1eb49f4d47ed914daa2663ed24a85f762daa3cdff43c
                ↪
      sample_stmt: INSERT INTO new_order (no_o_id, no_d_id, no_w_id)
                ↪ VALUES (?, ?, ?) params=[3077 6 1]
   sample_err_msg: ERROR 1062 (23000): Duplicate entry '1-6-3077' for
                ↪  key 'new_order.PRIMARY'
   sample_conn_id: 1356
sample_capture_time: 2024-10-17 12:59:15
 sample_replay_time: 2024-10-17 13:05:05
            count: 4
```

The `other_errors` table stores unexpected errors, such as network errors or database connection errors, with the following fields:

- `err_type`: the type of error, presented as a brief error message. For example, `i/o timeout`.
- `sample_err_msg`: the complete error message when the error first occurred.
- `sample_replay_time`: the time when the error occurred during replay. You can use this to view error information in the TiDB log file.
- `count`: the number of occurrences for this error.

The following is an example output of the `other_errors` table:

```
SELECT * FROM tiproxy_traffic_replay.other_errors LIMIT 1\G
```

```
*************************** 1. row ***************************
        err_type: failed to read the connection: EOF
   sample_err_msg: this is an error from the backend connection:
                ↪ failed to read the connection: EOF
```

```
sample_replay_time: 2024-10-17 12:57:39
             count: 1
```

Note:

- The table schema of `tiproxy_traffic_replay` might change in future versions. It is not recommended to directly read data from `tiproxy_traffic_replay` in your application or tool development.
- Replay does not guarantee that the transaction execution order between connections exactly matches the capture sequence. This might lead to incorrect error reports.
- TiProxy does not automatically delete the previous replay report when replaying traffic. You need to manually delete it.

13.13.3.3 Test throughput

To test cluster throughput, use the `--speed` option to adjust the replay rate.

For example, `--speed=2` executes SQL statements at twice the rate, reducing the total replay time by half:

```
tiproxyctl traffic replay --host 10.0.1.10 --port 3080 --username="u1" --
    ↪ password="123456" --input="/tmp/traffic" --speed=2
```

Increasing the replay rate only reduces idle time between SQL statements and does not increase the number of connections. When session idle time is already short, increasing the speed might not effectively improve throughput. In such cases, you can deploy multiple TiProxy instances to replay the same traffic files simultaneously, increasing concurrency to improve throughput.

13.13.3.4 View and manage tasks

During capture and replay, tasks automatically stop if unknown errors occur. To view the current task progress or error information from the last task, use the `tiproxyctl traffic show` command:

```
tiproxyctl traffic show --host 10.0.1.10 --port 3080
```

For example, the following output indicates a running capture task:

```
[
  {
    "type": "capture",
    "start_time": "2024-09-03T09:10:58.220644+08:00",
    "duration": "2h",
    "output": "/tmp/traffic",
```

```
    "progress": "45%",
    "status": "running"
  }
]
```

For more information, see `tiproxyctl traffic show`.

To cancel the current capture or replay task, use the `tiproxyctl traffic cancel` command:

```
tiproxyctl traffic cancel --host 10.0.1.10 --port 3080
```

For more information, see `tiproxyctl traffic cancel`.

13.13.3.5 Limitations

- TiProxy only supports replaying traffic files captured by TiProxy and does not support other file formats. Therefore, make sure to capture traffic from the production cluster using TiProxy first.
- TiProxy traffic replay does not support filtering SQL types and DML and DDL statements are replayed. Therefore, you need to restore the cluster data to its pre-replay state before replaying again.
- TiProxy traffic replay does not support testing Resource Control and privilege management because TiProxy uses the same username to replay traffic.
- TiProxy does not support replaying `LOAD DATA` statements.

13.13.3.6 More resources

For more information about the traffic replay of TiProxy, see the design document.

13.13.4 TiProxy Configuration File

This document introduces the configuration parameters related to the deployment and use of TiProxy. The following is an example configuration:

```
[proxy]
addr = "0.0.0.0:6000"
max-connections = 100

[api]
addr = "0.0.0.0:3080"

[ha]
virtual-ip = "10.0.1.10/24"
interface = "eth0"
```

```
[security]
[security.cluster-tls]
skip-ca = true

[security.sql-tls]
skip-ca = true
```

13.13.4.1 Configure the `tiproxy.toml` file

This section introduces the configuration parameters of TiProxy.

> **Tip:**
>
> If you need to adjust the value of a configuration item, refer to Modify the configuration. Normally the modification leads to a restart. Because TiProxy supports hot-reloading, you can skip restart by executing `tiup cluster reload --skip-restart`.

13.13.4.1.1 proxy

Configuration for SQL port.

`addr`

- Default value: `0.0.0.0:6000`
- Support hot-reload: no
- SQL gateway address. The format is `<ip>:<port>`.

`advertise-addr`

- Default value: `""`
- Support hot-reload: no
- Specifies the address that clients use to connect to this TiProxy instance. This configuration item is automatically set when you deploy TiProxy using TiUP or TiDB Operator. If not set, the external IP address of the TiProxy instance is used.

`graceful-wait-before-shutdown`

- Default value: `0`
- Support hot-reload: yes
- Unit: second

- When TiProxy shuts down, the HTTP status returns unhealthy but the SQL port still accepts new connections for `graceful-wait-before-shutdown` seconds. After that, it rejects new connections and drains clients. It is recommended to set it to `0` when there are no other proxies (e.g. NLB) between the client and TiProxy.

`graceful-close-conn-timeout`

- Default value: `15`
- Support hot-reload: yes
- Unit: second
- When TiProxy shuts down, it closes connections when they have completed their current transactions (also known as draining clients) within `graceful-close-conn-timeout` seconds. After that, all the connections are closed at once. `graceful-close-conn-timeout` happens after `graceful-wait-before-shutdown`. It is recommended to set this timeout longer than the lifecycle of a transaction.

`max-connections`

- Default value: `0`
- Support hot-reload: yes
- Each TiProxy instance can accept `max-connections` connections at most. `0` means no limitation.

`conn-buffer-size`

- Default value: `32768`
- Support hot-reload: yes, but only for new connections
- Range: `[1024, 16777216]`
- This configuration item lets you decide the connection buffer size. Each connection uses one read buffer and one write buffer. It is a tradeoff between memory and performance. A larger buffer might yield better performance results but consume more memory. When it is `0`, TiProxy uses the default buffer size.

`pd-addrs`

- Default value: `127.0.0.1:2379`
- Support hot-reload: no
- The PD addresses TiProxy connects to. TiProxy discovers TiDB instances by fetching the TiDB list from the PD. It is set automatically when TiProxy is deployed by TiUP or TiDB Operator.

`proxy-protocol`

- Default value: `""`
- Support hot-reload: yes, but only for new connections
- Possible values: `""`, `"v2"`
- Enable the PROXY protocol on the port. By enabling the PROXY protocol, TiProxy can pass the real client IP address to TiDB. `"v2"` indicates using the PROXY protocol version 2, and `""` indicates disabling the PROXY protocol. If the PROXY protocol is enabled on TiProxy, you need to also enable the PROXY protocol on the TiDB server.

13.13.4.1.2 api

Configurations for HTTP gateway.

`addr`

- Default value: `0.0.0.0:3080`
- Support hot-reload: no
- API gateway address. You can specify `ip:port`.

`proxy-protocol`

- Default value: `""`
- Support hot-reload: no
- Possible values: `""`, `"v2"`
- Enable the PROXY protocol on the port. `"v2"` indicates using the PROXY protocol version 2, and `""` indicates disabling the PROXY protocol.

13.13.4.1.3 balance

Configurations for the load balancing policy of TiProxy.

`label-name`

- Default value: `""`
- Support hot-reload: yes
- Specifies the label name used for label-based load balancing. TiProxy matches the label values of TiDB servers based on this label name and prioritizes routing requests to TiDB servers with the same label value as itself.
- The default value of `label-name` is an empty string, indicating that label-based load balancing is not used. To enable this load balancing policy, you need to set this configuration item to a non-empty string and configure both `labels` in TiProxy and `labels` in TiDB. For more information, see Label-based load balancing.

`policy`

- Default value: `resource`
- Support hot-reload: yes
- Possible values: `resource`, `location`, `connection`
- Specifies the load balancing policy. For the meaning of each possible value, see TiProxy load balancing policies.

13.13.4.1.4 ha

High availability configurations for TiProxy.

`virtual-ip`

- Default value: `""`
- Support hot-reload: no
- Specifies the virtual IP address in the CIDR format, such as `"10.0.1.10/24"`. In a cluster with multiple TiProxy instances, only one instance binds to the virtual IP. If this instance goes offline, another TiProxy instance will automatically bind to the IP, ensuring clients can always connect to an available TiProxy through the virtual IP.

> **Note:**
>
> - Virtual IP is only supported on Linux operating systems.
> - The Linux user running TiProxy must have permission to bind IP addresses.
> - The virtual IP and the IPs of all TiProxy instances must be within the same CIDR range.

`interface`

- Default value: `""`
- Support hot-reload: no
- Specifies the network interface to bind the virtual IP to, such as `"eth0"`. The virtual IP will be bound to a TiProxy instance only when both `ha.virtual-ip` and `ha.interface` are set.

13.13.4.1.5 labels

- Default value: `{}`
- Support hot-reload: yes
- Specifies server labels. For example, `{ zone = "us-west-1", dc = "dc1" }`.

13.13.4.1.6 log

`level`

- Default value: `info`
- Support hot-reload: yes

- Possible values: `debug`, `info`, `warn`, `error`, `panic`
- Specify the log level. With the `panic` level, TiProxy will panic on errors.

`encoder`

- Default value: `tidb`
- You can specify:
    - `tidb`: format used by TiDB. For details, refer to Unified Log Format.
    - `json`: structured JSON format.
    - `console`: human-readable log format.

13.13.4.1.7 log.log-file

`filename`

- Default value: `""`
- Support hot-reload: yes
- Log file path. Non empty value will enable logging to file. When TiProxy is deployed with TiUP, the filename is set automatically.

`max-size`

- Default value: `300`
- Support hot-reload: yes
- Unit: MB
- Specifies the maximum size for log files. A log file will be rotated if its size exceeds this limit.

`max-days`

- Default value: `3`
- Support hot-reload: yes
- Specifies the maximum number of days to keep old log files. Outdated log files are deleted after surpassing this period.

`max-backups`

- Default value: `3`
- Support hot-reload: yes
- Specifies the maximum number of log files to be retained. Surplus log files will be automatically deleted when an excessive number is reached.

13.13.4.1.8 security

There are four TLS objects in the `[security]` section with different names. They share the same configuration format and fields, but they are interpreted differently depending on their names.

```
[security]
    [sql-tls]
    skip-ca = true
    [server-tls]
    auto-certs = true
```

All TLS options are hot-reloaded.

TLS object fields:

- `ca`: specifies the CA
- `cert`: specifies the certificate
- `key`: specifies the private key
- `auto-certs`: mostly used for tests. It generates certificates if no certificate or key is specified.
- `skip-ca`: skips verifying certificates using CA on client object or skips server-side verification on server object.
- `min-tls-version`: sets the minimum TLS version. Possible values are `1.0`、`1.1`、`1.2`, and `1.3`. The default value is `1.2`, which allows v1.2 or higher TLS versions.
- `rsa-key-size`: sets the RSA key size when `auto-certs` is enabled.
- `autocert-expire-duration`: sets the default expiration duration for auto-generated certificates.

Objects are classified into client or server objects by their names.

For client TLS object:

- You must set either `ca` or `skip-ca` to skip verifying server certificates.
- Optionally, you can set `cert` or `key` to pass server-side client verification.
- Useless fields: auto-certs.

For server TLS object:

- You can set either `cert` or `key` or `auto-certs` to support TLS connections. Otherwise, TiProxy doesn't support TLS connections.
- Optionally, if `ca` is not empty, it enables server-side client verification. The client must provide their certificates. Alternatively, if both `skip-ca` is true and `ca` is not empty, the server will only verify client certificates if they provide one.

`cluster-tls`

A client TLS object. It is used to access TiDB or PD.

`require-backend-tls`

- Default value: `false`
- Support hot-reload: yes, but only for new connections
- Require TLS between TiProxy and TiDB servers. If the TiDB server does not support TLS, clients will report an error when connecting to TiProxy.

`sql-tls`

A client TLS object. It is used to access TiDB SQL port (4000).

`server-tls`

A server TLS object. It is used to provide TLS on SQL port (6000).

`server-http-tls`

A server TLS object. It is used to provide TLS on HTTP status port (3080).

13.13.5 TiProxy Command-Line Flags

This document introduces the command-line flags that you can use when you launch TiProxy. It also introduces flags of `tiproxyctl`.

13.13.5.1 TiProxy Server

This section lists the flags of the server program `tiproxy`.

13.13.5.1.1 `--advertise-addr`

- Specifies the address that clients use to connect to this TiProxy instance.
- Type: `string`
- Default: `""`
- This flag is automatically set when you deploy TiProxy using TiUP or TiDB Operator. If not set, the external IP address of the TiProxy instance is used.

13.13.5.1.2 `--config`

- Specifies the path of the TiProxy configuration file.
- Type: `string`
- Default: `""`
- You must specify the configuration file. For detailed configuration items, refer to Configure TiProxy. Note that TiProxy automatically reloads the configuration when the configuration file is modified. Therefore, do not directly modify the configuration file. It is recommended to modify the configuration by executing `tiup cluster edit-config` or `kubectl edit tc`.

13.13.5.2 TiProxy Control

This section introduces the installation methods, syntax, options, and commands of the client program `tiproxyctl`.

13.13.5.2.1 Install TiProxy Control

You can install TiProxy Control using one of the following two methods.

> **Note:**
>
> TiProxy Control is specifically designed for debugging purposes and might not be fully compatible with future capabilities introduced in TiProxy. It's not recommended to include this tool in application or utility development to get information.

Install using TiUP

After installing TiUP, you can use the `tiup install tiproxy` command to download and install the binary programs for TiProxy and TiProxy Control. After installation, you can use `tiup --binary tiproxy` to view the installation path of TiProxy. TiProxy Control is located in the same directory as TiProxy.

For example:

```
tiup install tiproxy
### download https://tiup-mirrors.pingcap.com/tiproxy-v1.3.0-linux-amd64.tar
    ↪ .gz 22.51 MiB / 22.51 MiB 100.00% 13.99 MiB/s
ls `tiup --binary tiproxy`ctl
### /root/.tiup/components/tiproxy/v1.3.0/tiproxyctl
```

Compile from source code

Compilation environment requirement: Go 1.21 or later

Compilation procedures: Go to the root directory of the TiProxy project, use the `make` command to compile and generate `tiproxyctl`.

```
git clone https://github.com/pingcap/tiproxy.git
cd tiproxy
make
ls bin/tiproxyctl
```

13.13.5.2.2 Syntax

```
tiproxyctl [flags] [command]
```

For example:

```
tiproxyctl --host 127.0.0.1 --port 3080 config get
```

13.13.5.2.3 Options

`--host`

- Specifies the TiProxy server address.
- Type: `string`
- Default: `localhost`

`--port`

- Specifies the port number of the TiProxy API gateway.
- Type: `int`
- Default: `3080`

`--log_encoder`

- Specifies the log format of `tiproxyctl`.
- Type: `string`
- Default: `"tidb"`
- It defaults to the same log format of TiDB. However, you can also specify it as one of the following:
  - `console`: a more human-readable format
  - `json`: a structured log format

`--log_level`

- Specifies the log level of tiproxyctl.
- Type: `string`
- Default: `"warn"`
- You can specify `debug`, `info`, `warn`, `error`, `panic`.

`-k, --insecure`

- Specifies whether to skip TLS CA verification when dialing to the server.
- Type: `boolean`
- Default: `false`
- Used for testing.

`--ca`

- Specifies the CA when dialing to the server.
- Type: `string`
- Default: `""`

`--cert`

- Specifies the certificate when dialing to the server.
- Type: `string`
- Default: `""`

13.13.5.2.4 Commands

`config set`

The `tiproxyctl config set` command reads a TOML-formatted configuration file from standard input and sets these configuration items to TiProxy. Unspecified configuration items will remain unchanged, so you only need to specify the items that you want to modify.

The following example sets `log.level` as `'warning'`, while leaving other configuration items unchanged.

```
$ cat test.toml
[log]
level='warning'
$ cat test.toml | tiproxyctl config set
""
$ tiproxyctl config get | grep level
level = 'warning'
```

`config get`

The `tiproxyctl config get` command is used to get the current TiProxy configuration in TOML format.

`health`

The `tiproxyctl health` command is used to get the health status of TiProxy and the checksum of the configuration. When TiProxy is running normally, it returns the checksum of the configuration. When TiProxy is shutting down or offline, it returns an error.

Example output:

```
{"config_checksum":3006078629}
```

`traffic capture`

The `tiproxyctl traffic capture` command is used to capture traffic.

Options:

- `--output`: (required) specifies the directory to store traffic files.
- `--duration`: (required) specifies the duration of capture. The unit is one of `m` (minutes), `h` (hours), or `d` (days). For example, `--duration=1h` captures traffic for one hour.

Example:

The following command connects to the TiProxy instance at `10.0.1.10:3080`, captures traffic for one hour, and saves it to the `/tmp/traffic` directory on the TiProxy instance:

```
tiproxyctl traffic capture --host 10.0.1.10 --port 3080 --output="/tmp/
    ↪ traffic" --duration=1h
```

`traffic replay`

The `tiproxyctl traffic replay` command is used to replay captured traffic.

Options:

- `--username`: (required) specifies the database username for replay.
- `--password`: (optional) specifies the password for the username. The default value is an empty string `""`.
- `--input`: (required) specifies the directory containing traffic files.
- `--speed`: (optional) specifies the replay speed multiplier. The range is `[0.1, 10]`. The default value is `1`, indicating replay at the original speed.

Example:

The following command connects to the TiProxy instance at `10.0.1.10:3080` using username `u1` and password `123456`, reads traffic files from the `/tmp/traffic` directory on the TiProxy instance, and replays the traffic at twice the original speed:

```
tiproxyctl traffic replay --host 10.0.1.10 --port 3080 --username="u1" --
    ↪ password="123456" --input="/tmp/traffic" --speed=2
```

`traffic cancel`

The `tiproxyctl traffic cancel` command is used to cancel the current capture or replay task.

`traffic show`

The `tiproxyctl traffic show` command is used to display historical capture and replay tasks.

The `status` field in the output indicates the task status, with the following possible values:

- `done`: the task completed normally.
- `canceled`: the task was canceled. You can check the `error` field for the reason.
- `running`: the task is running. You can check the `progress` field for the completion percentage.

Example output:

```
[
  {
    "type": "capture",
    "start_time": "2024-09-01T14:30:40.99096+08:00",
    "end_time": "2024-09-01T16:30:40.99096+08:00",

13.13.6 TiProxy Monitoring Metrics

This document describes the monitoring items of TiProxy.

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see Overview of the Monitoring Framework.

The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, TiProxy, and Node_exporter. A lot of metrics are there to help you diagnose. Each dashboard contains panel groups and their panels.

TiProxy has four panel groups. The metrics on these panels indicate the current status of TiProxy.

- **TiProxy-Server**: instance information.
- **TiProxy-Query-Summary**: SQL query metrics like CPS.
- **TiProxy-Backend**: information on TiDB nodes that TiProxy might connect to.
- **TiProxy-Balance**: load balancing metrics.

13.13.6.1 Server

- CPU Usage: the CPU utilization of each TiProxy instance
- Memory Usage: the memory usage of each TiProxy instance
- Uptime: the runtime of each TiProxy instance since last restart
- Connection Count: the number of clients connected to each TiProxy instance
- Create Connection OPM: the number of connections created on each TiProxy instance every minute
- Disconnection OPM: the number of disconnections for each reason every minute. Reasons include:
    - success: the client disconnects normally
    - client network break: the client does not send a `QUIT` command before it disconnects. It may also be caused by a network problem or the client shutting down
    - client handshake fail: the client fails to handshake with TiProxy
    - auth fail: the access is denied by TiDB
    - SQL error: TiDB returns other SQL errors
    - proxy shutdown: TiProxy is shutting down
    - malformed packet: TiProxy fails to parse the MySQL packet
    - get backend fail: TiProxy fails to find an available backend for the connection
    - proxy error: other TiProxy errors
    - backend network break: fails to read from or write to the TiDB. This may be caused by a network problem or the TiDB server shutting down
    - backend handshake fail: TiProxy fails to handshake with the TiDB server
- Goroutine Count: the number of Goroutines on each TiProxy instance
- Owner: the TiProxy instance that executes various tasks. For example, `10.24.31.1:3080 - vip` indicates that the TiProxy instance at `10.24.31.1:3080` is bound to a virtual IP. The tasks include the following:

- vip: binds a virtual IP
- metric_reader: reads monitoring data from TiDB servers

13.13.6.2 Query-Summary

- Duration: average, P95, P99 SQL statement execution duration. It includes the duration of SQL statement execution on TiDB servers, so it is higher than the duration on the TiDB Grafana panel
- P99 Duration By Instance: P99 statement execution duration of each TiProxy instance
- P99 Duration By Backend: P99 statement execution duration of the statements that are executed on each TiDB instance
- CPS by Instance: command per second of each TiProxy instance
- CPS by Backend: command per second of each TiDB instance
- CPS by CMD: command per second grouped by SQL command type
- Handshake Duration: average, P95, and P99 duration of the handshake phase between the client and TiProxy

13.13.6.3 Balance

- Backend Connections: connection counts between each TiDB instance and each TiProxy instance. For example, `10.24.31.1:6000 | 10.24.31.2:4000` indicates the connections between TiProxy instance `10.24.31.1:6000` and TiDB instance `10.24.31.2:4000`
- Session Migration OPM: the number of session migrations that happened every minute, recording sessions on which TiDB instance migrated to the other. For example, `succeed: 10.24.31.2:4000 => 10.24.31.3:4000` indicates the number of sessions that are successfully migrated from TiDB instance `10.24.31.2:4000` to TiDB instance `10.24.31.3:4000`
- Session Migration Duration: average, P95, P99 session migration duration.
- Session Migration Reasons: the number of session migrations that happened every minute and the reason for them. The reasons include the following:
  - `status`: TiProxy performed status-based load balancing.
  - `label`: TiProxy performed label-based load balancing.
  - `health`: TiProxy performed health-based load balancing.
  - `memory`: TiProxy performed memory-based load balancing.
  - `cpu`: TiProxy performed CPU-based load balancing.
  - `location`: TiProxy performed location-based load balancing.
  - `conn`: TiProxy performed connection count-based load balancing.

13.13.6.4 Backend

- Get Backend Duration: the average, p95, p99 duration of TiProxy connecting to a TiDB instance

- Ping Backend Duration: the network latency between each TiProxy instance and each TiProxy instance. For example, `10.24.31.1:6000 | 10.24.31.2:4000` indicates the network latency between TiProxy instance `10.24.31.1:6000` and TiDB instance `10.24.31.2:4000`
- Health Check Cycle: the duration of a cycle of the health check between a TiProxy instance and all TiDB instances. For example, `10.24.31.1:6000` indicates the duration of the latest health check that TiProxy instance `10.24.31.1:6000` executes on all the TiDB instances. If this duration is higher than 3 seconds, TiProxy may not be timely to refresh the backend TiDB list

13.13.6.5 Traffic

- Bytes/Second from Backends: the amount of data, in bytes, sent from each TiDB instance to each TiProxy instance per second.
- Packets/Second from Backends: the number of MySQL packets sent from each TiDB instance to each TiProxy instance per second.
- Bytes/Second to Backends: the amount of data, in bytes, sent from each TiProxy instance to each TiDB instance per second.
- Packets/Second to Backends: the number of MySQL packets sent from each TiProxy instance to each TiDB instance per second.
- Cross Location Bytes/Second: the amount of data, in bytes, sent from each TiProxy instance to TiDB instances in different locations per second.

13.13.7 TiProxy API

TiProxy provides API endpoints for accessing its configuration, health status, and monitoring data.

> **Note:**
>
> TiProxy API is specifically designed for debugging purposes and might not be fully compatible with future capabilities introduced in TiProxy. It's not recommended to include this tool in application or utility development to get information.

The address for accessing the TiProxy API is `http://${host}:${port}${path}`, where `${host}:${port}` is specified by the TiProxy configuration item `api.addr`, and `${path}` is the specific API endpoint you want to access. For example:

```
curl http://127.0.0.1:3080/api/admin/config/
```

13.13.7.1 Get TiProxy configuration

13.13.7.1.1 Request URI

`GET /api/admin/config/`

13.13.7.1.2 Parameter descriptions

The query parameter is as follows:

- `format`: (optional) specifies the format of the returned configuration. Value options are `json` and `toml`. The default value is `toml`.

13.13.7.1.3 Example

The following example gets the TiProxy configuration in JSON format:

```
curl "http://127.0.0.1:3080/api/admin/config/?format=json"
```

13.13.7.2 Set TiProxy configuration

Currently, you can only use the TOML format to modify TiProxy configuration. Unspecified configuration items will remain unchanged, so you only need to specify the items that you want to modify.

13.13.7.2.1 Request URI

`PUT /api/admin/config/`

13.13.7.2.2 Request body

You need to provide the TiProxy configuration in TOML format. For example:

```
[log]
level='warning'
```

13.13.7.2.3 Example

The following example sets `log.level` as `'warning'`, while leaving other configuration items unchanged.

1. Get the current TiProxy configuration:

   ```
   curl http://127.0.0.1:3080/api/admin/config/
   ```

   The output is as follows:

```
[log]
encoder = 'tidb'
level = 'info'
```

2. Specify the value of `log.level` in the `test.toml` file, and then send a `PUT /api/admin/config/` request to update the value of `log.level`:

```
$ cat test.toml
[log]
level='warning'
$ curl -X PUT --data-binary @test.toml http://127.0.0.1:3080/api/admin/config/
```

3. Get the modified TiProxy configuration:

```
curl http://127.0.0.1:3080/api/admin/config/
```

The output is as follows:

```
[log]
encoder = 'tidb'
level = 'warning'
```

13.13.7.3 Get TiProxy health status

This endpoint is used to get the health status of TiProxy and the checksum of the configuration. When TiProxy is running normally, this endpoint returns the checksum of the configuration. When TiProxy is shutting down or offline, it returns an error.

13.13.7.3.1 Request URI

`GET /api/debug/health`

13.13.7.3.2 Example

```
curl http://127.0.0.1:3080/api/debug/health
```

The output is as follows:

```
{"config_checksum":3006078629}
```

13.13.7.4 Get TiProxy monitoring data

13.13.7.4.1 Request URI

`GET /metrics/`

13.13.7.4.2 Example

```
curl http://127.0.0.1:3080/metrics/
```

13.13.8 Troubleshoot TiProxy

This document describes some common problems, causes, and solutions for TiProxy.

13.13.8.1 Cannot connect to TiProxy

You can troubleshoot the issue by following these steps:

1. Check if the connector version is supported. If the connector is not in the list, check if the connector supports authentication plugins.
2. If the client reports `No available TiDB instances, please make sure TiDB is available`, check if there is a TiDB server and if the SQL port and HTTP status port of the TiDB server can be connected normally.
3. If the client reports `Require TLS enabled on TiProxy when require-backend-tls=true`, check if TiProxy is correctly configured with TLS certificates.
4. If the client reports `Verify TiDB capability failed, please upgrade TiDB`, check if the TiDB server version is v6.5.0 or later.
5. If the client reports `TiProxy fails to connect to TiDB, please make sure TiDB is available`, check if the TiProxy node can connect to the TiDB server.
6. If the client reports `Require TLS enabled on TiDB when require-backend-tls=true`, check if TiDB is correctly configured with TLS certificates.
7. If the client reports `TiProxy fails to connect to TiDB, please make sure TiDB proxy-protocol is set correctly`, check if `proxy.proxy-protocol` is enabled on TiProxy and `proxy-protocol` is not enabled on the TiDB server.
8. Check if TiProxy is configured with `max-connections` and if the number of connections on TiProxy exceeds the maximum connection limit.
9. Check the TiProxy log for error messages.

13.13.8.2 TiProxy does not migrate connections

You can troubleshoot the issue by following these steps:

1. Whether the TiProxy limitations are not met. You can further confirm this by checking the TiProxy log.
2. Whether `security.session-token-signing-cert`, `security.session-token-signing-key`, and `graceful-wait-before-shutdown` are correctly configured on TiDB.

13.13.8.3 Unbalanced CPU usage on TiDB server

You can troubleshoot the issue by following these steps:

1. Check if there is a significant difference in CPU usage among TiDB servers. TiProxy does not guarantee identical CPU usage across TiDB servers. It only performs load balancing when the CPU usage difference is large enough to affect query latency.
2. If the connection count of a TiDB server gradually drops to zero, it might be affected by other load balancing policies. You can check the `Session Migration Reasons` metric in Grafana to see if there are migrations based on other policies.
3. Check if the TiProxy configuration item `policy` is set to `location`. If location-based prioritization is enabled, TiProxy does not balance CPU usage across different locations.
4. Check the version of TiProxy. Only v1.1.0 and later versions support CPU-based load balancing. Earlier versions use a load balancing policy based on minimum connection count.
5. If none of the preceding situations apply, the connection migration might have failed. To troubleshoot further, see TiProxy does not migrate connections.

13.13.8.4 Latency is significantly increased

You can troubleshoot the issue by following these steps:

1. Check the latency on TiProxy through Grafana. If the latency on TiProxy is not high, it means that the client load is high or the network latency between the client and TiProxy is high.
2. Check the latency on the TiDB server through Grafana. If the latency on the TiDB server is high, follow the steps in Latency increases significantly to troubleshoot.
3. Check the network duration between TiProxy and TiDB server through Grafana.
4. Check the CPU usage on TiProxy. If the CPU usage is over 90%, you need to scale out TiProxy.

13.13.9 TiProxy Performance Test Report

This report tests the performance of TiProxy in the OLTP scenario of Sysbench and compares it with HAProxy.

The results are as follows:

- The QPS upper limit of TiProxy is affected by the type of workload. Under the basic workloads of Sysbench and the same CPU usage, the QPS of TiProxy is about 25% lower than that of HAProxy.
- The number of TiDB server instances that TiProxy can hold varies according to the type of workload. Under the basic workloads of Sysbench, a TiProxy can hold 5 to 12 TiDB server instances of the same model.

- The row number of the query result set has a significant impact on the QPS of TiProxy, and the impact is the same as that of HAProxy.
- The performance of TiProxy increases almost linearly with the number of vCPUs. Therefore, increasing the number of vCPUs can effectively improve the QPS upper limit.
- The number of long connections and the frequency of creating short connections have minimal impact on the QPS of TiProxy.
- The higher the CPU usage of TiProxy, the greater the impact of enabling traffic capture on QPS. When the CPU usage of TiProxy is about 70%, enabling traffic capture leads to approximately 3% decrease in average QPS and 7% decrease in minimum QPS. The latter decrease is caused by periodic QPS drops during traffic file compression.

13.13.9.1 Test environment

13.13.9.1.1 Hardware configuration

Service	Machine type	CPU model	Instance count
TiProxy	4C8G	Intel(R) Xeon(R) Silver 4214R CPU @ 2.40GHz	1
HAProxy	4C8G	Intel(R) Xeon(R) Silver 4214R CPU @ 2.40GHz	1
PD	4C8G	Intel(R) Xeon(R) Silver 4214R CPU @ 2.40GHz	3
TiDB	8C16G	Intel(R) Xeon(R) Silver 4214R CPU @ 2.40GHz	8
TiKV	8C16G	Intel(R) Xeon(R) Silver 4214R CPU @ 2.40GHz	8
Sysbench	8C16G	Intel(R) Xeon(R) Silver 4214R CPU @ 2.40GHz	1

13.13.9.1.2 Software

Service	Software version
TiProxy	v1.0.0
HAProxy	2.9.0
PD	v8.0.0
TiDB	v8.0.0
TiKV	v8.0.0
Sysbench	1.0.17

13.13.9.1.3 Configuration

TiProxy configuration

In the test, TLS is not enabled between the client and TiProxy, or between TiProxy and TiDB server.

```
proxy.conn-buffer-size: 131072
```

HAProxy configuration - `haproxy.cfg` file

```
global                                  # Global configuration.
    log         127.0.0.1 local2        # Specifies the global syslog server.
       ↪  You can define up to two.
    pidfile     /var/run/haproxy.pid    # Write the PID of the HAProxy
       ↪ process to pidfile.
    maxconn     4096                    # The maximum number of concurrent
       ↪ connections that a single HAProxy process can accept, equivalent
       ↪ to the command line parameter "-n".
    nbthread    4                       # The maximum number of threads. The
       ↪ upper limit of the number of threads is the same as the number of
       ↪ CPUs.
    user        haproxy                 # Same as UID parameter.
    group       haproxy                 # Same as GID parameter. A dedicated
       ↪ user group is recommended.
    daemon                              # Run HAProxy as a daemon in the
       ↪ background, which is equivalent to the command line parameter "-D
       ↪ ". You can also disable it with the "-db" parameter on the command
       ↪  line.
    stats socket /var/lib/haproxy/stats # The location where the statistics
       ↪ are saved.

defaults                                # Default configuration.
    log global                          # Inherit the settings of the global
       ↪ configuration section.
    retries 2                           # The maximum number of times to try
       ↪ to connect to the upstream server. If the number of retries
       ↪ exceeds this value, the backend server is considered unavailable.
    timeout connect 2s                  # The timeout period for HAProxy to
       ↪ connect to the backend server. If the server is located on the
       ↪ same LAN as HAProxy, set it to a shorter time.
    timeout client 30000s               # The timeout period for the client
       ↪ to be inactive after the data transmission is completed.
    timeout server 30000s               # The timeout period for the server
       ↪ to be inactive.

listen tidb-cluster                     # Configure database load balancing.
    bind 0.0.0.0:3390                   # Floating IP address and listening
       ↪ port.
    mode tcp                            # HAProxy uses layer 4, the transport
       ↪  layer.
    balance leastconn                  # The server with the least number of
       ↪ connections receives the connection first. `leastconn` is
       ↪ recommended for long session services, such as LDAP, SQL, and TSE,
```

```
    ↪  rather than short session protocols, such as HTTP. This algorithm
    ↪  is dynamic, and the server weight is adjusted during operation
    ↪ for slow-start servers.
  server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
    ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
    ↪  detected as successful twice, the server is considered available;
    ↪  if it is detected as failed three times, the server is considered
    ↪  unavailable.
  server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

13.13.9.2 Basic workload test

13.13.9.2.1 Test plan

This test aims to compare the QPS of TiProxy and HAProxy under four types of workloads: point select, read only, write only, and read write. Each type of workload is tested with different concurrency to compare the QPS of TiProxy and HAProxy.

The following command is used to perform the test:

```
sysbench $testname \
    --threads=$threads \
    --time=1200 \
    --report-interval=10 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$host \
    --mysql-port=$port \
    run --tables=32 --table-size=1000000
```

13.13.9.2.2 Point Select

TiProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage
20	41273	0.48	0.64	190%	900%
50	100255	0.50	0.62	330%	1900%
100	137688	0.73	1.01	400%	2600%

HAProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	HAProxy CPU usage	TiDB overall CPU usage
20	44833	0.45	0.61	140%	1000%
50	103631	0.48	0.61	270%	2100%
100	163069	0.61	0.77	360%	3100%

13.13.9.2.3 Read Only

TiProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage
50	72076	11.09	12.75	290%	2500%
100	109704	14.58	17.63	370%	3800%
200	117519	27.21	32.53	400%	4100%

HAProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	HAProxy CPU usage	TiDB overall CPU usage
50	75760	10.56	12.08	250%	2600%
100	121730	13.14	15.83	350%	4200%
200	131712	24.27	30.26	370%	4500%

13.13.9.2.4 Write Only

TiProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage
100	81957	7.32	10.27	290%	3900%
300	103040	17.45	31.37	330%	4700%
500	104869	28.59	52.89	340%	4800%

HAProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	HAProxy CPU usage	TiDB overall CPU usage
100	81708	7.34	10.65	240%	3700%
300	106008	16.95	31.37	320%	4800%
500	122369	24.45	47.47	350%	5300%

13.13.9.2.5 Read Write

TiProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage
50	58571	17.07	19.65	250%	2600%
100	88432	22.60	29.19	330%	3900%
200	108758	36.73	51.94	380%	4800%

HAProxy test results:

Threads	QPS	Avg latency (ms)	P95 latency (ms)	HAProxy CPU usage	TiDB overall CPU usage
50	61226	16.33	19.65	190%	2800%
100	96569	20.70	26.68	290%	4100%
200	120163	31.28	49.21	340%	5200%

13.13.9.3 Result set test

13.13.9.3.1 Test plan

This test aims to compare the performance of TiProxy and HAProxy under different result set row numbers. This test uses 100 concurrency, and compares the QPS of TiProxy and HAProxy with result set row numbers of 10, 100, 1000, and 10000.

The following command is used to perform the test:

```
sysbench oltp_read_only \
    --threads=100 \
    --time=1200 \
    --report-interval=10 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$host \
    --mysql-port=$port \
    --skip_trx=true \
    --point_selects=0 \
    --sum_ranges=0 \
    --order_ranges=0 \
    --distinct_ranges=0 \
    --simple_ranges=1 \
    --range_size=$range_size
    run --tables=32 --table-size=1000000
```

13.13.9.3.2 Test results

TiProxy test results:

Range size	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage	Inbound network (MiB/s)	Outbound network (MiB/s)
10	80157	1.25	1.61	340%	2600%	140	140
100	55936	1.79	2.43	370%	2800%	820	820
1000	10313	9.69	13.70	310%	1500%	1370	1370
10000	1064	93.88	142.39	250%	600%	1430	1430

HAProxy test results:

Range size	QPS	Avg latency (ms)	P95 latency (ms)	HAProxy CPU usage	TiDB overall CPU usage	Inbound network (MiB/s)	Outbound network (MiB/s)
10	94376	1.06	1.30	250%	4000%	150	150
100	70129	1.42	1.76	270%	3300%	890	890
1000	9501	11.18	14.73	240%	1500%	1180	1180

13.13.9.4 Scalability test

13.13.9.4.1 Test plan

This test aims to verify that the performance of TiProxy is proportional to its specifications, to ensure that upgrading the specifications of TiProxy can improve its QPS upper limit. This test uses TiProxy instances with different vCPU numbers and concurrency to compare the QPS.

The following command is used to perform the test:

```
sysbench oltp_point_select \
    --threads=$threads \
    --time=1200 \
    --report-interval=10 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
```

```
    --mysql-host=$host \
    --mysql-port=$port \
    run --tables=32 --table-size=1000000
```

13.13.9.4.2 Test results

vCPU	Threads	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage
2	40	58508	0.68	0.97	190%	1200%
4	80	104890	0.76	1.16	390%	2000%
6	120	155520	0.77	1.14	590%	2900%
8	160	202134	0.79	1.18	800%	3900%

13.13.9.5 Long connection test

13.13.9.5.1 Test plan

This test aims to verify that a large number of idle connections have minimal impact on the QPS when the client uses long connections. This test creates 5000, 10000, and 15000 idle long connections, and then executes `sysbench`.

This test uses the default value for the `conn-buffer-size` configuration:

```
proxy.conn-buffer-size: 32768
```

Use the following command to perform the test:

```
sysbench oltp_point_select \
    --threads=50 \
    --time=1200 \
    --report-interval=10 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$host \
    --mysql-port=$port \
    run --tables=32 --table-size=1000000
```

13.13.9.5.2 Test results

Connection count	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiProxy memory usage (MB)	TiDB overall CPU usage
5000	96620	0.52	0.64	330%	920	1800%
10000	96143	0.52	0.65	330%	1710	1800%
15000	96048	0.52	0.65	330%	2570	1900%

13.13.9.6 Short connection test

13.13.9.6.1 Test plan

This test aims to verify that frequent creation and destruction of connections have minimal impact on the QPS when the client uses short connections. This test starts another client program to create and disconnect 100, 200, and 300 short connections per second while executing `sysbench`.

Use the following command to perform the test:

```
sysbench oltp_point_select \
    --threads=50 \
    --time=1200 \
    --report-interval=10 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$host \
    --mysql-port=$port \
    run --tables=32 --table-size=1000000
```

13.13.9.6.2 Test results

New connections per second	QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage	TiDB overall CPU usage
100	95597	0.52	0.65	330%	1800%
200	94692	0.53	0.67	330%	1800%
300	94102	0.53	0.68	330%	1900%

13.13.9.7 Traffic capture test

13.13.9.7.1 Test plan

This test aims to evaluate the performance impact of traffic capture on TiProxy. It uses TiProxy v1.3.0 and compares QPS and TiProxy CPU usage with traffic capture enabled and

disabled before executing `sysbench` with different concurrency. Due to periodic QPS fluctuations caused by traffic file compression, the test compares both the average and minimum QPS.

Use the following command to perform the test:

```
sysbench oltp_read_write \
    --threads=$threads \
    --time=1200 \
    --report-interval=5 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$host \
    --mysql-port=$port \
    run --tables=32 --table-size=1000000
```

13.13.9.7.2 Test results

Connection count	Traffic capture	Avg QPS	Min QPS	Avg latency (ms)	P95 latency (ms)	TiProxy CPU usage
20	Disabled	27653	26999	14.46	16.12	140%

100	Enabled	79819	69503	25.04	31.94	380%

14 Reference

14.1 Cluster Architecture

14.1.1 TiDB Architecture

Compared with the traditional standalone databases, TiDB has the following advantages:

- Has a distributed architecture with flexible and elastic scalability.
- Fully compatible with the MySQL protocol, common features and syntax of MySQL. To migrate your applications to TiDB, you do not need to change a single line of code in many cases.
- Supports high availability with automatic failover when a minority of replicas fail; transparent to applications.

- Supports ACID transactions, suitable for scenarios requiring strong consistency such as bank transfer.

- Provides a rich series of data migration tools for migrating, replicating, or backing up data.

As a distributed database, TiDB is designed to consist of multiple components. These components communicate with each other and form a complete TiDB system. The architecture is as follows:

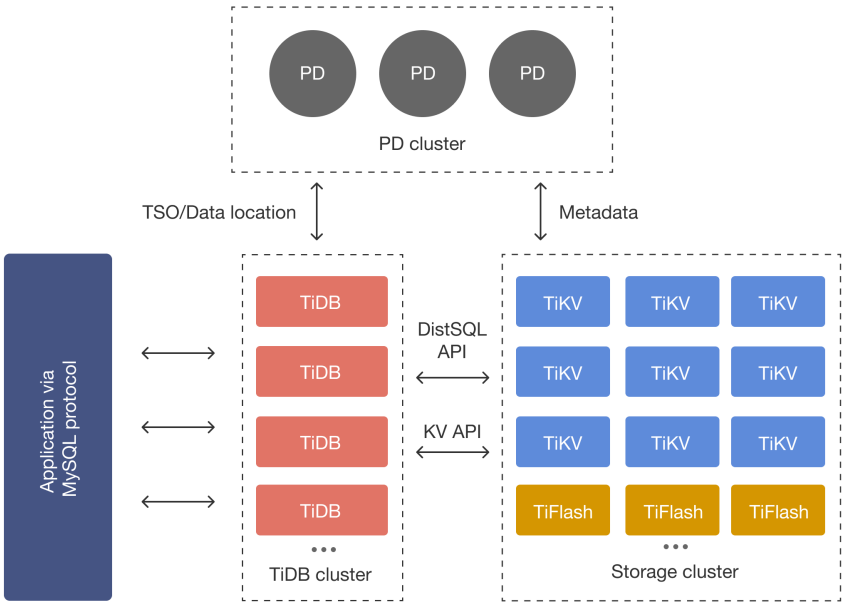

Figure 531: TiDB Architecture

14.1.1.1 TiDB server

The TiDB server is a stateless SQL layer that exposes the connection endpoint of the MySQL protocol to the outside. The TiDB server receives SQL requests, performs SQL parsing and optimization, and ultimately generates a distributed execution plan. It is horizontally scalable and provides the unified interface to the outside through the load balancing components such as TiProxy, Linux Virtual Server (LVS), HAProxy, ProxySQL or F5. It does not store data and is only for computing and SQL analyzing, transmitting actual data read request to TiKV nodes (or TiFlash nodes).

14.1.1.2 Placement Driver (PD) server

The PD server is the metadata managing component of the entire cluster. It stores metadata of real-time data distribution of every single TiKV node and the topology structure

of the entire TiDB cluster, provides the TiDB Dashboard management UI, and allocates transaction IDs to distributed transactions. The PD server is "the brain" of the entire TiDB cluster because it not only stores metadata of the cluster, but also sends data scheduling command to specific TiKV nodes according to the data distribution state reported by TiKV nodes in real time. In addition, the PD server consists of three nodes at least and has high availability. It is recommended to deploy an odd number of PD nodes.

14.1.1.3 Storage servers

14.1.1.3.1 TiKV server

The TiKV server is responsible for storing data. TiKV is a distributed transactional key-value storage engine.

Region is the basic unit to store data. Each Region stores the data for a particular Key Range which is a left-closed and right-open interval from StartKey to EndKey.

Multiple Regions exist in each TiKV node. TiKV APIs provide native support to distributed transactions at the key-value pair level and supports the Snapshot Isolation level isolation by default. This is the core of how TiDB supports distributed transactions at the SQL level. After processing SQL statements, the TiDB server converts the SQL execution plan to an actual call to the TiKV API. Therefore, data is stored in TiKV. All the data in TiKV is automatically maintained in multiple replicas (three replicas by default), so TiKV has native high availability and supports automatic failover.

14.1.1.3.2 TiFlash server

The TiFlash server is a special type of storage server. Unlike ordinary TiKV nodes, TiFlash stores data by column, mainly designed to accelerate analytical processing.

14.1.2 TiDB Storage

This document introduces some design ideas and key concepts of TiKV.

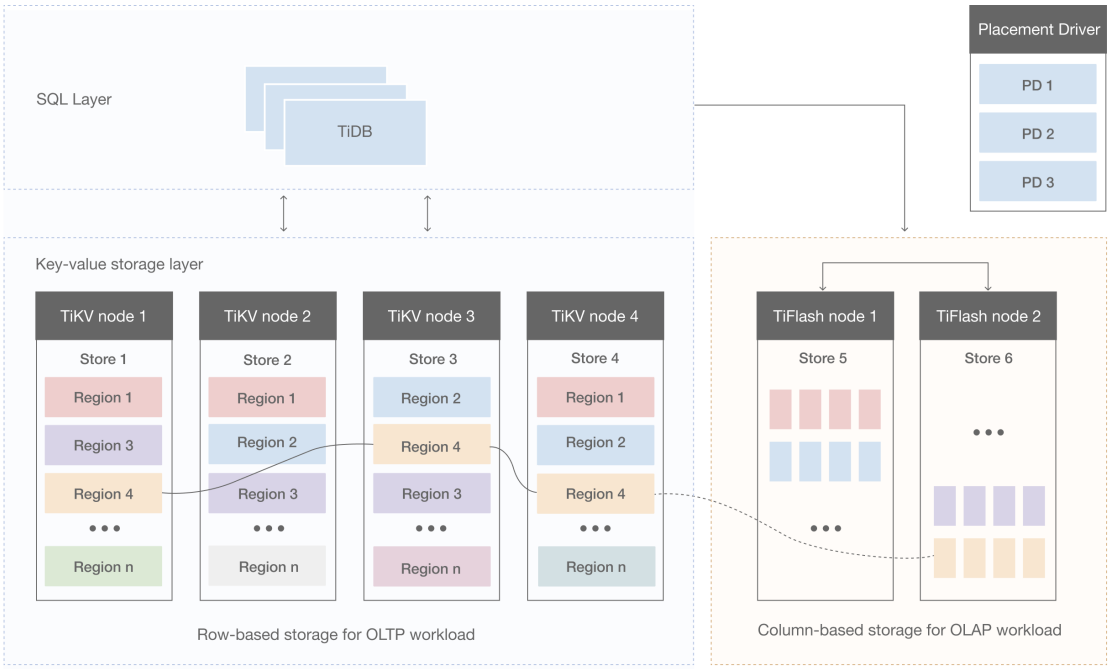

Figure 532: storage-architecture

14.1.2.1 Key-Value pairs

The first thing to decide for a data storage system is the data storage model, that is, in what form the data is saved. TiKV's choice is the Key-Value model and provides an ordered traversal method. There are two key points for TiKV data storage model:

- This is a huge Map (similar to `std::Map` in C++) , which stores Key-Value pairs.
- The Key-Value pair in the Map is ordered according to Keys' binary order, which means you can Seek the position of a particular Key and then call the Next method to get the Key-Value pairs larger than this Key in incremental order.

Note that the KV storage model for TiKV described in this document has nothing to do with tables of SQL. This document does not discuss any concepts related to SQL and only focuses on how to implement a high-performance, high-reliability, distributed Key-Value storage such as TiKV.

14.1.2.2 Local storage (RocksDB)

For any persistent storage engine, data is eventually saved on disk, and TiKV is no exception. TiKV does not write data directly on the disk, but stores data in RocksDB, which is responsible for the data storage. The reason is that it costs a lot to develop a

standalone storage engine, especially a high-performance standalone engine that requires careful optimization.

RocksDB is an excellent standalone storage engine open-sourced by Facebook. This engine can meet various requirements of TiKV for a single engine. Here, you can simply consider RocksDB as a single persistent Key-Value Map.

14.1.2.3 Raft protocol

What's more, the implementation of TiKV faces a more difficult thing: to secure data safety in case a single machine fails.

A simple way is to replicate data to multiple machines, so that even if one machine fails, the replicas on other machines are still available. In other words, you need a data replication scheme that is reliable, efficient, and able to handle the situation of a failed replica. All of these are made possible by the Raft algorithm.

Raft is a consensus algorithm. This document only briefly introduces Raft. For more details, you can see In Search of an Understandable Consensus Algorithm. The Raft has several important features:

- Leader election
- Membership changes (such as adding replicas, deleting replicas, and transferring leaders)
- Log replication

TiKV use Raft to perform data replication. Each data change will be recorded as a Raft log. Through Raft log replication, data is safely and reliably replicated to multiple nodes of the Raft group. However, according to Raft protocol, successful writes only need that data is replicated to the majority of nodes.

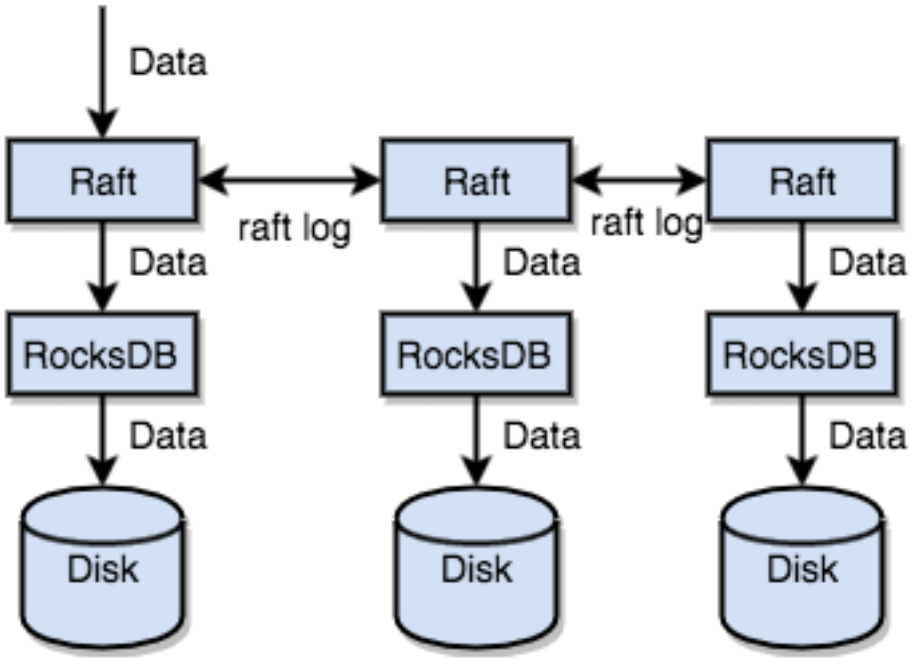

Figure 533: Raft in TiDB

In summary, TiKV can quickly store data on disk via the standalone machine RocksDB, and replicate data to multiple machines via Raft in case of machine failure. Data is written through the interface of Raft instead of to RocksDB. With the implementation of Raft, TiKV becomes a distributed Key-Value storage. Even with a few machine failures, TiKV can automatically complete replicas by virtue of the native Raft protocol, which does not impact the application.

14.1.2.4 Region

To make it easy to understand, let's assume that all data only has one replica. As mentioned earlier, TiKV can be regarded as a large, orderly KV Map, so data is distributed across multiple machines in order to achieve horizontal scalability. For a KV system, there are two typical solutions to distributing data across multiple machines:

- Hash: Create Hash by Key and select the corresponding storage node according to the Hash value.
- Range: Divide ranges by Key, where a segment of serial Key is stored on a node.

TiKV chooses the second solution that divides the whole Key-Value space into a series of consecutive Key segments. Each segment is called a Region. Each Region can be described by `[StartKey, EndKey)`, a left-closed and right-open interval. The default size limit for each Region is 256 MiB and the size can be configured.

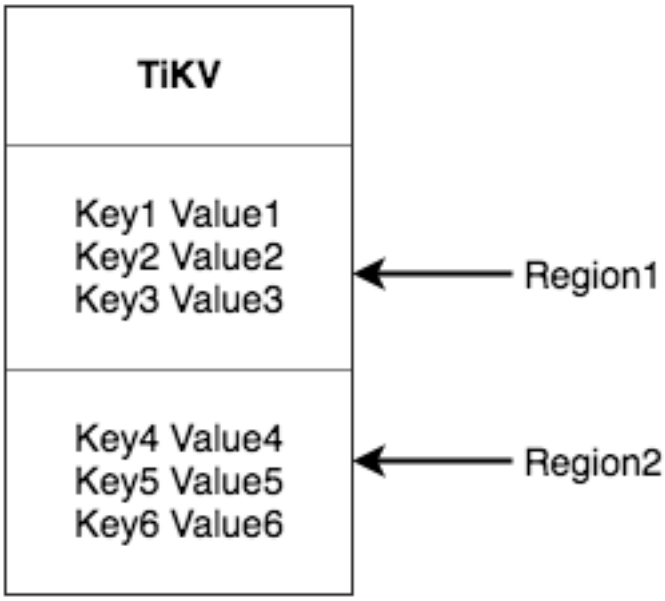

Figure 534: Region in TiDB

Note that the Region here has nothing to do with the table in SQL. In this document, forget about SQL and focus on KV for now. After dividing data into Regions, TiKV will perform two important tasks:

- Distributing data to all nodes in the cluster and use Region as the basic unit. Try its best to ensure that the number of Regions on each node is roughly similar.
- Performing Raft replication and membership management in Region.

These two tasks are very important and will be introduced one by one.

- First, data is divided into many Regions according to Key, and the data for each Region is stored on only one node (ignoring multiple replicas). The TiDB system has a PD component that is responsible for spreading Regions as evenly as possible across all nodes in the cluster. In this way, on one hand, the storage capacity is scaled horizontally (Regions on the other nodes are automatically scheduled to the newly added node); on the other hand, load balancing is achieved (the situation where one node has a lot of data while the others have little will not occur).

  At the same time, in order to ensure that the upper client can access the needed data, there is a component (PD) in the system to record the distribution of Regions on the node, that is, the exact Region of a Key and the node of that Region placed through any Key.

- For the second task, TiKV replicates data in Regions, which means that data in one Region will have multiple replicas with the name "Replica". Multiple Replicas of a

Region are stored on different nodes to form a Raft Group, which is kept consistent through the Raft algorithm.

One of the Replicas serves as the Leader of the Group and other as the Follower. By default, all reads and writes are processed through the Leader, where reads are done and write are replicated to followers. The following diagram shows the whole picture about Region and Raft group.

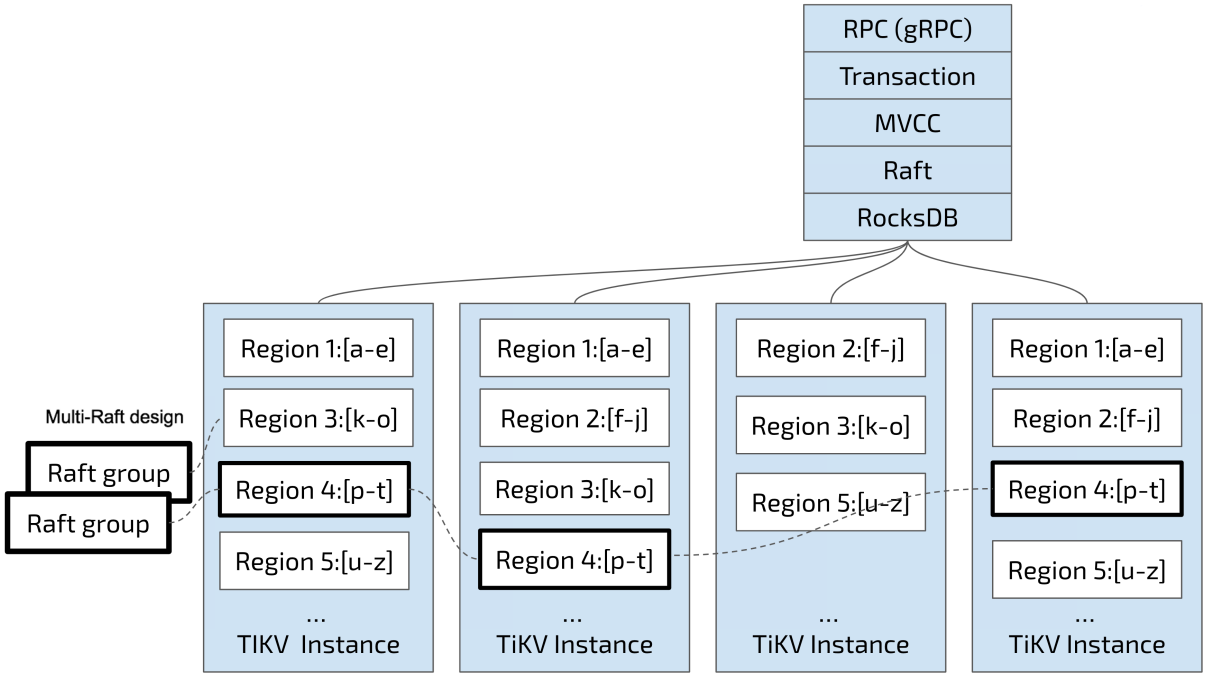

Figure 535: TiDB Storage

As we distribute and replicate data in Regions, we have a distributed Key-Value system that, to some extent, has the capability of disaster recovery. You no longer need to worry about the capacity, or disk failure and data loss.

14.1.2.5 MVCC

TiKV supports multi-version concurrency control (MVCC). Consider a scenario where Client A is writing to a key simultaneously as Client B is reading the same key. Without the MVCC mechanism, these read and write operations would be mutually exclusive, posing performance issues and deadlocks in a distributed scenario. However, With MVCC, as long as Client B performs a read operation at a logical time earlier than the Client A write operation, then Client B can correctly read the original value at the same time Client A performs the write operation. Even if the key is modified multiple times by multiple write operations, Client B can still read the old value according to its logical time.

TiKV MVCC is implemented by appending a version number to the key. Without MVCC, the Key-Value pairs of TiKV are as follows:

```
Key1 -> Value
Key2 -> Value
……
KeyN -> Value
```

With MVCC, the Key-Value pairs of TiKV are as follows:

```
Key1_Version3 -> Value
Key1_Version2 -> Value
Key1_Version1 -> Value
……
Key2_Version4 -> Value
Key2_Version3 -> Value
Key2_Version2 -> Value
Key2_Version1 -> Value
……
KeyN_Version2 -> Value
KeyN_Version1 -> Value
……
```

Note that for multiple versions of the same Key, versions with larger numbers are placed first (see the Key-Value section where Keys are arranged in order), so that when you obtain Value through Key + Version, the Key of MVCC can be constructed with Key and Version, which is `Key_Version`. Then you can directly locate the first position greater than or equal to this `Key_Version` through RocksDB's `SeekPrefix(Key_Version)` API.

14.1.2.6 Distributed ACID transaction

Transaction of TiKV adopts the model used by Google in BigTable: Percolator. TiKV's implementation is inspired by this paper, with a lot of optimizations. See transaction overview for details.

14.1.3 TiDB Computing

Based on the distributed storage provided by TiKV, TiDB builds the computing engine that combines great capability of transactional processing with that of data analysis. This document starts by introducing a data mapping algorithm that maps data from TiDB database tables to (Key, Value) key-value pairs in TiKV, then introduces how TiDB manages metadata, and finally illustrates the architecture of the TiDB SQL layer.

For the storage solution on which the computing layer is dependent, this document only introduces the row-based storage structure of TiKV. For OLAP services, TiDB introduces a column-based storage solution TiFlash as a TiKV extension.

14.1.3.1 Mapping table data to Key-Value

This section describes the scheme for mapping data to (Key, Value) key-value pairs in TiDB. Data to be mapped here includes the following two types:

- Data of each row in the table, hereinafter referred to as table data.
- Data of all indexes in the table, hereinafter referred to as index data.

14.1.3.1.1 Mapping of table data to Key-Value

In a relational database, a table might have many columns. To map the data of each column in a row to a (Key, Value) key-value pair, you need to consider how to construct the Key. First of all, in OLTP scenarios, there are many operations such as adding, deleting, changing, and searching for data on a single or multiple rows, which needs the database to read a row of data quickly. Therefore, each key should have a unique ID (either explicit or implicit) to make it quick to locate. Then, many OLAP queries require a full table scan. If you can encode the keys of all rows in a table into a range, the whole table can be efficiently scanned by range queries.

Based on the considerations above, the mapping of table data to Key-Value in TiDB is designed as follows:

- To ensure that data from the same table is kept together for easy searching, TiDB assigns a table ID to each table represented by `TableID`. Table ID is an integer that is unique throughout the cluster.
- TiDB assigns a row ID, represented by `RowID`, to each row of data in the table. The row ID is also an integer, unique within the table. For row ID, TiDB has made a small optimization: if a table has an integer type primary key, TiDB uses the value of this primary key as the row ID.

Each row of data is encoded as a (Key, Value) key-value pair according to the following rule:

```
Key:   tablePrefix{TableID}_recordPrefixSep{RowID}
Value: [col1, col2, col3, col4]
```

`tablePrefix` and `recordPrefixSep` are both special string constants used to distinguish other data in Key space. The exact values of the string constants are introduced in Summary of mapping relationships.

14.1.3.1.2 Mapping of indexed data to Key-Value

TiDB supports both primary keys and secondary indexes (both unique and non-unique indexes). Similar to the table data mapping scheme, TiDB assigns an index ID to each index of the table represented by `IndexID`.

For primary keys and unique indexes, it is needed to quickly locate the corresponding `RowID` based on the key-value pair, so such a key-value pair is encoded as follows.

```
Key:  tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: RowID
```

For ordinary secondary indexes that do not need to satisfy the uniqueness constraint, a single key might correspond to multiple rows. It needs to query corresponding `RowID` according to the range of keys. Therefore, the key-value pair must be encoded according to the following rule:

```
Key:  tablePrefix{TableID}_indexPrefixSep{IndexID}_indexedColumnsValue_{
    ↪ RowID}
Value: null
```

14.1.3.1.3 Summary of mapping relationships

`tablePrefix`, `recordPrefixSep`, and `indexPrefixSep` in all of the above encoding rules are string constants that are used to distinguish a KV from other data in the Key space, which are defined as follows:

```
tablePrefix   = []byte{'t'}
recordPrefixSep = []byte{'r'}
indexPrefixSep = []byte{'i'}
```

Also note that in the above encoding schemes, no matter table data or index data key encoding scheme, all rows in a table have the same key prefix, and all data of an index also has the same prefix. Data with the same prefixes are thus arranged together in TiKV's key space. Therefore, by carefully designing the encoding scheme of the suffix part to ensure that the pre-encoding and post-encoding comparisons remain the same, the table data or index data can be stored in TiKV in an ordered manner. Using this encoding scheme, all row data in a table is arranged orderly by `RowID` in the TiKV's key space, and the data of a particular index is also arranged sequentially in the key space according to the specific value of the index data (`indexedColumnsValue`).

14.1.3.1.4 Example of Key-Value mapping relationship

This section shows a simple example for you to understand the Key-Value mapping relationship of TiDB. Suppose the following table exists in TiDB.

```
CREATE TABLE User (
    ID int,
    Name varchar(20),
    Role varchar(20),
    Age int,
    PRIMARY KEY (ID),
    KEY idxAge (Age)
);
```

Suppose there are 3 rows of data in the table.

```
1, "TiDB", "SQL Layer", 10
2, "TiKV", "KV Engine", 20
3, "PD", "Manager", 30
```

Each row of data is mapped to a (Key, Value) key-value pair, and the table has an `int` type primary key, so the value of `RowID` is the value of this primary key. Suppose the table's `TableID` is `10`, and then its table data stored on TiKV is:

```
t10_r1 --> ["TiDB", "SQL Layer", 10]
t10_r2 --> ["TiKV", "KV Engine", 20]
t10_r3 --> ["PD", " Manager", 30]
```

In addition to the primary key, the table has a non-unique ordinary secondary index, `idxAge`. Suppose the `IndexID` is `1`, and then its index data stored on TiKV is:

```
t10_i1_10_1 --> null
t10_i1_20_2 --> null
t10_i1_30_3 --> null
```

The above example shows the mapping rule from a relational model to a Key-Value model in TiDB, and the consideration behind this mapping scheme.

14.1.3.2 Metadata management

Each database and table in TiDB has metadata that indicates its definition and various attributes. This information also needs to be persisted, and TiDB stores this information in TiKV as well.

Each database or table is assigned a unique ID. As the unique identifier, when table data is encoded to Key-Value, this ID is encoded in the Key with the `m_` prefix. This constructs a key-value pair with the serialized metadata stored in it.

In addition, TiDB also uses a dedicated (Key, Value) key-value pair to store the latest version number of structure information of all tables. This key-value pair is global, and its version number is increased by `1` each time the state of the DDL operation changes. TiDB stores this key-value pair persistently in the PD server with the key of `/tidb/ddl/global_schema_version`, and Value is the version number value of the `int64` type. Meanwhile, because TiDB applies schema changes online, it keeps a background thread that constantly checks whether the version number of the table structure information stored in the PD server changes. This thread also ensures that the changes of version can be obtained within a certain period of time.

14.1.3.3 SQL layer overview

TiDB's SQL layer, TiDB Server, translates SQL statements into Key-Value operations, forwards the operations to TiKV, the distributed Key-Value storage layer, assembles the results returned by TiKV, and finally returns the query results to the client.

The nodes at this layer are stateless. These nodes themselves do not store data and are completely equivalent.

14.1.3.3.1 SQL computing

The simplest solution to SQL computing is the mapping of table data to Key-Value as described in the previous section, which maps SQL queries to KV queries, acquires the corresponding data through the KV interface, and performs various computations.

For example, to execute the `select count(*)from user where name = "TiDB"` SQL statement, TiDB needs to read all data in the table, then checks whether the `name` field is `TiDB`, and if so, returns this row. The process is as follows:

1. Construct the Key Range: all `RowID` in a table are in `[0, MaxInt64)` range. According to the row data `Key` encoding rule, using `0` and `MaxInt64` can construct a `[StartKey ↪ , EndKey)` range that is left-closed and right-open.
2. Scan Key Range: read the data in TiKV according to the key range constructed above.
3. Filter data: for each row of data read, calculate the `name = "TiDB"` expression. If the result is `true`, return to this row. If not, skip this row.
4. Calculate `Count(*)`: for each row that meets the requirements, add up to the result of `Count(*)`.

The entire process is illustrated as follows:

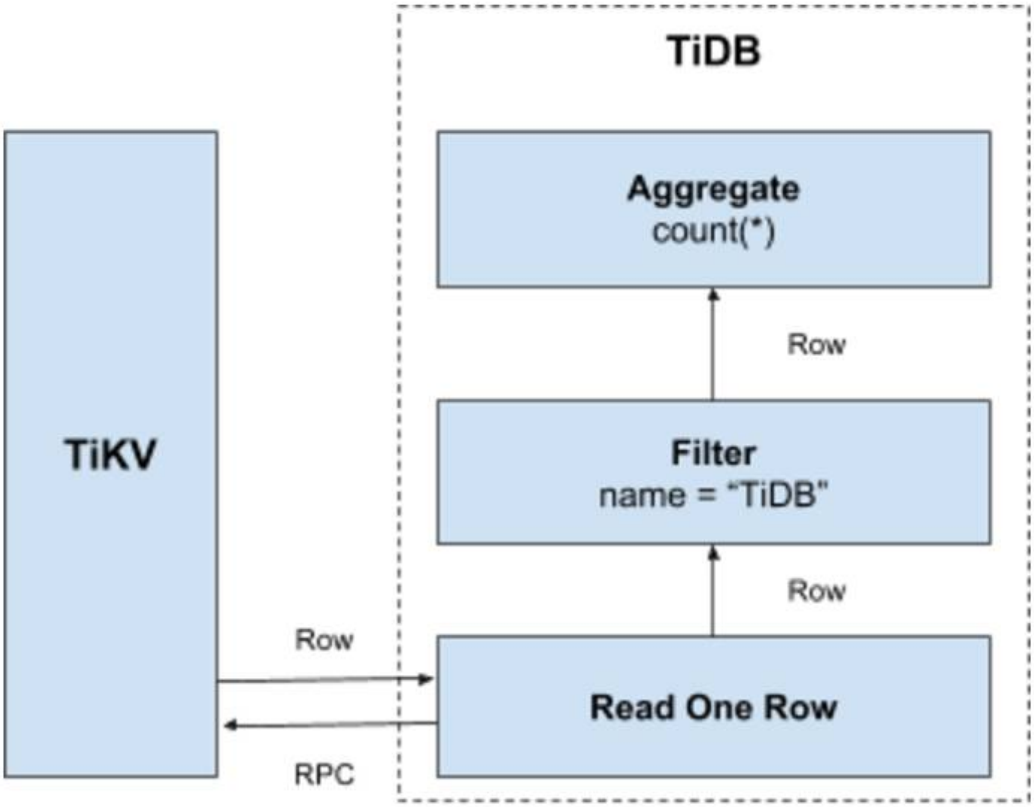

Figure 536: naive sql flow

This solution is intuitive and feasible, but has some obvious problems in a distributed database scenario:

- As the data is being scanned, each row is read from TiKV via a KV operation with at least one RPC overhead, which can be very high if there is a large amount of data to be scanned.
- It is not applicable to all rows. Data that does not meet the conditions does not need to be read.
- From the returned result of this query, only the number of rows that match the requirements is needed, not the value of those rows.

14.1.3.3.2 Distributed SQL operations

To solve the problems above, the computation should be as close to the storage node as possible to avoid a large number of RPC callings. First of all, the SQL predicate condition `name = "TiDB"` should be pushed down to the storage node for computation, so that only valid rows are returned, which avoids meaningless network transfers. Then, the aggregation

function `Count(*)` can also be pushed down to the storage nodes for pre-aggregation, and each node only has to return a result of `Count(*)`. The SQL layer will sum up the `Count(*)` results returned by each node.

The following image shows how data returns layer by layer:

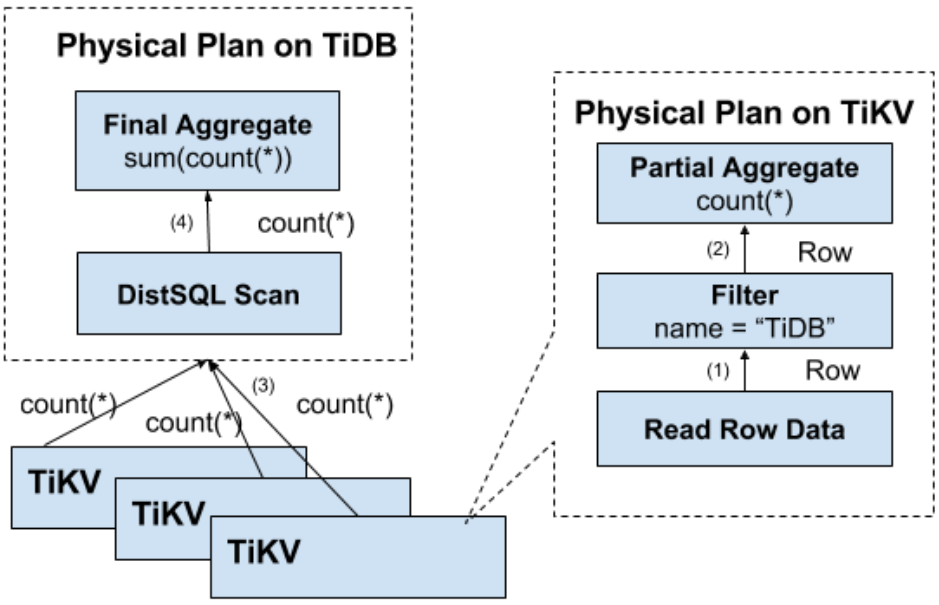

Figure 537: dist sql flow

14.1.3.3.3 Architecture of SQL layer

The previous sections introduce some functions of the SQL layer and I hope you have a basic understanding of how SQL statements are handled. In fact, TiDB's SQL layer is much more complicated, with many modules and layers. The following diagram lists the important modules and calling relationships:

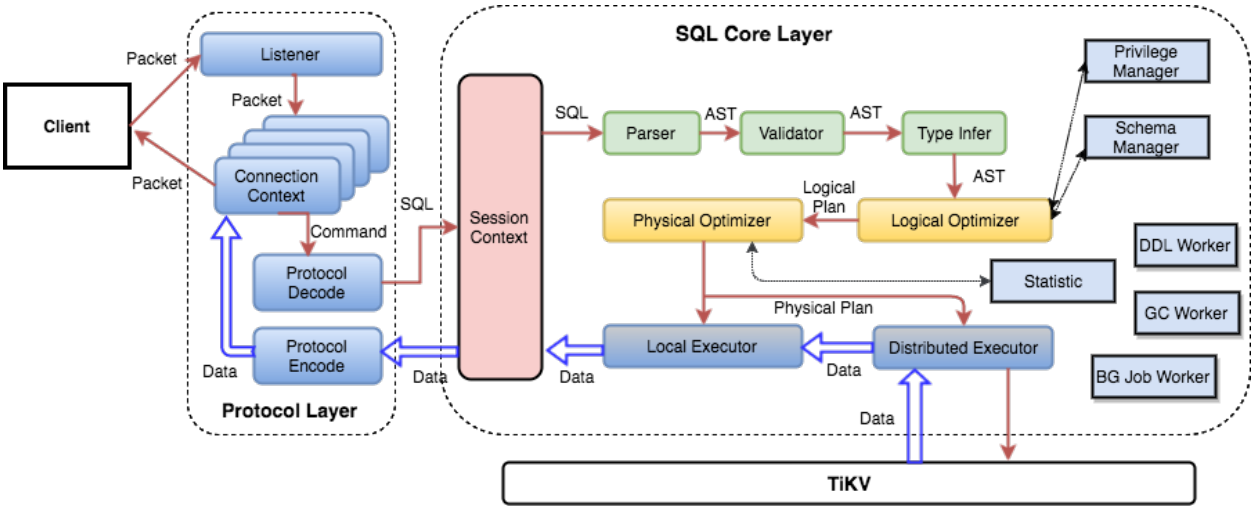

Figure 538: tidb sql layer

The user's SQL request is sent to TiDB Server either directly or via `Load Balancer`. TiDB Server will parse `MySQL Protocol Packet`, get the content of requests, parse the SQL request syntactically and semantically, develop and optimize query plans, execute a query plan, get and process the data. All data is stored in the TiKV cluster, so in this process, TiDB Server needs to interact with TiKV and get the data. Finally, TiDB Server needs to return the query results to the user.

14.1.4 TiDB Scheduling

The Placement Driver (PD) works as the manager in a TiDB cluster, and it also schedules Regions in the cluster. This article introduces the design and core concepts of the PD scheduling component.

14.1.4.1 Scheduling situations

TiKV is the distributed key-value storage engine used by TiDB. In TiKV, data is organized as Regions, which are replicated on several stores. In all replicas, a leader is responsible for reading and writing, and followers are responsible for replicating Raft logs from the leader.

Now consider about the following situations:

- To utilize storage space in a high-efficient way, multiple Replicas of the same Region need to be properly distributed on different nodes according to the Region size;
- For multiple data center topologies, one data center failure only causes one replica to fail for all Regions;
- When a new TiKV store is added, data can be rebalanced to it;
- When a TiKV store fails, PD needs to consider:

    - Recovery time of the failed store.
        - If it's short (for example, the service is restarted), whether scheduling is necessary or not.
        - If it's long (for example, disk fault and data is lost), how to do scheduling.
    - Replicas of all Regions.
        - If the number of replicas is not enough for some Regions, PD needs to complete them.
        - If the number of replicas is more than expected (for example, the failed store re-joins into the cluster after recovery), PD needs to delete them.
- Read/Write operations are performed on leaders, which cannot be distributed only on a few individual stores;
- Not all Regions are hot, so loads of all TiKV stores need to be balanced;
- When Regions are in balancing, data transferring utilizes much network/disk traffic and CPU time, which can influence online services.

These situations can occur at the same time, which makes it harder to resolve. Also, the whole system is changing dynamically, so a scheduler is needed to collect all information about the cluster, and then adjust the cluster. So, PD is introduced into the TiDB cluster.

14.1.4.2 Scheduling requirements

The above situations can be classified into two types:

1. A distributed and highly available storage system must meet the following requirements:

    - The right number of replicas.
    - Replicas need to be distributed on different machines according to different topologies.
    - The cluster can perform automatic disaster recovery from TiKV peers' failure.

2. A good distributed system needs to have the following optimizations:

    - All Region leaders are distributed evenly on stores;
    - Storage capacity of all TiKV peers are balanced;
    - Hot spots are balanced;
    - Speed of load balancing for the Regions needs to be limited to ensure that online services are stable;
    - Maintainers are able to take peers online/offline manually.

After the first type of requirements is satisfied, the system will be failure tolerable. After the second type of requirements is satisfied, resources will be utilized more efficiently and the system will have better scalability.

To achieve the goals, PD needs to collect information firstly, such as state of peers, information about Raft groups and the statistics of accessing the peers. Then we need to specify some strategies for PD, so that PD can make scheduling plans from these information and strategies. Finally, PD distributes some operators to TiKV peers to complete scheduling plans.

14.1.4.3 Basic scheduling operators

All scheduling plans contain three basic operators:

- Add a new replica
- Remove a replica
- Transfer a Region leader between replicas in a Raft group

They are implemented by the Raft commands `AddReplica`, `RemoveReplica`, and `TransferLeader`.

14.1.4.4 Information collection

Scheduling is based on information collection. In short, the PD scheduling component needs to know the states of all TiKV peers and all Regions. TiKV peers report the following information to PD:

- State information reported by each TiKV peer:

  Each TiKV peer sends heartbeats to PD periodically. PD not only checks whether the store is alive, but also collects `StoreState` in the heartbeat message. `StoreState` includes:

  - Total disk space
  - Available disk space
  - The number of Regions
  - Data read/write speed
  - The number of snapshots that are sent/received (The data might be replicated between replicas through snapshots)
  - Whether the store is overloaded
  - Labels (See Perception of Topology)

  You can use PD control to check the status of a TiKV store, which can be Up, Disconnect, Offline, Down, or Tombstone. The following is a description of all statuses and their relationship.

  - **Up**: The TiKV store is in service.
  - **Disconnect**: Heartbeat messages between the PD and the TiKV store are lost for more than 20 seconds. If the lost period exceeds the time specified by `max-store-down-time`, the status "Disconnect" changes to "Down".

- **Down**: Heartbeat messages between the PD and the TiKV store are lost for a time longer than `max-store-down-time` (30 minutes by default). In this status, the TiKV store starts replenishing replicas of each Region on the surviving store.
- **Offline**: A TiKV store is manually taken offline through PD Control. This is only an intermediate status for the store to go offline. The store in this status moves all its Regions to other "Up" stores that meet the relocation conditions. When `leader_count` and `region_count` (obtained through PD Control) both show `0`, the store status changes to "Tombstone" from "Offline". In the "Offline" status, **do not** disable the store service or the physical server where the store is located. During the process that the store goes offline, if the cluster does not have target stores to relocate the Regions (for example, inadequate stores to hold replicas in the cluster), the store is always in the "Offline" status.
- **Tombstone**: The TiKV store is completely offline. You can use the `remove-tombstone` interface to safely clean up TiKV in this status.

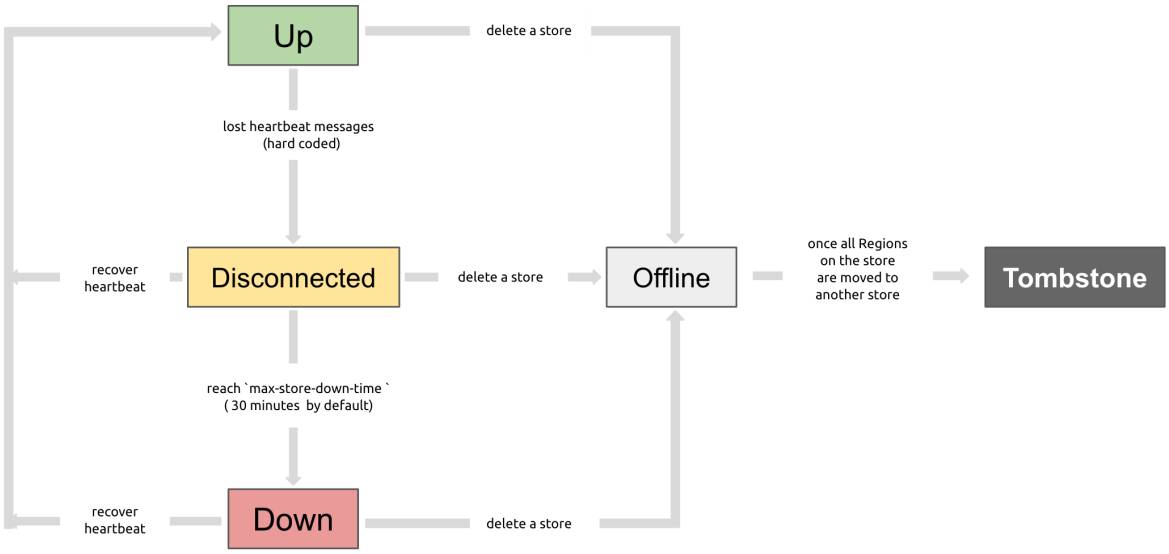

Figure 539: TiKV store status relationship

- Information reported by Region leaders:

  Each Region leader sends heartbeats to PD periodically to report `RegionState`, including:

  - Position of the leader itself
  - Positions of other replicas
  - The number of offline replicas

- data read/write speed

PD collects cluster information by the two types of heartbeats and then makes decision based on it.

Besides, PD can get more information from an expanded interface to make a more precise decision. For example, if a store's heartbeats are broken, PD can't know whether the peer steps down temporarily or forever. It just waits a while (by default 30min) and then treats the store as offline if there are still no heartbeats received. Then PD balances all regions on the store to other stores.

But sometimes stores are manually set offline by a maintainer, so the maintainer can tell PD this by the PD control interface. Then PD can balance all regions immediately.

14.1.4.5 Scheduling strategies

After collecting the information, PD needs some strategies to make scheduling plans.

Strategy 1: The number of replicas of a Region needs to be correct

PD can know that the replica count of a Region is incorrect from the Region leader's heartbeat. If it happens, PD can adjust the replica count by adding/removing replica(s). The reason for incorrect replica count can be:

- Store failure, so some Region's replica count is less than expected;
- Store recovery after failure, so some Region's replica count could be more than expected;
- `max-replicas` is changed.

Strategy 2: Replicas of a Region need to be at different positions

Note that here "position" is different from "machine". Generally PD can only ensure that replicas of a Region are not at a same peer to avoid that the peer's failure causes more than one replicas to become lost. However in production, you might have the following requirements:

- Multiple TiKV peers are on one machine;
- TiKV peers are on multiple racks, and the system is expected to be available even if a rack fails;
- TiKV peers are in multiple data centers, and the system is expected to be available even if a data center fails;

The key to these requirements is that peers can have the same "position", which is the smallest unit for failure toleration. Replicas of a Region must not be in one unit. So, we can configure labels for the TiKV peers, and set location-labels on PD to specify which labels are used for marking positions.

Strategy 3: Replicas need to be balanced between stores

The size limit of a Region replica is fixed, so keeping the replicas balanced between stores is helpful for data size balance.

Strategy 4: Leaders need to be balanced between stores

Read and write operations are performed on leaders according to the Raft protocol, so that PD needs to distribute leaders into the whole cluster instead of several peers.

Strategy 5: Hot spots need to be balanced between stores

PD can detect hot spots from store heartbeats and Region heartbeats, so that PD can distribute hot spots.

Strategy 6: Storage size needs to be balanced between stores

When started up, a TiKV store reports `capacity` of storage, which indicates the store's space limit. PD will consider this when scheduling.

Strategy 7: Adjust scheduling speed to stabilize online services

Scheduling utilizes CPU, memory, network and I/O traffic. Too much resource utilization will influence online services. Therefore, PD needs to limit the number of the concurrent scheduling tasks. By default this strategy is conservative, while it can be changed if quicker scheduling is required.

14.1.4.6 Scheduling implementation

PD collects cluster information from store heartbeats and Region heartbeats, and then makes scheduling plans from the information and strategies. Scheduling plans are a sequence of basic operators. Every time PD receives a Region heartbeat from a Region leader, it checks whether there is a pending operator on the Region or not. If PD needs to dispatch a new operator to a Region, it puts the operator into heartbeat responses, and monitors the operator by checking follow-up Region heartbeats.

Note that here "operators" are only suggestions to the Region leader, which can be skipped by Regions. Leader of Regions can decide whether to skip a scheduling operator or not based on its current status.

14.1.5 TimeStamp Oracle (TSO) in TiDB

In TiDB, the Placement Driver (PD) plays a pivotal role in allocating timestamps to various components within a cluster. These timestamps are instrumental in the assignment of temporal markers to transactions and data, a mechanism crucial for enabling the Percolator model within TiDB. The Percolator model is used to support Multi-Version Concurrency Control (MVCC) and transaction management.

The following example shows how to get the current TSO in TiDB:

```
BEGIN; SET @ts := @@tidb_current_ts; ROLLBACK;
Query OK, 0 rows affected (0.0007 sec)
```

```
Query OK, 0 rows affected (0.0002 sec)
Query OK, 0 rows affected (0.0001 sec)

SELECT @ts;
+--------------------+
| @ts                |
+--------------------+
| 443852055297916932 |
+--------------------+
1 row in set (0.00 sec)
```

Note that this is done in a transaction with `BEGIN; ...; ROLLBACK` because TSO timestamps are assigned per transaction.

The TSO timestamp you get from the preceding example is a decimal number. You can use the following SQL functions to parse the timestamp:

- TIDB_PARSE_TSO()
- TIDB_PARSE_TSO_LOGICAL()

```
SELECT TIDB_PARSE_TSO(443852055297916932);
+-----------------------------------+
| TIDB_PARSE_TSO(443852055297916932) |
+-----------------------------------+
| 2023-08-27 20:33:41.687000     |
+-----------------------------------+
1 row in set (0.00 sec)
```

```
SELECT TIDB_PARSE_TSO_LOGICAL(443852055297916932);
+-----------------------------------------+
| TIDB_PARSE_TSO_LOGICAL(443852055297916932) |
+-----------------------------------------+
|                                       4 |
+-----------------------------------------+
1 row in set (0.00 sec)
```

The following example shows what a TSO timestamp looks like in binary:

```
00000110001010001110000100010111101110001101110000000000000100 ← This is
    ↪ 443852055297916932 in binary
00000110001010001110000100010111101110001101110            ← The first 46
    ↪ bits are the physical timestamp
                                          00000000000000100 ← The last 18
                                             ↪ bits are the logical
                                             ↪ timestamp
```

There are two parts in a TSO timestamp:

- The physical timestamp: a UNIX timestamp in milliseconds since 1 January 1970.
- The logical timestamp: an incrementing counter, used in scenarios requiring multiple timestamps within the same millisecond, or in cases where certain events might trigger a reversal of the clock's progression. In such cases, the physical timestamp remains unchanged while the logical timestamp steadily advances. This mechanism ensures the integrity of the TSO timestamp, which always moves forward and never regresses.

With this knowledge, you can inspect the TSO timestamp a bit more in SQL:

```
SELECT @ts, UNIX_TIMESTAMP(NOW(6)), (@ts >> 18)/1000, FROM_UNIXTIME((@ts >>
    ↪ 18)/1000), NOW(6), @ts & 0x3FFFF\G
*************************** 1. row ***************************
                        @ts: 443852055297916932
        UNIX_TIMESTAMP(NOW(6)): 1693161835.502954
             (@ts >> 18)/1000: 1693161221.6870
FROM_UNIXTIME((@ts >> 18)/1000): 2023-08-27 20:33:41.6870
                      NOW(6): 2023-08-27 20:43:55.502954
                 @ts & 0x3FFFF: 4
1 row in set (0.00 sec)
```

The `>> 18` operation signifies a bitwise right shift by 18 bits, which is used to extract the physical timestamp. Because the physical timestamp is expressed in milliseconds, deviating from the more common UNIX timestamp format measured in seconds, you need to divide it by 1000 to convert it into a format compatible with `FROM_UNIXTIME()`. This process aligns with the functionality of `TIDB_PARSE_TSO()`.

You can also extract the logical timestamp `000000000000000100` in binary, which is equivalent to `4` in decimal.

You can also parse the timestamp via the CLI tool as follows:

```
$ tiup ctl:v7.1.0 pd tso 443852055297916932
```

```
system: 2023-08-27 20:33:41.687 +0200 CEST
logic:  4
```

Here you can see the physical timestamp in the line that starts with `system:` and the logical timestamp in the line that starts with `logic:`.

14.2 Storage Engine - TiKV

14.2.1 TiKV Overview

TiKV is a distributed and transactional key-value database, which provides transactional APIs with ACID compliance. With the implementation of the Raft consensus algorithm and

consensus state stored in RocksDB, TiKV guarantees data consistency between multiple replicas and high availability. As the storage layer of the TiDB distributed database, TiKV provides the read and write service, and persist the written data from applications. It also stores the statistics data of the TiDB cluster.

14.2.1.1 Architecture Overview

TiKV implements the multi-raft-group replica mechanism based on the design of Google Spanner. A Region is a basic unit of the key-value data movement and refers to a data range in a Store. Each Region is replicated to multiple nodes. These multiple replicas form a Raft group. A replica of a Region is called a Peer. Typically there are 3 peers in a Region. One of them is the leader, which provides the read and write services. The PD component balances all the Regions automatically to guarantee that the read and write throughput is balanced among all the nodes in the TiKV cluster. With PD and carefully designed Raft groups, TiKV excels in horizontal scalability and can easily scale to store more than 100 TBs of data.

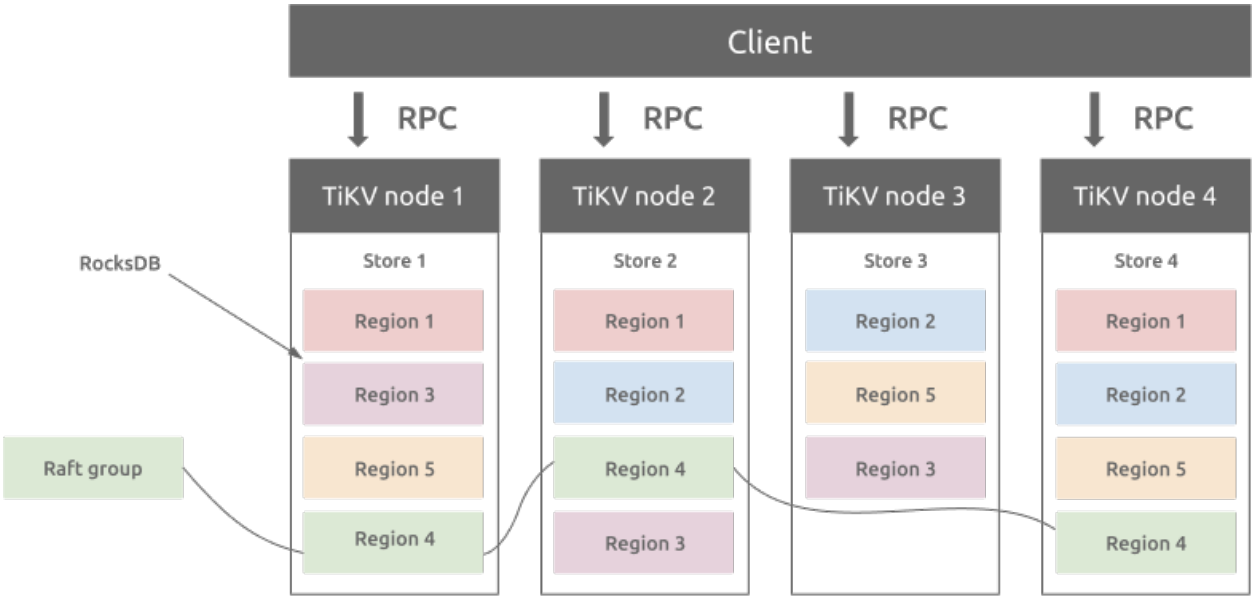

Figure 540: TiKV Architecture

14.2.1.1.1 Region and RocksDB

There is a RocksDB database within each Store and it stores data into the local disk. All the Region data are stored in the same RocksDB instance in each Store. All the logs used for the Raft consensus algorithm is stored in another RocksDB instance in each Store. This is because the performance of sequential I/O is better than random I/O. With different RocksDB instances storing raft logs and Region data, TiKV combines all the data write operations of raft logs and TiKV Regions into one I/O operation to improve the performance.

14.2.1.1.2 Region and Raft Consensus Algorithm

Data consistency between replicas of a Region is guaranteed by the Raft Consensus Algorithm. Only the leader of the Region can provide the writing service, and only when the data is written to the majority of replicas of a Region, the write operation succeeds.

TiKV tries to keep an appropriate size for each Region in the cluster. The Region size is currently 256 MiB by default. This mechanism helps the PD component to balance Regions among nodes in a TiKV cluster. When the size of a Region exceeds a threshold (384 MiB by default), TiKV splits it into two or more Regions. When the size of a Region is smaller than the threshold (54 MiB by default), TiKV merges the two smaller adjacent Regions into one Region.

When PD moves a replica from one TiKV node to another, it firstly adds a Learner replica on the target node, after the data in the Learner replica is nearly the same as that in the Leader replica, PD changes it to a Follower replica and removes the Follower replica on the source node.

Moving Leader replica from one node to another has a similar mechanism. The difference is that after the Learner replica becomes the Follower replica, there is a "Leader Transfer" operation in which the Follower replica actively proposes an election to elect itself as the Leader. Finally, the new Leader removes the old Leader replica in the source node.

14.2.1.2 Distributed Transaction

TiKV supports distributed transactions. Users (or TiDB) can write multiple key-value pairs without worrying about whether they belong to the same Region. TiKV uses two-phase commit to achieve ACID constraints. See TiDB Optimistic Transaction Model for details.

14.2.1.3 TiKV Coprocessor

TiDB pushes some data computation logic to TiKV Coprocessor. TiKV Coprocessor processes the computation for each Region. Each request sent to TiKV Coprocessor only involves the data of one Region.

14.2.2 RocksDB Overview

RocksDB is an LSM-tree storage engine that provides key-value store and read-write functions. It is developed by Facebook and based on LevelDB. Key-value pairs written by the user are firstly inserted into Write Ahead Log (WAL) and then written to the SkipList in memory (a data structure called MemTable). LSM-tree engines convert the random modification (insertion) to sequential writes to the WAL file, so they provide better write throughput than B-tree engines.

Once the data in memory reaches a certain size, RocksDB flushes the content into a Sorted String Table (SST) file in the disk. SST files are organized in multiple levels (the default is up to 6 levels). When the total size of a level reaches the threshold, RocksDB

chooses part of the SST files and merges them into the next level. Each subsequent level is 10 times larger than the previous one, so 90% of the data is stored in the last layer.

RocksDB allows users to create multiple Column Families (CFs). CFs have their own SkipList and SST files, and they share the same WAL file. In this way, different CFs can have different settings according to the application characteristics. It does not increase the number of writes to WAL at the same time.

14.2.2.1 TiKV architecture

The architecture of TiKV is illustrated as follows:

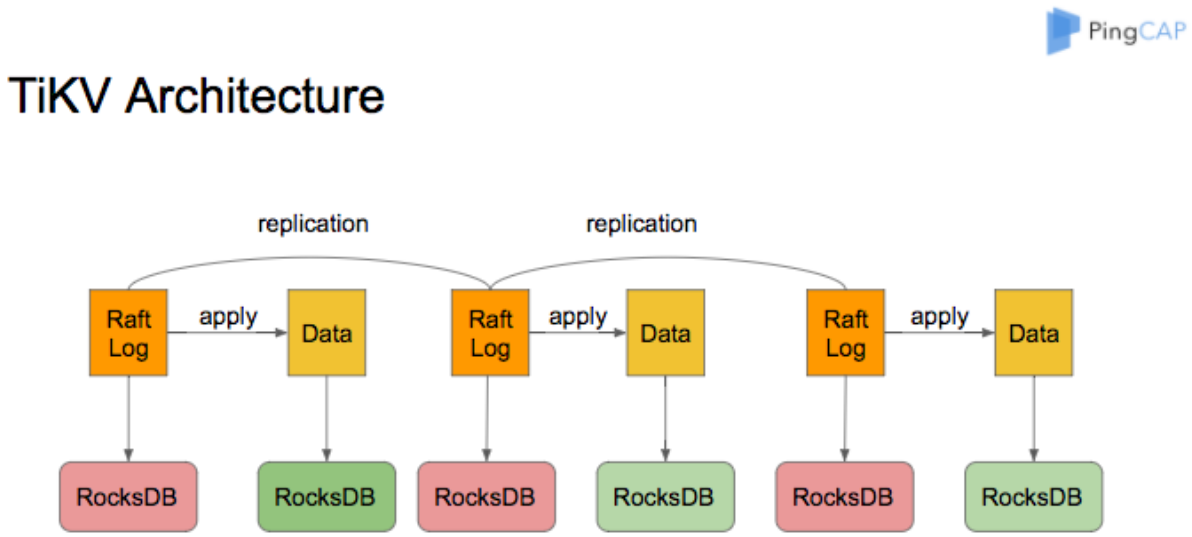

Figure 541: TiKV RocksDB

As the storage engine of TiKV, RocksDB is used to store Raft logs and user data. All data in a TiKV node shares two RocksDB instances. One is for Raft log (often called raftdb), and the other is for user data and MVCC metadata (often called kvdb). There are four CFs in kvdb: raft, lock, default, and write:

- raft CF: Store metadata of each Region. It occupies only a very small amount of space, and users do not need to care.
- lock CF: Store the pessimistic lock of pessimistic transactions and the Prewrite lock for distributed transactions. After the transaction is committed, the corresponding data in lock CF is deleted quickly. Therefore, the size of data in lock CF is usually very small (less than 1 GB). If the data in lock CF increases a lot, it means that a large number of transactions are waiting to be committed, and that the system meets a bug or failure.

- write CF: Store the user's real written data and MVCC metadata (the start timestamp and commit timestamp of the transaction to which the data belongs). When the user writes a row of data, it is stored in the write CF if the data length is less than 255 bytes. Otherwise, it is stored in the default CF. In TiDB, the secondary index only occupies the space of write CF, since the value stored in the non-unique index is empty and the value stored in the unique index is the primary key index.
- default CF: Store data longer than 255 bytes.

14.2.2.2 RocksDB memory usage

To improve the reading performance and reduce the reading operations to the disk, RocksDB divides the files stored on the disk into blocks based on a certain size (the default is 64 KB). When reading a block, it first checks if the data already exists in BlockCache in memory. If true, it can read the data directly from memory without accessing the disk.

BlockCache discards the least recently used data according to the LRU algorithm. By default, TiKV devotes 45% of the system memory to BlockCache. Users can also modify the `storage.block-cache.capacity` configuration to an appropriate value by themselves. However, it is not recommended to exceed 60% of the total system memory.

The data written to RocksDB is written to MemTable firstly. When the size of a MemTable exceeds 128 MB, it switches to a new MemTable. There are 2 RocksDB instances in TiKV, a total of 4 CFs. The size limit of a single MemTable for each CF is 128 MB. A maximum of 5 MemTables can exist at the same time; otherwise, the foreground writes is blocked. The memory occupied by this part is at most 2.5 GB (4 x 5 x 128 MB). It is not recommended to change this limit since it costs less memory.

14.2.2.3 RocksDB space usage

- Multi-version: As RocksDB is a key-value storage engine with LSM-tree structure, the data in MemTable is flushed to L0 first. Because the file is arranged in the order of which they are generated, there might be overlap between the ranges of SSTs at the L0. As a result, the same key might have multiple versions in L0. When a file is merged from L0 to L1, it is cut into multiple files in a certain size (the default is 8 MB). The key range of each file on the same level does not overlap with each other, so there is only one version for each key on L1 and subsequent levels.
- Space amplification: The total size of files on each level is x (the default is 10) times that of the previous level, so 90% of the data is stored in the last level. It also means that the space amplification of RocksDB does not exceed 1.11 (L0 has fewer data and can be ignored).
- Space amplification of TiKV: TiKV has it's own MVCC strategy. When a user writes a key, the real data written to RocksDB is key + commit_ts, that is to say, the update and deletion also write a new key to RocksDB. TiKV deletes the old version of the data (through the Delete interface of RocksDB) at intervals, so it can be considered that the actual space of the data stored by the user on TiKV is enlarged to 1.11 plus

the data written in the last 10 minutes (assuming that TiKV cleans up the old data promptly).

14.2.2.4 RocksDB background threads and compaction

In RocksDB, operations such as converting the MemTable into SST files and merging SST files at various levels are performed in the background thread pool. The default size of the background thread pool is 8. When the number of CPUs in the machine is less than or equal to 8, the default size of the background thread pool is the number of CPUs minus one.

Generally speaking, users do not need to change this configuration. If the user deploys multiple TiKV instances on a machine, or the machine has a relatively high read load and a low write load, you can adjust the `rocksdb/max-background-jobs` to 3 or 4 as appropriate.

14.2.2.5 WriteStall

The L0 of RocksDB is different from other levels. The SSTs of L0 are arranged in the order of generation. The key ranges between the SSTs can overlap. Therefore, each SST in L0 must be queried in turn when a query is performed. In order not to affect query performance, WriteStall is triggered to block writing when there are too many files in L0.

When encountering a sudden sharp increase in write delay, you can first check the **WriteStall Reason** metric on the Grafana RocksDB KV panel. If it is a WriteStall caused by too many L0 files, you can adjust the following configurations to 64.

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

14.2.3 Titan Overview

Titan is a high-performance RocksDB plugin for key-value separation. Titan can reduce write amplification in RocksDB when large values are used.

When the value size in Key-Value pairs is large (larger than 1 KB or 512 B), Titan performs better than RocksDB in write, update, and point read scenarios. However, Titan gets a higher write performance by sacrificing storage space and range query performance. As the price of SSDs continues to decrease, this trade-off will be more and more meaningful.

14.2.3.1 Key features

- Reduce write amplification by separating values from the log-structured merge-tree (LSM-tree) and storing them independently.

- Seamlessly upgrade RocksDB instances to Titan. The upgrade does not require human intervention and does not impact online services.
- Achieve 100% compatibility with all RocksDB features used by the current TiKV.

14.2.3.2 Usage scenarios

Titan is suitable for the scenarios where a huge volume of data is written to the TiKV foreground:

- RocksDB triggers a large amount of compactions, which consumes a lot of I/O bandwidth or CPU resources. This causes poor read and write performance of the foreground.
- The RocksDB compaction lags much behind (due to the I/O bandwidth limit or CPU bottleneck) and frequently causes write stalls.
- RocksDB triggers a large amount of compactions, which causes a lot of I/O writes and affects the life of the SSD disk.

14.2.3.3 Prerequisites

The prerequisites for enabling Titan are as follows:

- The average size of values is large, or the size of all large values accounts for much of the total value size. Currently, the size of a value greater than 1 KB is considered as a large value. In some situations, this number (1 KB) can be 512 B. Note that a single value written to TiKV cannot exceed 8 MB due to the limitation of the TiKV Raft layer. You can adjust the `raft-entry-max-size` configuration value to relax the limit.
- No range query will be performed or you do not need a high performance of range query. Because the data stored in Titan is not well-ordered, its performance of range query is poorer than that of RocksDB, especially for the query of a large range. According PingCAP's internal test, Titan's range query performance is 40% to a few times lower than that of RocksDB.
- Sufficient disk space (consider reserving a space twice of the RocksDB disk consumption with the same data volume). This is because Titan reduces write amplification at the cost of disk space. In addition, Titan compresses values one by one, and its compression rate is lower than that of RocksDB. RocksDB compresses blocks one by one. Therefore, Titan consumes more storage space than RocksDB, which is expected and normal. In some situations, Titan's storage consumption can be twice that of RocksDB.

Starting from v7.6.0, Titan is enabled by default for newly created clusters. Because small TiKV values remain stored in RocksDB, you can enable Titan in this scenario as well.

If you want to improve the performance of Titan, see the blog post Titan: A RocksDB Plugin to Reduce Write Amplification.

14.2.3.4 Architecture and implementation

The following figure shows the architecture of Titan:

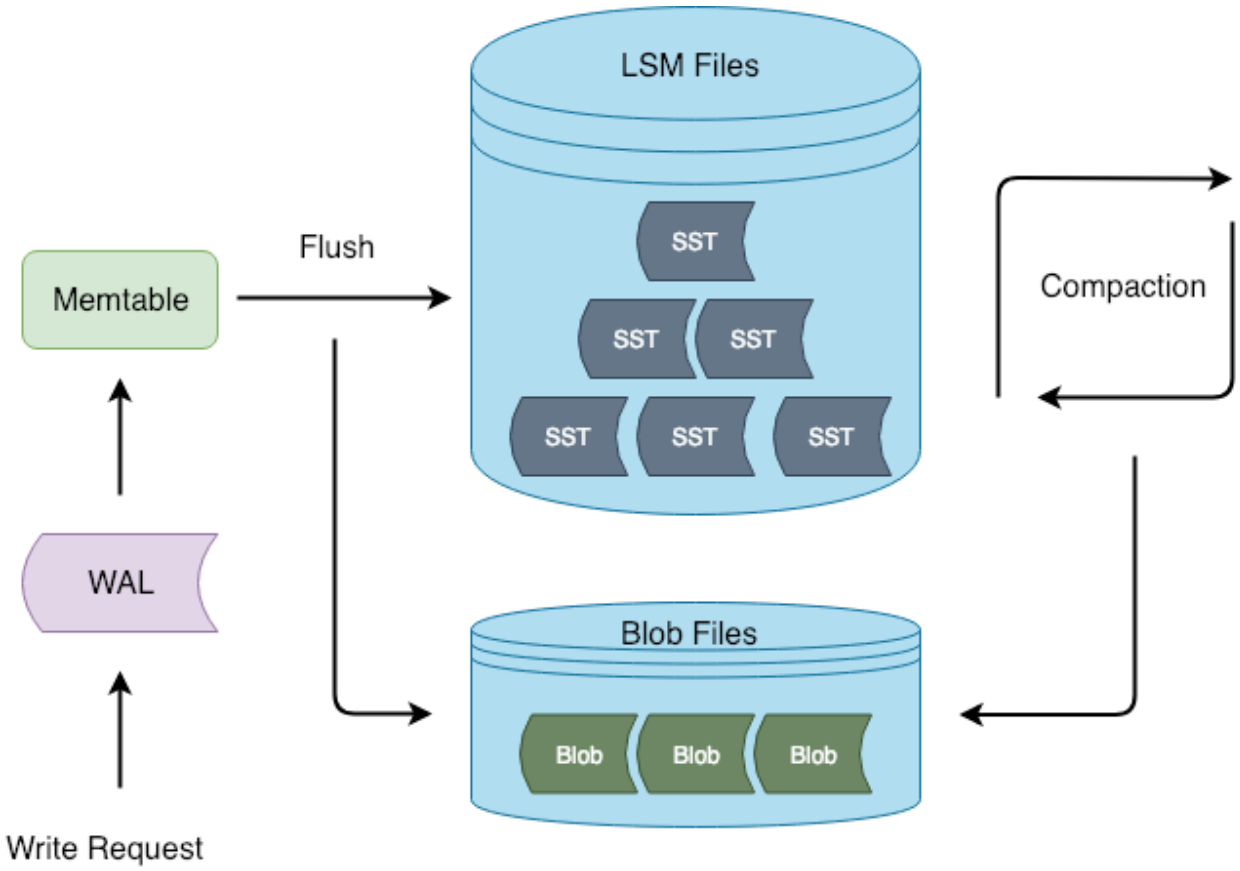

Figure 542: Titan Architecture

During flush and compaction operations, Titan separates values from the LSM-tree. The advantage of this approach is that the write process is consistent with RocksDB, which reduces the chance of invasive changes to RocksDB.

14.2.3.4.1 BlobFile

When Titan separates the value file from the LSM-tree, it stores the value file in the BlobFile. The following figure shows the BlobFile format:

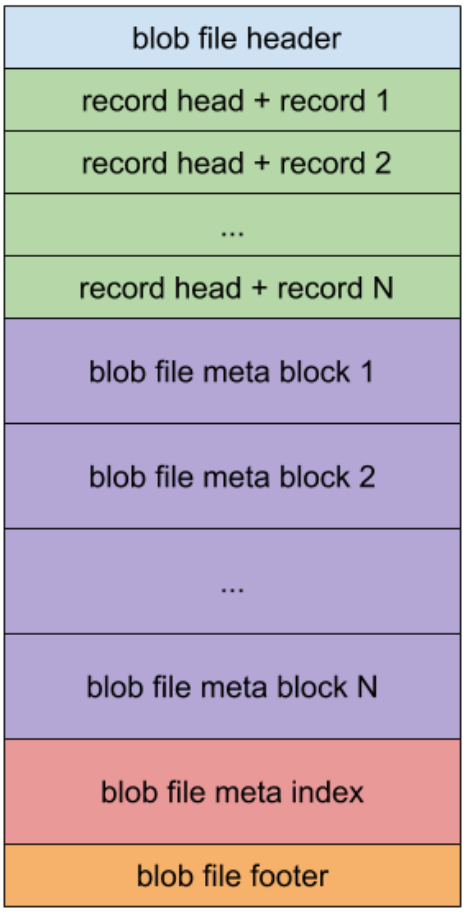

Figure 543: BlobFile Format

A blob file mainly consists of blob records, meta blocks, a meta index block, and a footer. Each block record stores a Key-Value pair. The meta blocks are used for scalability, and store properties related to the blob file. The meta index block is used for meta block searching.

Note:

- The Key-Value pairs in the blob file are stored in order, so that when the Iterator is implemented, the sequential reading performance can be improved via prefetching.
- Each blob record keeps a copy of the user key corresponding to the value. This way, when Titan performs Garbage Collection (GC), it can query the user key and identify whether the corresponding value is outdated. However, this process introduces some write amplification.

- BlobFile supports compression at the blob record level. Titan supports several compression algorithms, such as Snappy, `lz4`, and `zstd`. In versions prior to v7.6.0, the default compression algorithm is `lz4`. Starting from v7.6.0, the default compression algorithm is `zstd`.
- The Snappy compressed file must be in the official Snappy format. Other variants are not supported.

14.2.3.4.2 TitanTableBuilder

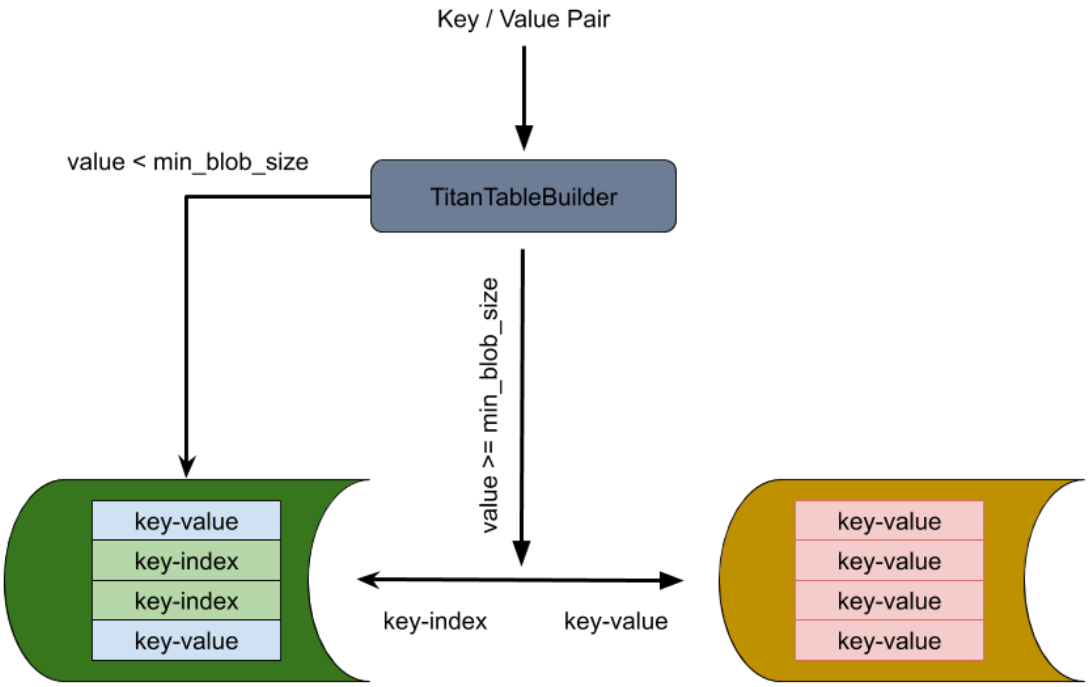

Figure 544: TitanTableBuilder

TitanTableBuilder is the key to achieving Key-Value separation. TitanTableBuilder determines the Key-Pair value size, and based on that, decides whether to separate the value from the Key-Value pair and store it in the blob file.

- If the value size is greater than or equal to `min_blob_size`, TitanTableBuilder separates the value and stores it in the blob file. TitanTableBuilder also generates an index and writes it into the SST.
- If the value size is smaller than `min_blob_size`, TitanTableBuilder writes the value directly into the SST.

Titan can also be downgraded to RocksDB in the process above. When RocksDB is performing compactions, the separated value can be written back to the newly generated SST files.

14.2.3.5 Garbage Collection

Titan uses Garbage Collection (GC) to reclaim space. As the keys are being reclaimed in the LSM-tree compaction, some values stored in blob files are not deleted at the same time. Therefore, Titan needs to perform GC periodically to delete outdated values. Titan provides the following two types of GC:

- Blob files are periodically integrated and rewritten to delete outdated values. This is the regular way of performing GC.
- Blob files are rewritten while the LSM-tree compaction is performed at the same time. This is the feature of Level Merge.

14.2.3.5.1 Regular GC

Titan uses the TablePropertiesCollector and EventListener components of RocksDB to collect the information for GC.

TablePropertiesCollector

RocksDB supports using BlobFileSizeCollector, a custom table property collector, to collect properties from the SST which are written into corresponding SST files. The collected properties are named BlobFileSizeProperties. The following figure shows the BlobFileSizeCollector workflow and data formats:

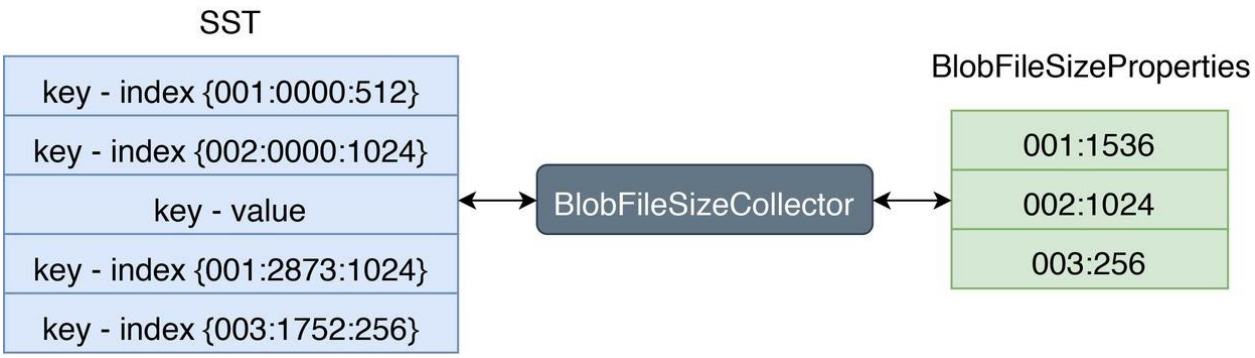

Figure 545: BlobFileSizeProperties

On the left is the SST index format. The first column is the blob file ID; the second column is the offset for the blob record in the blob file; the third column is the blob record size.

On the right is the BlobFileSizeProperties format. Each line represents a blob file and how much data is saved in this blob file. The first column is the blob file ID; the second column is the size of the data.

EventListener

RocksDB uses compaction to discard old data and reclaim space. After each compaction, some blob files in Titan might contain partly or entirely outdated data. Therefore, you can trigger GC by listening to compaction events. During compaction, you can collect and compare the input/output blob file size properties of SST to determine which blob files require GC. The following figure shows the general process:

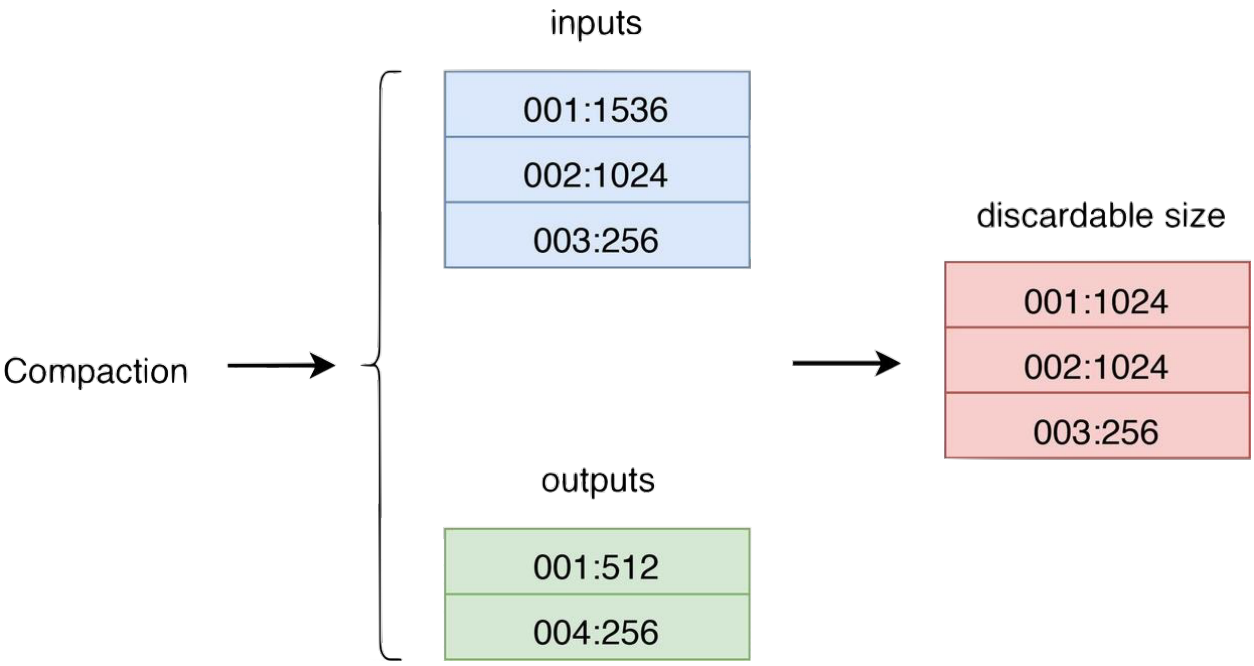

Figure 546: EventListener

- *inputs* stands for the blob file size properties for all SSTs that participate in the compaction.
- *outputs* stands for the blob file size properties for all SSTs generated in the compaction.
- *discardable size* is the size of the file to be discarded for each blob file, calculated based on inputs and outputs. The first column is the blob file ID. The second column is the size of the file to be discarded.

For each valid blob file, Titan maintains a discardable size variable in memory. After each compaction, this variable is accumulated for the corresponding blob file. Each time when GC starts, it picks the blob file with the greatest discardable size as the candidate file for GC. To reduce write amplification, a certain level of space amplification is allowed, which means GC can be started on a blob file only when the discardable file has reached a specific proportion in size.

For the selected blob file, Titan checks whether the blob index of the key corresponding to each value exists or has been updated to determine whether this value is outdated. If the value is not outdated, Titan merges and sorts the value into a new blob file, and writes the updated blob index into SST using WriteCallback or MergeOperator. Then, Titan records the latest sequence number of RocksDB and does not delete the old blob file until the sequence of the oldest snapshot exceeds the recorded sequence number. The reason is that after the blob index is written back to SST, the old blob index is still accessible via the previous snapshot. Therefore, we need to ensure that no snapshot will access the old blob index before GC can safely deletes the corresponding blob file.

14.2.3.5.2 Level Merge

Level Merge is a newly introduced algorithm in Titan. According to the implementation principle of Level Merge, Titan merges and rewrites blob file that corresponds to the SST file, and generates new blob file while compactions are performed in LSM-tree. The following figure shows the general process:

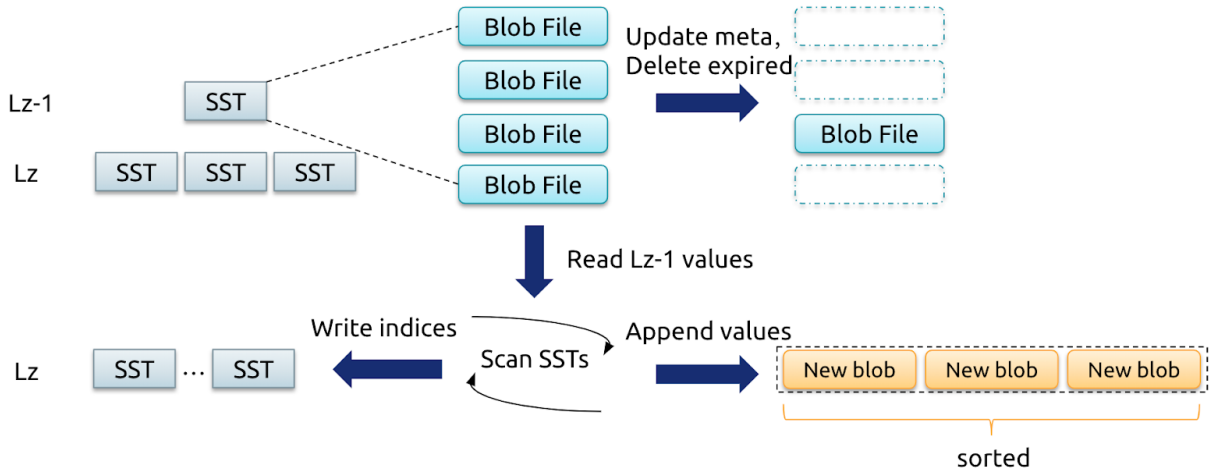

Figure 547: LevelMerge General Process

When compactions are performed on the SSTs of level z-1 and level z, Titan reads and writes Key-Value pairs in order. Then it writes the values of the selected blob files into new blob files in order, and updates the blob indexes of keys when new SSTs are generated. For the keys deleted in compactions, the corresponding values will not be written to the new blob file, which works similar to GC.

Compared with the regular way of GC, the Level Merge approach completes the blob GC while compactions are performed in LSM-tree. In this way, Titan no longer needs to check the status of blob index in LSM-tree or to write the new blob index into LSM-tree. This reduces the impact of GC on the foreground operations. As the blob file is repeatedly

rewritten, fewer files overlap with each other, which makes the whole system in better order and improves the performance of scan.

However, layering blob files similar to tiering compaction brings write amplification. Because 99% of the data in LSM-tree is stored at the lowest two levels, Titan performs the Level Merge operation on the blob files corresponding to the data that is compacted only to the lowest two levels of LSM-tree.

Range Merge

Range Merge is an optimized approach of GC based on Level Merge. However, the bottom level of LSM-tree might be in poorer order in the following situations:

- When `level_compaction_dynamic_level_bytes` is enabled, data volume at each level of LSM-tree dynamically increases, and the sorted runs at the bottom level keep increasing.
- A specific range of data is frequently compacted, and this causes a lot of sorted runs in that range.

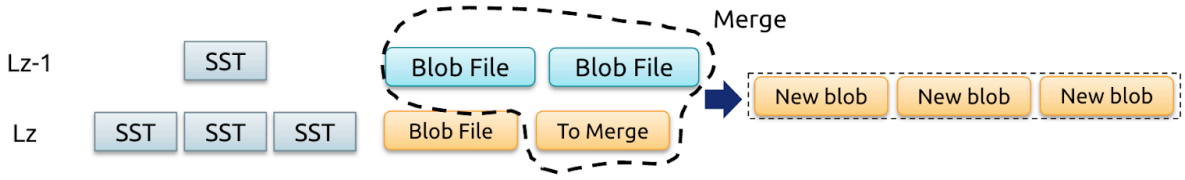

Figure 548: RangeMerge

Therefore, the Range Merge operation is needed to keep the number of sorted runs within a certain level. At the time of OnCompactionComplete, Titan counts the number of sorted runs in a range. If the number is large, Titan marks the corresponding blob file as ToMerge and rewrites it in the next compaction.

14.2.3.5.3 Scale out and scale in

For backward compatibility, the TiKV snapshots are still in the RocksDB format during scaling. Because the scaled nodes are all from RocksDB at the beginning, they carry the characteristics of RocksDB, such as higher compression rate than the old TiKV nodes, smaller store size, and relatively larger write amplification in compaction. These SST files in RocksDB format will be gradually converted to Titan format after compaction.

14.2.3.5.4 Impact of `min-blob-size` on performance

`min-blob-size` determines whether a value is stored in Titan. If the value is greater than or equal to `min-blob-size`, it is stored in Titan. Otherwise, it is stored in the native

RocksDB format. If `min-blob-size` is too small or too large, the performance will be affected.

The following table lists the QPS comparison of the YCSB workload based on different `min-blob-size` values. In each round of testing, the row width of the test data is equal to `min-blob-size`, so that the data is stored in Titan when Titan is enabled.

Row width (Bytes)	`Point_Get`	`Point_Get` (Titan)	scan100	scan100 (Titan)	scan10000	scan10000 (Titan)	`UPDATE`	`UPDATE` (Titan)
1KB	139255	140486	25171	21854	533	175	17913	30767
2KB	114201	124075	12466	11552	249	131	10369	27188
4KB	92385	103811	7918	5937	131	87	5327	22653
8KB	104380	130647	7365	5402	86.6	68	3180	16745
16KB	54234	54600	4937	5174	55.4	58.9	1753	10120
32KB	31035	31052	2705	3422	38	45.3	984	5844

Note:

`scan100` means scanning 100 records, and `scan10000` means scanning 10000 records.

From the table, you can see that when the row width is `16KB`, Titan outperforms RocksDB in all YCSB workloads. However, in some extreme scenarios with heavy scan loads, such as running Dumpling, Titan's performance with a row width of `16KB` decreases by 10%. Therefore, if the workload is mainly write and point read, it is recommended that you set `min-blob-size` to `1KB`. If the workload contains a large number of scans, it is recommended that you set `min-blob-size` to at least `16KB`.

14.2.4 Titan Configuration

This document introduces how to enable and disable Titan using the corresponding configuration items, data conversion mechanism, the relevant parameters, and the Level Merge feature.

14.2.4.1 Enable Titan

Note:

- Starting from TiDB v7.6.0, Titan is enabled by default for new clusters to enhance the performance of writing wide tables and JSON data. The default value of the `min-blob-size` threshold is changed from `1KB` to `32KB`.
- Existing clusters upgraded to v7.6.0 or later versions retain the original configuration, which means that if Titan is not explicitly enabled, it still uses RocksDB.
- If you have enabled Titan before upgrading a cluster to TiDB v7.6.0 or later versions, Titan will be enabled after the upgrade, and the configuration of `min-blob-size` before the upgrade will also be retained. If you do not explicitly configure the value before the upgrade, the default value of the old version `1KB` will be retained to ensure the stability of the cluster configuration after the upgrade.

Titan is compatible with RocksDB, so you can directly enable Titan on the existing TiKV instances that use RocksDB. You can use one of the following methods to enable Titan:

- Method 1: If you have deployed the cluster using TiUP, you can execute the `tiup cluster edit-config ${cluster-name}` command and edit the TiKV configuration file as the following example shows:

```
tikv:
  rocksdb.titan.enabled: true
```

  Reload the configuration and TiKV will be rolling restarted dynamically:

```
tiup cluster reload ${cluster-name} -R tikv
```

  For the detailed command, see Modify the configuration using TiUP.

- Method 2: Directly edit the TiKV configuration file to enable Titan (**NOT** recommended for the production environment).

```
[rocksdb.titan]
enabled = true
```

- Method 3: Edit the `${cluster_name}/tidb-cluster.yaml` configuration file for TiDB Operator:

```
spec:
  tikv:
    ## Base image of the component
    baseImage: pingcap/tikv
```

```
## tikv-server configuration
## Ref: https://docs.pingcap.com/tidb/stable/tikv-configuration-
   ↪ file
config: |
  log-level = "info"
  [rocksdb]
    [rocksdb.titan]
      enabled = true
```

Apply the configuration to trigger an online rolling restart of the TiDB cluster for the changes to take effect:

```
kubectl apply -f ${cluster_name} -n ${namespace}
```

For more information, refer to Configuring a TiDB Cluster in Kubernetes.

14.2.4.2 Data conversion

> **Warning:**
>
> When Titan is disabled, RocksDB cannot read data that has been moved to Titan. If Titan is incorrectly disabled on a TiKV instance with Titan already enabled (mistakenly set `rocksdb.titan.enabled` to `false`), TiKV will fail to start, and the `You have disabled titan when its data directory is not empty` error appears in the TiKV log. To correctly disabled Titan, see Disable Titan.

After Titan is enabled, the existing data stored in RocksDB is not immediately moved to the Titan engine. As new data is written to the TiKV and RocksDB performs compaction, **the values are progressively separated from keys and written to Titan**. Similarly, the data restored through BR snapshot/log, the data converted during scaling, or the data imported by TiDB Lightning Physical Import Mode, is not written directly into Titan. As compaction proceeds, the large values exceeding the default value (`32KB`) of `min-blob-size` in the processed SST files are separated into Titan. You can monitor the size of files stored in Titan by observing the **TiKV Details > Titan kv > blob file size** panel to estimate the data size.

If you want to speed up the writing process, you can use tikv-ctl to compact data of the whole TiKV cluster manually. For details, see manual compaction. The data access is continuous during the conversion from RocksDB to Titan, therefore the block cache of RocksDB significantly accelerates the data conversion process. In the test, by using tikv-ctl, a volume of 670 GiB TiKV data can be converted to Titan in one hour.

Note that the values in Titan Blob files are not continuous, and Titan's cache is at the value level, so the Blob Cache does not help during compaction. The conversion speed from Titan to RocksDB is an order of magnitude slower than that from RocksDB to Titan. In the test, it takes 12 hours to convert a volume of 800 GiB Titan data on a TiKV node to RocksDB by tikv-ctl in a full compaction.

14.2.4.3 Parameters

By properly configuring Titan parameters, you can effectively improve database performance and resource utilization. This section introduces some key parameters you can use.

14.2.4.3.1 `min-blob-size`

You can use `min-blob-size` to set the threshold for the value size to determine which data is stored in RocksDB and which in Titan's blob files. According to the test, `32KB` is an appropriate threshold. It ensures that Titan's performance does not regress compared with RocksDB. However, in many scenarios, this value is not optimal. It is recommended that you refer to Impact of `min-blob-size` on performance to choose an appropriate value. If you want to further improve write performance and can tolerate scan performance regression, you can set it to the minimum value `1KB`.

14.2.4.3.2 `blob-file-compression` and `zstd-dict-size`

You can use `blob-file-compression` to specify the compression algorithm used for values in Titan. You can also enable the `zstd` dictionary compression through `zstd-dict-size` to improve the compression rate.

14.2.4.3.3 `blob-cache-size`

You can use `blob-cache-size` to control the cache size of values in Titan. Larger cache size means higher read performance of Titan. However, too large a cache size causes Out of Memory (OOM) issues.

It is recommended to set the value of `storage.block-cache.capacity` to the store size minus the blob file size, and set `blob-cache-size` to `memory size * 50% - block cache size` according to the monitoring metrics when the database is running stably. This maximizes the blob cache size when the block cache is large enough for the whole RocksDB engine.

14.2.4.3.4 `discardable-ratio` and `max-background-gc`

The `discardable-ratio` parameter and `max-background-gc` parameter significantly impact Titan's read performance and garbage collection process.

When the ratio of obsolete data (the corresponding key has been updated or deleted) in a blob file exceeds the threshold set by `discardable-ratio`, Titan GC is triggered.

Reducing this threshold can reduce space amplification but can cause more frequent Titan GC. Increasing this value can reduce Titan GC, I/O bandwidth, and CPU consumption, but increase disk space usage.

If you observe that the Titan GC thread is in full load for a long time from **TiKV Details** - **Thread CPU** - **RocksDB CPU**, consider adjusting `max-background-gc` to increase the Titan GC thread pool size.

14.2.4.3.5 `rate-bytes-per-sec`

You can adjust `rate-bytes-per-sec` to limit the I/O rate of RocksDB compaction, reducing its impact on foreground read and write performance during high traffic.

14.2.4.3.6 `shared-blob-cache` (New in v8.0.0)

You can control whether to enable the shared cache for Titan blob files and RocksDB block files through `shared-blob-cache`. The default value is `true`. When the shared cache is enabled, block files have higher priority. This means that TiKV prioritizes meeting the cache needs of block files and then uses the remaining cache for blob files.

14.2.4.3.7 Titan configuration example

The following is an example of the Titan configuration file. You can either use TiUP to modify the configuration or configure a TiDB cluster on Kubernetes.

```
[rocksdb]
rate-bytes-per-sec = 0

[rocksdb.titan]
enabled = true
max-background-gc = 1

[rocksdb.defaultcf.titan]
min-blob-size = "32KB"
blob-file-compression = "zstd"
zstd-dict-size = "16KB"
discardable-ratio = 0.5
blob-run-mode = "normal"
level-merge = false
```

14.2.4.4 Disable Titan

To disable Titan, you can configure the `rocksdb.defaultcf.titan.blob-run-mode` option. The optional values for `blob-run-mode` are as follows:

- When the option is set to `normal`, Titan performs read and write operations normally.

- When the option is set to `read-only`, all newly written values are written into RocksDB, regardless of the value size.
- When the option is set to `fallback`, all newly written values are written into RocksDB, regardless of the value size. Also, all compacted values stored in the Titan blob file are automatically moved back to RocksDB.

To fully disable Titan for all existing and future data, you can follow these steps. Note that you can skip Step 2 because it greatly impacts online traffic performance. In fact even without Step 2, the data compaction consumes extra I/O and CPU resources when it moves data from Titan to RocksDB, and performance will degrade (sometimes as much as 50%) when TiKV I/O or CPU resources are limited.

1. Update the configuration of the TiKV nodes you wish to disable Titan for. You can update configuration in two methods:

    - Execute `tiup cluster edit-config`, edit the configuration file, and execute `tiup cluster reload -R tikv`.
    - Manually update the configuration file and restart TiKV.

    ```
    [rocksdb.defaultcf.titan]
    blob-run-mode = "fallback"
    discardable-ratio = 1.0
    ```

> **Note:**
>
> When there is insufficient disk space to accommodate both Titan and RocksDB data, it is recommended to use the default value of `0.5` for `discardable-ratio`. In general, the default value is recommended when available disk space is less than 50%. This is because when `discardable-ratio = 1.0`, the RocksDB data continues to increase. At the same time, the recycling of existing blob files in Titan requires all the data in that file to be converted to RocksDB, which is a slow process. However, if the disk size is large enough, setting `discardable-ratio = 1.0` can reduce the GC of the blob file itself during compaction, which saves bandwidth.

2. (Optional) Perform a full compaction using tikv-ctl. This process will consume a large amount of I/O and CPU resources.

> **Warning:**
>
> When disk space is insufficient, executing the following command might result in the entire cluster running out of available space and thus unable to write data.

```
tikv-ctl --pd <PD_ADDR> compact-cluster --bottommost force
```

3. After the compaction is finished, wait for the **Blob file count** metrics under **TiKV-Details/Titan - kv** to decrease to `0`.

4. Update the configuration of these TiKV nodes to disable Titan.

```
[rocksdb.titan]
enabled = false
```

14.2.4.5 Level Merge (experimental)

In TiKV 4.0, Level Merge, a new algorithm, is introduced to improve the performance of range query and to reduce the impact of Titan GC on the foreground write operations. You can enable Level Merge using the following option:

```
[rocksdb.defaultcf.titan]
level-merge = true
```

Enabling Level Merge has the following benefits:

- Greatly improve the performance of Titan range query.
- Reduce the impact of Titan GC on the foreground write operations and improve write performance.
- Reduce space amplification of Titan and the disk usage (compared to the disk usage with the default configuration).

Accordingly, the write amplification with Level Merge enabled is slightly higher than that of Titan but is still lower than that of the native RocksDB.

14.2.5 Partitioned Raft KV

> **Warning:**
>
> Partitioned Raft KV is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

Before v6.6.0, TiKV's Raft-based storage engine used a single RocksDB instance to store the data of all Regions of the TiKV instance.

To support larger clusters more stably, starting from TiDB v6.6.0, a new TiKV storage engine is introduced, which uses multiple RocksDB instances to store TiKV Region data, and the data of each Region is independently stored in a separate RocksDB instance.

The new engine can better control the number and level of files in each RocksDB instance, achieve physical isolation of data operations between Regions, and support stably managing more data. You can see it as TiKV managing multiple RocksDB instances through partitioning, which is why the feature is named Partitioned Raft KV.

14.2.5.1 Application scenarios

You can use this feature if your TiKV cluster has the following characteristics:

- A single TiKV instance needs to support more data.
- There are many write requests.
- Scale-in and scale-out operations are frequent.
- The workload has a serious read and write amplification.
- TiKV has sufficient memory.

Advantages of this feature are better write performance, faster scaling speed, and larger volume of data supported with the same hardware. It can also support larger cluster scale.

14.2.5.2 Usage

To enable Partitioned Raft KV, set the configuration item `storage.engine` to "`partitioned-raft-kv`" when creating a cluster. At the same time, you can use the configuration items `rocksdb.write-buffer-flush-oldest-first` and `rocksdb.write-buffer-limit` to control the memory usage of RocksDB when using Raft KV.

14.2.5.3 Restrictions

Partitioned Raft KV has the following restrictions:

- It does not support EBS volume snapshot backup yet.
- It does not support online unsafe recovery or Titan yet.
- It does not support the following subcommands of the tikv-ctl command-line tool:
  - `unsafe-recover`
  - `raw-scan`
  - `remove-fail-stores`
  - `recreate-region`
  - `reset-to-version`
- It is not compatible with TiFlash yet.
- You cannot enable or disable this feature after the cluster is initialized.

14.3 Storage Engine - TiFlash

14.3.1 TiFlash Overview

TiFlash is the key component that makes TiDB essentially an Hybrid Transactional/-Analytical Processing (HTAP) database. As a columnar storage extension of TiKV, TiFlash provides both good isolation level and strong consistency guarantee.

In TiFlash, the columnar replicas are asynchronously replicated according to the Raft Learner consensus algorithm. When these replicas are read, the Snapshot Isolation level of consistency is achieved by validating Raft index and multi-version concurrency control (MVCC).

14.3.1.1 Architecture

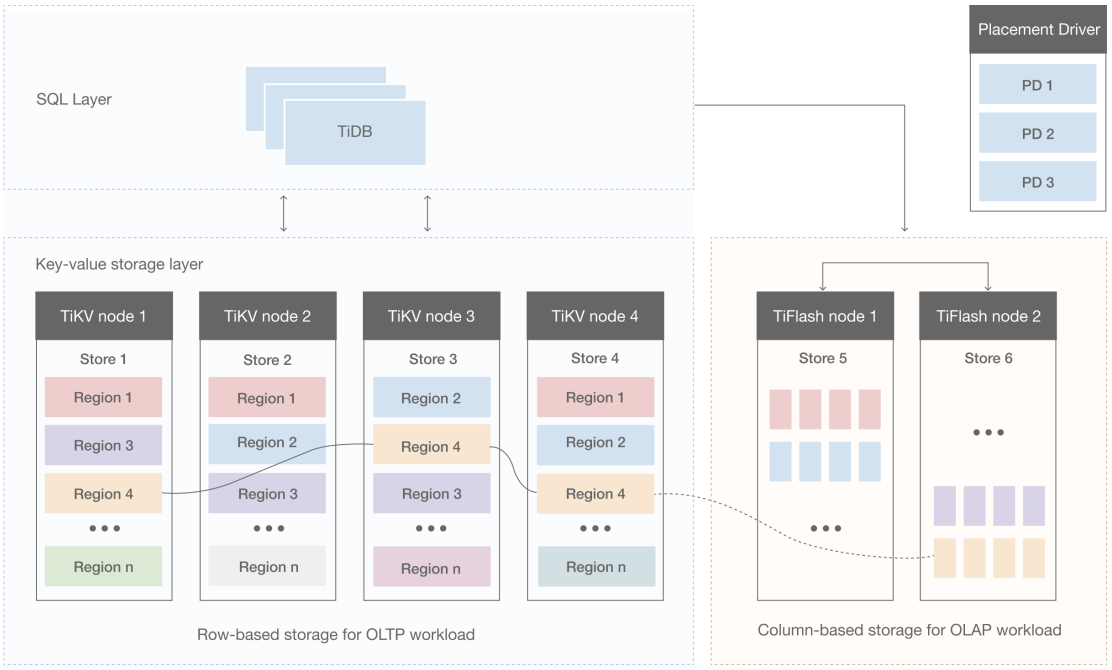

Figure 549: TiFlash Architecture

The above figure is the architecture of TiDB in its HTAP form, including TiFlash nodes.

TiFlash provides the columnar storage, with a layer of coprocessors efficiently implemented by ClickHouse. Similar to TiKV, TiFlash also has a Multi-Raft system, which supports replicating and distributing data in the unit of Region (see Data Storage for details).

TiFlash conducts real-time replication of data in the TiKV nodes at a low cost that does not block writes in TiKV. Meanwhile, it provides the same read consistency as in TiKV and ensures that the latest data is read. The Region replica in TiFlash is logically identical to those in TiKV, and is split and merged along with the Leader replica in TiKV at the same time.

To deploy TiFlash under the Linux AMD64 architecture, the CPU must support the AVX2 instruction set. Ensure that `grep avx2 /proc/cpuinfo` has output. To deploy TiFlash under the Linux ARM64 architecture, the CPU must support the ARMv8 instruction set architecture. Ensure that `grep 'crc32' /proc/cpuinfo | grep 'asimd'` has output. By using the instruction set extensions, TiFlash's vectorization engine can deliver better performance.

TiFlash is compatible with both TiDB and TiSpark, which enables you to freely choose between these two computing engines.

It is recommended that you deploy TiFlash in different nodes from TiKV to ensure workload isolation. It is also acceptable to deploy TiFlash and TiKV in the same node if no business isolation is required.

Currently, data cannot be written directly into TiFlash. You need to write data in TiKV and then replicate it to TiFlash, because it connects to the TiDB cluster as a Learner role. TiFlash supports data replication in the unit of table, but no data is replicated by default after deployment. To replicate data of a specified table, see Create TiFlash replicas for tables.

TiFlash has three components: the columnar storage module, `tiflash proxy`, and `pd buddy`. `tiflash proxy` is responsible for the communication using the Multi-Raft consensus algorithm. `pd buddy` works with PD to replicate data from TiKV to TiFlash in the unit of table.

When TiDB receives the DDL command to create replicas in TiFlash, the `pd buddy` component acquires the information of the table to be replicated via the status port of TiDB, and sends the information to PD. Then PD performs the corresponding data scheduling according to the information provided by `pd buddy`.

14.3.1.2 Key features

TiFlash has the following key features:

- Asynchronous replication
- Consistency
- Intelligent choice
- Computing acceleration

14.3.1.2.1 Asynchronous replication

The replica in TiFlash is asynchronously replicated as a special role, Raft Learner. This means when the TiFlash node is down or high network latency occurs, applications in TiKV

can still proceed normally.

This replication mechanism inherits two advantages of TiKV: automatic load balancing and high availability.

- TiFlash does not rely on additional replication channels, but directly receives data from TiKV in a many-to-many manner.
- As long as the data is not lost in TiKV, you can restore the replica in TiFlash at any time.

14.3.1.2.2 Consistency

TiFlash provides the same Snapshot Isolation level of consistency as TiKV, and ensures that the latest data is read, which means that you can read the data previously written in TiKV. Such consistency is achieved by validating the data replication progress.

Every time TiFlash receives a read request, the Region replica sends a progress validation request (a lightweight RPC request) to the Leader replica. TiFlash performs the read operation only after the current replication progress includes the data covered by the timestamp of the read request.

14.3.1.2.3 Intelligent choice

TiDB can automatically choose to use TiFlash (column-wise) or TiKV (row-wise), or use both of them in one query to ensure the best performance.

This selection mechanism is similar to that of TiDB which chooses different indexes to execute query. TiDB optimizer makes the appropriate choice based on statistics of the read cost.

14.3.1.2.4 Computing acceleration

TiFlash accelerates the computing of TiDB in two ways:

- The columnar storage engine is more efficient in performing read operation.
- TiFlash shares part of the computing workload of TiDB.

TiFlash shares the computing workload in the same way as the TiKV Coprocessor does: TiDB pushes down the computing that can be completed in the storage layer. Whether the computing can be pushed down depends on the support of TiFlash. For details, see Supported pushdown calculations.

14.3.1.3 Use TiFlash

After TiFlash is deployed, data replication does not automatically begin. You need to manually specify the tables to be replicated.

You can either use TiDB to read TiFlash replicas for medium-scale analytical processing, or use TiSpark to read TiFlash replicas for large-scale analytical processing, which is based on your own needs. See the following sections for details:

- Create TiFlash Replicas
- Use TiDB to Read TiFlash Replicas
- Use TiSpark to Read TiFlash Replicas
- Use MPP Mode

To experience the whole process from importing data to querying in a TPC-H dataset, refer to Quick Start Guide for TiDB HTAP.

14.3.2 Create TiFlash Replicas

This document introduces how to create TiFlash replicas for tables and for databases, and set available zones for replica scheduling.

14.3.2.1 Create TiFlash replicas for tables

After TiFlash is connected to the TiKV cluster, data replication by default does not begin. You can send a DDL statement to TiDB through a MySQL client to create a TiFlash replica for a specific table:

```
ALTER TABLE table_name SET TIFLASH REPLICA count;
```

The parameter of the above command is described as follows:

- `count` indicates the number of replicas. When the value is `0`, the replica is deleted.

Note:

For a TiDB Cloud Serverless cluster, the `count` of TiFlash replicas can only be `2`. If you set it to `1`, it will be automatically adjusted to `2` for execution. If you set it to a number larger than 2, you will get an error about the replica count.

If you execute multiple DDL statements on the same table, only the last statement is ensured to take effect. In the following example, two DDL statements are executed on the table `tpch50`, but only the second statement (to delete the replica) takes effect.

Create two replicas for the table:

```
ALTER TABLE `tpch50`.`lineitem` SET TIFLASH REPLICA 2;
```

Delete the replica:

```
ALTER TABLE `tpch50`.`lineitem` SET TIFLASH REPLICA 0;
```

Notes:

- If the table `t` is replicated to TiFlash through the above DDL statements, the table created using the following statement will also be automatically replicated to TiFlash:

  ```
  CREATE TABLE table_name like t;
  ```

- For versions earlier than v4.0.6, if you create the TiFlash replica before using TiDB Lightning to import the data, the data import will fail. You must import data to the table before creating the TiFlash replica for the table.
- If TiDB and TiDB Lightning are both v4.0.6 or later, no matter a table has TiFlash replica(s) or not, you can import data to that table using TiDB Lightning. Note that this might slow the TiDB Lightning procedure, which depends on the NIC bandwidth on the lightning host, the CPU and disk load of the TiFlash node, and the number of TiFlash replicas.
- It is recommended that you do not replicate more than 1,000 tables because this lowers the PD scheduling performance. This limit will be removed in later versions.
- In v5.1 and later versions, setting the replicas for the system tables is no longer supported. Before upgrading the cluster, you need to clear the replicas of the relevant system tables. Otherwise, you cannot modify the replica settings of the system tables after you upgrade the cluster to a later version.

14.3.2.1.1 Check replication progress

You can check the status of the TiFlash replicas of a specific table using the following statement. The table is specified using the `WHERE` clause. If you remove the `WHERE` clause, you will check the replica status of all tables.

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '<db_
    ↪ name>' and TABLE_NAME = '<table_name>';
```

In the result of above statement:

- `AVAILABLE` indicates whether the TiFlash replicas of this table are available or not. `1` means available and `0` means unavailable. Once the replicas become available, this status does not change. If you use DDL statements to modify the number of replicas, the replication status will be recalculated.
- `PROGRESS` means the progress of the replication. The value is between `0.0` and `1.0`. `1` means at least one replica is replicated.

14.3.2.2 Create TiFlash replicas for databases

Similar to creating TiFlash replicas for tables, you can send a DDL statement to TiDB through a MySQL client to create a TiFlash replica for all tables in a specific database:

```
ALTER DATABASE db_name SET TIFLASH REPLICA count;
```

In this statement, `count` indicates the number of replicas. When you set it to `0`, replicas are deleted.

Examples:

- Create two replicas for all tables in the database `tpch50`:

  ```
  ALTER DATABASE `tpch50` SET TIFLASH REPLICA 2;
  ```

- Delete TiFlash replicas created for the database `tpch50`:

  ```
  ALTER DATABASE `tpch50` SET TIFLASH REPLICA 0;
  ```

Note:

- This statement actually performs a series of DDL operations, which are resource-intensive. If the statement is interrupted during the execution, executed operations are not rolled back and unexecuted operations do not continue.

- After executing the statement, do not set the number of TiFlash replicas or perform DDL operations on this database until **all tables in this database are replicated**. Otherwise, unexpected results might occur, which include:
  - If you set the number of TiFlash replicas to 2 and then change the number to 1 before all tables in the database are replicated, the final number of TiFlash replicas of all the tables is not necessarily 1 or 2.
  - After executing the statement, if you create tables in this database before the completion of the statement execution, TiFlash replicas **might or might not** be created for these new tables.
  - After executing the statement, if you add indexes for tables in the database before the completion of the statement execution, the statement might hang and resume only after the indexes are added.
- If you create tables in this database **after** the completion of the statement execution, TiFlash replicas are not created automatically for these new tables.
- This statement skips system tables, views, temporary tables, and tables with character sets not supported by TiFlash.

14.3.2.2.1 Check replication progress

Similar to creating TiFlash replicas for tables, successful execution of the DDL statement does not mean the completion of replication. You can execute the following SQL statement to check the progress of replication on target tables:

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '<db_
    ↪ name>';
```

To check tables without TiFlash replicas in the database, you can execute the following SQL statement:

```
SELECT TABLE_NAME FROM information_schema.tables where TABLE_SCHEMA = "<db_
    ↪ name>" and TABLE_NAME not in (SELECT TABLE_NAME FROM information_
    ↪ schema.tiflash_replica where TABLE_SCHEMA = "<db_name>");
```

14.3.2.3 Speed up TiFlash replication

Before TiFlash replicas are added, each TiKV instance performs a full table scan and sends the scanned data to TiFlash as a "snapshot" to create replicas. By default, TiFlash replicas are added slowly with fewer resources usage in order to minimize the impact on the online service. If there are spare CPU and disk IO resources in your TiKV and TiFlash nodes, you can accelerate TiFlash replication by performing the following steps.

1. Temporarily increase the snapshot write speed limit for each TiKV and TiFlash instance by using the Dynamic Config SQL statement:

```
-- The default value for both configurations are 100MiB, i.e. the
   ↪ maximum disk bandwidth used for writing snapshots is no more
   ↪ than 100MiB/s.
SET CONFIG tikv `server.snap-io-max-bytes-per-sec` = '300MiB';
SET CONFIG tiflash `raftstore-proxy.server.snap-io-max-bytes-per-sec` =
   ↪  '300MiB';
```

   After executing these SQL statements, the configuration changes take effect immediately without restarting the cluster. However, since the replication speed is still restricted by the PD limit globally, you cannot observe the acceleration for now.

2. Use PD Control to progressively ease the new replica speed limit.

   The default new replica speed limit is 30, which means, approximately 30 Regions add TiFlash replicas every minute. Executing the following command will adjust the limit to 60 for all TiFlash instances, which doubles the original speed:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store limit
   ↪ all engine tiflash 60 add-peer
```

   In the preceding command, you need to replace `v<CLUSTER_VERSION>` with the actual cluster version, such as `v8.4.0` and `<PD_ADDRESS>:2379` with the address of any PD node. For example:

```
tiup ctl:v8.4.0 pd -u http://192.168.1.4:2379 store limit
   ↪ all engine tiflash 60 add-peer
```

   Within a few minutes, you will observe a significant increase in CPU and disk IO resource usage of the TiFlash nodes, and TiFlash should create replicas faster. At the same time, the TiKV nodes' CPU and disk IO resource usage increases as well.

   If the TiKV and TiFlash nodes still have spare resources at this point and the latency of your online service does not increase significantly, you can further ease the limit, for example, triple the original speed:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store limit
   ↪ all engine tiflash 90 add-peer
```

3. After the TiFlash replication is complete, revert to the default configuration to reduce the impact on online services.

   Execute the following PD Control command to restore the default new replica speed limit:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store limit
    ↪ all engine tiflash 30 add-peer
```

Execute the following SQL statements to restore the default snapshot write speed limit:

```
SET CONFIG tikv `server.snap-io-max-bytes-per-sec` = '100MiB';
SET CONFIG tiflash `raftstore-proxy.server.snap-io-max-bytes-per-sec` =
    ↪  '100MiB';
```

14.3.2.4 Set available zones

When configuring replicas, if you need to distribute TiFlash replicas to multiple data centers for disaster recovery, you can configure available zones by following the steps below:

1. Specify labels for TiFlash nodes in the cluster configuration file.

```
tiflash_servers:
  - host: 172.16.5.81
      logger.level: "info"
    learner_config:
      server.labels:
        zone: "z1"
  - host: 172.16.5.82
    config:
      logger.level: "info"
    learner_config:
      server.labels:
        zone: "z1"
  - host: 172.16.5.85
    config:
      logger.level: "info"
    learner_config:
      server.labels:
        zone: "z2"
```

Note that the `flash.proxy.labels` configuration in earlier versions cannot handle special characters in the available zone name correctly. It is recommended to use the `server.labels` in `learner_config` to configure the name of an available zone.

2. After starting a cluster, specify the labels when creating replicas.

```
ALTER TABLE table_name SET TIFLASH REPLICA count LOCATION LABELS
    ↪ location_labels;
```

For example:

```
ALTER TABLE t SET TIFLASH REPLICA 2 LOCATION LABELS "zone";
```

3. PD schedules the replicas based on the labels. In this example, PD respectively schedules two replicas of the table `t` to two available zones. You can use pd-ctl to view the scheduling.

```
> tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store

    ...
    "address": "172.16.5.82:23913",
    "labels": [
      { "key": "engine", "value": "tiflash"},
      { "key": "zone", "value": "z1" }
    ],
    "region_count": 4,

    ...
    "address": "172.16.5.81:23913",
    "labels": [
      { "key": "engine", "value": "tiflash"},
      { "key": "zone", "value": "z1" }
    ],
    "region_count": 5,
    ...

    "address": "172.16.5.85:23913",
    "labels": [
      { "key": "engine", "value": "tiflash"},
      { "key": "zone", "value": "z2" }
    ],
    "region_count": 9,
    ...
```

For more information about scheduling replicas by using labels, see Schedule Replicas by Topology Labels, Multiple Data Centers in One City Deployment, and Three Data Centers in Two Cities Deployment.

TiFlash supports configuring the replica selection strategy for different zones. For more information, see `tiflash_replica_read`.

14.3.3 Use TiDB to Read TiFlash Replicas

This document introduces how to use TiDB to read TiFlash replicas.

TiDB provides three ways to read TiFlash replicas. If you have added a TiFlash replica without any engine configuration, the CBO (cost-based optimization) mode is used by default.

14.3.3.1 Smart selection

For tables with TiFlash replicas, the TiDB optimizer automatically determines whether to use TiFlash replicas based on the cost estimation. You can use the `desc` or `explain analyze` statement to check whether or not a TiFlash replica is selected. For example:

```
desc select count(*) from test.t;
```

```
+-------------------------+---------+--------------+--------------+-------------------
    ↪
| id                      | estRows | task         | access object | operator
    ↪ info            |
+-------------------------+---------+--------------+--------------+-------------------
    ↪
| StreamAgg_9             | 1.00    | root         |               | funcs:count(1)
    ↪ ->Column#4    |
|  ─TableReader_17        | 1.00    | root         |               | data:
    ↪ TableFullScan_16      |
|    ─TableFullScan_16    | 1.00    | cop[tiflash] | table:t       | keep order:
    ↪ false, stats:pseudo |
+-------------------------+---------+--------------+--------------+-------------------
    ↪
3 rows in set (0.00 sec)
```

```
explain analyze select count(*) from test.t;
```

```
+-------------------------+---------+---------+--------------+--------------+---------
    ↪
| id                      | estRows | actRows | task     | access object |
    ↪ execution info                                          | operator
    ↪ info               | memory   | disk |
+-------------------------+---------+---------+--------------+--------------+---------
    ↪
| StreamAgg_9             | 1.00    | 1       | root         |               | time
    ↪ :83.8372ms, loops:2                                    | funcs:count
    ↪ (1)->Column#4    | 372 Bytes | N/A |
|  ─TableReader_17        | 1.00    | 1       | root         |               | time
    ↪ :83.7776ms, loops:2, rpc num: 1, rpc time:83.5701ms, proc keys:0 |
    ↪ data:TableFullScan_16 | 152 Bytes | N/A |
|    ─TableFullScan_16    | 1.00    | 1       | cop[tiflash] | table:t       |
    ↪ tiflash_task:{time:43ms, loops:1, threads:1}, tiflash_scan:{...} |
    ↪ keep order:false, stats:pseudo | N/A | N/A |
```

```
+-------------------------+---------+---------+-------------+--------------+---------
    ↪
```

`cop[tiflash]` means that the task will be sent to TiFlash for processing. If you have not selected a TiFlash replica, you can try to update the statistics using the `analyze table` statement, and then check the result using the `explain analyze` statement.

Note that if a table has only a single TiFlash replica and the related node cannot provide service, queries in the CBO mode will repeatedly retry. In this situation, you need to specify the engine or use the manual hint to read data from the TiKV replica.

14.3.3.2 Engine isolation

Engine isolation is to specify that all queries use a replica of the specified engine by configuring the corresponding variable. The optional engines are "tikv", "tidb" (indicates the internal memory table area of TiDB, which stores some TiDB system tables and cannot be actively used by users), and "tiflash".

You can specify the engines at the following two configuration levels:

- TiDB instance-level, namely, INSTANCE level. Add the following configuration item in the TiDB configuration file:

  ```
  [isolation-read]
  engines = ["tikv", "tidb", "tiflash"]
  ```

  The INSTANCE-level default configuration is `["tikv", "tidb", "tiflash"]` ↪ .

- SESSION level. Use the following statement to configure:

  ```
  set @@session.tidb_isolation_read_engines = "engine list separated by
      ↪ commas";
  ```

  or

  ```
  set SESSION tidb_isolation_read_engines = "engine list separated by
      ↪ commas";
  ```

  The default configuration of the SESSION level inherits from the configuration of the TiDB INSTANCE level.

The final engine configuration is the session-level configuration, that is, the session-level configuration overrides the instance-level configuration. For example, if you have configured "tikv" in the INSTANCE level and "tiflash" in the SESSION level, then the TiFlash replicas are read. If the final engine configuration is "tikv" and "tiflash", then the TiKV and TiFlash replicas are both read, and the optimizer automatically selects a better engine to execute.

Note:

Because TiDB Dashboard and other components need to read some system tables stored in the TiDB memory table area, it is recommended to always add the "tidb" engine to the instance-level engine configuration.

If the queried table does not have a replica of the specified engine (for example, the engine is configured as "tiflash" but the table does not have a TiFlash replica), the query returns an error.

14.3.3.3 Manual hint

Manual hint can force TiDB to use specified replicas for specific table(s) on the premise of satisfying engine isolation. Here is an example of using the manual hint:

```
select /*+ read_from_storage(tiflash[table_name]) */ ... from table_name;
```

If you set an alias to a table in a query statement, you must use the alias in the statement that includes a hint for the hint to take effect. For example:

```
select /*+ read_from_storage(tiflash[alias_a,alias_b]) */ ... from table_
    ↪ name_1 as alias_a, table_name_2 as alias_b where alias_a.column_1 =
    ↪ alias_b.column_2;
```

In the above statements, `tiflash[]` prompts the optimizer to read the TiFlash replicas. You can also use `tikv[]` to prompt the optimizer to read the TiKV replicas as needed. For hint syntax details, refer to READ_FROM_STORAGE.

If the table specified by a hint does not have a replica of the specified engine, the hint is ignored and a warning is reported. In addition, a hint only takes effect on the premise of engine isolation. If the engine specified in a hint is not in the engine isolation list, the hint is also ignored and a warning is reported.

Note:

The MySQL client of 5.7.7 or earlier versions clears optimizer hints by default. To use the hint syntax in these early versions, start the client with the `--
↪ comments` option, for example, `mysql -h 127.0.0.1 -P 4000 -uroot
↪ --comments`.

14.3.3.4 The relationship of smart selection, engine isolation, and manual hint

In the above three ways of reading TiFlash replicas, engine isolation specifies the overall range of available replicas of engines; within this range, manual hint provides statement-level and table-level engine selection that is more fine-grained; finally, CBO makes the decision and selects a replica of an engine based on cost estimation within the specified engine list.

Note:

- Before v4.0.3, the behavior of reading from TiFlash replica in a non-read-only SQL statement (for example, `INSERT INTO ... SELECT`, `SELECT ... FOR UPDATE`, `UPDATE ...`, `DELETE ...`) is undefined.
- For versions from v4.0.3 to v6.2.0, internally TiDB ignores the TiFlash replica for a non-read-only SQL statement to guarantee the data correctness. That is, for smart selection, TiDB automatically selects the non-TiFlash replica; for engine isolation that specifies TiFlash replica **only**, TiDB reports an error; and for manual hint, TiDB ignores the hint.
- For versions from v6.3.0 to v7.0.0, if the TiFlash replica is enabled, you can use the `tidb_enable_tiflash_read_for_write_stmt` variable to control whether TiDB uses the TiFlash replica for a non-read-only SQL statement.
- Starting from v7.1.0, if the TiFlash replica is enabled and the SQL Mode of the current session is not strict (which means the `sql_mode` value does not contain `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`), TiDB automatically decides whether to use the TiFlash replica for a non-read-only SQL statement based on cost estimation.

14.3.4 Use TiSpark to Read TiFlash Replicas

This document introduces how to use TiSpark to read TiFlash replicas.

Currently, you can use TiSpark to read TiFlash replicas in a method similar to the engine isolation in TiDB. This method is to configure the `spark.tispark.isolation_read_engines` parameter. The parameter value defaults to `tikv,tiflash`, which means that TiDB reads data from TiFlash or from TiKV according to CBO's selection. If you set the parameter value to `tiflash`, it means that TiDB forcibly reads data from TiFlash.

Note:

When this parameter is set to `tiflash`, only the TiFlash replicas of all tables involved in the query are read and these tables must have TiFlash replicas; for tables that do not have TiFlash replicas, an error is reported. When this parameter is set to `tikv`, only the TiKV replica is read.

You can configure this parameter in one of the following ways:

- Add the following item in the `spark-defaults.conf` file:

```
spark.tispark.isolation_read_engines tiflash
```

- Add `--conf spark.tispark.isolation_read_engines=tiflash` in the initialization command when initializing Spark shell or Thrift server.
- Set `spark.conf.set("spark.tispark.isolation_read_engines", "tiflash")` in Spark shell in a real-time manner.
- Set `set spark.tispark.isolation_read_engines=tiflash` in Thrift server after the server is connected via beeline.

14.3.5 Use TiFlash MPP Mode

This document introduces the Massively Parallel Processing (MPP) mode of TiFlash and how to use it.

TiFlash supports using the MPP mode to execute queries, which introduces cross-node data exchange (data shuffle process) into the computation. TiDB automatically determines whether to select the MPP mode using the optimizer's cost estimation. You can change the selection strategy by modifying the values of `tidb_allow_mpp` and `tidb_enforce_mpp`.

The following diagram shows how the MPP mode works.

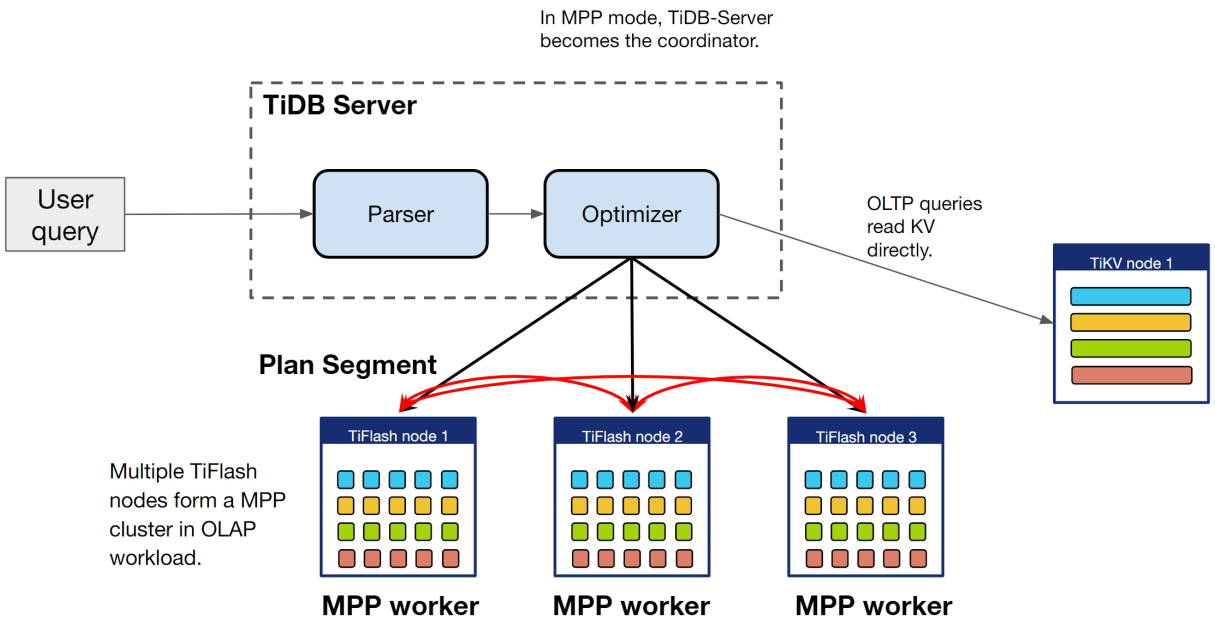

Figure 550: mpp-mode

14.3.5.1 Control whether to select the MPP mode

The `tidb_allow_mpp` variable controls whether TiDB can select the MPP mode to execute queries. The `tidb_enforce_mpp` variable controls whether the optimizer's cost estimation is ignored and the MPP mode of TiFlash is forcibly used to execute queries.

The results corresponding to all values of these two variables are as follows:

	tidb_allow_mpp=off	tidb_allow_mpp=on (by default)
tidb_enforce_mpp=off (by default)	The MPP mode is not used.	The optimizer selects the MPP mode based on cost estimation. (by default)
tidb_enforce_mpp=on	The MPP mode is not used.	TiDB ignores the cost estimation and selects the MPP mode.

For example, if you do not want to use the MPP mode, you can execute the following statements:

```
set @@session.tidb_allow_mpp=0;
```

If you want TiDB's cost-based optimizer to automatically decide whether to use the MPP mode (by default), you can execute the following statements:

```
set @@session.tidb_allow_mpp=1;
set @@session.tidb_enforce_mpp=0;
```

If you want TiDB to ignore the optimizer's cost estimation and to forcibly select the MPP mode, you can execute the following statements:

```
set @@session.tidb_allow_mpp=1;
set @@session.tidb_enforce_mpp=1;
```

The initial value of the `tidb_enforce_mpp` session variable is equal to the `enforce-mpp` configuration value of this tidb-server instance (which is `false` by default). If multiple tidb-server instances in a TiDB cluster only perform analytical queries and you want to make sure that the MPP mode is used on these instances, you can change their `enforce-mpp` configuration values to `true`.

Note:

When `tidb_enforce_mpp=1` takes effect, the TiDB optimizer will ignore the cost estimation to choose the MPP mode. However, if other factors block the MPP mode, TiDB will not select the MPP mode. These factors include the absence of TiFlash replica, unfinished replication of TiFlash replicas, and statements containing operators or functions that are not supported by the MPP mode.

If TiDB optimizer cannot select the MPP mode due to reasons other than cost estimation, when you use the `EXPLAIN` statement to check out the execution plan, a warning is returned to explain the reason. For example:

```
set @@session.tidb_enforce_mpp=1;
create table t(a int);
explain select count(*) from t;
show warnings;
```

```
+---------+------+-----------------------------------------------------------------
   ↪
| Level   | Code | Message
   ↪
   ↪ |
+---------+------+-----------------------------------------------------------------
   ↪
| Warning | 1105 | MPP mode may be blocked because there aren't
   ↪  tiflash replicas of table `t`. |
+---------+------+-----------------------------------------------------------------
   ↪
```

14.3.5.2 Algorithm support for the MPP mode

The MPP mode supports these physical algorithms: Broadcast Hash Join, Shuffled Hash Join, Shuffled Hash Aggregation, Union All, TopN, and Limit. The optimizer automatically determines which algorithm to be used in a query. To check the specific query execution plan, you can execute the `EXPLAIN` statement. If the result of the `EXPLAIN` statement shows ExchangeSender and ExchangeReceiver operators, it indicates that the MPP mode has taken effect.

The following statement takes the table structure in the TPC-H test set as an example:

```
explain select count(*) from customer c join nation n on c.c_nationkey=n.n_
    ↪ nationkey;
+--
    ↪ ----------------------------------------+-----------+--------------+----------
    ↪
| id                                    | estRows   | task         | access
    ↪ object | operator info
    ↪                                                          |
+--
    ↪ ----------------------------------------+-----------+--------------+----------
    ↪
| HashAgg_23                            | 1.00      | root         |
    ↪              | funcs:count(Column#16)->Column#15
    ↪                                    |
|  ─TableReader_25                       | 1.00      | root         |
    ↪              | data:ExchangeSender_24
    ↪                                                 |
|    ─ExchangeSender_24                  | 1.00      | mpp[tiflash] |
    ↪              | ExchangeType: PassThrough
    ↪                                               |
|      ─HashAgg_12                       | 1.00      | mpp[tiflash] |
    ↪              | funcs:count(1)->Column#16
    ↪                                              |
|        ─HashJoin_17                    | 3000000.00 | mpp[tiflash] |
    ↪            | inner join, equal:[eq(tpch.nation.n_nationkey, tpch.
    ↪ customer.c_nationkey)] |
|          ─ExchangeReceiver_21(Build) | 25.00     | mpp[tiflash] |
    ↪              |
    ↪                                                                    |
|            ─ExchangeSender_20          | 25.00     | mpp[tiflash] |
    ↪              | ExchangeType: Broadcast
    ↪                                                |
|              ─TableFullScan_18         | 25.00     | mpp[tiflash] | table:n
    ↪   | keep order:false
    ↪ |
|          ─TableFullScan_22(Probe)      | 3000000.00 | mpp[tiflash] | table:c
    ↪   | keep order:false                                                  |
```

```
+--
    ↪ ----------------------------------------+-----------+-------------+----------
    ↪
9 rows in set (0.00 sec)
```

In the example execution plan, the `ExchangeReceiver` and `ExchangeSender` operators are included. The execution plan indicates that after the `nation` table is read, the `ExchangeSender` operator broadcasts the table to each node, the `HashJoin` and `HashAgg` operations are performed on the `nation` table and the `customer` table, and then the results are returned to TiDB.

TiFlash provides the following 3 global/session variables to control whether to use Broadcast Hash Join:

- `tidb_broadcast_join_threshold_size`: The unit of the value is bytes. If the table size (in the unit of bytes) is less than the value of the variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.
- `tidb_broadcast_join_threshold_count`: The unit of the value is rows. If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set, so the size is determined by the number of rows in the result set. If the estimated number of rows in the subquery is less than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.
- `tidb_prefer_broadcast_join_by_exchange_data_size`: controls whether to use the algorithm with the minimum overhead of network transmission. If this variable is enabled, TiDB estimates the size of the data to be exchanged in the network using `Broadcast Hash Join` and `Shuffled Hash Join` respectively, and then chooses the one with the smaller size. `tidb_broadcast_join_threshold_count` and `tidb_
  ↪ broadcast_join_threshold_size` will not take effect after this variable is enabled.

14.3.5.3 Access partitioned tables in the MPP mode

To access partitioned tables in the MPP mode, you need to enable dynamic pruning mode first.

Example:

```
mysql> DROP TABLE if exists test.employees;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE test.employees
(id int(11) NOT NULL,
 fname varchar(30) DEFAULT NULL,
 lname varchar(30) DEFAULT NULL,
 hired date NOT NULL DEFAULT '1970-01-01',
 separated date DEFAULT '9999-12-31',
```

```
 job_code int DEFAULT NULL,
 store_id int NOT NULL) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=
    ↪ utf8mb4_bin
PARTITION BY RANGE (store_id)
(PARTITION p0 VALUES LESS THAN (6),
 PARTITION p1 VALUES LESS THAN (11),
 PARTITION p2 VALUES LESS THAN (16),
 PARTITION p3 VALUES LESS THAN (MAXVALUE));
Query OK, 0 rows affected (0.10 sec)

mysql> ALTER table test.employees SET tiflash replica 1;
Query OK, 0 rows affected (0.09 sec)

mysql> SET tidb_partition_prune_mode=static;
Query OK, 0 rows affected (0.00 sec)

mysql> explain SELECT count(*) FROM test.employees;
+--
    ↪ ---------------------------------+---------+------------------+----------------
    ↪
| id                            | estRows | task           | access object

14.3.6 Use FastScan

This document describes how to use FastScan to speed up queries in Online Analytical Processing (OLAP) scenarios.

By default, TiFlash guarantees the precision of query results and data consistency. With the feature FastScan, TiFlash provides more efficient query performance, but does not guarantee the accuracy of query results and data consistency.

Some OLAP scenarios allow for some tolerance to the accuracy of the query results. In these cases, if you need higher query performance, you can enable the FastScan feature at the session or global level. You can choose whether to enable the FastScan feature by configuring the variable `tiflash_fastscan`.

14.3.6.1 Restrictions

When the FastScan feature is enabled, your query results might include old data of a table. This means that you might get multiple historical versions of data with the same primary key or data that has been deleted.

For example:

```
CREATE TABLE t1 (a INT PRIMARY KEY, b INT);
ALTER TABLE t1 SET TIFLASH REPLICA 1;
INSERT INTO t1 VALUES(1,2);
INSERT INTO t1 VALUES(10,20);
UPDATE t1 SET b = 4 WHERE a = 1;
DELETE FROM t1 WHERE a = 10;
SET SESSION tidb_isolation_read_engines='tiflash';

SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|    1 |    4 |
+------+------+

SET SESSION tiflash_fastscan=ON;
SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|    1 |    2 |
```

```
|    1 |    4 |
|   10 |   20 |
+------+------+
```

Although TiFlash can automatically initiate compaction of old data in the background, the old data will not be cleaned up physically until it has been compacted and its data versions are older than the GC safe point. After the physical cleaning, the cleaned old data will no longer be returned in FastScan mode. The timing of data compaction is automatically triggered by various factors. You can also manually trigger data compaction using the `ALTER TABLE ... COMPACT` statement.

14.3.6.2 Enable and disable FastScan

By default, the variable is `tiflash_fastscan=OFF` at the session level and global level, that is, the FastScan feature is not enabled. You can view the variable information by using the following statement.

```
show variables like 'tiflash_fastscan';

+------------------+-------+
| Variable_name  | Value |
+------------------+-------+
| tiflash_fastscan | OFF |
+------------------+-------+
```

```
show global variables like 'tiflash_fastscan';

+------------------+-------+
| Variable_name  | Value |
+------------------+-------+
| tiflash_fastscan | OFF |
+------------------+-------+
```

You can configure the variable `tiflash_fastscan` at the session level and global level. If you need to enable FastScan in the current session, you can do so with the following statement:

```
set session tiflash_fastscan=ON;
```

You can also set `tiflash_fastscan` at the global level. The new setting will take effect in new sessions, but will not take effect in the current and previous sessions. Besides, in new sessions, `tiflash_fastscan` of the session level and global level will both take the new value.

```
set global tiflash_fastscan=ON;
```

You can disable FastScan using the following statement.

```
set session tiflash_fastscan=OFF;
set global tiflash_fastscan=OFF;
```

14.3.6.3 Mechanism of FastScan

Data in the storage layer of TiFlash is stored in two layers: Delta layer and Stable layer.

By default, FastScan is not enabled, and the TableScan operator processes data in the following steps:

1. Read data: create separate data streams in the Delta layer and Stable layer to read the respective data.
2. Sort Merge: merge the data streams created in step 1. Then return the data after sorting in the order of (primary key column, timestamp column).
3. Range Filter: according to the data range, filter the data generated in step 2, and then return the data.
4. MVCC + Column Filter: filter the data generated in step 3 through MVCC (that is, filtering the data version according to the primary key column and the timestamp column) and through columns (that is, filtering out unneeded columns), and then return the data.

FastScan gains faster query speed by sacrificing some data consistency. Step 2 and the MVCC part in step 4 in the normal scan process are omitted in FastScan, thus improving query performance.

14.3.7 TiFlash Disaggregated Storage and Compute Architecture and S3 Support

By default, TiFlash is deployed using the coupled storage and compute architecture, in which each TiFlash node acts as both storage and compute node. Starting from TiDB v7.0.0, TiFlash supports the disaggregated storage and compute architecture and allows to store data in Amazon S3 or S3-compatible object storage (such as MinIO).

14.3.7.1 Architecture overview

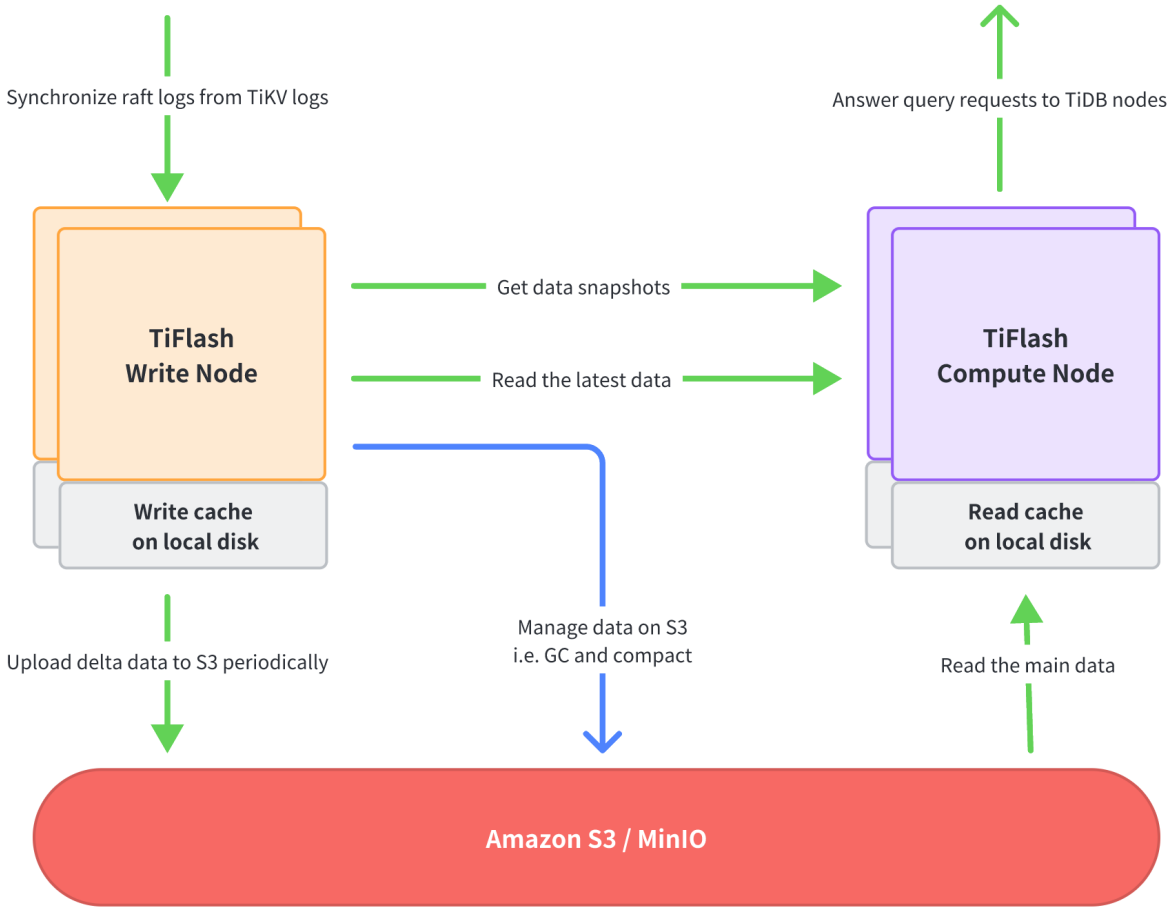

Figure 551: TiFlash Write and Compute Separation Architecture

In the disaggregated storage and compute architecture, different functionalities of the TiFlash process are divided and allocated to two types of nodes: the Write Node and the Compute Node. These two types of nodes can be deployed separately and scaled independently, which means that you can decide the number of Write Nodes and Compute Nodes to be deployed as needed.

- TiFlash Write Node

  The Write Node receives Raft logs data from TiKV, converts the data into the columnar format, and periodically packages and uploads all the updated data within a certain period to S3. In addition, the Write Node manages the data on S3, such as continuously organizing data to improve query performance and deleting useless data.

  The Write Node uses local disks (usually NVMe SSDs) to cache the latest written data to avoid excessive use of memory.

- TiFlash Compute Node

  The Compute Node executes query requests sent from a TiDB node. It first accesses a Write Node to obtain data snapshots, and then reads the latest data (that is, the data not been uploaded to S3 yet) from the Write Node and most of the remaining data from S3.

  The Compute Node uses local disks (usually NVMe SSDs) as a cache for data files to avoid repeatedly reading the same data from remote locations (Write Nodes or S3) and improve query performance.

  The Compute Node is stateless and its scaling speed is at a second level. You can use this feature to reduce costs as follows:

  - When the query workload is low, reduce the number of Compute Nodes to save costs. When there are no queries, you can even stop all Compute Nodes.
  - When the query workload increases, quickly increase the number of Compute Nodes to ensure query performance.

14.3.7.2 Scenarios

TiFlash disaggregated storage and compute architecture is suitable for cost-effective data analysis services. Because storage and compute resources can be scaled separately as needed in this architecture, you can get significant benefits in the following scenarios:

- The amount of data is large, but only a small amount of data is frequently queried. Most of the data is cold data and rarely queried. At this time, the frequently queried data is usually cached on the local SSD of the Compute Node to provide fast query performance, while most of the other cold data is stored in low-cost S3 or other object storage to save storage costs.
- The demand for compute resources has obvious peaks and valleys. For example, intensive reconciliation queries are usually performed at night, which demands high compute resources. In this case, you can consider temporarily adding more Compute Nodes at night. While at other times, you only need fewer Compute Nodes to complete regular query tasks.

14.3.7.3 Prerequisites

1. Prepare an Amazon S3 bucket for storing the TiFlash data.

   You can also use an existing bucket, but you need to reserve dedicated key prefixes for each TiDB cluster. For more information about S3 buckets, see AWS documentation.

   You can also use other S3-compatible object storage, such as MinIO.

   TiFlash needs to use the following S3 APIs for accessing data. Make sure that TiFlash nodes in your TiDB cluster have the necessary permissions for these APIs.

- PutObject
- GetObject
- CopyObject
- DeleteObject
- ListObjectsV2
- GetObjectTagging
- PutBucketLifecycle

2. Make sure that your TiDB cluster has no TiFlash nodes deployed using the coupled storage and compute architecture. If any, set the TiFlash replica count of all tables to 0 and then remove all TiFlash nodes. For example:

```
SELECT * FROM INFORMATION_SCHEMA.TIFLASH_REPLICA; # Query all tables
    ↪ with TiFlash replicas
ALTER TABLE table_name SET TIFLASH REPLICA 0; # Set the TiFlash
    ↪ replica count of all tables to `0`
```

```
tiup cluster scale-in mycluster -N 'node0,node1...' # Remove all
    ↪ TiFlash nodes
tiup cluster display mycluster                # Wait for all TiFlash
    ↪ nodes to enter the Tombstone state
tiup cluster prune mycluster                  # Remove all TiFlash nodes
    ↪  in the Tombstone state
```

14.3.7.4 Usage

By default, TiUP deploys TiFlash in the coupled storage and computation architecture. If you need to deploy TiFlash in the disaggregated storage and compute architecture, take the following steps for manual configuration:

1. Prepare a TiFlash topology configuration file, such as `scale-out.topo.yaml`, with the following configuration:

```
tiflash_servers:
  # In the TiFlash topology configuration file, the `storage.s3`
      ↪ configuration indicates that the disaggregated storage and
      ↪ compute architecture is used for deployment.
  # If `flash.disaggregated_mode: tiflash_compute` is configured for a
      ↪ node, it is a Compute Node.
  # If `flash.disaggregated_mode: tiflash_write` is configured for a
      ↪ node, it is a Write Node.

  # 172.31.8.1~2 are TiFlash Write Nodes
  - host: 172.31.8.1
    config:
```

```
    flash.disaggregated_mode: tiflash_write        # This is a Write
       ↪ Node
    storage.s3.endpoint: http://s3.{region}.amazonaws.com # S3
       ↪ endpoint address
    storage.s3.bucket: mybucket                    # TiFlash stores
       ↪ all data in this bucket
    storage.s3.root: /cluster1_data                # Root directory
       ↪ where data is stored in the S3 bucket
    storage.s3.access_key_id: {ACCESS_KEY_ID}      # Access S3 with
       ↪ ACCESS_KEY_ID
    storage.s3.secret_access_key: {SECRET_ACCESS_KEY} # Access S3 with
       ↪  SECRET_ACCESS_KEY
    storage.main.dir: ["/data1/tiflash/data"]      # Local data
       ↪ directory of the Write Node. Configure it in the same way
       ↪ as the directory configuration of the coupled storage and
       ↪ compute architecture
- host: 172.31.8.2
  config:
    flash.disaggregated_mode: tiflash_write        # This is a Write
       ↪ Node
    storage.s3.endpoint: http://s3.{region}.amazonaws.com # S3
       ↪ endpoint address
    storage.s3.bucket: mybucket                    # TiFlash stores
       ↪ all data in this bucket
    storage.s3.root: /cluster1_data                # Root directory
       ↪ where data is stored in the S3 bucket
    storage.s3.access_key_id: {ACCESS_KEY_ID}      # Access S3 with
       ↪ ACCESS_KEY_ID
    storage.s3.secret_access_key: {SECRET_ACCESS_KEY} # Access S3 with
       ↪  SECRET_ACCESS_KEY
    storage.main.dir: ["/data1/tiflash/data"]      # Local data
       ↪ directory of the Write Node. Configure it in the same way
       ↪ as the directory configuration of the coupled storage and
       ↪ compute architecture

# 172.31.9.1~2 are TiFlash Compute Nodes
- host: 172.31.9.1
  config:
    flash.disaggregated_mode: tiflash_compute      # This is a
       ↪ Compute Node
    storage.s3.endpoint: http://s3.{region}.amazonaws.com # S3
       ↪ endpoint address
    storage.s3.bucket: mybucket                    # TiFlash stores
       ↪ all data in this bucket
    storage.s3.root: /cluster1_data                # Root directory
```

```
      ↪ where data is stored in the S3 bucket
    storage.s3.access_key_id: {ACCESS_KEY_ID}      # Access S3 with
      ↪ ACCESS_KEY_ID
    storage.s3.secret_access_key: {SECRET_ACCESS_KEY} # Access S3 with
      ↪  SECRET_ACCESS_KEY
    storage.main.dir: ["/data1/tiflash/data"]      # Local data
      ↪ directory of the Compute Node. Configure it in the same way
      ↪  as the directory configuration of the coupled storage and
      ↪ compute architecture
    storage.remote.cache.dir: /data1/tiflash/cache # Local data cache
      ↪  directory of the Compute Node
    storage.remote.cache.capacity: 858993459200    # 800 GiB
- host: 172.31.9.2
  config:
    flash.disaggregated_mode: tiflash_compute      # This is a
      ↪ Compute Node
    storage.s3.endpoint: http://s3.{region}.amazonaws.com # S3
      ↪ endpoint address
    storage.s3.bucket: mybucket                    # TiFlash stores
      ↪ all data in this bucket
    storage.s3.root: /cluster1_data                # Root directory
      ↪ where data is stored in the S3 bucket
    storage.s3.access_key_id: {ACCESS_KEY_ID}      # Access S3 with
      ↪ ACCESS_KEY_ID
    storage.s3.secret_access_key: {SECRET_ACCESS_KEY} # Access S3 with
      ↪  SECRET_ACCESS_KEY
    storage.main.dir: ["/data1/tiflash/data"]      # Local data
      ↪ directory of the Compute Node. Configure it in the same way
      ↪  as the directory configuration of the coupled storage and
      ↪ compute architecture
    storage.remote.cache.dir: /data1/tiflash/cache # Local data cache
      ↪  directory of the Compute Node
    storage.remote.cache.capacity: 858993459200    # 800 GiB
```

- Note that the above `ACCESS_KEY_ID` and `SECRET_ACCESS_KEY` are directly written in the configuration file. You can also choose to configure them separately using environment variables. If both ways are configured, the environment variables have higher priority.

  To configure `ACCESS_KEY_ID` and `SECRET_ACCESS_KEY` through environment variables, switch to the user environment that starts the TiFlash process (usually `tidb`) on all machines where TiFlash processes are deployed, and then modify `~/.bash_profile` to add the following configurations:

```
export S3_ACCESS_KEY_ID={ACCESS_KEY_ID}
export S3_SECRET_ACCESS_KEY={SECRET_ACCESS_KEY}
```

- `storage.s3.endpoint` supports connecting to S3 using the `http` or `https` mode, and you can set the mode by directly modifying the URL. For example, `https ↪ ://s3.{region}.amazonaws.com`.

2. Add TiFlash nodes and reset the number of TiFlash replicas:

```
tiup cluster scale-out mycluster ./scale-out.topo.yaml
```

```
ALTER TABLE table_name SET TIFLASH REPLICA 1;
```

3. Modify the TiDB configuration to query TiFlash using the disaggregated storage and compute architecture.

    1. Open the TiDB configuration file in edit mode:

    ```
    shell  tiup cluster edit-config mycluster
    ```

    2. Add the following configuration items to the TiDB configuration file:

    ```
    server_configs:
    tidb:
    disaggregated-tiflash: true # Query TiFlash using the disaggregated
       ↪  storage and compute architecture
    ```

    3. Restart TiDB:

    ```
    tiup cluster reload mycluster -R tidb
    ```

14.3.7.5 Restrictions

- TiFlash does not support in-place switching between the **disaggregated storage and compute architecture** and the **coupled storage and compute architecture**. Before switching to the disaggregated architecture, you must remove all existing TiFlash nodes deployed using the coupled architecture.
- After the migration from one architecture to another, all TiFlash data needs to be replicated again.
- Only TiFlash nodes with the same architecture are allowed in the same TiDB cluster. Two architectures cannot coexist in one cluster.
- The disaggregated storage and compute architecture only supports object storage using the S3 API, while the coupled storage and compute architecture only supports local storage.
- When using S3 storage, TiFlash nodes cannot obtain the keys of files not on their own nodes, so the Encryption at Rest feature cannot be used.

14.3.8 Push-down Calculations Supported by TiFlash

This document introduces the push-down calculations supported by TiFlash.

14.3.8.1 Push-down operators

TiFlash supports the push-down of the following operators:

- TableScan: Reads data from tables.
- Selection: Filters data.
- HashAgg: Performs data aggregation based on the Hash Aggregation algorithm.
- StreamAgg: Performs data aggregation based on the Stream Aggregation algorithm. SteamAgg only supports the aggregation without the `GROUP BY` condition.
- TopN: Performs the TopN calculation.
- Limit: Performs the limit calculation.
- Project: Performs the projection calculation.
- HashJoin: Performs the join calculation using the Hash Join algorithm, but with the following conditions:
  - The operator can be pushed down only in the MPP mode.
  - Supported joins are Inner Join, Left Join, Semi Join, Anti Semi Join, Left Semi Join, and Anti Left Semi Join.
  - The preceding joins support both Equi Join and Non-Equi Join (Cartesian Join or Null-aware Semi Join). When calculating Cartesian Join or Null-aware Semi Join, the Broadcast algorithm, instead of the Shuffle Hash Join algorithm, is used.
- Window functions: Currently, TiFlash supports `ROW_NUMBER()`, `RANK()`, `DENSE_RANK()`, `LEAD()`, `LAG()`, `FIRST_VALUE()`, and `LAST_VALUE()`.

In TiDB, operators are organized in a tree structure. For an operator to be pushed down to TiFlash, all of the following prerequisites must be met:

- All of its child operators can be pushed down to TiFlash.
- If an operator contains expressions (most of the operators contain expressions), all expressions of the operator can be pushed down to TiFlash.

14.3.8.2 Push-down expressions

TiFlash supports the following push-down expressions:

Expression Type	Operations
Numeric functions and operators	`+`, `-`, `/`, `*`, `%`, `>=`, `<=`, `=`, `!=`, `<`, `>`, `ROUND()`, `ABS()`, `FLOOR(int)`, `CEIL(int)`, `CEILING(int)`, `SQRT()`, `LOG()`, `LOG2()`, `LOG10()`, `LN()`, `EXP()`, `POW()`, `POWER()`, `SIGN()`, `RADIANS()`, `DEGREES()`, `CONV()`, `CRC32()`, `GREATEST(int/real)`, `LEAST(int/real)`
Logical functions and operators	`AND`, `OR`, `NOT`, `CASE WHEN`, `IF()`, `IFNULL()`, `ISNULL()`, `IN`, `LIKE`, `ILIKE`, `COALESCE`, `IS`

Expression Type	Operations
Bitwise operations	& (bitand), | (bitor), ~ (bitneg), ^ (bitxor)
String functions	SUBSTR(), CHAR_LENGTH(), REPLACE(), CONCAT(), CONCAT_WS(), LEFT(), RIGHT(), ASCII(), LENGTH(), TRIM(), LTRIM(), RTRIM(), POSITION(), FORMAT(), LOWER(), UCASE(), UPPER(), SUBSTRING_INDEX(), LPAD(), RPAD(), STRCMP()
Regular expression functions and operators	REGEXP, REGEXP_LIKE(), REGEXP_INSTR(), REGEXP_SUBSTR(), REGEXP_REPLACE(), RLIKE
Date functions	DATE_FORMAT(), TIMESTAMPDIFF(), FROM_UNIXTIME(), UNIX_TIMESTAMP(int), UNIX_TIMESTAMP(decimal), STR_TO_DATE(date), STR_TO_DATE(datetime), DATEDIFF(), YEAR(), MONTH(), DAY(), EXTRACT(datetime), DATE(), HOUR(), MICROSECOND(), MINUTE(), SECOND(), SYSDATE(), DATE_ADD/ADDDATE(datetime, int), DATE_ADD/ADDDATE(string, int/real), DATE_SUB/SUBDATE(datetime, int), DATE_SUB/SUBDATE(string, int/real), QUARTER(), DAYNAME(), DAYOFMONTH(), DAYOFWEEK(), DAYOFYEAR(), LAST_DAY(), MONTHNAME(), TO_SECONDS(), TO_DAYS(), FROM_DAYS(), WEEKOFYEAR()
JSON function	JSON_LENGTH(), ->, ->>, JSON_EXTRACT(), JSON_ARRAY(), JSON_DEPTH(), JSON_VALID(), JSON_KEYS(), JSON_CONTAINS_PATH(), JSON_UNQUOTE()
Vector function	VEC_L2_DISTANCE, VEC_COSINE_DISTANCE, VEC_NEGATIVE_INNER_PRODUCT, VEC_L1_DISTANCE, VEC_DIMS, VEC_L2_NORM, VEC_AS_TEXT

Expression Type	Operations
Conversion functions	`CAST(int AS DOUBLE)`, `CAST(int AS DECIMAL)`, `CAST(int AS STRING)`, `CAST(int AS TIME)`, `CAST(double AS INT)`, `CAST(double AS DECIMAL)`, `CAST(double AS STRING)`, `CAST(double AS TIME)`, `CAST(string AS INT)`, `CAST(string AS DOUBLE)`, `CAST(string AS DECIMAL)`, `CAST(string AS TIME)`, `CAST(decimal AS INT)`, `CAST(decimal AS STRING)`, `CAST(decimal AS TIME)`, `CAST(decimal AS DOUBLE)`, `CAST(time AS INT)`, `CAST(time AS DECIMAL)`, `CAST(time AS STRING)`, `CAST(time AS REAL)`, `CAST(json AS JSON)`, `CAST(json AS STRING)`, `CAST(int AS JSON)`, `CAST(real AS JSON)`, `CAST(decimal AS JSON)`, `CAST(string AS JSON)`, `CAST(time AS JSON)`, `CAST(duration AS JSON)`
Aggregate functions	`MIN()`, `MAX()`, `SUM()`, `COUNT()`, `AVG()`, `APPROX_COUNT_DISTINCT()`, `GROUP_CONCAT()`
Miscellaneous functions	`INET_NTOA()`, `INET_ATON()`, `INET6_NTOA()`, `INET6_ATON()`

14.3.8.3 Restrictions

- Expressions that contain the Bit, Set, and Geometry types cannot be pushed down to TiFlash.
- The `DATE_ADD()`, `DATE_SUB()`, `ADDDATE()`, and `SUBDATE()` functions support the following interval types only. If other interval types are used, TiFlash reports errors.
    - DAY
    - WEEK

- MONTH
- YEAR
- HOUR
- MINUTE
- SECOND

If a query encounters unsupported push-down calculations, TiDB needs to complete the remaining calculations, which might greatly affect the TiFlash acceleration effect. The currently unsupported operators and expressions might be supported in future versions.

Functions like `MAX()` are supported for push-down when used as aggregate functions, but not as window functions.

14.3.8.4 Examples

This section provides some examples of pushing down operators and expressions to TiFlash.

14.3.8.4.1 Example 1: Push operators down to TiFlash

```
CREATE TABLE t(id INT PRIMARY KEY, a INT);
ALTER TABLE t SET TIFLASH REPLICA 1;

EXPLAIN SELECT * FROM t LIMIT 3;

+--
   ↪ ---------------------------+---------+-------------+---------------+---------
   ↪
| id                          | estRows | task        | access object | operator
   ↪ info            |
+--
   ↪ ---------------------------+---------+-------------+---------------+---------
   ↪
| Limit_9                     | 3.00    | root        |               | offset:0,
   ↪ count:3          |
| └─TableReader_17            | 3.00    | root        |               | data:
   ↪ ExchangeSender_16     |
|   └─ExchangeSender_16       | 3.00    | mpp[tiflash] |              |
   ↪ ExchangeType: PassThrough  |
|     └─Limit_15              | 3.00    | mpp[tiflash] |              | offset:0,
   ↪ count:3          |
|       └─TableFullScan_14    | 3.00    | mpp[tiflash] | table:t      | keep order
   ↪ :false, stats:pseudo |
+--
   ↪ ---------------------------+---------+-------------+---------------+---------
   ↪
```

```
5 rows in set (0.18 sec)
```

In the preceding example, the operator `Limit` is pushed down to TiFlash for filtering data, which helps reduce the amount of data to be transferred over the network and reduce the network overhead. This is indicated by the `mpp[tiflash]` value of the `task` column on the row of the `Limit_15` operator.

14.3.8.4.2 Example 2: Push expressions down to TiFlash

```
CREATE TABLE t(id INT PRIMARY KEY, a INT);
ALTER TABLE t SET TIFLASH REPLICA 1;
INSERT INTO t(id,a) VALUES (1,2),(2,4),(11,2),(12,4),(13,4),(14,7);

EXPLAIN SELECT MAX(id + a) FROM t GROUP BY a;

+--
   ↪ ---------------------------------+---------+-------------+---------------+----
   ↪
| id                                | estRows | task      | access object |
   ↪ operator info                                                  |
+--
   ↪ ---------------------------------+---------+-------------+---------------+----
   ↪
| TableReader_45                    | 4.80    | root        |               | data:
   ↪ ExchangeSender_44                                              |
|  ─ExchangeSender_44               | 4.80    | mpp[tiflash] |              |
   ↪ ExchangeType: PassThrough                                        |
|    ─Projection_39                 | 4.80    | mpp[tiflash] |              |
   ↪ Column#3                                                         |
|      ─HashAgg_37                  | 4.80    | mpp[tiflash] |              |
   ↪ group by:Column#9, funcs:max(Column#8)->Column#3                 |
|        ─Projection_46             | 6.00    | mpp[tiflash] |              | plus
   ↪ (test.t.id, test.t.a)->Column#8, test.t.a                      |
|          ─ExchangeReceiver_23     | 6.00    | mpp[tiflash] |              |
   ↪                                                                  |
|            ─ExchangeSender_22     | 6.00    | mpp[tiflash] |              |
   ↪ ExchangeType: HashPartition, Hash Cols: [name: test.t.a, collate:
   ↪ binary] |
|              ─TableFullScan_21    | 6.00    | mpp[tiflash] | table:t      | keep
   ↪  order:false, stats:pseudo                                       |
+--
   ↪ ---------------------------------+---------+-------------+---------------+----
   ↪
8 rows in set (0.18 sec)
```

In the preceding example, the expression `id + a` is pushed down to TiFlash for calculation in advance. This helps reduce the amount of data to be transferred over the network, thus reducing the network transmission overhead and improving the overall calculation performance. This is indicated by the `mpp[tiflash]` value in the `task` column of the row where the `operator` column has the `plus(test.t.id, test.t.a)` value.

14.3.8.4.3 Example 3: Restrictions for pushdown

```
CREATE TABLE t(id INT PRIMARY KEY, a INT);
ALTER TABLE t SET TIFLASH REPLICA 1;
INSERT INTO t(id,a) VALUES (1,2),(2,4),(11,2),(12,4),(13,4),(14,7);

EXPLAIN SELECT id FROM t WHERE TIME(now()+ a) < '12:00:00';

+--
   ↪ ------------------------+---------+-------------+---------------+----------
   ↪
| id                       | estRows | task      | access object | operator
   ↪ info
   ↪                                                                          |
+--
   ↪ ------------------------+---------+-------------+---------------+----------
   ↪
| Projection_4             | 4.80    | root        |               | test.t.id
   ↪
   ↪ |
|  ─Selection_6            | 4.80    | root        |               | lt(cast(
   ↪ time(cast(plus(20230110083056, test.t.a), var_string(20))), var_
   ↪ string(10)), "12:00:00") |
|    ─TableReader_11       | 6.00    | root        |               | data:
   ↪ ExchangeSender_10
   ↪                                                                      |
|      ─ExchangeSender_10  | 6.00    | mpp[tiflash] |              |
   ↪ ExchangeType: PassThrough
   ↪                                                                    |
|        ─TableFullScan_9  | 6.00    | mpp[tiflash] | table:t      | keep order:
   ↪ false, stats:pseudo
   ↪                                                              |
+--
   ↪ ------------------------+---------+-------------+---------------+----------
   ↪
5 rows in set, 3 warnings (0.20 sec)
```

The preceding example only performs `TableFullScan` on TiFlash. Other functions are calculated and filtered on `root` and are not pushed down to TiFlash.

You can identify the operators and expressions that cannot be pushed down to TiFlash by running the following command:

```
SHOW WARNINGS;

+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | Scalar function 'time'(signature: Time, return type:
    ↪ time) is not supported to push down to storage layer now.  |
| Warning | 1105 | Scalar function 'cast'(signature: CastDurationAsString,
    ↪ return type: var_string(10)) is not supported to push down to tiflash
    ↪  now. |
| Warning | 1105 | Scalar function 'cast'(signature: CastDurationAsString,
    ↪ return type: var_string(10)) is not supported to push down to tiflash
    ↪  now. |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
3 rows in set (0.18 sec)
```

The expressions in the preceding example cannot be completely pushed down to TiFlash, because the functions `Time` and `Cast` cannot be pushed down to TiFlash.

14.3.8.4.4 Example 4: Window functions

```
CREATE TABLE t(id INT PRIMARY KEY, c1 VARCHAR(100));
ALTER TABLE t SET TIFLASH REPLICA 1;
INSERT INTO t VALUES(1,"foo"),(2,"bar"),(3,"bar foo"),(10,"foo"),(20,"bar")
    ↪ ,(30,"bar foo");

EXPLAIN SELECT id, ROW_NUMBER() OVER (PARTITION BY id > 10) FROM t;
+--
    ↪ --------------------------------+----------+--------------+---------------+-----
    ↪
| id                              | estRows | task       | access object |
    ↪ operator info
    ↪
    ↪ |
```

```
+--
   ↪ ------------------------------+---------+-------------+---------------+-----
   ↪
| TableReader_30                | 10000.00 | root      |             |
   ↪ MppVersion: 1, data:ExchangeSender_29
   ↪                                                                  |
|  ─ExchangeSender_29           | 10000.00 | mpp[tiflash] |          |
   ↪ ExchangeType: PassThrough
   ↪
   ↪ |
|    ─Projection_7              | 10000.00 | mpp[tiflash] |          | test.
   ↪ t.id, Column#5, stream_count: 4
   ↪                                                                    |
|      ─Window_28               | 10000.00 | mpp[tiflash] |          | row_
   ↪ number()->Column#5 over(partition by Column#4 rows between current
   ↪ row and current row), stream_count: 4 |
|        ─Sort_14               | 10000.00 | mpp[tiflash] |          |
   ↪ Column#4, stream_count: 4
   ↪
   ↪ |
|          ─ExchangeReceiver_13 | 10000.00 | mpp[tiflash] |          |
   ↪ stream_count: 4
   ↪
   ↪ |
|            ─ExchangeSender_12 | 10000.00 | mpp[tiflash] |          |
   ↪ ExchangeType: HashPartition, Compression: FAST, Hash Cols: [name:
   ↪ Column#4, collate: binary], stream_count: 4 |
|              ─Projection_10   | 10000.00 | mpp[tiflash] |          | test.
   ↪ t.id, gt(test.t.id, 10)->Column#4
   ↪                                                                  |
|                ─TableFullScan_11 | 10000.00 | mpp[tiflash] | table:t | keep
   ↪  order:false, stats:pseudo
   ↪                                                                   |
+--
   ↪ ------------------------------+---------+-------------+---------------+-----
   ↪
9 rows in set (0.0073 sec)
```

In this output, you can see that the `Window` operation has a value of `mpp[tiflash]` in the `task` column, indicating that the `ROW_NUMBER()OVER (PARTITION BY id > 10)` operation can be pushed down to TiFlash.

```
CREATE TABLE t(id INT PRIMARY KEY, c1 VARCHAR(100));
ALTER TABLE t SET TIFLASH REPLICA 1;
```

```
INSERT INTO t VALUES(1,"foo"),(2,"bar"),(3,"bar foo"),(10,"foo"),(20,"bar")
    ↪ ,(30,"bar foo");

EXPLAIN SELECT id, MAX(id) OVER (PARTITION BY id > 10) FROM t;
+--
    ↪ -------------------------+---------+----------+--------------+-----------
    ↪
| id                        | estRows | task     | access object | operator
    ↪ info                                  |
+--
    ↪ -------------------------+---------+----------+--------------+-----------
    ↪
| Projection_6              | 10000.00 | root    |              | test.t1.id,
    ↪ Column#5                                |
|  ─Shuffle_14              | 10000.00 | root    |              | execution
    ↪ info: concurrency:5, data sources:[Projection_8] |
|    ─Window_7              | 10000.00 | root    |              | max(test.t1.
    ↪ id)->Column#5 over(partition by Column#4) |
|      ─Sort_13             | 10000.00 | root    |              | Column#4
    ↪                                          |
|        ─Projection_8      | 10000.00 | root    |              | test.t1.id,
    ↪ gt(test.t1.id, 10)->Column#4            |
|          ─TableReader_10  | 10000.00 | root    |              | data:
    ↪ TableFullScan_9                                 |
|            ─TableFullScan_9 | 10000.00 | cop[tikv] | table:t1 | keep order
    ↪ :false, stats:pseudo                    |
+--
    ↪ -------------------------+---------+----------+--------------+-----------
    ↪
7 rows in set (0.0010 sec)
```

In this output, you can see that the `Window` operation has a value of `root` in the `task` ↪ column, indicating that the `MAX(id)OVER (PARTITION BY id > 10)` operation cannot be pushed down to TiFlash. This is because `MAX()` is only supported for push-down as an aggregate function and not as a window function.

14.3.9 TiFlash Query Result Materialization

This document introduces how to save the TiFlash query result to a specified TiDB table in an `INSERT INTO SELECT` transaction.

Starting from v6.5.0, TiDB supports saving TiFlash query results in a table, that is, TiFlash query result materialization. During the execution of the `INSERT INTO SELECT` statement, if TiDB pushes down the `SELECT` subquery to TiFlash, the TiFlash query result can be saved to a TiDB table specified in the `INSERT INTO` clause. For TiDB versions earlier

than v6.5.0, the TiFlash query results are read-only, so if you want to save TiFlash query results, you have to obtain them from the application level, and then save them in a separate transaction or process.

Note:

By default (`tidb_allow_mpp = ON`), the optimizer intelligently decides whether to push a query down to TiFlash based on the SQL mode and the cost estimates of the TiFlash replica.

- If the SQL mode of the current session is not strict (which means the `sql_mode` value does not contain `STRICT_TRANS_TABLES`' and `STRICT` ↪ `_ALL_TABLES`), the optimizer intelligently decides whether to push the `SELECT` subquery in `INSERT INTO SELECT` down to TiFlash based on the cost estimates of the TiFlash replica. In this mode, if you want to ignore the cost estimates of the optimizer and enforce that the queries are pushed down to TiFlash, you can set the `tidb_enforce_mpp` system variable to `ON`.
- If the SQL mode of the current session is strict (which means the `sql` ↪ `_mode` value contains either `STRICT_TRANS_TABLES` or `STRICT_ALL` ↪ `_TABLES`), the `SELECT` subquery in `INSERT INTO SELECT` cannot be pushed down to TiFlash.

The syntax of `INSERT INTO SELECT` is as follows.

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name
    [PARTITION (partition_name [, partition_name] ...)]
    [(col_name [, col_name] ...)]
    SELECT ...
    [ON DUPLICATE KEY UPDATE assignment_list]value:
    {expr | DEFAULT}

assignment:
    col_name = valueassignment_list:
    assignment [, assignment] ...
```

For example, you can save the query result from table `t1` in the `SELECT` clause to table `t2` using the following `INSERT INTO SELECT` statement:

```
INSERT INTO t2 (name, country)
SELECT app_name, country FROM t1;
```

14.3.9.1 Typical and recommended usage scenarios

- Efficient BI solutions

  For many BI applications, the analysis query requests are very heavy. For example, when a lot of users access and refresh a report at the same time, a BI application needs to handle a lot of concurrent query requests. To deal with this situation effectively, you can use `INSERT INTO SELECT` to save the query results of the report in a TiDB table. Then, the end users can query data directly from the result table when the report is refreshed, which avoids multiple repeated computations and analyses. Similarly, by saving historical analysis results, you can further reduce the computation volume for long-time historical data analysis. For example, if you have a report `A` that is used to analyze daily sales profit, you can save the results of report `A` to a result table `T` using `INSERT INTO SELECT`. Then, when you need to generate a report `B` to analyze the sales profit of the past month, you can directly use the daily analysis results in table `T`. This way not only greatly reduces the computation volume but also improves the query response speed and reduces the system load.

- Serving online applications with TiFlash

  The number of concurrent requests supported by TiFlash depends on the volume of data and complexity of the queries, but it typically does not exceed 100 QPS. You can use `INSERT INTO SELECT` to save TiFlash query results, and then use the query result table to support highly concurrent online requests. The data in the result table can be updated in the background at a low frequency (for example, at an interval of 0.5 second), which is well below the TiFlash concurrency limit, while still maintaining a high level of data freshness.

14.3.9.2 Execution process

- During the execution of the `INSERT INTO SELECT` statement, TiFlash first returns the query results of the `SELECT` clause to a TiDB server in the cluster, and then writes the results to the target table, which can have a TiFlash replica.
- The execution of the `INSERT INTO SELECT` statement guarantees ACID properties.

14.3.9.3 Restrictions

- The TiDB memory limit on the `INSERT INTO SELECT` statement can be adjusted using the system variable `tidb_mem_quota_query`. Starting from v6.5.0, it is not recommended to use `txn-total-size-limit` to control transaction memory size.

  For more information, see TiDB memory control.

- TiDB has no hard limit on the concurrency of the `INSERT INTO SELECT` statement, but it is recommended to consider the following practices:

- When a "write transaction" is large, such as close to 1 GiB, it is recommended to control concurrency to no more than 10.
- When a "write transaction" is small, such as less than 100 MiB, it is recommended to control concurrency to no more than 30.
- Determine the concurrency based on testing results and specific circumstances.

14.3.9.4 Example

Data definition:

```
CREATE TABLE detail_data (
    ts DATETIME,             -- Fee generation time
    customer_id VARCHAR(20), -- Customer ID
    detail_fee DECIMAL(20,2)); -- Amount of fee

CREATE TABLE daily_data (
    rec_date DATE,           -- Date when data is collected
    customer_id VARCHAR(20), -- Customer ID
    daily_fee DECIMAL(20,2)); -- Amount of fee for per day

ALTER TABLE detail_data SET TIFLASH REPLICA 2;
ALTER TABLE daily_data SET TIFLASH REPLICA 2;

-- ... (detail_data table continues updating)
INSERT INTO detail_data(ts,customer_id,detail_fee) VALUES
('2023-1-1 12:2:3', 'cus001', 200.86),
('2023-1-2 12:2:3', 'cus002', 100.86),
('2023-1-3 12:2:3', 'cus002', 2200.86),
('2023-1-4 12:2:3', 'cus003', 2020.86),
('2023-1-5 12:2:3', 'cus003', 1200.86),
('2023-1-6 12:2:3', 'cus002', 20.86),
('2023-1-7 12:2:3', 'cus004', 120.56),
('2023-1-8 12:2:3', 'cus005', 320.16);

-- Execute the following SQL statement 13 times to insert a cumulative
   ↪ total of 65,536 rows into the table.
INSERT INTO detail_data SELECT * FROM detail_data;
```

Save daily analysis results:

```
SET @@sql_mode='NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO';

INSERT INTO daily_data (rec_date, customer_id, daily_fee)
SELECT DATE(ts), customer_id, sum(detail_fee) FROM detail_data WHERE DATE(
   ↪ ts) > DATE('2023-1-1 12:2:3') GROUP BY DATE(ts), customer_id;
```

Analyze monthly data based on daily analysis data:

```
SELECT MONTH(rec_date), customer_id, sum(daily_fee) FROM daily_data GROUP
    ↪ BY MONTH(rec_date), customer_id;
```

The preceding example materializes the daily analysis results and saves them to the daily result table, based on which the monthly data analysis is accelerated, thus improving data analysis efficiency.

14.3.10 TiFlash Late Materialization

> **Note:**
>
> TiFlash late materialization does not take effect in the fast scan mode.

TiFlash late materialization is an optimization method to accelerate queries in OLAP scenarios. You can use the `tidb_opt_enable_late_materialization` system variable to control whether to enable or disable TiFlash late materialization.

- When it is disabled, to process a `SELECT` statement with filter conditions (`WHERE` clause), TiFlash reads all the data from the columns required by the query, and then filters and aggregates the data based on the query conditions.
- When it is enabled, TiFlash supports pushing down part of the filter conditions to the TableScan operator. That is, TiFlash first scans the column data related to the filter conditions that are pushed down to the TableScan operator, filters the rows that meet the condition, and then scans the other column data of these rows for further calculation, thereby reducing IO scans and computations of data processing.

To improve the performance of certain queries in OLAP scenarios, starting from v7.1.0, the TiFlash late materialization feature is enabled by default. The TiDB optimizer can determine which filter conditions to be pushed down based on statistics and filter conditions, and prioritize pushing down the filter conditions with high filtration rates. For detailed algorithms, see the RFC document.

For example:

```
EXPLAIN SELECT a, b, c FROM t1 WHERE a < 1;
```

```
+-------------------------+---------+--------------+--------------+-------------------
    ↪
| id                      | estRows | task         | access object | operator
    ↪ info                                  |
```

```
+------------------------+---------+-------------+--------------+-------------------
   ↪
| TableReader_12       | 12288.00 | root      |              | MppVersion: 1,
   ↪  data:ExchangeSender_11          |
|  ─ExchangeSender_11  | 12288.00 | mpp[tiflash] |          | ExchangeType:
   ↪  PassThrough                      |
|    ─TableFullScan_9  | 12288.00 | mpp[tiflash] | table:t1 | pushed down
   ↪ filter:lt(test.t1.a, 1), keep order:false |
+------------------------+---------+-------------+--------------+-------------------
   ↪
```

In this example, the filter condition `a < 1` is pushed down to the TableScan operator. TiFlash first reads all data from column `a`, and then filters the rows that meet the `a < 1` condition. Next, TiFlash reads columns `b` and `c` from these filtered rows.

14.3.10.1 Enable or disable TiFlash late materialization

By default, the `tidb_opt_enable_late_materialization` system variable is `ON` at both the session and global levels, which means that the TiFlash late materialization feature is enabled. You can use the following statement to view the corresponding variable information:

```
SHOW VARIABLES LIKE 'tidb_opt_enable_late_materialization';
```

```
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| tidb_opt_enable_late_materialization | ON |
+---------------------------------------+-------+
```

```
SHOW GLOBAL VARIABLES LIKE 'tidb_opt_enable_late_materialization';
```

```
+---------------------------------------+-------+
| Variable_name                         | Value |
+---------------------------------------+-------+
| tidb_opt_enable_late_materialization | ON |
+---------------------------------------+-------+
```

You can modify the `tidb_opt_enable_late_materialization` variable at the session level or at the global level.

- To disable TiFlash late materialization in the current session, use the following statement:

  ```
  SET SESSION tidb_opt_enable_late_materialization=OFF;
  ```

- To disable TiFlash late materialization at the global level, use the following statement:

```
SET GLOBAL tidb_opt_enable_late_materialization=OFF;
```

  After this setting, the `tidb_opt_enable_late_materialization` variable will be enabled by default for both session and global levels in new sessions.

To enable TiFlash late materialization, use the following statements:

```
SET SESSION tidb_opt_enable_late_materialization=ON;
```

```
SET GLOBAL tidb_opt_enable_late_materialization=ON;
```

14.3.10.2 Implementation mechanism

When filter conditions are pushed down to the TableScan operator, the execution process of the TableScan operator mainly includes the following steps:

1. Reads the three columns `<handle, del_mark, version>`, performs multi-version concurrency control (MVCC) filtering, and then generates the MVCC Bitmap.
2. Reads the columns related to the filter conditions, filters the rows that meet the conditions, and then generates the Filter Bitmap.
3. Performs an `AND` operation between the MVCC Bitmap and Filter Bitmap to generate the Final Bitmap.
4. Reads the corresponding rows of the remaining columns according to the Final Bitmap.
5. Merges the data read in steps 2 and 4, and then returns the results.

14.3.11 TiFlash Spill to Disk

This document introduces how TiFlash spills data to disk during computation.

Starting from v7.0.0, TiFlash supports spilling intermediate data to disk to relieve memory pressure. The following operators are supported:

- Hash Join operators with equi-join conditions
- Hash Aggregation operators with `GROUP BY` keys
- TopN operators, and Sort operators in Window functions

14.3.11.1 Trigger the spilling

TiFlash provides two triggering mechanisms for spilling data to disk.

- Operator-level spilling: by specifying the data spilling threshold for each operator, you can control when TiFlash spills data of that operator to disk.
- Query-level spilling: by specifying the maximum memory usage of a query on a TiFlash node and the memory ratio for spilling, you can control when TiFlash spills data of supported operators in a query to disk as needed.

14.3.11.1.1 Operator-level spilling

Starting from v7.0.0, TiFlash supports automatic spilling at the operator level. You can control the threshold of data spilling for each operator using the following system variables. When the memory usage of an operator exceeds the threshold, TiFlash triggers spilling for the operator.

- tidb_max_bytes_before_tiflash_external_group_by
- tidb_max_bytes_before_tiflash_external_join
- tidb_max_bytes_before_tiflash_external_sort

Example

This example constructs a SQL statement that consumes a lot of memory to demonstrate the spilling of the Hash Aggregation operator.

1. Prepare the environment. Create a TiFlash cluster with 2 nodes and import the TPCH-100 data.
2. Execute the following statements. These statements do not limit the memory usage of the Hash Aggregation operator with `GROUP BY` keys.

```
SET tidb_max_bytes_before_tiflash_external_group_by = 0;
SELECT
  l_orderkey,
  MAX(L_COMMENT),
  MAX(L_SHIPMODE),
  MAX(L_SHIPINSTRUCT),
  MAX(L_SHIPDATE),
  MAX(L_EXTENDEDPRICE)
FROM lineitem
GROUP BY l_orderkey
HAVING SUM(l_quantity) > 314;
```

3. From the log of TiFlash, you can see that the query needs to consume 29.55 GiB of memory on a single TiFlash node:

```
[DEBUG] [MemoryTracker.cpp:69] ["Peak memory usage (total): 29.55 GiB
    ↪ ."] [source=MemoryTracker] [thread_id=468]
```

4. Execute the following statement. This statement limits the memory usage of the Hash Aggregation operator with `GROUP BY` keys to 10737418240 (10 GiB).

```
SET tidb_max_bytes_before_tiflash_external_group_by = 10737418240;
SELECT
  l_orderkey,
  MAX(L_COMMENT),
```

```
  MAX(L_SHIPMODE),
  MAX(L_SHIPINSTRUCT),
  MAX(L_SHIPDATE),
  MAX(L_EXTENDEDPRICE)
FROM lineitem
GROUP BY l_orderkey
HAVING SUM(l_quantity) > 314;
```

5. From the log of TiFlash, you can see that by configuring `tidb_max_bytes_before_tiflash_external_group_by`, TiFlash triggers the spilling of intermediate results, significantly reducing the memory used by the query.

```
[DEBUG] [MemoryTracker.cpp:69] ["Peak memory usage (total): 12.80 GiB."] [source=MemoryTracker] [thread_id=110]
```

14.3.11.1.2 Query-level spilling

Starting from v7.4.0, TiFlash supports automatic spilling at the query level. You can control this feature using the following system variables:

- `tiflash_mem_quota_query_per_node`: limits the maximum memory usage for a query on a TiFlash node.
- `tiflash_query_spill_ratio`: controls the memory ratio that triggers data spilling.

If both `tiflash_mem_quota_query_per_node` and `tiflash_query_spill_ratio` are set to values greater than 0, TiFlash automatically triggers spilling for supported operators in a query when the memory usage of a query exceeds `tiflash_mem_quota_query_per_node * tiflash_query_spill_ratio`.

Example

This example constructs a SQL statement that consumes a lot of memory to demonstrate the query-level spilling.

1. Prepare the environment. Create a TiFlash cluster with 2 nodes and import the TPCH-100 data.

2. Execute the following statements. These statements do not limit the memory usage of the query or the memory usage of the Hash Aggregation operator with `GROUP BY` keys.

```
SET tidb_max_bytes_before_tiflash_external_group_by = 0;
SET tiflash_mem_quota_query_per_node = 0;
SET tiflash_query_spill_ratio = 0;
SELECT
  l_orderkey,
  MAX(L_COMMENT),
```

```
  MAX(L_SHIPMODE),
  MAX(L_SHIPINSTRUCT),
  MAX(L_SHIPDATE),
  MAX(L_EXTENDEDPRICE)
FROM lineitem
GROUP BY l_orderkey
HAVING SUM(l_quantity) > 314;
```

3. From the log of TiFlash, you can see that the query consumes 29.55 GiB of memory on a single TiFlash node:

```
[DEBUG] [MemoryTracker.cpp:69] ["Peak memory usage (total): 29.55 GiB
    ↪ ."] [source=MemoryTracker] [thread_id=468]
```

4. Execute the following statements. These statements limit the maximum memory usage of the query on a TiFlash node to 5 GiB.

```
SET tiflash_mem_quota_query_per_node = 5368709120;
SET tiflash_query_spill_ratio = 0.7;
SELECT
  l_orderkey,
  MAX(L_COMMENT),
  MAX(L_SHIPMODE),
  MAX(L_SHIPINSTRUCT),
  MAX(L_SHIPDATE),
  MAX(L_EXTENDEDPRICE)
FROM lineitem
GROUP BY l_orderkey
HAVING SUM(l_quantity) > 314;
```

5. From the log of TiFlash, you can see that by configuring query-level spilling, TiFlash triggers the spilling of intermediate results, significantly reducing the memory used by the query.

```
[DEBUG] [MemoryTracker.cpp:101] ["Peak memory usage (for query): 3.94
    ↪ GiB."] [source=MemoryTracker] [thread_id=1547]
```

14.3.11.2 Notes

- When the Hash Aggregation operator does not have a `GROUP BY` key, it does not support spilling. Even if the Hash Aggregation operator contains a distinct aggregation function, it does not support spilling.

- Currently, the threshold for operator-level spilling is calculated for each operator separately. For a query containing two Hash Aggregation operators, if the query-level spilling is not configured and the threshold of the aggregation operator is set to 10 GiB, the two Hash Aggregation operators will only spill data when their respective memory usage exceeds 10 GiB.
- Currently, the Hash Aggregation operators and TopN/Sort operators use the merge aggregation and merge sort algorithm during the restore phase. Therefore, these two operators only trigger a single round of spill. If the memory demand is very high and the memory usage during the restore phase still exceeds the threshold, the spill will not be triggered again.
- Currently, the Hash Join operator uses the partition-based spill strategy. If the memory usage during the restore phase still exceeds the threshold, the spill will be triggered again. However, to control the scale of the spill, the number of rounds of spill is limited to three. If the memory usage during the restore phase still exceeds the threshold after the third round of spill, the spill will not be triggered again.
- When query-level spilling is configured (that is, both `tiflash_mem_quota_query_per_node` and `tiflash_query_spill_ratio` are greater than 0), TiFlash ignores spilling thresholds of individual operators and automatically triggers spilling for relevant operators in a query based on the query-level spilling thresholds.
- Even when query-level spilling is configured, if none of the operators used in a query support spilling, the intermediate computation results of that query still cannot be spilled to disk. In this case, when the memory usage of that query exceeds the related threshold, TiFlash will return an error and terminate the query.
- Even when query-level spilling is configured and a query contains operators that support spilling, the query might still return an error due to exceeding memory thresholds in either of the following scenarios:
    - Other non-spilling operators in the query consume too much memory.
    - The spilling operators do not spill to disk timely.

To address situations where spilling operators do not spill to disk in time, you can try reducing `tiflash_query_spill_ratio` to avoid memory threshold errors.

14.3.12 TiFlash Data validation

This document introduces the data validation mechanism and tools for TiFlash.

Data corruptions are usually caused by serious hardware failures. In such cases, even if you attempt to manually recover data, your data become less reliable.

To ensure data integrity, by default, TiFlash performs basic data validation on data files, using the `City128` algorithm. In the event of any data validation failure, TiFlash immediately reports an error and exits, avoiding secondary disasters caused by inconsistent data. At this time, you need to manually intervene and replicate the data again before you can restore the TiFlash node.

Starting from v5.4.0, TiFlash introduces more advanced data validation features. TiFlash uses the `XXH3` algorithm by default and allows you to customize the validation frame and algorithm.

14.3.12.1 Validation mechanism

The validation mechanism builds upon the DeltaTree File (DTFile). DTFile is the storage file that persists TiFlash data. DTFile has three formats:

Version	State	Validation mechanism	Notes
V1	Deprecated	Hashes are embedded in data files.	
V2	Default for versions < v6.0.0	Hashes are embedded in data files.	Compared to V1, V2 adds statistics of column data.

Version	State	Validation mechanism	Notes
V3	Default for versions >= v6.0.0	V3 contains metadata and token data checksum, and supports multiple hash algorithms.	New in v5.4.0.

DTFile is stored in the `stable` folder in the data file directory. All formats currently enabled are in folder format, which means the data is stored in multiple files under a folder with a name like `dmf_<file id>`.

14.3.12.1.1 Use data validation

TiFlash supports both automatic and manual data validation:

- Automatic data validation:
  - v6.0.0 and later versions use the V3 validation mechanism by default.
  - Versions earlier than v6.0.0 use the V2 validation mechanism by default.
  - To manually switch the validation mechanism, refer to TiFlash configuration file. However, the default configuration is verified by tests and therefore recommended.
- Manual data validation. Refer to `DTTool inspect`.

Warning:

After you enable the V3 validation mechanism, the newly generated DTFile cannot be directly read by TiFlash earlier than v5.4.0. Since v5.4.0, TiFlash supports both V2 and V3 and does not actively upgrade or downgrade versions. If you need to upgrade or downgrade versions for existing files, you need to manually switch versions.

14.3.12.1.2 Validation tool

In addition to automatic data validation performed when TiFlash reads data, a tool for manually checking data integrity is introduced in v5.4.0. For details, refer to DTTool.

14.3.13 TiFlash MinTSO Scheduler

The TiFlash MinTSO scheduler is a distributed scheduler for MPP tasks in TiFlash. This document describes the implementation principles of the TiFlash MinTSO scheduler.

14.3.13.1 Background

When processing an MPP query, TiDB splits the query into one or more MPP tasks and sends these MPP tasks to the corresponding TiFlash nodes for compilation and execution. Before TiFlash uses the pipeline execution model, TiFlash needs to use several threads to execute each MPP task, with the specific number of threads depending on the complexity of the MPP task and the concurrency parameters set in TiFlash.

In high concurrency scenarios, TiFlash nodes receive multiple MPP tasks simultaneously. If the execution of MPP tasks is not controlled, the number of threads that TiFlash needs to request from the system will increase linearly along with the increasing number of MPP tasks. Too many threads can affect the execution efficiency of TiFlash, and because the operating system itself supports a limited number of threads, TiFlash will encounter errors when it requests more threads than the operating system can provide.

To improve TiFlash's processing capability in high concurrency scenarios, an MPP task scheduler needs to be introduced into TiFlash.

14.3.13.2 Implementation principles

As mentioned in the background, the initial purpose of introducing the TiFlash task scheduler is to control the number of threads used during MPP query execution. A simple scheduling strategy is to specify the maximum number of threads TiFlash can request. For each MPP task, the scheduler decides whether the MPP task can be scheduled based on the

current number of threads used by the system and the expected number of threads the MPP task will use:

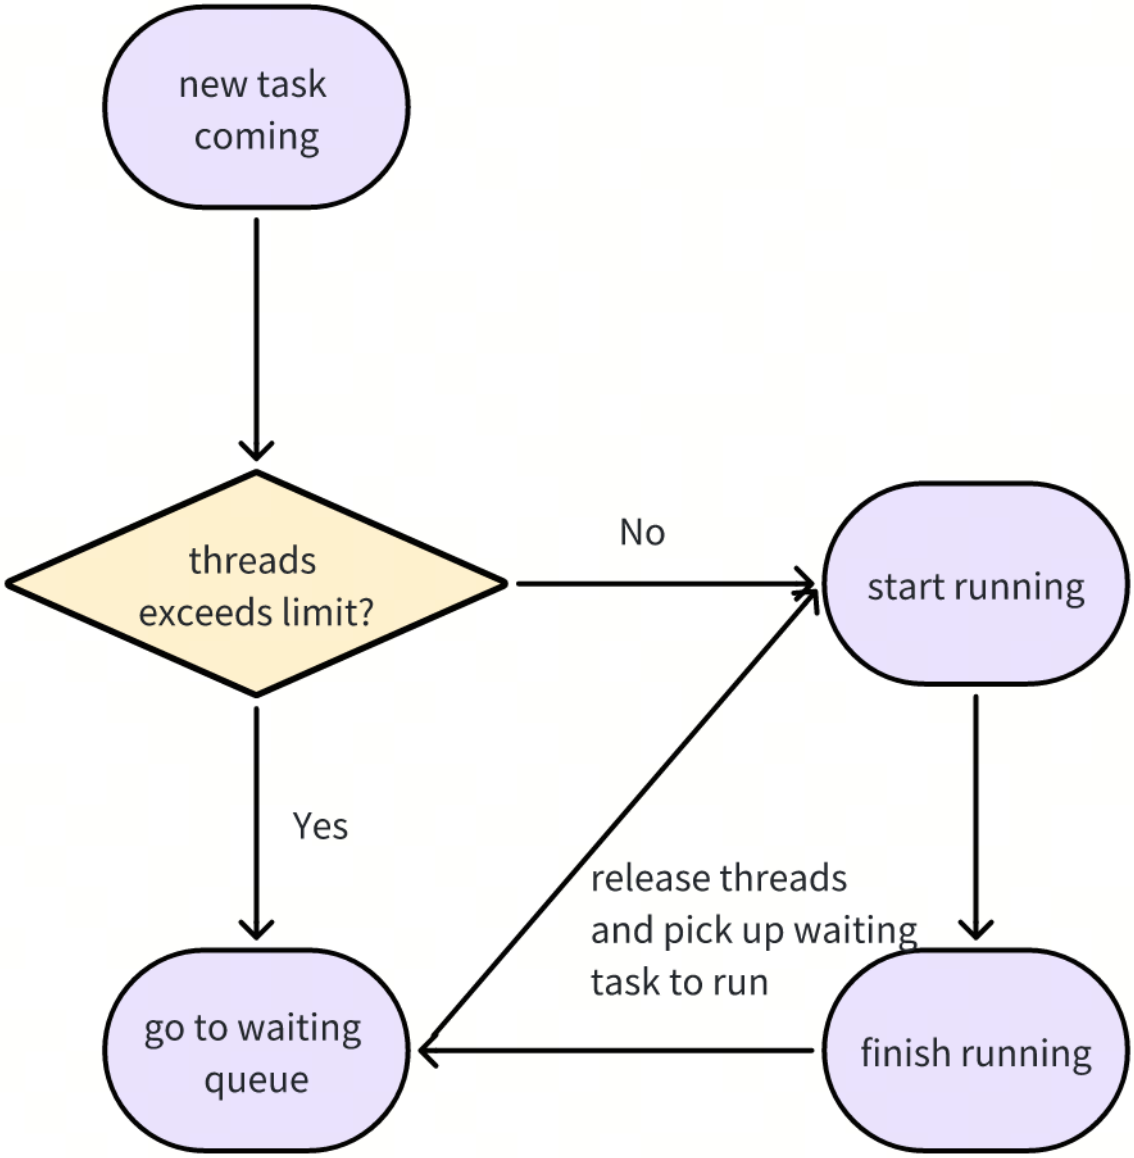

Figure 552: TiFlash MinTSO Scheduler v1

Although the preceding scheduling strategy can effectively control the number of system threads, an MPP task is not the smallest independent execution unit, and dependencies exist between different MPP tasks:

```
EXPLAIN SELECT count(*) FROM t0 a JOIN t0 b ON a.id = b.id;
```

```
+-------------------------------------------+---------+-------------+---------------+
| id                                        | estRows | task        | access
  ↪ object | operator info                                          |
+-------------------------------------------+---------+-------------+---------------+
| HashAgg_44                                | 1.00    | root        |
  ↪              | funcs:count(Column#8)->Column#7                    |
| ─TableReader_46                           | 1.00    | root        |
  ↪              | MppVersion: 2, data:ExchangeSender_45              |
|   ─ExchangeSender_45                      | 1.00    | mpp[tiflash] |
  ↪              | ExchangeType: PassThrough                          |
|     ─HashAgg_13                           | 1.00    | mpp[tiflash] |
  ↪              | funcs:count(1)->Column#8                           |
|       ─Projection_43                      | 12487.50 | mpp[tiflash] |
  ↪              | test.t0.id                                         |
|         ─HashJoin_42                      | 12487.50 | mpp[tiflash] |
  ↪              | inner join, equal:[eq(test.t0.id, test.t0.id)]     |
|           ─ExchangeReceiver_22(Build)     | 9990.00 | mpp[tiflash] |
  ↪              |                                                    |
|             ─ExchangeSender_21            | 9990.00 | mpp[tiflash] |
  ↪              | ExchangeType: Broadcast, Compression: FAST         |
|               ─Selection_20               | 9990.00 | mpp[tiflash] |
  ↪              | not(isnull(test.t0.id))                            |
|                 ─TableFullScan_19         | 10000.00 | mpp[tiflash] | table:a
  ↪   | pushed down filter:empty, keep order:false, stats:pseudo |
|           ─Selection_24(Probe)            | 9990.00 | mpp[tiflash] |
  ↪              | not(isnull(test.t0.id))                            |
|             ─TableFullScan_23             | 10000.00 | mpp[tiflash] | table:b
  ↪   | pushed down filter:empty, keep order:false, stats:pseudo |
+-------------------------------------------+---------+-------------+---------------+
  ↪
```

For example, the preceding query generates two MPP tasks on each TiFlash node, where the MPP task containing the `ExchangeSender_45` executor depends on the MPP task containing the `ExchangeSender_21` executor. In high concurrency scenarios, if the scheduler schedules the MPP task containing `ExchangeSender_45` for each query, the system will enter a deadlock state.

To avoid deadlock, TiFlash introduces the following two levels of thread limits:

- thread_soft_limit: used to limit the number of threads used by the system. For specific MPP tasks, this limit can be broken to avoid deadlock.
- thread_hard_limit: used to protect the system. Once the number of threads used by the system exceeds the hard limit, TiFlash will report an error to avoid deadlock.

The soft limit and hard limit work together to avoid deadlock as follows: the soft limit restricts the total number of threads used by all queries, enabling full use of resources while avoiding thread resource exhaustion; the hard limit ensures that in any situation, at least one query in the system can break the soft limit and continue to acquire thread resources and run, thus avoiding deadlock. As long as the number of threads does not exceed the hard limit, there will always be one query in the system where all its MPP tasks can be executed normally, thus preventing deadlock.

The goal of the MinTSO scheduler is to control the number of system threads while ensuring that there is always one and only one special query in the system, where all its MPP tasks can be scheduled. The MinTSO scheduler is a fully distributed scheduler, with each TiFlash node scheduling MPP tasks based only on its own information. Therefore, all MinTSO schedulers on TiFlash nodes need to identify the same "special" query. In TiDB, each query carries a read timestamp (`start_ts`), and the MinTSO scheduler defines the "special" query as the query with the smallest `start_ts` on the current TiFlash node. Based on the principle that the global minimum is also the local minimum, the "special" query selected by all TiFlash nodes must be the same, called the MinTSO query.

The scheduling process of the MinTSO Scheduler is as follows:

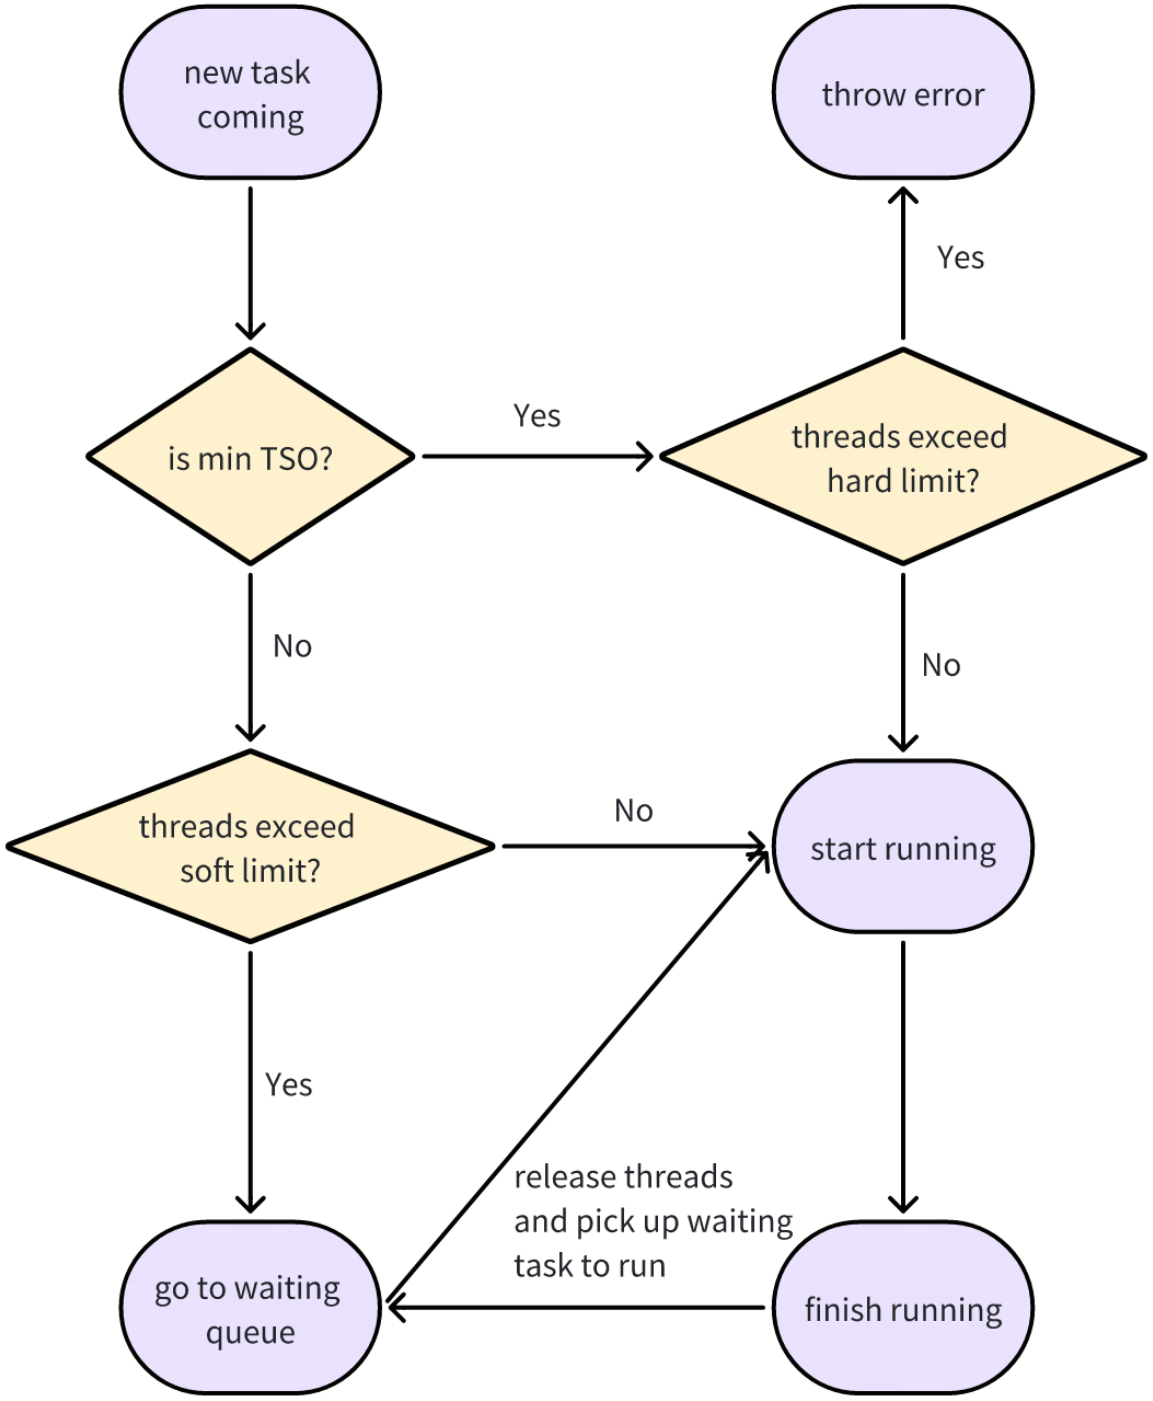

Figure 553: TiFlash MinTSO Scheduler v2

By introducing soft limit and hard limit, the MinTSO scheduler effectively avoids system deadlock while controlling the number of system threads. In high concurrency scenar-

ios, however, most queries might only have part of their MPP tasks scheduled. Queries with only part of MPP tasks scheduled cannot execute normally, leading to low system execution efficiency. To avoid this situation, TiFlash introduces a query-level limit for the MinTSO scheduler, called active_set_soft_limit. This limit allows only MPP tasks of up to active_set_soft_limit queries to participate in scheduling; MPP tasks of other queries do not participate in scheduling, and only after the current queries finish can new queries participate in scheduling. This limit is only a soft limit because for the MinTSO query, all its MPP tasks can be scheduled directly as long as the number of system threads does not exceed the hard limit.

14.3.13.3 See also

- Configure TiFlash: learn how to configure the MinTSO scheduler.

14.3.14 TiFlash Compatibility Notes

TiFlash is incompatible with TiDB in the following situations:

- In the TiFlash computation layer:
  - Checking overflowed numerical values is not supported. For example, adding two maximum values of the `BIGINT` type `9223372036854775807 + 9223372036854775807`. The expected behavior of this calculation in TiDB is to return the `ERROR 1690 (22003): BIGINT value is out of range` error. However, if this calculation is performed in TiFlash, an overflow value of `-2` is returned without any error.
  - The window function is not supported.
  - Reading data from TiKV is not supported.
  - Currently, the `sum` function in TiFlash does not support the string-type argument. But TiDB cannot identify whether any string-type argument has been passed into the `sum` function during the compiling. Therefore, when you execute statements similar to `select sum(string_col)from t`, TiFlash returns the `[FLASH:Coprocessor:Unimplemented] CastStringAsReal is not supported .` error. To avoid such an error in this case, you need to modify this SQL statement to `select sum(cast(string_col as double))from t`.
  - Currently, TiFlash's decimal division calculation is incompatible with that of TiDB. For example, when dividing decimal, TiFlash performs the calculation always using the type inferred from the compiling. However, TiDB performs this calculation using a type that is more precise than that inferred from the compiling. Therefore, some SQL statements involving the decimal division return different execution results when executed in TiDB + TiKV and in TiDB + TiFlash. For example:

```
mysql> create table t (a decimal(3,0), b decimal(10, 0));
Query OK, 0 rows affected (0.07 sec)
mysql> insert into t values (43, 1044774912);
Query OK, 1 row affected (0.03 sec)
mysql> alter table t set tiflash replica 1;
Query OK, 0 rows affected (0.07 sec)
mysql> set session tidb_isolation_read_engines='tikv';
Query OK, 0 rows affected (0.00 sec)
mysql> select a/b, a/b + 0.0000000000001 from t where a/b;
+--------+-----------------------+
| a/b    | a/b + 0.0000000000001 |
+--------+-----------------------+
| 0.0000 |     0.0000000410001 |
+--------+-----------------------+
1 row in set (0.00 sec)
mysql> set session tidb_isolation_read_engines='tiflash';
Query OK, 0 rows affected (0.00 sec)
mysql> select a/b, a/b + 0.0000000000001 from t where a/b;
Empty set (0.01 sec)
```

In the example above, `a/b`'s inferred type from the compiling is `Decimal(7,4)` both in TiDB and in TiFlash. Constrained by `Decimal(7,4)`, `a/b`'s returned type should be `0.0000`. In TiDB, `a/b`'s runtime precision is higher than `Decimal(7,4)`, so the original table data is not filtered by the `where a/b` condition. However, in TiFlash, the calculation of `a/b` uses `Decimal(7,4)` as the result type, so the original table data is filtered by the `where a/b` condition.

14.3.15 TiFlash Pipeline Execution Model

This document introduces the TiFlash pipeline execution model.

Starting from v7.2.0, TiFlash supports a new execution model, the pipeline execution model.

- For v7.2.0 and v7.3.0: The pipeline execution model is experimental and is controlled by `tidb_enable_tiflash_pipeline_model`.
- For v7.4.0 and later versions: The pipeline execution model becomes generally available. It is an internal feature of TiFlash and is tightly integrated with TiFlash resource control. When you enable TiFlash resource control, the pipeline execution model is automatically enabled. For more information about how to use TiFlash resource control, refer to Use resource control to achieve resource isolation. Additionally, starting from v7.4.0, the system variable `tidb_enable_tiflash_pipeline_model` is deprecated.

Inspired by the paper Morsel-Driven Parallelism: A NUMA-Aware Query Evaluation Framework for the Many-Core Age, the TiFlash pipeline execution model provides a fine-

grained task scheduling model, which is different from the traditional thread scheduling model. It reduces the overhead of operating system thread application and scheduling and provides a fine-grained scheduling mechanism.

14.3.15.1 Design and implementation

The original TiFlash stream model is a thread scheduling execution model. Each query independently applies for several threads to execute in coordination.

The thread scheduling model has the following two defects:

- In high-concurrency scenarios, too many threads cause a large number of context switches, resulting in high thread scheduling costs.
- The thread scheduling model cannot accurately measure the resource usage of queries or do fine-grained resource control.

The new pipeline execution model makes the following optimizations:

- The queries are divided into multiple pipelines and executed in sequence. In each pipeline, the data blocks are kept in the cache as much as possible to achieve better temporal locality and improve the efficiency of the entire execution process.
- To get rid of the native thread scheduling model of the operating system and implement a more fine-grained scheduling mechanism, each pipeline is instantiated into several tasks and uses the task scheduling model. At the same time, a fixed thread pool is used to reduce the overhead of operating system thread scheduling.

The architecture of the pipeline execution model is as follows:

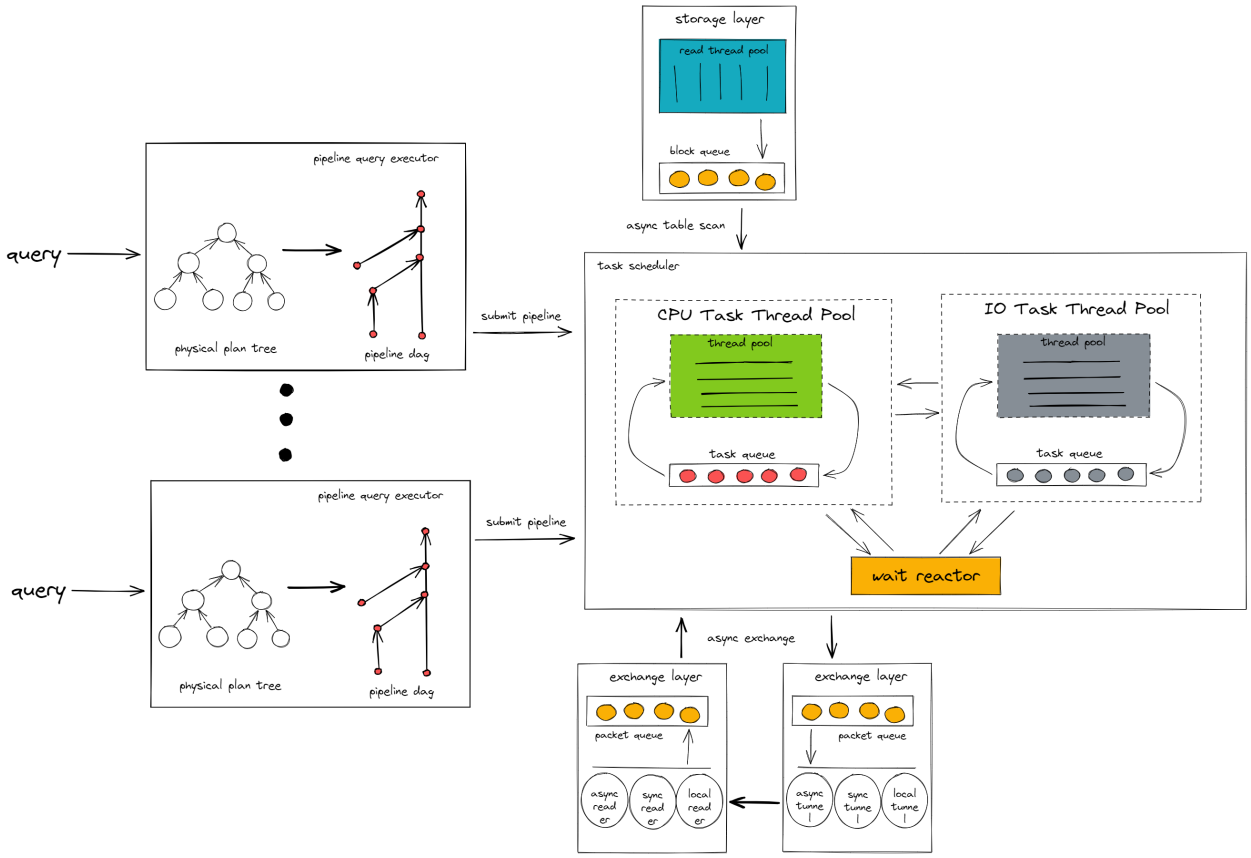

Figure 554: TiFlash pipeline execution model design

As shown in the preceding figure, the pipeline execution model consists of two main components: the pipeline query executor and the task scheduler.

- The pipeline query executor

  The pipeline query executor converts the query request sent from the TiDB node into a pipeline directed acyclic graph (DAG).

  It will find the pipeline breaker operators in the query and split the query into several pipelines according to the pipeline breakers. Then, it assembles the pipelines into a DAG according to the dependency relationship between the pipelines.

  A pipeline breaker is an operator that has a pause/blocking logic. This type of operator continuously receives data blocks from the upstream operator until all data blocks are received, and then return the processing result to the downstream operator. This type of operator breaks the data processing pipeline, so it is called a pipeline breaker. One of the pipeline breakers is the Aggregation operator, which writes all the data of the upstream operator into a hash table before calculating the data in the hash table and returning the result to the downstream operator.

After the query is converted into a pipeline DAG, the pipeline query executor executes each pipeline in sequence according to the dependency relationship. The pipeline is instantiated into several tasks according to the query concurrency and submitted to the task scheduler for execution.

- Task scheduler

  The task scheduler executes the tasks submitted by the pipeline query executor. The tasks are dynamically switched between different components in the task scheduler according to the different execution logic.

  - CPU task thread pool

    Executes the CPU-intensive calculation logic in the task, such as data filtering and function calculation.

  - IO task thread pool

    Executes the IO-intensive calculation logic in the task, such as writing intermediate results to disk.

  - Wait reactor

    Executes the wait logic in the task, such as waiting for the network layer to transfer the data packet to the calculation layer.

14.4 TiDB Distributed eXecution Framework (DXF)

14.4.1 TiDB Distributed eXecution Framework (DXF)

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

TiDB adopts a computing-storage separation architecture with excellent scalability and elasticity. Starting from v7.1.0, TiDB introduces a **Distributed eXecution Framework (DXF)** to further leverage the resource advantages of the distributed architecture. The goal of the DXF is to implement unified scheduling and distributed execution of tasks, and to provide unified resource management capabilities for both overall and individual tasks, which better meets users' expectations for resource usage.

This document describes the use cases, limitations, usage, and implementation principles of the DXF.

14.4.1.1 Use cases

In a database management system, in addition to the core transactional processing (TP) and analytical processing (AP) workloads, there are other important tasks, such as DDL operations, `IMPORT INTO`, TTL, `ANALYZE`, and Backup/Restore. These tasks need to process a large amount of data in database objects (tables), so they typically have the following characteristics:

- Need to process all data in a schema or a database object (table).
- Might need to be executed periodically, but at a low frequency.
- If the resources are not properly controlled, they are prone to affect TP and AP tasks, lowering the database service quality.

Enabling the DXF can solve the above problems and has the following three advantages:

- The framework provides unified capabilities for high scalability, high availability, and high performance.
- The DXF supports distributed execution of tasks, which can flexibly schedule the available computing resources of the entire TiDB cluster, thereby better utilizing the computing resources in a TiDB cluster.
- The DXF provides unified resource usage and management capabilities for both overall and individual tasks.

Currently, the DXF supports the distributed execution of the `ADD INDEX` and `IMPORT INTO` statements.

- `ADD INDEX` is a DDL statement used to create indexes. For example:

```
ALTER TABLE t1 ADD INDEX idx1(c1);
CREATE INDEX idx1 ON table t1(c1);
```

- `IMPORT INTO` is used to import data in formats such as CSV, SQL, and Parquet into an empty table.

14.4.1.2 Limitation

The DXF can only schedule up to 16 tasks (including `ADD INDEX` tasks and `IMPORT INTO` tasks) simultaneously.

14.4.1.3 Prerequisites

Before using the DXF to execute `ADD INDEX` tasks, you need to enable the Fast Online DDL mode.

1. Adjust the following system variables related to Fast Online DDL:

- `tidb_ddl_enable_fast_reorg`: used to enable Fast Online DDL mode. It is enabled by default starting from TiDB v6.5.0.
- `tidb_ddl_disk_quota`: used to control the maximum quota of local disks that can be used in Fast Online DDL mode.

2. Adjust the following configuration item related to Fast Online DDL:

    - `temp-dir`: specifies the local disk path that can be used in Fast Online DDL mode.

> **Note:**
>
> It is recommended that you prepare at least 100 GiB of free space for the TiDB `temp-dir` directory.

14.4.1.4 Usage

1. To enable the DXF, set the value of `tidb_enable_dist_task` to `ON`. Starting from v8.1.0, this variable is enabled by default. For newly created clusters of v8.1.0 or later versions, you can skip this step.

    ```
    SET GLOBAL tidb_enable_dist_task = ON;
    ```

    When the DXF tasks are running, the statements supported by the framework (such as `ADD INDEX` and `IMPORT INTO`) are executed in a distributed manner. All TiDB nodes run DXF tasks by default.

2. In general, for the following system variables that might affect the distributed execution of DDL tasks, it is recommended that you use their default values:

    - `tidb_ddl_reorg_worker_cnt`: use the default value `4`. The recommended maximum value is `16`.
    - `tidb_ddl_reorg_priority`
    - `tidb_ddl_error_count_limit`
    - `tidb_ddl_reorg_batch_size`: use the default value. The recommended maximum value is `1024`.

14.4.1.5 Task scheduling

By default, the DXF schedules all TiDB nodes to execute distributed tasks. Starting from v7.4.0, for TiDB Self-Managed clusters, you can control which TiDB nodes can be scheduled by the DXF to execute distributed tasks by configuring `tidb_service_scope`.

- For versions from v7.4.0 to v8.0.0, the optional values of `tidb_service_scope` are `''` or `background`. If the current cluster has TiDB nodes with `tidb_service_scope = 'background'`, the DXF schedules tasks to these nodes for execution. If the current cluster does not have TiDB nodes with `tidb_service_scope = 'background'`, whether due to faults or normal scaling in, the DXF schedules tasks to nodes with `tidb_service_scope = ''` for execution.
- Starting from v8.1.0, you can set `tidb_service_scope` to any valid value. When a distributed task is submitted, the task binds to the `tidb_service_scope` value of the currently connected TiDB node, and the DXF only schedules the task to the TiDB nodes with the same `tidb_service_scope` value for execution. However, for configuration compatibility with earlier versions, if a distributed task is submitted on a node with `tidb_service_scope = ''` and the current cluster has TiDB nodes with `tidb_service_scope = 'background'`, the DXF schedules the task to TiDB nodes with `tidb_service_scope = 'background'` for execution.

Starting from v8.1.0, if new nodes are added during task execution, the DXF determines whether to schedule tasks to the new nodes for execution based on the preceding rules. If you do not want newly added nodes to execute tasks, it is recommended to set a different `tidb_service_scope` for those newly added nodes in advance.

Note:

- For versions from v7.4.0 to v8.0.0, in clusters with multiple TiDB nodes, it is strongly recommended to set `tidb_service_scope` to `background` on two or more TiDB nodes. If this variable is set only on a single TiDB node, when that node restarts or fails, tasks will be rescheduled to TiDB nodes with `tidb_service_scope = ''`, which affects applications running on these TiDB nodes.
- During the execution of a distributed task, changes to the `tidb_service_scope` configuration do not take effect for the current task, but take effect from the next task.

14.4.1.6 Implementation principles

The architecture of the DXF is as follows:

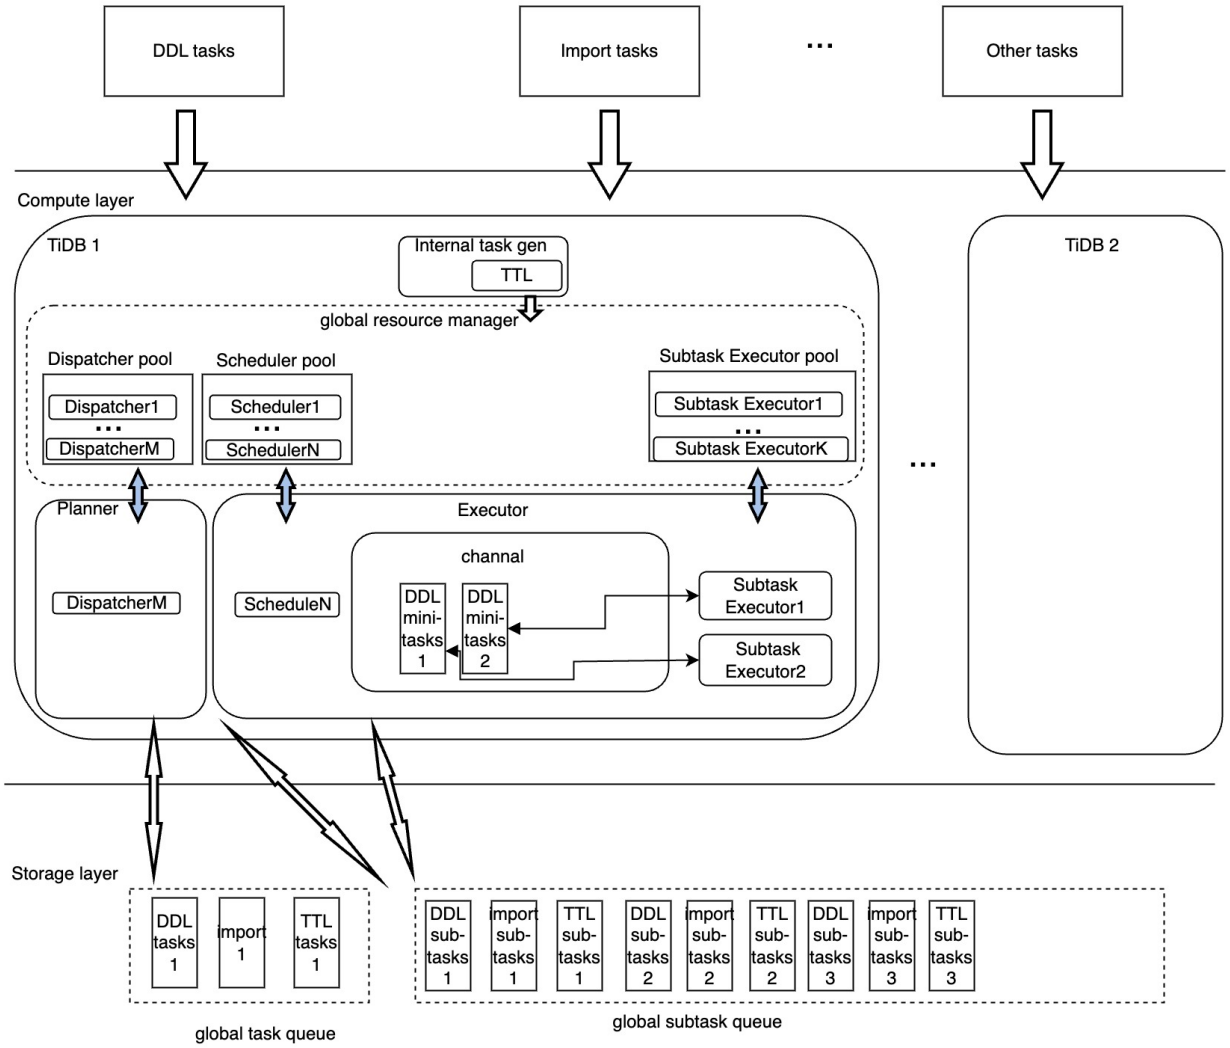

Figure 555: Architecture of the DXF

As shown in the preceding diagram, the execution of tasks in the DXF is mainly handled by the following modules:

- Dispatcher: generates the distributed execution plan for each task, manages the execution process, converts the task status, and collects and feeds back the runtime task information.
- Scheduler: replicates the execution of distributed tasks among TiDB nodes to improve the efficiency of task execution.
- Subtask Executor: the actual executor of distributed subtasks. In addition, the Subtask Executor returns the execution status of subtasks to the Scheduler, and the Scheduler updates the execution status of subtasks in a unified manner.
- Resource pool: provides the basis for quantifying resource usage and management by pooling computing resources of the above modules.

- Execution Principles and Best Practices of DDL Statements

14.4.2 TiDB Global Sort

> **Note:**
>
> - Currently, the Global Sort process consumes a large amount of computing and memory resources of TiDB nodes. In scenarios such as adding indexes online while user business applications are running, it is recommended to add new TiDB nodes to the cluster, configure the `tidb_service_scope` variable for these nodes, and connect to these nodes to create tasks. In this way, the distributed framework schedules tasks to these nodes, isolating the workload from other TiDB nodes to reduce the impact of executing backend tasks such as `ADD INDEX` and `IMPORT INTO` on user business applications.
> - When the Global Sort feature is used, it is recommended to use TiDB nodes with at least 16 cores of CPU and 32 GiB of memory to avoid OOM.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.4.2.1 Overview

The TiDB Global Sort feature enhances the stability and efficiency of data import and DDL (Data Definition Language) operations. It serves as a general operator in the TiDB Distributed eXecution Framework (DXF), providing a global sort service on cloud.

Currently, the Global Sort feature supports using Amazon S3 as cloud storage.

14.4.2.2 Use cases

The Global Sort feature enhances the stability and efficiency of `IMPORT INTO` and `CREATE INDEX`. By globally sorting the data that are processed by the tasks, it improves the

stability, controllability, and scalability of writing data to TiKV. This provides an enhanced user experience for data import and DDL tasks, as well as higher-quality services.

The Global Sort feature executes tasks within the unified DXF, ensuring efficient and parallel sorting of data on a global scale.

14.4.2.3 Limitations

Currently, the Global Sort feature is not used as a component of the query execution process responsible for sorting query results.

14.4.2.4 Usage

To enable Global Sort, follow these steps:

1. Enable the DXF by setting the value of `tidb_enable_dist_task` to `ON`. Starting from v8.1.0, this variable is enabled by default. For newly created clusters of v8.1.0 or later versions, you can skip this step.

```
SET GLOBAL tidb_enable_dist_task = ON;
```

2. Set `tidb_cloud_storage_uri` to a correct cloud storage path. See an example.

```
SET GLOBAL tidb_cloud_storage_uri = 's3://my-bucket/test-data?role-arn=
    ↪ arn:aws:iam::888888888888:role/my-role'
```

> **Note:**
>
> For `IMPORT INTO`, you can also specify the cloud storage path using the `CLOUD_STORAGE_URI` option. If both `tidb_cloud_storage_uri` and `CLOUD ↪ _STORAGE_URI` are configured with a valid cloud storage path, the configuration of `CLOUD_STORAGE_URI` takes effect for `IMPORT INTO`.

14.4.2.5 Implementation principles

The algorithm of the Global Sort feature is as follows:

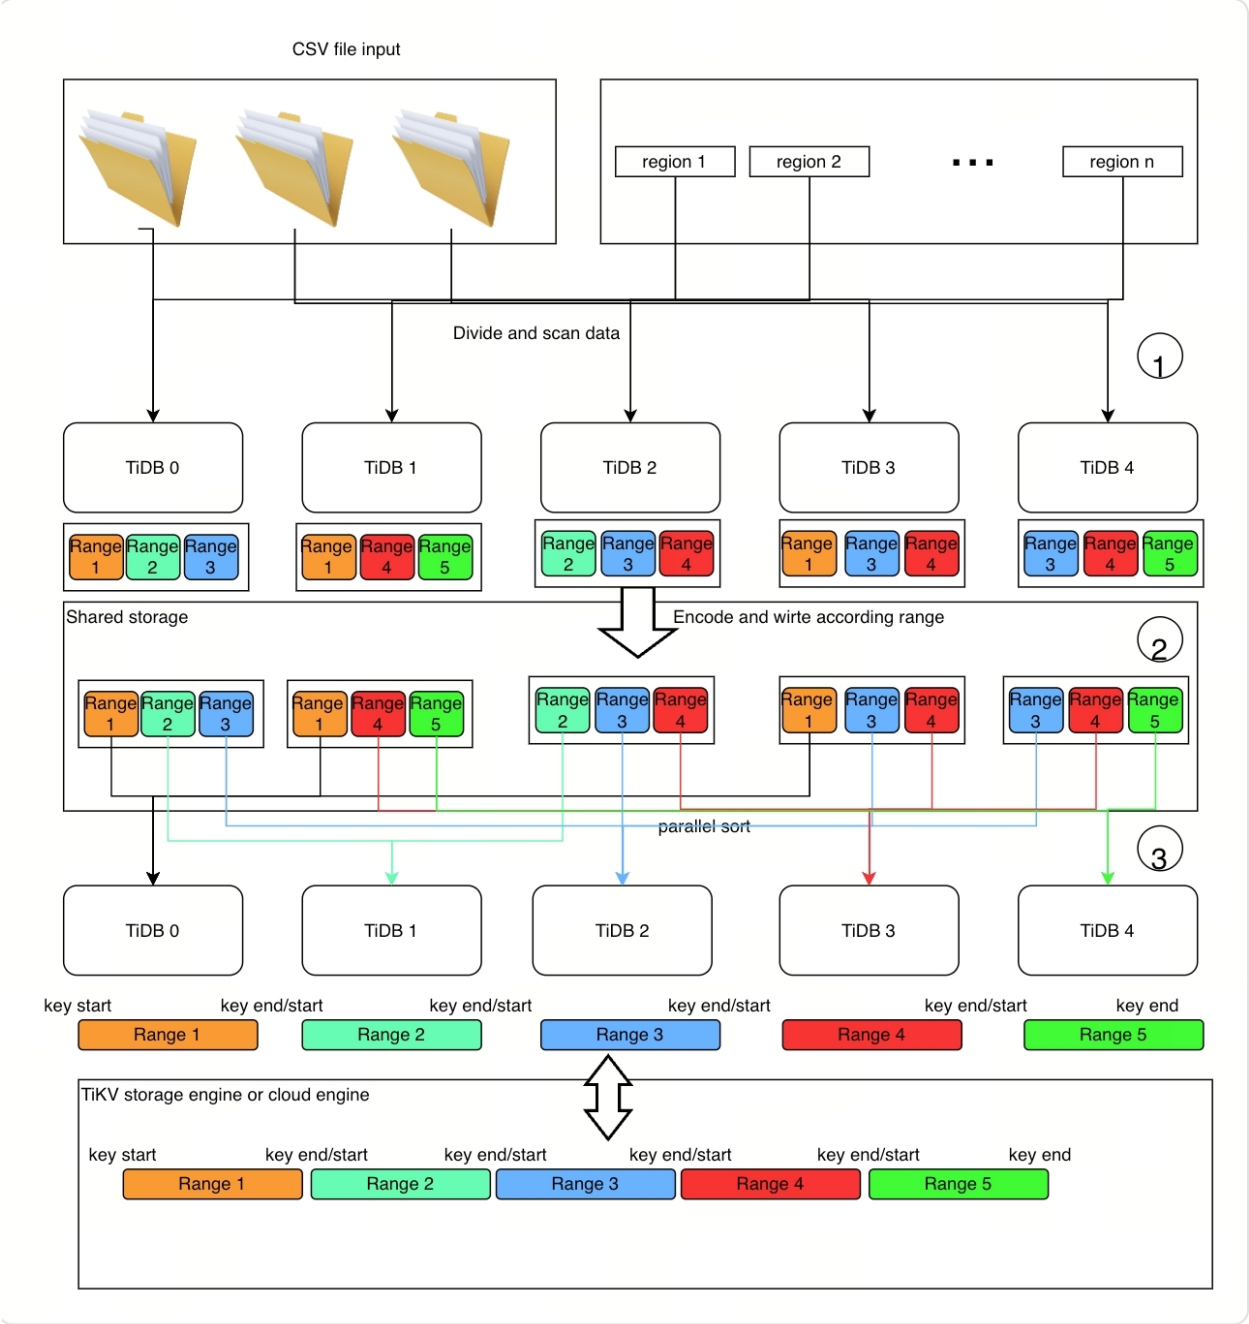

Figure 556: Algorithm of Global Sort

The detailed implementation principles are as follows:

14.4.2.5.1 Step 1: Scan and prepare data

1. After TiDB nodes scan a specific range of data (the data source can be either CSV data or table data in TiKV):

    1. TiDB nodes encode them into Key-Value pairs.
    2. TiDB nodes sort Key-Value pairs into several block data segments (the data segments are locally sorted), where each segment is one file and is uploaded into the cloud storage.

2. The TiDB node also records a serial actual Key-Value ranges for each segment (referred to as a statistics file), which is a key preparation for scalable sort implementation. These files are then uploaded into the cloud storage along with the real data.

14.4.2.5.2 Step 2: Sort and distribute data

From step 1, the Global Sort program obtains a list of sorted blocks and their corresponding statistics files, which provide the number of locally sorted blocks. The program also has a real data scope that can be used by PD to split and scatter. The following steps are performed:

1. Sort the records in the statistics file to divide them into nearly equal-sized ranges, which are subtasks that will be executed in parallel.
2. Distribute the subtasks to TiDB nodes for execution.
3. Each TiDB node independently sorts the data of subtasks into ranges and ingests them into TiKV without overlap.

14.5 System Variables

TiDB system variables behave similar to MySQL, in that settings apply on a `SESSION` or `GLOBAL` scope:

- Changes on a `SESSION` scope will only affect the current session.
- Changes on a `GLOBAL` scope apply immediately. If this variable is also`SESSION` scoped, all sessions (including your session) will continue to use their current session value.
- Changes are made using the `SET` statement:

```
## These two identical statements change a session variable
SET tidb_distsql_scan_concurrency = 10;
SET SESSION tidb_distsql_scan_concurrency = 10;

## These two identical statements change a global variable
SET @@global.tidb_distsql_scan_concurrency = 10;
SET GLOBAL tidb_distsql_scan_concurrency = 10;
```

Note:

Several `GLOBAL` variables persist to the TiDB cluster. Some variables in this document have a `Persists to cluster` setting, which can be configured to `Yes` or `No`.

- For variables with the `Persists to cluster: Yes` setting, when a global variable is changed, a notification is sent to all TiDB servers to refresh their system variable cache. When you add additional TiDB servers or restart existing TiDB servers, the persisted configuration value is automatically used.
- For variables with the `Persists to cluster: No` setting, changes only apply to the local TiDB instance that you are connected to. To retain any values set, you need to specify the variables in your `tidb.toml` configuration file.

Additionally, TiDB presents several MySQL variables as both readable and settable. This is required for compatibility, because it is common for both applications and connectors to read MySQL variables. For example, JDBC connectors both read and set query cache settings, despite not relying on the behavior.

Note:

Larger values do not always yield better performance. It is also important to consider the number of concurrent connections that are executing statements, because most settings apply to each connection.

Consider the unit of a variable when you determine safe values:

- For threads, safe values are typically up to the number of CPU cores.
- For bytes, safe values are typically less than the amount of system memory.
- For time, pay attention that the unit might be seconds or milliseconds.

Variables using the same unit might compete for the same set of resources.

Starting from v7.4.0, you can temporarily modify the value of some `SESSION` variables during statement execution using `SET_VAR`. After the statement is executed, the value of the system variable in the current session is automatically changed back to the original value. This hint can be used to modify some system variables related to the optimizer and

executor. Variables in this document have a `Applies to hint SET_VAR` setting, which can be configured to `Yes` or `No`.

- For variables with the `Applies to hint SET_VAR: Yes` setting, you can use the `SET_VAR` hint to modify the value of the system variable in the current session during statement execution.
- For variables with the `Applies to hint SET_VAR: No` setting, you cannot use the `SET_VAR` hint to modify the value of the system variable in the current session during statement execution.

For more information about the `SET_VAR` hint, see SET_VAR.

14.5.1 Variable reference

14.5.1.1 allow_auto_random_explicit_insert New in v4.0.3

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- Determines whether to allow explicitly specifying the values of the column with the `AUTO_RANDOM` attribute in the `INSERT` statement.

14.5.1.2 authentication_ldap_sasl_auth_method_name New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `SCRAM-SHA-1`
- Possible values: `SCRAM-SHA-1`, `SCRAM-SHA-256`, and `GSSAPI`.
- For LDAP SASL authentication, this variable specifies the authentication method name.

14.5.1.3 authentication_ldap_sasl_bind_base_dn New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP SASL authentication, this variable limits the search scope within the search tree. If a user is created without the `AS ...` clause, TiDB will automatically search the `dn` in LDAP server according to the user name.

14.5.1.4 authentication_ldap_sasl_bind_root_dn New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP SASL authentication, this variable specifies the `dn` used to log in to the LDAP server to search users.

14.5.1.5 authentication_ldap_sasl_bind_root_pwd New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP SASL authentication, this variable specifies the password used to log in to the LDAP server to search users.

14.5.1.6 authentication_ldap_sasl_ca_path New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP SASL authentication, this variable specifies the absolute path of the certificate authority file for StartTLS connections.

14.5.1.7 authentication_ldap_sasl_init_pool_size New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `10`
- Range: `[1, 32767]`
- For LDAP SASL authentication, this variable specifies the initial connections in the connection pool to the LDAP server.

14.5.1.8 authentication_ldap_sasl_max_pool_size New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1000`
- Range: `[1, 32767]`
- For LDAP SASL authentication, this variable specifies the maximum connections in the connection pool to the LDAP server.

14.5.1.9 authentication_ldap_sasl_server_host New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP SASL authentication, this variable specifies the LDAP server host name or IP address.

14.5.1.10 authentication_ldap_sasl_server_port New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `389`
- Range: `[1, 65535]`
- For LDAP SASL authentication, this variable specifies the TCP/IP port number of the LDAP server.

14.5.1.11 authentication_ldap_sasl_tls New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- For LDAP SASL authentication, this variable controls whether connections by the plugin to the LDAP server are protected with StartTLS.

14.5.1.12 authentication_ldap_simple_auth_method_name New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `SIMPLE`
- Possible values: `SIMPLE`.
- For LDAP simple authentication, this variable specifies the authentication method name. The only supported value is `SIMPLE`.

14.5.1.13 authentication_ldap_simple_bind_base_dn New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: ""
- For LDAP simple authentication, this variable limits the search scope within the search tree. If a user is created without the `AS ...` clause, TiDB will automatically search the `dn` in LDAP server according to the user name.

14.5.1.14 authentication_ldap_simple_bind_root_dn New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: ""
- For LDAP simple authentication, this variable specifies the `dn` used to log in to the LDAP server to search users.

14.5.1.15 authentication_ldap_simple_bind_root_pwd New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: ""
- For LDAP simple authentication, this variable specifies the password used to log in to the LDAP server to search users.

14.5.1.16 authentication_ldap_simple_ca_path New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP simple authentication, this variable specifies the absolute path of the certificate authority file for StartTLS connections.

14.5.1.17 authentication_ldap_simple_init_pool_size New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `10`
- Range: `[1, 32767]`
- For LDAP simple authentication, this variable specifies the initial connections in the connection pool to the LDAP server.

14.5.1.18 authentication_ldap_simple_max_pool_size New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1000`
- Range: `[1, 32767]`
- For LDAP simple authentication, this variable specifies the maximum connections in the connection pool to the LDAP server.

14.5.1.19 authentication_ldap_simple_server_host New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: “”
- For LDAP simple authentication, this variable specifies the LDAP server host name or IP address.

14.5.1.20 authentication_ldap_simple_server_port New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `389`
- Range: `[1, 65535]`
- For LDAP simple authentication, this variable specifies the TCP/IP port number of the LDAP server.

14.5.1.21 authentication_ldap_simple_tls New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- For LDAP simple authentication, this variable controls whether connections by the plugin to the LDAP server are protected with StartTLS.

14.5.1.22 auto_increment_increment

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[1, 65535]`
- Controls the step size of `AUTO_INCREMENT` values to be allocated to a column, and allocation rules for `AUTO_RANDOM` IDs. It is often used in combination with `auto_increment_offset`.

14.5.1.23 auto_increment_offset

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[1, 65535]`
- Controls the initial offset of `AUTO_INCREMENT` values to be allocated to a column, and allocation rules for `AUTO_RANDOM` IDs. This setting is often used in combination with `auto_increment_increment`. For example:

```
mysql> CREATE TABLE t1 (a int not null primary key auto_increment);
Query OK, 0 rows affected (0.10 sec)

mysql> set auto_increment_offset=1;
Query OK, 0 rows affected (0.00 sec)

mysql> set auto_increment_increment=3;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (),(),(),();
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+
| a  |
+----+
|  1 |
|  4 |
|  7 |
| 10 |
+----+
4 rows in set (0.00 sec)
```

14.5.1.24 autocommit

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- Controls whether statements should automatically commit when not in an explicit transaction. See Transaction Overview for more information.

14.5.1.25 block_encryption_mode

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `aes-128-ecb`

- Value options: `aes-128-ecb`, `aes-192-ecb`, `aes-256-ecb`, `aes-128-cbc`, `aes-192-cbc`, `aes-256-cbc`, `aes-128-ofb`, `aes-192-ofb`, `aes-256-ofb`, `aes-128-cfb`, `aes-192-cfb`, `aes-256-cfb`
- This variable sets the encryption mode for the built-in functions `AES_ENCRYPT()` and `AES_DECRYPT()`.

14.5.1.26 character_set_client

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4`
- The character set for data sent from the client. See Character Set and Collation for details on the use of character sets and collations in TiDB. It is recommended to use `SET NAMES` to change the character set when needed.

14.5.1.27 character_set_connection

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4`
- The character set for string literals that do not have a specified character set.

14.5.1.28 character_set_database

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4`
- This variable indicates the character set of the default database in use. **It is NOT recommended to set this variable**. When a new default database is selected, the server changes the variable value.

14.5.1.29 character_set_results

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4`
- The character set that is used when data is sent to the client.

14.5.1.30 character_set_server

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4`
- The default character set for the server.

14.5.1.31 collation_connection

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4_bin`
- This variable indicates the collation used in the current connection. It is consistent with the MySQL variable `collation_connection`.

14.5.1.32 collation_database

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4_bin`
- This variable indicates the default collation of the database in use. **It is NOT recommended to set this variable**. When a new database is selected, TiDB changes this variable value.

14.5.1.33 collation_server

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `utf8mb4_bin`
- The default collation used when the database is created.

14.5.1.34 cte_max_recursion_depth

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `1000`
- Range: `[0, 4294967295]`
- Controls the maximum recursion depth in Common Table Expressions.

14.5.1.35 datadir

> **Note:**
>
> This variable is not supported on TiDB Cloud Serverless.

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: it depends on the component and the deployment method.
  - `/tmp/tidb`: when you set `"unistore"` for `--store` or if you don't set `--store`.
  - `${pd-ip}:${pd-port}`: when you use TiKV, which is the default storage engine for TiUP and TiDB Operator for Kubernetes deployments.
- This variable indicates the location where data is stored. This location can be a local path `/tmp/tidb`, or point to a PD server if the data is stored on TiKV. A value in the format of `${pd-ip}:${pd-port}` indicates the PD server that TiDB connects to on startup.

14.5.1.36 ddl_slow_threshold

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `300`
- Range: `[0, 2147483647]`
- Unit: Milliseconds
- Log DDL operations whose execution time exceeds the threshold value.

14.5.1.37 default_authentication_plugin

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `mysql_native_password`
- Possible values: `mysql_native_password`, `caching_sha2_password`, `tidb_sm3_password`, `tidb_auth_token`, `authentication_ldap_sasl`, and `authentication_ldap_simple`.

- This variable sets the authentication method that the server advertises when the server-client connection is being established.
- To authenticate using the `tidb_sm3_password` method, you can connect to TiDB using TiDB-JDBC.

For more possible values of this variable, see Authentication plugin status.

14.5.1.38 default_collation_for_utf8mb4 New in v7.4.0

- Scope: GLOBAL | SESSION
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: String
- Default value: `utf8mb4_bin`
- Value options: `utf8mb4_bin`, `utf8mb4_general_ci`, `utf8mb4_0900_ai_ci`
- This variable is used to set the default collation for the `utf8mb4` character set. It affects the behavior of the following statements:
  - The default collation displayed in the `SHOW COLLATION` and `SHOW CHARACTER SET` statements.
  - If `CREATE TABLE` and `ALTER TABLE` statements contain the `CHARACTER SET utf8mb4` clause against a table or a column without specifying a collation, the collation specified by this variable is used. This does not affect the behavior when `CHARACTER SET` clause is not used.
  - If `CREATE DATABASE` and `ALTER DATABASE` statements contain `CHARACTER SET utf8mb4` clause without specifying a collation, the collation specified by this variable is used. This does not affect the behavior when `CHARACTER SET` clause is not used.
  - If the `COLLATE` clause is not used, any literal string in the format of `_utf8mb4'string'` uses the collation specified by this variable.

14.5.1.39 default_password_lifetime New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 65535]`
- Sets the global policy for automatic password expiration. The default value `0` indicates that the password never expires. If this system variable is set to a positive integer `N`, it means that the password lifetime is `N` days, and you must change your password within `N` days.

14.5.1.40 default_week_format

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 7]`
- Sets the week format used by the `WEEK()` function.

14.5.1.41 disconnect_on_expired_password New in v6.5.0

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is read-only. It indicates whether TiDB disconnects the client connection when the password is expired. If the variable is set to `ON`, the client connection is disconnected when the password is expired. If the variable is set to `OFF`, the client connection is restricted to the "sandbox mode" and the user can only execute the password reset operation.

- If you need to change the behavior of the client connection for the expired password, modify the `security.disconnect-on-expired-password` configuration item in the configuration file.

14.5.1.42 div_precision_increment New in v8.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `4`
- Range: `[0, 30]`
- This variable specifies the number of digits by which to increase the scale of the result of a division operation performed using the `/` operator. This variable is the same as MySQL.

14.5.1.43 error_count

- Scope: SESSION
- Applies to hint SET_VAR: No

- Type: Integer
- Default value: `0`
- A read-only variable that indicates the number of errors that resulted from the last statement that generated messages.

14.5.1.44 foreign_key_checks

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: Before v6.6.0, the default value is `OFF`. Starting from v6.6.0, the default value is `ON`.
- This variable controls whether to enable foreign key constraint checking.

14.5.1.45 group_concat_max_len

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1024`
- Range: `[4, 18446744073709551615]`
- The maximum buffer size for items in the `GROUP_CONCAT()` function.

14.5.1.46 have_openssl

- Scope: NONE
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `DISABLED`
- A read-only variable for MySQL compatibility. Set to `YES` by the server when the server has TLS enabled.

14.5.1.47 have_ssl

- Scope: NONE
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `DISABLED`
- A read-only variable for MySQL compatibility. Set to `YES` by the server when the server has TLS enabled.

14.5.1.48 hostname

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: (system hostname)
- The hostname of the TiDB server as a read-only variable.

14.5.1.49 identity New in v5.3.0

This variable is an alias for `last_insert_id`.

14.5.1.50 init_connect

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: “”
- The `init_connect` feature permits a SQL statement to be automatically executed when you first connect to a TiDB server. If you have the `CONNECTION_ADMIN` or `SUPER` privileges, this `init_connect` statement will not be executed. If the `init_connect` statement results in an error, your user connection will be terminated.

14.5.1.51 innodb_lock_wait_timeout

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `50`
- Range: `[1, 3600]`
- Unit: Seconds
- The lock wait timeout for pessimistic transactions (default).

14.5.1.52 interactive_timeout

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `28800`
- Range: `[1, 31536000]`
- Unit: Seconds
- This variable represents the idle timeout of the interactive user session. Interactive user session refers to the session established by calling `mysql_real_connect()` API using the `CLIENT_INTERACTIVE` option (for example, MySQL Shell and MySQL Client). This variable is fully compatible with MySQL.

14.5.1.53 last_insert_id

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 18446744073709551615]`
- This variable returns the last `AUTO_INCREMENT` or `AUTO_RANDOM` value generated by an insert statement.
- The value of `last_insert_id` is the same as the value returned by the function `LAST_INSERT_ID()`.

14.5.1.54 last_plan_from_binding New in v4.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to show whether the execution plan used in the previous statement was influenced by a plan binding

14.5.1.55 last_plan_from_cache New in v4.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to show whether the execution plan used in the previous `execute` statement is taken directly from the plan cache.

14.5.1.56 last_sql_use_alloc New in v6.4.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: `OFF`
- This variable is read-only. It is used to show whether the previous statement uses a cached chunk object (chunk allocation).

14.5.1.57 license

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: `Apache License 2.0`
- This variable indicates the license of your TiDB server installation.

14.5.1.58 max_allowed_packet New in v6.1.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `67108864`
- Range: `[1024, 1073741824]`
- The value should be an integer multiple of 1024. If the value is not divisible by 1024, a warning will be prompted and the value will be rounded down. For example, when the value is set to 1025, the actual value in TiDB is 1024.
- The maximum packet size allowed by the server and the client in one transmission of packets.
- In the `SESSION` scope, this variable is read-only.
- This variable is compatible with MySQL.

14.5.1.59 password_history New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer

- Default value: `0`
- Range: `[0, 4294967295]`
- This variable is used to establish a password reuse policy that allows TiDB to limit password reuse based on the number of password changes. The default value `0` means disabling the password reuse policy based on the number of password changes. When this variable is set to a positive integer `N`, the reuse of the last `N` passwords is not allowed.

14.5.1.60 mpp_exchange_compression_mode New in v6.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `UNSPECIFIED`
- Value options: `NONE`, `FAST`, `HIGH_COMPRESSION`, `UNSPECIFIED`
- This variable is used to specify the data compression mode of the MPP Exchange operator. This variable takes effect when TiDB selects the MPP execution plan with the version number `1`. The meanings of the variable values are as follows:
  - `UNSPECIFIED`: means unspecified. TiDB will automatically select the compression mode. Currently, TiDB automatically selects the `FAST` mode.
  - `NONE`: no data compression is used.
  - `FAST`: fast mode. The overall performance is good and the compression ratio is less than `HIGH_COMPRESSION`.
  - `HIGH_COMPRESSION`: the high compression ratio mode.

14.5.1.61 mpp_version New in v6.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `UNSPECIFIED`
- Value options: `UNSPECIFIED`, `0`, `1`, `2`
- This variable is used to specify different versions of the MPP execution plan. After a version is specified, TiDB selects the specified version of the MPP execution plan. The meanings of the variable values are as follows:
  - `UNSPECIFIED`: means unspecified. TiDB automatically selects the latest version `2`.
  - `0`: compatible with all TiDB cluster versions. Features with the MPP version greater than `0` do not take effect in this mode.
  - `1`: new in v6.6.0, used to enable data exchange with compression on TiFlash. For details, see MPP version and exchange data compression.
  - `2`: new in v7.3.0, used to provide more accurate error messages when MPP tasks encounter errors on TiFlash.

14.5.1.62 password_reuse_interval New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 4294967295]`
- This variable is used to establish a password reuse policy that allows TiDB to limit password reuse based on time elapsed. The default value `0` means disabling the password reuse policy based on time elapsed. When this variable is set to a positive integer `N`, the reuse of any password used in the last `N` days is not allowed.

14.5.1.63 max_connections

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 100000]`
- The maximum number of concurrent connections permitted for a single TiDB instance. This variable can be used for resources control.
- The default value `0` means no limit. When the value of this variable is larger than `0` ↪ , and the number of connections reaches the value, the TiDB server rejects new connections from clients.

14.5.1.64 max_execution_time

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- Unit: Milliseconds
- The maximum execution time of a statement. The default value is unlimited (zero).

Note:

> Before v6.4.0, the `max_execution_time` system variable takes effect on all types of statements. Starting from v6.4.0, this variable only controls the maximum execution time of read-only statements. The precision of the timeout value is roughly 100ms. This means the statement might not be terminated in exact milliseconds as you specify.

For a SQL statement with the `MAX_EXECUTION_TIME` hint, the maximum execution time of this statement is limited by the hint instead of this variable. The hint can also be used with SQL bindings as described in the SQL FAQ.

14.5.1.65 max_prepared_stmt_count

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[-1, 1048576]`
- Specifies the maximum number of `PREPARE` statements in the current TiDB instance.
- The value of `-1` means no limit on the maximum number of `PREPARE` statements in the current TiDB instance.
- If you set the variable to a value that exceeds the upper limit `1048576`, `1048576` is used instead:

```
mysql> SET GLOBAL max_prepared_stmt_count = 1048577;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+--
    ↪ -------+------+-----------------------------------------------------------------+
    ↪
| Level   | Code | Message                                                         |
+--
    ↪ -------+------+-----------------------------------------------------------------+
    ↪
| Warning | 1292 | Truncated incorrect max_prepared_stmt_count value: '
    ↪ 1048577' |
+--
    ↪ -------+------+-----------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

```
mysql> SHOW GLOBAL VARIABLES LIKE 'max_prepared_stmt_count';
+--------------------------+---------+
| Variable_name            | Value   |
+--------------------------+---------+
| max_prepared_stmt_count | 1048576 |
+--------------------------+---------+
1 row in set (0.00 sec)
```

14.5.1.66 pd_enable_follower_handle_region New in v7.6.0

> **Warning:**
>
> The Active PD Follower feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the Active PD Follower feature (currently only applicable to requests for Region information). When the value is `OFF`, TiDB only obtains Region information from the PD leader. When the value is `ON`, TiDB evenly distributes requests for Region information to all PD servers, and PD followers can also handle Region requests, thereby reducing the CPU pressure on the PD leader.
- Scenarios for enabling Active PD Follower:
  - In a cluster with a large number of Regions, the PD leader experiences high CPU pressure due to the increased overhead of handling heartbeats and scheduling tasks.
  - In a TiDB cluster with many TiDB instances, the PD leader experiences high CPU pressure due to a high concurrency of requests for Region information.

14.5.1.67 plugin_dir

> **Note:**
>
> This variable is not supported on TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Default value: ""
- Indicates the directory to load plugins as specified by a command-line flag.

14.5.1.68 plugin_load

> **Note:**
>
> This variable is not supported on TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Default value: ""
- Indicates the plugins to load when TiDB is started. These plugins are specified by a command-line flag and separated by commas.

14.5.1.69 port

- Scope: NONE
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4000`
- Range: `[0, 65535]`
- The port that the `tidb-server` is listening on when speaking the MySQL protocol.

14.5.1.70 rand_seed1

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- This variable is used to seed the random value generator used in the `RAND()` SQL function.
- The behavior of this variable is MySQL compatible.

14.5.1.71 rand_seed2

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- This variable is used to seed the random value generator used in the `RAND()` SQL function.
- The behavior of this variable is MySQL compatible.

14.5.1.72 require_secure_transport New in v6.1.0

> **Note:**
>
> Currently, this variable is not supported on TiDB Cloud Dedicated. DO **NOT** enable this variable for TiDB Cloud Dedicated clusters. Otherwise, you might get SQL client connection failures. This restriction is a temporary control measure and will be resolved in a future release.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF` for TiDB Self-Managed and TiDB Cloud Dedicated, `ON` for TiDB Cloud Serverless

- This variable ensures that all connections to TiDB are either on a local socket, or using TLS. See Enable TLS between TiDB Clients and Servers for additional details.

- Setting this variable to `ON` requires you to connect to TiDB from a session that has TLS enabled. This helps prevent lock-out scenarios when TLS is not configured correctly.
- This setting was previously a `tidb.toml` option (`security.require-secure-transport`), but changed to a system variable starting from TiDB v6.1.0.
- Starting from v6.5.6, v7.1.2, v7.5.1, and v8.0.0, when Security Enhanced Mode (SEM) is enabled, setting this variable to `ON` is prohibited to avoid potential connectivity issues for users.

14.5.1.73 skip_name_resolve New in v5.2.0

Note:

This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether the `tidb-server` instance resolves hostnames as a part of the connection handshake.
- When the DNS is unreliable, you can enable this option to improve network performance.

Note:

When `skip_name_resolve=ON`, users with a hostname in their identity will no longer be able to log into the server. For example:

```
CREATE USER 'appuser'@'apphost' IDENTIFIED BY 'app-password';
```

In this example, it is recommended to replace `apphost` with an IP address or the wildcard (`%`).

14.5.1.74 socket

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: “”
- The local unix socket file that the `tidb-server` is listening on when speaking the MySQL protocol.

14.5.1.75 sql_mode

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes

- Default value: `ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`
- This variable controls a number of MySQL compatibility behaviors. See SQL Mode for more information.

14.5.1.76 sql_require_primary_key New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enforce the requirement that a table has a primary key. After this variable is enabled, attempting to create or alter a table without a primary key will produce an error.
- This feature is based on the similarly named `sql_require_primary_key` in MySQL 8.0.
- It is strongly recommended to enable this variable when using TiCDC. This is because replicating changes to a MySQL sink requires that tables have a primary key.

- If you enable this variable and are using TiDB Data Migration (DM) to migrate data, it is recommended that you add `sql_require_primary_key` to the `session` part in the DM Task Configuration File and set it to `OFF`. Otherwise, it will cause DM to fail to create tasks.

14.5.1.77 sql_select_limit New in v4.0.2

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `18446744073709551615`
- Range: `[0, 18446744073709551615]`
- Unit: Rows
- The maximum number of rows returned by the `SELECT` statements.

14.5.1.78 ssl_ca

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: “”
- The location of the certificate authority file (if there is one). The value of this variable is defined by the TiDB configuration item `ssl-ca`.

14.5.1.79 ssl_cert

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: “”
- The location of the certificate file (if there is a file) that is used for SSL/TLS connections. The value of this variable is defined by the TiDB configuration item `ssl-cert`.

14.5.1.80 ssl_key

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: “”
- The location of the private key file (if there is one) that is used for SSL/TLS connections. The value of this variable is defined by TiDB configuration item `ssl-key`.

14.5.1.81 system_time_zone

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: (system dependent)
- This variable shows the system time zone from when TiDB was first bootstrapped. See also `time_zone`.

14.5.1.82 tidb_adaptive_closest_read_threshold New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4096`
- Range: `[0, 9223372036854775807]`
- Unit: Bytes
- This variable is used to control the threshold at which the TiDB server prefers to send read requests to a replica in the same availability zone as the TiDB server when `tidb_replica_read` is set to `closest-adaptive`. If the estimated result is higher than or equal to this threshold, TiDB prefers to send read requests to a replica in the same availability zone. Otherwise, TiDB sends read requests to the leader replica.

14.5.1.83 tidb_allow_tiflash_cop New in v7.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- When TiDB pushes computation tasks down to TiFlash, there are three methods (or protocols) to choose from: Cop, BatchCop, and MPP. Compared to Cop and BatchCop, the MPP protocol is more mature and offers better task and resource management. Therefore, it is recommended to use the MPP protocol.
    - `0` or `OFF`: the optimizer only generates plans using the TiFlash MPP protocol.
    - `1` or `ON`: the optimizer determines whether to use the Cop, BatchCop, or MPP protocol to generate execution plans based on the cost estimation.

14.5.1.84 tidb_allow_batch_cop New in v4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `1`
- Range: `[0, 2]`
- This variable is used to control how TiDB sends a coprocessor request to TiFlash. It has the following values:
    - `0`: Never send requests in batches
    - `1`: Aggregation and join requests are sent in batches
    - `2`: All coprocessor requests are sent in batches

14.5.1.85 tidb_allow_fallback_to_tikv New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: “”
- This variable is used to specify a list of storage engines that might fall back to TiKV. If the execution of a SQL statement fails due to a failure of the specified storage engine in the list, TiDB retries executing this SQL statement with TiKV. This variable can be set to “” or “tiflash”. When this variable is set to “tiflash”, if TiFlash returns a timeout error (error code: ErrTiFlashServerTimeout), TiDB retries executing this SQL statement with TiKV.

14.5.1.86 tidb_allow_function_for_expression_index New in v5.2.0

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: `json_array, json_array_append, json_array_insert, json_contains, json_contains_path, json_depth, json_extract, json_insert, json_keys, json_length, json_merge_patch, json_merge_preserve, json_object, json_pretty, json_quote, json_remove, json_replace, json_schema_valid, json_search, json_set, json_storage_size, json_type, json_unquote, json_valid, lower, md5, reverse, tidb_shard, upper, vitess_hash`
- This read-only variable is used to show the functions that are allowed to be used for creating expression indexes.

14.5.1.87 tidb_allow_mpp New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- Controls whether to use the MPP mode of TiFlash to execute queries. The value options are as follows:
  - `0` or `OFF`, which means that the MPP mode will not be used. For v7.3.0 or a later version, if you set the value of this variable to `0` or `OFF`, you also need to enable the `tidb_allow_tiflash_cop` variable. Otherwise, queries might return errors.
  - `1` or `ON`, which means that the optimizer determines whether to use the MPP mode based on the cost estimation (by default).

MPP is a distributed computing framework provided by the TiFlash engine, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. For details about the selection of the MPP mode, refer to Control whether to select the MPP mode.

14.5.1.88 tidb_allow_remove_auto_inc New in v2.1.18 and v3.0.4

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether the `AUTO_INCREMENT` property of a column is allowed to be removed by executing `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE` statements. It is not allowed by default.

14.5.1.89 tidb_analyze_column_options New in v8.3.0

> **Note:**
>
> - This variable only works when `tidb_analyze_version` is set to `2`.
> - If you upgrade your TiDB cluster from a version earlier than v8.3.0 to v8.3.0 or later, this variable is set to `ALL` by default to keep the original behavior.
> - Starting from v8.3.0, for a newly deployed TiDB cluster, this variable is set to `PREDICATE` by default.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `PREDICATE`
- Value options:`ALL`, `PREDICATE`
- This variable controls the behavior of the `ANALYZE TABLE` statement. Setting it to `PREDICATE` means only collecting statistics for predicate columns; setting it to `ALL` means collecting statistics for all columns. In scenarios where OLAP queries are used, it is recommended to set it to `ALL`, otherwise collecting statistics can result in a significant drop in query performance.

14.5.1.90 tidb_analyze_distsql_scan_concurrency New in v7.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4`
- Range: `[0, 4294967295]`. In versions earlier than v8.2.0, the minimum value is `1`. When you set it to `0`, it adaptively adjusts the concurrency based on the cluster size.
- This variable is used to set the concurrency of the `scan` operation when executing the `ANALYZE` operation.

14.5.1.91 tidb_analyze_partition_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No

- Default value: 2. The default value is 1 for v7.4.0 and earlier versions.
- Range: [1, 128]. Before v8.4.0, the value range is [1, 18446744073709551615].
- This variable specifies the concurrency for writing collected statistics when TiDB analyzes a partitioned table.

14.5.1.92 tidb_analyze_version New in v5.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: 2
- Range: [1, 2]
- Controls how TiDB collects statistics.
    - For TiDB Self-Managed, the default value of this variable changes from 1 to 2 starting from v5.3.0.
    - For TiDB Cloud, the default value of this variable changes from 1 to 2 starting from v6.5.0.
    - If your cluster is upgraded from an earlier version, the default value of tidb_analyze_version does not change after the upgrade.
- For detailed introduction about this variable, see Introduction to Statistics.

14.5.1.93 tidb_analyze_skip_column_types New in v7.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: "json,blob,mediumblob,longblob,mediumtext,longtext". Before v8.2.0, the default value is "json,blob,mediumblob,longblob".
- Possible values: "json,blob,mediumblob,longblob,text,mediumtext,longtext"
- This variable controls which types of columns are skipped for statistics collection when executing the ANALYZE command to collect statistics. The variable is only applicable for tidb_analyze_version = 2. Even if you specify a column using ANALYZE TABLE t COLUMNS c1, ... , cn, no statistics will be collected for the specified column if its type is in tidb_analyze_skip_column_types.

```
mysql> SHOW CREATE TABLE t;
+-------+-------------------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
```

```
+-------+-------------------------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` int(11) DEFAULT NULL,
  `b` varchar(10) DEFAULT NULL,
  `c` json DEFAULT NULL,
  `d` blob DEFAULT NULL,
  `e` longblob DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+-------+-------------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)

mysql> SELECT @@tidb_analyze_skip_column_types;
+----------------------------------+
| @@tidb_analyze_skip_column_types |
+----------------------------------+
| json,blob,mediumblob,longblob |
+----------------------------------+
1 row in set (0.00 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.05 sec)

mysql> SELECT job_info FROM mysql.analyze_jobs ORDER BY end_time DESC LIMIT
    ↪ 1;
+-------------------------------------------------------------------+
| job_info                                                          |
+-------------------------------------------------------------------+
| analyze table columns a, b with 256 buckets, 500 topn, 1 samplerate |
+-------------------------------------------------------------------+
1 row in set (0.00 sec)

mysql> ANALYZE TABLE t COLUMNS a, c;
Query OK, 0 rows affected, 1 warning (0.04 sec)

mysql> SELECT job_info FROM mysql.analyze_jobs ORDER BY end_time DESC LIMIT
    ↪ 1;
+-------------------------------------------------------------------+
| job_info                                                          |
+-------------------------------------------------------------------+
| analyze table columns a with 256 buckets, 500 topn, 1 samplerate |
+-------------------------------------------------------------------+
1 row in set (0.00 sec)
```

14.5.1.94 tidb_auto_analyze_concurrency New in v8.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[1, 2147483647]`
- This variable controls the number of concurrent auto-analyze operations that can run in a TiDB cluster. Before v8.4.0, this concurrency is fixed at 1. To accelerate statistics collection tasks, you can increase this concurrency based on the available resources in your cluster.

14.5.1.95 tidb_auto_analyze_end_time

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Time
- Default value: `23:59 +0000`
- This variable is used to restrict the time window that the automatic update of statistics is permitted. For example, to only allow automatic statistics updates between 1 AM and 3 AM in UTC time, set `tidb_auto_analyze_start_time='01:00 +0000'` and `tidb_auto_analyze_end_time='03:00 +0000'`.

14.5.1.96 tidb_auto_analyze_partition_batch_size New in v6.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `8192`. Before v7.6.0, the default value is `1`. For versions from v7.6.0 to v8.1.x, the default value is `128`. Starting from v8.2.0, the default value changes to `8192`.
- Range: `[1, 8192]`. Before v8.2.0, the value range is `[1, 1024]`.
- This variable specifies the number of partitions that TiDB automatically analyzes when analyzing a partitioned table (which means automatically collecting statistics on a partitioned table).
- If the value of this variable is smaller than the number of partitions, TiDB automatically analyzes all partitions of the partitioned table in multiple batches. If the value of this variable is greater than or equal to the number of partitions, TiDB analyzes all partitions of the partitioned table at the same time.
- If the number of partitions of a partitioned table is far greater than this variable value and the auto-analyze takes a long time, you can increase the value of this variable to reduce the time consumption.

14.5.1.97 tidb_auto_analyze_ratio

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0.5`
- Range: `(0, 1]`. The range for v8.0.0 and earlier versions is `[0, 18446744073709551615]` ↪ .
- This variable is used to set the threshold when TiDB automatically executes `ANALYZE` ↪ `TABLE` in a background thread to update table statistics. For example, a value of 0.5 means that auto-analyze is triggered when greater than 50% of the rows in a table have been modified. Auto-analyze can be restricted to only execute during certain hours of the day by specifying `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end` ↪ `_time`.

> **Note:**
>
> This feature requires the system variable `tidb_enable_auto_analyze` set to `ON`.

14.5.1.98 tidb_auto_analyze_start_time

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Time
- Default value: `00:00 +0000`
- This variable is used to restrict the time window that the automatic update of statistics is permitted. For example, to only allow automatic statistics updates between 1 AM and 3 AM in UTC time, set `tidb_auto_analyze_start_time='01:00 +0000'` and `tidb_auto_analyze_end_time='03:00 +0000'`.

14.5.1.99 tidb_auto_build_stats_concurrency New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[1, 256]`
- This variable is used to set the concurrency of executing the automatic update of statistics.

14.5.1.100 tidb_backoff_lock_fast

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `10`
- Range: `[1, 2147483647]`
- This variable is used to set the `backoff` time when the read request meets a lock.

14.5.1.101 tidb_backoff_weight

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `2`
- Range: `[0, 2147483647]`
- This variable is used to increase the weight of the maximum time of TiDB `backoff`, that is, the maximum retry time for sending a retry request when an internal network or other component (TiKV, PD) failure is encountered. This variable can be used to adjust the maximum retry time and the minimum value is 1.

  For example, the base timeout for TiDB to take TSO from PD is 15 seconds. When `tidb_backoff_weight = 2`, the maximum timeout for taking TSO is: *base time * 2 = 30 seconds*.

  In the case of a poor network environment, appropriately increasing the value of this variable can effectively alleviate error reporting to the application end caused by timeout. If the application end wants to receive the error information more quickly, minimize the value of this variable.

14.5.1.102 tidb_batch_commit

> **Warning:**
>
> It is **NOT** recommended to enable this variable.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- The variable is used to control whether to enable the deprecated batch-commit feature. When this variable is enabled, a transaction might be split into multiple transactions by grouping a few statements and committed non-atomically, which is not recommended.

14.5.1.103 tidb_batch_delete

> **Warning:**
>
> This variable is associated with the deprecated batch-dml feature, which might cause data corruption. Therefore, it is not recommended to enable this variable for batch-dml. Instead, use non-transactional DML.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable the batch-delete feature, which is a part of the deprecated batch-dml feature. When this variable is enabled, `DELETE` statements might be split into multiple transactions and committed non-atomically. To make it work, you also need to enable `tidb_enable_batch_dml` and set a positive value for `tidb_dml_batch_size`, which is not recommended.

14.5.1.104 tidb_batch_insert

> **Warning:**
>
> This variable is associated with the deprecated batch-dml feature, which might cause data corruption. Therefore, it is not recommended to enable this variable for batch-dml. Instead, use non-transactional DML.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- This variable is used to control whether to enable the batch-insert feature, which is a part of the deprecated batch-dml feature. When this variable is enabled, `INSERT` statements might be split into multiple transactions and committed non-atomically. To make it work, you also need to enable `tidb_enable_batch_dml` and set a positive value for `tidb_dml_batch_size`, which is not recommended.

14.5.1.105 tidb_batch_pending_tiflash_count New in v6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4000`
- Range: `[0, 4294967295]`
- Specifies the maximum number of permitted unavailable tables when you use `ALTER DATABASE SET TIFLASH REPLICA` to add TiFlash replicas. If the number of unavailable tables exceeds this limit, the operation will be stopped or setting TiFlash replicas for the remaining tables will be very slow.

14.5.1.106 tidb_broadcast_join_threshold_count New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `10240`
- Range: `[0, 9223372036854775807]`
- Unit: Rows
- If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set. In this situation, the size is determined by the number of rows in the result set. If the estimated number of rows in the subquery is less than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.
- This variable will not take effect after `tidb_prefer_broadcast_join_by_exchange_data_size` is enabled.

14.5.1.107 tidb_broadcast_join_threshold_size New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `104857600` (100 MiB)

- Range: `[0, 9223372036854775807]`
- Unit: Bytes
- If the table size is less than the value of the variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.
- This variable will not take effect after `tidb_prefer_broadcast_join_by_exchange_data_size` is enabled.

14.5.1.108 tidb_build_stats_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `2`. The default value is `4` for v7.4.0 and earlier versions.
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of executing the `ANALYZE` statement.
- When the variable is set to a larger value, the execution performance of other queries is affected.

14.5.1.109 tidb_build_sampling_stats_concurrency New in v7.5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Unit: Threads
- Default value: `2`
- Range: `[1, 256]`
- This variable is used to set the sampling concurrency in the `ANALYZE` process.
- When the variable is set to a larger value, the execution performance of other queries is affected.

14.5.1.110 tidb_capture_plan_baselines New in v4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable the baseline capturing feature. This feature depends on the statement summary, so you need to enable the statement summary before you use baseline capturing.

- After this feature is enabled, the historical SQL statements in the statement summary are traversed periodically, and bindings are automatically created for SQL statements that appear at least twice.

14.5.1.111 tidb_cdc_write_source New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION
- Persists to cluster: No
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 15]`
- When this variable is set to a value other than 0, data written in this session is considered to be written by TiCDC. This variable can only be modified by TiCDC. Do not manually modify this variable in any case.

14.5.1.112 tidb_check_mb4_value_in_utf8

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to enforce that the `utf8` character set only stores values from the Basic Multilingual Plane (BMP). To store characters outside the BMP, it is recommended to use the `utf8mb4` character set.
- You might need to disable this option when upgrading your cluster from an earlier version of TiDB where the `utf8` checking was more relaxed. For details, see FAQs After Upgrade.

14.5.1.113 tidb_checksum_table_concurrency

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the scan index concurrency of executing the `ADMIN CHECKSUM TABLE` statement.
- When the variable is set to a larger value, the execution performance of other queries is affected.

14.5.1.114 tidb_committer_concurrency New in v6.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `128`
- Range: `[1, 10000]`
- The number of goroutines for requests related to executing commit in the commit phase of the single transaction.
- If the transaction to commit is too large, the waiting time for the flow control queue when the transaction is committed might be too long. In this situation, you can increase the configuration value to speed up the commit.
- This setting was previously a `tidb.toml` option (`performance.committer-concurrency`), but changed to a system variable starting from TiDB v6.1.0.

14.5.1.115 tidb_config

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Default value: ""
- This variable is read-only. It is used to obtain the configuration information of the current TiDB server.

14.5.1.116 tidb_constraint_check_in_place

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable only applies to optimistic transactions. For pessimistic transactions, use `tidb_constraint_check_in_place_pessimistic` instead.
- When this variable is set to `OFF`, checking for duplicate values in unique indexes is deferred until the transaction commits. This helps improve performance but might be an unexpected behavior for some applications. See Constraints for details.
  - When setting `tidb_constraint_check_in_place` to `OFF` and using optimistic transactions:

```
tidb> create table t (i int key);
tidb> insert into t values (1);
tidb> begin optimistic;
tidb> insert into t values (1);
Query OK, 1 row affected
tidb> commit; -- Check only when a transaction is committed.
ERROR 1062 : Duplicate entry '1' for key 't.PRIMARY'
```

  - When setting `tidb_constraint_check_in_place` to `ON` and using optimistic transactions:

```
tidb> set @@tidb_constraint_check_in_place=ON;
tidb> begin optimistic;
tidb> insert into t values (1);
ERROR 1062 : Duplicate entry '1' for key 't.PRIMARY'
```

14.5.1.117 tidb_constraint_check_in_place_pessimistic New in v6.3.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: By default, the `pessimistic-txn.constraint-check-in-place-pessimistic` configuration item is `true` so the default value of this variable is `ON`. When `pessimistic-txn.constraint-check-in-place-pessimistic` is set to `false`, the default value of this variable is `OFF`.

- This variable only applies to pessimistic transactions. For optimistic transactions, use `tidb_constraint_check_in_place` instead.
- When this variable is set to `OFF`, TiDB defers the unique constraint check of a unique index (to the next time when executing a statement that requires a lock to the index or to the time when committing the transaction). This helps improve performance but might be an unexpected behavior for some applications. See Constraints for details.
- Disabling this variable might cause TiDB to return a `LazyUniquenessCheckFailure` error in pessimistic transactions. When this error occurs, TiDB rolls back the current transaction.
- When this variable is disabled, you cannot use `SAVEPOINT` in pessimistic transactions.
- When this variable is disabled, committing a pessimistic transaction might return a `Write conflict` or `Duplicate entry` error. When such an error occurs, TiDB rolls back the current transaction.
    - When setting `tidb_constraint_check_in_place_pessimistic` to `OFF` and using pessimistic transactions:

```
set @@tidb_constraint_check_in_place_pessimistic=OFF;
create table t (i int key);
insert into t values (1);
begin pessimistic;
insert into t values (1);
```

```
Query OK, 1 row affected
```

```
tidb> commit; -- Check only when a transaction is committed.
```

```
ERROR 1062 : Duplicate entry '1' for key 't.PRIMARY'
```

    - When setting `tidb_constraint_check_in_place_pessimistic` to `ON` and using pessimistic transactions:

```
set @@tidb_constraint_check_in_place_pessimistic=ON;
begin pessimistic;
insert into t values (1);
```

```
ERROR 1062 : Duplicate entry '1' for key 't.PRIMARY'
```

14.5.1.118 tidb_cost_model_version New in v6.2.0

Note:

- Since TiDB v6.5.0, the newly created cluster uses Cost Model Version 2 by default. If you upgrade from a TiDB version earlier than v6.5.0 to v6.5.0 or later, the `tidb_cost_model_version` value does not change.
- Switching the version of the cost model might cause changes to query plans.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `2`
- Value options:
  - `1`: enables the Cost Model Version 1, which is used by default in TiDB v6.4.0 and earlier versions.
  - `2`: enables the Cost Model Version 2, which is generally available in TiDB v6.5.0 and is more accurate than the version 1 in internal tests.
- The version of cost model affects the plan decision of optimizer. For more details, see Cost Model.

14.5.1.119 tidb_current_ts

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 9223372036854775807]`
- This variable is read-only. It is used to obtain the timestamp of the current transaction.

14.5.1.120 tidb_ddl_disk_quota New in v6.3.0

Note:

This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `107374182400` (100 GiB)
- Range: `[107374182400, 1125899906842624]` ([100 GiB, 1 PiB])
- Unit: Bytes
- This variable only takes effect when `tidb_ddl_enable_fast_reorg` is enabled. It sets the usage limit of local storage during backfilling when creating an index.

14.5.1.121 tidb_ddl_enable_fast_reorg New in v6.3.0

> **Note:**
>
> - If you are using a TiDB Cloud Dedicated cluster, to improve the speed for index creation using this variable, make sure that your TiDB cluster is hosted on AWS and your TiDB node size is at least 8 vCPU.
> - For TiDB Cloud Serverless clusters, this variable is read-only.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to enable the acceleration of `ADD INDEX` and `CREATE INDEX` to improve the speed of backfilling for index creation. Setting this variable value to `ON` can bring performance improvement for index creation on tables with a large amount of data.
- Starting from v7.1.0, the index acceleration operation supports checkpoints. Even if the TiDB owner node is restarted or changed due to failures, TiDB can still recover progress from checkpoints that are automatically updated on a regular basis.
- To verify whether a completed `ADD INDEX` operation is accelerated, you can execute the `ADMIN SHOW DDL JOBS` statement to see whether `ingest` is displayed in the `JOB_TYPE` column.

> **Note:**

- Index acceleration requires a temp-dir that is writable and has enough free space. If the temp-dir is unusable, TiDB falls back to non-accelerated index building. It is recommended to put the temp-dir on a SSD disk.
- Before you upgrade TiDB to v6.5.0 or later, it is recommended that you check whether the temp-dir path of TiDB is correctly mounted to an SSD disk. Make sure that the operating system user that runs TiDB has the read and write permissions for this directory. Otherwise, The DDL operations might experience unpredictable issues. This path is a TiDB configuration item, which takes effect after TiDB is restarted. Therefore, setting this configuration item before upgrading can avoid another restart.

14.5.1.122 tidb_enable_dist_task New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: ON
- This variable is used to control whether to enable the TiDB Distributed eXecution Framework (DXF). After the framework is enabled, the DXF tasks such as DDL and import will be distributedly executed and completed by multiple TiDB nodes in the cluster.
- Starting from TiDB v7.1.0, the DXF supports distributedly executing the ADD INDEX statement for partitioned tables.
- Starting from TiDB v7.2.0, the DXF supports distributedly executing the IMPORT INTO statement for import jobs.
- Starting from TiDB v8.1.0, this variable is enabled by default. If you want to upgrade a cluster with the DXF enabled to v8.1.0 or later, disable the DXF (by setting tidb_enable_dist_task to OFF) before the upgrade, which avoids ADD INDEX operations during the upgrade causing data index inconsistency. After the upgrade, you can manually enable the DXF.
- This variable is renamed from tidb_ddl_distribute_reorg.

14.5.1.123 tidb_cloud_storage_uri New in v7.4.0

Note:

Currently, the Global Sort process consumes a large amount of computing and memory resources of TiDB nodes. In scenarios such as adding indexes

online while user business applications are running, it is recommended to add new TiDB nodes to the cluster, configure the `tidb_service_scope` variable for these nodes, and connect to these nodes to create tasks. In this way, the distributed framework schedules tasks to these nodes, isolating the workload from other TiDB nodes to reduce the impact of executing backend tasks such as `ADD INDEX` and `IMPORT INTO` on user business applications.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `""`
- This variable is used to specify the Amazon S3 cloud storage URI to enable Global Sort. After enabling the TiDB Distributed eXecution Framework (DXF), you can use the Global Sort feature by configuring the URI and pointing it to an appropriate cloud storage path with the necessary permissions to access the storage. For more details, see Amazon S3 URI format.
- The following statements can use the Global Sort feature.
  - The `ADD INDEX` statement.
  - The `IMPORT INTO` statement for import jobs.

14.5.1.124 tidb_ddl_error_count_limit

Note:

This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `512`
- Range: `[0, 9223372036854775807]`
- This variable is used to set the number of retries when the DDL operation fails. When the number of retries exceeds the parameter value, the wrong DDL operation is canceled.

14.5.1.125 tidb_ddl_flashback_concurrency New in v6.3.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `64`
- Range: `[1, 256]`
- This variable controls the concurrency of `FLASHBACK CLUSTER`.

14.5.1.126 tidb_ddl_reorg_batch_size

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `256`
- Range: `[32, 10240]`
- Unit: Rows
- This variable is used to set the batch size during the `re-organize` phase of the DDL operation. For example, when TiDB executes the `ADD INDEX` operation, the index data needs to backfilled by `tidb_ddl_reorg_worker_cnt` (the number) concurrent workers. Each worker backfills the index data in batches.
    - If `tidb_ddl_enable_fast_reorg` is set to `OFF`, `ADD INDEX` is executed as a transaction. If there are many update operations such as `UPDATE` and `REPLACE` in the target columns during the `ADD INDEX` execution, a larger batch size indicates a larger probability of transaction conflicts. In this case, it is recommended that you set the batch size to a smaller value. The minimum value is 32.
    - If the transaction conflict does not exist, or if `tidb_ddl_enable_fast_reorg` is set to `ON`, you can set the batch size to a large value. This makes data backfilling faster but also increases the write pressure on TiKV. For a proper batch size, you also need to refer to the value of `tidb_ddl_reorg_worker_cnt`. See Interaction Test on Online Workloads and `ADD INDEX` Operations for reference.

- Starting from v8.3.0, this parameter is supported at the SESSION level. Modifying the parameter at the GLOBAL level will not impact currently running DDL statements. It will only apply to DDLs submitted in new sessions.

14.5.1.127 tidb_ddl_reorg_priority

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `PRIORITY_LOW`
- Value options: `PRIORITY_LOW`, `PRIORITY_NORMAL`, `PRIORITY_HIGH`
- This variable is used to set the priority of executing the `ADD INDEX` operation in the `re-organize` phase.
- You can set the value of this variable to `PRIORITY_LOW`, `PRIORITY_NORMAL` or `PRIORITY_HIGH`.

14.5.1.128 tidb_ddl_reorg_worker_cnt

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of the DDL operation in the `re-organize` phase.
- Starting from v8.3.0, this parameter is supported at the SESSION level. Modifying the parameter at the GLOBAL level will not impact currently running DDL statements. It will only apply to DDLs submitted in new sessions.

14.5.1.129 `tidb_enable_fast_create_table` New in v8.0.0

> **Warning:**
>
> This variable is currently an experimental feature and it is not recommended to use in a production environment. This feature might change or be removed without prior notice. If you find a bug, please give feedback by raising an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable TiDB Accelerated Table Creation.
- Starting from v8.0.0, TiDB supports accelerating table creation by the `CREATE TABLE` statement using `tidb_enable_fast_create_table`.
- This variable is renamed from the variable `tidb_ddl_version` that is introduced in v7.6.0. Starting from v8.0.0, `tidb_ddl_version` no longer takes effect.

14.5.1.130 tidb_default_string_match_selectivity New in v6.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Default value: `0.8`
- Range: `[0, 1]`
- This variable is used to set the default selectivity of `like`, `rlike`, and `regexp` functions in the filter condition when estimating the number of rows. This variable also controls whether to enable TopN to help estimate these functions.
- TiDB tries to estimate `like` in the filter condition using statistics. But when `like` matches a complex string, or when using `rlike` or `regexp`, TiDB often fails to fully use statistics, and the default value `0.8` is set as the selectivity rate instead, resulting in inaccurate estimation.
- This variable is used to change the preceding behavior. If the variable is set to a value other than `0`, the selectivity rate is the specified variable value instead of `0.8`.
- If the variable is set to `0`, TiDB tries to evaluate using TopN in statistics to improve the accuracy and consider the NULL number in statistics when estimating the preceding three functions. The prerequisite is that statistics are collected when `tidb_analyze_version` is set to `2`. Such evaluation might slightly affect the performance.
- If the variable is set to a value other than the `0.8`, TiDB adjusts the estimation for `not like`, `not rlike`, and `not regexp` accordingly.

14.5.1.131 tidb_disable_txn_auto_retry

> **Warning:**
>
> Starting from v8.0.0, this variable is deprecated, and TiDB no longer supports automatic retries of optimistic transactions. As an alternative, when encountering optimistic transaction conflicts, you can capture the error and retry transactions in your application, or use the Pessimistic transaction mode instead.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to set whether to disable the automatic retry of explicit optimistic transactions. The default value of `ON` means that transactions will not automatically retry in TiDB and `COMMIT` statements might return errors that need to be handled in the application layer.

  Setting the value to `OFF` means that TiDB will automatically retry transactions, resulting in fewer errors from `COMMIT` statements. Be careful when making this change, because it might result in lost updates.

  This variable does not affect automatically committed implicit transactions and internally executed transactions in TiDB. The maximum retry count of these transactions is determined by the value of `tidb_retry_limit`.

  For more details, see limits of retry.

  This variable only applies to optimistic transactions, not to pessimistic transactions. The number of retries for pessimistic transactions is controlled by `max_retry_count`.

14.5.1.132 tidb_distsql_scan_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `15`
- Range: `[1, 256]`

- Unit: Threads
- This variable is used to set the concurrency of the `scan` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.
- For OLAP scenarios, the maximum value should not exceed the number of CPU cores of all the TiKV nodes.
- If a table has a lot of partitions, you can reduce the variable value appropriately (determined by the size of the data to be scanned and the frequency of the scan) to avoid TiKV becoming out of memory (OOM).
- For a simple query with only a `LIMIT` clause, if the `LIMIT` value is less than 100000, the scan operation pushed down to TiKV treats the value of this variable as `1` to enhance execution efficiency.
- For the `SELECT MAX/MIN(col)FROM ...` query, if the `col` column has an index sorted in the same order required by the `MAX(col)` or `MIN(col)` function, TiDB will rewrite the query to `SELECT col FROM ... LIMIT 1` for processing, and the value of this variable will also be processed as `1`. For example, for `SELECT MIN(col)FROM ...`, if the `col` column has an ascending index, TiDB can quickly obtain the `MIN(col)` value by rewriting the query to `SELECT col FROM ... LIMIT 1` and directly reading the first row of the index.

14.5.1.133 tidb_dml_batch_size

> **Warning:**
>
> This variable is associated with the deprecated batch-dml feature, which might cause data corruption. Therefore, it is not recommended to enable this variable for batch-dml. Instead, use non-transactional DML.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- Unit: Rows
- When this value is greater than `0`, TiDB will batch commit statements such as `INSERT` ↪ into smaller transactions. This reduces memory usage and helps ensure that the `txn-total-size-limit` is not reached by bulk modifications.
- Only the value `0` provides ACID compliance. Setting this to any other value will break the atomicity and isolation guarantees of TiDB.
- To make this variable work, you also need to enable `tidb_enable_batch_dml` and at least one of `tidb_batch_insert` and `tidb_batch_delete`.

Note:

Starting from v7.0.0, `tidb_dml_batch_size` no longer takes effect on the `LOAD DATA` statement.

14.5.1.134 tidb_dml_type New in v8.0.0

Warning:

The bulk DML execution mode (`tidb_dml_type = "bulk"`) is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue. In the current version, when TiDB performs large transactions using the bulk DML mode, it might affect the memory usage and execution efficiency of TiCDC, TiFlash, and the resolved-ts module of TiKV, and might cause OOM issues. Additionally, BR might be blocked and fail to process when encountering locks. Therefore, it is not recommended to use this mode when these components or features are enabled.

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Type: String
- Default value: `"standard"`
- Value options: `"standard"`, `"bulk"`
- This variable controls the execution mode of DML statements.
    - `"standard"` indicates the standard DML execution mode, where TiDB transactions are cached in memory before being committed. This mode is suitable for high-concurrency transaction scenarios with potential conflicts and is the default recommended execution mode.
    - `"bulk"` indicates the bulk DML execution mode, which is suitable for scenarios where a large amount of data is written, causing excessive memory usage in TiDB.
        - During the execution of TiDB transactions, the data is not fully cached in the TiDB memory, but is continuously written to TiKV to reduce memory usage and smooth the write pressure.
        - Only `INSERT`, `UPDATE`, `REPLACE`, and `DELETE` statements are affected by the `"bulk"` mode. Due to the pipelined execution in `"bulk"` mode, the usage of `INSERT IGNORE ... ON DUPLICATE UPDATE ...` might result in

a `Duplicate entry` error when updates cause conflicts. In contrast, in `"standard"` mode, because the `IGNORE` keyword is set, this error would be ignored and not be returned to the user.

- `"bulk"` mode is only suitable for scenarios where a large amount of **data is written without conflicts**. This mode is not efficient for handling write conflicts, as write-write conflicts might cause large transactions to fail and be rolled back.
- `"bulk"` mode only takes effect on statements with auto-commit enabled, and requires the `pessimistic-auto-commit` configuration item to be set to `false` ↪ .
- When using the `"bulk"` mode to execute statements, ensure that the meta-data lock remains enabled during the execution process.
- `"bulk"` mode cannot be used on temporary tables and cached tables.
- `"bulk"` mode cannot be used on tables containing foreign keys and tables referenced by foreign keys when the foreign key constraint check is enabled (`foreign_key_checks = ON`).
- In situations that the environment does not support or is incompatible with the `"bulk"` mode, TiDB falls back to the `"standard"` mode and returns a warning message. To verify if the `"bulk"` mode is used, you can check the `pipelined` field using `tidb_last_txn_info`. A `true` value indicates that the `"bulk"` mode is used.
- When executing large transactions in the `"bulk"` mode, the transaction duration might be long. For transactions in this mode, the maximum TTL of the transaction lock is the greater value between `max-txn-ttl` and 24 hours. Additionally, if the transaction execution time exceeds the value set by `tidb` ↪ `_gc_max_wait_time`, the GC might force a rollback of the transaction, leading to its failure.
- When TiDB executes transactions in the `"bulk"` mode, transaction size is not limited by the TiDB configuration item `txn-total-size-limit`.
- This mode is implemented by the Pipelined DML feature. For detailed design and GitHub issues, see Pipelined DML and #50215.

14.5.1.135 tidb_enable_1pc New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean

- Default value: `ON`
- This variable is used to specify whether to enable the one-phase commit feature for transactions that only affect one Region. Compared with the often-used two-phase commit, one-phase commit can greatly reduce the latency of transaction commit and increase the throughput.

> **Note:**
>
> - The default value of `ON` only applies to new clusters. if your cluster was upgraded from an earlier version of TiDB, the value `OFF` will be used instead.
> - Enabling this parameter only means that one-phase commit becomes an optional mode of transaction commit. In fact, the most suitable mode of transaction commit is determined by TiDB.

14.5.1.136 tidb_enable_analyze_snapshot New in v6.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to read historical data or the latest data when performing `ANALYZE`. If this variable is set to `ON`, `ANALYZE` reads the historical data available at the time of `ANALYZE`. If this variable is set to `OFF`, `ANALYZE` reads the latest data.
- Before v5.2, `ANALYZE` reads the latest data. From v5.2 to v6.1, `ANALYZE` reads the historical data available at the time of `ANALYZE`.

> **Warning:**
>
> If `ANALYZE` reads the historical data available at the time of `ANALYZE`, the long duration of `AUTO ANALYZE` might cause the `GC life time is shorter than transaction duration` error because the historical data is garbage-collected.

14.5.1.137 tidb_enable_async_commit New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to enable the async commit feature for the second phase of the two-phase transaction commit to perform asynchronously in the background. Enabling this feature can reduce the latency of transaction commit.

> **Note:**
>
> - The default value of `ON` only applies to new clusters. if your cluster was upgraded from an earlier version of TiDB, the value `OFF` will be used instead.
> - Enabling this parameter only means that Async Commit becomes an optional mode of transaction commit. In fact, the most suitable mode of transaction commit is determined by TiDB.

14.5.1.138 tidb_enable_auto_analyze New in v6.1.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- Determines whether TiDB automatically updates table statistics as a background operation.

- This setting was previously a `tidb.toml` option (`performance.run-auto-analyze`), but changed to a system variable starting from TiDB v6.1.0.

14.5.1.139 tidb_enable_auto_analyze_priority_queue New in v8.0.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the priority queue to schedule the tasks of automatically collecting statistics. When this variable is enabled, TiDB prioritizes collecting statistics for tables that are more valuable to collect, such as newly created indexes and partitioned tables with partition changes. Additionally, TiDB prioritizes tables with lower health scores, placing them at the front of the queue.

14.5.1.140 tidb_enable_auto_increment_in_generated

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to determine whether to include the `AUTO_INCREMENT` columns when creating a generated column or an expression index.

14.5.1.141 tidb_enable_batch_dml

> **Warning:**
>
> This variable is associated with the deprecated batch-dml feature, which might cause data corruption. Therefore, it is not recommended to enable this variable for batch-dml. Instead, use non-transactional DML.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- This variable controls whether to enable the deprecated batch-dml feature. When it is enabled, certain statements might be split into multiple transactions, which is non-atomic and should be used with care. When using batch-dml, you must ensure that there are no concurrent operations on the data you are operating on. To make it work, you must also specify a positive value for `tidb_batch_dml_size` and enable at least one of `tidb_batch_insert` and `tidb_batch_delete`.

14.5.1.142 tidb_enable_cascades_planner

> **Warning:**
>
> Currently, cascades planner is an experimental feature. It is not recommended that you use it in production environments.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable the cascades planner.

14.5.1.143 tidb_enable_check_constraint New in v7.2.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable the `CHECK` constraint feature.

14.5.1.144 tidb_enable_chunk_rpc New in v4.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the `Chunk` data encoding format in Coprocessor.

14.5.1.145 tidb_enable_clustered_index New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `ON`
- Possible values: `OFF`, `ON`, `INT_ONLY`
- This variable is used to control whether to create the primary key as a clustered index by default. "By default" here means that the statement does not explicitly specify the keyword `CLUSTERED/NONCLUSTERED`. Supported values are `OFF`, `ON`, and `INT_ONLY`:
  - `OFF` indicates that primary keys are created as non-clustered indexes by default.
  - `ON` indicates that primary keys are created as clustered indexes by default.
  - `INT_ONLY` indicates that the behavior is controlled by the configuration item `alter-primary-key`. If `alter-primary-key` is set to `true`, all primary keys are created as non-clustered indexes by default. If it is set to `false`, only the primary keys which consist of an integer column are created as clustered indexes.

14.5.1.146 tidb_enable_ddl New in v6.3.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Default value: `ON`
- Possible values: `OFF`, `ON`
- This variable controls whether the corresponding TiDB instance can become a DDL owner or not. If there is only one TiDB instance in the current TiDB cluster, you cannot prevent it from becoming a DDL owner, which means you cannot set it to `OFF`.

14.5.1.147 tidb_enable_collect_execution_info

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to record the execution information of each operator in the slow query log and whether to record the usage statistics of indexes.

14.5.1.148 tidb_enable_column_tracking New in v5.4.0

> **Warning:**
>
> Starting from v8.3.0, this variable is deprecated. TiDB tracks predicate columns by default. For more information, see `tidb_analyze_column_options`.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`. Before v8.3.0, the default value is `OFF`.
- This variable controls whether to enable TiDB to collect `PREDICATE COLUMNS`. After enabling the collection, if you disable it, the information of previously collected `PREDICATE COLUMNS` is cleared. For details, see Collect statistics on some columns.

14.5.1.149 tidb_enable_enhanced_security

- Scope: NONE
- Applies to hint SET_VAR: No
- Type: Boolean

- Default value: `OFF`
- This variable indicates whether the TiDB server you are connected to has the Security Enhanced Mode (SEM) enabled. To change its value, you need to modify the value of `enable-sem` in your TiDB server configuration file and restart the TiDB server.

- SEM is inspired by the design of systems such as Security-Enhanced Linux. It reduces the abilities of users with the MySQL `SUPER` privilege and instead requires `RESTRICTED` fine-grained privileges to be granted as a replacement. These fine-grained privileges include:

- `RESTRICTED_TABLES_ADMIN`: The ability to write data to system tables in the `mysql` schema and to see sensitive columns on `information_schema` tables.
- `RESTRICTED_STATUS_ADMIN`: The ability to see sensitive variables in the command `SHOW STATUS`.
- `RESTRICTED_VARIABLES_ADMIN`: The ability to see and set sensitive variables in `SHOW [GLOBAL] VARIABLES` and `SET`.
- `RESTRICTED_USER_ADMIN`: The ability to prevent other users from making changes or dropping a user account.

14.5.1.150 tidb_enable_exchange_partition

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to enable the `exchange partitions with tables` feature. The default value is `ON`, that is, `exchange partitions with tables` is enabled by default.
- This variable is deprecated since v6.3.0. Its value will be fixed to the default value `ON`, that is, `exchange partitions with tables` is enabled by default.

14.5.1.151 tidb_enable_extended_stats

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable indicates whether TiDB can collect the extended statistic to guide the optimizer. See Introduction to Extended Statistics for more information.

14.5.1.152 tidb_enable_external_ts_read New in v6.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- If this variable is set to `ON`, TiDB reads data with the timestamp specified by `tidb_external_ts`.

14.5.1.153 tidb_external_ts New in v6.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- If `tidb_enable_external_ts_read` is set to `ON`, TiDB reads data with the timestamp specified by this variable.

14.5.1.154 tidb_enable_fast_analyze

> **Warning:**
>
> Starting from v7.5.0, this variable is deprecated.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether to enable the statistics `Fast Analyze` feature.
- If the statistics `Fast Analyze` feature is enabled, TiDB randomly samples about 10,000 rows of data as statistics. When the data is distributed unevenly or the data size is small, the statistics accuracy is low. This might lead to a non-optimal execution plan, for example, selecting a wrong index. If the execution time of the regular `Analyze` statement is acceptable, it is recommended to disable the `Fast Analyze` feature.

14.5.1.155 tidb_enable_fast_table_check New in v7.2.0

> **Note:**
>
> This variable does not work for multi-valued indexes and prefix indexes.

- Scope: SESSION | GLOBAL
- Persists to the cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean

- Default value: `ON`
- This variable is used to control whether to use a checksum-based approach to quickly check the integrity of data and indexes in a table. The default value `ON` means this feature is enabled by default.
- When this variable is enabled, TiDB can execute the `ADMIN CHECK [TABLE|INDEX]` statement in a faster way.

14.5.1.156 tidb_enable_foreign_key New in v6.3.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: Before v6.6.0, the default value is `OFF`. Starting from v6.6.0, the default value is `ON`.
- This variable controls whether to enable the `FOREIGN KEY` feature.

14.5.1.157 tidb_enable_gc_aware_memory_track

> **Warning:**
>
> This variable is an internal variable for debugging in TiDB. It might be removed in a future release. **Do not** set this variable.

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable GC-Aware memory track.

14.5.1.158 tidb_enable_global_index New in v7.6.0

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to support creating global indexes for partitioned tables. When this variable is enabled, TiDB allows you to create unique indexes that **do not include all the columns used in the partition expressions** by specifying `GLOBAL` in the index definition.
- This variable is deprecated since v8.4.0. Its value will be fixed to the default value `ON`, that is, global indexes is enabled by default.

14.5.1.159 tidb_enable_lazy_cursor_fetch New in v8.3.0

> **Warning:**
>
> The feature controlled by this variable is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- Possible values: `OFF`, `ON`
- This variable controls the behavior of the Cursor Fetch feature.
    - When Cursor Fetch is enabled and this variable is set to `OFF`, TiDB reads all the data at the start of statement execution, stores the data into TiDB's memory, and returns it to the client based on the client's specified `FetchSize` for subsequent client reads. If the result set is too large, TiDB might temporarily write the result to the hard disk.
    - When Cursor Fetch is enabled and this variable is set to `ON`, TiDB does not read all the data into the TiDB node at once, but reads data into the TiDB node incrementally as the client fetches it.
- The feature controlled by this variable has the following limitations:
    - It does not support statements within explicit transactions.
    - It only supports execution plans that contain and only contain `TableReader`, `IndexReader`, `IndexLookUp`, `Projection`, and `Selection` operators.

    - For statements using Lazy Cursor Fetch, execution information does not appear in the statements summary and slow query log.
- For unsupported scenarios, its behavior is the same as when setting this variable to `OFF`.

14.5.1.160 tidb_enable_non_prepared_plan_cache

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the Non-prepared plan cache feature.
- Enabling this feature might incur additional memory and CPU overhead and might not be suitable for all situations. Please determine whether to enable this feature according to your actual scenario.

14.5.1.161 tidb_enable_non_prepared_plan_cache_for_dml New in v7.1.0

> **Warning:**
>
> The non-prepared execution plan cache for DML statements is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`.
- This variable controls whether to enable the Non-prepared plan cache feature for DML statements.

14.5.1.162 tidb_enable_gogc_tuner New in v6.4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to enable GOGC Tuner.

14.5.1.163 tidb_enable_historical_stats

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`. Before v8.2.0, the default value is `ON`.
- This variable controls whether to enable historical statistics. The default value is `OFF`, which means that historical statistics are disabled by default.

14.5.1.164 tidb_enable_historical_stats_for_capture

> **Warning:**
>
> The feature controlled by this variable is not fully functional in the current TiDB version. Do not change the default value.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether the information captured by `PLAN REPLAYER CAPTURE` includes historical statistics by default. The default value `OFF` means that historical statistics are not included by default.

14.5.1.165 tidb_enable_index_merge New in v4.0

> **Note:**

- After upgrading a TiDB cluster from versions earlier than v4.0.0 to v5.4.0 or later, this variable is disabled by default to prevent performance regression due to changes of execution plans.
- After upgrading a TiDB cluster from v4.0.0 or later to v5.4.0 or later, this variable remains the setting before the upgrade.
- Since v5.4.0, for a newly deployed TiDB cluster, this variable is enabled by default.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the index merge feature.

14.5.1.166 tidb_enable_index_merge_join

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- Specifies whether to enable the `IndexMergeJoin` operator.
- This variable is used only for the internal operation of TiDB. It is **NOT recommended** to adjust it. Otherwise, data correctness might be affected.

14.5.1.167 tidb_enable_legacy_instance_scope New in v6.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable permits `INSTANCE` scoped variables to be set using the `SET SESSION` as well as `SET GLOBAL` syntax.
- This option is enabled by default for compatibility with earlier versions of TiDB.

14.5.1.168 tidb_enable_list_partition New in v5.0

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to set whether to enable the `LIST (COLUMNS)TABLE PARTITION` feature.
- This variable is deprecated since v8.4.0. Its value will be fixed to the default value `ON`, that is, List partitioning is enabled by default.

14.5.1.169 tidb_enable_local_txn

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used for an unreleased feature. **Do not change the variable value**.

14.5.1.170 tidb_enable_metadata_lock New in v6.3.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to set whether to enable the Metadata lock feature. Note that when setting this variable, you need to make sure that there are no running DDL statements in the cluster. Otherwise, the data might be incorrect or inconsistent.

14.5.1.171 tidb_enable_mutation_checker New in v6.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`

- This variable is used to control whether to enable TiDB mutation checker, which is a tool used to check consistency between data and indexes during the execution of DML statements. If the checker returns an error for a statement, TiDB rolls back the execution of the statement. Enabling this variable causes a slight increase in CPU usage. For more information, see Troubleshoot Inconsistency Between Data and Indexes.
- For new clusters of v6.0.0 or later versions, the default value is `ON`. For existing clusters that upgrade from versions earlier than v6.0.0, the default value is `OFF`.

14.5.1.172 tidb_enable_new_cost_interface New in v6.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- TiDB v6.2.0 refactors the implementation of previous cost model. This variable controls whether to enable the refactored Cost Model implementation.
- This variable is enabled by default because the refactored Cost Model uses the same cost formula as before, which does not change the plan decision.
- If your cluster is upgraded from v6.1 to v6.2, this variable remains `OFF`, and it is recommended to enable it manually. If your cluster is upgraded from a version earlier than v6.1, this variable sets to `ON` by default.

14.5.1.173 tidb_enable_new_only_full_group_by_check New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable controls the behavior when TiDB performs the `ONLY_FULL_GROUP_BY` ↪ check. For detailed information about `ONLY_FULL_GROUP_BY`, see the MySQL documentation. In v6.1.0, TiDB handles this check more strictly and correctly.
- To avoid potential compatibility issues caused by version upgrades, the default value of this variable is `OFF` in v6.1.0.

14.5.1.174 tidb_enable_noop_functions New in v4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration

- Default value: `OFF`
- Possible values: `OFF`, `ON`, `WARN`
- By default, TiDB returns an error when you attempt to use the syntax for functionality that is not yet implemented. When the variable value is set to `ON`, TiDB silently ignores such cases of unavailable functionality, which is helpful if you cannot make changes to the SQL code.
- Enabling `noop` functions controls the following behaviors:
    - `LOCK IN SHARE MODE` syntax
    - `SQL_CALC_FOUND_ROWS` syntax
    - `START TRANSACTION READ ONLY` and `SET TRANSACTION READ ONLY` syntax
    - The `tx_read_only`, `transaction_read_only`, `offline_mode`, `super_read_only` ↪ , `read_only` and `sql_auto_is_null` system variables
    - `GROUP BY <expr> ASC|DESC` syntax

> **Warning:**
>
> Only the default value of `OFF` can be considered safe. Setting `tidb_enable` ↪ `_noop_functions=1` might lead to unexpected behaviors in your application, because it permits TiDB to ignore certain syntax without providing an error. For example, the syntax `START TRANSACTION READ ONLY` is permitted, but the transaction remains in read-write mode.

14.5.1.175 tidb_enable_noop_variables New in v6.2.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- If you set the variable value to `OFF`, TiDB behaves as follows:
    - When you use `SET` to set a `noop` variable, TiDB returns the `"setting *variable` ↪ `_name* has no effect in TiDB"` warning.
    - The result of `SHOW [SESSION | GLOBAL] VARIABLES` does not include `noop` variables.
    - When you use `SELECT` to read a `noop` variable, TiDB returns the `"variable *` ↪ `variable_name* has no effect in TiDB"` warning.
- To check whether a TiDB instance has set and read the `noop` variable, you can use the `SELECT * FROM INFORMATION_SCHEMA.CLIENT_ERRORS_SUMMARY_GLOBAL;` statement.

14.5.1.176 tidb_enable_null_aware_anti_join New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: Before v7.0.0, the default value is `OFF`. Starting from v7.0.0, the default value is `ON`.
- Type: Boolean
- This variable controls whether TiDB applies Null Aware Hash Join when ANTI JOIN is generated by subqueries led by special set operators `NOT IN` and `!= ALL`.
- When you upgrade from an earlier version to a v7.0.0 or later cluster, the feature is automatically enabled, meaning that this variable is set to `ON`.

14.5.1.177 tidb_enable_outer_join_reorder New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- Since v6.1.0, the Join Reorder algorithm of TiDB supports Outer Join. This variable controls whether TiDB enables the Join Reorder's support for Outer Join.
- If your cluster is upgraded from an earlier version of TiDB, note the following:
  - If the TiDB version before the upgrade is earlier than v6.1.0, the default value of this variable after the upgrade is `ON`.
  - If the TiDB version before the upgrade is v6.1.0 or later, the default value of the variable after the upgrade follows the value before the upgrade.

14.5.1.178 tidb_enable_inl_join_inner_multi_pattern New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`. The default value is `OFF` for v8.3.0 and earlier versions.
- This variable controls whether Index Join is supported when the inner table has `Selection`, `Aggregation`, or `Projection` operators on it. The default value `OFF` means that Index Join is not supported in this scenario.
- If you upgrade your TiDB cluster from a version earlier than v7.0.0 to v8.4.0 or later, this variable is set to `OFF` by default, indicating that Index Join is not supported in this scenario.

14.5.1.179 tidb_enable_instance_plan_cache New in v8.4.0

> **Warning:**
>
> Currently, Instance Plan Cache is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the Instance Plan Cache feature. This feature implements instance-level execution plan cache, which allows all sessions within the same TiDB instance to share the execution plan cache, thereby improving memory utilization. Before enabling Instance Plan Cache, it is recommended to disable session-level Prepared execution plan cache and Non-prepared execution plan cache.

14.5.1.180 tidb_enable_ordered_result_mode

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- Specifies whether to sort the final output result automatically.
- For example, with this variable enabled, TiDB processes `SELECT a, MAX(b)FROM t GROUP BY a` as `SELECT a, MAX(b)FROM t GROUP BY a ORDER BY a, MAX(b)`.

14.5.1.181 tidb_enable_paging New in v5.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`

- This variable controls whether to use the method of paging to send coprocessor requests. For TiDB versions in [v5.4.0, v6.2.0), this variable only takes effect on the `IndexLookup` operator; for v6.2.0 and later, this variable takes effect globally. Starting from v6.4.0, the default value of this variable is changed from `OFF` to `ON`.
- User scenarios:
  - In all OLTP scenarios, it is recommended to use the method of paging.
  - For read queries that use `IndexLookup` and `Limit` and that `Limit` cannot be pushed down to `IndexScan`, there might be high latency for the read queries and high usage for TiKV `Unified read pool CPU`. In such cases, because the `Limit` operator only requires a small set of data, if you set `tidb_enable_paging` to `ON`, TiDB processes less data, which reduces query latency and resource consumption.
  - In scenarios such as data export using Dumpling and full table scan, enabling paging can effectively reduce the memory consumption of TiDB processes.

> **Note:**
>
> In OLAP scenarios where TiKV is used as the storage engine instead of TiFlash, enabling paging might cause performance regression in some cases. If the regression occurs, consider using this variable to disable paging, or using the `tidb_min_paging_size` and `tidb_max_paging_size` variables to adjust the range of rows for paging size.

14.5.1.182 tidb_enable_parallel_apply New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable concurrency for the `Apply` operator. The number of concurrencies is controlled by the `tidb_executor_concurrency` variable. The `Apply` operator processes correlated subqueries and has no concurrency by default, so the execution speed is slow. Setting this variable value to `1` can increase concurrency and speed up execution. Currently, concurrency for `Apply` is disabled by default.

14.5.1.183 tidb_enable_parallel_hashagg_spill New in v8.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether TiDB supports disk spill for the parallel HashAgg algorithm. When it is `ON`, the HashAgg operator can automatically trigger data spill based on memory usage under any parallel conditions, thus balancing performance and data throughput. It is not recommended to set this variable to `OFF`. Starting from v8.2.0, setting it to `OFF` will report an error. This variable will be deprecated in a future release.

14.5.1.184 tidb_enable_pipelined_window_function

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable specifies whether to use the pipeline execution algorithm for window functions.

14.5.1.185 tidb_enable_plan_cache_for_param_limit New in v6.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether Prepared Plan Cache caches execution plans with a variable as the `LIMIT` parameter (`LIMIT ?`). The default value is `ON`, which means Prepared Plan Cache supports caching such execution plans. Note that Prepared Plan Cache does not support caching execution plans with a variable that is greater than 10000.

14.5.1.186 tidb_enable_plan_cache_for_subquery New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether Prepared Plan Cache caches queries that contain subqueries.

14.5.1.187 tidb_enable_plan_replayer_capture

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to enable the `PLAN REPLAYER CAPTURE` feature. The default value `ON` means to enable the `PLAN REPLAYER CAPTURE` feature.

14.5.1.188 tidb_enable_plan_replayer_continuous_capture New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the `PLAN REPLAYER CONTINUOUS CAPTURE` feature. The default value `OFF` means to disable the feature.

14.5.1.189 tidb_enable_prepared_plan_cache New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- Determines whether to enable Prepared Plan Cache. When it is enabled, the execution plans of `Prepare` and `Execute` are cached so that the subsequent executions skip optimizing the execution plans, which brings performance improvement.
- This setting was previously a `tidb.toml` option (`prepared-plan-cache.enabled`), but changed to a system variable starting from TiDB v6.1.0.

14.5.1.190 tidb_enable_prepared_plan_cache_memory_monitor New in v6.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- This variable controls whether to count the memory consumed by the execution plans cached in the Prepared Plan Cache. For details, see Memory management of Prepared Plan Cache.

14.5.1.191 tidb_enable_pseudo_for_outdated_stats New in v5.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable controls the behavior of the optimizer on using statistics of a table when the statistics are outdated.

- The optimizer determines whether the statistics of a table is outdated in this way: since the last time `ANALYZE` is executed on a table to get the statistics, if 80% of the table rows are modified (the modified row count divided by the total row count), the optimizer determines that the statistics of this table is outdated. You can change this ratio using the `pseudo-estimate-ratio` configuration.

- By default (with the variable value `OFF`), when the statistics of a table is outdated, the optimizer still keeps using the statistics of the table. If you set the variable value to `ON`, the optimizer determines that the statistics of the table is no longer reliable except for the total row count. Then, the optimizer uses the pseudo statistics.
- If the data on a table is frequently modified without executing `ANALYZE` on this table in time, to keep the execution plan stable, it is recommended to set the variable value to `OFF`.

14.5.1.192 tidb_enable_rate_limit_action

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the dynamic memory control feature for the operator that reads data. By default, this operator enables the maximum number of threads that `tidb_distsql_scan_concurrency` allows to read data. When the memory usage of a single SQL statement exceeds `tidb_mem_quota_query` each time, the operator that reads data stops one thread.

- When the operator that reads data has only one thread left and the memory usage of a single SQL statement constantly exceeds `tidb_mem_quota_query`, this SQL statement triggers other memory control behaviors, such as spilling data to disk.
- This variable controls memory usage effectively when an SQL statement only reads data. If computing operations (such as join or aggregation operations) are required, memory usage might not be under the control of `tidb_mem_quota_query`, which increases the risk of OOM.

14.5.1.193 tidb_enable_resource_control New in v6.6.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- Type: Boolean
- This variable is a switch for the resource control feature. When this variable is set to `ON`, the TiDB cluster can isolate application resources based on resource groups.

14.5.1.194 tidb_enable_reuse_chunk New in v6.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- Value options: `OFF`, `ON`
- This variable controls whether TiDB enables chunk objects cache. If the value is `ON`, TiDB prefers to use the cached chunk object and only requests from the system if the requested object is not in the cache. If the value is `OFF`, TiDB requests chunk objects from the system directly.

14.5.1.195 tidb_enable_shared_lock_promotion New in v8.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the feature of upgrading shared locks to exclusive locks. TiDB does not support `SELECT LOCK IN SHARE MODE` by default. When the variable value is `ON`, TiDB tries to upgrade the `SELECT LOCK IN SHARE MODE` statement to `SELECT FOR UPDATE` and add a pessimistic lock. The default value of this variable is `OFF`, which means that the feature of upgrading shared locks to exclusive locks is disabled.
- Enabling this variable takes effect on the `SELECT LOCK IN SHARE MODE` statement, regardless of whether `tidb_enable_noop_functions` is enabled or not.

14.5.1.196 tidb_enable_slow_log

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the slow log feature.

14.5.1.197 tidb_enable_tmp_storage_on_oom

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- Value options: `OFF`, `ON`
- Controls whether to enable the temporary storage for some operators when a single SQL statement exceeds the memory quota specified by the system variable `tidb_mem_quota_query`.
- Before v6.3.0, you can enable or disable this feature by using the TiDB configuration item `oom-use-tmp-storage`. After upgrading the cluster to v6.3.0 or a later version, the TiDB cluster will initialize this variable using the value of `oom-use-tmp-storage` automatically. After that, changing the value of `oom-use-tmp-storage` **does not** take effect anymore.

14.5.1.198 tidb_enable_stats_owner New in v8.4.0

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Default value: `ON`
- Possible values: `OFF`, `ON`
- This variable controls whether the corresponding TiDB instance can run automatic statistics update tasks. If there is only one TiDB instance in the current TiDB cluster, you cannot disable automatic statistics update on this instance, which means you cannot set this variable to `OFF`.

14.5.1.199 tidb_enable_stmt_summary New in v3.0.4

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the statement summary feature. If enabled, SQL execution information like time consumption is recorded to the `information_schema.STATEMENTS_SUMMARY` system table to identify and troubleshoot SQL performance issues.

14.5.1.200 tidb_enable_strict_double_type_check New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control if tables can be created with invalid definitions of type `DOUBLE`. This setting is intended to provide an upgrade path from earlier versions of TiDB, which were less strict in validating types.
- The default value of `ON` is compatible with MySQL.

For example, the type `DOUBLE(10)` is now considered invalid because the precision of floating point types is not guaranteed. After changing `tidb_enable_strict_double_type_check` to `OFF`, the table is created:

```
mysql> CREATE TABLE t1 (id int, c double(10));
ERROR 1149 (42000): You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your MySQL server version for the right syntax to
    ↪  use

mysql> SET tidb_enable_strict_double_type_check = 'OFF';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id int, c double(10));
Query OK, 0 rows affected (0.09 sec)
```

> **Note:**
>
> This setting only applies to the type `DOUBLE` since MySQL permits precision for `FLOAT` types. This behavior is deprecated starting with MySQL 8.0.17, and it is not recommended to specify precision for either `FLOAT` or `DOUBLE` types.

14.5.1.201 tidb_enable_table_partition

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `ON`
- This variable is deprecated since v8.4.0. Its value will be fixed to the default value `ON`, that is, table partitioning is enabled by default.

14.5.1.202 tidb_enable_telemetry New in v4.0.2 and deprecated in v8.1.0

> **Warning:**
>
> Starting from v8.1.0, the telemetry feature in TiDB is removed, and this variable is no longer functional. It is retained solely for compatibility with earlier versions.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- Before v8.1.0, this variable controls whether to enable the telemetry collection in TiDB.

14.5.1.203 tidb_enable_tiflash_read_for_write_stmt New in v6.3.0

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes

- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether read operations in SQL statements containing `INSERT`, `DELETE`, and `UPDATE` can be pushed down to TiFlash. For example:
  - `SELECT` queries in `INSERT INTO SELECT` statements (typical usage scenario: TiFlash query result materialization)
  - `WHERE` condition filtering in `UPDATE` and `DELETE` statements
- Starting from v7.1.0, this variable is deprecated. When `tidb_allow_mpp = ON`, the optimizer intelligently decides whether to push a query down to TiFlash based on the SQL mode and the cost estimates of the TiFlash replica. Note that TiDB allows read operations in SQL statements containing `INSERT`, `DELETE`, and `UPDATE` (such as `INSERT INTO SELECT`) to be pushed down to TiFlash only when the SQL Mode of the current session is not strict, which means that the `sql_mode` value does not contain `STRICT_TRANS_TABLES` and `STRICT_ALL_TABLES`.

14.5.1.204 tidb_enable_top_sql New in v5.4.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable the Top SQL feature.

14.5.1.205 tidb_enable_tso_follower_proxy New in v5.3.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the TSO Follower Proxy feature. When the value is `OFF`, TiDB only gets TSO from the PD leader. When the value is `ON`, TiDB evenly distributes requests for TSO to all PD servers, and PD followers can also handle TSO requests, thereby reducing the CPU pressure on the PD leader.
- Scenarios for enabling TSO Follower Proxy:
    - Due to the high pressure of TSO requests, the CPU of the PD leader reaches a bottleneck, which causes high latency of TSO RPC requests.
    - The TiDB cluster has many TiDB instances, and increasing the value of `tidb_tso_client_batch_max_wait_time` cannot alleviate the high latency issue of TSO RPC requests.

> **Note:**
>
> - Suppose that the TSO RPC latency increases for reasons other than a CPU usage bottleneck of the PD leader (such as network issues). In this case, enabling the TSO Follower Proxy might increase the execution latency in TiDB and affect the QPS performance of the cluster.
> - This feature is incompatble with `tidb_tso_client_rpc_mode`. If this feature is enabled, `tidb_tso_client_rpc_mode` does not take effect.

14.5.1.206 tidb_enable_unsafe_substitute New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to replace expressions with generated columns in an unsafe way. The default value is `OFF`, which means that unsafe replacement is disabled by default. For more details, see Generated Columns.

14.5.1.207 tidb_enable_vectorized_expression New in v4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable vectorized execution.

14.5.1.208 tidb_enable_window_function

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the support for window functions. Note that window functions might use reserved keywords. This might cause SQL statements that can be executed normally to fail to be parsed after TiDB is upgraded. In this case, you can set `tidb_enable_window_function` to `OFF`.

14.5.1.209 `tidb_enable_row_level_checksum` New in v7.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- This variable is used to control whether to enable the TiCDC data integrity validation for single-row data feature.

- You can use the `TIDB_ROW_CHECKSUM()` function to get the checksum value of a row.

14.5.1.210 tidb_enforce_mpp New in v5.1

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`

- To change this default value, modify the `performance.enforce-mpp` configuration value.

- Controls whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution. The value options are as follows:

- `0` or `OFF`, which means that the MPP mode is not forcibly used (by default).
- `1` or `ON`, which means that the cost estimation is ignored and the MPP mode is forcibly used. Note that this setting only takes effect when `tidb_allow_mpp=true`.

MPP is a distributed computing framework provided by the TiFlash engine, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. For details about the selection of the MPP mode, refer to Control whether to select the MPP mode.

14.5.1.211 tidb_evolve_plan_baselines New in v4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to enable the baseline evolution feature. For detailed introduction or usage , see Baseline Evolution.
- To reduce the impact of baseline evolution on the cluster, use the following configurations:
  - Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is 600s.
  - Set `tidb_evolve_plan_task_start_time` and `tidb_evolve_plan_task_end_time` to limit the time window. The default values are respectively `00:00 +0000` and `23:59 +0000`.

14.5.1.212 tidb_evolve_plan_task_end_time New in v4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Time
- Default value: `23:59 +0000`
- This variable is used to set the end time of baseline evolution in a day.

14.5.1.213 tidb_evolve_plan_task_max_time New in v4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer

- Default value: `600`
- Range: `[-1, 9223372036854775807]`
- Unit: Seconds
- This variable is used to limit the maximum execution time of each execution plan in the baseline evolution feature.

14.5.1.214 tidb_evolve_plan_task_start_time New in v4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Time
- Default value: `00:00 +0000`
- This variable is used to set the start time of baseline evolution in a day.

14.5.1.215 tidb_executor_concurrency New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `5`
- Range: `[1, 256]`
- Unit: Threads

This variable is used to set the concurrency of the following SQL operators (to one value):

- `index lookup`
- `index lookup join`
- `hash join`
- `hash aggregation` (the `partial` and `final` phases)
- `window`
- `projection`
- `sort`

`tidb_executor_concurrency` incorporates the following existing system variables as a whole for easier management:

- `tidb_index_lookup_concurrency`
- `tidb_index_lookup_join_concurrency`
- `tidb_hash_join_concurrency`
- `tidb_hashagg_partial_concurrency`
- `tidb_hashagg_final_concurrency`

- `tidb_projection_concurrency`
- `tidb_window_concurrency`

Since v5.0, you can still separately modify the system variables listed above (with a deprecation warning returned) and your modification only affects the corresponding single operators. After that, if you use `tidb_executor_concurrency` to modify the operator concurrency, the separately modified operators will not be affected. If you want to use `tidb_executor_concurrency` to modify the concurrency of all operators, you can set the values of all variables listed above to `-1`.

For a system upgraded to v5.0 from an earlier version, if you have not modified any value of the variables listed above (which means that the `tidb_hash_join_concurrency` value is `5` and the values of the rest are `4`), the operator concurrency previously managed by these variables will automatically be managed by `tidb_executor_concurrency`. If you have modified any of these variables, the concurrency of the corresponding operators will still be controlled by the modified variables.

14.5.1.216 tidb_expensive_query_time_threshold

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `60`
- Range: `[10, 2147483647]`
- Unit: Seconds
- This variable is used to set the threshold value that determines whether to print expensive query logs. The difference between expensive query logs and slow query logs is:
    - Slow logs are printed after the statement is executed.
    - Expensive query logs print the statements that are being executed, with execution time exceeding the threshold value, and their related information.

14.5.1.217 tidb_expensive_txn_time_threshold New in v7.2.0

- Scope: GLOBAL

- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `600`
- Range: `[60, 2147483647]`
- Unit: Seconds
- This variable controls the threshold for logging expensive transactions, which is 600 seconds by default. When the duration of a transaction exceeds the threshold, and the transaction is neither committed nor rolled back, it is considered an expensive transaction and will be logged.

14.5.1.218 tidb_force_priority

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `NO_PRIORITY`
- Possible values: `NO_PRIORITY`, `LOW_PRIORITY`, `HIGH_PRIORITY`, `DELAYED`
- This variable is used to change the default priority for statements executed on a TiDB server. A use case is to ensure that a particular user that is performing OLAP queries receives lower priority than users performing OLTP queries.
- The default value `NO_PRIORITY` means that the priority for statements is not forced to change.

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.5.1.219 tidb_gc_concurrency New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `-1` or `[1, 256]`
- Unit: Threads
- This variable controls the number of concurrent threads during the Resolve Locks step of the Garbage Collection (GC) process.
- Starting from v8.3.0, this variable also controls the number of concurrent threads during the Delete Ranges step of the GC process.
- By default, this variable is `-1`, allowing TiDB to automatically determine the appropriate number of threads based on workloads.
- When this variable is set to a number in the range of `[1, 256]`:
    - Resolve Locks directly uses the value set for this variable as the number of threads.
    - Delete Range uses one-fourth of the value set for this variable as the number of threads.

14.5.1.220 tidb_gc_enable New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- Enables garbage collection for TiKV. Disabling garbage collection will reduce system performance, as old versions of rows will no longer be purged.

14.5.1.221 tidb_gc_life_time New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Duration
- Default value: `10m0s`
- Range: `[10m0s, 8760h0m0s]`
- The time limit during which data is retained for each GC, in the format of Go Duration. When a GC happens, the current time minus this value is the safe point.

> **Note:**
>
> - In scenarios of frequent updates, a large value (days or even months) for `tidb_gc_life_time` may cause potential issues, such as:
>   - Larger storage use
>   - A large amount of history data may affect performance to a certain degree, especially for range queries such as `select count(*)from t`
> - If there is any transaction that has been running longer than `tidb_gc_life_time`, during GC, the data since `start_ts` is retained for this transaction to continue execution. For example, if `tidb_gc_life_time` is configured to 10 minutes, among all transactions being executed, the transaction that starts earliest has been running for 15 minutes, GC will retain data of the recent 15 minutes.

14.5.1.222 tidb_gc_max_wait_time New in v6.1.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `86400`
- Range: `[600, 31536000]`
- Unit: Seconds
- This variable is used to set the maximum time that active transactions block the GC safe point. During each time of GC, the safe point does not exceed the start time of the ongoing transactions by default. If the runtime of active transactions does not exceed this variable value, the GC safe point will be blocked until the runtime exceeds this value.

14.5.1.223 tidb_gc_run_interval New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Duration
- Default value: `10m0s`
- Range: `[10m0s, 8760h0m0s]`
- Specifies the GC interval, in the format of Go Duration, for example, `"1h30m"`, and `"15m"`

14.5.1.224 tidb_gc_scan_lock_mode New in v5.0

> **Warning:**
>
> Currently, Green GC is an experimental feature. It is not recommended that you use it in production environments.

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `LEGACY`
- Possible values: `PHYSICAL`, `LEGACY`
    - `LEGACY`: Uses the old way of scanning, that is, disable Green GC.
    - `PHYSICAL`: Uses the physical scanning method, that is, enable Green GC.

- This variable specifies the way of scanning locks in the Resolve Locks step of GC. When the variable value is set to `LEGACY`, TiDB scans locks by Regions. When the value `PHYSICAL` is used, it enables each TiKV node to bypass the Raft layer and directly scan data, which can effectively mitigate the impact of GC wakening up all Regions when the Hibernate Region feature is enabled, thus improving the execution speed in the Resolve Locks step.

14.5.1.225 tidb_general_log

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- This variable is used to set whether to record all SQL statements in the log. This feature is disabled by default. If maintenance personnel needs to trace all SQL statements when locating issues, they can enable this feature.

- To see all records of this feature in the log, you need to set the TiDB configuration item `log.level` to `"info"` or `"debug"` and then query the `"GENERAL_LOG"` string. The following information is recorded:

    - `conn`: The ID of the current session.
    - `user`: The current session user.
    - `schemaVersion`: The current schema version.
    - `txnStartTS`: The timestamp at which the current transaction starts.

- `forUpdateTS`: In the pessimistic transactional mode, `forUpdateTS` is the current timestamp of the SQL statement. When a write conflict occurs in the pessimistic transaction, TiDB retries the SQL statement currently being executed and updates this timestamp. You can configure the number of retries via `max-retry-count`. In the optimistic transactional model, `forUpdateTS` is equivalent to `txnStartTS`.
- `isReadConsistency`: Indicates whether the current transactional isolation level is Read Committed (RC).
- `current_db`: The name of the current database.
- `txn_mode`: The transactional mode. Value options are `OPTIMISTIC` and `PESSIMISTIC`.
- `sql`: The SQL statement corresponding to the current query.

14.5.1.226 tidb_non_prepared_plan_cache_size

> **Warning:**
>
> Starting from v7.1.0, this variable is deprecated. Instead, use `tidb_session_plan_cache_size` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `100`
- Range: `[1, 100000]`
- This variable controls the maximum number of execution plans that can be cached by Non-prepared plan cache.

14.5.1.227 tidb_pre_split_regions New in v8.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 15]`
- This variable is used to set the default number of row split shards for newly created tables. When this variable is set to a non-zero value, TiDB will automatically apply this attribute to tables that allow the use of `PRE_SPLIT_REGIONS` (for example,

`NONCLUSTERED` tables) when executing `CREATE TABLE` statements. For more information, see `PRE_SPLIT_REGIONS`. This variable is typically used in conjunction with `tidb_shard_row_id_bits` to shard new tables and pre-split the Regions of new tables.

14.5.1.228 tidb_generate_binary_plan New in v6.2.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to generate binary-encoded execution plans in slow logs and statement summaries.
- When this variable is set to `ON`, you can view visual execution plans in TiDB Dashboard. Note that TiDB Dashboard only provides visual display for execution plans generated after this variable is enabled.
- You can execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific plan from a binary plan.

14.5.1.229 tidb_gogc_tuner_max_value New in v7.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `500`
- Range: `[10, 2147483647]`
- The variable is used to control the maximum value of GOGC that the GOGC Tuner can adjust.

14.5.1.230 tidb_gogc_tuner_min_value New in v7.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No

- Type: Integer
- Default value: `100`
- Range: `[10, 2147483647]`
- The variable is used to control the minimum value of GOGC that the GOGC Tuner can adjust.

14.5.1.231 tidb_gogc_tuner_threshold New in v6.4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `0.6`
- Range: `[0, 0.9)`
- This variable specifies the maximum memory threshold for tuning GOGC. When the memory exceeds this threshold, GOGC Tuner stops working.

14.5.1.232 tidb_guarantee_linearizability New in v5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls the way commit TS is calculated for async commit. By default (with the `ON` value), the two-phase commit requests a new TS from the PD server and uses the TS to calculate the final commit TS. In this situation, linearizability is guaranteed for all the concurrent transactions.
- If you set this variable to `OFF`, the process of fetching TS from the PD server is skipped, with the cost that only causal consistency is guaranteed but not linearizability. For more details, see the blog post Async Commit, the Accelerator for Transaction Commit in TiDB 5.0.

- For scenarios that require only causal consistency, you can set this variable to `OFF` to improve performance.

14.5.1.233 tidb_hash_exchange_with_new_collation

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether the MPP hash partition exchange operator is generated in a cluster with new collation enabled. `true` means to generate the operator, and `false` means not to generate it.
- This variable is used for the internal operation of TiDB. It is **NOT recommended** to set this variable.

14.5.1.234 tidb_hash_join_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of the `hash join` algorithm.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.235 tidb_hash_join_version New in v8.4.0

> **Warning:**

> The feature controlled by this variable is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration
- Default value: `legacy`
- Possible values: `legacy`, `optimized`
- This variable is used to control whether TiDB uses an optimized version of hash join. The value is `legacy` by default, which means the optimized version is not used. If it is set to `optimized`, TiDB uses the optimized version to execute hash join for better performance.

> **Note:**
>
> - Currently, the optimized hash join only supports inner join and outer join, so for other joins, even if `tidb_hash_join_version` is set to `optimized`, TiDB still uses the legacy hash join.
> - Currently, the optimized hash join does not support spilling to disk when the memory is out of quota.

14.5.1.236 tidb_hashagg_final_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer

- Default value: `-1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of executing the concurrent `hash aggregation` algorithm in the `final` phase.
- When the parameter of the aggregate function is not distinct, `HashAgg` is run concurrently and respectively in two phases - the `partial` phase and the `final` phase.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.237 tidb_hashagg_partial_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of executing the concurrent `hash aggregation` algorithm in the `partial` phase.
- When the parameter of the aggregate function is not distinct, `HashAgg` is run concurrently and respectively in two phases - the `partial` phase and the `final` phase.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.238 tidb_historical_stats_duration New in v6.6.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Duration
- Default value: `168h`, which means 7 days
- This variable controls the duration that the historical statistics are retained in the storage.

14.5.1.239 tidb_idle_transaction_timeout New in v7.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 31536000]`
- Unit: Seconds
- This variable controls the idle timeout for transactions in a user session. When a user session is in a transactional state and remains idle for a duration exceeding the value of this variable, TiDB will terminate the session. An idle user session means that there are no active requests and the session is waiting for new requests.
- The default value `0` means unlimited.

14.5.1.240 tidb_ignore_prepared_cache_close_stmt New in v6.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether to ignore the commands for closing prepared statement cache.
- When this variable is set to `ON`, the `COM_STMT_CLOSE` command of the Binary protocol and the `DEALLOCATE PREPARE` statement of the text protocol are ignored. For details, see Ignore the `COM_STMT_CLOSE` command and the `DEALLOCATE PREPARE` statement.

14.5.1.241 tidb_ignore_inlist_plan_digest New in v7.6.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable controls whether TiDB ignores the element differences in the `IN` list across different queries when generating Plan Digests.
    - When it is the default value `OFF`, TiDB does not ignore the element differences (including the difference in the number of elements) in the `IN` list when generating Plan Digests. The element differences in the `IN` list result in different Plan Digests.

- When it is set to `ON`, TiDB ignores the element differences (including the difference in the number of elements) in the `IN` list and uses `...` to replace elements in the `IN` list in Plan Digests. In this case, TiDB generates the same Plan Digests for `IN` queries of the same type.

14.5.1.242 tidb_index_join_batch_size

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `25000`
- Range: `[1, 2147483647]`
- Unit: Rows
- This variable is used to set the batch size of the `index lookup join` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.

14.5.1.243 tidb_index_join_double_read_penalty_cost_rate New in v6.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Default value: `0`
- Range: `[0, 18446744073709551615]`
- This variable determines whether to apply a penalty cost to the selection of index join, which reduces the likelihood of the optimizer selecting index join, and increases the likelihood of selecting alternative join methods such as hash join and tiflash join.
- When index join is selected, many table lookup requests are triggered, which consumes too many resources. You can use this variable to reduce the likelihood of the optimizer selecting index join.
- This variable takes effect only when the `tidb_cost_model_version` variable is set to `2`.

14.5.1.244 tidb_index_lookup_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of the `index lookup` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.245 tidb_index_lookup_join_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of the `index lookup join` algorithm.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.246 tidb_index_merge_intersection_concurrency New in v6.5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `-1`
- Range: `[1, 256]`
- This variable sets the maximum concurrency for the intersection operations that index merge performs. It is effective only when TiDB accesses partitioned tables in the dynamic pruning mode. The actual concurrency is the smaller value of `tidb_index_merge_intersection_concurrency` and the number of partitions of the partitioned table.

- The default value `-1` means that the value of `tidb_executor_concurrency` is used.

14.5.1.247 tidb_index_lookup_size

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `20000`
- Range: `[1, 2147483647]`
- Unit: Rows
- This variable is used to set the batch size of the `index lookup` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.

14.5.1.248 tidb_index_serial_scan_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of the `serial scan` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.

14.5.1.249 tidb_init_chunk_size

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `32`
- Range: `[1, 32]`
- Unit: Rows
- This variable is used to set the number of rows for the initial chunk during the execution process. The number of rows for a chunk directly affects the amount of memory required for a single query. You can roughly estimate the memory needed for a single chunk by considering the total width of all columns in the query and the number of rows for the chunk. Combining this with the concurrency of the executor, you can make a rough estimation of the total memory required for a single query. It is recommended that the total memory for a single chunk does not exceed 16 MiB.

14.5.1.250 tidb_instance_plan_cache_reserved_percentage New in v8.4.0

> **Warning:**
>
> Currently, Instance Plan Cache is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0.1`
- Range: `[0, 1]`
- This variable controls the percentage of idle memory reserved for Instance Plan Cache after memory eviction. When the memory used by Instance Plan Cache reaches the limit set by `tidb_instance_plan_cache_max_size`, TiDB starts evicting execution plans from memory using the Least Recently Used (LRU) algorithm until the idle memory percentage exceeds the value set by `tidb_instance_plan_cache_reserved_percentage`.

14.5.1.251 tidb_instance_plan_cache_max_size New in v8.4.0

> **Warning:**
>
> Currently, Instance Plan Cache is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `125829120` (which is 120 MiB)
- Unit: Bytes
- This variable sets the maximum memory usage for Instance Plan Cache.

14.5.1.252 tidb_isolation_read_engines New in v4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Default value: `tikv,tiflash,tidb`
- This variable is used to set the storage engine list that TiDB can use when reading data.

14.5.1.253 tidb_last_ddl_info New in v6.0.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: ""
- Type: String
- This is a read-only variable. It is internally used in TiDB to get the information of the last DDL operation within the current session.
    - "query": The last DDL query string.
    - "seq_num": The sequence number for each DDL operation. It is used to identify the order of DDL operations.

14.5.1.254 tidb_last_query_info New in v4.0.14

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: ""
- This is a read-only variable. It is internally used in TiDB to query the transaction information of the last DML statement. The information includes:
    - `txn_scope`: The scope of the transaction, which can be `global` or `local`.
    - `start_ts`: The start timestamp of the transaction.
    - `for_update_ts`: The `for_update_ts` of the previously executed DML statement. This is an internal term of TiDB used for tests. Usually, you can ignore this information.
    - `error`: The error message, if any.
    - `ru_consumption`: Consumed RU for executing the statement.

14.5.1.255 tidb_last_txn_info New in v4.0.9

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: String
- This variable is used to get the last transaction information within the current session. It is a read-only variable. The transaction information includes:
  - The transaction scope.
  - The start and commit TS.
  - The transaction commit mode, which might be a two-phase, one-phase, or async commit.
  - The information of transaction fallback from async commit or one-phase commit to two-phase commit.
  - The error encountered.

14.5.1.256 tidb_last_plan_replayer_token New in v6.3.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: String
- This variable is read-only and is used to obtain the result of the last `PLAN REPLAYER DUMP` execution in the current session.

14.5.1.257 tidb_load_based_replica_read_threshold New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `"1s"`
- Range: `[0s, 1h]`
- Type: String
- This variable is used to set the threshold for triggering load-based replica read. When the estimated queue time of the leader node exceeds the threshold, TiDB prioritizes reading data from the follower node. The format is a time duration, such as `"100ms"` or `"1s"`. For more details, see Troubleshoot Hotspot Issues.

14.5.1.258 tidb_load_binding_timeout New in v8.0.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer

- Default value: `200`
- Range: `(0, 2147483647]`
- Unit: Milliseconds
- This variable is used to control the timeout of loading bindings. If the execution time of loading bindings exceeds this value, the loading will stop.

14.5.1.259 `tidb_lock_unchanged_keys` New in v7.1.1 and v7.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to lock specific keys in the following scenarios. When the value is set to `ON`, these keys are locked. When the value is set to `OFF`, these keys are not locked.
    - Duplicate keys in `INSERT IGNORE` and `REPLACE` statements. Before v6.1.6, these keys were not locked. This issue has been fixed in #42121.
    - Unique keys in `UPDATE` statements when the values of the keys are not changed. Before v6.5.2, these keys were not locked. This issue has been fixed in #36438.
- To maintain the consistency and rationality of the transaction, it is not recommended to change this value. If upgrading TiDB causes severe performance issues due to these two fixes, and the behavior without locks is acceptable (see the preceding issues), you can set this variable to `OFF`.

14.5.1.260 tidb_log_file_max_days New in v5.3.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`

- This variable is used to set the maximum days that the log is retained on the current TiDB instance. Its value defaults to the value of the `max-days` configuration in the configuration file. Changing the variable value only affects the current TiDB instance. After TiDB is restarted, the variable value is reset and the configuration value is not affected.

14.5.1.261 tidb_low_resolution_tso

- Scope: SESSION | GLOBAL
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether to enable the low-precision TSO feature. After this feature is enabled, TiDB uses the cached timestamp to read data. The cached timestamp is updated every 2 seconds by default. Starting from v8.0.0, you can configure the update interval by `tidb_low_resolution_tso_update_interval`.
- The main applicable scenario is to reduce the overhead of acquiring TSO for small read-only transactions when reading old data is acceptable.
- Starting from v8.3.0, this variable supports the GLOBAL scope.

14.5.1.262 `tidb_low_resolution_tso_update_interval` New in v8.0.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `2000`
- Range: `[10, 60000]`
- Unit: Milliseconds
- This variable is used to set the update interval of the cached timestamp used in the low-precision TSO feature, in milliseconds.
- This variable is only available when `tidb_low_resolution_tso` is enabled.

14.5.1.263 tidb_max_auto_analyze_time New in v6.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `43200`
- Range: `[0, 2147483647]`
- Unit: Seconds

- This variable is used to specify the maximum execution time of automatic `ANALYZE` tasks. When the execution time of an automatic `ANALYZE` task exceeds the specified time, the task will be terminated. When the value of this variable is `0`, there is no limit to the maximum execution time of automatic `ANALYZE` tasks.

14.5.1.264 tidb_max_bytes_before_tiflash_external_group_by New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `-1`
- Range: `[-1, 9223372036854775807]`
- This variable is used to specify the maximum memory usage of the Hash Aggregation operator with `GROUP BY` in TiFlash, in bytes. When the memory usage exceeds the specified value, TiFlash triggers the Hash Aggregation operator to spill to disk. When the value of this variable is `-1`, TiDB does not pass this variable to TiFlash. Only when the value of this variable is greater than or equal to `0`, TiDB passes this variable to TiFlash. When the value of this variable is `0`, it means that the memory usage is unlimited, that is, TiFlash Hash Aggregation operator will not trigger spilling. For details, see TiFlash Spill to Disk.

> **Note:**
>
> - If a TiDB cluster has multiple TiFlash nodes, aggregation is usually distributedly executed on multiple TiFlash nodes. This variable controls the maximum memory usage of the aggregation operator on a single TiFlash node.
> - When this variable is set to `-1`, TiFlash determines the maximum memory usage of the aggregation operator based on the value of its own configuration item `max_bytes_before_external_group_by`.

14.5.1.265 tidb_max_bytes_before_tiflash_external_join New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `-1`

- Range: `[-1, 9223372036854775807]`
- This variable is used to specify the maximum memory usage of the Hash Join operator with `JOIN` in TiFlash, in bytes. When the memory usage exceeds the specified value, TiFlash triggers the Hash Join operator to spill to disk. When the value of this variable is `-1`, TiDB does not pass this variable to TiFlash. Only when the value of this variable is greater than or equal to `0`, TiDB passes this variable to TiFlash. When the value of this variable is `0`, it means that the memory usage is unlimited, that is, TiFlash Hash Join operator will not trigger spilling. For details, see TiFlash Spill to Disk.

Note:

- If a TiDB cluster has multiple TiFlash nodes, join is usually distributedly executed on multiple TiFlash nodes. This variable controls the maximum memory usage of the join operator on a single TiFlash node.
- When this variable is set to `-1`, TiFlash determines the maximum memory usage of the join operator based on the value of its own configuration item `max_bytes_before_external_join`.

14.5.1.266 tidb_max_bytes_before_tiflash_external_sort New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `-1`
- Range: `[-1, 9223372036854775807]`
- This variable is used to specify the maximum memory usage of the TopN and Sort operators in TiFlash, in bytes. When the memory usage exceeds the specified value, TiFlash triggers the TopN and Sort operators to spill to disk. When the value of this variable is `-1`, TiDB does not pass this variable to TiFlash. Only when the value of this variable is greater than or equal to `0`, TiDB passes this variable to TiFlash. When the value of this variable is `0`, it means that the memory usage is unlimited, that is, TiFlash TopN and Sort operators will not trigger spilling. For details, see TiFlash Spill to Disk.

Note:

- If a TiDB cluster has multiple TiFlash nodes, TopN and Sort are usually distributedly executed on multiple TiFlash nodes. This variable controls

the maximum memory usage of the TopN and Sort operators on a single TiFlash node.
- When this variable is set to `-1`, TiFlash determines the maximum memory usage of the TopN and Sort operators based on the value of its own configuration item `max_bytes_before_external_sort`.

14.5.1.267 tidb_max_chunk_size

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1024`
- Range: `[32, 2147483647]`
- Unit: Rows
- This variable is used to set the maximum number of rows in a chunk during the execution process. Setting to too large of a value may cause cache locality issues. The recommended value for this variable is no larger than 65536. The number of rows for a chunk directly affects the amount of memory required for a single query. You can roughly estimate the memory needed for a single chunk by considering the total width of all columns in the query and the number of rows for the chunk. Combining this with the concurrency of the executor, you can make a rough estimation of the total memory required for a single query. It is recommended that the total memory for a single chunk does not exceed 16 MiB. When the query involves a large amount of data and a single chunk is insufficient to handle all the data, TiDB processes it multiple times, doubling the chunk size with each processing iteration, starting from `tidb_init_chunk_size` until the chunk size reaches the value of `tidb_max_chunk_size`.

14.5.1.268 tidb_max_delta_schema_count New in v2.1.18 and v3.0.5

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1024`
- Range: `[100, 16384]`
- This variable is used to set the maximum number of schema versions (the table IDs modified for corresponding versions) allowed to be cached. The value range is 100 ~ 16384.

14.5.1.269 tidb_max_paging_size New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `50000`
- Range: `[1, 9223372036854775807]`
- Unit: Rows
- This variable is used to set the maximum number of rows during the coprocessor paging request process. Setting it to too small a value increases the RPC count between TiDB and TiKV, while setting it to too large a value results in excessive memory usage in some cases, such as loading data and full table scan. The default value of this variable brings better performance in OLTP scenarios than in OLAP scenarios. If the application only uses TiKV as the storage engine, consider increasing the value of this variable when executing OLAP workload queries, which might bring you better performance.

14.5.1.270 tidb_max_tiflash_threads New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[-1, 256]`
- Unit: Threads
- This variable is used to set the maximum concurrency for TiFlash to execute a request. The default value is `-1`, indicating that this system variable is invalid and the maximum concurrency depends on the setting of the TiFlash configuration `profiles.default.max_threads`. When the value is `0`, the maximum number of threads is automatically configured by TiFlash.

14.5.1.271 tidb_mem_oom_action New in v6.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `CANCEL`
- Possible values: `CANCEL`, `LOG`

- Specifies what operation TiDB performs when a single SQL statement exceeds the memory quota specified by `tidb_mem_quota_query` and cannot be spilled over to disk. See TiDB Memory Control for details.

- The default value is `CANCEL`, but in TiDB v4.0.2 and earlier versions, the default value is `LOG`.
- This setting was previously a `tidb.toml` option (`oom-action`), but changed to a system variable starting from TiDB v6.1.0.

14.5.1.272 tidb_mem_quota_analyze New in v6.1.0

> **Warning:**
>
> Currently, the `ANALYZE` memory quota is an experimental feature, and the memory statistics might be inaccurate in production environments.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[-1, 9223372036854775807]`
- Unit: Bytes
- This variable controls the maximum memory usage of TiDB updating statistics. Such a memory usage occurs when you manually execute `ANALYZE TABLE` and when TiDB automatically analyzes tasks in the background. When the total memory usage exceeds this threshold, user-executed `ANALYZE` will exit, and an error message is reported that reminds you to try a lower sampling rate or retry later. If the automatic task in the TiDB background exits because the memory threshold is exceeded, and the sampling rate used is higher than the default value, TiDB will retry the update using the default sampling rate. When this variable value is negative or zero, TiDB does not limit the memory usage of both the manual and automatic update tasks.

> **Note:**
>
> `auto_analyze` will be triggered in a TiDB cluster only when `run-auto-analyze` is enabled in the TiDB startup configuration file.

14.5.1.273 tidb_mem_quota_apply_cache New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `33554432` (32 MiB)
- Range: `[0, 9223372036854775807]`
- Unit: Bytes
- This variable is used to set the memory usage threshold of the local cache in the `Apply` operator.
- The local cache in the `Apply` operator is used to speed up the computation of the `Apply` operator. You can set the variable to `0` to disable the `Apply` cache feature.

14.5.1.274 tidb_mem_quota_binding_cache New in v6.0.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `67108864`
- Range: `[0, 2147483647]`
- Unit: Bytes
- This variable is used to set the threshold of the memory used for caching bindings.
- If a system creates or captures excessive bindings, resulting in overuse of memory space, TiDB returns a warning in the log. In this case, the cache cannot hold all available bindings or determine which bindings to store. For this reason, some queries might miss their bindings. To address this problem, you can increase the value of this variable, which increases the memory used for caching bindings. After modifying this parameter, you need to run `admin reload bindings` to reload bindings and validate the modification.

14.5.1.275 tidb_mem_quota_query

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1073741824` (1 GiB)
- Range: `[-1, 9223372036854775807]`
- Unit: Bytes

- For versions earlier than TiDB v6.1.0, this is a session scope variable and uses the value of `mem-quota-query` from `tidb.toml` as an initial value. Starting from v6.1.0, `tidb_mem_quota_query` is a `SESSION | GLOBAL` scope variable.
- For versions earlier than TiDB v6.5.0, this variable is used to set the threshold value of memory quota for **a query**. If the memory quota of a query during execution exceeds the threshold value, TiDB performs the operation defined by `tidb_mem_oom_action`.

- For TiDB v6.5.0 and later versions, this variable is used to set the threshold value of memory quota for **a session**. If the memory quota of a session during execution exceeds the threshold value, TiDB performs the operation defined by `tidb_mem_oom_action`. Note that starting from TiDB v6.5.0, the memory usage of a session contains the memory consumed by the transactions in the session. For the control behavior of transaction memory usage in TiDB v6.5.0 and later versions, see `txn-total-size-limit`.
- When you set the variable value to `0` or `-1`, the memory threshold is positive infinity. When you set a value smaller than 128, the value will be defaulted to `128`.

14.5.1.276 tidb_memory_debug_mode_alarm_ratio

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0`
- This variable represents the memory statistics error value allowed in the TiDB memory debug mode.
- This variable is used for the internal testing of TiDB. It is **NOT recommended** to set this variable.

14.5.1.277 tidb_memory_debug_mode_min_heap_inuse

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- This variable is used for the internal testing of TiDB. It is **NOT recommended** to set this variable. Enabling this variable will affect the performance of TiDB.
- After configuring this parameter, TiDB will enter the memory debug mode to analyze the accuracy of memory tracking. TiDB will frequently trigger GC during the execution of subsequent SQL statements, and compare the actual memory usage and memory statistics. If the current memory usage is greater than `tidb_memory_debug_mode_min_heap_inuse` and the memory statistics error exceeds `tidb_memory_debug_mode_alarm_ratio`, TiDB will output the relevant memory information to the log and file.

14.5.1.278 tidb_memory_usage_alarm_ratio

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0.7`
- Range: `[0.0, 1.0]`

- This variable sets the memory usage ratio that triggers the tidb-server memory alarm. By default, TiDB prints an alarm log when TiDB memory usage exceeds 70% of its total memory and any of the alarm conditions is met.
- When this variable is configured to `0` or `1`, it means the memory threshold alarm feature is disabled.
- When this variable is configured to a value greater than `0` and less than `1`, it means that the memory threshold alarm feature is enabled.
    - If the value of the system variable `tidb_server_memory_limit` is `0`, the memory alarm threshold is `tidb_memory-usage-alarm-ratio * system memory size`.
    - If the value of the system variable `tidb_server_memory_limit` is set to greater than 0, the memory alarm threshold is `tidb_memory-usage-alarm-ratio * tidb_server_memory_limit`.

14.5.1.279 tidb_memory_usage_alarm_keep_record_num New in v6.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `5`
- Range: `[1, 10000]`
- When the tidb-server memory usage exceeds the memory alarm threshold and triggers an alarm, TiDB only retains the status files generated during the recent 5 alarms by default. You can adjust this number with this variable.

14.5.1.280 tidb_merge_join_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Range: `[1, 256]`
- Default value: `1`
- This variable sets the concurrency of the `MergeJoin` operator when a query is executed.
- It is **NOT recommended** to set this variable. Modifying the value of this variable might cause data correctness issues.

14.5.1.281 tidb_merge_partition_stats_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `1`
- This variable specifies the concurrency of merging statistics for a partitioned table when TiDB analyzes the partitioned table.

14.5.1.282 tidb_enable_async_merge_global_stats New in v7.5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`. When you upgrade TiDB from a version earlier than v7.5.0 to v7.5.0 or a later version, the default value is `OFF`.
- This variable is used for TiDB to merge global statistics asynchronously to avoid OOM issues.

14.5.1.283 tidb_metric_query_range_duration New in v4.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `60`
- Range: `[10, 216000]`
- Unit: Seconds
- This variable is used to set the range duration of the Prometheus statement generated when querying `METRICS_SCHEMA`.

14.5.1.284 tidb_metric_query_step New in v4.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `60`
- Range: `[10, 216000]`
- Unit: Seconds
- This variable is used to set the step of the Prometheus statement generated when querying `METRICS_SCHEMA`.

14.5.1.285 tidb_min_paging_size New in v6.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `128`
- Range: `[1, 9223372036854775807]`
- Unit: Rows
- This variable is used to set the minimum number of rows during the coprocessor paging request process. Setting it to a too small value increases the RPC request count between TiDB and TiKV, while setting it to a too large value might cause a performance decrease when executing queries using IndexLookup with Limit. The default value of this variable brings better performance in OLTP scenarios than in OLAP scenarios. If the application only uses TiKV as the storage engine, consider increasing the value of this variable when executing OLAP workload queries, which might bring you better performance.

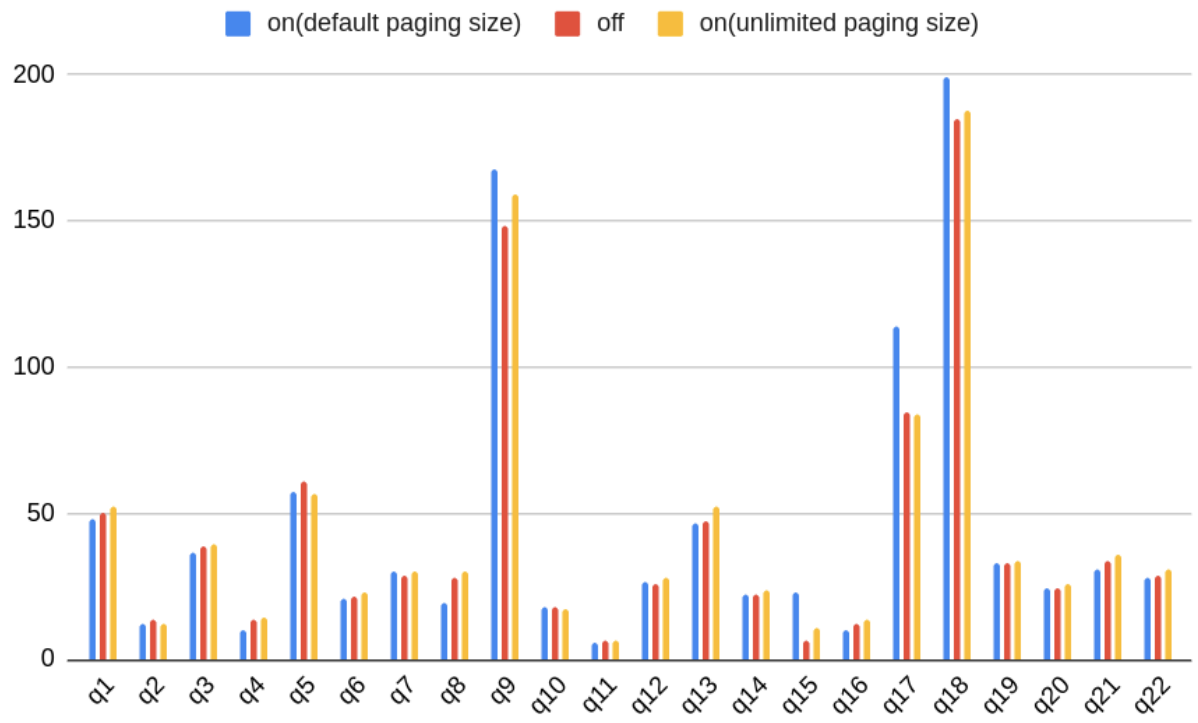

Figure 557: Paging size impact on TPCH

As shown in this diagram, when `tidb_enable_paging` is enabled, the performance of TPCH is affected by the settings of `tidb_min_paging_size` and `tidb_max_paging_size`. The vertical axis is the execution time, and it is the smaller the better.

14.5.1.286 tidb_mpp_store_fail_ttl

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Duration
- Default value: `60s`
- The newly started TiFlash node does not provide services. To prevent queries from failing, TiDB limits the tidb-server sending queries to the newly started TiFlash node. This variable indicates the time range in which the newly started TiFlash node is not sent requests.

14.5.1.287 tidb_multi_statement_mode New in v4.0.11

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `OFF`
- Possible values: `OFF`, `ON`, `WARN`
- This variable controls whether to allow multiple queries to be executed in the same `COM_QUERY` call.
- To reduce the impact of SQL injection attacks, TiDB now prevents multiple queries from being executed in the same `COM_QUERY` call by default. This variable is intended to be used as part of an upgrade path from earlier versions of TiDB. The following behaviors apply:

Client setting	`tidb_multi_statement_mode` value	Multiple statements permitted?
Multiple Statements = ON	OFF	Yes
Multiple Statements = ON	ON	Yes
Multiple Statements = ON	WARN	Yes
Multiple Statements = OFF	OFF	No
Multiple Statements = OFF	ON	Yes
Multiple Statements = OFF	WARN	Yes (+warning returned)

Note:

Only the default value of `OFF` can be considered safe. Setting `tidb_multi_statement_mode=ON` might be required if your application was specifically designed for an earlier version of TiDB. If your application requires multiple statement support, it is recommended to use the setting provided by your client library instead of the `tidb_multi_statement_mode` option. For example:

- go-sql-driver (`multiStatements`)
- Connector/J (`allowMultiQueries`)
- PHP mysqli (`mysqli_multi_query`)

14.5.1.288 tidb_nontransactional_ignore_error New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- This variable specifies whether to return an error immediately when the error occurs in a non-transactional DML statement.
- When the value is set to `OFF`, the non-transactional DML statement stops immediately at the first error and returns the error. All the following batches are canceled.
- When the value is set to `ON` and an error occurs in a batch, the following batches will continue to be executed until all batches are executed. All errors occurred during the execution process are returned together in the result.

14.5.1.289 tidb_opt_agg_push_down

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether the optimizer executes the optimization operation of pushing down the aggregate function to the position before Join, Projection, and UnionAll.
- When the aggregate operation is slow in query, you can set the variable value to ON.

14.5.1.290 tidb_opt_broadcast_cartesian_join

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `1`
- Range: `[0, 2]`
- Indicates whether to allow the Broadcast Cartesian Join.
- `0` means that the Broadcast Cartesian Join is not allowed. `1` means that it is allowed based on `tidb_broadcast_join_threshold_count`. `2` means that it is always allowed even if the table size exceeds the threshold.
- This variable is internally used in TiDB, and it is **NOT** recommended to modify its value.

14.5.1.291 tidb_opt_concurrency_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 18446744073709551615]`
- Default value: `3.0`
- Indicates the CPU cost of starting a Golang goroutine in TiDB. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.292 tidb_opt_copcpu_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 18446744073709551615]`
- Default value: `3.0`
- Indicates the CPU cost for TiKV Coprocessor to process one row. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.293 tidb_opt_correlation_exp_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `1`
- Range: `[0, 2147483647]`
- When the method that estimates the number of rows based on column order correlation is not available, the heuristic estimation method is used. This variable is used to control the behavior of the heuristic method.
  - When the value is 0, the heuristic method is not used.
  - When the value is greater than 0:
    - A larger value indicates that an index scan will probably be used in the heuristic method.
    - A smaller value indicates that a table scan will probably be used in the heuristic method.

14.5.1.294 tidb_opt_correlation_threshold

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Default value: `0.9`
- Range: `[0, 1]`
- This variable is used to set the threshold value that determines whether to enable estimating the row count by using column order correlation. If the order correlation between the current column and the `handle` column exceeds the threshold value, this method is enabled.

14.5.1.295 tidb_opt_cpu_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 2147483647]`
- Default value: `3.0`
- Indicates the CPU cost for TiDB to process one row. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.296 `tidb_opt_derive_topn` New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- Controls whether to enable the optimization rule of Deriving TopN or Limit from window functions.

14.5.1.297 tidb_opt_desc_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 18446744073709551615]`
- Default value: `3.0`
- Indicates the cost for TiKV to scan one row from the disk in descending order. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.298 tidb_opt_disk_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 18446744073709551615]`
- Default value: `1.5`
- Indicates the I/O cost for TiDB to read or write one byte of data from or to the temporary disk. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.299 tidb_opt_distinct_agg_push_down

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether the optimizer executes the optimization operation of pushing down the aggregate function with `distinct` (such as `select count(distinct a)from t`) to Coprocessor.
- When the aggregate function with the `distinct` operation is slow in the query, you can set the variable value to `1`.

In the following example, before `tidb_opt_distinct_agg_push_down` is enabled, TiDB needs to read all data from TiKV and execute `distinct` on the TiDB side. After `tidb_opt_distinct_agg_push_down` is enabled, `distinct a` is pushed down to Coprocessor, and a `group by` column `test.t.a` is added to `HashAgg_5`.

```
mysql> desc select count(distinct a) from test.t;
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪                     |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| StreamAgg_6           | 1.00    | root    |               | funcs:count(

```

14.5.1.300 tidb_opt_enable_correlation_adjustment

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether the optimizer estimates the number of rows based on column order correlation

14.5.1.301 tidb_opt_enable_hash_join New in v6.5.6, v7.1.2, and v7.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether the optimizer selects hash joins for tables. The value is `ON` by default. If it is set to `OFF`, the optimizer avoids selecting hash joins when generating execution plans, unless no other join algorithm is available.
- If both the system variable `tidb_opt_enable_hash_join` and the `HASH_JOIN` hint are configured, the `HASH_JOIN` hint takes precedence. Even if `tidb_opt_enable_hash_join` is set to `OFF`, when you specify a `HASH_JOIN` hint in a query, the TiDB optimizer still enforces a hash join plan.

14.5.1.302 tidb_opt_enable_non_eval_scalar_subquery New in v7.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether the `EXPLAIN` statement disables the execution of constant subqueries that can be expanded at the optimization stage. When this variable is set to `OFF`, the `EXPLAIN` statement expands the subquery in advance at the optimization stage. When this variable is set to `ON`, the `EXPLAIN` statement does not expand the subquery at the optimization stage. For more information, see Disable subquery expansion.

14.5.1.303 tidb_opt_enable_late_materialization New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the TiFlash late materialization feature. Note that TiFlash late materialization does not take effect in the fast scan mode.
- When this variable is set to `OFF` to disable the TiFlash late materialization feature, to process a `SELECT` statement with filter conditions (`WHERE` clause), TiFlash scans all the data of the required columns before filtering. When this variable is set to `ON` to enable the TiFlash late materialization feature, TiFlash can first scan the column data related to the filter conditions that are pushed down to the TableScan operator, filter the rows that meet the conditions, and then scan the data of other columns of these rows for further calculations, thereby reducing IO scans and computations of data processing.

14.5.1.304 tidb_opt_enable_mpp_shared_cte_execution New in v7.2.0

> **Warning:**
>
> The feature controlled by this variable is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable controls whether the non-recursive Common Table Expressions (CTE) can be executed on TiFlash MPP. By default, when this variable is disabled, CTE is executed on TiDB, which has a large performance gap compared with enabling this feature.

14.5.1.305 tidb_opt_enable_fuzzy_binding New in v7.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable controls whether to enable the Cross-database binding feature.

14.5.1.306 tidb_opt_fix_control New in v6.5.3 and v7.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: String
- Default value: `""`
- This variable is used to control some internal behaviors of the optimizer.
- The optimizer's behavior might vary depending on user scenarios or SQL statements. This variable provides a more fine-grained control over the optimizer and helps to prevent performance regression after upgrading caused by behavior changes in the optimizer.
- For a more detailed introduction, see Optimizer Fix Controls.

14.5.1.307 tidb_opt_force_inline_cte New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether common table expressions (CTEs) in the entire session are inlined or not. The default value is `OFF`, which means that inlining CTE is not enforced by default. However, you can still inline CTE by specifying the `MERGE()` hint. If the variable is set to `ON`, all CTEs (except recursive CTE) in this session are forced to be inlined.

14.5.1.308 tidb_opt_advanced_join_hint New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether the Join Method hint, such as `HASH_JOIN()` hint and `MERGE_JOIN()` hint, affects the Join Reorder optimization process, including the use of `LEADING()` hint. The default value is `ON`, which means that it does not affect. If it is set to `OFF`, there might be conflicts in some scenarios where both Join Method hint and `LEADING()` hint are used at the same time.

> **Note:**
>
> The behavior of versions earlier than v7.0.0 is consistent with that of setting this variable to `OFF`. To ensure forward compatibility, when you upgrade from an earlier version to a v7.0.0 or later cluster, this variable is set to `OFF`. To obtain more flexible hint behavior, it is strongly recommended to switch this variable to `ON` under the condition that there is no performance regression.

14.5.1.309 tidb_opt_insubq_to_join_and_agg

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable is used to set whether to enable the optimization rule that converts a subquery to join and aggregation.
- For example, after you enable this optimization rule, the subquery is converted as follows:

```
select * from t where t.a in (select aa from t1);
```

The subquery is converted to join as follows:

```
select t.* from t, (select aa from t1 group by aa) tmp_t where t.a =
    ↪ tmp_t.aa;
```

If `t1` is limited to be `unique` and `not null` in the `aa` column. You can use the following statement, without aggregation.

```
select t.* from t, t1 where t.a=t1.aa;
```

14.5.1.310 tidb_opt_join_reorder_threshold

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- This variable is used to control the selection of the TiDB Join Reorder algorithm. When the number of nodes participating in Join Reorder is greater than this threshold, TiDB selects the greedy algorithm, and when it is less than this threshold, TiDB selects the dynamic programming algorithm.
- Currently, for OLTP queries, it is recommended to keep the default value. For OLAP queries, it is recommended to set the variable value to 10~15 to get better connection orders in OLAP scenarios.

14.5.1.311 tidb_opt_limit_push_down_threshold

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `100`
- Range: `[0, 2147483647]`
- This variable is used to set the threshold that determines whether to push the Limit or TopN operator down to TiKV.
- If the value of the Limit or TopN operator is smaller than or equal to this threshold, these operators are forcibly pushed down to TiKV. This variable resolves the issue that the Limit or TopN operator cannot be pushed down to TiKV partly due to wrong estimation.

14.5.1.312 tidb_opt_memory_factor

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 2147483647]`
- Default value: `0.001`
- Indicates the memory cost for TiDB to store one row. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.313 tidb_opt_mpp_outer_join_fixed_build_side New in v5.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- When the variable value is `ON`, the left join operator always uses inner table as the build side and the right join operator always uses outer table as the build side. If you set the value to `OFF`, the outer join operator can use either side of the tables as the build side.

14.5.1.314 tidb_opt_network_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 2147483647]`
- Default value: `1.0`
- Indicates the net cost of transferring 1 byte of data through the network. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.315 tidb_opt_objective New in v7.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration
- Default value: `moderate`
- Possible values: `moderate`, `determinate`
- This variable controls the objective of the optimizer. `moderate` maintains the default behavior in versions prior to TiDB v7.4.0, where the optimizer tries to use more information to generate better execution plans. `determinate` mode tends to be more conservative and makes the execution plan more stable.

- The real-time statistics are the total number of rows and the number of modified rows that are automatically updated based on DML statements. When this variable is set to `moderate` (default), TiDB generates the execution plan based on real-time statistics. When this variable is set to `determinate`, TiDB does not use real-time statistics for generating the execution plan, which will make execution plans more stable.
- For long-term stable OLTP workload, or if the user is affirmative on the existing execution plans, it is recommended to use the `determinate` mode to reduce the possibility of unexpected execution plan changes. Additionally, you can use the `LOCK STATS` to prevent the statistics from being modified and further stabilize the execution plan.

14.5.1.316 tidb_opt_ordering_index_selectivity_ratio New in v8.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Default value: `-1`
- Range: `[-1, 1]`
- This variable controls the estimated number of rows for an index that matches the SQL statement `ORDER BY` when there are `ORDER BY` and `LIMIT` clauses in a SQL statement, but does not cover some filter conditions.
- This addresses the same query patterns as the system variable tidb_opt_ordering_index_selectivity_
- It differs in implementation by applying a ratio or percentage of the possible range that the qualified rows will be found.
- A value of `-1` (default) or less than `0` disables this ratio. Any value between `0` and `1` applies a ratio of 0% to 100% (for example, `0.5` corresponds to `50%`).
- In the following examples, the table `t` has a total of 1,000,000 rows. The same query is used, but different values for `tidb_opt_ordering_index_selectivity_ratio` are used. The query in the example contains a `WHERE` clause predicate that qualifies a small percentage of rows (9,000 out of 1,000,000). There is an index that supports the `ORDER BY a` (index `ia`), but the filter on `b` is not included in this index. Depending on the actual data distribution, the rows matching the `WHERE` clause and `LIMIT 1` might be found as the first row accessed when scanning the non-filtering index, or at worst, after nearly all the rows have been processed.
- Each example uses an index hint to demonstrate the impact on estRows. The final plan selection depends on the availability and cost of other plans.

- The first example uses the default value `-1`, which uses the existing estimation formula. By default, a small percentage of rows are scanned for estimation before the qualified rows are found.

```
> SET SESSION tidb_opt_ordering_index_selectivity_ratio = -1;

> EXPLAIN SELECT * FROM t USE INDEX (ia) WHERE b <= 9000 ORDER BY a
    ↪ LIMIT 1;
+--
    ↪ ---------------------------------+---------+-----------+--------------------
    ↪
| id                                | estRows | task    | access object
    ↪      | operator info                |
+--
    ↪ ---------------------------------+---------+-----------+--------------------
    ↪
| Limit_12                          | 1.00    | root      |
    ↪                      | offset:0, count:1            |
|  ─Projection_22                   | 1.00    | root      |
    ↪                      | test.t.a, test.t.b, test.t.c |
|    ─IndexLookUp_21                | 1.00    | root      |
    ↪                      |                              |
|      ─IndexFullScan_18(Build)     | 109.20 | cop[tikv] | table:t, index:
    ↪ ia(a) | keep order:true          |
|      ─Selection_20(Probe)         | 1.00    | cop[tikv] |
    ↪                    | le(test.t.b, 9000)           |
|        ─TableRowIDScan_19         | 109.20 | cop[tikv] | table:t
    ↪           | keep order:false             |
+--
    ↪ ---------------------------------+---------+-----------+--------------------
    ↪
```

- The second example uses `0`, which assumes that 0% of rows will be scanned before the qualified rows are found.

```
> SET SESSION tidb_opt_ordering_index_selectivity_ratio = 0;

> EXPLAIN SELECT * FROM t USE INDEX (ia) WHERE b <= 9000 ORDER BY a
    ↪ LIMIT 1;
+--
    ↪ ---------------------------------+---------+-----------+--------------------
    ↪
| id                                | estRows | task    | access object
    ↪      | operator info                |
+--
    ↪ ---------------------------------+---------+-----------+--------------------
```

```
    ↪
| Limit_12                      | 1.00   | root     |
    ↪                     | offset:0, count:1           |
|  └─Projection_22              | 1.00   | root     |
    ↪                     | test.t.a, test.t.b, test.t.c |
|    └─IndexLookUp_21           | 1.00   | root     |
    ↪                     |                             |
|      ├─IndexFullScan_18(Build)  | 1.00   | cop[tikv] | table:t, index:

    ↪                     | le(test.t.b, 9000)          |
|        └─TableRowIDScan_19      | 1.00   | cop[tikv] | table:t
    ↪           | keep order:false            |
+--
    ↪ ---------------------------------+---------+----------+--------------------
    ↪
```

- The third example uses `0.1`, which assumes that 10% of rows will be scanned before the qualified rows are found. This condition is highly selective, with only 1% of rows meeting the condition. Therefore, in the worst-case scenario, it might be necessary to scan 99% of rows before finding the 1% that qualify. 10% of that 99% is approximately 9.9%, which is reflected in the estRows.

```
> SET SESSION tidb_opt_ordering_index_selectivity_ratio = 0.1;

> EXPLAIN SELECT * FROM t USE INDEX (ia) WHERE b <= 9000 ORDER BY a
    ↪ LIMIT 1;
+--

    ↪      | operator info               |
+--
    ↪ -------------------------------+----------+----------+-----------------
    ↪
| Limit_12                      | 1.00     | root     |
    ↪                     | offset:0, count:1           |
|  └─Projection_22              | 1.00     | root     |
    ↪                     | test.t.a, test.t.b, test.t.c |
|    └─IndexLookUp_21           | 1.00     | root     |
    ↪                     |                             |
|      ├─IndexFullScan_18(Build)  | 990843.14 | cop[tikv] | table:t,
    ↪ index:ia(a) | keep order:true       |
|      └─Selection_20(Probe)      | 1.00     | cop[tikv] |
    ↪                   | le(test.t.b, 9000)          |
|        └─TableRowIDScan_19      | 990843.14 | cop[tikv] | table:t
    ↪         | keep order:false            |
+--
    ↪ -------------------------------+----------+----------+-----------------
    ↪
```

- The fifth example also uses `1.0`, but adds a predicate on `a`, limiting the scan range in the worst-case scenario. This is because `WHERE a <= 9000` matches the index, with approximately 9,000 rows would qualify. Given that the filter predicate on `b` is not in the index, all the approximately 9,000 rows are considered to be scanned before finding a row that matches `b <= 9000`.

```
> SET SESSION tidb_opt_ordering_index_selectivity_ratio = 1;
```

```
> EXPLAIN SELECT * FROM t USE INDEX (ia) WHERE a <= 9000 AND b <= 9000
    ↪  ORDER BY a LIMIT 1;

14.5.1.317 tidb_opt_ordering_index_selectivity_threshold New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Default value: `0`
- Range: `[0, 1]`
- This variable is used to control how the optimizer selects an index when there are `ORDER BY` and `LIMIT` clauses with filter conditions in a SQL statement.
- For such queries, the optimizer considers selecting the corresponding index to satisfy the `ORDER BY` and `LIMIT` clauses (even if this index does not satisfy any filter conditions). However, due to the complexity of data distribution, the optimizer might select a suboptimal index in this scenario.
- This variable represents a threshold. When an index exists that can satisfy filtering conditions and its selectivity estimate is lower than this threshold, the optimizer will avoid selecting an index used to satisfy `ORDER BY` and `LIMIT`. Instead, it prioritizes an index that satisfies the filtering conditions.

- For example, when the variable is set to `0`, the optimizer maintains its default behavior; when it is set to `1`, the optimizer always prioritizes selecting indexes that satisfy the filter conditions and avoids selecting indexes that satisfy both `ORDER BY` and `LIMIT` clauses.
- In the following example, table `t` has a total of 1,000,000 rows. When using an index on column `b`, its estimated row count is approximately 8,748, so its selectivity estimate value is about 0.0087. By default, the optimizer selects an index on column `a`. However, after setting this variable to 0.01, since the selectivity of an index on column `b` (0.0087) is less than 0.01, the optimizer selects an index on column `b`.

```
> EXPLAIN SELECT * FROM t WHERE b <= 9000 ORDER BY a LIMIT 1;

14.5.1.318 tidb_opt_prefer_range_scan New in v5.0

> **Note:**
>
> Starting from v8.4.0, the default value of this variable is changed from `OFF` to `ON`.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- When the value of this variable is `ON`, the optimizer prefers range scans over full table scans for tables without statistics (pseudo statistics) or empty tables (zero statistics).
- In the following example, before you enable `tidb_opt_prefer_range_scan`, the TiDB optimizer performs a full table scan. After you enable `tidb_opt_prefer_range_scan`, the optimizer selects an index range scan.

```
explain select * from t where age=5;
+--

14.5.1.319 tidb_opt_prefix_index_single_scan New in v6.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `ON`
- This variable controls whether the TiDB optimizer pushes down some filter conditions to the prefix index to avoid unnecessary table lookup and to improve query performance.
- When this variable value is set to `ON`, some filter conditions are pushed down to the prefix index. Suppose that the `col` column is the index prefix column in a table. The

`col is null` or `col is not null` condition in the query is handled as a filter condition on the index instead of a filter condition for the table lookup, so that unnecessary table lookup is avoided.

Usage example of tidb_opt_prefix_index_single_scan

Create a table with a prefix index:

```
CREATE TABLE t (a INT, b VARCHAR(10), c INT, INDEX idx_a_b(a, b(5)));
```

Disable `tidb_opt_prefix_index_single_scan`:

```
SET tidb_opt_prefix_index_single_scan = 'OFF';
```

For the following query, the execution plan uses the prefix index `idx_a_b` but requires a table lookup (the `IndexLookUp` operator appears).

```
EXPLAIN FORMAT='brief' SELECT COUNT(1) FROM t WHERE a = 1 AND b IS NOT NULL
    ↪ ;
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
| id                          | estRows | task    | access object             |
    ↪  operator info                                  |
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
| HashAgg                     | 1.00    | root      |                           |
    ↪  funcs:count(Column#8)->Column#5                |
|  ─IndexLookUp               | 1.00    | root      |
    ↪ |                                               |
|    ─IndexRangeScan(Build)   | 99.90   | cop[tikv] | table:t, index:idx_a_b(a
    ↪ , b) | range:[1 -inf,1 +inf], keep order:false, stats:pseudo |
|    ─HashAgg(Probe)          | 1.00    | cop[tikv] |
    ↪ | funcs:count(1)->Column#8                      |
|      ─Selection             | 99.90   | cop[tikv] |
    ↪ | not(isnull(test.t.b))                         |
|        ─TableRowIDScan      | 99.90   | cop[tikv] | table:t
    ↪ | keep order:false, stats:pseudo                |
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
6 rows in set (0.00 sec)
```

Enable `tidb_opt_prefix_index_single_scan`:

```
SET tidb_opt_prefix_index_single_scan = 'ON';
```

After enabling this variable, for the following query, the execution plan uses the prefix index `idx_a_b` but does not require a table lookup.

```
EXPLAIN FORMAT='brief' SELECT COUNT(1) FROM t WHERE a = 1 AND b IS NOT NULL
    ↪ ;
+--
    ↪ ----------------------+---------+-----------+---------------------------+--
    ↪
| id                    | estRows | task    | access object             |
    ↪ operator info                                 |

    ↪
4 rows in set (0.00 sec)
```

14.5.1.320 tidb_opt_projection_push_down New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`. Before v8.3.0, the default value is `OFF`.
- Specifies whether to allow the optimizer to push the `Projection` operator down to the TiKV coprocessor. When enabled, the optimizer might push the following three types of `Projection` operators down to TiKV:
    - The top-level expressions of the operator are all JSON query functions or JSON value attribute functions. For example: `SELECT JSON_EXTRACT(data, '$.name ↪ ')FROM users;`.
    - The top-level expressions of the operator include a mix of JSON query functions or JSON value attribute functions, and direct column reads. For example: `SELECT ↪  JSON_DEPTH(data), name FROM users;`.
    - The top-level expressions of the operator are all direct column reads, and the number of output columns is less than the number of input columns. For example:

`SELECT name FROM users;`.

- The final decision to push down a `Projection` operator also depends on the optimizer's comprehensive evaluation of query cost.
- For TiDB clusters that are upgraded from a version earlier than v8.3.0 to v8.3.0 or later, the default value of this variable is `OFF`.

14.5.1.321 tidb_opt_range_max_size New in v6.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `67108864` (64 MiB)
- Scope: `[0, 9223372036854775807]`
- Unit: Bytes
- This variable is used to set the upper limit of memory usage for the optimizer to build scan ranges. When the variable value is `0`, there is no memory limit for building scan ranges. If building exact scan ranges consumes memory that exceeds the limit, the optimizer uses more relaxed scan ranges (such as `[[NULL,+inf]]`). If the execution plan does not use exact scan ranges, you can increase the value of this variable to let the optimizer build exact scan ranges.

The usage example of this variable is as follows:

tidb_opt_range_max_size usage examples

View the default value of this variable. From the result, you can see that the optimizer uses up to 64 MiB of memory to build scan ranges.

```
SELECT @@tidb_opt_range_max_size;

```

```
EXPLAIN SELECT * FROM t use index (idx) WHERE a IN (10,20,30) AND b IN
    ↪ (40,50,60);
```

In the 64 MiB memory upper limit, the optimizer builds the following exact scan ranges `[10 40,10 40]`, `[10 50,10 50]`, `[10 60,10 60]`, `[20 40,20 40]`, `[20 50,20 50]`, ↪ `[20 60,20 60]`, `[30 40,30 40]`, `[30 50,30 50]`, `[30 60,30 60]`, as shown in the following execution plan result.

```
+--
   ↪ ----------------------------+---------+-----------+-----------------------+-
   ↪
| id                           | estRows | task    | access object         |
   ↪ operator info
   ↪
   ↪ |
+--
   ↪ ----------------------------+---------+-----------+-----------------------+-
   ↪
| IndexLookUp_7                | 0.90    | root      |                       |
   ↪
   ↪ |
|  ─IndexRangeScan_5(Build)  | 0.90    | cop[tikv] | table:t, index:idx(a, b)
   ↪  | range:[10 40,10 40], [10 50,10 50], [10 60,10 60], [20 40,20 40],
   ↪ [20 50,20 50], [20 60,20 60], [30 40,30 40], [30 50,30 50], [30 60,30
   ↪  60], keep order:false, stats:pseudo |
|  ─TableRowIDScan_6(Probe)  | 0.90    | cop[tikv] | table:t               |
   ↪ keep order:false, stats:pseudo
   ↪
   ↪ |
+--
   ↪ ----------------------------+---------+-----------+-----------------------+-
   ↪
3 rows in set (0.00 sec)
```

Now set the upper limit of memory usage for the optimizer to build scan ranges to 1500 bytes.

```
SET @@tidb_opt_range_max_size = 1500;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
EXPLAIN SELECT * FROM t USE INDEX (idx) WHERE a IN (10,20,30) AND b IN
   ↪ (40,50,60);
```

In the 1500-byte memory limit, the optimizer builds more relaxed scan ranges `[10,10]`, ↪ `[20,20]`, `[30,30]`, and uses a warning to inform the user that the memory usage required to build exact scan ranges exceeds the limit of `tidb_opt_range_max_size`.

```
+--
   ↪ ----------------------------+---------+-----------+-----------------------+-
   ↪
| id                           | estRows | task    | access object         |
   ↪ operator info                                                 |
```

```
+--
   ↪ ---------------------------+---------+----------+-------------------------+-
   ↪

   ↪                                                 |
|  ─Selection_7(Build)       | 0.09    | cop[tikv] |                        | in
   ↪ (test.t.b, 40, 50, 60)                         |
|    ─IndexRangeScan_5       | 30.00   | cop[tikv] | table:t, index:idx(a, b)
   ↪  | range:[10,10], [20,20], [30,30], keep order:false, stats:pseudo |
|  ─TableRowIDScan_6(Probe)  | 0.09    | cop[tikv] | table:t                 |
   ↪ keep order:false, stats:pseudo                  |
+--
   ↪ ---------------------------+---------+----------+-------------------------+-
   ↪
4 rows in set, 1 warning (0.00 sec)
```

```
SHOW WARNINGS;
```

```
+--
   ↪ -------+------+-----------------------------------------------------------
   ↪
| Level   | Code | Message
   ↪
   ↪ |
+--
   ↪ -------+------+-----------------------------------------------------------
   ↪
| Warning | 1105 | Memory capacity of 1500 bytes for 'tidb_opt_range_max_
   ↪ size' exceeded when building ranges. Less accurate ranges such as
   ↪ full range are chosen |
+--
   ↪ -------+------+-----------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

Then set the upper limit of memory usage to 100 bytes:

```
set @@tidb_opt_range_max_size = 100;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
EXPLAIN SELECT * FROM t USE INDEX (idx) WHERE a IN (10,20,30) AND b IN
   ↪ (40,50,60);
```

In the 100-byte memory limit, the optimizer chooses `IndexFullScan`, and uses a warning to inform the user that the memory required to build exact scan ranges exceeds the limit of `tidb_opt_range_max_size`.

```

14.5.1.322 tidb_opt_scan_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 2147483647]`
- Default value: `1.5`
- Indicates the cost for TiKV to scan one row of data from the disk in ascending order. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.323 tidb_opt_seek_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 2147483647]`
- Default value: `20`
- Indicates the start-up cost for TiDB to request data from TiKV. This variable is internally used in the Cost Model, and it is **NOT** recommended to modify its value.

14.5.1.324 tidb_opt_skew_distinct_agg New in v6.2.0

> **Note:**
>
> The query performance optimization by enabling this variable is effective **only for TiFlash**.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable sets whether the optimizer rewrites the aggregate functions with `DISTINCT` to the two-level aggregate functions, such as rewriting `SELECT b, COUNT(DISTINCT a)FROM t GROUP BY b` to `SELECT b, COUNT(a)FROM (SELECT b, a FROM t GROUP BY b, a)t GROUP BY b`. When the aggregation column has serious skew and the `DISTINCT` column has many different values, this rewriting can avoid the data skew in the query execution and improve the query performance.

14.5.1.325 tidb_opt_three_stage_distinct_agg New in v6.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `ON`
- This variable specifies whether to rewrite a `COUNT(DISTINCT)` aggregation into a three-stage aggregation in MPP mode.
- This variable currently applies to an aggregation that only contains one `COUNT(DISTINCT)`.

14.5.1.326 tidb_opt_tiflash_concurrency_factor

- Scope: SESSION | GLOBAL
- Persists to cluster: YES
- Applies to hint SET_VAR: Yes
- Type: Float
- Range: `[0, 2147483647]`
- Default value: `24.0`
- Indicates the concurrency number of TiFlash computation. This variable is internally used in the Cost Model, and it is NOT recommended to modify its value.

14.5.1.327 tidb_opt_use_invisible_indexes New in v8.0.0

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable controls whether the optimizer can select invisible indexes for query optimization in the current session. Invisible indexes are maintained by DML statements, but will not be used by the query optimizer. This is useful in scenarios where you want to double-check before removing an index permanently. When the variable is set to `ON`, the optimizer can select invisible indexes for query optimization in the session.

14.5.1.328 tidb_opt_write_row_id

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to allow `INSERT`, `REPLACE`, and `UPDATE` statements to operate on the `_tidb_rowid` column. This variable can be used only when you import data using TiDB tools.

14.5.1.329 tidb_optimizer_selectivity_level

- Scope: SESSION
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- This variable controls the iteration of the optimizer's estimation logic. After changing the value of this variable, the estimation logic of the optimizer will change greatly. Currently, `0` is the only valid value. It is not recommended to set it to other values.

14.5.1.330 tidb_partition_prune_mode New in v5.1

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration
- Default value: `dynamic`
- Possible values: `static`, `dynamic`, `static-only`, `dynamic-only`
- Specifies whether to use `dynamic` or `static` mode for partitioned tables. Note that dynamic partitioning is effective only after full table-level statistics, or GlobalStats, are collected. Before GlobalStats are collected, TiDB will use the `static` mode instead. For detailed information about GlobalStats, see Collect statistics of partitioned tables in dynamic pruning mode. For details about the dynamic pruning mode, see Dynamic Pruning Mode for Partitioned Tables.

14.5.1.331 tidb_persist_analyze_options New in v5.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to enable the ANALYZE configuration persistence feature.

14.5.1.332 tidb_pessimistic_txn_fair_locking New in v7.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- Determines whether to use enhanced pessimistic locking wake-up model for pessimistic transactions. This model strictly controls the wake-up order of pessimistic transactions in the pessimistic locking single-point conflict scenarios to avoid unnecessary wake-ups. It greatly reduces the uncertainty brought by the randomness of the existing wake-up mechanism. If you encounter frequent single-point pessimistic locking conflicts in your business scenario (such as frequent updates to the same row of data), and thus cause frequent statement retries, high tail latency, or even occasional `pessimistic lock retry limit reached` errors, you can try to enable this variable to solve the problem.
- This variable is disabled by default for TiDB clusters that are upgraded from versions earlier than v7.0.0 to v7.0.0 or later versions.

> **Note:**
>
> - Depending on the specific business scenario, enabling this option might cause a certain degree of throughput reduction (average latency increase) for transactions with frequent lock conflicts.
> - This option only takes effect on statements that need to lock a single key. If a statement needs to lock multiple rows at the same time, this option will not take effect on such statements.
> - This feature is introduced in v6.6.0 by the `tidb_pessimistic_txn_aggressive_locking` variable, which is disabled by default.

14.5.1.333 tidb_placement_mode New in v6.0.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `STRICT`
- Possible values: `STRICT`, `IGNORE`
- This variable controls whether DDL statements ignore the placement rules specified in SQL. When the variable value is `IGNORE`, all placement rule options are ignored.
- It is intended to be used by logical dump/restore tools to ensure that tables can always be created even if invalid placement rules are assigned. This is similar to how mysqldump writes `SET FOREIGN_KEY_CHECKS=0;` to the start of every dump file.

14.5.1.334 `tidb_plan_cache_invalidation_on_fresh_stats` New in v7.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to invalidate the plan cache automatically when statistics on related tables are updated.
- After enabling this variable, plan cache can make use of statistics more sufficiently to generate execution plans. For example:
    - If execution plans are generated before statistics are available, plan cache re-generates execution plans once the statistics are available.
    - If the data distribution of a table changes, causing the previously optimal execution plan to become non-optimal, plan cache re-generates execution plans after the statistics are re-collected.
- This variable is disabled by default for TiDB clusters that are upgraded from a version earlier than v7.1.0 to v7.1.0 or later.

14.5.1.335 `tidb_plan_cache_max_plan_size` New in v7.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `2097152` (which is 2 MiB)
- Range: `[0, 9223372036854775807]`, in bytes. The memory format with the units "KiB|MiB|GiB|TiB" is also supported. `0` means no limit.
- This variable controls the maximum size of a plan that can be cached in prepared or non-prepared plan cache. If the size of a plan exceeds this value, the plan will not be cached. For more details, see Memory management of prepared plan cache and Non-prepared plan cache.

14.5.1.336 tidb_pprof_sql_cpu New in v4.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 1]`
- This variable is used to control whether to mark the corresponding SQL statement in the profile output to identify and troubleshoot performance issues.

14.5.1.337 tidb_prefer_broadcast_join_by_exchange_data_size New in v7.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Default value: `OFF`
- This variable controls whether to use the algorithm with the minimum overhead of network transmission when TiDB selects the MPP Hash Join algorithm. If this variable is enabled, TiDB estimates the size of the data to be exchanged in the network using `Broadcast Hash Join` and `Shuffled Hash Join` respectively, and then chooses the one with the smaller size.
- `tidb_broadcast_join_threshold_count` and `tidb_broadcast_join_threshold_size` will not take effect after this variable is enabled.

14.5.1.338 tidb_prepared_plan_cache_memory_guard_ratio New in v6.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0.1`
- Range: `[0, 1]`
- The threshold at which the prepared plan cache triggers a memory protection mechanism. For details, see Memory management of Prepared Plan Cache.
- This setting was previously a `tidb.toml` option (`prepared-plan-cache.memory-guard-ratio`), but changed to a system variable starting from TiDB v6.1.0.

14.5.1.339 tidb_prepared_plan_cache_size New in v6.1.0

> **Warning:**
>
> Starting from v7.1.0, this variable is deprecated. Instead, use `tidb_session_plan_cache_size` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `100`
- Range: `[1, 100000]`
- The maximum number of plans that can be cached in a session. For details, see Memory management of Prepared Plan Cache.
- This setting was previously a `tidb.toml` option (`prepared-plan-cache.capacity`), but changed to a system variable starting from TiDB v6.1.0.

14.5.1.340 tidb_projection_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[-1, 256]`
- Unit: Threads
- This variable is used to set the concurrency of the `Projection` operator.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.341 tidb_query_log_max_len

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4096` (4 KiB)
- Range: `[0, 1073741824]`
- Unit: Bytes
- The maximum length of the SQL statement output. When the output length of a statement is larger than the `tidb_query_log_max_len` value, the statement is truncated to output.
- This setting was previously also available as a `tidb.toml` option (`log.query-log-max-len`), but is only a system variable starting from TiDB v6.1.0.

14.5.1.342 tidb_rc_read_check_ts New in v6.0.0

Warning:

- This feature is incompatible with `replica-read`. Do not enable `tidb_rc_read_check_ts` and `replica-read` at the same time.
- If your client uses a cursor, it is not recommended to enable `tidb_rc_read_check_ts` in case that the previous batch of returned data has already been used by the client and the statement eventually fails.
- Starting from v7.0.0, this variable is no longer valid for the cursor fetch read mode that uses the prepared statement protocol.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to optimize the timestamp acquisition, which is suitable for scenarios with read-committed isolation level where read-write conflicts are rare. Enabling this variable can avoid the latency and cost of getting the global timestamp, and can optimize the transaction-level read latency.
- If read-write conflicts are severe, enabling this feature will increase the cost and latency of getting the global timestamp, and might cause performance regression. For details, see Read Committed isolation level.

14.5.1.343 tidb_rc_write_check_ts New in v6.3.0

Warning:

This feature is currently incompatible with `replica-read`. After this variable is enabled, all requests sent by the client cannot use `replica-read`. Therefore, do not enable `tidb_rc_write_check_ts` and `replica-read` at the same time.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to optimize the acquisition of timestamps and is suitable for scenarios with few point-write conflicts in `READ-COMMITTED` isolation level of pessimistic transactions. Enabling this variable can avoid the latency and overhead brought by obtaining the global timestamps during the execution of point-write statements. Currently, this variable is applicable to three types of point-write statements: `UPDATE`, `DELETE`, and `SELECT ..... FOR UPDATE`. A point-write statement refers to a write statement that uses the primary key or unique key as a filter condition and the final execution operator contains `POINT-GET`.
- If the point-write conflicts are severe, enabling this variable will increase extra overhead and latency, resulting in performance regression. For details, see Read Committed isolation level.

14.5.1.344 tidb_read_consistency New in v5.4.0

- Scope: SESSION
- Applies to hint SET_VAR: Yes (Note that if non-transactional DML statements exist, modifying the value of this variable using hint might not take effect.)
- Type: String
- Default value: `strict`
- This variable is used to control the read consistency for an auto-commit read statement.
- If the variable value is set to `weak`, the locks encountered by the read statement are skipped directly and the read execution might be faster, which is the weak consistency read mode. However, the transaction semantics (such as atomicity) and distributed consistency (such as linearizability) are not guaranteed.
- For user scenarios where the auto-commit read needs to return fast and weak consistency read results are acceptable, you can use the weak consistency read mode.

14.5.1.345 tidb_read_staleness New in v5.4.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[-2147483648, 0]`
- This variable is used to set the time range of historical data that TiDB can read in the current session. After setting the value, TiDB selects a timestamp as new as possible from the range allowed by this variable, and all subsequent read operations are performed against this timestamp. For example, if the value of this variable is set to `-5`, on the condition that TiKV has the corresponding historical version's data, TiDB selects a timestamp as new as possible within a 5-second time range.

14.5.1.346 tidb_record_plan_in_slow_log

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to include the execution plan of slow queries in the slow log.

14.5.1.347 tidb_redact_log

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `OFF`

- Possible values: `OFF`, `ON`, `MARKER`
- This variable controls whether to hide the user information in the SQL statement being recorded into the TiDB log and slow log.
- The default value is `OFF`, which means that the user information is not processed in any way.
- When you set the variable to `ON`, the user information is hidden. For example, if the executed SQL statement is `INSERT INTO t VALUES (1,2)`, the statement is recorded as `INSERT INTO t VALUES (?,?)` in the log.
- When you set the variable to `MARKER`, the user information is wrapped in `‹ ›`. For example, if the executed SQL statement is `INSERT INTO t VALUES (1,2)`, the statement is recorded as `INSERT INTO t VALUES (‹1›,‹2›)` in the log. If user data contains `‹` or `›`, `‹` is escaped as `‹‹`, and `›` is escaped as `››`. Based on the marked logs, you can decide whether to desensitize the marked information when the logs are displayed.

14.5.1.348 tidb_regard_null_as_point New in v5.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether the optimizer can use a query condition including null equivalence as a prefix condition for index access.
- This variable is enabled by default. When it is enabled, the optimizer can reduce the volume of index data to be accessed, which accelerates query execution. For example, if a query involves multiple-column indexes `index(a, b)` and the query condition contains `a<=>null and b=1`, the optimizer can use both `a<=>null` and `b=1` in the query condition for index access. If the variable is disabled, because `a<=>null and b =1` includes the null equivalence condition, the optimizer does not use `b=1` for index access.

14.5.1.349 tidb_remove_orderby_in_subquery New in v6.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: Before v7.2.0, the default value is `OFF`. Starting from v7.2.0, the default value is `ON`.
- Specifies whether to remove `ORDER BY` clause in a subquery.
- In the ISO/IEC SQL standard, `ORDER BY` is mainly used to sort the results of top-level queries. For subqueries, the standard does not require that the results be sorted by `ORDER BY`.

- To sort subquery results, you can usually handle it in the outer query, such as using the window function or using `ORDER BY` again in the outer query. Doing so ensures the order of the final result set.

14.5.1.350 tidb_replica_read New in v4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration
- Default value: `leader`
- Possible values: `leader`, `follower`, `leader-and-follower`, `prefer-leader`, `closest-replicas`, `closest-adaptive`, and `learner`. The `learner` value is introduced in v6.6.0.
- This variable is used to control where TiDB reads data.
- For more details about usage and implementation, see Follower read.

14.5.1.351 tidb_restricted_read_only New in v5.2.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- `tidb_restricted_read_only` and `tidb_super_read_only` behave similarly. In most cases, you should use `tidb_super_read_only` only.
- Users with the `SUPER` or `SYSTEM_VARIABLES_ADMIN` privilege can modify this variable. However, if the Security Enhanced Mode is enabled, the additional `RESTRICTED_VARIABLES_ADMIN` privilege is required to read or modify this variable.
- `tidb_restricted_read_only` affects `tidb_super_read_only` in the following cases:
  - Setting `tidb_restricted_read_only` to `ON` will update `tidb_super_read_only` to `ON`.
  - Setting `tidb_restricted_read_only` to `OFF` leaves `tidb_super_read_only` unchanged.
  - If `tidb_restricted_read_only` is `ON`, `tidb_super_read_only` cannot be set to `OFF`.

- For DBaaS providers of TiDB, if a TiDB cluster is a downstream database of another database, to make the TiDB cluster read-only, you might need to use `tidb_restricted_read_only` with Security Enhanced Mode enabled, which prevents your customers from using `tidb_super_read_only` to make the cluster writable. To achieve this, you need to enable Security Enhanced Mode, use an admin user with the `SYSTEM_VARIABLES_ADMIN` and `RESTRICTED_VARIABLES_ADMIN` privileges to control `tidb_restricted_read_only`, and let your database users use the root user with the `SUPER` privilege to control `tidb_super_read_only` only.
- This variable controls the read-only status of the entire cluster. When the variable is `ON`, all TiDB servers in the entire cluster are in the read-only mode. In this case, TiDB only executes the statements that do not modify data, such as `SELECT`, `USE`, and `SHOW`. For other statements such as `INSERT` and `UPDATE`, TiDB rejects executing those statements in the read-only mode.
- Enabling the read-only mode using this variable only ensures that the entire cluster finally enters the read-only status. If you have changed the value of this variable in a TiDB cluster but the change has not yet propagated to other TiDB servers, the un-updated TiDB servers are still **not** in the read-only mode.
- TiDB checks the read-only flag before SQL statements are executed. Since v6.2.0, the flag is also checked before SQL statements are committed. This helps prevent the case where long-running auto commit statements might modify data after the server has been placed in read-only mode.
- When this variable is enabled, TiDB handles the uncommitted transactions in the following ways:
    - For uncommitted read-only transactions, you can commit the transactions normally.
    - For uncommitted transactions that are not read-only, SQL statements that perform write operations in these transactions are rejected.
    - For uncommitted read-only transactions with modified data, the commit of these transactions is rejected.
- After the read-only mode is enabled, all users (including the users with the `SUPER` privilege) cannot execute the SQL statements that might write data unless the user is explicitly granted the `RESTRICTED_REPLICA_WRITER_ADMIN` privilege.

14.5.1.352 tidb_request_source_type New in v7.4.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: String
- Default value: `""`
- Possible values: `"ddl"`, `"stats"`, `"br"`, `"lightning"`, `"background"`
- This variable is used to explicitly specify the task type for the current session, which is identified and controlled by Resource Control. For example: `SET @@tidb_request_source_type = "background"`.

14.5.1.353 tidb_resource_control_strict_mode New in v8.2.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether privilege control is applied to the `SET RESOURCE GROUP` statement and the `RESOURCE_GROUP()` optimizer hint. When this system variable is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege to change the bound resource group of the current session or current statement via these two ways. When it is set to `OFF`, none of these privileges are required, and the behavior is the same as earlier TiDB versions without this variable.
- When you upgrade your TiDB cluster from an earlier version to v8.2.0 or later, the default value of this variable is set to `OFF`, which means this feature is disabled by default.

14.5.1.354 tidb_retry_limit

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `10`
- Range: `[-1, 9223372036854775807]`
- This variable is used to set the maximum number of the retries for optimistic transactions. When a transaction encounters retryable errors (such as transaction conflicts, very slow transaction commit, or table schema changes), this transaction is re-executed according to this variable. Note that setting `tidb_retry_limit` to `0` disables the automatic retry. This variable only applies to optimistic transactions, not to pessimistic transactions.

14.5.1.355 tidb_row_format_version

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No

- Type: Integer
- Default value: `2`
- Range: `[1, 2]`
- Controls the format version of the newly saved data in the table. In TiDB v4.0, the new storage row format version `2` is used by default to save new data.
- If you upgrade from a TiDB version earlier than v4.0.0 to v4.0.0 or later versions, the format version is not changed, and TiDB continues to use the old format of version `1` to write data to the table, which means that **only newly created clusters use the new data format by default**.
- Note that modifying this variable does not affect the old data that has been saved, but applies the corresponding version format only to the newly written data after modifying this variable.

14.5.1.356 tidb_runtime_filter_mode New in v7.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration
- Default value: `OFF`
- Possible values: `OFF`, `LOCAL`
- Controls the mode of Runtime Filter, that is, the relationship between the **Filter Sender operator** and **Filter Receiver operator**. There are two modes: `OFF` and `LOCAL`. `OFF` means disabling Runtime Filter. `LOCAL` means enabling Runtime Filter in the local mode. For more information, see Runtime Filter mode.

14.5.1.357 tidb_runtime_filter_type New in v7.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration
- Default value: `IN`
- Possible values: `IN`
- Controls the type of predicate used by the generated Filter operator. Currently, only one type is supported: `IN`. For more information, see Runtime Filter type.

14.5.1.358 tidb_scatter_region

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `""`
- Possible values: `""`, `table`, `global`
- If the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` parameters are set during table creation, then the system automatically splits the table into a specified number of Regions upon successful creation. This variable controls the scattering strategy for these split Regions. TiDB processes the Regions based on the selected scattering strategy. It is important to note that because the table creation operation waits for the scattering process to complete before returning a success status, enabling this variable might significantly increase the execution time of the `CREATE TABLE` statement. Compared to the scenario where this variable is disabled, the execution time could be several times longer. Descriptions of possible values are as follows:
    - `""`: the default value, indicating that the Regions of the table are not scattered after table creation.
    - `table`: indicates that if you set the `PRE_SPLIT_REGIONS` or `SHARD_ROW_ID_BITS` ↪ attribute when you create a table, in the scenario of pre-splitting multiple Regions, the Regions of these tables are scattered according to the granularity of the tables. However, if you do not set the preceding attribute when you create a table, in the scenario of creating a large number of tables rapidly, it will cause the Regions of these tables to be concentrated on a few TiKV nodes, resulting in an uneven distribution of Regions.
    - `global`: indicates that TiDB scatters the Regions of newly created tables according to the data distribution of the entire cluster. Especially when creating a large number of tables rapidly, using the `global` option helps prevent Regions from becoming overly concentrated on a few TiKV nodes, ensuring a more balanced distribution of Regions across the cluster.

14.5.1.359 tidb_schema_cache_size New in v8.0.0

> **Warning:**
>
> The feature controlled by this variable is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `536870912` (512 MiB)
- Range: `0` or `[67108864, 9223372036854775807]`
- Before TiDB v8.4.0, the default value of this variable is `0`.
- Starting from TiDB v8.4.0, the default value is `536870912`. When you upgrade from an earlier version to v8.4.0 or later, the old value set in the earlier version is used.
- This variable controls the size of the schema cache in TiDB. The unit is byte. Setting this variable to `0` means the cache limit feature is disabled. To enable this feature, you need to set a value within the range `[67108864, 9223372036854775807]`. TiDB will use this value as the maximum available memory limit and apply the Least Recently Used (LRU) algorithm to cache the required tables, effectively reducing the memory used by schema information.

14.5.1.360 tidb_schema_version_cache_limit New in v7.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `16`
- Range: `[2, 255]`
- This variable limits how many historical schema versions can be cached in a TiDB instance. The default value is `16`, which means that TiDB caches 16 historical schema versions by default.
- Generally, you do not need to modify this variable. When the Stale Read feature is used and DDL operations are executed very frequently, it will cause the schema version to change very frequently. Consequently, when Stale Read tries to obtain schema information from a snapshot, it might take a lot of time to rebuild the information due to schema cache misses. In this case, you can increase the value of `tidb_schema_version_cache_limit` (for example, `32`) to avoid the problem of schema cache misses.
- Modifying this variable causes the memory usage of TiDB to increase slightly. Monitor the memory usage of TiDB to avoid OOM problems.

14.5.1.361 tidb_server_memory_limit New in v6.4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `80%`
- Range:
    - You can set the value in the percentage format, which means the percentage of the memory usage relative to the total memory. The value range is `[1%, 99%]`.
    - You can also set the value in memory size. The value range is `0` and `[536870912, 9223372036854775807]` in bytes. The memory format with the units "KiB|MiB|GiB|TiB" is supported. `0` means no memory limit.
    - If this variable is set to a memory size that is less than 512 MiB but not `0`, TiDB uses 512 MiB as the actual size.
- This variable specifies the memory limit for a TiDB instance. When the memory usage of TiDB reaches the limit, TiDB cancels the currently running SQL statement with the highest memory usage. After the SQL statement is successfully canceled, TiDB tries to call Golang GC to immediately reclaim memory to relieve memory stress as soon as possible.
- Only the SQL statements with more memory usage than the `tidb_server_memory_limit_sess_min_size` limit are selected as the SQL statements to be canceled first.
- Currently, TiDB cancels only one SQL statement at a time. After TiDB completely cancels a SQL statement and recovers resources, if the memory usage is still greater than the limit set by this variable, TiDB starts the next cancel operation.

14.5.1.362 tidb_server_memory_limit_gc_trigger New in v6.4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `70%`
- Range: `[50%, 99%]`
- The threshold at which TiDB tries to trigger GC. When the memory usage of TiDB reaches the value of `tidb_server_memory_limit` * the value of `tidb_server_memory_limit_gc_trigger`, TiDB will actively trigger a Golang GC operation. Only one GC operation will be triggered in one minute.

14.5.1.363 tidb_server_memory_limit_sess_min_size New in v6.4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `134217728` (which is 128 MiB)
- Range: `[128, 9223372036854775807]`, in bytes. The memory format with the units "KiB|MiB|GiB|TiB" is also supported.
- After you enable the memory limit, TiDB will terminate the SQL statement with the highest memory usage on the current instance. This variable specifies the minimum memory usage of the SQL statement to be terminated. If the memory usage of a TiDB instance that exceeds the limit is caused by too many sessions with low memory usage, you can properly lower the value of this variable to allow more sessions to be canceled.

14.5.1.364 tidb_service_scope New in v7.4.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: String
- Default value: ""
- Optional value: a string with a length of up to 64 characters. Valid characters include digits `0-9`, letters `a-zA-Z`, underscores `_`, and hyphens `-`.
- This variable is an instance-level system variable. You can use it to control the service scope of each TiDB node under the TiDB Distributed eXecution Framework (DXF). The DXF determines which TiDB nodes can be scheduled to execute distributed tasks based on the value of this variable. For specific rules, see Task scheduling.

14.5.1.365 tidb_session_alias New in v7.4.0

- Scope: SESSION
- Persists to cluster: No
- Applies to hint SET_VAR: Yes
- Default value: “”
- You can use this variable to customize the value of the `session_alias` column in the logs related to the current session, which helps identify the session in troubleshooting. This setting affects the logs of multiple nodes involved in the statement execution (including TiKV). The maximum length of this variable is limited to 64 characters, and any characters exceeding the length will be truncated automatically. Spaces at the end of the value will also be removed automatically.

14.5.1.366 tidb_session_plan_cache_size New in v7.1.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `100`
- Range: `[1, 100000]`
- This variable controls the maximum number of plans that can be cached. Prepared plan cache and non-prepared plan cache share the same cache.
- When you upgrade from an earlier version to a v7.1.0 or later version, this variable remains the same value as `tidb_prepared_plan_cache_size`

14.5.1.367 tidb_shard_allocate_step New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `9223372036854775807`
- Range: `[1, 9223372036854775807]`
- This variable controls the maximum number of continuous IDs to be allocated for the `AUTO_RANDOM` or `SHARD_ROW_ID_BITS` attribute. Generally, `AUTO_RANDOM` IDs or the `SHARD_ROW_ID_BITS` annotated row IDs are incremental and continuous in one transaction. You can use this variable to solve the hotspot issue in large transaction scenarios.

14.5.1.368 tidb_shard_row_id_bits New in v8.4.0

- Scope: SESSION | GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 15]`
- This variable is used to set the default number of row ID shards for newly created tables. When this variable is set to a non-zero value, TiDB will automatically apply this attribute to tables that allow the use of `SHARD_ROW_ID_BITS` (for example, `NONCLUSTERED` tables) when executing `CREATE TABLE` statements. For more information, see `SHARD_ROW_ID_BITS`.

14.5.1.369 tidb_simplified_metrics

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- When this variable is enabled, TiDB does not collect or record the metrics that are not used in the Grafana panels.

14.5.1.370 tidb_skip_ascii_check New in v5.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to set whether to skip ASCII validation.
- Validating ASCII characters affects the performance. When you are sure that the input characters are valid ASCII characters, you can set the variable value to `ON`.

14.5.1.371 tidb_skip_isolation_level_check

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes

- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- After this switch is enabled, if an isolation level unsupported by TiDB is assigned to `tx_isolation`, no error is reported. This helps improve compatibility with applications that set (but do not depend on) a different isolation level.

```
tidb> set tx_isolation='serializable';
ERROR 8048 (HY000): The isolation level 'serializable' is not supported.
    ↪ Set tidb_skip_isolation_level_check=1 to skip this error
tidb> set tidb_skip_isolation_level_check=1;
Query OK, 0 rows affected (0.00 sec)

tidb> set tx_isolation='serializable';
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

14.5.1.372 tidb_skip_missing_partition_stats New in v7.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- When accessing a partitioned table in dynamic pruning mode, TiDB aggregates the statistics of each partition to generate GlobalStats. This variable controls the generation of GlobalStats when partition statistics are missing.
    - If this variable is `ON`, TiDB skips missing partition statistics when generating GlobalStats so the generation of GlobalStats is not affected.
    - If this variable is `OFF`, TiDB stops generating GlobalStats when it detects any missing partition statistics.

14.5.1.373 tidb_skip_utf8_check

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`

- This variable is used to set whether to skip UTF-8 validation.
- Validating UTF-8 characters affects the performance. When you are sure that the input characters are valid UTF-8 characters, you can set the variable value to `ON`.

> **Note:**
>
> If the character check is skipped, TiDB might fail to detect illegal UTF-8 characters written by the application, cause decoding errors when `ANALYZE` is executed, and introduce other unknown encoding issues. If your application cannot guarantee the validity of the written string, it is not recommended to skip the character check.

14.5.1.374 tidb_slow_log_threshold

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL
- Persists to cluster: No, only applicable to the current TiDB instance that you are connecting to.
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `300`
- Range: `[-1, 9223372036854775807]`
- Unit: Milliseconds
- This variable outputs the threshold value of the time consumed by the slow log, and is set to 300 milliseconds by default. When the time consumed by a query is larger than this value, this query is considered as a slow query and its log is output to the slow query log. Note that when the output level of `log.level` is `"debug"`, all queries are recorded in the slow query log, regardless of the setting of this variable.

14.5.1.375 tidb_slow_query_file

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: ""
- When `INFORMATION_SCHEMA.SLOW_QUERY` is queried, only the slow query log name set by `slow-query-file` in the configuration file is parsed. The default slow query log name is "tidb-slow.log". To parse other logs, set the `tidb_slow_query_file` session variable to a specific file path, and then query `INFORMATION_SCHEMA.SLOW_QUERY` to parse the slow query log based on the set file path.

For details, see Identify Slow Queries.

14.5.1.376 tidb_slow_txn_log_threshold New in v7.0.0

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Unsigned integer
- Default value: `0`
- Range: `[0, 9223372036854775807]`
- Unit: Milliseconds
- This variable sets the threshold for slow transaction logging. When the execution time of a transaction exceeds this threshold, TiDB logs detailed information about the transaction. When the value is set to `0`, this feature is disabled.

14.5.1.377 tidb_snapshot

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: ""
- This variable is used to set the time point at which the data is read by the session. For example, when you set the variable to "2017-11-11 20:20:20" or a TSO number like "400036290571534337", the current session reads the data of this moment.

14.5.1.378 tidb_source_id New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[1, 15]`

- This variable is used to configure the different cluster IDs in a bi-directional replication cluster.

14.5.1.379 tidb_stats_cache_mem_quota New in v6.1.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Unit: Byte
- Default value: `0`, which means that the memory quota is automatically set to half of the total memory size of the TiDB instance.
- Range: `[0, 1099511627776]`
- This variable sets the memory quota for the TiDB statistics cache.

14.5.1.380 tidb_stats_load_pseudo_timeout New in v5.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls how TiDB behaves when the waiting time of SQL optimization reaches the timeout to synchronously load complete column statistics. The default value `ON` means that the SQL optimization gets back to using pseudo statistics after the timeout. If this variable to `OFF`, SQL execution fails after the timeout.

14.5.1.381 tidb_stats_load_sync_wait New in v5.4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `100`
- Range: `[0, 2147483647]`
- Unit: Milliseconds
- This variable controls whether to enable the synchronously loading statistics feature. The value `0` means that the feature is disabled. To enable the feature, you can set this variable to a timeout (in milliseconds) that SQL optimization can wait for at most to synchronously load complete column statistics. For details, see Load statistics.

14.5.1.382 tidb_stmt_summary_enable_persistent New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is read-only. It controls whether to enable statements summary persistence.

- The value of this variable is the same as that of the configuration item `tidb_stmt_summary_enable_persistent`.

14.5.1.383 tidb_stmt_summary_filename New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: String
- Default value: `"tidb-statements.log"`
- This variable is read-only. It specifies the file to which persistent data is written when statements summary persistence is enabled.

- The value of this variable is the same as that of the configuration item `tidb_stmt_summary_filename`.

14.5.1.384 tidb_stmt_summary_file_max_backups New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- This variable is read-only. It specifies the maximum number of data files that can be persisted when statements summary persistence is enabled.

- The value of this variable is the same as that of the configuration item `tidb_stmt_summary_file_max_backups`.

14.5.1.385 tidb_stmt_summary_file_max_days New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `3`
- Unit: day
- This variable is read-only. It specifies the maximum number of days to keep persistent data files when statements summary persistence is enabled.

- The value of this variable is the same as that of the configuration item `tidb_stmt_summary_file_max_days`.

14.5.1.386 tidb_stmt_summary_file_max_size New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `64`
- Unit: MiB
- This variable is read-only. It specifies the maximum size of a persistent data file when statements summary persistence is enabled.

- The value of this variable is the same as that of the configuration item `tidb_stmt_summary_file_max_size`.

14.5.1.387 tidb_stmt_summary_history_size New in v4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `24`
- Range: `[0, 255]`
- This variable is used to set the history capacity of statement summary tables.

14.5.1.388 tidb_stmt_summary_internal_query New in v4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether to include the SQL information of TiDB in statement summary tables.

14.5.1.389 tidb_stmt_summary_max_sql_length New in v4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `4096`
- Range: `[0, 2147483647]`
- Unit: Bytes

- This variable is used to control the length of the SQL string in statement summary tables and the TiDB Dashboard.

14.5.1.390 tidb_stmt_summary_max_stmt_count New in v4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `3000`
- Range: `[1, 32767]`
- This variable is used to set the maximum number of statements that statement summary tables store in memory.

14.5.1.391 tidb_stmt_summary_refresh_interval New in v4.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1800`
- Range: `[1, 2147483647]`
- Unit: Seconds
- This variable is used to set the refresh time of statement summary tables.

14.5.1.392 tidb_store_batch_size

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `4`
- Range: `[0, 25000]`
- This variable is used to control the batch size of the Coprocessor Tasks of the `IndexLookUp` operator. `0` means to disable batch. When the number of tasks is relatively large and slow queries occur, you can increase this variable to optimize the query.

14.5.1.393 tidb_store_limit New in v3.0.4 and v4.0

- Scope: GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 9223372036854775807]`
- This variable is used to limit the maximum number of requests TiDB can send to TiKV at the same time. 0 means no limit.

14.5.1.394 tidb_streamagg_concurrency

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- This variable sets the concurrency of the `StreamAgg` operator when queries are executed.
- It is **NOT recommended** to set this variable. Modifying the variable value might cause data correctness issues.

14.5.1.395 tidb_super_read_only New in v5.3.1

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- `tidb_super_read_only` aims to be implemented as a replacement of the MySQL variable `super_read_only`. However, because TiDB is a distributed database, `tidb_super_read_only` does not make the database read-only immediately after execution, but eventually.
- Users with the `SUPER` or `SYSTEM_VARIABLES_ADMIN` privilege can modify this variable.
- This variable controls the read-only status of the entire cluster. When the variable is `ON`, all TiDB servers in the entire cluster are in the read-only mode. In this case, TiDB only executes the statements that do not modify data, such as `SELECT`, `USE`, and `SHOW`. For other statements such as `INSERT` and `UPDATE`, TiDB rejects executing those statements in the read-only mode.
- Enabling the read-only mode using this variable only ensures that the entire cluster finally enters the read-only status. If you have changed the value of this variable in a TiDB cluster but the change has not yet propagated to other TiDB servers, the un-updated TiDB servers are still **not** in the read-only mode.
- TiDB checks the read-only flag before SQL statements are executed. Since v6.2.0, the flag is also checked before SQL statements are committed. This helps prevent the case

where long-running auto commit statements might modify data after the server has been placed in read-only mode.
- When this variable is enabled, TiDB handles the uncommitted transactions in the following ways:
    - For uncommitted read-only transactions, you can commit the transactions normally.
    - For uncommitted transactions that are not read-only, SQL statements that perform write operations in these transactions are rejected.
    - For uncommitted read-only transactions with modified data, the commit of these transactions is rejected.
- After the read-only mode is enabled, all users (including the users with the `SUPER` privilege) cannot execute the SQL statements that might write data unless the user is explicitly granted the `RESTRICTED_REPLICA_WRITER_ADMIN` privilege.
- When the `tidb_restricted_read_only` system variable is set to `ON`, `tidb_super_read_only` is affected by `tidb_restricted_read_only` in some cases. For detailed impact, see the description of `tidb_restricted_read_only`.

14.5.1.396 tidb_sysdate_is_now New in v6.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether the `SYSDATE` function can be replaced by the `NOW` function. This configuration item has the same effect as the MySQL option `sysdate-is-now`.

14.5.1.397 tidb_sysproc_scan_concurrency New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`

- Range: `[0, 4294967295]`. The maximum value for v7.5.0 and earlier versions is `256`. Before v8.2.0, the minimum value is `1`. When you set it to `0`, it adaptively adjusts the concurrency based on the cluster size.
- This variable is used to set the concurrency of scan operations performed when TiDB executes internal SQL statements (such as an automatic update of statistics).

14.5.1.398 tidb_table_cache_lease New in v6.0.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `3`
- Range: `[1, 10]`
- Unit: Seconds
- This variable is used to control the lease time of cached tables with a default value of `3`. The value of this variable affects the modification to cached tables. After a modification is made to cached tables, the longest waiting time might be `tidb_table_cache_lease` seconds. If the table is read-only or can accept a high write latency, you can increase the value of this variable to increase the valid time for caching tables and to reduce the frequency of lease renewal.

14.5.1.399 tidb_tmp_table_max_size New in v5.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `67108864`
- Range: `[1048576, 137438953472]`
- Unit: Bytes
- This variable is used to set the maximum size of a single temporary table. Any temporary table with a size larger than this variable value causes error.

14.5.1.400 tidb_top_sql_max_meta_count New in v6.0.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

- Scope: GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `5000`
- Range: `[1, 10000]`

- This variable is used to control the maximum number of SQL statement types collected by Top SQL per minute.

14.5.1.401 tidb_top_sql_max_time_series_count New in v6.0.0

> **Note:**
>
> This TiDB variable is not applicable to TiDB Cloud.

> **Note:**
>
> Currently, the Top SQL page in TiDB Dashboard only displays the top 5 types of SQL queries that contribute the most to the load, which is irrelevant with the configuration of `tidb_top_sql_max_time_series_count`.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `100`
- Range: `[1, 5000]`

- This variable is used to control how many SQL statements that contribute the most to the load (that is, top N) can be recorded by Top SQL per minute.

14.5.1.402 tidb_track_aggregate_memory_usage

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`

- This variable controls whether TiDB tracks the memory usage of aggregate functions.

> **Warning:**
>
> If you disable this variable, TiDB might not accurately track the memory usage and cannot control the memory usage of the corresponding SQL statements.

14.5.1.403 tidb_tso_client_batch_max_wait_time New in v5.3.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0`
- Range: `[0, 10]`
- Unit: Milliseconds
- This variable is used to set the maximum waiting time for a batch operation when TiDB requests TSO from PD. The default value is `0`, which means no extra waiting time.
- When obtaining TSO requests from PD each time, PD Client, used by TiDB, collects as many TSO requests received at the same time as possible. Then, PD Client merges the collected requests in batch into one RPC request and sends the request to PD. This helps reduce the pressure on PD.
- After setting this variable to a value greater than `0`, TiDB waits for the maximum duration of this value before the end of each batch merge. This is to collect more TSO requests and improve the effect of batch operations.
- Scenarios for increasing the value of this variable:
    - Due to the high pressure of TSO requests, the CPU of the PD leader reaches a bottleneck, which causes high latency of TSO RPC requests.
    - There are not many TiDB instances in the cluster, but every TiDB instance is in high concurrency.
- It is recommended to set this variable to a value as small as possible.

Note:

- Suppose that the TSO RPC latency increases for reasons other than a CPU usage bottleneck of the PD leader (such as network issues). In this case, increasing the value of `tidb_tso_client_batch_max_wait_time` ↪ might increase the execution latency in TiDB and affect the QPS performance of the cluster.
- This feature is incompatible with `tidb_tso_client_rpc_mode`. If this variable is set to a non-zero value, `tidb_tso_client_rpc_mode` does not take effect.

14.5.1.404 tidb_tso_client_rpc_mode New in v8.4.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `DEFAULT`
- Value options: `DEFAULT`, `PARALLEL`, `PARALLEL-FAST`
- This variable switches the mode in which TiDB sends TSO RPC requests to PD. The mode determines whether TSO RPC requests are processed in parallel and affects the time spent on batch-waiting for each TS retrieval operation, thereby helping reduce the wait time for retrieving TS during query execution in certain scenarios.
    - `DEFAULT`: TiDB collects TS retrieval operations over a specific period into a single TSO RPC request and sends it to PD to get timestamps in a batch. Therefore, the duration of each TS retrieval operation consists of the time spent waiting to be batched and the time spent performing the RPC. In `DEFAULT` mode, different TSO RPC requests are processed serially, and the average duration of each TS retrieval operation is about 1.5 times the actual time cost of a TSO RPC request.
    - `PARALLEL`: In this mode, TiDB attempts to reduce the duration for collecting each batch to half of that in `DEFAULT` mode and tries to maintain two concurrent TSO RPC requests. In this way, the average duration of each TS retrieval operation can theoretically be reduced to about 1.25 times the TSO RPC duration, which is about 83% of the time cost in `DEFAULT` mode. However, the effect of batching will be reduced, and the number of TSO RPC requests will increase to roughly double that in `DEFAULT` mode.

- `PARALLEL-FAST`: Similar to `PARALLEL` mode, in this mode, TiDB attempts to reduce the duration for collecting each batch to a quarter of that in `DEFAULT` mode and tries to maintain four concurrent TSO RPC requests. In this way, the average duration of each TS retrieval operation can theoretically be reduced to about 1.125 times the TSO RPC duration, which is about 75% of the time cost in `DEFAULT` mode. However, the effect of batching will be further reduced, and the number of TSO RPC requests will increase to roughly four times that in `DEFAULT` mode.

- When the following conditions are met, you can consider switching this variable to `PARALLEL` or `PARALLEL-FAST` for potential performance improvements:

  - TSO waiting time constitutes a significant portion of the total execution time of SQL queries.
  - The TSO allocation in PD has not reached its bottleneck.
  - PD and TiDB nodes have sufficient CPU resources.
  - The network latency between TiDB and PD is significantly higher than the time PD takes to allocate TSO (that is, network latency accounts for the majority of TSO RPC duration).
    - To get the duration of TSO RPC requests, check the **PD TSO RPC Duration** panel in the PD Client section of the Grafana TiDB dashboard.
    - To get the duration of PD TSO allocation, check the **PD server TSO handle duration** panel in the TiDB section of the Grafana PD dashboard.
  - The additional network traffic resulting from more TSO RPC requests between TiDB and PD (twice for `PARALLEL` or four times for `PARALLEL-FAST`) is acceptable.

Note:

- `PARALLEL` and `PARALLEL-FAST` modes are incompatible with `tidb_tso_client_batch_max_wait_time` and `tidb_enable_tso_follower_proxy`. If either `tidb_tso_client_batch_max_wait_time` is set to a non-zero value or `tidb_enable_tso_follower_proxy` is enabled, configuring `tidb_tso_client_rpc_mode` does not take effect, and TiDB always works in `DEFAULT` mode.
- `PARALLEL` and `PARALLEL-FAST` modes are designed to reduce the average time for retrieving TS in TiDB. In situations with significant latency fluctuations, such as long-tail latency or latency spikes, these two modes might not provide any remarkable performance improvements.

14.5.1.405 tidb_ttl_delete_rate_limit New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `0`
- Range: `[0, 9223372036854775807]`
- This variable is used to limit the rate of `DELETE` statements in TTL jobs on each TiDB node. The value represents the maximum number of `DELETE` statements allowed per second in a single node in a TTL job. When this variable is set to `0`, no limit is applied. For more information, refer to Time to Live.

14.5.1.406 tidb_ttl_delete_batch_size New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `100`
- Range: `[1, 10240]`
- This variable is used to set the maximum number of rows that can be deleted in a single `DELETE` transaction in a TTL job. For more information, refer to Time to Live.

14.5.1.407 tidb_ttl_delete_worker_count New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL

- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `4`
- Range: `[1, 256]`
- This variable is used to set the maximum concurrency of TTL jobs on each TiDB node. For more information, refer to Time to Live.

14.5.1.408 tidb_ttl_job_enable New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- Type: Boolean
- This variable is used to control whether TTL jobs are enabled. If it is set to `OFF`, all tables with TTL attributes automatically stop cleaning up expired data. For more information, refer to Time to Live.

14.5.1.409 tidb_ttl_scan_batch_size New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `500`
- Range: `[1, 10240]`
- This variable is used to set the `LIMIT` value of each `SELECT` statement used to scan expired data in a TTL job. For more information, refer to Time to Live.

14.5.1.410 tidb_ttl_scan_worker_count New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `4`
- Range: `[1, 256]`
- This variable is used to set the maximum concurrency of TTL scan jobs on each TiDB node. For more information, refer to Time to Live.

14.5.1.411 tidb_ttl_job_schedule_window_start_time New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Time
- Persists to cluster: Yes
- Default value: `00:00 +0000`
- This variable is used to control the start time of the scheduling window of TTL jobs in the background. When you modify the value of this variable, be cautious that a small window might cause the cleanup of expired data to fail. For more information, refer to Time to Live.

14.5.1.412 tidb_ttl_job_schedule_window_end_time New in v6.5.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Applies to hint SET_VAR: No
- Type: Time
- Persists to cluster: Yes
- Default value: `23:59 +0000`
- This variable is used to control the end time of the scheduling window of TTL jobs in the background. When you modify the value of this variable, be cautious that a small window might cause the cleanup of expired data to fail. For more information, refer to Time to Live.

14.5.1.413 tidb_ttl_running_tasks New in v7.0.0

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `-1` and `[1, 256]`
- Specifies the maximum number of running TTL tasks in the entire cluster. `-1` means the number of TTL tasks is equivalent to the number of TiKV nodes. For more information, refer to Time to Live.

14.5.1.414 tidb_txn_assertion_level New in v6.0.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `FAST`
- Possible values: `OFF`, `FAST`, `STRICT`
- This variable is used to control the assertion level. Assertion is a consistency check between data and indexes, which checks whether a key being written exists in the transaction commit process. For more information, see Troubleshoot Inconsistency Between Data and Indexes.

- `OFF`: Disable this check.
- `FAST`: Enable most of the check items, with almost no impact on performance.
- `STRICT`: Enable all check items, with a minor impact on pessimistic transaction performance when the system workload is high.

- For new clusters of v6.0.0 or later versions, the default value is `FAST`. For existing clusters that upgrade from versions earlier than v6.0.0, the default value is `OFF`.

14.5.1.415 tidb_txn_commit_batch_size New in v6.2.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `16384`
- Range: `[1, 1073741824]`
- Unit: Bytes

- This variable is used to control the batch size of transaction commit requests that TiDB sends to TiKV. If most of the transactions in the application workload have a large number of write operations, adjusting this variable to a larger value can improve the performance of batch processing. However, if this variable is set to too large a value and exceeds the limit of TiKV's `raft-entry-max-size`, the commits might fail.

14.5.1.416 tidb_txn_entry_size_limit New in v7.6.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 125829120]`
- Unit: Bytes

- This variable is used to dynamically modify the TiDB configuration item `performance ↪ .txn-entry-size-limit`. It limits the size of a single row of data in TiDB, which is equivalent to the configuration item. The default value of this variable is `0`, which means that TiDB uses the value of the configuration item `txn-entry-size-limit` by default. When this variable is set to a non-zero value, `txn-entry-size-limit` is also set to the same value.

Note:

Modifying this variable with the SESSION scope only affects the current user session, not the internal TiDB session. This might lead to transaction failure if the entry size of an internal TiDB transaction exceeds the limit of the configuration item. Therefore, to dynamically increase the limit, it is recommended that you modify the variable with the GLOBAL scope.

14.5.1.417 tidb_txn_mode

Note:

This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `pessimistic`
- Possible values: `pessimistic`, `optimistic`
- This variable is used to set the transaction mode. TiDB 3.0 supports the pessimistic transactions. Since TiDB 3.0.8, the pessimistic transaction mode is enabled by default.
- If you upgrade TiDB from v3.0.7 or earlier versions to v3.0.8 or later versions, the default transaction mode does not change. **Only the newly created clusters use the pessimistic transaction mode by default**.
- If this variable is set to "optimistic" or "", TiDB uses the optimistic transaction mode.

14.5.1.418 tidb_use_plan_baselines New in v4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable is used to control whether to enable the execution plan binding feature. It is enabled by default, and can be disabled by assigning the `OFF` value. For the use of the execution plan binding, see Execution Plan Binding.

14.5.1.419 tidb_wait_split_region_finish

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- It usually takes a long time to scatter Regions, which is determined by PD scheduling and TiKV loads. This variable is used to set whether to return the result to the client after all Regions are scattered completely when the `SPLIT REGION` statement is being executed:
  - `ON` requires that the `SPLIT REGIONS` statement waits until all Regions are scattered.
  - `OFF` permits the `SPLIT REGIONS` statement to return before finishing scattering all Regions.
- Note that when scattering Regions, the write and read performances for the Region that is being scattered might be affected. In batch-write or data importing scenarios, it is recommended to import data after Regions scattering is finished.

14.5.1.420 tidb_wait_split_region_timeout

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `300`
- Range: `[1, 2147483647]`
- Unit: Seconds
- This variable is used to set the timeout for executing the `SPLIT REGION` statement. If a statement is not executed completely within the specified time value, a timeout error is returned.

14.5.1.421 tidb_window_concurrency New in v4.0

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `-1`
- Range: `[1, 256]`
- Unit: Threads
- This variable is used to set the concurrency degree of the window operator.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

14.5.1.422 tiflash_fastscan New in v6.3.0

- Scope: SESSION | GLOBAL
- Applies to hint SET_VAR: Yes
- Default value: `OFF`
- Type: Boolean
- If FastScan is enabled (set to `ON`), TiFlash provides more efficient query performance, but does not guarantee the accuracy of the query results or data consistency.

14.5.1.423 tiflash_fine_grained_shuffle_batch_size New in v6.2.0

- Scope: SESSION | GLOBAL
- Applies to hint SET_VAR: Yes
- Default value: `8192`
- Range: `[1, 18446744073709551615]`
- When Fine Grained Shuffle is enabled, the window function pushed down to TiFlash can be executed in parallel. This variable controls the batch size of the data sent by the sender.
- Impact on performance: set a reasonable size according to your business requirements. Improper setting affects the performance. If the value is set too small, for example `1`, it causes one network transfer per Block. If the value is set too large, for example, the total number of rows of the table, it causes the receiving end to spend most of the

time waiting for data, and the piplelined computation cannot work. To set a proper value, you can observe the distribution of the number of rows received by the TiFlash receiver. If most threads receive only a few rows, for example a few hundred, you can increase this value to reduce the network overhead.

14.5.1.424 tiflash_fine_grained_shuffle_stream_count New in v6.2.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Integer
- Default value: `0`
- Range: `[-1, 1024]`
- When the window function is pushed down to TiFlash for execution, you can use this variable to control the concurrency level of the window function execution. The possible values are as follows:
    - -1: the Fine Grained Shuffle feature is disabled. The window function pushed down to TiFlash is executed in a single thread.
    - 0: the Fine Grained Shuffle feature is enabled. If `tidb_max_tiflash_threads` is set to a valid value (greater than 0), then `tiflash_fine_grained_shuffle_stream_count` is set to the value of `tidb_max_tiflash_threads`. Otherwise, it is automatically estimated based on the CPU resources of the TiFlash compute node. The actual concurrency level of the window function on TiFlash is: min(`tiflash_fine_grained_shuffle_stream_count`, the number of physical threads on TiFlash nodes).
    - Integer greater than 0: the Fine Grained Shuffle feature is enabled. The window function pushed down to TiFlash is executed in multiple threads. The concurrency level is: min(`tiflash_fine_grained_shuffle_stream_count`, the number of physical threads on TiFlash nodes).
- Theoretically, the performance of the window function increases linearly with this value. However, if the value exceeds the actual number of physical threads, it instead leads to performance degradation.

14.5.1.425 tiflash_mem_quota_query_per_node New in v7.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No

- Type: Integer
- Default value: `0`
- Range: `[-1, 9223372036854775807]`
- This variable limits the maximum memory usage for a query on a TiFlash node. When the memory usage of a query exceeds this limit, TiFlash returns an error and terminates the query. Setting this variable to `-1` or `0` means no limit. When this variable is set to a value greater than `0` and `tiflash_query_spill_ratio` is set to a valid value, TiFlash enables query-level spilling.

14.5.1.426 tiflash_query_spill_ratio New in v7.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0.7`
- Range: `[0, 0.85]`
- This variable controls the threshold for TiFlash query-level spilling. `0` means disabling the automatic query-level spilling. When this variable is greater than `0` and the memory usage of a query exceeds `tiflash_mem_quota_query_per_node` * `tiflash_query_spill_ratio`, TiFlash triggers query-level spilling, which spills data of supported operators in the query as needed.

Note:

- This variable only takes effect when `tiflash_mem_quota_query_per_node` is greater than `0`. In other words, if tiflash_mem_quota_query_per_node is `0` or `-1`, query-level spilling will not be enabled even if `tiflash_query_spill_ratio` is greater than `0`.
- When TiFlash query-level spilling is enabled, the spilling thresholds for individual TiFlash operators automatically become invalidated. In other words, if both `tiflash_mem_quota_query_per_node` and `tiflash_query_spill_ratio` are greater than 0, the three variables tidb_max_bytes_before_tiflash_external_sort, tidb_max_bytes_before_tiflash_external_group_by, and tidb_max_bytes_before_tiflash_external_join become invalidated automatically, equivalent to setting them to `0`.

14.5.1.427 tiflash_replica_read New in v7.3.0

Note:

This TiDB variable is not applicable to TiDB Cloud.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `all_replicas`
- Value options: `all_replicas`, `closest_adaptive`, or `closest_replicas`
- This variable is used to set the strategy for selecting TiFlash replicas when a query requires the TiFlash engine.
    - `all_replicas` means using all available TiFlash replicas for analytical computing.
    - `closest_adaptive` means preferring to use TiFlash replicas in the same zone as the TiDB node initiating the query. If replicas in this zone do not contain all the required data, the query will involve TiFlash replicas from other zones along with their corresponding TiFlash nodes.
    - `closest_replicas` means using only TiFlash replicas in the same zone as the TiDB node initiating the query. If replicas in this zone do not contain all the required data, the query will return an error.

Note:

- If TiDB nodes do not have zone attributes configured and `tiflash_replica_read` is not set to `all_replicas`, TiFlash ignores the replica selection strategy. Instead, it uses all TiFlash replicas for queries and returns the `The variable tiflash_replica_read is ignored.` warning.
- If TiFlash nodes do not have zone attributes configured, they are treated as nodes not belonging to any zone.

14.5.1.428 tiflash_hashagg_preaggregation_mode New in v8.3.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: Yes
- Type: Enumeration

- Default value: `force_preagg`
- Value options: `force_preagg`, `force_streaming`, `auto`
- This variable controls the pre-aggregation strategy used during the first stage of two-stage or three-stage HashAgg operations pushed down to TiFlash:
    - `force_preagg`: TiFlash forces pre-aggregation during the first stage of HashAgg. This behavior is consistent with the behavior before v8.3.0.
    - `force_streaming`: TiFlash directly sends data to the next stage of HashAgg without pre-aggregation.
    - `auto`: TiFlash automatically chooses whether to perform pre-aggregation based on the current workload's aggregation degree.

14.5.1.429 tikv_client_read_timeout New in v7.4.0

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `0`
- Range: `[0, 2147483647]`
- Unit: Millisecond
- You can use `tikv_client_read_timeout` to set the timeout for TiDB to send a TiKV RPC read request in a query. When a TiDB cluster is in an environment with unstable network or serious TiKV I/O latency jitter, and your application is sensitive to the latency of the SQL queries, you can set `tikv_client_read_timeout` to reduce the timeout of the TiKV RPC read requests. In this case, when a TiKV node has I/O latency jitter, TiDB can time out quickly and re-send the RPC request to the TiKV node where the next TiKV Region Peer is located. If the requests of all TiKV Region Peers time out, TiDB will retry with the default timeout (usually 40 seconds).
- You can also use the optimizer hint `/*+ SET_VAR(TIKV_CLIENT_READ_TIMEOUT=N)*/` in a query to set the timeout for TiDB to send a TiKV RPC read request. If both the optimizer hint and this system variable are set, the optimizer hint takes higher priority.
- The default value `0` indicates that the default timeout (usually 40 seconds) is used.

Note:

- Normally, a regular query takes a few milliseconds, but occasionally when a TiKV node is in unstable network or gets I/O jitter, the query can take more than 1 second or even 10 seconds. In this case, you can set the TiKV RPC read request timeout to 100 milliseconds for a specific query by using the optimizer hint `/*+ SET_VAR(TIKV_CLIENT_READ_TIMEOUT =100)*/`. In this way, even if the response of a TiKV node is slow,

TiDB can quickly time out and then re-send the RPC request to the TiKV node where the next TiKV Region Peer is located. Because the probability of two TiKV nodes getting I/O jitter simultaneously is low, the query can be completed usually within a few milliseconds to 110 milliseconds.

- Do not set too small values (for example, 1 millisecond) for `tikv_client ↪ _read_timeout`. Otherwise, the requests might time out easily when the workload of a TiDB cluster is high, and subsequent retries will further increase the load on the TiDB cluster.
- If you need to set different timeout values for different types of queries, it is recommended to use optimizer hints.

14.5.1.430 time_zone

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `SYSTEM`
- This variable returns the current time zone. Values can be specified as either an offset such as '-8:00' or a named zone 'America/Los_Angeles'.
- The value `SYSTEM` means that the time zone should be the same as the system host, which is available via the `system_time_zone` variable.

14.5.1.431 timestamp

- Scope: SESSION
- Applies to hint SET_VAR: No
- Type: Float
- Default value: `0`
- Range: `[0, 2147483647]`
- A non-empty value of this variable indicates the UNIX epoch that is used as the timestamp for `CURRENT_TIMESTAMP()`, `NOW()`, and other functions. This variable might be used in data restore or replication.

14.5.1.432 transaction_isolation

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration

- Default value: `REPEATABLE-READ`
- Possible values: `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`
- This variable sets the transaction isolation. TiDB advertises `REPEATABLE-READ` for compatibility with MySQL, but the actual isolation level is Snapshot Isolation. See transaction isolation levels for further details.

14.5.1.433 tx_isolation

This variable is an alias for `transaction_isolation`.

14.5.1.434 tx_isolation_one_shot

> **Note:**
>
> This variable is internally used in TiDB. You are not expected to use it.

Internally, the TiDB parser transforms the `SET TRANSACTION ISOLATION LEVEL [READ COMMITTED| REPEATABLE READ | ...]` statements to `SET @@SESSION.TX_ISOLATION_ONE_SHOT = [READ COMMITTED| REPEATABLE READ | ...]`.

14.5.1.435 tx_read_ts

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: “”
- In the Stale Read scenarios, this session variable is used to help record the Stable Read timestamp value.
- This variable is used for the internal operation of TiDB. It is **NOT recommended** to set this variable.

14.5.1.436 txn_scope

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION

- Applies to hint SET_VAR: No
- Default value: `global`
- Value options: `global` and `local`
- This variable is used to set whether the current session transaction is a global transaction or a local transaction.
- This variable is used for the internal operation of TiDB. It is **NOT recommended** to set this variable.

14.5.1.437 validate_password.check_user_name New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `ON`
- Type: Boolean
- This variable is a check item in the password complexity check. It checks whether the password matches the username. This variable takes effect only when `validate_password.enable` is enabled.
- When this variable is effective and set to `ON`, if you set a password, TiDB compares the password with the username (excluding the hostname). If the password matches the username, the password is rejected.
- This variable is independent of `validate_password.policy` and not affected by the password complexity check level.

14.5.1.438 validate_password.dictionary New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `""`
- Type: String
- This variable is a check item in the password complexity check. It checks whether the password matches the dictionary. This variable takes effect only when `validate_password.enable` is enabled and `validate_password.policy` is set to `2` (STRONG).
- This variable is a string not longer than 1024 characters. It contains a list of words that cannot exist in the password. Each word is separated by semicolon (`;`).
- This variable is set to an empty string by default, which means no dictionary check is performed. To perform the dictionary check, you need to include the words to be matched in the string. If this variable is configured, when you set a password, TiDB compares each substring (length in 4 to 100 characters) of the password with the words in the dictionary. If any substring of the password matches a word in the dictionary, the password is rejected. The comparison is case-insensitive.

14.5.1.439 validate_password.enable New in v6.5.0

> **Note:**
>
> This variable is always enabled for TiDB Cloud Serverless.

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Default value: `OFF`
- Type: Boolean
- This variable controls whether to perform password complexity check. If this variable is set to `ON`, TiDB performs the password complexity check when you set a password.

14.5.1.440 validate_password.length New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `8`
- Range: `[0, 2147483647]` for TiDB Self-Managed and TiDB Cloud Dedicated, `[8, 2147483647]` for TiDB Cloud Serverless
- This variable is a check item in the password complexity check. It checks whether the password length is sufficient. By default, the minimum password length is `8`. This variable takes effect only when `validate_password.enable` is enabled.
- The value of this variable must not be smaller than the expression: `validate_password.number_count + validate_password.special_char_count + (2 * validate_password.mixed_case_count)`.
- If you change the value of `validate_password.number_count`, `validate_password.special_char_count`, or `validate_password.mixed_case_count` such that the expression value is larger than `validate_password.length`, the value of `validate_password.length` is automatically changed to match the expression value.

14.5.1.441 validate_password.mixed_case_count New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`

- Range: `[0, 2147483647]` for TiDB Self-Managed and TiDB Cloud Dedicated, `[1, 2147483647]` for TiDB Cloud Serverless
- This variable is a check item in the password complexity check. It checks whether the password contains sufficient uppercase and lowercase letters. This variable takes effect only when `validate_password.enable` is enabled and `validate_password.policy` is set to `1` (MEDIUM) or larger.
- Neither the number of uppercase letters nor the number of lowercase letters in the password can be fewer than the value of `validate_password.mixed_case_count`. For example, when the variable is set to `1`, the password must contain at least one uppercase letter and one lowercase letter.

14.5.1.442 validate_password.number_count New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[0, 2147483647]` for TiDB Self-Managed and TiDB Cloud Dedicated, `[1, 2147483647]` for TiDB Cloud Serverless
- This variable is a check item in the password complexity check. It checks whether the password contains sufficient numbers. This variable takes effect only when `validate_password.enable` is enabled and `validate_password.policy` is set to `1` (MEDIUM) or larger.

14.5.1.443 validate_password.policy New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Enumeration
- Default value: `1`
- Value options: `0`, `1`, and `2` for TiDB Self-Managed and TiDB Cloud Dedicated; `1` and `2` for TiDB Cloud Serverless
- This variable controls the policy for the password complexity check. This variable takes effect only when `validate_password.enable` is enabled. The value of this variable determines whether other `validate-password` variables take effect in the password complexity check, except for `validate_password.check_user_name`.
- This value of this variable can be `0`, `1`, or `2` (corresponds to LOW, MEDIUM, or STRONG). Different policy levels have different checks:
    - 0 or LOW: password length.
    - 1 or MEDIUM: password length, uppercase and lowercase letters, numbers, and special characters.

- 2 or STRONG: password length, uppercase and lowercase letters, numbers, special characters, and dictionary match.

14.5.1.444 validate_password.special_char_count New in v6.5.0

- Scope: GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `1`
- Range: `[0, 2147483647]` for TiDB Self-Managed and TiDB Cloud Dedicated, `[1, 2147483647]` for TiDB Cloud Serverless
- This variable is a check item in the password complexity check. It checks whether the password contains sufficient special characters. This variable takes effect only when `validate_password.enable` is enabled and `validate_password.policy` is set to `1` (MEDIUM) or larger.

14.5.1.445 version

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: `8.0.11-TiDB-`(tidb version)
- This variable returns the MySQL version, followed by the TiDB version. For example '8.0.11-TiDB-v8.4.0'.

14.5.1.446 version_comment

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: (string)
- This variable returns additional details about the TiDB version. For example, 'TiDB Server (Apache License 2.0) Community Edition, MySQL 8.0 compatible'.

14.5.1.447 version_compile_machine

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: (string)
- This variable returns the name of the CPU architecture on which TiDB is running.

14.5.1.448 version_compile_os

- Scope: NONE
- Applies to hint SET_VAR: No
- Default value: (string)
- This variable returns the name of the OS on which TiDB is running.

14.5.1.449 wait_timeout

> **Note:**
>
> This variable is read-only for TiDB Cloud Serverless.

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Integer
- Default value: `28800`
- Range: `[0, 31536000]`
- Unit: Seconds
- This variable controls the idle timeout of user sessions. A zero-value means unlimited.

14.5.1.450 warning_count

- Scope: SESSION
- Applies to hint SET_VAR: No
- Default value: `0`
- This read-only variable indicates the number of warnings that occurred in the statement that was previously executed.

14.5.1.451 windowing_use_high_precision

- Scope: SESSION | GLOBAL
- Persists to cluster: Yes
- Applies to hint SET_VAR: No
- Type: Boolean
- Default value: `ON`
- This variable controls whether to use the high precision mode when computing the window functions.

14.6 Server Status Variables

Server status variables provide information about the global status of the server and the status of the current session in TiDB. Most of these variables are designed to be compatible with MySQL.

You can retrieve the global status using the SHOW GLOBAL STATUS command, and the status of the current session using the SHOW SESSION STATUS command.

Additionally, the FLUSH STATUS command is supported for MySQL compatibility.

14.6.1 Variable reference

14.6.1.1 Compression

- Scope: SESSION
- Type: Boolean
- Indicates if the MySQL Protocol uses compression or not.

14.6.1.2 Compression_algorithm

- Scope: SESSION
- Type: String
- Indicates the compression algorithm that is used for the MySQL Protocol.

14.6.1.3 Compression_level

- Scope: SESSION
- Type: Integer
- The compression level that is used for the MySQL Protocol.

14.6.1.4 Ssl_cipher

- Scope: SESSION | GLOBAL
- Type: String
- TLS Cipher that is in use.

14.6.1.5 Ssl_cipher_list

- Scope: SESSION | GLOBAL
- Type: String
- The list of TLS Ciphers that the server supports.

14.6.1.6 Ssl_server_not_after

- Scope: SESSION | GLOBAL
- Type: Date
- The expiration date of the X.509 certificate of the server that is used for TLS connections.

14.6.1.7 Ssl_server_not_before

- Scope: SESSION | GLOBAL
- Type: String
- The start date of the X.509 certificate of the server that is used for TLS connections.

14.6.1.8 Ssl_verify_mode

- Scope: SESSION | GLOBAL
- Type: Integer
- The TLS verification mode bitmask.

14.6.1.9 Ssl_version

- Scope: SESSION | GLOBAL
- Type: String
- The version of the TLS protocol that is used

14.6.1.10 Uptime

- Scope: SESSION | GLOBAL
- Type: Integer
- Uptime of the server in seconds.

14.6.1.11 ddl_schema_version

- Scope: SESSION | GLOBAL
- Type: Integer
- The version of the DDL schema that is used.

14.6.1.12 last_plan_binding_update_time New in v5.2.0

- Scope: SESSION
- Type: Timestamp
- The time and date of the last plan binding update.

14.6.1.13 server_id

- Scope: SESSION | GLOBAL
- Type: String
- The UUID of the server.

14.6.1.14 tidb_gc_last_run_time

- Scope: SESSION | GLOBAL
- Type: String
- The timestamp of the last run of GC.

14.6.1.15 tidb_gc_leader_desc

- Scope: SESSION | GLOBAL
- Type: String
- Information about GC leader, including the hostname and process id (pid).

14.6.1.16 tidb_gc_leader_lease

- Scope: SESSION | GLOBAL
- Type: String
- The timestamp of the GC lease.

14.6.1.17 tidb_gc_leader_uuid

- Scope: SESSION | GLOBAL
- Type: String
- The UUID of the GC leader.

14.6.1.18 tidb_gc_safe_point

- Scope: SESSION | GLOBAL
- Type: String
- The timestamp of the GC safe point.

14.7 Configuration File Parameters

14.7.1 TiDB Configuration File

The TiDB configuration file supports more options than command-line parameters. You can download the default configuration file `config.toml.example` and rename it to `config.toml`. This document describes only the options that are not involved in command line options.

> **Tip:**
>
> If you need to adjust the value of a configuration item, refer to Modify the configuration.

14.7.1.0.1 `split-table`

- Determines whether to create a separate Region for each table.
- Default value: `true`
- It is recommended to set it to `false` if you need to create a large number of tables (for example, more than 100 thousand tables).

14.7.1.0.2 `tidb-max-reuse-chunk` New in v6.4.0

- Controls the maximum cached chunk objects of chunk allocation. Setting this configuration item to too large a value might increase the risk of OOM.
- Default value: `64`
- Minimum value: `0`
- Maximum value: `2147483647`

14.7.1.0.3 `tidb-max-reuse-column` New in v6.4.0

- Controls the maximum cached column objects of chunk allocation. Setting this configuration item to too large a value might increase the risk of OOM.
- Default value: `256`
- Minimum value: `0`
- Maximum value: `2147483647`

14.7.1.0.4 `token-limit`

- The number of sessions that can execute requests concurrently.
- Type: Integer
- Default value: `1000`
- Minimum value: `1`
- Maximum value: `1048576`

14.7.1.0.5 `temp-dir` New in v6.3.0

- File system location used by TiDB to store temporary data. If a feature requires local storage in TiDB nodes, TiDB stores the corresponding temporary data in this location.
- When creating an index, if `tidb_ddl_enable_fast_reorg` is enabled, data that needs to be backfilled for a newly created index will be at first stored in the TiDB local temporary directory, and then imported into TiKV in batches, thus accelerating the index creation.
- When `IMPORT INTO` is used to import data, the sorted data is first stored in the TiDB local temporary directory, and then imported into TiKV in batches.
- Default value: `"/tmp/tidb"`

> **Note:**
>
> If the directory does not exist, TiDB will automatically create it upon startup. If the directory creation fails or TiDB does not have the read and write permissions on that directory, `Fast Online DDL` might experience unpredictable issues.

14.7.1.0.6 `oom-use-tmp-storage`

> **Warning:**
>
> Since v6.3.0, this configuration item is deprecated and superseded by the system variable `tidb_enable_tmp_storage_on_oom`. When the TiDB cluster is upgraded to v6.3.0 or a later version, it will automatically initialize the variable with the value of `oom-use-tmp-storage`. After that, changing the value of `oom-use-tmp-storage` **does not** take effect anymore.

- Controls whether to enable the temporary storage for some operators when a single SQL statement exceeds the memory quota specified by the system variable tidb_mem_quota_query.
- Default value: true

14.7.1.0.7 tmp-storage-path

- Specifies the temporary storage path for some operators when a single SQL statement exceeds the memory quota specified by the system variable tidb_mem_quota_query.
- Default value: <temporary directory of OS>/<OS user ID>_tidb/MC4wLjAuMDo0MDAwLzAuMC4wL=/tmp-storage. MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA= is the Base64 encoding result of <host>:<port>/<statusHost>:<statusPort>.
- This configuration takes effect only when the system variable tidb_enable_tmp_storage_on_oom is ON.

14.7.1.0.8 tmp-storage-quota

- Specifies the quota for the storage in tmp-storage-path. The unit is byte.
- When a single SQL statement uses a temporary disk and the total volume of the temporary disk of the TiDB server exceeds this configuration value, the current SQL operation is cancelled and the Out of Global Storage Quota! error is returned.
- When the value of this configuration is smaller than 0, the above check and limit do not apply.
- Default value: -1
- When the remaining available storage in tmp-storage-path is lower than the value defined by tmp-storage-quota, the TiDB server reports an error when it is started, and exits.

14.7.1.0.9 lease

- The timeout of the DDL lease.
- Default value: 45s
- Unit: second

14.7.1.0.10 compatible-kill-query

- Determines whether to set the KILL statement to be MySQL compatible.
- Default value: false
- compatible-kill-query takes effect only when enable-global-kill is set to false.
- When enable-global-kill is false, compatible-kill-query controls whether you need to append the TIDB keyword when killing a query.

  - When `compatible-kill-query` is `false`, the behavior of `KILL xxx` in TiDB is different from that in MySQL. To kill a query in TiDB, you need to append the `TIDB` keyword, such as `KILL TIDB xxx`.
  - When `compatible-kill-query` is `true`, to kill a query in TiDB, there is no need to append the `TIDB` keyword. It is **STRONGLY NOT RECOMMENDED** to set `compatible-kill-query` to `true` in your configuration file UNLESS you are certain that clients will be always connected to the same TiDB instance. This is because pressing Control+C in the default MySQL client opens a new connection in which `KILL` is executed. If there is a proxy between the client and the TiDB cluster, the new connection might be routed to a different TiDB instance, which possibly kills a different session by mistake.

- When `enable-global-kill` is `true`, `KILL xxx` and `KILL TIDB xxx` have the same effect.
- For more information about the `KILL` statement, see KILL [TIDB].

14.7.1.0.11 `check-mb4-value-in-utf8`

- Determines whether to enable the `utf8mb4` character check. When this feature is enabled, if the character set is `utf8` and the `mb4` characters are inserted in `utf8`, an error is returned.
- Default value: `false`
- Since v6.1.0, whether to enable the `utf8mb4` character check is determined by the TiDB configuration item `instance.tidb_check_mb4_value_in_utf8` or the system variable `tidb_check_mb4_value_in_utf8`. `check-mb4-value-in-utf8` still takes effect. But if both `check-mb4-value-in-utf8` and `instance.tidb_check_mb4_value_in_utf8` are set, the latter takes effect.

14.7.1.0.12 `treat-old-version-utf8-as-utf8mb4`

- Determines whether to treat the `utf8` character set in old tables as `utf8mb4`.
- Default value: `true`

14.7.1.0.13 `alter-primary-key` (Deprecated)

- Determines whether to add or remove the primary key constraint to or from a column.
- Default value: `false`
- With this default setting, adding or removing the primary key constraint is not supported. You can enable this feature by setting `alter-primary-key` to `true`. However, if a table already exists before the switch is on, and the data type of its primary key column is an integer, dropping the primary key from the column is not possible even if you set this configuration item to `true`.

Note:

This configuration item has been deprecated, and currently takes effect only when the value of `@tidb_enable_clustered_index` is `INT_ONLY`. If you need to add or remove the primary key, use the `NONCLUSTERED` keyword instead when creating the table. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

14.7.1.0.14 `server-version`

- Modifies the version string returned by TiDB in the following situations:
  - When the built-in `VERSION()` function is used.
  - When TiDB establishes the initial connection to the client and returns the initial handshake packet with version string of the server. For details, see MySQL Initial Handshake Packet.
- Default value: ""
- By default, the format of the TiDB version string is `8.0.11-TiDB-${tidb_version}`.

Note:

TiDB nodes use the value of `server-version` to verify the current TiDB version. Therefore, to avoid unexpected behaviors, before upgrading the TiDB cluster, you need to set the value of `server-version` to empty or the real version of the current TiDB cluster.

14.7.1.0.15 `repair-mode`

- Determines whether to enable the untrusted repair mode. When the `repair-mode` is set to `true`, bad tables in the `repair-table-list` cannot be loaded.
- Default value: `false`
- The `repair` syntax is not supported by default. This means that all tables are loaded when TiDB is started.

14.7.1.0.16 `repair-table-list`

- `repair-table-list` is only valid when `repair-mode` is set to `true`. `repair-table-list` is a list of bad tables that need to be repaired in an instance. An example of the list is: ["db.table1","db.table2"...].
- Default value: []
- The list is empty by default. This means that there are no bad tables that need to be repaired.

14.7.1.0.17 `new_collations_enabled_on_first_bootstrap`

- Enables or disables the new collation support.
- Default value: `true`
- Note: This configuration takes effect only for the TiDB cluster that is first initialized. After the initialization, you cannot use this configuration item to enable or disable the new collation support.

14.7.1.0.18 `max-server-connections`

- The maximum number of concurrent client connections allowed in TiDB. It is used to control resources.
- Default value: `0`
- By default, TiDB does not set limit on the number of concurrent client connections. When the value of this configuration item is greater than `0` and the number of actual client connections reaches this value, the TiDB server rejects new client connections.
- Since v6.2.0, the TiDB configuration item `instance.max_connections` or the system variable `max_connections` is used to set the maximum number of concurrent client connections allowed in TiDB. `max-server-connections` still takes effect. But if `max-server-connections` and `instance.max_connections` are set at the same time, the latter takes effect.

14.7.1.0.19 `max-index-length`

- Sets the maximum allowable length of the newly created index.
- Default value: `3072`
- Unit: byte
- Currently, the valid value range is `[3072, 3072*4]`. MySQL and TiDB (version < v3.0.11) do not have this configuration item, but both limit the length of the newly created index. This limit in MySQL is `3072`. In TiDB (version =< 3.0.7), this limit is `3072*4`. In TiDB (3.0.7 < version < 3.0.11), this limit is `3072`. This configuration is added to be compatible with MySQL and earlier versions of TiDB.

14.7.1.0.20 `table-column-count-limit` New in v5.0

- Sets the limit on the number of columns in a single table.
- Default value: `1017`
- Currently, the valid value range is `[1017, 4096]`.

14.7.1.0.21 `index-limit` New in v5.0

- Sets the limit on the number of indexes in a single table.
- Default value: `64`
- Currently, the valid value range is `[64, 512]`.

14.7.1.0.22 `enable-telemetry` New in v4.0.2 and deprecated in v8.1.0

> **Warning:**
>
> Starting from v8.1.0, the telemetry feature in TiDB is removed, and this configuration item is no longer functional. It is retained solely for compatibility with earlier versions.

- Before v8.1.0, this configuration item controls whether to enable telemetry collection in a TiDB instance.
- Default value: `false`

14.7.1.0.23 `deprecate-integer-display-length`

- Deprecates the display width for integer types when this configuration item is set to `true`.
- Default value: `false`

14.7.1.0.24 `enable-tcp4-only` New in v5.0

- Enables or disables listening on TCP4 only.
- Default value: `false`
- Enabling this option is useful when TiDB is used with LVS for load balancing because the real client IP from the TCP header can be correctly parsed by the "tcp4" protocol.

14.7.1.0.25 `enable-enum-length-limit` New in v5.0

- Determines whether to limit the maximum length of a single `ENUM` element and a single `SET` element.
- Default value: `true`
- When this configuration value is `true`, the maximum length of a single `ENUM` element and a single `SET` element is 255 characters, which is compatible with MySQL 8.0. When this configuration value is `false`, there is no limit on the length of a single element, which is compatible with TiDB (earlier than v5.0).

14.7.1.0.26 `graceful-wait-before-shutdown` New in v5.0

- Specifies the number of seconds that TiDB waits when you shut down the server, which allows the clients to disconnect.
- Default value: `0`
- When TiDB is waiting for shutdown (in the grace period), the HTTP status will indicate a failure, which allows the load balancers to reroute traffic.

> **Note:**
>
> The duration that TiDB waits before shutting down the server is also affected by the following parameters:
>
> - When you use a platform that employs SystemD, the default stop timeout is 90 seconds. If you need a longer timeout, you can set `TimeoutStopSec=`.
> - When you use the TiUP Cluster component, the default `--wait-timeout` is 120 seconds.
> - When you use Kubernetes, the default `terminationGracePeriodSeconds` is 30 seconds.

14.7.1.0.27 `enable-global-kill` New in v6.1.0

- Controls whether to enable the Global Kill (terminating queries or connections across instances) feature.
- Default value: `true`
- When the value is `true`, both `KILL` and `KILL TIDB` statements can terminate queries or connections across instances so you do not need to worry about erroneously terminating queries or connections. When you use a client to connect to any TiDB instance and execute the `KILL` or `KILL TIDB` statement, the statement will be forwarded to the target TiDB instance. If there is a proxy between the client and the TiDB cluster, the `KILL` and `KILL TIDB` statements will also be forwarded to the target TiDB instance for execution.
- Starting from v7.3.0, you can terminate a query or connection using the MySQL command line Control+C when both `enable-global-kill` and `enable-32bits-connection-id` are set to `true`. For more information, see `KILL`.

14.7.1.0.28 `enable-32bits-connection-id` New in v7.3.0

- Controls whether to enable the 32-bit connection ID feature.

- Default value: `true`
- When both this configuration item and `enable-global-kill` are set to `true`, TiDB generates 32-bit connection IDs. This enables you to terminate queries or connections by the MySQL command-line Control+C.

> **Warning:**
>
> When the number of TiDB instances in the cluster exceeds 2048 or the concurrent connection count of a single TiDB instance exceeds 1048576, the 32-bit connection ID space becomes insufficient and is automatically upgraded to 64-bit connection IDs. During the upgrade process, existing business and established connections are unaffected. However, subsequent new connections cannot be terminated using Control+C in the MySQL command-line.

14.7.1.0.29 `initialize-sql-file` New in v6.6.0

- Specifies the SQL script to be executed when the TiDB cluster is started for the first time.
- Default value: `""`
- All SQL statements in this script are executed with the highest privilege without any privilege check. If the specified SQL script fails to execute, the TiDB cluster might fail to start.
- This configuration item is used to perform such operations as modifying the value of a system variable, creating a user, or granting privileges.

14.7.1.0.30 `enable-forwarding` New in v5.0.0

- Controls whether the PD client and TiKV client in TiDB forward requests to the leader via the followers in the case of possible network isolation.
- Default value: `false`
- If the environment might have isolated network, enabling this parameter can reduce the window of service unavailability.
- If you cannot accurately determine whether isolation, network interruption, or downtime has occurred, using this mechanism has the risk of misjudgment and causes reduced availability and performance. If network failure has never occurred, it is not recommended to enable this parameter.

14.7.1.0.31 `enable-table-lock` New in v4.0.0

Warning:

The table lock is an experimental feature. It is not recommended that you use it in the production environment.

- Controls whether to enable the table lock feature.
- Default value: `false`
- The table lock is used to coordinate concurrent access to the same table among multiple sessions. Currently, the `READ`, `WRITE`, and `WRITE LOCAL` lock types are supported. When the configuration item is set to `false`, executing the `LOCK TABLES` or `UNLOCK TABLES` statement does not take effect and returns the "LOCK/UNLOCK TABLES is not supported" warning. For more information, see `LOCK TABLES` and `UNLOCK TABLES`.

14.7.1.0.32 `labels`

- Specify server labels. For example, `{ zone = "us-west-1", dc = "dc1", rack = "rack1", host = "tidb1" }`.
- Default value: `{}`

Note:

- In TiDB, the `zone` label is specially used to specify the zone where a server is located. If `zone` is set to a non-null value, the corresponding value is automatically used by features such as `txn-score` and `Follower read`.
- The `group` label has a special use in TiDB Operator. For clusters deployed using TiDB Operator, it is **NOT** recommended that you specify the `group` label manually.

14.7.1.1 Log

Configuration items related to log.

14.7.1.1.1 `level`

- Specifies the log output level.
- Value options: `debug`, `info`, `warn`, `error`, and `fatal`.
- Default value: `info`

14.7.1.1.2 `format`

- Specifies the log output format.
- Value options: `json` and `text`.
- Default value: `text`

14.7.1.1.3 `enable-timestamp`

- Determines whether to enable timestamp output in the log.
- Default value: `null`
- If you set the value to `false`, the log does not output timestamp.

> **Note:**
>
> - To be backward compatible, the initial `disable-timestamp` configuration item remains valid. But if the value of `disable-timestamp` semantically conflicts with the value of `enable-timestamp` (for example, if both `enable-timestamp` and `disable-timestamp` are set to `true`), TiDB ignores the value for `disable-timestamp`.
> - Currently, TiDB use `disable-timestamp` to determine whether to output timestamps in the log. In this situation, the value of `enable-timestamp` is `null`.
> - In later versions, the `disable-timestamp` configuration will be removed. Discard `disable-timestamp` and use `enable-timestamp` which is semantically easier to understand.

14.7.1.1.4 `enable-slow-log`

- Determines whether to enable the slow query log.
- Default value: `true`
- To enable the slow query log, set `enable-slow-log` to `true`. Otherwise, set it to `false`.
- Since v6.1.0, whether to enable slow query log is determined by the TiDB configuration item `instance.tidb_enable_slow_log` or the system variable `tidb_enable_slow_log`. `enable-slow-log` still takes effect. But if `enable-slow-log` and `instance.tidb_enable_slow_log` are set at the same time, the latter takes effect.

14.7.1.1.5 slow-query-file

- The file name of the slow query log.
- Default value: `tidb-slow.log`
- The format of the slow log is updated in TiDB v2.1.8, so the slow log is output to the slow log file separately. In versions before v2.1.8, this variable is set to "" by default.
- After you set it, the slow query log is output to this file separately.

14.7.1.1.6 slow-threshold

- Outputs the threshold value of consumed time in the slow log.
- Default value: `300`
- Unit: Milliseconds
- When the time consumed by a query is larger than this value, this query is considered as a slow query and its log is output to the slow query log. Note that when the output level of `log.level` is `"debug"`, all queries are recorded in the slow query log, regardless of the setting of this parameter.
- Since v6.1.0, the threshold value of consumed time in the slow log is specified by the TiDB configuration item `instance.tidb_slow_log_threshold` or the system variable `tidb_slow_log_threshold`. `slow-threshold` still takes effect. But if `slow-threshold` and `instance.tidb_slow_log_threshold` are set at the same time, the latter takes effect.

14.7.1.1.7 record-plan-in-slow-log

- Determines whether to record execution plans in the slow log.
- Default value: `1`
- Since v6.1.0, whether to record execution plans in the slow log is determined by the TiDB configuration item `instance.tidb_record_plan_in_slow_log` or the system variable `tidb_record_plan_in_slow_log`. `record-plan-in-slow-log` still takes effect. But if `record-plan-in-slow-log` and `instance.tidb_record_plan_in_slow_log` are set at the same time, the latter takes effect.

14.7.1.1.8 expensive-threshold

> **Warning:**
>
> Starting from v5.4.0, the `expensive-threshold` configuration item is deprecated and replaced by the system variable `tidb_expensive_query_time_threshold`.

- Outputs the threshold value of the number of rows for the `expensive` operation.
- Default value: `10000`
- When the number of query rows (including the intermediate results based on statistics) is larger than this value, it is an `expensive` operation and outputs log with the `[ ↪ EXPENSIVE_QUERY]` prefix.

14.7.1.1.9 `general-log-file` New in v8.0.0

- The filename of the general log.
- Default value: `""`
- If you specify a filename, the general log is written to this specified file. If the value is blank, the general log is written to the server log of the TiDB instance. You can specify the name of the server log using `filename`.

14.7.1.1.10 `timeout` New in v7.1.0

- Sets the timeout for log-writing operations in TiDB. In case of a disk failure that prevents logs from being written, this configuration item can trigger the TiDB process to panic instead of hang.
- Default value: `0`, indicating no timeout is set.
- Unit: second
- In some user scenarios, TiDB logs might be stored on hot-pluggable or network-attached disks, which might become permanently unavailable. In these cases, TiDB cannot recover automatically from such disaster and the log-writing operations will be permanently blocked. Although the TiDB process might seem to be running, it does not respond to any requests. This configuration item is designed to handle such situations.

14.7.1.2 log.file

Configuration items related to log files.

`filename`

- The file name of the general log file.
- Default value: “”
- If you set it, the log is output to this file.

`max-size`

- The size limit of the log file.
- Default value: 300
- Unit: MB
- The maximum value is 4096.

`max-days`

- The maximum number of days that the log is retained.
- Default value: `0`
- The log is retained by default. If you set the value, the expired log is cleaned up after `max-days`.

`max-backups`

- The maximum number of retained logs.
- Default value: `0`
- All the log files are retained by default. If you set it to `7`, seven log files are retained at maximum.

`compression` New in v8.0.0

- The compression method for the log.
- Default value: `""`
- Value options: `""`, `"gzip"`
- The default value is `""`, which means no compression. To enable the gzip compression, set this value to `"gzip"`. After compression is enabled, all log files are affected, such as `slow-query-file` and `general-log-file`.

14.7.1.3 Security

Configuration items related to security.

14.7.1.3.1 `enable-sem`

- Enables the Security Enhanced Mode (SEM).
- Default value: `false`
- The status of SEM is available via the system variable `tidb_enable_enhanced_security`.

14.7.1.3.2 `ssl-ca`

- The file path of the trusted CA certificate in the PEM format.
- Default value: “”
- If you set this option and `--ssl-cert`, `--ssl-key` at the same time, TiDB authenticates the client certificate based on the list of trusted CAs specified by this option when the client presents the certificate. If the authentication fails, the connection is terminated.
- If you set this option but the client does not present the certificate, the secure connection continues without client certificate authentication.

14.7.1.3.3 `ssl-cert`

- The file path of the SSL certificate in the PEM format.
- Default value: “”
- If you set this option and `--ssl-key` at the same time, TiDB allows (but not forces) the client to securely connect to TiDB using TLS.
- If the specified certificate or private key is invalid, TiDB starts as usual but cannot receive secure connection.

14.7.1.3.4 `ssl-key`

- The file path of the SSL certificate key in the PEM format, that is, the private key of the certificate specified by `--ssl-cert`.
- Default value: “”
- Currently, TiDB does not support loading the private keys protected by passwords.

14.7.1.3.5 `cluster-ssl-ca`

- The CA root certificate used to connect TiKV or PD with TLS.
- Default value: “”

14.7.1.3.6 `cluster-ssl-cert`

- The path of the SSL certificate file used to connect TiKV or PD with TLS.
- Default value: “”

14.7.1.3.7 `cluster-ssl-key`

- The path of the SSL private key file used to connect TiKV or PD with TLS.
- Default value: “”

14.7.1.3.8 `cluster-verify-cn`

- A list of acceptable X.509 Common Names in certificates presented by clients. Requests are permitted only when the presented Common Name is an exact match with one of the entries in the list.
- Default value: [], which means that the client certificate CN check is disabled.

14.7.1.3.9 `spilled-file-encryption-method`

- Determines the encryption method used for saving the spilled files to disk.
- Default value: `"plaintext"`, which disables encryption.
- Optional values: `"plaintext"` and `"aes128-ctr"`

14.7.1.3.10 `auto-tls`

- Determines whether to automatically generate the TLS certificates on startup.
- Default value: `false`

14.7.1.3.11 `tls-version`

> **Warning:**
>
> `"TLSv1.0"` and `"TLSv1.1"` protocols are deprecated in TiDB v7.6.0, and will be removed in v8.0.0.

- Set the minimum TLS version for MySQL Protocol connections.
- Default value: "", which allows TLSv1.2 or later versions. Before TiDB v7.6.0, the default value allows TLSv1.1 or later versions.
- Optional values: `"TLSv1.2"` and `"TLSv1.3"`. Before TiDB v8.0.0, `"TLSv1.0"` and `"TLSv1.1"` are also allowed.

14.7.1.3.12 `auth-token-jwks` New in v6.4.0

- Set the local file path of the JSON Web Key Sets (JWKS) for the `tidb_auth_token` authentication method.
- Default value: `""`

14.7.1.3.13 `auth-token-refresh-interval` New in v6.4.0

- Set the JWKS refresh interval for the `tidb_auth_token` authentication method.
- Default value: `1h`

14.7.1.3.14 `disconnect-on-expired-password` New in v6.5.0

- Determines whether TiDB disconnects the client connection when the password is expired.
- Default value: `true`
- Optional values: `true`, `false`
- If you set it to `true`, the client connection is disconnected when the password is expired. If you set it to `false`, the client connection is restricted to the "sandbox mode" and the user can only execute the password reset operation.

14.7.1.3.15 `session-token-signing-cert` New in v6.4.0

- The certificate file path, which is used by TiProxy for session migration.
- Default value: ""
- Empty value will cause TiProxy session migration to fail. To enable session migration, all TiDB nodes must set this to the same certificate and key. This means that you should store the same certificate and key on every TiDB node.

14.7.1.3.16 `session-token-signing-key` New in v6.4.0

- The key file path used by TiProxy for session migration.
- Default value: ""
- Refer to the descriptions of `session-token-signing-cert`.

14.7.1.4 Performance

Configuration items related to performance.

14.7.1.4.1 `max-procs`

- The number of CPUs used by TiDB.
- Default value: `0`
- The default `0` indicates using all the CPUs on the machine. You can also set it to n, and then TiDB uses n CPUs.

14.7.1.4.2 `server-memory-quota` New in v4.0.9

> **Warning:**
>
> Since v6.5.0, the `server-memory-quota` configuration item is deprecated and replaced by the system variable `tidb_server_memory_limit`.

- The memory usage limit of tidb-server instances.
- Default value: `0` (in bytes), which means no memory limit.

14.7.1.4.3 `max-txn-ttl`

- The longest time that a single transaction can hold locks. If this time is exceeded, the locks of a transaction might be cleared by other transactions so that this transaction cannot be successfully committed.

- Default value: `3600000`
- Unit: Millisecond
- The transaction that holds locks longer than this time can only be committed or rolled back. The commit might not be successful.
- For transactions executed using the `"bulk"` DML mode, the maximum TTL can exceed the limit of this configuration item. The maximum value is the greater value between this configuration item and 24 hours.

14.7.1.4.4 `stmt-count-limit`

- The maximum number of statements allowed in a single TiDB transaction.
- Default value: `5000`
- If a transaction does not roll back or commit after the number of statements exceeds `stmt-count-limit`, TiDB returns the `statement count 5001 exceeds the transaction limitation, autocommit = false` error. This configuration takes effect **only** in the retryable optimistic transaction. If you use the pessimistic transaction or have disabled the transaction retry, the number of statements in a transaction is not limited by this configuration.

14.7.1.4.5 `txn-entry-size-limit` New in v4.0.10 and v5.0.0

- The size limit of a single row of data in TiDB.
- Default value: `6291456` (in bytes)
- The size limit of a single key-value record in a transaction. If the size limit is exceeded, TiDB returns the `entry too large` error. The maximum value of this configuration item does not exceed `125829120` (120 MB).
- Starting from v7.6.0, you can use the system variable `tidb_txn_entry_size_limit` to dynamically modify the value of this configuration item.
- Note that TiKV has a similar limit. If the data size of a single write request exceeds `raft-entry-max-size`, which is 8 MB by default, TiKV refuses to process this request. When a table has a row of large size, you need to modify both configurations at the same time.
- The default value of `max_allowed_packet` (the maximum size of a packet for the MySQL protocol) is 67108864 (64 MiB). If a row is larger than `max_allowed_packet`, the row gets truncated.
- The default value of `txn-total-size-limit` (the size limit of a single transaction in TiDB) is 100 MiB. If you increase the `txn-entry-size-limit` value to be over 100 MiB, you need to increase the `txn-total-size-limit` value accordingly.

14.7.1.4.6 `txn-total-size-limit`

- The size limit of a single transaction in TiDB.
- Default value: `104857600` (in bytes)

- In a single transaction, the total size of key-value records cannot exceed this value. The maximum value of this parameter is `1099511627776` (1 TB).
- In TiDB v6.5.0 and later versions, this configuration is no longer recommended. The memory size of a transaction will be accumulated into the memory usage of the session, and the `tidb_mem_quota_query` variable will take effect when the session memory threshold is exceeded. To be compatible with previous versions, this configuration works as follows when you upgrade from an earlier version to TiDB v6.5.0 or later:
    - If this configuration is not set or is set to the default value (`104857600`), after an upgrade, the memory size of a transaction will be accumulated into the memory usage of the session, and the `tidb_mem_quota_query` variable will take effect.
    - If this configuration is not defaulted (`104857600`), it still takes effect and its behavior on controlling the size of a single transaction remains unchanged before and after the upgrade. This means that the memory size of the transaction is not controlled by the `tidb_mem_quota_query` variable.
- When TiDB executes transactions in the `tidb_dml_type` `"bulk"` mode, transaction size is not limited by the TiDB configuration item `txn-total-size-limit`.

14.7.1.4.7 `tcp-keep-alive`

- Determines whether to enable `keepalive` in the TCP layer.
- Default value: `true`

14.7.1.4.8 `tcp-no-delay`

- Determines whether to enable TCP_NODELAY at the TCP layer. After it is enabled, TiDB disables the Nagle algorithm in the TCP/IP protocol and allows sending small data packets to reduce network latency. This is suitable for latency-sensitive applications with a small transmission volume of data.
- Default value: `true`

14.7.1.4.9 `cross-join`

- Default value: `true`
- TiDB supports executing the `JOIN` statement without any condition (the `WHERE` field) of both sides tables by default; if you set the value to `false`, the server refuses to execute when such a `JOIN` statement appears.

> **Note:**
>
> When creating a cluster, **DO NOT** set `cross-join` to false. Otherwise, the cluster will fail to start up.

14.7.1.4.10 `stats-lease`

- The time interval of reloading statistics, updating the number of table rows, checking whether it is needed to perform the automatic analysis, using feedback to update statistics and loading statistics of columns.
- Default value: `3s`
    - At intervals of `stats-lease` time, TiDB checks the statistics for updates and updates them to the memory if updates exist.
    - At intervals of `20 * stats-lease` time, TiDB updates the total number of rows generated by DML and the number of modified rows to the system table.
    - At intervals of `stats-lease`, TiDB checks for tables and indexes that need to be automatically analyzed.
    - At intervals of `stats-lease`, TiDB checks for column statistics that need to be loaded to the memory.
    - At intervals of `200 * stats-lease`, TiDB writes the feedback cached in the memory to the system table.
    - At intervals of `5 * stats-lease`, TiDB reads the feedback in the system table, and updates the statistics cached in the memory.
- When `stats-lease` is set to 0s, TiDB periodically reads the feedback in the system table, and updates the statistics cached in the memory every three seconds. But TiDB no longer automatically modifies the following statistics-related system tables:
    - `mysql.stats_meta`: TiDB no longer automatically records the number of table rows that are modified by the transaction and updates it to this system table.
    - `mysql.stats_histograms`/`mysql.stats_buckets` and `mysql.stats_top_n`: TiDB no longer automatically analyzes and proactively updates statistics.
    - `mysql.stats_feedback`: TiDB no longer updates the statistics of the tables and indexes according to a part of statistics returned by the queried data.

14.7.1.4.11 `pseudo-estimate-ratio`

- The ratio of (number of modified rows)/(total number of rows) in a table. If the value is exceeded, the system assumes that the statistics have expired and the pseudo statistics will be used.
- Default value: `0.8`
- The minimum value is `0` and the maximum value is `1`.

14.7.1.4.12 `force-priority`

- Sets the priority for all statements.
- Default value: `NO_PRIORITY`
- Value options: The default value `NO_PRIORITY` means that the priority for statements is not forced to change. Other options are `LOW_PRIORITY`, `DELAYED`, and `HIGH_PRIORITY` in ascending order.

- Since v6.1.0, the priority for all statements is determined by the TiDB configuration item instance.tidb_force_priority or the system variable tidb_force_priority. force-priority still takes effect. But if force-priority and instance.tidb_force_priority are set at the same time, the latter takes effect.

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.7.1.4.13 distinct-agg-push-down

- Determines whether the optimizer executes the operation that pushes down the aggregation function with Distinct (such as select count(distinct a)from t) to Coprocessors.
- Default: false
- This variable is the initial value of the system variable tidb_opt_distinct_agg_push_down.

14.7.1.4.14 enforce-mpp

- Determines whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution.
- Default value: false
- This configuration item controls the initial value of tidb_enforce_mpp. For example, when this configuration item is set to true, the default value of tidb_enforce_mpp is ON.

14.7.1.4.15 enable-stats-cache-mem-quota New in v6.1.0

- Controls whether to enable the memory quota for the statistics cache.
- Default value: true

14.7.1.4.16 `stats-load-concurrency` New in v5.4.0

- The maximum number of columns that the TiDB synchronously loading statistics feature can process concurrently.
- Default value: `0`. Before v8.2.0, the default value is `5`.
- Currently, the valid value range is `[0, 128]`. The value `0` means the automatic mode, which automatically adjusts concurrency based on the configuration of the server. Before v8.2.0, the minimum value is `1`.

14.7.1.4.17 `stats-load-queue-size` New in v5.4.0

- The maximum number of column requests that the TiDB synchronously loading statistics feature can cache.
- Default value: `1000`
- Currently, the valid value range is `[1, 100000]`.

14.7.1.4.18 `concurrently-init-stats` New in v8.1.0 and v7.5.2

- Controls whether to initialize statistics concurrently during TiDB startup. This configuration item takes effect only when `lite-init-stats` is set to `false`.
- Default value: `false` for versions earlier than v8.2.0, `true` for v8.2.0 and later versions.

14.7.1.4.19 `lite-init-stats` New in v7.1.0

- Controls whether to use lightweight statistics initialization during TiDB startup.
- Default value: `false` for versions earlier than v7.2.0, `true` for v7.2.0 and later versions.
- When the value of `lite-init-stats` is `true`, statistics initialization does not load any histogram, TopN, or Count-Min Sketch of indexes and columns into memory. When the value of `lite-init-stats` is `false`, statistics initialization loads histograms, TopN, and Count-Min Sketch of indexes into memory but does not load any histogram, TopN, or Count-Min Sketch of primary keys and columns into memory. When the optimizer needs the histogram, TopN, and Count-Min Sketch of a specific primary key or column, the necessary statistics are loaded into memory synchronously or asynchronously (controlled by `tidb_stats_load_sync_wait`).
- Setting `lite-init-stats` to `true` speeds up statistics initialization and reduces TiDB memory usage by avoiding unnecessary statistics loading. For details, see Load statistics.

14.7.1.4.20 `force-init-stats` New in v6.5.7 and v7.1.0

- Controls whether to wait for statistics initialization to finish before providing services during TiDB startup.

- Default value: `false` for versions earlier than v7.2.0, `true` for v7.2.0 and later versions.
- When the value of `force-init-stats` is `true`, TiDB needs to wait until statistics initialization is finished before providing services upon startup. Note that if there are a large number of tables and partitions and the value of `lite-init-stats` is `false`, setting `force-init-stats` to `true` might prolong the time it takes for TiDB to start providing services.
- When the value of `force-init-stats` is `false`, TiDB can still provide services before statistics initialization is finished, but the optimizer uses pseudo statistics to make decisions, which might result in suboptimal execution plans.

14.7.1.5 opentracing

Configuration items related to opentracing.

14.7.1.5.1 `enable`

- Enables opentracing to trace the call overhead of some TiDB components. Note that enabling opentracing causes some performance loss.
- Default value: `false`

14.7.1.5.2 `rpc-metrics`

- Enables RPC metrics.
- Default value: `false`

14.7.1.6 opentracing.sampler

Configuration items related to opentracing.sampler.

14.7.1.6.1 `type`

- Specifies the type of the opentracing sampler. The string value is case-insensitive.
- Default value: `"const"`
- Value options: `"const"`, `"probabilistic"`, `"ratelimiting"`, `"remote"`

14.7.1.6.2 `param`

- The parameter of the opentracing sampler.
  - For the `const` type, the value can be `0` or `1`, which indicates whether to enable the `const` sampler.
  - For the `probabilistic` type, the parameter specifies the sampling probability, which can be a float number between `0` and `1`.

- For the `ratelimiting` type, the parameter specifies the number of spans sampled per second.
- For the `remote` type, the parameter specifies the sampling probability, which can be a float number between `0` and `1`.

- Default value: `1.0`

14.7.1.6.3 `sampling-server-url`

- The HTTP URL of the jaeger-agent sampling server.
- Default value: `""`

14.7.1.6.4 `max-operations`

- The maximum number of operations that the sampler can trace. If an operation is not traced, the default probabilistic sampler is used.
- Default value: `0`

14.7.1.6.5 `sampling-refresh-interval`

- Controls the frequency of polling the jaeger-agent sampling policy.
- Default value: `0`

14.7.1.7 opentracing.reporter

Configuration items related to opentracing.reporter.

14.7.1.7.1 `queue-size`

- The queue size with which the reporter records spans in memory.
- Default value: `0`

14.7.1.7.2 `buffer-flush-interval`

- The interval at which the reporter flushes the spans in memory to the storage.
- Default value: `0`

14.7.1.7.3 `log-spans`

- Determines whether to print the log for all submitted spans.
- Default value: `false`

14.7.1.7.4 `local-agent-host-port`

- The address at which the reporter sends spans to the jaeger-agent.
- Default value: `""`

14.7.1.8 tikv-client

14.7.1.8.1 `grpc-connection-count`

- The maximum number of connections established with each TiKV.
- Default value: `4`

14.7.1.8.2 `grpc-keepalive-time`

- The `keepalive` time interval of the RPC connection between TiDB and TiKV nodes. If there is no network packet within the specified time interval, the gRPC client executes `ping` command to TiKV to see if it is alive.
- Default: `10`
- Minimum value: `1`
- Unit: second

14.7.1.8.3 `grpc-keepalive-timeout`

- The timeout of the RPC `keepalive` check between TiDB and TiKV nodes.
- Default value: `3`
- Minimum value: `0.05`
- Unit: second

14.7.1.8.4 `grpc-compression-type`

- Specifies the compression type used for data transfer from TiDB nodes to TiKV nodes. The default value is `"none"`, which means no compression. To enable the gzip compression, set this value to `"gzip"`.
- Default value: `"none"`
- Value options: `"none"`, `"gzip"`

> **Note:**
>
> The compression algorithm for response messages returned from TiKV nodes to TiDB nodes is controlled by the TiKV configuration item `grpc-compression-type`.

14.7.1.8.5 `commit-timeout`

- The maximum timeout when executing a transaction commit.
- Default value: `41s`
- It is required to set this value larger than twice of the Raft election timeout.

14.7.1.8.6 `batch-policy` New in v8.3.0

- Controls the batching strategy for requests from TiDB to TiKV. When sending requests to TiKV, TiDB always encapsulates the requests in the current waiting queue into a `BatchCommandsRequest` and sends it to TiKV as a packet. This is the basic batching strategy. When the TiKV load throughput is high, TiDB decides whether to wait for an additional period after the basic batching based on the value of `batch-policy` ↪ . This additional batching allows more requests to be encapsulated in a single `BatchCommandsRequest`.
- Default value: `"standard"`
- Value options:
  - `"basic"`: the behavior is consistent with versions before v8.3.0, where TiDB performs additional batching only if `tikv-client.max-batch-wait-time` is greater than 0 and the load of TiKV exceeds the value of `tikv-client.overload-` ↪ `threshold`.
  - `"standard"`: TiDB dynamically batches requests based on the arrival time intervals of recent requests, suitable for high-throughput scenarios.
  - `"positive"`: TiDB always performs additional batching, suitable for high-throughput testing scenarios to achieve optimal performance. However, in low-load scenarios, this strategy might introduce unnecessary batching wait time, potentially reducing performance.
  - `"custom{...}"`: allows customization of batching strategy parameters. This option is intended for the internal testing of TiDB and is **NOT recommended** for general use.

14.7.1.8.7 `max-batch-size`

- The maximum number of RPC packets sent in batch. If the value is not `0`, the `BatchCommands` API is used to send requests to TiKV, and the RPC latency can be reduced in the case of high concurrency. It is recommended that you do not modify this value.
- Default value: `128`

14.7.1.8.8 `max-batch-wait-time`

- Waits for `max-batch-wait-time` to encapsulate the data packets into a large packet in batch and send it to the TiKV node. It is valid only when the value of `tikv-client.max-batch-size` is greater than `0`. It is recommended not to modify this value.
- Default value: `0`
- Unit: nanoseconds

14.7.1.8.9 `batch-wait-size`

- The maximum number of packets sent to TiKV in batch. It is recommended not to modify this value.
- Default value: `8`
- If the value is `0`, this feature is disabled.

14.7.1.8.10 `overload-threshold`

- The threshold of the TiKV load. If the TiKV load exceeds this threshold, more `batch` packets are collected to relieve the pressure of TiKV. It is valid only when the value of `tikv-client.max-batch-size` is greater than `0`. It is recommended not to modify this value.
- Default value: `200`

14.7.1.8.11 `copr-req-timeout` New in v7.5.0

> **Warning:**
>
> This configuration parameter might be deprecated in future versions. **DO NOT** change the value of it.

- The timeout of a single Coprocessor request.
- Default value: `60`
- Unit: second

14.7.1.8.12 `enable-replica-selector-v2` New in v8.0.0

> **Warning:**
>
> Starting from v8.2.0, this configuration item is deprecated. The new version of the Region replica selector is used by default when sending RPC requests to TiKV.

- Whether to use the new version of the Region replica selector when sending RPC requests to TiKV.
- Default value: `true`

14.7.1.9 tikv-client.copr-cache New in v4.0.0

This section introduces configuration items related to the Coprocessor Cache feature.

14.7.1.9.1 `capacity-mb`

- The total size of the cached data. When the cache space is full, old cache entries are evicted. When the value is `0.0`, the Coprocessor Cache feature is disabled.
- Default value: `1000.0`
- Unit: MB
- Type: Float

14.7.1.10 txn-local-latches

Configuration items related to the transaction latch. These configuration items might be deprecated in the future. It is not recommended to use them.

14.7.1.10.1 `enabled`

- Determines whether to enable the memory lock of transactions.
- Default value: `false`

14.7.1.10.2 `capacity`

- The number of slots corresponding to Hash, which automatically adjusts upward to an exponential multiple of 2. Each slot occupies 32 Bytes of memory. If set too small, it might result in slower running speed and poor performance in the scenario where data writing covers a relatively large range (such as importing data).
- Default value: `2048000`

14.7.1.11 status

Configuration related to the status of TiDB service.

14.7.1.11.1 `report-status`

- Enables or disables the HTTP API service.
- Default value: `true`

14.7.1.11.2 `record-db-qps`

- Determines whether to transmit the database-related QPS metrics to Prometheus.
- Default value: `false`

14.7.1.11.3 `record-db-label`

- Determines whether to transmit the database-related QPS metrics to Prometheus.
- Supports more metircs types than `record-db-qps`, for example, duration and statements.
- Default value: `false`

14.7.1.12 pessimistic-txn

For pessimistic transaction usage, refer to TiDB Pessimistic Transaction Mode.

14.7.1.12.1 max-retry-count

- The maximum number of retries of each statement in pessimistic transactions. If the number of retries exceeds this limit, an error occurs.
- Default value: `256`

14.7.1.12.2 deadlock-history-capacity

- The maximum number of deadlock events that can be recorded in the `INFORMATION_SCHEMA.DEADLOCKS` table of a single TiDB server. If this table is in full volume and an additional deadlock event occurs, the earliest record in the table will be removed to make place for the newest error.
- Default value: `10`
- Minimum value: `0`
- Maximum value: `10000`

14.7.1.12.3 deadlock-history-collect-retryable

- Controls whether the `INFORMATION_SCHEMA.DEADLOCKS` table collects the information of retryable deadlock errors. For the description of retryable deadlock errors, see Retryable deadlock errors.
- Default value: `false`

14.7.1.12.4 pessimistic-auto-commit New in v6.0.0

- Determines the transaction mode that the auto-commit transaction uses when the pessimistic transaction mode is globally enabled (`tidb_txn_mode='pessimistic'`). By default, even if the pessimistic transaction mode is globally enabled, the auto-commit transaction still uses the optimistic transaction mode. After enabling `pessimistic-auto-commit` (set to `true`), the auto-commit transaction also uses pessimistic mode, which is consistent with the other explicitly committed pessimistic transactions.
- For scenarios with conflicts, after enabling this configuration, TiDB includes auto-commit transactions into the global lock-waiting management, which avoids deadlocks and mitigates the latency spike brought by deadlock-causing conflicts.
- For scenarios with no conflicts, if there are many auto-commit transactions (the specific number is determined by the real scenarios. For example, the number of auto-commit transactions accounts for more than half of the total number of applications), and a single transaction operates a large data volume, enabling this configuration causes performance regression. For example, the auto-commit `INSERT INTO SELECT` statement.
- When the session-level system variable `tidb_dml_type` is set to `"bulk"`, the effect of this configuration in the session is equivalent to setting it to `false`.
- Default value: `false`

14.7.1.12.5 constraint-check-in-place-pessimistic New in v6.4.0

- Controls the default value of the system variable `tidb_constraint_check_in_place_pessimistic`.
- Default value: `true`

14.7.1.13 isolation-read

Configuration items related to read isolation.

14.7.1.13.1 engines

- Controls from which engine TiDB allows to read data.
- Default value: ["tikv", "tiflash", "tidb"], indicating that the engine is automatically selected by the optimizer.
- Value options: Any combinations of "tikv", "tiflash", and "tidb", for example, ["tikv", "tidb"] or ["tiflash", "tidb"]

14.7.1.14 instance

14.7.1.14.1 `tidb_enable_collect_execution_info`

- This configuration controls whether to record the execution information of each operator in the slow query log and whether to record the usage statistics of indexes.
- Default value: `true`
- Before v6.1.0, this configuration is set by `enable-collect-execution-info`.

14.7.1.14.2 `tidb_enable_slow_log`

- This configuration is used to control whether to enable the slow log feature.
- Default value: `true`
- Value options: `true` or `false`
- Before v6.1.0, this configuration is set by `enable-slow-log`.

14.7.1.14.3 `tidb_slow_log_threshold`

- Outputs the threshold value of the time consumed by the slow log.
- Default value: `300`
- Range: `[-1, 9223372036854775807]`
- Unit: Milliseconds
- When the time consumed by a query is larger than this value, this query is considered as a slow query and its log is output to the slow query log. Note that when the output level of `log.level` is `"debug"`, all queries are recorded in the slow query log, regardless of the setting of this parameter.
- Before v6.1.0, this configuration is set by `slow-threshold`.

14.7.1.14.4 `in-mem-slow-query-topn-num` New in v7.3.0

- The configuration controls the number of slowest queries that are cached in memory.
- Default value: 30

14.7.1.14.5 `in-mem-slow-query-recent-num` New in v7.3.0

- The configuration controls the number of recently used slow queries that are cached in memory.
- Default value: 500

14.7.1.14.6 `tidb_expensive_query_time_threshold`

- This configuration is used to set the threshold value that determines whether to print expensive query logs. The difference between expensive query logs and slow query logs is:
  - Slow logs are printed after the statement is executed.
  - Expensive query logs print the statements that are being executed, with execution time exceeding the threshold value, and their related information.
- Default value: `60`
- Range: `[10, 2147483647]`
- Unit: Seconds
- Before v5.4.0, this configuration is set by `expensive-threshold`.

14.7.1.14.7 `tidb_record_plan_in_slow_log`

- This configuration is used to control whether to include the execution plan of slow queries in the slow log.
- Default value: `1`
- Value options: `1` (enabled, default) or `0` (disabled).
- The value of this configuration will initialize the value of system variable `tidb_record_plan_in_slow_log`
- Before v6.1.0, this configuration is set by `record-plan-in-slow-log`.

14.7.1.14.8 `tidb_force_priority`

- This configuration is used to change the default priority for statements executed on a TiDB server.
- Default value: `NO_PRIORITY`
- The default value `NO_PRIORITY` means that the priority for statements is not forced to change. Other options are `LOW_PRIORITY`, `DELAYED`, and `HIGH_PRIORITY` in ascending order.
- Before v6.1.0, this configuration is set by `force-priority`.

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.7.1.14.9 `max_connections`

- The maximum number of connections permitted for a single TiDB instance. It can be used for resources control.
- Default value: `0`
- Range: `[0, 100000]`
- The default value `0` means no limit. When the value of this variable is larger than `0`, and the number of connections reaches the value, the TiDB server will reject new connections from clients.
- The value of this configuration will initialize the value of system variable `max_connections`
- Before v6.2.0, this configuration is set by `max-server-connections`.

14.7.1.14.10 `tidb_enable_ddl`

- This configuration controls whether the corresponding TiDB instance can become a DDL owner or not.
- Default value: `true`
- Possible values: `OFF`, `ON`
- The value of this configuration will initialize the value of the system variable `tidb_enable_ddl`
- Before v6.3.0, this configuration is set by `run-ddl`.

14.7.1.14.11 `tidb_enable_stats_owner` New in v8.4.0

- This configuration controls whether the corresponding TiDB instance can run automatic statistics update tasks.
- Default value: `true`
- Possible values: `true`, `false`
- The value of this configuration will initialize the value of the system variable `tidb_enable_stats_owner`.

14.7.1.14.12 `tidb_stmt_summary_enable_persistent` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Controls whether to enable statements summary persistence.
- Default value: `false`
- For more details, see Persist statements summary.

14.7.1.14.13 `tidb_stmt_summary_filename` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the file to which persistent data is written.
- Default value: `tidb-statements.log`

14.7.1.14.14 `tidb_stmt_summary_file_max_days` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the maximum number of days to keep persistent data files.
- Default value: `3`
- Unit: day
- You can adjust the value based on the data retention requirements and disk space usage.

14.7.1.14.15 `tidb_stmt_summary_file_max_size` New in v6.6.0

Warning:

Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the maximum size of a persistent data file.
- Default value: `64`
- Unit: MiB
- You can adjust the value based on the data retention requirements and disk space usage.

14.7.1.14.16 `tidb_stmt_summary_file_max_backups` New in v6.6.0

Warning:

Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the maximum number of data files that can be persisted. `0` means no limit on the number of files.
- Default value: `0`
- You can adjust the value based on the data retention requirements and disk space usage.

14.7.1.15 proxy-protocol

Configuration items related to the PROXY protocol.

14.7.1.15.1 `networks`

- The list of proxy server's IP addresses allowed to connect to TiDB using the PROXY protocol
- Default value: ""

- In general cases, when you access TiDB behind a reverse proxy, TiDB takes the IP address of the reverse proxy server as the IP address of the client. By enabling the PROXY protocol, reverse proxies that support this protocol, such as HAProxy, can pass the real client IP address to TiDB.
- After configuring this parameter, TiDB allows the configured source IP address to connect to TiDB using the PROXY protocol; if a protocol other than PROXY is used, this connection will be denied. If this parameter is left empty, no IP address can connect to TiDB using the PROXY protocol. The value can be an IP address (192.168.1.50) or CIDR (192.168.1.0/24) with `,` as the separator. `*` means any IP addresses.

> **Warning:**
>
> Use `*` with caution because it might introduce security risks by allowing a client of any IP address to report its IP address. In addition, using `*` might also cause the internal component that directly connects to TiDB (such as TiDB Dashboard) to be unavailable.

14.7.1.15.2 `fallbackable` New in v6.5.1

- Controls whether to enable the PROXY protocol fallback mode. If this configuration item is set to `true`, TiDB can accept clients that belong to `proxy-protocol.networks` ↪ to connect to TiDB without using the PROXY protocol specification or without sending the PROXY protocol header. By default, TiDB only accepts client connections that belong to `proxy-protocol.networks` and send a PROXY protocol header.
- Default value: `false`

14.7.1.16 experimental

The `experimental` section, introduced in v3.1.0, describes the configurations related to the experimental features of TiDB.

14.7.1.16.1 `allow-expression-index` New in v4.0.0

- Controls whether an expression index can be created. Since TiDB v5.2.0, if the function in an expression is safe, you can create an expression index directly based on this function without enabling this configuration. If you want to create an expression index based on other functions, you can enable this configuration, but correctness issues might exist. By querying the `tidb_allow_function_for_expression_index` variable, you can get the functions that are safe to be directly used for creating an expression.
- Default value: `false`

14.7.2 TiKV Configuration File

The TiKV configuration file supports more options than command-line parameters. You can find the default configuration file in etc/config-template.toml and rename it to `config.toml`.

This document only describes the parameters that are not included in command-line parameters. For more details, see command-line parameter.

> **Tip:**
>
> If you need to adjust the value of a configuration item, refer to Modify the configuration.

14.7.2.1 Global configuration

14.7.2.1.1 `abort-on-panic`

- Sets whether to call `abort()` to exit the process when TiKV panics. This option affects whether TiKV allows the system to generate core dump files.
  - If the value of this configuration item is `false`, when TiKV panics, it calls `exit()` to exit the process.
  - If the value of this configuration item is `true`, when TiKV panics, TiKV calls `abort()` to exit the process. At this time, TiKV allows the system to generate core dump files when exiting. To generate the core dump file, you also need to perform the system configuration related to core dump (for example, setting the size limit of the core dump file via `ulimit -c` command, and configure the core dump path. Different operating systems have different related configurations). To avoid the core dump files occupying too much disk space and causing insufficient TiKV disk space, it is recommended to set the core dump generation path to a disk partition different to that of TiKV data.
- Default value: `false`

14.7.2.1.2 `slow-log-file`

- The file that stores slow logs
- If this configuration item is not set, but `log.file.filename` is set, slow logs are output to the log file specified by `log.file.filename`.
- If neither `slow-log-file` nor `log.file.filename` are set, all logs are output to "stderr" by default.

- If both configuration items are set, ordinary logs are output to the log file specified by `log.file.filename`, and slow logs are output to the log file set by `slow-log-file`.
- Default value: `""`

14.7.2.1.3 `slow-log-threshold`

- The threshold for outputting slow logs. If the processing time is longer than this threshold, slow logs are output.
- Default value: `"1s"`

14.7.2.1.4 `memory-usage-limit`

- The limit on memory usage of the TiKV instance. When the memory usage of TiKV almost reaches this threshold, internal cache will be evicted to release memory.
- In most cases, the TiKV instance is set to use 75% of the total available system memory, so you do not need to explicitly specify this configuration item. The rest 25% of the memory is reserved for the OS page cache. See `storage.block-cache.capacity` for details.
- When deploying multiple TiKV nodes on a single physical machine, you still do not need to set this configuration item. In this case, the TiKV instance uses `5/3 * block -cache.capacity` of memory.
- The default value for different system memory capacity is as follows:
  - system=8G block-cache=3.6G memory-usage-limit=6G page-cache=2G
  - system=16G block-cache=7.2G memory-usage-limit=12G page-cache=4G
  - system=32G block-cache=14.4G memory-usage-limit=24G page-cache=8G

14.7.2.2 log New in v5.4.0

- Configuration items related to the log.
- From v5.4.0, to make the log configuration items of TiKV and TiDB consistent, TiKV deprecates the former configuration item `log-rotation-timespan` and changes `log-level`, `log-format`, `log-file`, `log-rotation-size` to the following ones. If you only set the old configuration items, and their values are set to non-default values, the old items remain compatible with the new items. If both old and new configuration items are set, the new items take effect.

14.7.2.2.1 `level` New in v5.4.0

- The log level
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`
- Default value: `"info"`

14.7.2.2.2 `format` New in v5.4.0

- The log format
- Optional values: `"json"`, `"text"`
- Default value: `"text"`

14.7.2.2.3 `enable-timestamp` New in v5.4.0

- Determines whether to enable or disable the timestamp in the log
- Optional values: `true`, `false`
- Default value: `true`

14.7.2.3 log.file New in v5.4.0

- Configuration items related to the log file.

14.7.2.3.1 `filename` New in v5.4.0

- The log file. If this configuration item is not set, logs are output to "stderr" by default. If this configuration item is set, logs are output to the corresponding file.
- Default value: `""`

14.7.2.3.2 `max-size` New in v5.4.0

- The maximum size of a single log file. When the file size is larger than the value set by this configuration item, the system automatically splits the single file into multiple files.
- Default value: `300`
- Maximum value: `4096`
- Unit: MiB

14.7.2.3.3 `max-days` New in v5.4.0

- The maximum number of days that TiKV keeps log files.
    - If the configuration item is not set, or the value of it is set to the default value `0`, TiKV does not clean log files.
    - If the parameter is set to a value other than `0`, TiKV cleans up the expired log files after `max-days`.
- Default value: `0`

14.7.2.3.4 `max-backups` New in v5.4.0

- The maximum number of log files that TiKV keeps.
  - If the configuration item is not set, or the value of it is set to the default value `0`, TiKV keeps all log files.
  - If the configuration item is set to a value other than `0`, TiKV keeps at most the number of old log files specified by `max-backups`. For example, if the value is set to `7`, TiKV keeps up to 7 old log files.
- Default value: `0`

14.7.2.4 server

- Configuration items related to the server.

14.7.2.4.1 `addr`

- The listening IP address and the listening port
- Default value: `"127.0.0.1:20160"`

14.7.2.4.2 `advertise-addr`

- Advertise the listening address for client communication
- If this configuration item is not set, the value of `addr` is used.
- Default value: `""`

14.7.2.4.3 `status-addr`

- The configuration item reports TiKV status directly through the `HTTP` address

> **Warning:**
> If this value is exposed to the public, the status information of the TiKV server might be leaked.

- To disable the status address, set the value to `""`.
- Default value: `"127.0.0.1:20180"`

14.7.2.4.4 status-thread-pool-size

- The number of worker threads for the HTTP API service
- Default value: 1
- Minimum value: 1

14.7.2.4.5 grpc-compression-type

- The compression algorithm for gRPC messages, which affects gRPC messages between TiKV nodes and gRPC response messages sent from TiKV to TiDB
- Optional values: "none", "deflate", "gzip"
- Default value: "none"

14.7.2.4.6 grpc-concurrency

- The number of gRPC worker threads. When you modify the size of the gRPC thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: 5
- Minimum value: 1

14.7.2.4.7 grpc-concurrent-stream

- The maximum number of concurrent requests allowed in a gRPC stream
- Default value: 1024
- Minimum value: 1

14.7.2.4.8 grpc-memory-pool-quota

- Limits the memory size that can be used by gRPC
- Default value: No limit
- Limit the memory in case OOM is observed. Note that limit the usage can lead to potential stall

14.7.2.4.9 grpc-raft-conn-num

- The maximum number of connections between TiKV nodes for Raft communication
- Default value: 1
- Minimum value: 1

14.7.2.4.10 `max-grpc-send-msg-len`

- Sets the maximum length of a gRPC message that can be sent
- Default value: `10485760`
- Unit: Bytes
- Maximum value: `2147483647`

14.7.2.4.11 `grpc-stream-initial-window-size`

- The window size of the gRPC stream
- Default value: `2MiB`
- Unit: KiB|MiB|GiB
- Minimum value: `"1KiB"`

14.7.2.4.12 `grpc-keepalive-time`

- The time interval at which that gRPC sends `keepalive` Ping messages
- Default value: `"10s"`
- Minimum value: `"1s"`

14.7.2.4.13 `grpc-keepalive-timeout`

- Disables the timeout for gRPC streams
- Default value: `"3s"`
- Minimum value: `"1s"`

14.7.2.4.14 `concurrent-send-snap-limit`

- The maximum number of snapshots sent at the same time
- Default value: `32`
- Minimum value: `1`

14.7.2.4.15 `concurrent-recv-snap-limit`

- The maximum number of snapshots received at the same time
- Default value: `32`
- Minimum value: `1`

14.7.2.4.16 `end-point-recursion-limit`

- The maximum number of recursive levels allowed when TiKV decodes the Coprocessor DAG expression
- Default value: `1000`
- Minimum value: `1`

14.7.2.4.17 `end-point-request-max-handle-duration`

- The longest duration allowed for a TiDB's push down request to TiKV for processing tasks
- Default value: `"60s"`
- Minimum value: `"1s"`

14.7.2.4.18 `snap-io-max-bytes-per-sec`

- The maximum allowable disk bandwidth when processing snapshots
- Default value: `"100MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"1KiB"`

14.7.2.4.19 `snap-min-ingest-size` New in v8.1.2

- Specifies the minimum threshold for whether TiKV adopts the ingest method when processing snapshots.
    - When the snapshot size exceeds this threshold, TiKV adopts the ingest method, which imports SST files from the snapshot into RocksDB. This method is faster for large files.
    - When the snapshot size does not exceed this threshold, TiKV adopts the direct write method, which writes each piece of data into RocksDB individually. This method is more efficient for small files.
- Default value: `"2MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `0`

14.7.2.4.20 `enable-request-batch`

- Determines whether to process requests in batches
- Default value: `true`

14.7.2.4.21 `labels`

- Specifies server attributes, such as `{ zone = "us-west-1", disk = "ssd" }`.
- Default value: `{}`

14.7.2.4.22 `background-thread-count`

- The working thread count of the background pool, including endpoint threads, BR threads, split-check threads, Region threads, and other threads of delay-insensitive tasks.
- Default value: when the number of CPU cores is less than 16, the default value is `2`; otherwise, the default value is `3`.

14.7.2.4.23 `end-point-slow-log-threshold`

- The time threshold for a TiDB's push-down request to output slow log. If the processing time is longer than this threshold, the slow logs are output.
- Default value: `"1s"`
- Minimum value: `0`

14.7.2.4.24 `raft-client-queue-size`

- Specifies the queue size of the Raft messages in TiKV. If too many messages not sent in time result in a full buffer, or messages discarded, you can specify a greater value to improve system stability.
- Default value: `8192`

14.7.2.4.25 `simplify-metrics` New in v6.2.0

- Specifies whether to simplify the returned monitoring metrics. After you set the value to `true`, TiKV reduces the amount of data returned for each request by filtering out some metrics.
- Default value: `false`

14.7.2.4.26 `forward-max-connections-per-address` New in v5.0.0

- Sets the size of the connection pool for service and forwarding requests to the server. Setting it to too small a value affects the request latency and load balancing.
- Default value: `4`

14.7.2.5 readpool.unified

Configuration items related to the single thread pool serving read requests. This thread pool supersedes the original storage thread pool and coprocessor thread pool since the 4.0 version.

14.7.2.5.1 `min-thread-count`

- The minimal working thread count of the unified read pool
- Default value: `1`

14.7.2.5.2 `max-thread-count`

- The maximum working thread count of the unified read pool or the UnifyReadPool thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Value range: `[min-thread-count, MAX(4, CPU quota * 10)]`. `MAX(4, CPU quota * 10)` takes the greater value out of `4` and the `CPU quota * 10`.
- Default value: MAX(4, CPU * 0.8)

> **Note:**
>
> Increasing the thread count will lead to more context switches, which might cause a performance decrease. It is not recommended to modify the value of this configuration item.

14.7.2.5.3 `stack-size`

- The stack size of the threads in the unified thread pool
- Type: Integer + Unit
- Default value: `"10MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"2MiB"`
- Maximum value: The number of Kbytes output in the result of the `ulimit -sH` command executed in the system.

14.7.2.5.4 `max-tasks-per-worker`

- The maximum number of tasks allowed for a single thread in the unified read pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.7.2.5.5 auto-adjust-pool-size New in v6.3.0

- Controls whether to automatically adjust the thread pool size. When it is enabled, the read performance of TiKV is optimized by automatically adjusting the UnifyReadPool thread pool size based on the current CPU usage. The possible range of the thread pool is `[max-thread-count, MAX(4, CPU)]`. The maximum value is the same as the one of `max-thread-count`.
- Default value: `false`

14.7.2.6 readpool.storage

Configuration items related to storage thread pool.

14.7.2.6.1 use-unified-pool

- Determines whether to use the unified thread pool (configured in `readpool.unified`) for storage requests. If the value of this parameter is `false`, a separate thread pool is used, which is configured through the rest parameters in this section (`readpool.storage`).
- Default value: If this section (`readpool.storage`) has no other configurations, the default value is `true`. Otherwise, for the backward compatibility, the default value is `false`. Change the configuration in `readpool.unified` as needed before enabling this option.

14.7.2.6.2 high-concurrency

- The allowable number of concurrent threads that handle high-priority `read` requests
- When `8 cpu num 16`, the default value is `cpu_num * 0.5`; when `cpu num` is smaller than `8`, the default value is `4`; when `cpu num` is greater than `16`, the default value is `8`.
- Minimum value: `1`

14.7.2.6.3 normal-concurrency

- The allowable number of concurrent threads that handle normal-priority `read` requests
- When `8 cpu num 16`, the default value is `cpu_num * 0.5`; when `cpu num` is smaller than `8`, the default value is `4`; when `cpu num` is greater than `16`, the default value is `8`.
- Minimum value: `1`

14.7.2.6.4 low-concurrency

- The allowable number of concurrent threads that handle low-priority `read` requests
- When `8 cpu num 16`, the default value is `cpu_num * 0.5`; when `cpu num` is smaller than `8`, the default value is `4`; when `cpu num` is greater than `16`, the default value is `8`.
- Minimum value: `1`

14.7.2.6.5 `max-tasks-per-worker-high`

- The maximum number of tasks allowed for a single thread in a high-priority thread pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.7.2.6.6 `max-tasks-per-worker-normal`

- The maximum number of tasks allowed for a single thread in a normal-priority thread pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.7.2.6.7 `max-tasks-per-worker-low`

- The maximum number of tasks allowed for a single thread in a low-priority thread pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.7.2.6.8 `stack-size`

- The stack size of threads in the Storage read thread pool
- Type: Integer + Unit
- Default value: `"10MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"2MiB"`
- Maximum value: The number of Kbytes output in the result of the `ulimit -sH` command executed in the system.

14.7.2.7 `readpool.coprocessor`

Configuration items related to the Coprocessor thread pool.

14.7.2.7.1 `use-unified-pool`

- Determines whether to use the unified thread pool (configured in `readpool.unified` ↪) for coprocessor requests. If the value of this parameter is `false`, a separate thread pool is used, which is configured through the rest parameters in this section (`readpool.coprocessor`).
- Default value: If none of the parameters in this section (`readpool.coprocessor`) are set, the default value is `true`. Otherwise, the default value is `false` for the backward compatibility. Adjust the configuration items in `readpool.unified` before enabling this parameter.

14.7.2.7.2 `high-concurrency`

- The allowable number of concurrent threads that handle high-priority Coprocessor requests, such as checkpoints
- Default value: `CPU * 0.8`
- Minimum value: `1`

14.7.2.7.3 `normal-concurrency`

- The allowable number of concurrent threads that handle normal-priority Coprocessor requests
- Default value: `CPU * 0.8`
- Minimum value: `1`

14.7.2.7.4 `low-concurrency`

- The allowable number of concurrent threads that handle low-priority Coprocessor requests, such as table scan
- Default value: `CPU * 0.8`
- Minimum value: `1`

14.7.2.7.5 `max-tasks-per-worker-high`

- The number of tasks allowed for a single thread in a high-priority thread pool. When this number is exceeded, `Server Is Busy` is returned.
- Default value: `2000`
- Minimum value: `2`

14.7.2.7.6 `max-tasks-per-worker-normal`

- The number of tasks allowed for a single thread in a normal-priority thread pool. When this number is exceeded, `Server Is Busy` is returned.
- Default value: `2000`
- Minimum value: `2`

14.7.2.7.7 `max-tasks-per-worker-low`

- The number of tasks allowed for a single thread in a low-priority thread pool. When this number is exceeded, `Server Is Busy` is returned.
- Default value: `2000`
- Minimum value: `2`

14.7.2.7.8 `stack-size`

- The stack size of the thread in the Coprocessor thread pool
- Type: Integer + Unit
- Default value: `"10MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"2MiB"`
- Maximum value: The number of Kbytes output in the result of the `ulimit -sH` command executed in the system.

14.7.2.8 storage

Configuration items related to storage.

14.7.2.8.1 `data-dir`

- The storage path of the RocksDB directory
- Default value: `"./"`

14.7.2.8.2 `engine` New in v6.6.0

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Specifies the engine type. This configuration can only be specified when creating a new cluster and cannot be modifies once being specified.
- Default value: `"raft-kv"`
- Value options:
  - `"raft-kv"`: The default engine type in versions earlier than TiDB v6.6.0.
  - `"partitioned-raft-kv"`: The new storage engine type introduced in TiDB v6.6.0.

14.7.2.8.3 `scheduler-concurrency`

- A built-in memory lock mechanism to prevent simultaneous operations on a key. Each key has a hash in a different slot.
- Default value: `524288`
- Minimum value: `1`

14.7.2.8.4 `scheduler-worker-pool-size`

- The number of threads in the Scheduler thread pool. Scheduler threads are mainly used for checking transaction consistency before data writing. If the number of CPU cores is greater than or equal to `16`, the default value is `8`; otherwise, the default value is `4`. When you modify the size of the Scheduler thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `4`
- Value range: `[1, MAX(4, CPU)]`. In `MAX(4, CPU)`, `CPU` means the number of your CPU cores. `MAX(4, CPU)` takes the greater value out of `4` and the `CPU`.

14.7.2.8.5 `scheduler-pending-write-threshold`

- The maximum size of the write queue. A `Server Is Busy` error is returned for a new write to TiKV when this value is exceeded.
- Default value: `"100MiB"`
- Unit: MiB|GiB

14.7.2.8.6 `enable-async-apply-prewrite`

- Determines whether Async Commit transactions respond to the TiKV client before applying prewrite requests. After enabling this configuration item, latency can be easily reduced when the apply duration is high, or the delay jitter can be reduced when the apply duration is not stable.
- Default value: `false`

14.7.2.8.7 `reserve-space`

- When TiKV is started, some space is reserved on the disk as disk protection. When the remaining disk space is less than the reserved space, TiKV restricts some write operations. The reserved space is divided into two parts: 80% of the reserved space is used as the extra disk space required for operations when the disk space is insufficient, and the other 20% is used to store the temporary file. In the process of reclaiming space, if the storage is exhausted by using too much extra disk space, this temporary file serves as the last protection for restoring services.
- The name of the temporary file is `space_placeholder_file`, located in the `storage.` ↪ `data-dir` directory. When TiKV goes offline because its disk space ran out, if you restart TiKV, the temporary file is automatically deleted and TiKV tries to reclaim the space.
- When the remaining space is insufficient, TiKV does not create the temporary file. The effectiveness of the protection is related to the size of the reserved space. The size of the reserved space is the larger value between 5% of the disk capacity and this configuration value. When the value of this configuration item is `"0MiB"`, TiKV disables this disk protection feature.

- Default value: `"5GiB"`
- Unit: MiB|GiB

14.7.2.8.8 `enable-ttl`

Warning:

- Set `enable-ttl` to `true` or `false` **ONLY WHEN** deploying a new TiKV cluster. **DO NOT** modify the value of this configuration item in an existing TiKV cluster. TiKV clusters with different `enable-ttl` values use different data formats. Therefore, if you modify the value of this item in an existing TiKV cluster, the cluster will store data in different formats, which causes the "can't enable TTL on a non-ttl" error when you restart the TiKV cluster.
- Use `enable-ttl` **ONLY IN** a TiKV cluster. **DO NOT** use this configuration item in a cluster that has TiDB nodes (which means setting `enable-ttl` to `true` in such clusters) unless `storage.api-version = 2` is configured. Otherwise, critical issues such as data corruption and the upgrade failure of TiDB clusters will occur.

- TTL is short for "Time to live". If this item is enabled, TiKV automatically deletes data that reaches its TTL. To set the value of TTL, you need to specify it in the requests when writing data via the client. If the TTL is not specified, it means that TiKV does not automatically delete the corresponding data.
- Default value: `false`

14.7.2.8.9 `ttl-check-poll-interval`

- The interval of checking data to reclaim physical spaces. If data reaches its TTL, TiKV forcibly reclaims its physical space during the check.
- Default value: `"12h"`
- Minimum value: `"0s"`

14.7.2.8.10 `background-error-recovery-window` New in v6.1.0

- The maximum allowable time for TiKV to recover after RocksDB detects a recoverable background error. If some background SST files are damaged, RocksDB will report to PD via heartbeat after locating the Peer to which the damaged SST files belong. PD then performs scheduling operations to remove this Peer. Finally, the damaged SST files are deleted directly, and the TiKV background will work as normal again.

- The damaged SST files still exist before the recovery finishes. During such a period, RocksDB can continue writing data, but an error will be reported when the damaged part of the data is read.
- If the recovery fails to finish within this time window, TiKV will panic.
- Default value: 1h

14.7.2.8.11 `api-version` New in v6.1.0

- The storage format and interface version used by TiKV when TiKV serves as the RawKV store.
- Value options:
  - `1`: Uses API V1, does not encode the data passed from the client, and stores data as it is. In versions earlier than v6.1.0, TiKV uses API V1 by default.
  - `2`: Uses API V2:
    - The data is stored in the Multi-Version Concurrency Control (MVCC) format, where the timestamp is obtained from PD (which is TSO) by tikv-server.
    - Data is scoped according to different usage and API V2 supports co-existence of TiDB, Transactional KV, and RawKV applications in a single cluster.
    - When API V2 is used, you are expected to set `storage.enable-ttl = true` at the same time. Because API V2 supports the TTL feature, you must turn on `enable-ttl` explicitly. Otherwise, it will be in conflict because `storage.enable-ttl` defaults to `false`.
    - When API V2 is enabled, you need to deploy at least one tidb-server instance to reclaim obsolete data. This tidb-server instance can provide read and write services at the same time. To ensure high availability, you can deploy multiple tidb-server instances.
    - Client support is required for API V2. For details, see the corresponding instruction of the client for the API V2.
    - Since v6.2.0, Change Data Capture (CDC) for RawKV is supported. Refer to RawKV CDC.
- Default value: `1`

Warning:

- API V1 and API V2 are different from each other in the storage format. You can enable or disable API V2 directly **only** when TiKV contains only TiDB data. In other scenarios, you need to deploy a new cluster, and migrate data using RawKV Backup & Restore.

- After API V2 is enabled, you **cannot** downgrade the TiKV cluster to a version earlier than v6.1.0. Otherwise, data corruption might occur.

14.7.2.9 storage.block-cache

Configuration items related to the sharing of block cache among multiple RocksDB Column Families (CF).

14.7.2.9.1 `capacity`

- The size of the shared block cache.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is 45% of the size of total system memory.
  - When `storage.engine="partitioned-raft-kv"`, the default value is 30% of the size of total system memory.
- Unit: KiB|MiB|GiB

14.7.2.9.2 `low-pri-pool-ratio` New in v8.0.0

- Controls the proportion of the entire block cache that the Titan component can use.
- Default value: `0.2`

14.7.2.10 storage.flow-control

Configuration items related to the flow control mechanism in TiKV. This mechanism replaces the write stall mechanism in RocksDB and controls flow at the scheduler layer, which avoids secondary disasters caused by the stuck Raftstore or Apply threads.

14.7.2.10.1 `enable`

- Determines whether to enable the flow control mechanism. After it is enabled, TiKV automatically disables the write stall mechanism of KvDB and the write stall mechanism of RaftDB (excluding memtable).
- Default value: `true`

14.7.2.10.2 memtables-threshold

- When the number of kvDB memtables reaches this threshold, the flow control mechanism starts to work. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|writecf|lockcf).max-write-buffer-number`.
- Default value: `5`

14.7.2.10.3 l0-files-threshold

- When the number of kvDB L0 files reaches this threshold, the flow control mechanism starts to work. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|writecf|lockcf).level0-slowdown-writes-trigger`.
- Default value: `20`

14.7.2.10.4 soft-pending-compaction-bytes-limit

- When the pending compaction bytes in KvDB reach this threshold, the flow control mechanism starts to reject some write requests and reports the `ServerIsBusy` error. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|writecf|lockcf).soft-pending-compaction-bytes-limit`.
- Default value: `"192GiB"`

14.7.2.10.5 hard-pending-compaction-bytes-limit

- When the pending compaction bytes in KvDB reach this threshold, the flow control mechanism rejects all write requests and reports the `ServerIsBusy` error. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|writecf|lockcf).hard-pending-compaction-bytes-limit`.
- Default value: `"1024GiB"`

14.7.2.11 storage.io-rate-limit

Configuration items related to the I/O rate limiter.

14.7.2.11.1 max-bytes-per-sec

- Limits the maximum I/O bytes that a server can write to or read from the disk (determined by the `mode` configuration item below) in one second. When this limit is reached, TiKV prefers throttling background operations over foreground ones. The value of this configuration item should be set to the disk's optimal I/O bandwidth, for example, the maximum I/O bandwidth specified by your cloud disk vendor. When this configuration value is set to zero, disk I/O operations are not limited.
- Default value: `"0MiB"`

14.7.2.11.2 `mode`

- Determines which types of I/O operations are counted and restrained below the `max-bytes-per-sec` threshold. Currently, only the write-only mode is supported.
- Value options: `"read-only"`, `"write-only"`, and `"all-io"`
- Default value: `"write-only"`

14.7.2.12 pd

14.7.2.12.1 `enable-forwarding` New in v5.0.0

- Controls whether the PD client in TiKV forwards requests to the leader via the followers in the case of possible network isolation.
- Default value: `false`
- If the environment might have isolated network, enabling this parameter can reduce the window of service unavailability.
- If you cannot accurately determine whether isolation, network interruption, or downtime has occurred, using this mechanism has the risk of misjudgment and causes reduced availability and performance. If network failure has never occurred, it is not recommended to enable this parameter.

14.7.2.12.2 `endpoints`

- The endpoints of PD. When multiple endpoints are specified, you need to separate them using commas.
- Default value: `["127.0.0.1:2379"]`

14.7.2.12.3 `retry-interval`

- The interval for retrying the PD connection.
- Default value: `"300ms"`

14.7.2.12.4 `retry-log-every`

- Specified the frequency at which the PD client skips reporting errors when the client observes errors. For example, when the value is `5`, after the PD client observes errors, the client skips reporting errors every 4 times and reports errors every 5th time.
- To disable this feature, set the value to `1`.
- Default value: `10`

14.7.2.12.5 `retry-max-count`

- The maximum number of times to retry to initialize PD connection
- To disable the retry, set its value to `0`. To release the limit on the number of retries, set the value to `-1`.
- Default value: `-1`

14.7.2.13 raftstore

Configuration items related to Raftstore.

14.7.2.13.1 `prevote`

- Enables or disables `prevote`. Enabling this feature helps reduce jitter on the system after recovery from network partition.
- Default value: `true`

14.7.2.13.2 `capacity`

- The storage capacity, which is the maximum size allowed to store data. If `capacity` is left unspecified, the capacity of the current disk prevails. To deploy multiple TiKV instances on the same physical disk, add this parameter to the TiKV configuration. For details, see Key parameters of the hybrid deployment.
- Default value: `0`
- Unit: KiB|MiB|GiB

14.7.2.13.3 `raftdb-path`

- The path to the Raft library, which is `storage.data-dir/raft` by default
- Default value: `""`

14.7.2.13.4 `raft-base-tick-interval`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The time interval at which the Raft state machine ticks
- Default value: `"1s"`
- Minimum value: greater than `0`

14.7.2.13.5 `raft-heartbeat-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The number of passed ticks when the heartbeat is sent. This means that a heartbeat is sent at the time interval of `raft-base-tick-interval` * `raft-heartbeat-ticks`.
- Default value: `2`
- Minimum value: greater than `0`

14.7.2.13.6 `raft-election-timeout-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The number of passed ticks when Raft election is initiated. This means that if Raft group is missing the leader, a leader election is initiated approximately after the time interval of `raft-base-tick-interval` * `raft-election-timeout-ticks`.
- Default value: `10`
- Minimum value: `raft-heartbeat-ticks`

14.7.2.13.7 `raft-min-election-timeout-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The minimum number of ticks during which the Raft election is initiated. If the number is `0`, the value of `raft-election-timeout-ticks` is used. The value of this parameter must be greater than or equal to `raft-election-timeout-ticks`.
- Default value: `0`
- Minimum value: `0`

14.7.2.13.8 `raft-max-election-timeout-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The maximum number of ticks during which the Raft election is initiated. If the number is `0`, the value of `raft-election-timeout-ticks` * `2` is used.
- Default value: `0`
- Minimum value: `0`

14.7.2.13.9 `raft-max-size-per-msg`

- The soft limit on the size of a single message packet
- Default value: `"1MiB"`
- Minimum value: greater than `0`
- Maximum value: `3GiB`
- Unit: KiB|MiB|GiB

14.7.2.13.10 `raft-max-inflight-msgs`

- The number of Raft logs to be confirmed. If this number is exceeded, the Raft state machine slows down log sending.
- Default value: `256`
- Minimum value: greater than `0`
- Maximum value: `16384`

14.7.2.13.11 `raft-entry-max-size`

- The hard limit on the maximum size of a single log
- Default value: `"8MiB"`
- Minimum value: `0`
- Unit: MiB|GiB

14.7.2.13.12 `raft-log-compact-sync-interval` New in v5.3

- The time interval to compact unnecessary Raft logs
- Default value: `"2s"`
- Minimum value: `"0s"`

14.7.2.13.13 `raft-log-gc-tick-interval`

- The time interval at which the polling task of deleting Raft logs is scheduled. `0` means that this feature is disabled.
- Default value: `"3s"`
- Minimum value: `"0s"`

14.7.2.13.14 `raft-log-gc-threshold`

- The soft limit on the maximum allowable count of residual Raft logs
- Default value: `50`
- Minimum value: `1`

14.7.2.13.15 `raft-log-gc-count-limit`

- The hard limit on the allowable number of residual Raft logs
- Default value: the log number that can be accommodated in the 3/4 Region size (calculated as 1MiB for each log)
- Minimum value: `0`

14.7.2.13.16 `raft-log-gc-size-limit`

- The hard limit on the allowable size of residual Raft logs
- Default value: 3/4 of the Region size
- Minimum value: greater than `0`

14.7.2.13.17 `raft-log-reserve-max-ticks` New in v5.3

- After the number of ticks set by this configuration item passes, even if the number of residual Raft logs does not reach the value set by `raft-log-gc-threshold`, TiKV still performs garbage collection (GC) to these logs.
- Default value: `6`
- Minimum value: greater than `0`

14.7.2.13.18 `raft-engine-purge-interval`

- The interval for purging old TiKV log files to recycle disk space as soon as possible. Raft engine is a replaceable component, so the purging process is needed for some implementations.
- Default value: `"10s"`

14.7.2.13.19 `raft-entry-cache-life-time`

- The maximum remaining time allowed for the log cache in memory
- Default value: `"30s"`
- Minimum value: `0`

14.7.2.13.20 `max-apply-unpersisted-log-limit` New in v8.1.0

- The maximum number of committed but not persisted Raft logs that can be applied.
    - Setting this configuration item to a value greater than `0` enables the TiKV node to apply committed but not persisted Raft logs in advance, effectively reducing long-tail latency caused by IO jitter on that node. However, it might also increase the memory usage of TiKV and the disk space occupied by Raft logs.
    - Setting this configuration item to `0` disables this feature, meaning that TiKV must wait until Raft logs are both committed and persisted before applying them. This behavior is consistent with the behavior before v8.2.0.
- Default value: `1024`
- Minimum value: `0`

14.7.2.13.21 `hibernate-regions`

- Enables or disables Hibernate Region. When this option is enabled, a Region idle for a long time is automatically set as hibernated. This reduces the extra overhead caused by heartbeat messages between the Raft leader and the followers for idle Regions. You can use `peer-stale-state-check-interval` to modify the heartbeat interval between the leader and the followers of hibernated Regions.
- Default value: `true` in v5.0.2 and later versions; `false` in versions before v5.0.2

14.7.2.13.22 `split-region-check-tick-interval`

- Specifies the interval at which to check whether the Region split is needed. `0` means that this feature is disabled.
- Default value: `"10s"`
- Minimum value: `0`

14.7.2.13.23 `region-split-check-diff`

- The maximum value by which the Region data is allowed to exceed before Region split
- Default value: 1/16 of the Region size.
- Minimum value: `0`

14.7.2.13.24 `region-compact-check-interval`

- The time interval at which to check whether it is necessary to manually trigger RocksDB compaction. `0` means that this feature is disabled.
- Default value: `"5m"`
- Minimum value: `0`

14.7.2.13.25 `region-compact-check-step`

- The number of Regions checked at one time for each round of manual compaction
- Default value:
    - When `storage.engine="raft-kv"`, the default value is `100`.
    - When `storage.engine="partitioned-raft-kv"`, the default value is `5`.
- Minimum value: `0`

14.7.2.13.26 `region-compact-min-tombstones`

- The number of tombstones required to trigger RocksDB compaction
- Default value: `10000`
- Minimum value: `0`

14.7.2.13.27 `region-compact-tombstones-percent`

- The proportion of tombstone required to trigger RocksDB compaction
- Default value: `30`
- Minimum value: `1`
- Maximum value: `100`

14.7.2.13.28 `region-compact-min-redundant-rows` New in v7.1.0

- The number of redundant MVCC rows required to trigger RocksDB compaction.
- Default value: `50000`
- Minimum value: `0`

14.7.2.13.29 `region-compact-redundant-rows-percent` New in v7.1.0

- The percentage of redundant MVCC rows required to trigger RocksDB compaction.
- Default value: `20`
- Minimum value: `1`
- Maximum value: `100`

14.7.2.13.30 report-region-buckets-tick-interval New in v6.1.0

> **Warning:**
>
> `report-region-buckets-tick-interval` is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

- The interval at which TiKV reports bucket information to PD when `enable-region-bucket` is true.
- Default value: `10s`

14.7.2.13.31 pd-heartbeat-tick-interval

- The time interval at which a Region's heartbeat to PD is triggered. `0` means that this feature is disabled.
- Default value: `"1m"`
- Minimum value: `0`

14.7.2.13.32 pd-store-heartbeat-tick-interval

- The time interval at which a store's heartbeat to PD is triggered. `0` means that this feature is disabled.
- Default value: `"10s"`
- Minimum value: `0`

14.7.2.13.33 pd-report-min-resolved-ts-interval New in v7.6.0

> **Note:**
>
> This configuration item is renamed from `report-min-resolved-ts-interval`. Starting from v7.6.0, `report-min-resolved-ts-interval` is no longer effective.

- Specifies the minimum interval for TiKV to report Resolved TS to the PD leader. Setting it to `0` disables the reporting.
- Default value: `"1s"`, which is the minimum positive value. Before v6.3.0, the default value is `"0s"`.
- Minimum value: `0`
- Unit: second

14.7.2.13.34 `snap-mgr-gc-tick-interval`

- The time interval at which the recycle of expired snapshot files is triggered. `0` means that this feature is disabled.
- Default value: `"1m"`
- Minimum value: `0`

14.7.2.13.35 `snap-gc-timeout`

- The longest time for which a snapshot file is saved
- Default value: `"4h"`
- Minimum value: `0`

14.7.2.13.36 `snap-generator-pool-size` New in v5.4.0

- Configures the size of the `snap-generator` thread pool.
- To make Regions generate snapshot faster in TiKV in recovery scenarios, you need to increase the count of the `snap-generator` threads of the corresponding worker. You can use this configuration item to increase the size of the `snap-generator` thread pool.
- Default value: `2`
- Minimum value: `1`

14.7.2.13.37 `lock-cf-compact-interval`

- The time interval at which TiKV triggers a manual compaction for the Lock Column Family
- Default value: `"10m"`
- Minimum value: `0`

14.7.2.13.38 `lock-cf-compact-bytes-threshold`

- The size out of which TiKV triggers a manual compaction for the Lock Column Family
- Default value: `"256MiB"`
- Minimum value: `0`
- Unit: MiB

14.7.2.13.39 `notify-capacity`

- The longest length of the Region message queue.
- Default value: `40960`
- Minimum value: `0`

14.7.2.13.40 `messages-per-tick`

- The maximum number of messages processed per batch
- Default value: `4096`
- Minimum value: `0`

14.7.2.13.41 `max-peer-down-duration`

- The longest inactive duration allowed for a peer. A peer with timeout is marked as `down`, and PD tries to delete it later.
- Default value: `"10m"`
- Minimum value: When Hibernate Region is enabled, the minimum value is `peer-stale-state-check-interval * 2`; when Hibernate Region is disabled, the minimum value is `0`.

14.7.2.13.42 `max-leader-missing-duration`

- The longest duration allowed for a peer to be in the state where a Raft group is missing the leader. If this value is exceeded, the peer verifies with PD whether the peer has been deleted.
- Default value: `"2h"`
- Minimum value: greater than `abnormal-leader-missing-duration`

14.7.2.13.43 `abnormal-leader-missing-duration`

- The longest duration allowed for a peer to be in the state where a Raft group is missing the leader. If this value is exceeded, the peer is seen as abnormal and marked in metrics and logs.
- Default value: `"10m"`
- Minimum value: greater than `peer-stale-state-check-interval`

14.7.2.13.44 `peer-stale-state-check-interval`

- The time interval to trigger the check for whether a peer is in the state where a Raft group is missing the leader.
- Default value: `"5m"`
- Minimum value: greater than `2 * election-timeout`

14.7.2.13.45 `leader-transfer-max-log-lag`

- The maximum number of missing logs allowed for the transferee during a Raft leader transfer
- Default value: `128`
- Minimum value: `10`

14.7.2.13.46 `max-snapshot-file-raw-size` New in v6.1.0

- When the size of a snapshot file exceeds this configuration value, this file will be split into multiple files.
- Default value: `100MiB`
- Minimum value: `100MiB`

14.7.2.13.47 `snap-apply-batch-size`

- The memory cache size required when the imported snapshot file is written into the disk
- Default value: `"10MiB"`
- Minimum value: `0`
- Unit: MiB

14.7.2.13.48 `consistency-check-interval`

> **Warning:**
>
> It is **NOT** recommended to enable the consistency check in production environments, because it affects cluster performance and is incompatible with the garbage collection in TiDB.

- The time interval at which the consistency check is triggered. `0` means that this feature is disabled.
- Default value: `"0s"`
- Minimum value: `0`

14.7.2.13.49 `raft-store-max-leader-lease`

- The longest trusted period of a Raft leader
- Default value: `"9s"`
- Minimum value: `0`

14.7.2.13.50 `right-derive-when-split`

- Specifies the start key of the new Region when a Region is split. When this configuration item is set to `true`, the start key is the maximum split key. When this configuration item is set to `false`, the start key is the original Region's start key.
- Default value: `true`

14.7.2.13.51 `merge-max-log-gap`

- The maximum number of missing logs allowed when `merge` is performed
- Default value: `10`
- Minimum value: greater than `raft-log-gc-count-limit`

14.7.2.13.52 `merge-check-tick-interval`

- The time interval at which TiKV checks whether a Region needs merge
- Default value: `"2s"`
- Minimum value: greater than `0`

14.7.2.13.53 `use-delete-range`

- Determines whether to delete data from the `rocksdb delete_range` interface
- Default value: `false`

14.7.2.13.54 `cleanup-import-sst-interval`

- The time interval at which the expired SST file is checked. `0` means that this feature is disabled.
- Default value: `"10m"`
- Minimum value: `0`

14.7.2.13.55 `local-read-batch-size`

- The maximum number of read requests processed in one batch
- Default value: `1024`
- Minimum value: greater than `0`

14.7.2.13.56 `apply-yield-write-size` New in v6.4.0

- The maximum number of bytes that the Apply thread can write for one FSM (Finite-state Machine) in one round of poll. This is a soft limit.
- Default value: `"32KiB"`
- Minimum value: greater than `0`
- Unit: KiB|MiB|GiB

14.7.2.13.57 apply-max-batch-size

- Raft state machines process data write requests in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can process the requests in one batch.
- Default value: 256
- Minimum value: greater than 0
- Maximum value: 10240

14.7.2.13.58 apply-pool-size

- The allowable number of threads in the pool that flushes data to the disk, which is the size of the Apply thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: 2
- Value ranges: [1, CPU * 10]. CPU means the number of your CPU cores.

14.7.2.13.59 store-max-batch-size

- Raft state machines process requests for flushing logs into the disk in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can process the requests in one batch.
- If hibernate-regions is enabled, the default value is 256. If hibernate-regions is disabled, the default value is 1024.
- Minimum value: greater than 0
- Maximum value: 10240

14.7.2.13.60 store-pool-size

- The allowable number of threads in the pool that processes Raft, which is the size of the Raftstore thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: 2
- Value ranges: [1, CPU * 10]. CPU means the number of your CPU cores.

14.7.2.13.61 store-io-pool-size New in v5.3.0

- The allowable number of threads that process Raft I/O tasks, which is the size of the StoreWriter thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: 1 (Before v8.0.0, the default value is 0)
- Minimum value: 0

14.7.2.13.62 `future-poll-size`

- The allowable number of threads that drive `future`
- Default value: `1`
- Minimum value: greater than `0`

14.7.2.13.63 `cmd-batch`

- Controls whether to enable batch processing of the requests. When it is enabled, the write performance is significantly improved.
- Default value: `true`

14.7.2.13.64 `inspect-interval`

- At a certain interval, TiKV inspects the latency of the Raftstore component. This parameter specifies the interval of the inspection. If the latency exceeds this value, this inspection is marked as timeout.
- Judges whether the TiKV node is slow based on the ratio of timeout inspection.
- Default value: `"100ms"`
- Minimum value: `"1ms"`

14.7.2.13.65 `raft-write-size-limit` New in v5.3.0

- Determines the threshold at which Raft data is written into the disk. If the data size is larger than the value of this configuration item, the data is written to the disk. When the value of `store-io-pool-size` is `0`, this configuration item does not take effect.
- Default value: `1MiB`
- Minimum value: `0`

14.7.2.13.66 `evict-cache-on-memory-ratio` New in v7.5.0

- When the memory usage of TiKV exceeds 90% of the system available memory, and the memory occupied by Raft entry cache exceeds the used memory * `evict-cache-on-memory-ratio`, TiKV evicts the Raft entry cache.
- If this value is set to `0`, it means that this feature is disabled.
- Default value: `0.1`
- Minimum value: `0`

14.7.2.13.67 `periodic-full-compact-start-times` New in v7.6.0

Warning:

Periodic full compaction is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Set the specific times that TiKV initiates periodic full compaction. You can specify multiple time schedules in an array. For example:
  - `periodic-full-compact-start-times = ["03:00", "23:00"]` indicates that TiKV performs full compaction daily at 03:00 AM and 11:00 PM, based on the local time zone of the TiKV node.
  - `periodic-full-compact-start-times = ["03:00 +0000", "23:00 +0000"]` indicates that TiKV performs full compaction daily at 03:00 AM and 11:00 PM in UTC timezone.
  - `periodic-full-compact-start-times = ["03:00 +0800", "23:00 +0800"]` indicates that TiKV performs full compaction daily at 03:00 AM and 11:00 PM in UTC+08:00 timezone.
- Default value: `[]`, which means periodic full compaction is disabled by default.

14.7.2.13.68 `periodic-full-compact-start-max-cpu` New in v7.6.0

- Limits the maximum CPU usage rate for TiKV periodic full compaction.
- Default value: `0.1`, which means that the maximum CPU usage for periodic compaction processes is 10%.

14.7.2.14 coprocessor

Configuration items related to Coprocessor.

14.7.2.14.1 `split-region-on-table`

- Determines whether to split Region by table. It is recommended for you to use the feature only in TiDB mode.
- Default value: `false`

14.7.2.14.2 `batch-split-limit`

- The threshold of Region split in batches. Increasing this value speeds up Region split.
- Default value: `10`
- Minimum value: `1`

14.7.2.14.3 `region-max-size`

- The maximum size of a Region. When the value is exceeded, the Region splits into many.
- Default value: `region-split-size / 2 * 3`
- Unit: KiB|MiB|GiB

14.7.2.14.4 `region-split-size`

- The size of the newly split Region. This value is an estimate.
- Default value: `"256MiB"`. Before v8.4.0, the default value is `"96MiB"`.
- Unit: KiB|MiB|GiB

14.7.2.14.5 `region-max-keys`

- The maximum allowable number of keys in a Region. When this value is exceeded, the Region splits into many.
- Default value: `region-split-keys / 2 * 3`

14.7.2.14.6 `region-split-keys`

- The number of keys in the newly split Region. This value is an estimate.
- Default value: `2560000`. Before v8.4.0, the default value is `960000`.

14.7.2.14.7 `consistency-check-method`

- Specifies the method of data consistency check
- For the consistency check of MVCC data, set the value to `"mvcc"`. For the consistency check of raw data, set the value to `"raw"`.
- Default value: `"mvcc"`

14.7.2.15 coprocessor-v2

14.7.2.15.1 `coprocessor-plugin-directory`

- The path of the directory where compiled coprocessor plugins are located. Plugins in this directory are automatically loaded by TiKV.
- If this configuration item is not set, the coprocessor plugin is disabled.
- Default value: `"./coprocessors"`

14.7.2.15.2 `enable-region-bucket` New in v6.1.0

- Determines whether to divide a Region into smaller ranges called buckets. The bucket is used as the unit of the concurrent query to improve the scan concurrency. For more about the design of the bucket, refer to Dynamic size Region.
- Default value: false

> **Warning:**
>
> - `enable-region-bucket` is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.
> - This configuration makes sense only when `region-split-size` is twice of `region-bucket-size` or above; otherwise, no bucket is actually generated.
> - Adjusting `region-split-size` to a larger value might have the risk of performance regression and slow scheduling.

14.7.2.15.3 `region-bucket-size` New in v6.1.0

- The size of a bucket when `enable-region-bucket` is true.
- Default value: Starting from v7.3.0, the default value is changed from `96MiB` to `50MiB`.

> **Warning:**
>
> `region-bucket-size` is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

14.7.2.16 rocksdb

Configuration items related to RocksDB

14.7.2.16.1 `max-background-jobs`

- The number of background threads in RocksDB. When you modify the size of the RocksDB thread pool, refer to Performance tuning for TiKV thread pools.
- Default value:

    - When the number of CPU cores is 10, the default value is `9`.
    - When the number of CPU cores is 8, the default value is `7`.
    - When the number of CPU cores is `N`, the default value is `max(2, min(N - 1, 9))`.
- Minimum value: `2`

14.7.2.16.2 `max-background-flushes`

- The maximum number of concurrent background memtable flush jobs
- Default value:
    - When the number of CPU cores is 10, the default value is `3`.
    - When the number of CPU cores is 8, the default value is `2`.
    - When the number of CPU cores is `N`, the default value is `[(max-background-jobs + 3)/ 4]`.
- Minimum value: `1`

14.7.2.16.3 `max-sub-compactions`

- The number of sub-compaction operations performed concurrently in RocksDB
- Default value: `3`
- Minimum value: `1`

14.7.2.16.4 `max-open-files`

- The total number of files that RocksDB can open
- Default value: `40960`
- Minimum value: `-1`

14.7.2.16.5 `max-manifest-file-size`

- The maximum size of a RocksDB Manifest file
- Default value: `"128MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.6 `create-if-missing`

- Determines whether to automatically create a DB switch
- Default value: `true`

14.7.2.16.7 `wal-recovery-mode`

- WAL recovery mode
- Optional values:
  - `"tolerate-corrupted-tail-records"`: tolerates and discards the records that have incomplete trailing data on all logs
  - `"absolute-consistency"`: abandons recovery when corrupted logs are found
  - `"point-in-time"`: recovers logs sequentially until the first corrupted log is encountered
  - `"skip-any-corrupted-records"`: post-disaster recovery. The data is recovered as much as possible, and corrupted records are skipped.
- Default value: `"point-in-time"`

14.7.2.16.8 `wal-dir`

- The directory in which WAL files are stored. If not specified, the WAL files will be stored in the same directory as the data.
- Default value: `""`

14.7.2.16.9 `wal-ttl-seconds`

- The living time of the archived WAL files. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- unit: second

14.7.2.16.10 `wal-size-limit`

- The size limit of the archived WAL files. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.11 `max-total-wal-size`

- The maximum RocksDB WAL size in total, which is the size of `*.log` files in the `data-dir`.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `"4GiB"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `1`.

14.7.2.16.12 `stats-dump-period`

- The interval at which statistics are output to the log.
- Default value:
    - When `storage.engine="raft-kv"`, the default value is `"10m"`.
    - When `storage.engine="partitioned-raft-kv"`, the default value is `"0"`.

14.7.2.16.13 `compaction-readahead-size`

- Enables the readahead feature during RocksDB compaction and specifies the size of readahead data. If you are using mechanical disks, it is recommended to set the value to 2MiB at least.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.14 `writable-file-max-buffer-size`

- The maximum buffer size used in WritableFileWrite
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.15 `use-direct-io-for-flush-and-compaction`

- Determines whether to use `O_DIRECT` for both reads and writes in the background flush and compactions. The performance impact of this option: enabling `O_DIRECT` bypasses and prevents contamination of the OS buffer cache, but the subsequent file reads require re-reading the contents to the buffer cache.
- Default value: `false`

14.7.2.16.16 `rate-bytes-per-sec`

- When Titan is disabled, this configuration item limits the I/O rate of RocksDB compaction to reduce the impact of RocksDB compaction on the foreground read and write performance during traffic peaks. When Titan is enabled, this configuration item limits the summed I/O rates of RocksDB compaction and Titan GC. If you find that the I/O or CPU consumption of RocksDB compaction and Titan GC is too large, set this configuration item to an appropriate value according the disk I/O bandwidth and the actual write traffic.
- Default value: `10GiB`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.17 `rate-limiter-refill-period`

- Controls how often I/O tokens are refilled. A smaller value reduces I/O bursts but causes more CPU overhead.
- Default value: `"100ms"`

14.7.2.16.18 `rate-limiter-mode`

- RocksDB's compaction rate limiter mode
- Optional values: `"read-only"`, `"write-only"`, `"all-io"`
- Default value: `"write-only"`

14.7.2.16.19 `rate-limiter-auto-tuned` New in v5.0

- Determines whether to automatically optimize the configuration of the RocksDB's compaction rate limiter based on recent workload. When this configuration is enabled, compaction pending bytes will be slightly higher than usual.
- Default value: `true`

14.7.2.16.20 `enable-pipelined-write`

- Controls whether to enable Pipelined Write. When this configuration is enabled, the previous Pipelined Write is used. When this configuration is disabled, the new Pipelined Commit mechanism is used.
- Default value: `false`

14.7.2.16.21 `bytes-per-sync`

- The rate at which OS incrementally synchronizes files to disk while these files are being written asynchronously
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.22 `wal-bytes-per-sync`

- The rate at which OS incrementally synchronizes WAL files to disk while the WAL files are being written
- Default value: `"512KiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.16.23 info-log-max-size

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item log.file.max-size.

- The maximum size of Info log
- Default value: "1GiB"
- Minimum value: 0
- Unit: B|KiB|MiB|GiB

14.7.2.16.24 info-log-roll-time

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated. TiKV no longer supports automatic log splitting based on time. Instead, you can use the configuration item log.file.max-size to set the threshold for automatic log splitting based on file size.

- The time interval at which Info logs are truncated. If the value is 0s, logs are not truncated.
- Default value: "0s"

14.7.2.16.25 info-log-keep-log-file-num

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item log.file.max-backups.

- The maximum number of kept log files
- Default value: 10
- Minimum value: 0

14.7.2.16.26 `info-log-dir`

- The directory in which logs are stored
- Default value: `""`

14.7.2.16.27 `info-log-level`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.level`.

- Log levels of RocksDB
- Default value: `"info"`

14.7.2.16.28 `write-buffer-flush-oldest-first` New in v6.6.0

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Specifies the flush strategy used when the memory usage of `memtable` of the current RocksDB reaches the threshold.
- Default value: `false`
- Value options:
  - `false`: `memtable` with the largest data volume is flushed to SST files.
  - `true`: The earliest `memtable` is flushed to SST files. This strategy can clear the `memtable` of cold data, which is suitable for scenarios with obvious cold and hot data.

14.7.2.16.29 `write-buffer-limit` New in v6.6.0

Warning:

This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Specifies the total memory limit of `memtable` for all RocksDB instances in a single TiKV. `0` means no limit.
- Default value:
    - When `storage.engine="raft-kv"`, the default value is `0`, which means no limit.
    - When `storage.engine="partitioned-raft-kv"`, the default value is 20% of the size of total system memory.
- Unit: KiB|MiB|GiB

14.7.2.16.30 `track-and-verify-wals-in-manifest` New in v6.5.9, v7.1.5, v7.5.2, and v8.0.0

- Controls whether to record information about Write Ahead Log (WAL) files in the RocksDB MANIFEST file and whether to verify the integrity of WAL files during startup. For more information, see RocksDB Track WAL in MANIFEST.
- Default value: `true`
- Value options:
    - `true`: records information about WAL files in the MANIFEST file and verifies the integrity of WAL files during startup.
    - `false`: does not record information about WAL files in the MANIFEST file and does not verify the integrity of WAL files during startup.

14.7.2.17 rocksdb.titan

Configuration items related to Titan.

14.7.2.17.1 `enabled`

Note:

- To enhance the performance of wide table and JSON data writing and point query, starting from TiDB v7.6.0, the default value changes from `false` to `true`, which means that Titan is enabled by default.
- Existing clusters upgraded to v7.6.0 or later versions retain the original configuration, which means that if Titan is not explicitly enabled, it still uses RocksDB.
- If the cluster has enabled Titan before upgrading to TiDB v7.6.0 or later versions, Titan will be retained after the upgrade, and the `min-blob-size` configuration before the upgrade will be retained. If you do not explicitly configure the value before the upgrade, the default value of the previous version `1KiB` will be retained to ensure the stability of the cluster configuration after the upgrade.

- Enables or disables Titan.
- Default value: `true`

14.7.2.17.2 `dirname`

- The directory in which the Titan Blob file is stored
- Default value: `"titandb"`

14.7.2.17.3 `disable-gc`

- Determines whether to disable Garbage Collection (GC) that Titan performs to Blob files
- Default value: `false`

14.7.2.17.4 `max-background-gc`

- The maximum number of GC threads in Titan. From the **TiKV Details** > **Thread CPU** > **RocksDB CPU** panel, if you observe that the Titan GC threads are at full capacity for a long time, consider increasing the size of the Titan GC thread pool.
- Default value: `1`. Before v8.0.0, the default value is `4`.
- Minimum value: `1`

14.7.2.18 rocksdb.defaultcf | rocksdb.writecf | rocksdb.lockcf

Configuration items related to `rocksdb.defaultcf`, `rocksdb.writecf`, and `rocksdb.lockcf`.

14.7.2.18.1 `block-size`

- The default size of a RocksDB block
- Default value for `defaultcf` and `writecf`: `"32KiB"`
- Default value for `lockcf`: `"16KiB"`
- Minimum value: `"1KiB"`
- Unit: KiB|MiB|GiB

14.7.2.18.2 `block-cache-size`

> **Warning:**
>
> Starting from v6.6.0, this configuration is deprecated.

- The cache size of a RocksDB block.
- Default value for `defaultcf`: `Total machine memory * 25%`
- Default value for `writecf`: `Total machine memory * 15%`
- Default value for `lockcf`: `Total machine memory * 2%`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.18.3 `disable-block-cache`

- Enables or disables block cache
- Default value: `false`

14.7.2.18.4 `cache-index-and-filter-blocks`

- Enables or disables caching index and filter
- Default value: `true`

14.7.2.18.5 `pin-l0-filter-and-index-blocks`

- Determines whether to pin the index and filter blocks of the level 0 SST files in memory.
- Default value: `true`

14.7.2.18.6 `use-bloom-filter`

- Enables or disables bloom filter
- Default value: `true`

14.7.2.18.7 `optimize-filters-for-hits`

- Determines whether to optimize the hit ratio of filters
- Default value for `defaultcf`: `true`
- Default value for `writecf` and `lockcf`: `false`

14.7.2.18.8 `optimize-filters-for-memory` New in v7.2.0

- Determines whether to generate Bloom/Ribbon filters that minimize memory internal fragmentation.
- Note that this configuration item takes effect only when `format-version` >= 5.
- Default value: `false`

14.7.2.18.9 `whole-key-filtering`

- Determines whether to put the entire key to bloom filter
- Default value for `defaultcf` and `lockcf`: `true`
- Default value for `writecf`: `false`

14.7.2.18.10 `bloom-filter-bits-per-key`

- The length that bloom filter reserves for each key
- Default value: `10`
- Unit: byte

14.7.2.18.11 `block-based-bloom-filter`

- Determines whether each block creates a bloom filter
- Default value: `false`

14.7.2.18.12 `ribbon-filter-above-level` New in v7.2.0

- Determines whether to use Ribbon filters for levels greater than or equal to this value and use non-block-based bloom filters for levels less than this value. When this configuration item is set, `block-based-bloom-filter` will be ignored.
- Note that this configuration item takes effect only when `format-version` >= 5.
- Default value: `false`

14.7.2.18.13 `read-amp-bytes-per-bit`

- Enables or disables statistics of read amplification.
- Optional values: `0` (disabled), > `0` (enabled).
- Default value: `0`
- Minimum value: `0`

14.7.2.18.14 `compression-per-level`

- The default compression algorithm for each level
- Default value for `defaultcf`: [“no”, “no”, “lz4”, “lz4”, “lz4”, “zstd”, “zstd”]
- Default value for `writecf`: [“no”, “no”, “lz4”, “lz4”, “lz4”, “zstd”, “zstd”]
- Default value for `lockcf`: [“no”, “no”, “no”, “no”, “no”, “no”, “no”]

14.7.2.18.15 `bottommost-level-compression`

- Sets the compression algorithm of the bottommost layer. This configuration item overrides the `compression-per-level` setting.
- Ever since data is written to LSM-tree, RocksDB does not directly adopt the last compression algorithm specified in the `compression-per-level` array for the bottommost layer. `bottommost-level-compression` enables the bottommost layer to use the compression algorithm of the best compression effect from the beginning.
- If you do not want to set the compression algorithm for the bottommost layer, set the value of this configuration item to `disable`.
- Default value: `"zstd"`

14.7.2.18.16 `write-buffer-size`

- Memtable size
- Default value for `defaultcf` and `writecf`: `"128MiB"`
- Default value for `lockcf`:
  - When `storage.engine="raft-kv"`, the default value is `"32MiB"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `"4MiB"`.
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.18.17 `max-write-buffer-number`

- The maximum number of memtables. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.memtables-threshold` overrides this configuration item.
- Default value: `5`
- Minimum value: `0`

14.7.2.18.18 `min-write-buffer-number-to-merge`

- The minimum number of memtables required to trigger flush
- Default value: `1`
- Minimum value: `0`

14.7.2.18.19 `max-bytes-for-level-base`

- The maximum number of bytes at base level (level-1). Generally, it is set to 4 times the size of a memtable. When the level-1 data size reaches the limit value of `max-bytes-for-level-base`, the SST files of level-1 and their overlapping SST files of level-2 will be compacted.
- Default value for `defaultcf` and `writecf`: `"512MiB"`
- Default value for `lockcf`: `"128MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB
- It is recommended that the value of `max-bytes-for-level-base` is set approximately equal to the data volume in L0 to reduce unnecessary compaction. For example, if the compression method is "no:no:lz4:lz4:lz4:lz4:lz4", the value of `max-bytes-for-level-base` should be `write-buffer-size * 4`, because there is no compression of L0 and L1 and the trigger condition of compaction for L0 is that the number of the SST files reaches 4 (the default value). When L0 and L1 both adopt compaction, you need to analyze RocksDB logs to understand the size of an SST file compressed from a memtable. For example, if the file size is 32 MiB, it is recommended to set the value of `max-bytes-for-level-base` to 128 MiB (`32 MiB * 4`).

14.7.2.18.20 `target-file-size-base`

- The size of the target file at base level. This value is overridden by `compaction-guard-max-output-file-size` when the `enable-compaction-guard` value is `true`.
- Default value: `"8MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.18.21 `level0-file-num-compaction-trigger`

- The maximum number of files at L0 that trigger compaction
- Default value for `defaultcf` and `writecf`: `4`
- Default value for `lockcf`: `1`
- Minimum value: `0`

14.7.2.18.22 `level0-slowdown-writes-trigger`

- The maximum number of files at L0 that trigger write stall. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.l0-files-threshold` overrides this configuration item.
- Default value: `20`
- Minimum value: `0`

14.7.2.18.23 `level0-stop-writes-trigger`

- The maximum number of files at L0 required to completely block write
- Default value: `36`
- Minimum value: `0`

14.7.2.18.24 `max-compaction-bytes`

- The maximum number of bytes written into disk per compaction
- Default value: `"2GiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.18.25 `compaction-pri`

- The priority type of compaction
- Optional values:
    - `"by-compensated-size"`: compact files in order of file size and large files are compacted with higher priority.
    - `"oldest-largest-seq-first"`: prioritize compaction on files with the oldest update time. Use this value **only** when updating hot keys in small ranges.
    - `"oldest-smallest-seq-first"`: prioritize compaction on files with ranges that are not compacted to the next level for a long time. If you randomly update hot keys across the key space, this value can slightly reduce write amplification.
    - `"min-overlapping-ratio"`: prioritize compaction on files with a high overlap ratio. When a file is small in different levels (the result of `the file size in the next level ÷ the file size in this level` is small), TiKV compacts this file first. In many cases, this value can effectively reduce write amplification.
- Default value for `defaultcf` and `writecf`: `"min-overlapping-ratio"`
- Default value for `lockcf`: `"by-compensated-size"`

14.7.2.18.26 `dynamic-level-bytes`

- Determines whether to optimize dynamic level bytes
- Default value: `true`

14.7.2.18.27 `num-levels`

- The maximum number of levels in a RocksDB file
- Default value: `7`

14.7.2.18.28 `max-bytes-for-level-multiplier`

- The default amplification multiple for each layer
- Default value: `10`

14.7.2.18.29 `compaction-style`

- Compaction method
- Optional values: `"level"`, `"universal"`, `"fifo"`
- Default value: `"level"`

14.7.2.18.30 `disable-auto-compactions`

- Determines whether to disable auto compaction.
- Default value: `false`

14.7.2.18.31 `soft-pending-compaction-bytes-limit`

- The soft limit on the pending compaction bytes. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.soft-pending-compaction-bytes-limit` overrides this configuration item.
- Default value: `"192GiB"`
- Unit: KiB|MiB|GiB

14.7.2.18.32 `hard-pending-compaction-bytes-limit`

- The hard limit on the pending compaction bytes. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.hard-pending-compaction-bytes-limit` overrides this configuration item.
- Default value: `"256GiB"`
- Unit: KiB|MiB|GiB

14.7.2.18.33 `enable-compaction-guard`

- Enables or disables the compaction guard, which is an optimization to split SST files at TiKV Region boundaries. This optimization can help reduce compaction I/O and allows TiKV to use larger SST file size (thus less SST files overall) and at the time efficiently clean up stale data when migrating Regions.
- Default value for `defaultcf` and `writecf`: `true`
- Default value for `lockcf`: `false`

14.7.2.18.34 `compaction-guard-min-output-file-size`

- The minimum SST file size when the compaction guard is enabled. This configuration prevents SST files from being too small when the compaction guard is enabled.
- Default value: `"8MiB"`
- Unit: KiB|MiB|GiB

14.7.2.18.35 `compaction-guard-max-output-file-size`

- The maximum SST file size when the compaction guard is enabled. The configuration prevents SST files from being too large when the compaction guard is enabled. This configuration overrides `target-file-size-base` for the same column family.
- Default value: `"128MiB"`
- Unit: KiB|MiB|GiB

14.7.2.18.36 `format-version` New in v6.2.0

- The format version of SST files. This configuration item only affects newly written tables. For existing tables, the version information is read from the footer.
- Optional values:
  - `0`: Can be read by all TiKV versions. The default checksum type is CRC32 and this version does not support changing the checksum type.
  - `1`: Can be read by all TiKV versions. Supports non-default checksum types like xxHash. RocksDB only writes data when the checksum type is not CRC32. (version `0` is automatically upgraded)
  - `2`: Can be read by all TiKV versions. Changes the encoding of compressed blocks using LZ4, BZip2 and Zlib compression.
  - `3`: Can be read by TiKV v2.1 and later versions. Changes the encoding of the keys in index blocks.
  - `4`: Can be read by TiKV v3.0 and later versions. Changes the encoding of the values in index blocks.
  - `5`: Can be read by TiKV v6.1 and later versions. Full and partitioned filters use a faster and more accurate Bloom filter implementation with a different schema.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `2`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `5`.

14.7.2.18.37 `ttl` New in v7.2.0

- SST files with updates older than the TTL will be automatically selected for compaction. These SST files will go through the compaction in a cascading way so that they can be compacted to the bottommost level or file.
- Default value: `"0s"`, meaning that no SST file is selected by default.
- Unit: s(second)|h(hour)|d(day)

14.7.2.18.38 `periodic-compaction-seconds` New in v7.2.0

- The time interval for periodic compaction. SST files with updates older than this value will be selected for compaction and rewritten to the same level where these SST files originally reside.
- Default value: `"0s"`, meaning that periodic compaction is disabled by default.
- Unit: s(second)|h(hour)|d(day)

14.7.2.19 rocksdb.defaultcf.titan

> **Note:**
>
> Titan can only be enabled in `rocksdb.defaultcf`. It is not supported to enable Titan in `rocksdb.writecf`.

Configuration items related to `rocksdb.defaultcf.titan`.

14.7.2.19.1 `min-blob-size`

> **Note:**
>
> - Starting from TiDB v7.6.0, Titan is enabled by default to enhance the performance of wide table and JSON data writing and point query. The default value of `min-blob-size` changes from `1KiB` to `32KiB`. This means that values exceeding `32KiB` is stored in Titan, while other data continues to be stored in RocksDB.
> - To ensure configuration consistency, for existing clusters upgrading to TiDB v7.6.0 or later versions, if you do not explicitly set `min-blob-size` before the upgrade, TiDB retains the previous default value of `1KiB`.

- A value smaller than `32KiB` might affect the performance of range scans. However, if the workload primarily involves heavy writes and point queries, you can consider decreasing the value of `min-blob-size` for better performance.

- The smallest value stored in a Blob file. Values smaller than the specified size are stored in the LSM-Tree.
- Default value: `"32KiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.19.2 `blob-file-compression`

Note:

- Snappy compressed files must be in the official Snappy format. Other variants of Snappy compression are not supported.
- Starting from TiDB v7.6.0, the default value of `blob-file-compression` changes from `"lz4"` to `"zstd"`.

- The compression algorithm used in a Blob file
- Optional values: `"no"`, `"snappy"`, `"zlib"`, `"bzip2"`, `"lz4"`, `"lz4hc"`, `"zstd"`
- Default value: `"zstd"`

14.7.2.19.3 `zstd-dict-size`

- The zstd dictionary compression size. The default value is `"0KiB"`, which means to disable the zstd dictionary compression. In this case, Titan compresses data based on single values, whereas RocksDB compresses data based on blocks (`32KiB` by default). When the average size of Titan values is less than `32KiB`, Titan's compression ratio is lower than that of RocksDB. Taking JSON as an example, the store size in Titan can be 30% to 50% larger than that of RocksDB. The actual compression ratio depends on whether the value content is suitable for compression and the similarity among different values. You can enable the zstd dictionary compression to increase the compression ratio by configuring `zstd-dict-size` (for example, set it to `16KiB`). The actual store size can be lower than that of RocksDB. But the zstd dictionary compression might lead to about 10% performance regression in specific workloads.
- Default value: `"0KiB"`
- Unit: KiB|MiB|GiB

14.7.2.19.4 `blob-cache-size`

- The cache size of a Blob file
- Default value: `"0GiB"`
- Minimum value: `0`
- Recommended value: `0`. Starting from v8.0.0, TiKV introduces the `shared-blob-cache` configuration item and enables it by default, so there is no need to set `blob-cache-size` separately. The configuration of `blob-cache-size` only takes effect when `shared-blob-cache` is set to `false`.
- Unit: KiB|MiB|GiB

14.7.2.19.5 `shared-blob-cache` (New in v8.0.0)

- Controls whether to enable the shared cache for Titan blob files and RocksDB block files.
- Default value: `true`. When the shared cache is enabled, block files have higher priority. This means that TiKV prioritizes meeting the cache needs of block files and then uses the remaining cache for blob files.

14.7.2.19.6 `min-gc-batch-size`

- The minimum total size of Blob files required to perform GC for one time
- Default value: `"16MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.19.7 `max-gc-batch-size`

- The maximum total size of Blob files allowed to perform GC for one time
- Default value: `"64MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.19.8 `discardable-ratio`

- When the ratio of obsolete data (the corresponding key has been updated or deleted) in a Blob file exceeds the following threshold, Titan GC is triggered. When Titan writes the valid data of this Blob file to another file, you can use the `discardable-ratio` value to estimate the upper limits of write amplification and space amplification (assuming the compression is disabled).

  Upper limit of write amplification = 1 / `discardable-ratio`

Upper limit of space amplification = 1 / (1 - `discardable-ratio`)

From these two equations, you can see that decreasing the value of `discardable_ratio` can reduce space amplification but results in more frequent GC in Titan. Increasing the value reduces the frequency of Titan GC, thereby lowering the corresponding I/O bandwidth and CPU usage, but increases disk usage.

- Default value: `0.5`
- Minimum value: `0`
- Maximum value: `1`

14.7.2.19.9 `sample-ratio`

- The ratio of (data read from a Blob file/the entire Blob file) when sampling the file during GC
- Default value: `0.1`
- Minimum value: `0`
- Maximum value: `1`

14.7.2.19.10 `merge-small-file-threshold`

- When the size of a Blob file is smaller than this value, the Blob file might still be selected for GC. In this situation, `discardable-ratio` is ignored.
- Default value: `"8MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.7.2.19.11 `blob-run-mode`

- Specifies the running mode of Titan.
- Optional values:
  - `normal`: Writes data to the blob file when the value size exceeds `min-blob-size`.
  - `read-only`: Refuses to write new data to the blob file, but still reads the original data from the blob file.
  - `fallback`: Writes data in the blob file back to LSM.
- Default value: `normal`

14.7.2.19.12 `level-merge`

- Determines whether to optimize the read performance. When `level-merge` is enabled, there is more write amplification.
- Default value: `false`

14.7.2.20 raftdb

Configuration items related to `raftdb`

14.7.2.20.1 `max-background-jobs`

- The number of background threads in RocksDB. When you modify the size of the RocksDB thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `4`
- Minimum value: `2`

14.7.2.20.2 `max-sub-compactions`

- The number of concurrent sub-compaction operations performed in RocksDB
- Default value: `2`
- Minimum value: `1`

14.7.2.20.3 `max-open-files`

- The total number of files that RocksDB can open
- Default value: `40960`
- Minimum value: `-1`

14.7.2.20.4 `max-manifest-file-size`

- The maximum size of a RocksDB Manifest file
- Default value: `"20MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.5 `create-if-missing`

- If the value is `true`, the database will be created if it is missing
- Default value: `true`

14.7.2.20.6 `stats-dump-period`

- The interval at which statistics are output to the log
- Default value: `10m`

14.7.2.20.7 `wal-dir`

- The directory in which Raft RocksDB WAL files are stored, which is the absolute directory path for WAL. **Do not** set this configuration item to the same value as `rocksdb.wal-dir`.
- If this configuration item is not set, the log files are stored in the same directory as data.
- If there are two disks on the machine, storing RocksDB data and WAL logs on different disks can improve performance.
- Default value: `""`

14.7.2.20.8 `wal-ttl-seconds`

- Specifies how long the archived WAL files are retained. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- Unit: second

14.7.2.20.9 `wal-size-limit`

- The size limit of the archived WAL files. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.10 `max-total-wal-size`

- The maximum RocksDB WAL size in total
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `"4GiB"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `1`.

14.7.2.20.11 `compaction-readahead-size`

- Controls whether to enable the readahead feature during RocksDB compaction and specify the size of readahead data.
- If you use mechanical disks, it is recommended to set the value to `2MiB` at least.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.12 `writable-file-max-buffer-size`

- The maximum buffer size used in WritableFileWrite
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.13 `use-direct-io-for-flush-and-compaction`

- Determines whether to use `O_DIRECT` for both reads and writes in the background flush and compactions. The performance impact of this option: enabling `O_DIRECT` bypasses and prevents contamination of the OS buffer cache, but the subsequent file reads require re-reading the contents to the buffer cache.
- Default value: `false`

14.7.2.20.14 `enable-pipelined-write`

- Controls whether to enable Pipelined Write. When this configuration is enabled, the previous Pipelined Write is used. When this configuration is disabled, the new Pipelined Commit mechanism is used.
- Default value: `true`

14.7.2.20.15 `allow-concurrent-memtable-write`

- Controls whether to enable concurrent memtable write.
- Default value: `true`

14.7.2.20.16 `bytes-per-sync`

- The rate at which OS incrementally synchronizes files to disk while these files are being written asynchronously
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.17 `wal-bytes-per-sync`

- The rate at which OS incrementally synchronizes WAL files to disk when the WAL files are being written
- Default value: `"512KiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.18 `info-log-max-size`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.file.max-size`.

- The maximum size of Info logs
- Default value: `"1GiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.7.2.20.19 `info-log-roll-time`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated. TiKV no longer supports automatic log splitting based on time. Instead, you can use the configuration item `log.file.max-size` to set the threshold for automatic log splitting based on file size.

- The interval at which Info logs are truncated. If the value is `0s`, logs are not truncated.
- Default value: `"0s"` (which means logs are not truncated)

14.7.2.20.20 `info-log-keep-log-file-num`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.file.max-backups`.

- The maximum number of Info log files kept in RaftDB
- Default value: `10`
- Minimum value: `0`

14.7.2.20.21 `info-log-dir`

- The directory in which Info logs are stored
- Default value: `""`

14.7.2.20.22 `info-log-level`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.level`.

- Log levels of RaftDB
- Default value: `"info"`

14.7.2.21 raft-engine

Configuration items related to Raft Engine.

> **Note:**
>
> - When you enable Raft Engine for the first time, TiKV transfers its data from RocksDB to Raft Engine. Therefore, you need to wait extra tens of seconds for TiKV to start.
> - The data format of Raft Engine in TiDB v5.4.0 is not compatible with earlier TiDB versions. Therefore, if you need to downgrade a TiDB cluster from v5.4.0 to an earlier version, **before** downgrading, disable Raft Engine by setting `enable` to `false` and restart TiKV for the configuration to take effect.

14.7.2.21.1 `enable`

- Determines whether to use Raft Engine to store Raft logs. When it is enabled, configurations of `raftdb` are ignored.
- Default value: `true`

14.7.2.21.2 `dir`

- The directory at which raft log files are stored. If the directory does not exist, it will be created when TiKV is started.
- If this configuration item is not set, `{data-dir}/raft-engine` is used.
- If there are multiple disks on your machine, it is recommended to store the data of Raft Engine on a different disk to improve TiKV performance.
- Default value: `""`

14.7.2.21.3 `spill-dir` New in v8.4.0

- The auxiliary directory for storing Raft log files. When the disk for the `dir` directory is full, new Raft logs will be stored under this directory. If this auxiliary directory does not exist after configuration, it will be automatically created when TiKV is started.
- If this configuration is not set, the auxiliary directory is not enabled.

Note:

- This configuration takes effect only when the `dir` and `spill-dir` of the Raft Engine are set to different disk drives.
- After enabling this feature, if you want to disable it, you need to perform the following operations before restarting TiKV. Otherwise, TiKV will fail to start.
  1. Stop TiKV.
  2. Copy all the Raft Logs from the `spill-dir` directory to the `dir` directory.
  3. Remove this configuration from the TiKV configuration file.
  4. Restart TiKV.

14.7.2.21.4 `batch-compression-threshold`

- Specifies the threshold size of a log batch. A log batch larger than this configuration is compressed. If you set this configuration item to `0`, compression is disabled.
- Default value: `"8KiB"`

14.7.2.21.5 `bytes-per-sync`

Warning:

Starting from v6.5.0, Raft Engine writes logs to disk directly without buffering. Therefore, this configuration item is deprecated and no longer functional.

- Specifies the maximum accumulative size of buffered writes. When this configuration value is exceeded, buffered writes are flushed to the disk.
- If you set this configuration item to `0`, incremental sync is disabled.
- Before v6.5.0, the default value is `"4MiB"`.

14.7.2.21.6 `target-file-size`

- Specifies the maximum size of log files. When a log file is larger than this value, it is rotated.
- Default value: `"128MiB"`

14.7.2.21.7 `purge-threshold`

- Specifies the threshold size of the main log queue. When this configuration value is exceeded, the main log queue is purged.
- This configuration can be used to adjust the disk space usage of Raft Engine.
- Default value: `"10GiB"`

14.7.2.21.8 `recovery-mode`

- Determines how to deal with file corruption during recovery.
- Value options: `"absolute-consistency"`, `"tolerate-tail-corruption"`, `"tolerate-any-corruption"`
- Default value: `"tolerate-tail-corruption"`

14.7.2.21.9 `recovery-read-block-size`

- The minimum I/O size for reading log files during recovery.
- Default value: `"16KiB"`
- Minimum value: `"512B"`

14.7.2.21.10 `recovery-threads`

- The number of threads used to scan and recover log files.
- Default value: `4`
- Minimum value: `1`

14.7.2.21.11 `memory-limit`

- Specifies the limit on the memory usage of Raft Engine.
- When this configuration value is not set, 15% of the available system memory is used.
- Default value: `Total machine memory * 15%`

14.7.2.21.12 `format-version` New in v6.3.0

> **Note:**
>
> After `format-version` is set to `2`, if you need to downgrade a TiKV cluster from v6.3.0 to an earlier version, take the following steps **before** the downgrade:
>
> 1. Disable Raft Engine by setting `enable` to `false` and restart TiKV to make the configuration take effect.
> 2. Set `format-version` to `1`.
> 3. Enable Raft Engine by setting `enable` to `true` and restart TiKV to make the configuration take effect.

- Specifies the version of log files in Raft Engine.
- Value options:
  - `1`: Default log file version for TiKV earlier than v6.3.0. Can be read by TiKV >= v6.1.0.
  - `2`: Supports log recycling. Can be read by TiKV >= v6.3.0.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `2`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `5`.

14.7.2.21.13 `enable-log-recycle` New in v6.3.0

> **Note:**
>
> This configuration item is only available when `format-version` >= 2.

- Determines whether to recycle stale log files in Raft Engine. When it is enabled, logically purged log files will be reserved for recycling. This reduces the long tail latency on write workloads.
- Default value: `true`

14.7.2.21.14 `prefill-for-recycle` New in v7.0.0

> **Note:**
>
> This configuration item only takes effect when `enable-log-recycle` is set to `true`.

- Determines whether to generate empty log files for log recycling in Raft Engine. When it is enabled, Raft Engine will automatically fill a batch of empty log files for log recycling during initialization, making log recycling effective immediately after initialization.
- Default value: `false`

14.7.2.22 security

Configuration items related to security.

14.7.2.22.1 `ca-path`

- The path of the CA file
- Default value: `""`

14.7.2.22.2 `cert-path`

- The path of the Privacy Enhanced Mail (PEM) file that contains the X.509 certificate
- Default value: `""`

14.7.2.22.3 `key-path`

- The path of the PEM file that contains the X.509 key
- Default value: `""`

14.7.2.22.4 `cert-allowed-cn`

- A list of acceptable X.509 Common Names in certificates presented by clients. Requests are permitted only when the presented Common Name is an exact match with one of the entries in the list.
- Default value: `[]`. This means that the client certificate CN check is disabled by default.

14.7.2.22.5 `redact-info-log` New in v4.0.8

- This configuration item enables or disables log redaction. Value options: `true`, `false`, `"on"`, `"off"`, and `"marker"`. The `"on"`, `"off"`, and `"marker"` options are introduced in v8.3.0.
- If the configuration item is set to `false` or `"off"`, log redaction is disabled.
- If the configuration item is set to `true` or `"on"`, all user data in the log is replaced by `?`.
- If the configuration item is set to `"marker"`, all user data in the log is wrapped in `‹ ›`. If user data contains `‹` or `›`, `‹` is escaped as `‹‹`, and `›` is escaped as `››`. Based on the marked logs, you can decide whether to desensitize the marked information when the logs are displayed.
- Default value: `false`
